Keywords: Intrinsic motivation to learn among millennial, harmonious passion, obsessive passion, self-efficacy.

Introduction

Millennials is generally describing a person who reaches adulthood in the early 21 st century and covers the generation of people born between 1980 and 2000. Millennial possess many characteristics that are unique in comparison to past generation. Millennial tend to be excited about their jobs, work hard and efficiently. Millennials comprise up to 25% workforce in Asia Pacific and the number is expected to grow continuously. It is estimated that millennials will make up 55% of global workforce by 2020 as reported Jobstreet.com. Hence, millennial is the largest generation in workplace, and they will give biggest influence on organizational performance and sustainability especially in Malaysia. This millennial plays an important role towards organizational performance. As millennial grow in the workforce, it will eventually replace the position of Generation X and Baby Boomers.

Intrinsic motivation is powerful element of human development and refer to doing activities doing activity for internal satisfaction rather than external intention (Ryan & Deci, 2000 and Vallerand, 2004). Intrinsic motivation to learn also helps individual develop their own objectives in achieving what they desire. When individuals have intrinsic motivation, they have the motivation to succeed and successfully achieved the desired objectives. In addition, positive attitudes will come out naturally throughout the learning process (Gamboa; Mauricio; Andres, 2013). Millennial are now

facing with the competitive environment and unrealistic expectation especially in education sector. In education sector, intrinsic motivation is the most important factor in helping students to improves learning of study and ability to manage difficulties (Endler, Rey & Butz, 2002). Banfield & Wilkerson (2014) believed that intrinsic motivation among millennial can be contributed to various factors such as job readiness, interest learning tasks, freedom of choice, level of involvement, and personality factors in educational sector. Since Millennial highly regard self-concept as important in life, this study aim to 1) determine the relationship between passion; obsessive and harmonious and intrinsic motivation to learn among millennial; 2) determine the relationship between self-efficacy and intrinsic motivation to learn among millennial.

Intrinsic Motivation

Intrinsic motivation in education expressed by Gottfried (1982), in general we have would neglect the subject of what keeps students inspired by the movement of learning, in the accomplishment of skill past minimum essential and first result. A developing number of specialists and educators concur that expanding student motivation is the way to upgrading learning and execution in school (Linnenbrink and Pintrinch, 2002). Motivation must be portrayed in a quantitative way between two endpoints on a continuum (Linnenbrink and Pintrinch, 2002). Lately, it has been acknowledged that motivation is not a stable characteristic of an individual, but instead a contextual and domain specific construct. Linnenbrink and Pintrinch (2002) have made wide explanation that took into consideration the advancement of different theories with respect to student motivation. According to Csiksezentmihalyi and Nakamura (1989), intrinsic motivation is a connected with mental and physical activities. They remain extremely attract through these exercises with characterized objectives, self-basic, self-think about their own behaviour and they are normally loose and not hesitant to failed in learning. Students that have high intrinsic motivation can adapt new ideas effectively and show better comprehension of the topic (Stipek, Salmon, Givvin, Kazemi, Sage and MacGravers, 1998).

Relationship between passions and intrinsic motivation to learn

Passion is a strong tendency toward a self-defining activity that one likes, find it crucial and meaningful and in which one invest time and energy (Vallerand 2003). The concept of passion has received a little attention in psychology. Psychologists who have looked at the concept have emphasized its motivational aspect. Passion has two dimensions which is harmonious passion and obsessive passion. Harmonious passion indicates a positive relationship to intrinsic motivation where a person will experience a positive cognitive, affective and behavioural consequence during and after activity commitment. Somehow, harmonious passion has a mediator to the intrinsic motivation which is mindfulness which harmonious passion helps a person obtain their self- esteem in their activities and be open; passionate engaged in the activities (Brown & Ryan, 2003). For the obsessive passion, is a result from a controlled internalization of the activity into one`s identity. Such internalization originates from intrapersonal or interpersonal pressure either because certain contingencies are attached to the activity such as feelings of social acceptance or self-esteem, or because the sense of excitement derived from activity engagement becomes uncontrollable.

Relationship between self-efficacy and intrinsic motivation to learn

Self-efficacy is the belief in one`s ability to influence events that effect one`s life and control over the way these events are experienced (Bandura 1994). Self-efficacy reflects confidence in the ability to exert control over one's own motivation, behaviour, and social environment. These cognitive self-evaluations influence all manner of human experience, including the goals for which people strive, the amount of energy expended toward goal achievement, and likelihood of attaining particular levels of behavioural performance. A study conducted by Lane, Andrew and Kyprianou (2015) investigated relationship between self efficacy and academic motivation performance among a sample of 205 postgraduates' students. Correlation result indicated significant relationship between self efficacy and achievement motivation. Kheirkhah (2017) who conducted a study on midwife students in Iran found positive relationship between self efficacy and motivation. Study by Laura (2012) had studied

about the relationship between self efficacy and managers' motivation. Positive relationship was found between self efficacy and manager motivation.

Research Methodology

The type of investigation is based on quantitative study. A total of 375 questionnaires distributed to the respondents. The population is referring all the student from six faculty in UiTM Puncak Alam that are Faculty of Business and Management, Faculty of Pharmacy, Faculty of Accountancy, Faculty of Hotel and Tourism, Faculty of Health and Science and Faculty of Education. The total of population in this study is approximately of 14,714 students which obtain by researcher. Based on simplified table in choosing the sample size done by Krejie and Morgan (1970) chose all 14,714 millennial students (N=15000) as the population size thus the sample size is 375. However, the researcher only received back 215 set of questionnaires and none of them are omissible. The time frame of this research is from early September to the end of December. This research will be using the non-probability sampling which is elements in the population will have any probabilities attached to being chosen as sample subject. The type of sampling used is purposive sampling technique. Purposive sampling is chosen to focus on the characteristics of millennial workers such as conscious about the environment. All primary data processed and analysed using Statistical Package for Social Science Version 23.

Questionnaires for this research were divided into three sections in order to study the intrinsic motivation to learn among millennial in Malaysia, the role of passion and self efficacy. The measurement were adopted from prominent researchers and the responses were standardised according to Likert Scale from 1 to 5 which valued 1= (Strongly Disagree), 2= (Disagree), 3= (Neither agree nor disagree) / (Undecided), 4= (Agree) until 5= (Strongly Agree). The measurement for intrinsic motivation was adopted from Musa (2012), passion from Vallerand, Blanchard, Mageau, Koestner, Ratelle, Leonard, Gagne, and Marsolais (2003) and self-efficacy from Chen, Gully and Eden (2001).

Result and Discussion

Table 1: Demographic Profile

Variable	Frequency	%
Gender		
Male	73	34
Female	142	66
Age		
20-24 years old	193	89.8
25-29 years old	21	9.8
30 years and above	1	5
Faculty		
Business and Management	156	72.6
Pharmacy	9	4.2
Accountancy	11	5.1
Hotel and Tourism	12	5.6
Health and Science	20	9.3
Education	7	3.3

CGPA		
1.50-1.99	1	5
2.00-2.49	7	3.3
2.50-2.99	29	13.5
3.00-3.49	125	58.1
3.50-4.00	53	42.7

The total numbers of respondents are 215. Based on the findings in Table 1, it shows 34 percent of the respondents are male and 66 percent are female respondents. 89.8 percent of respondents who participated in this research between 20-24 years old that makes up as majority. The larger propositions of respondents are from Business and Management Faculty with a percentage of 72.6. 3.00-3.49 CGPA makes up as majority with 58.1 percent.

Table 2: Reliability Analysis

Variable	Original Items	Items Dropped	Cronbach`s Alpha
Intrinsic Motivation	12	-	0.84
Harmonious Passion	6	-	0.69
Obsessive Passion	6	-	0.75
Self-efficacy	8	-	0.85

As shown in Table 2, the reliability test result revealed that all the 6 constructs are above satisfactory as their values are above 0.6. Reliability test such as internal consistency has been done in this study. This test is to determine the reliability of each variable. Table show the interpretation of reliability based on Cronbach Alpha for 215 respondents. Based on Cronbach Alpha result for intrinsic motivation the value is 0.84 which is good with 12 questions. Next, the value harmonious passion is 0.69 showing good result with 6 items. Followed by obsessive passion with 0.75 Cronbach Alpha and also give a good result with 6 questions. Lastly is self-efficacy which is Cronbach alpha value is 0.85 with a good result and 8 questions.

Table 3: Descriptive Analysis

Variable	Mean	Standard Deviation
Intrinsic Motivation	3.98	.45
Harmonious Passion	3.96	.47
Obsessive Passion	3.82	.55
Self-efficacy	3.89	.56

Table 3 shows that descriptive analysis consists of mean and standard deviation of the dependent variable and independent variable. Based on the score given, the highest mean is scored by intrinsic motivation while the lowest mean is by obsessive passion. Result shows that several score for every different variable, which is dependent variable for intrinsic motivation (M= 3.98, SD= .45.) This is followed by the two more independent variables which is harmonious passion (M= 3.96, SD= .47), obsessive passion (M= 3.82, SD= .55) and for self-efficacy it shows (M= 3.89, SD= .56).

Table 4: Correlation Analysis of Passion, Harmonious Passion, Obsessive Passion, Self-efficacy and Intrinsic Motivation

	HP	OP	SE	IM
Harmonious Passion	1	.57**	.45**	.48**
Obsessive Passion	.57**	1	.50**	.49**
Self-efficacy	.45**	.50**	1	.50**
Intrinsic motivation	.48**	.49**	.50**	1

Table 4 shows that the entire summary of findings. The result found the correlation between independent variables that is harmonious passion, obsessive passion and self efficacy at the 0.01 level (1-tailed) towards the dependent variable (intrinsic motivation). The correlation analysis between harmonious passion and intrinsic motivation shows a positive significant correlation with ($r = .48$, $p<0.01$) where it is a medium degree of harmonious passion with medium degree of intrinsic motivation. Moreover, correlation between obsessive passion and intrinsic motivation was also show a positive significant correlation with ($r = .49$, $p<0.01$) which it also shows a medium degree of obsessive passion with a medium degree of intrinsic motivation. There is no dimension for both self-efficacy and intrinsic motivation. Thus, the third correlation between self-efficacy and intrinsic motivation is ($r = .50$, $p<0.01$). This shows that there is a positive significant correlation which there is a large degree of self-efficacy with large degree of intrinsic motivation.

Table 5: Regression Analysis

	Dependent Variable: Intrinsic Motivation β
Independent Variable:	
Harmonious Passion	.23**
Obsessive Passion	.22**
Self-efficacy	.29**
F Value	40.02**
R^2	.36
Adjusted R^2	.35

Based on the result as stated in table 4.7, R^2 for the model between passion with two dimensions; harmonious passion and obsessive passion, self-efficacy and intrinsic motivation is .36. While the adjusted R^2 the value is .35. Therefore, the model explains 36 percent of variance in explaining intrinsic motivation. The other 64 percent were explained by other factors. The F value of the model is 40.02 and significant at ($p<0.01$), which indicate that the model is considerably fit. Harmonious passion and obsessive passion and self-efficacy have a positive significant relationship with intrinsic motivation. Thus, for harmonious passion, shows a positive significant relationship with intrinsic motivation ($\beta = .23$, $p<0.01$) obsessive passion, it makes contribution to intrinsic motivation with ($\beta = .22$, $p<0.01$). While for self-efficacy contribute with ($\beta = .29$, $p<0.01$).

Table 6: Summary of Hypotheses

	Hypothesis	Result
H1a	There is a positive significant relationship between harmonious passion and intrinsic motivation	Supported
H1b	There is a positive significant relationship between obsessive passion and intrinsic motivation	Supported
H2	There is a positive significant relationship between self-efficacy and intrinsic motivation	Supported

Table 6 shows the summary of hypotheses for this study from multiple regression analysis that has been done by the researcher. H1a indicate that there is a significant and positive relationship between harmonious passions with intrinsic motivation. While for H1b that represent also show a positive and significant relationship between obsessive passions with intrinsic motivation. H2 that represent the relationship between self-efficacy and intrinsic motivation also have a positive and significant relationship.

Conclusion and Recommendations

In conclusion, this research has successfully achieved the research objectives accordingly, which is to examine relationship between harmonious passion, obsessive passion and self efficacy towards intrinsic motivation to learn among millennial. All independent variables have a significant relationship with the dependent variable. Moreover, the entire tested hypothesis shows positive relationship between both variable. After completing this research, the researcher has gaining new knowledge and more ideas on how intrinsic motivation plays as a role and it is important towards an individual's life in a way to get their own self-satisfaction. According to the studies that have been conducted, researcher is aware about how the condition of surroundings can affected our motivation to learn. Researcher also gets the chances to know better how passion and self-efficacy emerges and influence factors of intrinsic motivation to learn. For the recommendation to the future researcher, it is good if the researcher use the longitudinal research design in the study because it would help the researcher to know about the people or phenomena in a long time of period in a way to meet the research objective. It may take more time, cost and effort to compare with cross-sectional studies for the time horizon. Next is, future researcher can make more sample for the study to get more accurate information towards the research findings. It is because when the researcher is using more samples to answer the questionnaire survey, the outcome that the researcher will get is high in term of its accuracy of the information.

Towards Human-Machine Partnership in Strategic Management

Katarzyna LIWARSKA-FULCZYK

The Wrocław University of Economics and Business, Wrocław, Poland, katarzyna.liwarska-fulczyk@ue.wroc.pl

Abstract

Increasing capabilities of artificial intelligence and other cognitive technologies allow humans to collaborate with computers as associates on a scale never before. This, by contrast, implies a new level of challenge for the analysis of human-machine collaboration in various business domains. Despite a growing stream of literature on the cooperation between humans and AI, there are few academic research papers devoted to the question of cooperation among business executives and machines. Accordingly, this paper discusses the human-machine partnership in the process of strategic management. For this purpose, the author provides an in-depth analysis of the current and evolving capacities of AI. Additionally, a thorough review of existing research is conducted. The key findings of the study reveal that to embrace the promise of AI strategic management is to be redesigned around both humans as well as machines' capabilities. This requires human-machine integration that resembles a shifting division of work between business executives and artificial intelligence.

Keywords: artificial intelligence, cognitive computing, human-machine partnership, strategic management

Introduction

Artificial intelligence (AI) [1] has been in existence for over six decades and has gone through multiple boom and bust cycles. Nevertheless, at present, it has gained momentum. The flurry of AI's remarkable advances has been possible with the confluence of three factors: new algorithmic developments (Cheng and Yu, 2019), the significant increase in supercomputing power as well as the explosion of swathes of data (Duan, Edwards and Dwivedi, 2019). It has taken a long time for decades-old AI computation models to re-emerge. When chess champion Garry Kasparov was defeated by IBM's Deep Blue machine in 1997, its main advantages were in memory and computing. By contrast, machine learning (ML) algorithms have been the driving impetus behind many of the recent breakthroughs (Tegmark, 2017). The IBM Watson, the IBM Project Debater, and Alpha Go system gained their super efficiency with the use of deep learning (DL), a particular type of artificial neural network (ANN) and a subset of ML (Duan, Edwards and Dwivedi, 2019). DL is the characteristics of a broader trend: 'intelligent' technology that is capable of learning and improving (Reeves and Ueda, 2016). The self-learning capacities of algorithms make way for the rapid developments in cognitive computing [2] that bolsters 'thinking' and analytical capabilities of AI. As a result, in addition to executing well-defined tasks, repetitive activities and routine physical activities AI, and other cognitive technologies are beginning to handle more complex business tasks requiring cognitive skills (Davenport, 2019; Mahroof, 2019; Davenport and Ronanki, 2018; Jarrahi, 2018; Reeves and Ueda, 2016).

The evolving capabilities of AI shape the evolution of the collaborative practices between humans and machines in business practices (Malone, 2018). Ubiquitous technologies at workplaces, together with the ability to perform more complex tasks by machines, and computers translate into situations in which they support humans with their specific tasks becoming sort of 'partners' or 'teammates' rather than 'tools' (Wesche and Sonderegger, 2019). Going forward, Wilson and Daugherty (2019) posit that humans and machines are symbiotic partners, augmenting each other's strengths and compensating for one's weaknesses. With this mind, it is necessary to devise novel ways of involving business experts with the technology required to scale AI in organizations (Ransbotham et al., 2018) and balancing strengths and weaknesses of human and algorithmic intelligence (Günther et al., 2017).

This paper contributes to the emerging discussion on new forms of human-machine collaboration in corporate contexts. Accordingly, the ultimate goal of this paper is to explore the interplay of AI technologies and strategic management in the context of the human-AI partnership.

The structure of this paper is as follows. The next section gives a brief overview of AI's history, its capabilities relevant to strategic management as well as limits. In the following section of the paper, the author moves to discuss corporate strategy and then turns to consider AI's applications in strategic management. Finally, the author highlights the complementarity and collaboration between business executives and machines.

Artificial Intelligence - the background

AI is a relatively new field in science and engineering as the name itself was first coined in 1956 by John McCarthy, one of the founding fathers of AI. The symbolic victories, of IBM's Watson and Google DeepMind's Alpha Go over men, sparked the age of 'intelligent algorithms' and ushered in AI 'renaissance' - a new 'AI spring'. Along with many definitions of AI, one of the commonly-accepted textbook definition defines AI as "the designing and building of intelligent agents that receive percepts from the environment and take actions that affect that environment" (Norvig and Russell, 2016). This view of AI brings together a vast number of subfields, ranging from natural language processing to knowledge representation to automated reasoning to machine learning, and robotics to computer vision (Norvig and Russell, 2016).

The strengths of AI

Launching AI applications should be preceded by analyzing AI through the lens of business capabilities and comprehending its strengths and limitations (Davenport and Ronanki, 2018). In the context of strategic management, AI capabilities evolve around analytical, cognitive, and predictive competencies.

The world has now stepped into a new machine age triggered by AI-enabled automation as well as the convergence of AI abilities with a wide range of other evolving technologies (Brynjolfsson and McAfee, 2017). While automation, per se, has been in existence for years, it was very limited in intelligence as such and relatively inflexible (Miller, 2018). However, with the explosive development of ML techniques, AI is gaining more autonomy in simulating different aspects of human cognition, including self-learning (Zamora and Herrera, 2018). Given the increasing self-learning capacities of ML techniques that imitate human thought through data mining (Pah, Lazarowich and Snyder, 2019) and their ability to unravel 'model' out of 'data' (Krichevsky and Serova, 2019), machines exhibit more autonomy in the area 'thinking work' (Phan et al., 2017) than ever before. Thus the capability of AI is currently expanding beyond mechanical and repetitive to analytical and 'thinking'.

Modern AI is adept at processing enormous amounts of data with exceptional speed (Günther et al.,

2017). Needless to say that machines outperform humans on high combinational complexity (Bolander, 2019) and at various circumscribed tasks (Guszcza and Lewis, 2017). Prompted by high-advanced automated data analysis (AI is good at mass data interpretation) and the self-learning systems, analytical capabilities of machines evolved to the point that they are capable of providing cognitive insights (Kaur et al., 2019; Davenport, 2019; Davenport and Ronanki, 2018). Much more data-intensive cognitive analytics (Davenport and Ronanki, 2018) creates the exceptional opportunity of mass storage facilities for structured and semi-structured data (Williams, 2016) with extensive processing capabilities of mass data to generate relevant business insights (Kaur et al., 2019). The AI-based systems with growing degrees of cognitive analytical competencies and extracted knowledge from data enable enhanced information provisioning.

Moreover, with new methods of data processing, the predictive power of AI systems emerge on the horizon. Through analyzing and learning from a wide array of unstructured, complex, historical, and synthetic data, ML algorithms can create new information and make predictions from data (Cheng and Yu, 2019; Shrestha, Ben-Menahem and Krogh, 2019; Tegmark, 2017). A new stream of AI systems has increased the ability of an organization to use data to forecast, and dramatically reduced the cost of making predictions (Agrawal, Gans and Goldfrab, 2018). Malone (2019) points out the utility of another AI tool for automated predictions. With Bayesian Networks (the probabilistic technique used by ML), organizations have achieved the ability to simulate future incidents and developments (Malone, 2019).

The weakness of AI

Despite the increasing capabilities of AI, some major limits remain. First and foremost, Malone (2018) cites that contemporary intelligent systems such as ML and DL are characterized by specialized intelligence, which means they are capable of performing specific tasks. They lack human-typical intelligence. The IBM Watson program won in Jeopardy but can play neither TicTacToe nor chess since it is not taught to play the games (Malone, 2018). Computers drive cars, engage in conversations, diagnose cancers as a result of being programmed for the specific application (Bolander, 2019; Malone, 2018). Encoding all types of knowledge to increase general understanding competencies of machines is still many years away (Malone, 2018), which makes algorithmic intelligence limited. Narrow intelligence of AI imposes some constraints on business. Although organizations can benefit from AI-enabled systems for particular tasks, they would not implement them for broad problem solving and common-sense reasoning. Findings by Duan, Edwards, and Dwivedi (2019) reveal that the effectiveness of AI at all levels of decision making can be realized chiefly through human users. Machines do not match the rank of truly remarkable human capabilities: emotional, intuitive, reasoning, ethical, and creative.

On top of that, they lack big-picture, abstract and intuitive thinking as well as the exercise of imagination (Bolander, 2019; Daugherty and Wilson, 2018; Jarrahi, 2018; Martin and Golsby-Smith, 2017). Moreover, machines are not able to grasp human social and situational contexts, along with experiences (Miller, 2018). Automated simulations and predictions must be supplemented with humans assets that are hard to codify and capture by data: human experience, common sense, domain expertise, critical analysis, and contextual knowledge (Daugherty and Wilson, 2019; Günther et al., 2017). Also, many AI techniques suffer from weaknesses such as lack of transparency and explainability (Bolander, 2019). Algorithmic decision-making is much less trustworthy as machines are not capable of delivering comprehensive explanations about their reasoning and decisions (Bolander, 2019). It is not clear how algorithms arrive at specific results, patterns, and decisions. Accordingly, AI algorithms are frequently referred to as 'black box' models. In the neural network (considered as 'black box'), the inputs and outputs are known, but unknown are processes that are running inside (Krichevsky and Serova, 2019). The issue of 'black box' generates distrust in AI-based decision

outcomes (Shresthal, Ben-Menahem, and Krogh, 2019). Finally, learning systems creating own training data are confined in their scope (Zamora and Herrera, 2018).

Strategic management

A strategy is a management tool that serves as a guideline for organizational growth in terms of its position among competitors (Krichevsky and Serova, 2019). Rothaermel's definition is corroborated by Wheelend and Hunger (2012). They perceive strategic management as the combination of managerial decisions and actions that determine the company's performance in the long term, which includes: environmental mapping (both external and internal), strategy formulation, strategy implementation, and evaluation.

All strategic decisions rest upon information processing, and analytic capabilities of organizations (Dubey et al. 2017) as strategy grounds on the collection of information on market dynamics and competitors' activities extracted from data to provide predefined input to the decision-making process (Constantiou and Kallinikos, 2015). Organizations utilize different data collection methods to inform specific models to enhance the accuracy of future events predictions (Constantiou and Kallinikos, 2015). However, overreliance on models provided by computers may turn out a baleful consequence. Reeved and Ueda (2016) cite an example of LTCM that trusted in its predictive models on hedging against a potential Russian default (predictive systems did not figure out that it was under-hedged and exposed to liquidity risk) and lost $4.6 billion. This example illustrates that algorithmic processing of information should be accompanied by humans, who derive insights from the wide array of data. This is because strategic management addresses decisional situations about complex, ambiguous, unstructured problems often under the conditions of uncertainty (Agrawal, Gans and Goldfrab, 2019; Duan, Edwards and Dwivedi, 2019).

The imperative of a new strategic partnership

Drawing on the literature, Günther et al. (2017) underline the significance of human intelligence in handling problems for which the conditions are unknown and ambiguous. In line with this, Wilson and Daugherty (2018) posit that, regardless of state-of-the-art capabilities of machines, human intelligence remains in the loop on account of its unique features and abilities to extract and deploy insights. Therefore, it is better to leverage the use of AI as a means for augmentation rather than automation (Wilson and Daugherty, 2018).
As humans and machines have at their disposal a distinct set of assets, the combination of people and computers together can provide better service than either can alone. In light of the above, the scholars from the field highlight the integration of human and algorithmic intelligence into strategic management (Agrawal, Gans and Goldfrab, 2018; Davenport and Ronanki, 2018; Ferràs-Hernández 2018; Malone, 2019; Wilson and Daugherty, 2018; Davenport, 2016; Reeves and Ueda, 2016). The vision of human-machine partnership represents valuable enabler for executives. It drives the payoff for strategic management in the process of which humans and machines play their roles in an integrated manner.

The interplay of AI and strategic management

AI can gain significant traction in the process of strategic management since it holds promise for addressing many strategic needs. First fo all, AI-based systems can relieve managers from much of the quantitative work of strategic planning by running the numbers and data (Malone, 2019) and usher in enhanced productivity of executives taking away from them some tedious tasks. The province of machines could become sorting out and retrieving streams of data from an array of sources (Bolton et al., 2018), and generating specific business insights that are hard to capture through tra-

ditional data analysis. Davenport and Ronanki (2018) suggest that through ML, new data are accessible for better analytics as ML can detect probabilistic matches across databases. They bring an example of GE that took advantage of ML to automate supplier data, and in effect, eliminated redundancies and negotiating contracts previously supervised at the business unit level (Davenport and Ronanki, 2018). Given the analytic capacity of AI, the possibility arises for AI to step into the early phase of strategic planning that encompasses internal environment analysis, external environment analysis, and competitor analysis. This is in line with the studies of Constantiou and Kallinikos (2015), who underline the opportunity to integrate AI into the strategy development process to extend traditional information sources about the business environment. AI systems increase the variety of organizational knowledge as it can offer their support in analyzing customer, financial, and investment data, along with analyzing socio-economic, environmental data (Kaur et al., 2019). Thus, AI-supported automation may support managers with knowledge-intensive activities. On top of that Gupta et al. (2018) point out that contrary to present systems that can augment strategic planning by forecasting trends, cognitive versions of AI-enabled analytics can help human strategists identify new sources of growth and manage disruption as they hold the exponential potential for uncovering newer areas that may be completely unexpected and unexplored. Cognitive insights provided by AI may allow companies to develop new products and services or indicate new areas to explore. Extracted knowledge from data creates new expertise that can serve as a pillar for new business models. For example, Netflix Inc., based on advanced, analytics moved into the online streaming business even though their core business of mailing DVDs was going well. Coupling external and internal data sets to offer more sophisticated and richer insights can serve as a relevant input for strategy making. Cognitive insights provided by AI-generated analytics may help leaders visualize the future to pursue and specify actions that will help them to get there. Vendors such as Inspirient develops a cognitive analytics system that allows managers to obtain critical strategical insights upon which they can act. Inspirient utilizes methods from probabilistic reasoning to fully automate the data analysis process. Deloitte, the strategy consulting company, also moves into automating some aspects of strategy as it develops semi-automated sensing of an organization's external environment (Davenport, 2016).

In addition to cognitive analytics that enables new intangible assets (Constantiou and Kallinikos, 2015), AI systems provide data for automated simulations. With automated simulations accompanied by computational methods and models, scenario modeling, development of hypotheses, detailed knowledge of the connections between problem variables, AI can continually synthesize robust patterns from large data sets. On this basis, it creates predictions and makes choices (Malone, 2019; Shrestha, Ben-Menahem and Krogh, 2019). With automated predictions, managers can evaluate the present position of their organizations and forecast how it may change in the near future. They can also estimate the demand for the product, identify regions for expansion or specific sites for retail stores. Such forecasts can offer useful strategic guidelines and help to define strategic priorities. Netflix Inc. offers a case in point. It uses predictive analytics to help to decide what TV programs to produce. Hence prospects are pointing to the possibility of automating strategy evaluation (Malone, 2019).

Moreover predictions can assist in dealing with risks and uncertainty embedded among others in expansion strategies. IBM Corp., for instance, applies AI technologies to evaluate potential acquisition markets (Davenport, 2016). This is in line with Chui and Ip (2017) who suggest that that applying fuzzy logic (a powerful problem-solving technique of AI that determines the probability of different hazards) can provide insight into M&A evaluation and serve as indicators in M&A transactions. On top of that, AI, with its capabilities of predicting the proximity of the given outcome, can help handle complexity (Jarrahi, 2018), which is inherent to strategy formulation. Automated predictions, specifying the confidence of probability of an outcome and thereby reducing uncertainty, can serve as a significant input into decision making (Agrawal, Gans and Goldfrab, 2019), and underpin strategic decisions. Given the predictions and cognitive insights provided by

algorithms, executives can under certain circumstances take more nuanced and improved decisions and handle choice overload (Agrawal, Gans and Goldfrab, 2018) as well as high dimensional information (Miller, 2018). Moreover, Shrestha, Ben-Menahem and Krogh (2019) underline that algorithms may counterweight to biases and errors incorporated into human decision making.

A trade-off: Human-Machine collaboration

The information and predictions reported by the machines are not the only elements of decision making. Rigorous analysis of data cannot drive every business decision and action (Martin and Tony Golsby-Smith, 2017). An example cited by Martin and Golsby-Smith (2017) makes a case for it. When Jørgen Vig Knudstorp was the CEO of Lego company back in 2008, the data showed that girls were much less interested in their toy bricks than boys, which at first glance explained why 85 percent of the Lego players were boys. The information that girls are inherently less likely to play with the bricks did not convince Knudstrop. The question, he thought, was that Lego had not yet learned how to get girls to play with building toys. A few years later, Lego launched the successful Friends line (Martin and Tony Golsby-Smith, 2017). The Lego case illustrates that human insights empower the realm of possibilities and opportunities delivered by algorithms, and that data is not always logic (Martin and Tony Golsby-Smith, 2017). The interpretation of the world provided by AI systems is probabilistic, based on statistical learning. Therefore computer simulations and recommendations must be supported by skills that machine lack and which are a crucial success factor in business decision making: judgment, imagination, creativity, and intuition (Malone, 2019; Ferras-Hernandez, 2018). It is human strategists' role to associate toolkits of data and analytics with their expertise and skills to drive choices and possibilities and decide on a course of action. A human intermediary is required to evaluate the payoffs connected with different results (Agrawal, Gans, and Goldfarb, 2019). An example comes from Correlation Ventures. It runs the data through its predictive analytics algorithms to determine investment opportunities, and then managers conduct a more thorough analysis of the possibilities provided by algorithms (Reeves and Ueda, 2016). Given the above, the most promising opportunities for strategic management arise when human intelligence is put in the loop, enhanced and augmented by increasing intelligence of machines (Duan, Edwards and Dwivedi, 2019; Agrawal, Gans and Goldfrab, 2018; Jarrahi, 2018; Wilson and Daugherthy, 2018). Humans and machines taking advantage of their respective strengths emerge as a trade-off for strategic management.

Enriching this discussion, Reeves and Ueda (2016) have developed a concept of integrated strategy machine. They apply the term to the collection of technological and human resources that collaborate to develop and execute strategies. Davenport (2016), in turn, adopts 'integrated strategy approach' - the situation when the cognitive capabilities of machines are combined with the intelligence of human managers. In a similar vein, Malone (2019) calls the system in which machines and humans join forces in corporate strategic planning as 'cyber human-strategy machine'.

Conclusions

This paper contributes to the emerging discussion on AI deployment in strategic management by analyzing the scope of complementarity and collaboration between executives and machines. The findings reinforce the idea that human-machine powerful duets unleash. Executives and AI-enabled systems can work closely together to develop a strategy with new kinds of collaborative partnerships (Miller, 2018), each working to its strengths and compensating one's weaknesses. Such a partnership may result in a strategy that is much data-intensive, informative, and more intelligent (Malone, 2019). The analytical and predictive power of AI systems may greatly benefit board decision making and spark new dimensions of human-machine cooperation. Deep Knowledge Ventures, a firm that focuses on age-related disease drugs and regenerative medicine projects, makes a case for it. It has given a seat on a corporate board to an algorithm that is the member of DKV's board. The program,

called Vital, fed with the inputs from streaming data, gets to vote and makes investment recommendations about life sciences firms (Pagallo, 2018). Hence, the idea of integrated human-machine teams making critical strategic decisions does not seem inconceivable. However, AI-based decision making triggers challenges for established accountability, transparency, and, consequently, trust in AI-based decisions (Shrestha, Ben-Menahem and Krogh, 2019). Furthermore, AI, becoming increasingly capable of adding intelligence to strategic management, redefines the role executives have assumed in the process of strategy making (Constantiou and Kallinikos, 2015). With thriving cognitive and predictive capabilities of AI, executives can concentrate their skills on more complex issues that require domain knowledge and critical analysis (Wilson and Daugherty, 2019). Ongoing applications of AI-enabled systems in strategic management makes it necessary for managers to understand the full extent of what AI can do for them and what parameters they can set to ensure the use of the technology is ethical and responsible. The avenue for future research may encourage to explore a new set of skills on demand among business executives as well as strategic decision delegation to algorithms in corporate contexts. Empirical examination on the scope of the partnership between machines and human strategists in organizational settings would also benefit from further research.

Endnotes

[1] Throughout this paper, the term 'artificial intelligence' designates the broad suite of technologies (e.g., machine learning, deep learning, neural networks, natural language processing, expert systems, human-computer interaction) that allow machines and computers to simulate human intelligence.

[2] 'Cognitive computing' combines the spectrum of AI technologies to emulate the human brain's abilities for perception, action, and cognition.

Aleksandr V. KURDYUMOV
Ural State University of Economics, Ekaterinburg, Russian Federation, kurdyumov@usue.ru

Abstract

This article discusses the development and creation of a computer software system designed to solve automation problems in agriculture and food security in the field of agriculture. The relevance of the article is due to the powerful development of the information-digital economy and its influence on all spheres of activity of the state economy. The purpose of the study is to present the development of a software system that allows the calculation of indicators of the yield of grain crops, the norms of sowing seeds of agricultural crops, doses of mineral fertilizers in crop rotation. Issues related to the design of a software control system in agricultural production using high-level programming methods are considered. A structural scheme of the software control system for the processes under consideration at an agricultural enterprise is presented. Further directions for the development of this topic may be related to the development of software tools that automate various tasks of agronomy using artificial intelligence technologies, the Internet of things, and UAVs.

Keywords: software system, yield calculation, fertilizer doses, agronomy, agriculture, agricultural enterprise, agricultural production, food security.

Introduction

Traditionally, when it comes to agricultural production, food security and crops, they primarily mean the role of agronomy. Its basis is many years of experience, enshrined in the laws and traditions of practical farming and summarized in numerous instructions, guidelines and technological maps. Modern agronomy involves, on the one hand, the development of ways to harvest, and on the other, a set of agrotechnological techniques carried out at different time levels in specific soil and climatic conditions that ensure the harvest. A set of such actions, differentiated by natural and economic parameters, contributes to the high productivity of crops and the stable functioning of production with simultaneous reproduction of soil fertility and ecological purity of agricultural products.

The development of software systems for agriculture and the control of ecologically harmonious agricultural technologies is an important task of today's agronomy, which requires solving with the help of modern tools [Thomas, F. et al., 2019; Díez, L. et al., 2018; Aksyonov, K. et al., 2015]. An effective solution to the problem under consideration is possible precisely with the help of computer technologies, since the adoption of optimal control decisions in agronomy is associated with the analysis and processing of a sufficiently large amount of knowledge and heterogeneous information, in which it is difficult for a specialist directly involved in the production of cultivated plants to fully evaluate them and therefore to develop an acceptable management strategy (Forecast of scientific and technological development of the agro-industrial complex of the Russian Federation for the period until 2030 , 2017).

The agro-industrial complex is one of the most dynamic and promising points of application of infocommunication technologies. Currently, there are various software systems for agriculture, ranging from electronic document management systems to business intelligence solutions (Fedorenko, 2017; Lutsenko, Pechurina, 2019; Ruzakova, Butsenko, Kurdyumov, 2019).

The main technological trend in agriculture is precision farming. Precision farming consists in the most efficient, from an economic and environmental point of view, use of each hectare of land, as well as seeds, fertilizers, fuels and lubricants, plant protection products (Schrijver, 2016). As a result, there is a reduction in the cost of producing one centner of production and an increase in yield (Truflyak, 2017).

First of all, the introduction of differentiated technologies that allow the use of certain resources in an optimal ratio based on the structure of the soil, its mineral composition, and so on, is aimed at improving the efficiency of the entire enterprise (Semin, Kibirov, Rassukhanov, 2018).

In connection with the above, the development of new software tools that contribute to increasing the profitability of agricultural production, strengthening stability and sustainable development of agriculture is an important task in the development of this field of activity.

Development of a software system for control crop production

Let us consider briefly the functional elements of the system and their purpose.

A calculator is a system that allows you to calculate the value of the following indicators of crop production in agriculture.

1. Productivity. The system allows you to calculate the amount of yield, centners / hectare. To do this, provide the information:
- the number of ears per $1m^2$;
- the number of grains in the ear;
- mass of a thousand grains, gram.

2. The rate of seeding. The system allows you to calculate the number of seeds cultivated per 1 hectare, which provide a full crop. To do this, you must provide:
- the number of germinating seeds per 1 hectare;
- mass of a thousand seeds, grams;
- seed purity, %;
- germination of seeds, %.

3. Calculation of doses of fertilizers. The system allows you to calculate the rate of application of mineral fertilizers: nitrogen, phosphorus and potassium. To do this, you must:
- choose a culture;
- choose the type of soil;
- indicate yield, centners / hectare;
- indicate the content of a particular nutrient in the soil, mg / kg.

The general scheme of this software system is shown in Fig. 1.

In this program, there are several modes for working with calculations.
Calculator operation mode number = 1 - yield calculation.
Calculator mode number = 2 - determination of the seeding rate.
Calculator mode number = 3 - calculation of fertilizer doses.

The software system has the following structure in a high-level programming language:

Crop - a class whose instance is a specific culture;
Soil - a class whose instance is a specific soil;
TYieldCalculatorForm - a class whose methods provide user interaction with the head of the calculator form;
TFormOfParameters is a class whose methods provide user interaction with the form of the calculator necessary to set parameters for crops and soils.

Fig. 1: The algorithm of the software system

The input variables of the calculator are:

PV - an array containing the values of the parameters of the formulas for calculations; type: array [1..4] of real;
Mode - calculator mode number; type: byte; possible values:
1 - yield calculation;
2 - calculation of the seeding rate;

3 - calculation of doses of fertilizers.
ListOfCrop - a list of objects of the *Crop* class representing certain cultures; type: TObjectList;
ListOfSoil - a list of Soil class objects representing certain soils; type: TObjectList;
NameOfCrop - field of a specific object of the *Crop* class that stores the name of a specific culture; type: string;
TakeAway - a field of a specific object of class *Crop*, which stores the take-out of each nutrient of a certain culture, kg / c; type: array [0..2] of real;
NameOfSoil - field of a specific object of the *Soil* class that stores the name of a specific soil; type: string;
Coefficient - the field of a particular object of the *Soil* class, representing the utilization rates of nutrients from the soil and fertilizers, %; type: array [0..1] of array [0..2] of real;
ConversionRate - field of a specific object of the *Soil* class, representing the conversion factor from mg / kg to kg / hectare; type: real.

The output variable is *y* - the value of the calculated yield indicator or the rate of seeding, depending on the mode; type: real. Fertilizer doses are calculated without storing its value in a separate variable.

The following is a list of the main software methods of the system:
procedure Calculate - a method within which calculations are made with respect to all calculator modes;
function CalculateDose (NumberOfIndicator: byte; Value, Yield: real): real - a method that calculates the dose of fertilizers and returns the value of the calculated dose of type real. The parameters are:
NumberOfIndicator - the number of the battery, where 0 is nitrogen, 1 is phosphorus, 2 is potassium;
Value - nutrient content in the soil, mg / kg;
Yield - productivity, centners / hectare.
procedure SetMode (NumberOfMode: byte) - a method that determines the calculator mode, where *NumberOfMode* is the new mode value;
procedure ModeSeedingRateClick (Sender: TObject) - the calculator mode change event handler in the main menu with the head of the calculator form;
procedure EdParam1Change (Sender: TObject) - the handler of the text change event in the input fields of the calculator main form;
procedure EdParam4KeyPress (Sender: TObject; var Key: Char) - an event handler for pressing keys that are responsible for a certain ASCII character in any input field of the calculator's main form;
procedure EdParam4KeyDown (Sender: TObject; var Key: Word; Shift: TShiftState) - an event handler for pressing and releasing keys that are responsible for any character in any input field of the calculator's main form. As part of the handler, it is checked whether the Shift keys are pressed;
procedure FilterEdit (Sender: TObject) - a method that removes forbidden characters from input fields. The method is launched in event handlers for changing the text of those input fields that can contain only numerical values;
procedure MenAddCropClick (Sender: TObject) - the event handler for clicking the left mouse button on the main menu of the calculator's main form. As part of the processor, the form required to add a new crop to the system is opened;
procedure MenAddSoilClick (Sender: TObject) - event handler for clicking the left mouse button on the main menu of the calculator main form. As part of the processor, the form required to add a new type of soil to the system is opened;
procedure MenChangeDelCropClick (Sender: TObject) - the event handler for clicking the left mouse button on the main menu of the calculator's main form. Within the framework of the processor, the opening of the form necessary for changing or removing any crop is performed;
procedure MenChangeDelSoilClick (Sender: TObject) - the event handler for clicking the left mouse button on the main menu of the calculator main form. As part of the processor, the form required to change or remove any type of soil is opened;
procedure BtSaveClick (Sender: TObject) - an event handler for a keystroke that saves information about a crop or soil. The key is on the form of a calculator, necessary for setting parameters for crops and soils;

procedure BtDelClick (Sender: TObject) - an event handler for a keystroke to delete all information about a particular crop or soil. The key is on the form of a calculator, necessary for setting parameters for crops and soils;
procedure ComCropChange (Sender: TObject) - an event handler for a change in crop or soil choice, part of the data of which acts as parameters when calculating fertilizer doses. The choice is made through the drop-down lists located on the main form of the calculator;
function PrintText (X, Y: integer; Text: string; Form: TForm; Formula: boolean; Print: boolean = true): integer is a method that:

writes the *Text* formula to the *Form* in the location with the coordinates *X* and *Y*, provided that the *Formula* and *Print* parameters are *true*;
calculates and returns the length of the *Text* text in pixels;
procedure UpdateLists - a method that updates the drop-down lists of soils and crops located on the main form of the calculator;

function EventOfPutInEdits (Sender: TObject; Key: Char; Form: TForm): char - a method that sets the focus to the next or previous component (input fields, drop-down lists). The parameters are:
Sender - the component on which focus is set;

Key - the pressed key that should correspond to the Enter key;
Form - the form on which the components are located;
procedure PrepareForm () - a method of the *TYieldCalculatorForm* class, in which the *ListOfCrop* and *ListOfSoil* are compiled according to the data of an external file;

procedure PrepareForm (TOO, NOI: integer) - a method of the *TFormOfParameters* class, within the framework of which the preparation of the form necessary for setting parameters for crops and soils takes place. The parameters are:

TOO - object type: 0 - work with crops, 1 - work with soils;
NOI - number of the selected object from the drop-down list of crops or soils located on the main form of the calculator;

procedure FormClose (Sender: TObject; var Action: TCloseAction) - the event handler for closing the main form of the calculator, in which the data on crops and soils are written to an external file.

Here is a description of the operation of the software system in question.

All calculated actions in the system in question occur in the two methods described above *procedure Calculate* and *function CalculateDose*.

The *Calculate* method is launched in any case, despite the operation mode, the value of which is stored in the *Mode* variable. If the value of the *Mode* variable is equal to 3, the *CalculateDose* method is launched, which calculates the dose of fertilizer according to the formula (1):

$$\frac{100*Yield*TakeAway[i]-ConversionRate*Value*Coefficient[0,i]}{Coefficient[1,i]}, \quad (1)$$

where *Yield* - productivity, centners / hectare; *TakeAway [i]* - take-out of each food item of an agricultural crop, kg / c, where *i* is the number of a food item that takes a value in the range [0..2]:
0 - nitrogen removal;

1 - phosphorus removal;
2 - removal of potassium;

ConversionRate - conversion factor from mg / kg to kg / hectare; *Value* - the content of a particular nutrient in the soil, mg / kg; *Coefficient* [0*, i*] is the coefficient of use of nutrients from the soil,%, where i is the number of nutrients;

Coefficient [1*, i*] coefficient of use of agricultural nutrient elements from fertilizers, %, where *i* is the number of agricultural nutrient element.

If the value of the variable *Mode* is not equal to the value 3, then the method calculates the yield according to the formula (2) or calculates the seeding rate according to the formula (3):

$$\frac{PV[1]*PV[2]*PV[3]}{10000}, \quad (2)$$

where *PV* [1] is the number of ears per 1 m^2; *PV* [2] is the number of grains in an ear; *PV* [3] - mass of a thousand grains, gram.

$$\frac{PV[1]*PV[2]*100}{\frac{PV[3]*PV[4]}{100}}, \quad (3)$$

where *PV* [1] - the number of germinating seeds per 1 hectare; *PV* [2] - mass of a thousand seeds, gram; *PV* [3] - seed purity, %; *PV* [4] - seed germination, %.

Conclusion

The above analysis and description of the software system as a new means of supporting control decision-making in agricultural technology indicates that at present, information technology is firmly integrated into the production processes of modern agricultural entities.

The development of modern tools for the automated control of various subsystems of an agricultural enterprise is a necessary process for its future development. By optimally managing its subsystems, the organization seeks to create and consolidate its competitive advantages.

The development of digital technologies and means of communication helps farmers to reduce costs, while increasing field productivity and ultimate business profitability.

Using the developed software to determine the yield, calculate the volume of sowing seeds and doses of mineral fertilizers in agriculture will allow the company to develop steadily, economically, which is a priority for any business entity in the current conditions of society.

Abstract

This study aims to analyze the bankruptcy risks among Indonesian construction firms during different presidency regimes. We use 50 construction firms listed on the Indonesian stock exchange based on three prediction measurements: Z-score, Z''-score, and S-score for the 2014 and 2018 periods, reflecting the end of President Susilo Bambang Yudhoyono's period and the end of the first President Jokowi's period. Regression analysis conducted and we found that bankruptcy prediction scores, Z-score and Z"-score, increased from 2014 to 2018. However, the S-score shows a different result. It is found from the regression analysis that there is a significant difference in the bankruptcy risk of construction firms in different presidency periods. This analysis has controlled for firms' size, business risk, and degree of financial leverage.

Keywords: Bankruptcy risk, Financial distress, Altman Z-score, Springate, bankruptcy prediction, Indonesia.

1 Introduction

The study of economic development has stated that to create and improve national economic activities in a country, adequate infrastructure is required for a country. The increasing number of infrastructure development projects has indirectly supported economic growth. This development has led the Indonesian government to provide a better framework for attracting investors to invest in Indonesia (Atmaja & Mahalli, 2014). Bank Indonesia reported that the performance of construction sector firms highly increased due to the positive impact of accelerated infrastructure development. Growth in 2017 was recorded at 6.79%, and is a higher yield compared to growth in 2016, which was 5.22% (Bank Indonesia, 2017).

Most infrastructure projects in Indonesia are private projects, including state-owned enterprises. Based on the analysis of the Standard & Poor's Global Rating institution, in 2018, there were 20 construction firms that had a 5 times increase in debt ratio against EBITDA (S&P Khawatirkan rasio utang BUMN, 2018). A company that has a very large debt will certainly become riskier to financial distress. Financial distress can be considered as a warning to the company to reorganize its financial condition because it provides the potential for bankruptcy (Ross, Westerfield, & Jaffe, 2010). Therefore, firms need to predict bankruptcy, for example, by using data from financial statements to find a ratio that can prove the potential for bankruptcy based on the bankruptcy prediction analysis model.

In the last two different presidency periods in Indonesia, there was a significant difference between their plans and targets concerning the state budget. The period of Jokowi's administration had a larger budget for infrastructure compared to the SBY administration. The addition of the infrastructure budget in Jokowi's period is allocation from the fuel subsidy funds, and during SBY's period, the fuel subsidies were a budget that continued to soar every year. The fuel subsidy budget cuts were then allocated to other sector budgets such as infrastructure, education, and health in Jokowi's period (Winati, 2016). Previous study conducted by Setiawan, et. al.(2020) shows that there is increasing in bankruptcy risks among Indonesian listed company during Jokowi's presidency period, but not specify for construction firms. This research conducted to fill the gap.

Various literature on bankruptcy prediction analysis has been published and used in various financial statement analyses. The Altman and Springate models are some examples of popular models (Altman E. , 2000). Research on similar topics about financial difficulties has also been carried out, such as research from Citrawati and Gede

(2014) and Setiawan et al (2020) by comparing the Altman, Springate, and Zmijewski models at food manufacturing firms. The results of the study using three methods showed that the company's performance, in general, was healthy or not in a potentially bankrupt condition.

Based on the problem stated above, the purposes of this research are as follows; first, classify which firm from construction sector in Indonesia that has been classified as healthy, a gray area, or bankrupt based on three models and between two different periods; and second, to understand the effect of different presidency periods on the condition of construction sector in Indonesia based on the bankruptcy prediction model.

2 Literature Review and Hypothesis Development

Financial distress prediction has become an important factor in conducting efficient development in every capital market. The problem of bankruptcy and financial distress has become a serious problem, since it could reflect a company's management performance and also critical condition. It is necessary to compare, evaluate, and analyze the financial distress and bankruptcy prediction to prevent investment loss.

2.1. Financial Distress

Financial difficulties are situations in which the operating cash flow of a company is unable to meet liability requirements (such as trade credit or interest costs), and the company will be forced to take action to improve it. Financial difficulties usually end in default, and the company will be asked to restructure its financial conditions both from internal firms, to creditors, and also to shareholders investors (Ross, Westerfield, & Jaffe, 2010).

2.2. Altman Z-Score Model

One of the bankruptcy prediction analysis models that is often used and still relevant today is the model made by Altman (Z-score). Altman used the multivariate discriminant analysis (MDA) model in his research. Altman's model is as follows (Altman E. , 2000)

$$Z = 1.2X_1 + 1.4X_2 + 3.3X_3 + 0.6X_4 + 0.99X_5 \quad (1)$$

Where each variable is X_1 is Working Capital / Total Assets; X_2 is Retained Earnings / Total Assets; X_3 is Earnings Before Interest & Tax / Total Assets; X_4 is Market Value of Equity / Total Liabilities, and; X_5 is Total Sales / Total Assets. Altman's model divides firms into three categories based on the Z-score obtained. When the Z-score is ≥ 2.9, it indicates the company is still in good health; Z-score from 2.9 to 1.81 indicates the company is in the gray area; and a Z-score of ≤ 1.81 indicates the company has the potential to go bankrupt.

2.3. Altman EMS Z"-Score Model

Altman's original model has limitations that only apply to manufacturing firms and are public property, so it is further analyzed using stock price data. In 1983, Altman made a new model with an adjustment for firms that were sampled as private firms by changing the market value in X_4 to the book value (Altman, Iwanicz-Drozdowska, Laitinen, & Suvas, 2014). The modified Altman model is as follows:

$$Z'' = 6.56X_1 + 3.26X_2 + 6.72X_3 + 1.05X_4 + 3.25 \quad (2)$$

Where each variable is X_1 for Working Capital / Total Assets; X_2 is for Retained Earnings / Total Assets; X_3 is for Earnings Before Interest & Tax / Total Assets, and; X_4 is for Book Value of Equity / Total Liabilities.

2.4. Springate Model

The Springate model was first developed by LV Springate Gorgon in 1978. This model is a ratio model that uses multiple discriminant analysis (MDA) to select four ratios from 19 financial ratios that are commonly used in the literature that can distinguish between bankrupt and healthy firms (Wulandari, DP, & Julita, 2014). The Springate model is as follows:

$$S = 1.03A + 3.07B + 0.66C + 0.4D \quad (3)$$

The financial ratio for variable A is Working Capital / Total Assets; B is Earnings Before Interest & Tax / Total Assets; C is Profit Before Tax / Current Liabilities, and; D is Sales / Total Assets. This model has a classification standard like the Altman model, where an S-score ≥ 0.862; indicates the company is still safe from bankruptcy, and an S-score <0.862; indicates the company has the potential to experience bankruptcy.

2.5. Degree of Financial Leverage (DFL)

A company is considered as leveraged if it has debt in its capital structure and thus giving the tax shield profit. But if the company decides to use debt in its capital structure, there will be a fixed cost required to be paid. Generally, a capital structure that required a higher level of debt will impact a bigger DFL. According to previous research, calculation of DFL consists of several method but in this research, the ratio of income before interest (EBIT) to income after interest (EBT) will be used. This calculation method has been widely used in previous studies and also provided explanation of interest cost's influence on a company's net income (Gatsie, Gadzo, & Akoto, 2013).

$$\mathrm{DFL} = \frac{\mathrm{EBIT}}{\mathrm{EBIT} - \mathrm{Interest}} \tag{4}$$

2.6. Revenue Volatility

Revenue volatility is often interpreted as the extent to which net income fluctuates during one business cycle. Volatility of revenue is a serious problem for management to assist the decision making process. Uncertainty in revenue estimates that will be obtained provides difficulties to make accurate forecasting for future cash flow and the formation of long-term financial plans for more stable operations (Kwak, 2011).

2.7. Firm Size

Firm size is the total number of data in the financial statements that describe the size of a company that is shown from the total assets account, amount, average sales, and the average total assets. Generally, the size of a company has an equivalent value to the amount of assets owned by the company (Mukaromah & Amboningtyas, 2018). There are some bankruptcy prediction models that used the firm size as a determinant or variable that could influences the value of bankruptcy predictions. Ohlson's research (1980) tested three models for predicting bankruptcy and the results of the study found that the three models had a significant effect on firm size. However, some previous studies also contradicted the results of Ohlson's (1980) study, According to Sun (2012), firm size does have a significant influence on the prediction of corporate bankruptcy, but some company-specific factors can result a negative or positive influence on bankruptcy predictions.

2.8. Previous Researches and Hypothesis Development

Marcinkevicius, et al (2014) has conducted bankruptcy prediction research of firms in construction sector in Lithuania. Taffler, Tishaw, Chesser, Altman, and Springate model was used in the research. The research had been conducted as an evaluation and comparison of before and after financial crisis that had happened few years back. The research has concluded that Springate, Altman, and Chesser model were the most accurate compared to Taffler and Tisshaw model. Thus, giving a conclusion that Springate, Altman, and Chesser model are appropriate to predict bankruptcy of construction firm.

Sun (2012) also has conducted an analysis of the effects of client's firm size and stress on bankruptcy prediction models. The result was that the firm size has a significant effect on the bankruptcy prediction model but under certain firm-specific condition, the result could differ. Meanwhile, Meeampol, et al. (2014) presented a research that compare Z-score and modified Z-score for developing countries (EMS) of listed companies in Thailand stock exchange. The research presented that both model has a legitimate ability to predict bankruptcy of the observed firms. To conduct the analysis, it is recommended to conduct the prediction two years prior to the bankruptcy. Karas and Režnáková (2014) conducted a research of bankruptcy prediction model from four different countries to compare the accuracy of bankruptcy prediction if used in a different environment. Due to the heterogeneity data, the accuracy of the prediction model may vary and could be improved by reducing the heterogeneity. This research proved possible to identify those macroeconomic factors that show similar correlation patterns between given environments as investigated by the accuracy of the bankruptcy model. These factors include the performance of the economy, inflation, and unemployment rate.

Asnudin (2008) has done research to describe how the business of construction firm work in Indonesia and what factors that each construction firm should be aware of due to the risk of construction business in Indonesia. This research describes how the government needs of infrastructure development could affect the relationship between the construction firm and the government. Based on the previous researches, this research aims to compare three different prediction bankruptcy model results with two different data period, specifically two different presidency regimes, and how the difference of the data period affects each bankruptcy prediction model's value. Thus, the development of hypotheses for this research will be based on:

- H_0: The difference between SBY and Jokowi's presidency period has no significant effect on the Altman Z-score model of construction firms in Indonesia.

- H_0: The difference between SBY and Jokowi's presidency period has no significant effect on the Altman Z-score EMS model of construction firms in Indonesia.
- H_0: The difference between SBY and Jokowi's presidency period has no significant effect on the Springate S-score model of construction firms in Indonesia.

3 Methods

This chapter provides the research methodology for the applicability of the bankruptcy prediction models in the construction sector. While organizing this research, the population, sampling, scope, screening, and method of sourcing the data was determined. The data used in this study is secondary data, namely data collected from other sources and already available through open media before conducting this research. The data were the financial ratios based on financial reports during 2012–-2014 and 2016–2018 and thus were adjusted to become the dependent variables in each of the Altman and Springate models. The data collection sources will be processed and analyzed in research obtained from the official website of the Indonesia Stock Exchange (IDX) and Thomson Reuters's Screeners.

This research conducted a sample population of firms listed in the IDX as construction, real estate, and property industries. The total number of firms acquired from this category was 79 firms, but due to the availability of the data, the final number of firms used for observation was 50 firms. Firms that were concluded as having financial distress were classified based on the condition of its current ratio under 1 and a profitability ratio that showed a negative value of growth each year (Kristanti, Rahayu, & Huda, 2016). Financial ratios data were collected and processed and then calculated to become dependent variables according to each model. Each model's score has a classification to decide whether the current firm-year observation was concluded as bankrupt.

Table 1: The cut-off point for each model conducted in the research

	Altman	**Altman EMS**	**Springate**
Healthy	$Z \geq 2.9$	$Z \geq 2.6$	$S \geq 0.862$
Gray Area	$1.81 < Z < 2.9$	$1.1 > Z > 2.9$	-
Bankrupt	$Z \leq 1.81$	$Z \leq 1.1$	$S < 0.862$

Each model will generate the value of each model, the independent variables, or the value as a "score" (Z-score for the Altman Model and Altman EMS, and S-score for the Springate model). The scores will then be classified based on the data in Table 1. After the score for each year and each firm were collected, the regression analysis was then initiated using the additional control variable firm size, the degree of financial ratio, and the revenue volatility. Revenue volatility is derived from the standard deviation of revenue from each observed firms in last three years before the end of each presidency's period. In this model, the presidency period is a dummy independent variable, in which the bankruptcy prediction score during the SBY period (2014) will have value of 0 and the bankruptcy prediction score during the Jokowi period (2018) will have a value of 1. The bankruptcy prediction score is considered as the dependent variable. Thus, the models that will be used in this research are:

$$Z_i = \alpha_1 + \beta_1\, dPRES_i + \beta_2 Ln(TA)_i + \beta_3 DFL_i + \beta_4 . RV_i + \varepsilon_1 \quad (5)$$

$$Z''_i = \alpha_2 + \beta_5\, dPRES_i + \beta_6 Ln(TA)_i + \beta_7 DFL_i + \beta_8 RV_i + \varepsilon_2 \quad (6)$$

$$S_i = \alpha_3 + \beta_9\, dPRES_{it} + \beta_{10} Ln(TA)_{it} + \beta_{13} DFL_{it} + \beta_{11} RV_{it} + \varepsilon_3 \quad (7)$$

Whereas:

Z_i = Z-score of firm i
Z''_i = Z-score EMS of firm i
S_i = S-score of firm i
$dPRES_i$ = *dummy* of firm i
$Ln(TA)_I$ = *firm size* of firm i
DFL_i = *degree of financial leverage* of firm i
RV_i = *revenue volatility* of firm i

4 Results and Discussion

According to the research conducted, the results of each model calculation are shown in Table 2.

Table 2: Number of firm classifications based on each model result

Condition	Z-score		Z”-score EMS		S-score	
	2014	2018	2014	2018	2014	2018
Healthy	21	10	32	29	24	34
Gray Area	13	12	13	14	-	-
Bankrupt	16	28	5	7	26	16
Total	50	50	50	50	50	50

Among the three prediction models used in this research, the S-score model gave the best results because the number of firms included in the healthy category increased from 2014 to 2018 compared to the other two models which both show a declining number of healthy firms from 2014 to 2018. As a comparison between the Z-score and Z”-score EMS models, even though both experienced a decline in the classification of healthy firms and an increase in the classification of bankrupt firms, the Z”–score EMS model provided better output because the number of firms classified as healthy in the year 2018 is higher than provided by the Z-score in 2018. This result is consistent with a statement by Altman where the Z”-score EMS model was indeed adjusted to the condition of business development in emerging countries. Moreover, the constants of each variable are also different when compared to Z-score (Altman E. , 2000).

The result of the regression analysis is shown below in Table 3:

Table 3: Regression result for Altman Z-score

Independent Variables	Coefficient	z	P>|z|
dPRES	-0.990	-3.20	0.001*
LNTA	-0.288	-1.52	0.129
RV	0.613	1.09	0.276
DFL	0.123	2.91	0.004*
C	11.295	2.07	0.039*
Firms Observed	100		
Cross-Section	50		
R-squared	19.20%		
Prob > chi2	0.000		

**Significant at 5%*

The dPRES variable had a significant effect on the value of Z-score for the construction sector. The effects of presidential differences on the value of bankruptcy predictions cannot just be reviewed using the policies made by each president. During Jokowi’s period, many macroeconomic factors affected the stability of Indonesia's economic growth, including the Fed's policy of raising interest rates in the US, natural disasters, and the trade wars between China and the US affecting the import–export policy in ASEAN countries (Asmara, 2018).

Speaking of policies between the two presidents, both of them had significant differences in planning the state budget and the target of development in economic sectors. During SBY's period, the state budget was allocated to short-term needs such as food and fuel subsidies, thus providing slow growth in sectors that are useful for the long term such as infrastructure. Meanwhile, for Jokowi's period, the state budget policy has been running well, with Jokowi cutting subsidies for fuel and allocating them to other long-term sectors such as infrastructure and education (Winati, 2016). A p-value below 0.05 proves the significant effect of the dPRES variable.

Meanwhile, the DFL also has a significant influence on the value of Z-score in the construction sector in Indonesia. The higher the DFL level, the greater the financial risk it offers (Luoma & Spiller Jr., 2001). In this study, the EBIT/EBT ratio was used as the DFL value. The interest payment is the main factor in the size of the DFL, where the larger the company’s interest payment cost, the greater the DFL. Therefore, firms with smaller DFL values will have lower financial risks. To anticipate the number of interest costs, firms must get greater profits to compensate for returns to shareholders for using too much debt (Gunarathna, 2016).
Regression result for Altman Z”-score EMS model is shown in Table 4. Similar to the Z-score model, the dPRES variable has a p-value of less than 0.05, meaning that the PRES variable has a significant effect on the Z”-Score EMS.

Besides the dPRES variable, other variables like firm size, revenue volatility, and degree of financial leverage have a significant effect on Z"-score EMS. Firms that have greater assets generally have more ability to generate greater revenue. This research is consistent with researches carried out by Gunarathna (2016) and Sun (2012), where the magnitude of total assets has a significant influence on financial risk and the bankruptcy prediction value. A relatively small sized firm, on the other hand, has a large financial risk because small firms frequently have high debt levels, thus, increasing the leverage value of the firm (Gunarathna, 2016).

Table 4: Regression result for Altman Z"-score EMS

Independent Variables	Coefficient	z	P>|z|
dPRES	1.989	4.42	0.000*
LNTA	-0.843	-4.94	0.000*
RV	6.419	2.50	0.013*
DFL	0.158	15.07	0.000*
C	29.228	6.55	0.000*
Firms Observed	100		
Cross-Section	50		
R-squared	9.43%		
Prob > chi2	0.0295		

**Significant at 5%*

The RV variable in this study is revenue volatility or based on previous research can be called volatility earnings. Revenue variability is also commonly called business risk. Revenue volatility is often associated with financial manager decisions in determining the use of debt or leverage from the firms. If volatility revenue of some project has a low value, then the firm has confidence in the revenue gained in the future, and the manager can determine the optimal level of debt usage based on the revenue they will gain. That way, revenue volatility has an influence on the potential bankruptcy or financial risk of the company (Alnajjar, 2015).

The Degree of Financial Leverage (DFL) has p-value under 0.05, therefore it also has a significant influence on the Z"-score EMS. Just like the Altman Z-Score, the DFL is influenced primarily by the level of debt or interest costs the company must incur. In this case, a greater interest rate will increase the DFL value so that as the DFL increased, financial risk will follow (Gunarathna, 2016).

Table 5: Regression result for Springate S-score

Independent Variables	Coefficient	z	P>|z|
dPRES	-0.307	-2.96	0.003*
LNTA	0.053	1.29	0.198
RV	0.009	0.06	0.953
DFL	0.017	1.38	0.169
C	-0.685	-0.57	0.570
Firms Observed	100		
Cross-Section	50		
R-squared	14.85%		
Prob > chi2	0.0000		

**Significant at 5%*

The regression result of Springate S-score model is shown in Table 5. The independent variable that affects the model is only the dPRES variable since it's p-value is below 0.05. Similar with the two previous models, the differences in the period of government did have a significant influence on the bankruptcy prediction values of firms in Indonesia. Not only multinational macroeconomic factors, such as foreign exchange or the China–US trade war, can affect the economy of an industry, but economic policy, or rather budgetary policies, for economic sector development are also able to influence the industrial sector. During Jokowi's period, the economic development mainly focused on the infrastructure and construction sectors (Winati, 2016). With the p-value of the dPRES variable less than 0.05.

5 Conclusion Result

With the observation data of 50 firms in the construction sector in Indonesia, the Altman Z-score model predicted that in 2014 there were 21 firms classified as healthy, 13 in the gray area, and 16 as bankrupt, while for 2018, there were firms classified as healthy, 12 in the gray area, and 28 as bankrupt. For the Z"-score EMS model, in 2014 there were 32 firms classified as healthy, 13 in the gray area, and 5 as the bankrupt, while for 2018, 29 firms were classified as healthy, 14 in the gray area, and 7 as bankrupt. Meanwhile, for the S-score model, in 2014, 24 firms were classified as healthy and 26 firms as bankrupt. In 2018, there were 34 classified as healthy, and 16 firms were classified as bankrupt.

Our research has shown that the different presidency periods in Indonesia, in this case SBY (2014) and Jokowi (2018), had an influence on the three bankruptcy prediction models used. In addition, the DFL variable also has a significant influence on the Altman Z-score model. For the Z"-score EMS model, every independent and control variable also had a significant influence. It is acceptable that the different period of presidency could affect the bankruptcy prediction model of construction firm in Indonesia. During Jokowi's period, the number of infrastructure project in Indonesia has risen due to the report published by the World Bank in 2014 that stated the economic development of Indonesia is slowly increasing compared to the other ASEAN countries (Bank Indonesia, 2017). Therefore, Jokowi in 2015 planned the state budget for that year would be more focused on infrastructure development.

However, this research has some limitations. The firms observed in the research were only construction firms because between the two periods, the number of construction projects in Indonesia rose. However, that doesn't mean that only the firms in the construction sector had a significant effect. Therefore, for future research, using different industries seems favorable for research to see whether the different presidency period also has a significant impact on different sectors or industries.

Abstract

This research examines the relationship between corporate governance mechanisms, such as board size, board independence, female directorship, ownership concentration, director's ownership and audit reputation on firm performance and examines the effect of financial leverage in mediating corporate governance and firm performance. This research was conducted on 113 manufacturing companies listed on the Indonesia Stock Exchange during 2013-2017, with a total of 565 observations. A panel data regression using the STATA 15.0 program is done to test the hypothesis. We find that board size has a positive effect on firm performance, while female directorship and ownership concentration have a negative effect on firm performance. Financial leverage partially mediates the effect of board size on firm performance. This study contributes to corporate governance literature, especially factors that can mediate the relationship between corporate governance and firm performance.

Keywords: Corporate governance, Good corporate governance, Firm's performance, Financial leverage, Indonesia

Introduction

In this highly competitive era, almost all companies, especially public companies, are listing their shares on the stock exchange to get as much investment funding as possible from investors. This effort is carried out by companies in various ways, for example through developing or innovating products and/or business forms, reputation enhancement, education and information and even non-ethical ways, such as information blurring, which misguides investors and tempts them to invest. In fact, companies that are worth investing in are companies that truly have good performance and that also have the opportunity to continue to perform well in the future, which will increase the company's value. One reflection of a company's performance is the financial performance as shown in financial statements.

Not only are they detrimental to investors, but unethical business practices will also harm society and the state, because such practices can create a business environment that is not good for healthy market competition. If unethical practices continue to happen, this will, in the end, affect the investment climate in a country. In fact, this poor business practice can lead to economic crises, like those experienced by Indonesia a few years ago (Ariyanti, 2014). To avoid the occurrence of such business practices, after the crisis in 1997, the concept of Good Corporate Governance (GCG), which contains norms/principles for companies to manage their companies well, began to be widely discussed in Indonesia. In 2002, regulations concerning GCG began to be implemented in the form of regulations for state-owned companies. In 1999, the government also formed a committee specifically dealing with the implementation of GCG, called KNKG. KNKG issued guidance on GCG implementation in 2001 and was refined in 2006.

The drive to implement GCG comes not only from within the country but also from the world community. GCG is an important indicator, and in a report on one of the online news portals in 2017, the Financial Services Authority's Board of Commissioners stated that Indonesia was lagging behind

in implementing GCG when compared to countries in ASEAN, where only two Indonesian companies were included in the 50 best issuers listed by the ASEAN Capital Markets Forum (ACMF). That figure is far below other countries, especially Thailand, which had 23 companies on the list (Primadhyta, 2017). Based on the assessment conducted by ACMF in 2015 (Asian Development Bank, 2015), the following results were obtained.

Figure 1. Corporate Governance Mean Scores by Country

Based on the information and the graph above, it seems clear that Indonesia must pursue the level of success achieved by other countries. Nevertheless, based on the graph, an increase in GCG continues to occur, which shows that companies and governments in Indonesia are concerned with continuing to increase the implementation of GCG.

Then what is the relationship between corporate governance and company performance? As previously described, in principle, GCG regulates companies to carry out their business practices properly. Therefore, when speaking of corporate governance, it cannot be separated from several theories relating to GCG. The principles contained in GCG encourage business people to overcome the problems that exist in their companies, such as the existence of information asymmetry and agency problems that indirectly affect the performance of a company. Some theories and previous research have proved this, including agency theory (Jensen & Meckling, 1976) and research conducted by Ciftci, Tatoglu, Wood, Demirbag, and Zaim (2019) and Esra and Hamdan (2015), which empirically required several corporate governance variables to affect company performance. However, that does not mean it is without debate. Some studies have seen different results, such as the research conducted by Chen, Cheung, Stouraitis, and Wong (2005) and Detthamrong, Chancharat, and Vithessonthi (2017), who found no link between corporate governance and company performance. Detthamrong et al. (2017) also tried to find factors that bridged the relationship between corporate governance and company performance (in this case using financial leverage as a mediator variable), but they did not get significant results.

Therefore, although there have been several previous studies that found evidence that corporate governance did not affect the company's performance, we were interested in conducting similar research by placing manufacturing companies listed on the Indonesia Stock Exchange in the 2013-2017 period as the research samples. Manufacturing companies were chosen because in Indonesia, most manufacturing companies have the characteristics of implementing corporate governance generally applied so that they can represent the entire company in Indonesia. Moreover, the research of Detthamrong et al. (2017) was carried out by taking samples from different countries, namely non-financial companies in Thailand that have relatively implemented GCG in their companies so that GCG might no longer be a competitive advantage in that country. We feel the need to carry out this research to assess the urgency of GCG implementation for companies and also to provide insight for investors and creditors in determining their investments.

This research will be continued into several sections of the discussion consisting of literature reviews relating to this research, followed by the methodology section used to collect data, the fourth part will discuss the data obtained and analyze the results, and the last part will be completed with conclusions from the research.

Literature Review

Agency theory identifies agency relationships where one party (principal) delegates work to other parties (agents) (Jensen & Meckling, 1976). In a company, principals and agents can be interpreted as company owners (shareholders) and management. This agency relationship can cause a number of problems where the agency relationship can cause harm to the principal because the agent has the opportunity to fulfill his own interests. This problem is called the *agency problem*. For example, a manager might not take a new project with risk because the bonus target has been met. This condition causes losses to the principal due to opportunity cost—in this case, the agent did not act to fulfill the principal's interests but rather saved his personal interests. Another example of an agency problem is the occurrence of information asymmetry between management and principals, where agents certainly have more information than the principal.

Managers should be agents of company owners, but managers must be monitored and institutional arrangements must provide checks and balances to ensure that the manager does not abuse his authority. Costs arising from managers misusing their positions, as well as the costs of monitoring and disciplining them to prevent abuse are called agency costs (Blair, 1996). However, this agency theory also has a weakness, where the delegation of duties from the principal to this agent is actually needed, regardless of the potential problems and costs described above. Syafrida, Latumeten, and Suryandono (2019) stated that shareholders who also act as directors can cause ultra vires behavior or actions that exceed authority limits, therefore not supporting GCG principles. In addition, the existence of this dual role can also result in ineffectiveness in carrying out the supervisory function. Moreover, in listed companies that have minority shareholders, the existence of a dual role of shareholders and management makes justice for minority shareholders not guaranteed, which violates GCG principles.

Corporate governance is the procedure and process of a directed and controlled organization. Corporate governance structures determine the distribution of rights and responsibilities among members in an organization, such as boards of directors, managers, shareholders, and other stakeholders, and establish rules and procedures for decision making (OECD, 2014). Corporate governance aims to help companies build trust, transparency, and accountability, which are needed to foster long-term investment, financial stability, and honesty/integrity in conducting business to support sustainable growth and a more inclusive society (OECD, 2015). In implementation of corporate governance, several studies have used multiple indicators in the area of corporate governance in a company.

Firm performance is a measure of how efficiently and effectively an organization or manager achieves adequate goals (Stoner et al., 1996). Company performance can be measured from various sides, though the easiest is based on financial performance. The company's financial performance can be obtained from the numbers on the company's financial statements.

Higgins, Koski, and Mitton (2012) stated that *financial leverage* is a tool to increase the rate of return expected by owners with higher risk. Financial leverage involves replacing a fixed loan cost for the owner's equity; financial leverage then increases returns to the owner. Therefore, financial leverage is like a double-edged sword that can increase the expected rate of return of the owner but also increase the risk.

Corporate Governance in Financial Leverage

Financial leverage increases with increasing board size. Companies with a small board size are advised to enlarge the board size to use more debt financing than equity financing (Jensen, 1986). Consistent with the literature, we suggest the following hypothesis:
H1.1 : There is a positive effect of board size on financial leverage.

Board independence is a board of directors who are not a majority shareholder or group of shareholders and executives of a company. Directors must have expertise that is in accordance with what is required by the board of directors, according to the unique nature of a company. As an independent director, a director must have knowledge and information that allows the company to get

a higher level of leverage, and the presence of independent directors is expected to get higher leverage (Berger, Ofek, & Yermack, 1997). Therefore we suggest the following hypothesis:
H1.2 : There is a positive effect of board independence on financial leverage.

Previous studies have shown that many companies in developed countries have low financial leverage. The presence of female directors in companies with low financial leverage can encourage these companies to increase leverage (Detthamrong et al., 2017). Because companies in developing countries are generally more constrained financially than those in developed countries, we believe that female directors will increase the company's financial leverage. Thus, our hypothesis is as follows:
H1.3 : There is a positive effect of female directorship on financial leverage.

Family companies with sole ownership are believed to have significantly higher debt (Detthamrong et al., 2017). Wiwattanakantang (1999) found that ownership concentration has a positive correlation with financial leverage. Paligorova and Xu (2012) found that companies with more concentrated ownership have higher financial leverage than companies with smaller concentration of ownership. His findings believe that ownership concentration can force managers to increase financial leverage in order to reduce managerial opportunism. Those literatures bring us to the next hypothesis:
H1.4 : There is a positive effect of ownership concentration on financial leverage.

Managerial shareholders can encourage managers to use the optimal amount of debt, because they will experience losses just as other shareholders will when using debt that is less than the optimal level for that company's capital structure (Abor, 2008). Previous research has found that the size of managerial shareholders is tied to a high debt policy. Kim and Sorensen (1986) showed that insider shareholders increase the company's financial leverage (Abobakr and Elgiziry, 2016). This positive effect was also obtained in the studies by Ooi (2000), Arko and Bokpin (2009), and Wellalage & Locke (2012). Therefore:
H1.5 : There is a positive effect of director's ownership on financial leverage.

The auditor’s reputation plays a significant role in reducing the risk of information obtained by investors, thereby reducing the cost of capital (Azizkhani et al., 2010). This condition allows companies to get more funding through financial leverage. Based on this, we suggest:
H1.6 : There is a positive effect of reputation audits on financial leverage.

Corporate Governance on Firm Performance

Some theories see that the number of directors in a company will affect the company's performance. This allows for constructive debates and effective decision making, and it ensures that the experience and capabilities of supervisory board members are in accordance with company requirements (Mallin, 2013).

A large board size provides a wider range of resources than a small board. Boards of directors with varying experience and knowledge will probably have more learning experience and are more careful in making decisions, resulting in a better company performance (Detthamrong et al., 2017).

The board of directors is one of the most important elements of the corporate governance mechanism in overseeing effective and efficient operations of a company. The board of directors plays an important role in mitigating the failure of a company (Chancharat et al., 2012).

Family effects can be reduced through increasing the number of councils. At least, consensus must be falsified first among the main family parts (Topak, 2011). Compliance will also increase along with the increase in the number of directors (Mallin & Ow-Yong, 2011). This brings us to the following hypothesis:
H2.1 : There is a positive effect of the board size on firm performance (ROE).

The representation of the independent director in board composition should be positively correlated with firm performance. If there is no correlation or the relationship turns out to be negative with the performance firm, then the performance of the independent director is in danger (Fuzi, Adliana Abdul Halim, & Julizaerma, 2016). In addition, based on the agency theory, the existence of an independent

director will indirectly improve the supervision function within the company. Consistent with the theory and research, we suggest:
H.2.2 : There is a positive effect of board independence on firm performance (ROE).

Differences produce innovation and creativity. Historically, most boards of directors consisted mostly of male directors. In recent years, there has been a strong argument that having female directors provide different points of view that can improve company performance (Detthamrong et al., 2017).

Female directors support company management by using their expertise and legal abilities, HR management, communication and public relations more than men (Zelechowski & Bilimoria, 2004). Other studies have found that female directorship significantly increases ROA and ROE (Bennouri, Chtioui, Nagati, & Nekhili, 2018). Thus, we suggest:
H2.3 : There is a positive effect of female directorship on firm performance (ROE).

Fragmented supervision and ownership provides opportunities for managers to take action that benefits themselves, which is dangerous for the company's performance (Detthamrong et al., 2017). The presence of controlling shareholders can provide a strong impetus in overseeing managers and maximizing company value. Ownership concentration can reduce the occurrence of agency problems between owners and managers (Maury, 2006). Concentrated ownership can improve managerial supervision so as to improve company performance (Agrawal & Knoeber, 1996). Consistent with the results of these studies, we present the following hypothesis:
H2.4 : There is a positive effect of ownership concentration on firm performance (ROE).

As has been explained above, agency theory has a weakness wherein shareholders who also play a role as management can reduce company performance. Although many results of the study stated that managerial ownership has a positive impact on company performance because it can reduce agency problems, we still believe that managerial ownership can have a negative effect on the company's performance with regard to its dual role, whereby it can lead to actions beyond authority (ultra vires) (Syafrida et al., 2019). Consistent with the literature, our hypothesis is therefore:
H2.5 : There is a negative effect of director's ownership on firm performance (ROE).

One of the things to be achieved by implementing GCG in a company is to minimize agency problems, one of which is information asymmetry between owners and agents. The recruitment of trusted external auditors (in this case the Big Four) will be able to overcome or reduce these problems. Thus, the company's performance can be improved. For this reason, we suggest:
H2.6 : There is a positive effect of reputation audit on firm performance (ROE).

Financial Leverage on Firm Performance

Referring to the Modigliani Miller Preposition II theory as outlined in the previous chapter, the effect of financial leverage on firm performance in terms of ROE should be positive, unless the risk level of the company's bankruptcy is within an alarming threshold (Ross, Westerfield, & Jaffe, 2013). Miller (2005) stated that firm leverage has a positive effect on the company's financial performance where the company gets incentives from the use of debt. Therefore, our hypothesis is:
H3 : There is a positive effect of financial leverage on firm performance (ROE).

Mediating Effect of Leverage on Financial Leverage to Firms Performance

The link between corporate governance and firm performance is still not very clear, in the sense that corporate governance does not directly affect a firm’s performance, so what variables are mediating variables needs to be examined; in this case, the mediator variable is financial leverage (Detthamrong et al., 2017). The choice of financial leverage as a mediator variable is because, based on previous research, financial leverage was found to affect corporate governance, and financial leverage affects firm performance. Thus, we suggest:
H4.1 : Financial leverage has a mediating effect on the relationship between board size and firm performance (ROE).
H4.2 : Financial leverage has a mediating effect on the relationship between board independence and firm performance (ROE).

H4.3 : Financial leverage has a mediating effect on the relationship between female directorship and firm performance (ROE).
H4.4 : Financial leverage has a mediating effect on the relationship between ownership concentration and firm performance (ROE).
H4.5 : Financial leverage has a mediating effect on the relationship between director's ownership and firm performance (ROE).
H4.6 : Financial leverage has a mediating effect on the relationship between audit reputation and firm performance (ROE).

Methods

In this study, data processing was performed using the program panel data regression STATA 15.0 with the Panel Corrected Standard Error (PCSE) model, because the classic assumption test showed that the data had problems with heteroscedasticity and autocorrelation.

Research Model

The model used in this research is in accordance with the hypotheses proposed. The model was previously used by Detthamrong et al. (2017) in his research. The research model consists of four equations in order to get results for testing hypotheses that have been developed previously.

Equation 1. Effects of Corporate Governance on Financial Leverage

$$LEV_{i,t} = \alpha + \beta CG_{i,t-1} + \gamma Z_{i,t-1} + \varepsilon_{i,t} \quad (1)$$

Equation 2. Effect of Corporate Governance on Firm Performance

$$ROE_{i,t} = \alpha + \beta CG_{i,t-1} + \gamma Z_{i,t-1} + \varepsilon_{i,t} \quad (2)$$

Equation 3. Effect of Financial Leverage on Firm Performance

$$ROE_{i,t} = \alpha + \beta LEV_{i,t-1} + \gamma Z_{i,t-1} + \varepsilon_{i,t} \quad (3)$$

Equation 4. Effect of Corporate Governance and Financial Leverage on Firm Performance

$$ROE_{i,t} = \alpha + \beta CG_{i,t-1} + \delta LEV_{i,t-1} + \gamma Z_{i,t-1} + \varepsilon_{i,t} \quad (4)$$

As for testing the effect of financial leverage as a mediator variable between corporate governance and firm performance, we used the causal step method developed by Baron and Kenny (1986).

Data and Sample

The sample of this research is manufacturing companies listed on the Indonesia Stock Exchange in the period of 2013–2017. Badan Pusat Statistik (2017) provided a definition of manufacturing companies, namely companies whose business activities change raw materials and/or semi-finished goods into goods through a process of steps to increase the value of the item. The determination of the company is carried out based on the classification of business sectors and sub-sectors found on the IDX. Based on the data collected from the Indonesia Stock Exchange, Eikon Thomson Reuters, and Yahoo Finance, taking into account the completeness of the data in the study period, 113 sample companies were established, with a total of 565 observations. To minimize outliers and possible data recording errors, we winsorized all variables at the 5th and 95th percentiles.

Variables

The dependent variable in this study is firm performance, which is measured by the company's Return on Equity (ROE). In this study, ROE is the proportion between net income to total equity and minority interest.

The independent variable in this study is the mechanism of corporate governance, including board size, which was measured by the number of board of commissioners and board of directors; board independence, which was measured by the ratio of the number of independent commissioners to the number of commissioners; female directorship, which was measured by the ratio of the number of female directors and commissioners to the number of directors and commissioners; ownership concentration, which was measured by the percentage of common stock held by shareholders of more

than 5% of the total common stock, in line with research conducted by Ciftci, Tatoglu, Wood, Demirbag, and Zaim (2019) and Nguyen, Locke, & Reddy (2014); director's ownership, which was measured by the proportion of common stock held by directors and/or commissioners; and audit reputation, which will be worth 1 if the company is audited by an audit company in the Big Four category (Deloitte, PWC, EY, and KPMG) and 0 otherwise.

In this study, the control variables used are market to book value, which was measured by the proportion between common stock market prices after adjustments and book value of common stock; firm size, which was measured by the natural logarithm of total assets; and firm age, which was measured by the natural logarithm of the number of years the company is listed on the stock. We used financial leverage as a mediator variable that will mediate the effect of corporate governance on firm performance. Besides being a mediator variable, financial leverage is also an independent variable in equation 1 and an independent variable in equation 3.

Result and Discussion

Descriptive Statistic

Table 1 presents the descriptive statistics of the variables used in this article for the final sample of 565 firm-year observations over the period 2013–2017.

Table 1: Descriptive Statistic

Variables	Mean	Median	St. Deviation	Minimum	Maximum
Board Size$_{(t-1)}$	9.4248	9.0000	3.8022	4.0000	23.0000
Board Independence$_{(t-1)}$	0.4003	0.3333	0.0991	0.2000	0.8000
Female Directorship$_{(t-1)}$	0.1207	0.1111	0.1243	0.0000	0.6250
Director's Ownership$_{(t-1)}$	0.0391	0.0001	0.1107	0.0000	0.7393
Ownership Concentration$_{(t-1)}$	0.7355	0.7693	0.1566	0.1316	0.9977
Audit Reputation$_{(t-1)}$	0.4248	0.0000	0.4943	0.0000	1.0000
ROE	0.0710	0.0566	0.2829	-2.5396	2.3502
Financial Leverage	0.2872	0.2497	0.4283	0.0000	4.7473
Financial Leverage$_{(t-1)}$	0.2788	0.2449	0.3965	0.0000	4.7473
Market to Book Value $_{(t-1)}$	2.0530	0.9363	5.0273	-2.9389	60.5308
Ln Firm Size$_{(t-1)}$	28.3883	28.1897	1.5987	25.2455	33.1988
Ln Firm Age$_{(t-1)}$	2.7812	3.0565	0.7584	-3.3377	3.6736

From Table 1 above, it can be seen that the board size has a mean value of 9.4248, board independence has a mean value of 0.4003, female directorship has a mean value of 0.1207, director's ownership has a mean value of 0.0391, ownership concentration has a mean value of 0.7355, and audit reputation has a mean value of 0.4248.

Regression Result

In this section, we present our empirical results regarding the effects of corporate governance on financial leverage. Table 2 and 3 present the goodness of fit of model and regression result, where the dependent variable is financial leverage as Eq. (1), and the dependent variable is firm performance as Eq. (2), (3), and (4).

Table 2: Goodness of Fit

	Eq. (1)	Eq. (2)	Eq. (3)	Eq. (4)

The Effect of Corporate Governance on Financial Leverage

Based on the Eq. (1) the corporate governance variables that have a statistically significant effect on financial leverage (*p-value* below 0.05) are the board size, ownership concentration, and audit reputation, while other variables have no effect on financial leverage. However, even though the board size, ownership concentration, and audit reputation have a statistically significant effect on financial leverage, those three variables cannot support the hypothesis because it has a negative coefficient value. The coefficient of determination (R-squared) of 0.2409 indicates that variations in leverage can be explained by corporate governance variables of 24.09%.

The results are in line with the research of Bodaghi and Ahmadpour (2010) and Anderson, Mansi, and Reeb (2004), who found that board size and financial leverage were negatively correlated. The results are also in line with Farooq (2015), who found that high ownership concentration would actually make shareholders fear the risk of bankruptcy. While the results that show that board independence and female directorship do not affect financial leverage, they are in line with the research by Detthamrong et al. (2017).

The Effect of Corporate Governance on Firm Performance

Board size has a significant positive effect on ROE. These results support hypothesis 2.1, where the board size has a significant positive effect on firm performance. This result is consistent with Jackling and Johl (2009). In contrast to the research hypothesis, the regression results show that female directorship has a significant negative effect on ROE (coefficient -0.1095; *p-value* 0.0235). The

results are in line with the research conducted by Adams and Ferreira (2009) and Nguyen, Locke, and Reddy (2014), who found that the effect of gender diversity on firm performance was negative. Joecks, Pull, and Vetter (2013) found that gender diversity initially had a negative effect on firm performance and increased when "critical mass" (about 30%) for the proportion of women was achieved. Frink et al. (2003) stated that the business sector also was affected wherein women's performance will increase in the service sector/large trade/retail industry.

Variable ownership concentration has a significant negative effect (coefficient -0.0992; *p-value* 0.0090) on ROE. Bhaumik and Selarka (2012), in their research, gave reasons why ownership concentration can have a negative effect on firm performance, whereas ownership concentration indeed reduces agency conflict between owners but can cause conflicts between principals so that it can reduce company performance. The remaining factors, namely independent director, director's ownership, and audit reputation, have no effect on firm performance. The results are in line with research conducted by Haniffa and Hudaib (2006) in Malaysia, Hu and Izumida (2008) in Japan, and Chen et al. (2005) in Hong Kong where board independence does not affect company performance, along with the research conducted by Elewa and El-Haddad (2019) and Sayyar, Basiruddin, Rasid, and Elhabib (2015), who found that audit reputation did not affect ROE.

The Effect of Financial Leverage on Firm Performance

From the results of the research in Table 3 Eq. (3), it can be seen that financial leverage has a significant negative effect on ROE. The results of this study are in line with the results of the study of Antoniou, Guney, and Paudyal (2008) and Vithessonthi and Tongurai (2015), where financial leverage has a negative effect on company performance. Detthamrong et al. (2017) stated that the negative relationship between financial leverage and company performance is caused by the cost of financial distress greater than the profit of the funding itself.

The Mediating Effect of Financial Leverage

As previously described, the mediating effect of *financial leverage* was carried out using a causal step method developed by Baron and Kenny (1986). We found that the mediator variable is declared as full mediation if after entering the mediator variable in the equation, the effect of the independent variable on the dependent variable in Eq. (4) becomes insignificant. Mediator variables are expressed as partial mediation if after entering the mediator variable in the equation, the effect of the independent variable on the dependent variable in Eq. (4) is weaker than that in Eq. (2). Based on the test results in Table 3 Eq. (4), there is one variable that meets the requirements as described above: board size.

The financial leverage variable has a negative correlation (-0.0976) to the ROE variable with a *p-value* of 0.0035. The board size variable has a negative correlation (-0.0052) to the financial leverage variable with a *p-value* of 0.0445 and has a positive correlation (0.0067) to the ROE variable with a *p-value* of 0.0010. After including financial leverage variables in the equation, the significance of the board size variable to the ROE variable decreased to *p-value* of 0.0015.

Based on the description, because the effect of the one independent variable on the dependent variable in Eq. (4) is weaker than that in Eq. (2), it can be concluded that the financial leverage variable provides a partial mediation effect on the board size relationship to firm performance.

Conclusion

Based on the results, we can conclude that board size is the only variable that supports the research hypothesis where board size is positively correlated with firm performance. This means that the increase/increase in the size of the board of commissioners and/or directors will indirectly improve company performance, while female directorship and ownership concentration actually have a significant negative impact on performance firms. We also found the effect of corporate governance on financial leverage is reflected in board size, ownership concentration, and audit reputation

variables, where all three have a negative effect on financial leverage. Although significant, this result does not support the hypothesis because it has a negative correlation value. The negative effect of financial leverage on ROE shows that financial leverage in manufacturing companies has not been able to play its role as leverage or leverage of company returns. In this case, financial leverage actually appears to provide an additional burden for the company in the form of financing costs that have a negative impact on the company's ROE. Financial leverage has a partial mediation effect on the relationship between board size and firm performance. The existence of a negative effect of several corporate governance variables on financial leverage and the added negative effect of financial leverage on ROE provides the possibility that manufacturing companies in the study period are facing financial difficulties and the risk of bankruptcy.

Acknowledgment

This research was conducted with the support of Universitas Indonesia trough the PITMA Program 2019. We thank all the contributing parties who assisted in the completion of this research.

L'Intelligence Artificielle au Service de l'Évaluation Formative

Allal MOKEDDEM

Maitre de conférences, Université Alger 3, Département de management et technologie,
Algiers, Algérie
mokeddem.allal@yahoo.fr

Résumé

Aujourd'hui, le numérique à très grande échelle accompagne les enseignants dans leurs activités, désormais des outils extrêmement variés pour renforcer leurs pratiques pédagogiques au quotidien et cela s'incarne dans l'évaluation. Dans l'ère de l'intelligence artificielle (IA) une évaluation formative est devenue un véritable moyen de prendre en compte le travail personnel de l'apprenant et soit lisible, transparente et partagée avec ses pairs. À cet égard, l'IA propose des environnements d'évaluation qui génèrent un ensemble d'informations et de conseils au cours de la formation. Dans la première partie, nous analysons un ensemble d'études et de techniques qui examinent le processus d'évaluation formative dans les domaines de formation suivants: Science, Technology, Engineering et Mathematics (STEM). Enfin, nous concluons ce papier par une démonstration analytique à quoi offert l'évaluation formative au profit de l'apprentissage en profondeur et vice-versa.

Mots-clés : L'intelligence artificielle (IA), L'apprentissage en profondeur, L'évaluation formative, STEM.

Introduction

Dans nos jours, les établissements d'enseignement supérieur exercent dans un environnement complexe et diversifié. Les solutions technologiques sont devenues plus sophistiqués avec l'arrivée de l'interaction homme-machine. Les interfaces homme-machine présentent le potentiel immédiat pour changer la façon dont nous apprenons, mémorisons, créons et valorisons nos connaissances Popenici et Kerr (2017). À cet égard, les méthodes d'évaluation évoluent afin de rassurer une meilleure production académique et scientifique. Selon Fu (2020), une évaluation formative devrait être effectuée pendant le processus d'apprentissage. Une évaluation instantanée devrait aider les enseignants et les apprenants à analyser la qualité de connaissances développées en temps réel et déterminer les lacunes existantes dans le processus d'apprentissage. D'après Han et Fan (2020) les méthodes d'évaluation formative permettant de générer des commentaires formatifs lors de l'apprentissage et de changer le comportement et l'attitude de l'apprenant, cela se répercute sur les pratiques pédagogiques de l'enseignant afin d'atteindre une meilleure performance académique.
Ce papier explore le rôle unique de certaines conceptions de l'évaluation formative destinée aux domaines de la formation STEM (Sciences, Technologie, Ingénierie, Mathématiques) Peterson et Hipple (2020). Ensuite, la dernière partie de ce papier est réservée à quoi, comment et pourquoi l'évaluation formative est utile pour surveiller régulièrement le processus d'apprentissage en profondeur et vice-versa.

Méthodologie

Cette étude suit une méthodologie d'analyse descriptive et analytique. D'abord, une présentation conceptuelle de la littérature sur la mise en œuvre des méthodes d'évaluation formative dans le champ de la formation STEM. Ensuite, une démonstration analytique sur le double intérêt qui rejoint l'évaluation formative et l'apprentissage en profondeur en faveur de la régularité et l'efficacité du processus d'apprentissage. Le diagramme suivant illustre le modèle conceptuel suivi au cours de cette étude.

Fig. 1 : Cadre méthodologique

Revue De La Littérature

Le développement d'une pensée complexe commence par des stratégies plus complètes en matière d'observation, d'interprétation et d'évaluation de résultats. Dans leurs études, Sugahara et Dellaportas (2018) ont montré que l'introduction des méthodes d'enseignement novatrices axées sur l'apprenant améliore les capacités de mémorisation et d'engagement des apprenants. Dans cette dynamique l'apprenant est favorablement motivé pour non seulement gérer une situation d'apprentissage mais gérer les différents niveaux d'abstraction d'une situation d'apprentissage. Dans ce contexte, l'apprentissage en profondeur a produit des résultats très prometteurs pour différents niveaux de compréhension, notamment la classification des sujets, l'analyse des sentiments et les réponses aux questions de Bordes et al (2014). A ce stade, des progrès significatifs ont été réalisés dans le champ de l'IA grâce à des systèmes qui combinent l'apprentissage par l'action avec une logique et un raisonnement complexe. Ce développement a conduit à l'émergence de méthodes d'évaluation qui pourrait rendre l'apprentissage avec ses différentes contraintes plus homogènes et plus valorisables.

L'évaluation formative, à quoi ça sert ?

Au 21e siècle, le développement des compétences s'est concentré sur des domaines spécifiques, notamment les disciplines appelées STEM (Science, Technology, Engineering and Mathematics Johnson et al (2016). Des domaines de formation très pointus qui nécessitent des moyens et des techniques d'évaluation avancées. Dans l'ère de la nouvelle technologie, les supports d'évaluation formative ont créé de nouvelles demandes de la rétroaction en temps opportun. L'évaluation constructive ou formative crée des opportunités de promouvoir le développement des compétences en matière d'explication, d'interprétation et de raisonnement Bulunuz et al (2016). Dans cette atmosphère, l'approche de l'évaluation formative consiste à déterminer comment le système d'IA peut prédire les situations les plus difficiles dans un processus de formation. Des situations qui nécessitent un feedback instantané à la fois directif et suggestif.

La voie de la rétroaction enseignant-apprenant n'est pas le seul moyen pour fournir un retour d'information efficace. Selon Spector et al (2016) l'autoévaluation et l'évaluation par les pairs peuvent être considérées comme une composition intéressante dans la voie de la rétroaction formative. Dans ce contexte, l'apprenant doit développer ses capacités de contrôler la qualité de son propre travail mettant des critères d'évaluation de son état d'avancement individuelle, afin de comparer son travail avec les normes et les standards de performance de haut niveau. Le tableau suivant présente les différents aspects de l'évaluation formative d'après Wiliam.

Table 1 : Les différentes formes d'évaluation formative

	Où les apprenants vont-ils ?	Où en sont-ils dans leurs apprentissages ?	Comment et par quelles étapes, peuvent-ils atteindre les buts visés ?
Enseignant	Clarifier, partager et faire comprendre les intentions d'apprentissage et les critères de réussite.	Organiser de véritables discussions, activités et taches qui produisent des preuves sur l'apprentissage.	Donner un feedback qui fait progresser les élèves.
Pairs		Inciter les apprenants à être des ressources pour leurs paires.	
Apprenant		Inciter les apprenants à être responsable de leurs apprentissages.	

Afin d'approuver l'apport de l'évaluation formative sur le processus du développement des connaissances, des études théoriques ont été menés selon le domaine de compétence STEM. Le tableau suivant illustre les différentes études réalisées sur l'approche d'évaluation formative en sein des institutions publiques (école, collège, université).

Table 2 : L'evaluations formative de point de vue théorique et pratique

Domaine	Type d'étude	Objectif	Catégories et tranche d'âge	Mesure de la population	Collecte de données	Compétences attendues	Auteurs
1) Mathématique	Qualitative : Méthode des cas	Résolution collective de problèmes mathématiques	6 ème primaire, 11-12 ans, 8 élèves partagés en deux groupes régulés par un enseignant.	S'exprimant facilement à l'oral	Enregistrements audio et vidéo ; une caméra, située au fond de la classe et centrée sur l'enseignante ; caméra fixe est centrée sur un groupe d'élèves.	Dévolution d'une responsabilité en mathématique, d'auto confrontation d'idées mathématique, évolution de la conceptualisation de l'enseignant.	Lepareur et al (2017)
2) Science Fondés sur l'Investigation (sciences mathématique, physiques et chimiques, sciences de la vie et de la terre)	Approche méthodologique mixte : qualitative : codage des données vidéo et catégorisation et quantitatives : L'analyse factorielle des correspondances multiples (AFCM)	Offrir une image plus conforme de l'activité scientifique. Et éveiller l'intérêt des élèves en mettant l'accent sur leur rôle actif dans le processus d'apprentissage.	**Enseignant** : Trois enseignants de mathématiques ; deux enseignants de sciences de la vie et de la terre (SVT) ; deux enseignants de sciences physiques et chimiques (SPC). **Élève** : Deux à quatre élèves selon les disciplines. **Groupe mathématique** : 6 ème primaire, 11-12 ans. ; **Groupe physiques**: 5ème (12-13 ans) et **Groupe sciences de la vie et de la terre :** 4ème (13-14 ans).	Un niveau scolaire moyen, ayant certaines affinités, ou ayant l'habitude de travailler ensemble, et s'exprimant facilement à l'oral.	Enregistrements vidéo et audio. Une grille d'indicateurs.	L'évaluation se fait en relation avec : ***Buts*** : L'enseignant explicite les buts de l'activité et les sous-buts intermédiaires ; **Critère** : L'enseignant explicite les critères de réussite, les compétences évaluées et les attentes ; **Avancée tâche** : L'enseignant prend des indices sur l'état d'avancée des élèves dans la tâche/ activité ; **Compréhension :** L'enseignant questionne les élèves sur leur compréhension de ce qui est demandé ; **Connaissances :** L'enseignant prend des indices sur les connaissances (préalables) des élèves ; **Autoévaluation** ; **Feedback** ; **Responsabilisation** ; **Echanges groupe** et **Echanges classe entière.**	Lepareur (2016).
3) Engineering	Qualitative : taxonomie de qualification	**Niveau** 1 : Savoir comprendre les compétences de rappel, de compréhension et d'application. **Niveau 2** : savoir analyser, synthétiser et évaluer vos connaissances. **Niveau 3** : Valider votre modèle d'ingénierie routière afin de formuler un équilibre entre : la valeur future + la valeur présente + la valeur résiduelle de la route.	Etudiants de maîtrise	Deuxième cycle universitaire	Questionnaire	Modèle RECAP (Recall, Comprehension, Application, Problem solving) Imrie (1995). L'étudiant doit se souvenir (se rappeler), comprendre (comprendre) et utiliser (appliquer) plusieurs concepts d'ingénierie enseignés en classe. L'étudiant doit associer ces concepts avec des formules économiques et des techniques mathématiques pour trouver la solution (résolution de problèmes).	Burrow et al (2005).
4) Technologie	Quantitative : Alpha Cronbach, test de la variance Anova one Way	Compléter et corriger le code source sous Fortran, ainsi que l'écriture de code Fortran à partir de zéro. Comparer la performance entre les étudiants qui travail via la version papier et la version informatique.	211 étudiants au niveau de l'École de génie chimique de l'Université technique nationale d'Athènes.	Premier cycle universitaire	Questionnaire	L'évaluation se fait en relation avec : La déclaration de données ; La références de données ; les calculs; les comparaisons; le contrôle de flux ; Les Entrées / Sorties ; L'interface de commentaire ; La Modularité et l'utilisation du stockage.	Kalogeropoulos et al (2013)

Evaluation formative et l'investigation mathématique

L'apprentissage n'est pas soumis un processus linéaire. L'étude de Lepareur et al (2017) confirme cela et sers à développer les compétences des élèves de 6e année primaire en mathématiques. Il ne s'agit donc pas de faire rechercher une réponse correcte unique, mais d'amener les élèves à interpréter le problème, identifier et évaluer les solutions possibles en faisant des essais et formuler des conclusions. La séance d'investigation retenue par l'équipe de recherche porte sur le nombre de diagonale d'un polygone. L'auto-évaluation a été utilisée comme un support d'évaluation formative. Les enseignants offrent au profit des étudiants une grille d'évaluation intégrée dans la feuille d'énoncer. Une telle démarche d'évaluation formative, change les modalités de la gestion et de l'organisation d'une classe. Des stratégies d'évaluation vers une plus grande valorisation des échanges et de la responsabilisation de l'élève. D'autant plus, la grille d'auto-évaluation présentée anticipe les difficultés des élèves a modifié l'avancée du savoir dans la classe et a permis de dégager suffisamment de temps d'échanges collectifs.

Evaluation formative fondée sur la Science de l'Investigation

L'enseignement scientifique fondé sur l'investigation vise à rendre l'apprenant plus conforme à l'activité scientifique. Dans ce contexte, le processus d'apprentissage de l'apprenant sera soumis à des pratiques d'investigation et de questionnement continus. L'étude de Lepareur et al (2016) vise à introduire la démarche d'investigation scientifique dans le contenu académique des sciences mathématiques, physiques et chimiques, sciences de la vie et de la terre. Une méthode d'investigation dans l'ordre : Raisonner, Rédiger, Communiquer par un schéma et S'informer a été mesuré via un barème graduel de 0 à 3. Afin d'analyser le degré de rétention du processus d'investigation, une étude expérimentale mixte a été menée auprès des apprenants 6 e, 5 e année du cycle primaire et 4 e année du cycle intermédiaire. À cet égard, deux situations ont été menées. La première correspondait aux évaluations formatives telles que les enseignants la mettent en œuvre dans leurs pratiques quotidiennes. La deuxième concernait les pratiques évaluatives mises en œuvre par les mêmes enseignants de l'année suivante, après qu'un retour réflexif sur leur séance ait été conduit. Après une deuxième situation, l'apprenant allant vers plus grande responsabilisation avec une autorégulation de leur comportement au profit du temps passé à produire des stratégies de résolution d'un meilleur engagement dans la tâche.

Evaluation formative aux services de l'ingénierie

L'étude de Burrow et al (2005) s'intéresse à produire une approche d'évaluation formative informatisée pour deux unités pédagogiques destinées aux étudiants de 1 ère année maitrise, à savoir la gestion routière et l'ingénierie. Pour ce besoin, une taxinomie appropriée a été choisie pour évaluer le niveau de la compréhension des étudiants. La taxinomie adoptée était le modèle RECAP (Recall, Comprehension, Application and Problem resolution). Le contenu de l'unité de l'évaluation est déterminé par la valeur monétaire d'une route dans 10 ans d'exploitation. Dans ce contexte, toutes les compétences de la taxinomie RECAP soumises à des tests selon la contrainte de 10 ans. Cela afin de répondre à la question, l'apprenant doit se rappeler, comprendre et utiliser plusieurs concepts d'ingénierie enseignés en classe. Enfin, l'étudiant doit associer ces concepts développés avec des formules économiques et des techniques mathématiques pour trouver la solution (résolution de problèmes). Cette rubrique ne s'affiche que si l'étudiant atteint le score minimal pour la question traitée. L'équation développée sera approuvée par une liste des références, des notes de cours et des textes complémentaires obtenus en cliquant sur le lien approprié.

Evaluation formative dans le domaine IT

Un programme informatique efficace ne consiste pas seulement à traiter les erreurs de syntaxe, mais aussi à diagnostiquer les erreurs sémantiques. Dans ce contexte, l'évaluation instantanée d'un code source peut dégager beaucoup du temps et d'information. L'étude de Kalogeropoulos et al (2013) cherche à étudier l'équivalence des scores d'un traitement de code source sous Fortran via l'approche d'évaluation informatisée par rapport à la version papier. Un échantillon d'étudiants de premier cycle de l'école de génie chimique de l'Université technique nationale d'Athènes a été examiné. Les deux types d'évaluation comprenaient les mêmes questions de type à choix multiples, complétant et corrigeant le code source, ainsi que l'écriture de code fortran à partir de zéro. Un ensemble de compétences au menu sont : savoir maitriser la déclaration de données, les références de données, les fonctions de calcul et de comparaison, les fonctions d'entrée sortie, les espaces de commentaire. Les résultats ont montré que, en général, les élèves réussissaient mieux et obtenu des scores plus élevés sous l'évaluation informatisée par rapport à la version papier.

Évaluation formative et l'apprentissage en profondeur : y a-t-il un conjoint d'intérêt ?

Selon Adnan et al, (2019), une mise en œuvre efficace et équitable de l'évaluation avec ses différentes alternatives est extrêmement impérative vers le changement du processus d'apprentissage. Dans ce contexte, l'évaluation formative augmente le pourcentage de la rétention du savoir. L'apprenant sait ce qui leur manque et où se concentrer à retenir les connaissances les plus profondes en termes d'importance et de liaison avec le domaine d'étude Jain et al (2014). En un mot, une évaluation formative efficace est celle introduite comme une pratique intégrée et alignée avec les objectifs éducatifs. À cet égard, une évaluation formative inviterait les apprenants à suivre leurs progrès d'apprentissage, réajuste la barre d'objectif très haute et déterminer les mesures à prendre et comment s'y prendre.

En conséquence, les données et les commentaires générés durant le processus d'apprentissage, transforme le rôle confié aux étudiants qui deviennent des apprenants profonds avec un grand potentiel et un engagement personnel lors de la formation. À cet égard, l'apprenant sera impliqué dans la réflexion de haut niveau et d'autres compétences supérieure au rendez-vous telle que la pensée cognitive, critique et créative Asikainen et Gijbels (2017). En plus, l'étude de Healy et al (2014) indique que l'évaluation formative efficace peut ressortir le besoin d'une collaboration en équipe qui convient parfaitement avec les difficultés liées au travail en équipe.

Selon Rothman (2018), la composante d'une situation d'apprentissage en profondeur impliquant le module d'évaluation formative est basée sur une rétroaction instantanée qui fournit des informations qui peuvent être utilisées pour changer les stratégies et le chemin d'exploration des connaissances. Le

module d'évaluation alerte les apprenants sur ce qu'ils doivent savoir et comment et par quelle mesure où les tâches sont comprises et exécutées. De plus, le module d'évaluation formative entre dans le corps du système d'apprentissage, nous lions la rétroaction des tâches qui ne sont pas efficaces avec la rétroaction du processus, afin de comprendre et d'exécuter efficacement les tâches planifiées. Une telle approche d'apprentissage en profondeur, peut déterminer non seulement si un apprenant a obtenu la bonne réponse, mais aussi comment le problème a été résolu.

L'apprentissage en profondeur de son propre sens nécessite des mesures d'évaluation très spécifiques. Les évaluations visent à mesurer ce que les apprenants ont appris (évaluation de l'apprentissage), à éclairer l'enseignement (évaluation pour l'apprentissage) et à fournir des tâches éducatives (évaluation en tant qu'apprentissage). De cette façon, les apprenants peuvent comprendre à quoi ressemble un travail plus complexe et les enseignants peuvent comprendre où les apprenants sont sur la voie de la compétence. Ces progressions d'apprentissage permettent d'identifier où se trouvent les apprenants le long de la trajectoire vers la finalité pédagogique, puis d'ajuster l'enseignement en fonction des résultats. Le schéma suivant présente un diagramme d'exécution du processus d'évaluation formative dans un contexte d'apprentissage en profondeur.

Fig. 2 : L'évaluation formative vis-à-vis l'apprentissage en profondeur, Source Rothman (2018)

Conclusion

La création du savoir est un processus très pointu et très sensible. Ce dernier nécessite des moyens techniques, humains et organisationnels très sophistiqués. Dans ce contexte, les études antérieures ont prouvées que la création d'une situation d'apprentissage efficace est celle qui valorise et prévoit toute source d'information pouvant être utilisée par l'apprenant au cours du processus d'apprentissage. En conséquence, avec l'avènement de l'IA et ses techniques d'apprentissage en profondeur, l'analyse et la valorisation des connaissances développées nécessitent des méthodes d'évaluation plus flexibles qui peuvent suivre la trajectoire de la connaissance développée, via des commentaires et des indications instantanés. Immédiatement, l'apprentissage en profondeur pourrait également servir le processus d'apprentissage, il dissèque le processus d'apprentissage en phases distinctes, cela facilitera la détermination des ressources dont ils auront besoin?, et par quels moyens auront évalué ?, dans le but d'atteindre les finalités pédagogiques souhaitées.

Challenges in The Provision of Accounting Education to Generation Z Students in Poland

Anna KONIECZNA

MSc. Eng., Wroclaw University of Economics and Business, Wroclaw, Poland,
anna.konieczna@ue.wroc.pl

Abstract

This paper presents approaches to accounting education displayed by Generation Z (Gen Z) students, analysed with the purpose of determining whether such changes may require a shift of accounting education methodology. The significance of this aspect of education is evidenced in the observation that methods poorly adjusted to the requirements of their recipients lead to ineffective and wasteful use of both the academic resources and the aptitudes of students. The study was conducted using CAWI technique addressed to those students and graduates of economic courses of studies involving accounting education who were born between the years 1990-2000. With 123 valid responses collected, the project may be regarded as a pilot study. The first section of this paper presents fundamental theoretical principles employed for the evaluation of cross-generational differences in the distribution of individual properties and traits. This is followed by presentation of research methods and findings obtained from the study. The last section provides analytical evaluations of the findings and a number of conclusions. As the aspect under study proved spacious enough to invite further studies, two research hypotheses were formulated as basis for the planned continuation of this project: (1) students seem to take preference in these forms of accounting education which involve computer programs and apps, (2) problem-based learning in accounting education offers more effective development of analytical skills, improving the employment potential of students.

Keywords: Generation Z, Accounting, Teaching Methods.

Introduction

Differences between generations can be attributed to varied conditions associated with their upbringing and education. Based on this assumption, representatives of each of the present generations (the silent generation; baby boomers; generations X, Y, and Z) display different attitudes, traits and, consequently, also outlooks and learning preferences. Gen Z is a generation immersed in technology. Their lives have always been accompanied by technological props: TVs, phones, computers, and the Web. To them, the ubiquitous flood of information is a natural phenomenon. However, an important question can be raised in this context: does this technological environment in any way affect the concentration and apprehension of Gen Z students and what methods of learning are most suitable for this group?

This study attempts to determine whether Gen Z students perceive the need for changes in the present methodological approach to accounting education. To address this question, the following research hypotheses were formulated: (1) in accounting education, Gen Z students display preference for Web sources, (2) Gen Z students are not disposed to verify their Web-based information against other sources, such as professional literature or acts of legislation, (3) Gen Z students perceive and voice the need for changes in the present methodological approach to accounting education.

The findings presented herein are the effect of surveys conducted among students and graduates of economic courses of studies involving accounting education.

Literature Studies

Each generation is born and raised under specific sets of conditions. Intergenerational differences have long been studied from the viewpoint of specific behaviours, personal traits, skills, abilities, and

outlooks. At least five distinct generations can be distinguished in human populations living at present [Zarządzanie różnorodnością… 2016]:

1) The silent generation, representing people born between the years 1928 and 1944 [Howe, 2014].
2) Baby Boomers, i.e. people born between 1945 and 1964 [The Baby… 2000].
3) Generation X, born between 1965 and 1979 [Zarządzanie różnorodnością… 2016].
4) Generation Y, born between 1980 and 1994 [Innowacyjne rozwiązania… 2015].
5) Generation Z, representing people born after 1995, i.e. [The challenge… 2017].

It may be useful to emphasise that the above time brackets are not definitive. Many authors provide different brackets in their descriptions of the modern generations. Thus, the term Generation Z may just as well represent a reference to persons born after the year 1990 [Pokolenie Z wkracza… 2016].

Gen Z representatives display a specific approach to learning and knowledge acquisition. They do not seem to condone with the traditional learning methods. Therefore, lectures and presentations are not the best way to approach this segment. Gen Z students show preference for shared projects, interactive gaming, and advanced challenges. Learning methods addressed to this segment should favour interactive and networking solutions. Students in this group are also quite partial to learning material provided in electronic form and to examinations held in a computer environment. At the same time, Gen Z is not quite ready for a full transition into a virtual environment; many of them are adamant in attaching great value to more direct and personal contacts with their tutors [The challenge of teaching…2017]

Research methods and study findings

The survey, in the form of a CAWI questionnaire, was performed in early December 2019 and was addressed to persons born between 1990 and 2000, namely: students and graduates of economic courses of studies involving tutorship in the subject of accounting. The survey for was published on Facebooks and disseminated among the associated user groups. A total of 123 valid responses to the survey were collected, with 89% representation of females and 11% of males. In terms of year representation, the largest groups were those of persons born in: 1998 (24%), 1999 (21%), 1996 (20%), and 1997 (15%).

The survey included 5 questions, each with a choice of three responses: “no”, “I don’t know/I have no opinion”, and “yes”:

- Do you find accounting an interesting subject of study?
    - no – 24%
    - I don’t know/I have no opinion – 20%
    - yes – 56%
- Are there any obstacles/problems in your learning of the subject of accounting?
    - no – 46%
    - I don’t know/I have no opinion – 18%
    - yes – 36%
- Are you able to remain focused and concentrated over the course of your classes in accounting?
    - no – 56%
    - I don’t know/I have no opinion – 12%
    - yes – 32%
- Do you reach for a phone during your accounting classes (for reasons other than those related to your present assignment)?
    - no – 50%
    - I don’t know/I have no opinion – 12%
    - yes – 38%
- Do you seek verification of your accounting knowledge gathered from the Web with other sources, such as professional literature and acts of legislation?
    - no – 42%
    - I don’t know/I have no opinion –17%
    - yes – 41%

In addition, the survey included a single-choice question on respondents' preferences for specific sources of information for purposes related to their learning of accounting. The responses were as follows:

- Internet – 69%
- Acts of legislation – 3%
- Professional literature – 28%

The last question in the survey was a multiple-choice query of the most effective (in respondents' opinion) methods of those used in the subject of accounting:

- Hand-down methods (informational lecture, speech, description, presentation) – 11%
- Problem-solving methods (such as case studies, didactic games, brainstorming) – 33%
- Exposition methods (film, exhibition, performance with experiential involvement) – 1%
- Algorithmic methods (software applications, guided handbooks) – 16%
- Practical methods (display, training exercise, project) – 40%

A marked majority of the respondents (56%) confirmed that the subject of accounting was of interest to them. Only 24% reported their clear lack of interest in the subject, and the remaining 20% provided a non-committed answer. 46% of the respondents reported no problems in their acquisition of accounting knowledge, with 36% confirming their difficulties, and 18% providing a non-committed answer. By juxtaposing the findings from the two sections, it may be concluded that, of all persons declaring no interest or indifference with respect to the subject under study, as many as 48% believed to have problems acquiring this particular set of knowledge, with 22% having no opinion in this respect, and further 30% confirming that their good understanding and facile acquisition of accounting is not reflected in their interest in the subject.

Students report problems keeping their focus and attention over the course of their accounting classes. This was confirmed by 56% of the respondent sample, with 12% providing no clear opinion, and 32% reporting no problems whatsoever. At the same time, 38% admitted to reaching for their phone during classes for reasons unrelated to the subject, with 12% providing a non-committing answer, and 50% declaring to refrain from such activities.

A decided majority (69%) use the Web as their main source of knowledge for purposes related to the study of accounting, with only 28% admitting on verifying their knowledge against that contained in professional literature, and only 3% were inclined to reach for current legislation as the principal source of subject knowledge. As many as 42% reported their complete disregard for confirmation of their Web-based information against more reliable sources, such as professional literature or current legislation. At the same time, 44% of those respondents who admitted to their use of the Web as the main source of their accounting knowledge were also disinclined to verify this type of information against other sources.

At present, universities and economic schools provide accounting education mostly through the use of hand-down methods (lectures), practical methods (training of skills), problem-solving methods (lectures and assignments) and algorithmic methods (laboratory assignments). Students, on the other hand, believe that the most effective of those are the practical (40%) and problem-solving methods (33%), with less regard for the utility of algorithmic (16%) and hand-down methods (11%), and only a marginal interest in exposition methods (1%).

Conclusions

Findings obtained in the course of this pilot study seem to confirm the hypothesis that, in their learning of the subject of accounting, students show strong preference for Web-based information. At the same time, and quite alarmingly, they tend to place unfounded trust in this type of content, to the effect of not being bothered with verification of such information against more reliable sources, such as professional literature or legislation – in confirmation of the second hypothesis. The last hypothesis (and the main research question of the study) was not confirmed by the findings. For the majority of

respondents, preferences for specific methods of education in accounting were fairly consistent with those presently on offer. However, educators should be aware of the fact that hand-down methods (such as lectures) are decidedly less effective compared to problem-solving approaches. This should form a basis for more informed analyses of methods employed in this segment of economic education. At the same time, it must be noted that students displaying lack of interest (appeal) in accounting are also quite often unable to comprehend it, as evidenced by reports of short attention span and frequent distractions (phone). It may be useful in this context to consider the use of more involving methods to stimulate student focus and interest on the subject, as opposed to the passive reception of hand-down information. Further analyses of methods and approaches to education in the subject of accounting are a rational continuation of this approach. For this purpose, the author formulated two additional hypotheses to be addressed in the future follow-up study: (1) students seem to take preference in these forms of accounting education which involve computer programs and apps, (2) problem-based learning in accounting education offers more effective development of analytical skills, improving the employment potential of students.

L'intelligence Artificielle au Service des Bibliothèques

Allal MOKEDDEM

Maitre de conférences, Université Alger 3, Département de management et technologie, Algiers, Algérie, mokeddem.allal@yahoo.fr

Résumé

À l'ère de l'intelligence artificielle (IA), fournir une bonne documentation ciblée était la principale mission menée par les bibliothèques. Dans ce contexte, chacun est soucieux de connaître les répercussions de l'introduction de l'IA dans les pratiques de la gestion d'une bibliothèque. En conséquence, une étude comparative a été menée dans le but de présenter les changements fondamentaux prévus dans le système de gestion des bibliothèques par rapport aux approches de gestion traditionnelles. Les changements fondamentaux prévus affectent quatre niveaux de gestion: 1) l'accès à l'information, 2) l'interaction de la bibliothèque avec son environnement, 3) l'adaptation de la technologie en fonction de la tâche et 4) la reproduction d'une documentation spécialisée via des techniques d'apprentissage en profondeur.

Mots Clés : Approche IA, Approche Traditionnelle, Processus Bibliothécaire.

Introduction

À l'ère des nouvelles technologies, la production académique et scientifique ne cesse pas de ce développé. À cet égard, face au nombre croissant d'utilisateurs, le besoin d'information se développe de plus en plus en matière : de variétés et de transversalité de l'information envers les autres disciplines. Dans le but de valoriser l'activité académique et scientifique, la bibliothèque est devenue comme un agent du changement afin de rendre l'information accessible et plus valorisable. La bibliothéconomie, en tant que collection de techniques de gestion et d'organisation, ne sert qu'à justifier que la gestion d'une bibliothèque soit soumise à des approches scientifiques. Au monde, les bibliothèques reconnues par leurs lointaines de la vie numérique Wheatley et Hervieux (2019). Cette situation a entraîné un ralentissement vers le développement de pistes de recherche prometteuses qui garantissent le caractère interdisciplinaire de la recherche.

Afin de développer une source d'information cohérente et efficace, l'optimisation de la source d'information ciblée est fortement recommandée. L'optimisation à grande échelle nécessite une forte organisation et une structuration efficace des informations. Dans ce contexte, les nouvelles technologies offrent la possibilité d'accéder à des métas-données grâce à des techniques d'analyse approfondie. Néanmoins, malgré les modestes expériences à travers le monde, quelques associations et organisations ont déjà fait le pas pour reconnaitre le rôle de l'intelligence artificiel (IA) dans l'avenir de la bibliothéconomie, notamment la Fédération Internationale des Associations de Bibliothécaires et de Bibliothèques (IFLA), l'American Library Association (ALA) et la Fédération Canadienne des Associations de Bibliothèques (FCAB-CFLA).

Le but de ce papier est d'analyser les effets attendus suite à l'introduction de l'IA dans les pratiques de gestion des bibliothèques. À ce stade, un ensemble de questions seront abordés: comment pouvons-nous tirer parti de l'IA pour soutenir la mission des bibliothèques ? Et comment l'AI peut-elle aider les autres à améliorer le processus de gestion de la bibliothèque ?, Pour des raisons scientifiques, ce papier a été divisé en trois parties distinctes. La première partie a été consacrée à l'évolution du contexte en relation avec les TIC. Nous abordons cette partie par présenter les anciennes pratiques d'utilisation de la technologie dans la gestion des bibliothèques, jusqu'à l'apparition de l'IA comme une nouvelle approche de gestion. La deuxième partie est dédiée aux répercussions de l'approche d'IA sur le système de gestion de bibliothèque (voir Tableau 2). Enfin, la dernière partie nommée

discussion présente les études comparatives qui rejoignent les pratiques de gestion des bibliothèques, comparent l'approche de l'utilisation de l'IA à celle de l'approche traditionnelle.

Méthodologie Et Matériel

Cette étude suit une méthodologie d'analyse descriptive et analytique. Tout d'abord, une revue de la littérature qui présente les changements fondamentaux qui menacent les anciennes pratiques de la gestion des bibliothèques. Pour des raisons scientifiques, une vue d'ensemble décrit l'évolution de la gestion des bibliothèques depuis les années 80 à ce jour. Ensuite, une démonstration conceptuelle expose l'impact de l'IA sur le processus de gestion de bibliothèque. Enfin, une analyse comparative met en lumière la contribution de l'approche de la gestion traditionnelle par rapport à l'approche de l'IA. Le diagramme suivant illustre la méthodologie et le matériel de l'étude suivi au cours de cette étude.

Fig. 1 : Cadre méthodologique

L'IA Et Le Processus Bibliothécaire

Au début des années 80, la relation des bibliothèques avec la technologie a été réservée aux transactions quotidiennes, telles que l'acquisition, le catalogage et la circulation de l'information. Une bibliothèque automatisée apparait aux utilisateurs comme un catalogue d'accès public en ligne (OPAC), à travers lequel ils peuvent rapidement rechercher et obtenir les informations souhaitées Leeves (1994). Dans un système pareil, la recherche bibliographique se fait en fonction du nom de l'auteur, du titre de l'étude et de l'année de la publication.

Depuis les années 90, la recherche d'informations rejoindre la dimension linguistique de la source d'information. Dans ce contexte, d'après Michos et al (1999), la collecte efficace des informations se fera via un bon système de traduction. Un système qui déchiffre la demande via un système tripolaire. À cet égard, trois approches au programme, à savoir la traduction de termes basés sur un dictionnaire (DICT), la traduction de termes basés sur la translation de sens du mot (EBT) et la traduction de termes basés sur la translation de sens du mot dans la phrase (EBS) Yang et al (1997). Selon les résultats de cette enquête, l'accès multilingue aux catalogues en ligne peut améliorer remarquablement la qualité des services fournis. À ce stade, la bibliothèque nationale du Canada a été l'une des premières bibliothèques à offrir un accès multilingue à ses utilisateurs Buchinski et al (1976).

La gestion efficace du système de bibliothèque est basée sur l'utilisation optimale des ressources matérielles et immatérielles. Un système qui optimise l'accès à l'information pertinente via une approche beaucoup plus ciblée. Dans un premier temps, l'utilisateur interagit avec le système translateur en choisissant la langue et le modèle d'entrée et de sortie, ainsi que les zones de recherche, les rubriques clés de recherche et le type de recherche souhaité. Le système translateur combine toutes ces informations puis les transferts vers le gestionnaire du système de bibliothèque. Ce dernier est connecté à une base de données que ce soit à partir d'une base de données locale ou une base de données distante. Dans le cas où le translateur sélectionne et renvoie des requêtes vides, l'utilisateur peut répéter la recherche en utilisant des synonymes, des super-catégories ou des sous-catégories et des mots-clés de recherche différente.

À partir des années 2000, l'étude menée par Ex Libris Future Library Survey (2018) qui perçoit la bibliothèque comme un moyen qui soutient : la productivité des étudiants et des chercheurs, confirmer que la bibliothèque suit les dernières tendances et savoir offrir aux utilisateurs une nouvelle

expérience améliorée. À cet égard, afin d'accomplir les tâches de plus grandes valeurs, les bibliothèques doivent trouver un moyen d'automatiser ses activités, assister son personnel dans leurs opérations quotidiennes grâce à des technologies utiles et pratiques. Selon SCONUL Library Design Awards (2019) les gestionnaires de bibliothèque sont bien conscients de la nécessité d'offrir de nouveaux services. La plupart montrent leurs intentions et leurs confiances d'adopter de technologies avancées telles que l'impression 3D, la gamification, la reconnaissance vocale, l'intelligence artificielle, etc. Le tableau suivant montre le pourcentage d'adoption et de non-adoption de la technologie dans les bibliothèques britanniques.

Tableau 1 : La bibliothèque et la nouvelle technologie Sconul (2018)

	Déjà adopté	**Sera adopté**	**Sera partiellement adopté**	**Ne sera pas adopté**	**Totale**
Intelligence artificielle / Apprentissage automatique	10.88 %	35.37 %	35.37%	18.37%	147
Reconnaissance vocale	4.79%	38.36 %	34.93%	21.92%	146
Réalité augmentée	14.08 %	30.28 %	35.92%	19.72%	142
Réalité virtuelle	20.27 %	25.00 %	34.46%	20.27%	148
Impression en 3D	51.95 %	25.79 %	10.39%	11.69%	154
Automatisation de l'exécution via des kiosques / robots	40.79 %	26.97 %	19.74%	12.50%	152
Gamification / Living labs Technologies susceptibles d'améliorer l'enseignement et l'apprentissage	34.00 %	37.33 %	20.67%	8.00%	150
Autres technologies avancées	7.84%	25.49 %	17.65%	49.02%	51

Selon l'étude de Massis (2018), la bibliothèque en tant qu'espace de recherche d'informations interdisciplinaire valorise l'inclusion et offre la possibilité face aux utilisateurs d'apprendre de nouvelles compétences en matière de l'IA. L'enquête menée par Ex Libris a révélé que si près de 80% des bibliothèques de recherche explorent l'utilisation de l'IA et de l'apprentissage automatique, seuls 5% environ tirent actuellement parti de cette technologie. De là, nous explorons dans la section ci-dessous les effets de l'introduction de l'IA dans le processus de gestion des activités de la bibliothèque.

Tableau 2 : Avantages d'utilisation de l'IA sur le processus de gestion des activités de la bibliothèque

Plus de 30 000 images de documents de recherche sont traitées. Les tableaux peuvent avoir différentes structures et peuvent impliquer différents types d'informations.	Sethi, et al (2018)

Discussion

Compte tenu de la variété et la complexité de l'accès à l'information, les responsables chargés de bibliothèques rencontrent un nouveau contexte lié à de nouvelles techniques et de nouvelles approches de gestion. Face aux moyens et aux technologies avancées, la source d'information est mesurée en fonction du besoin de chaque utilisateur Ma et al (2020). Nous citions les travaux de Eybers et al (2019) qui ont évalué le besoin de l'utilisateur en fonction de trois tâches distinctes au qui sont : les tâches non-routinières, la tâche dépendante de l'autre et les tâches critiques temporelles. En contrepartie, les approches de recommandations traditionnelles s'incarnent dans la classification avec des outils de repérage (catalogues) et d'accès (cote, signalétique)... Selon Naak et al (2009) les systèmes de recommandations traditionnelles n'étaient pas suffisants car ils devaient prendre en compte le contexte de l'utilisateur. À ce stade, l'opérationnalisation de la technologie au profit des besoins de l'utilisateur qu'il soit enseignant-chercheur ou apprenant ne se limite pas à recevoir les informations génériques mais de capturer des informations les plus approfondies en fonction de son statut de recherche (débutant, intermédiaire, avancé et expert), son champ d'expertise, son degré de contribution académique et scientifique et sa relation envers les autres disciplines.

Dans les travaux de Shimmon (2004), les bibliothèques acquièrent traditionnellement des supports imprimés tels que des journaux, des cartes, des articles, des illustrations ainsi que diverses données parmi lesquelles des livres. Ce réservoir de documents a été associé à des services plus ou moins étendus assurés par le personnel tels que le: le repérage ou à la recherche d'information, aide au choix, consultation sur place, prêt et reproduction d'extraits…etc. De l'autre côté, l'exploitation des études préexistantes est considérée comme le point d'entrée pour développer et produire d'autres travaux académiques et scientifiques.

Dans ce contexte, et grâce à des techniques avancées telles que le Deep Learning, le chercheur peut extérioriser des connaissances qui optimisent les décisions et les moyens déployées. Cela contribuera non seulement à l'apparition de nouveaux modèles, mais développera d'autres pistes de recherche

prometteuse. À cet égard, les expériences des bibliothèques avec les techniques d'apprentissage en profondeur ont rendu la mission de l'utilisateur magique et stimulante. L'étude de Coleman (2017) considère les profonds changements que l'IA peut apporter en tant qu'outil puissant pour l'érudition et la recherche, elle permet à une vaste collection de bibliothèques d'être découvertes, consultables et analysables. En conséquence, et face à la diversité d'informations, comment pourrait mieux interagir les compétences et les connaissances du personnel de la bibliothèque avec les communautés académiques et scientifiques ?

Des développements reconnus dans le domaine de la technologie ont offert à l'académicien et au chercheur un nouvel espace de recherche avec un accès illimité à l'information. À ce niveau, l'utilisateur a besoin d'accéder à des informations à grande échelle. Contrairement aux approches traditionnelles, l'accès aux ressources est choisi selon une politique d'acquisition plus ou moins explicite Sutter (1998). L'approche contemporaine offre la possibilité de rechercher des informations en soi et de consulter et recevoir les informations en permanence Accart (2016). Dans ce contexte, les agents conventionnels peuvent jouer le rôle d'un service d'allocation d'informations. Les modèles de conception d'un agent conventionnel regroupent différentes dimensions, la dimension informative, d'assistance et d'interaction sociale sont souvent présentés dans les activités menées par les bibliothécaires. Dans le même temps, les travaux de Skov-Nielson (2008) indiquent que l'agent conventionnel génère du trafic vers le site Web de la bibliothèque et a donc accru la visibilité de la bibliothèque dans la communauté du campus. Cependant, les agents traditionnels sont plus étroits en matière d'interaction entre le prestataire de services et leurs usagers Gilbert (2010), Ainsi, dans l'étude de Brophy (2002), les agents traditionnels ont un contact direct avec le public, ce qui peut affecter la qualité des informations fournies à l'utilisateur. Cette situation est dûe aux manques d'informations la plus adéquate reliant avec le statut de l'utilisateur.

Dans ce cadre, l'existence des agents conversationnels peuvent servir tout le monde via des réponses moins répétitives et prédéterminées car les réponses peuvent être hautement contextualisées Heudin (2007). Pour l'utilisateur, les agents conversationnels réduisent la nécessité de parcourir des quantités d'informations écrasantes en format textuel, et créent des liens vers la section appropriée de la ressource où il peut fournir une réponse brévité.

Conclusion

Les bibliothèques sont au cœur de la ressource la plus riche pour le développement de l'économie et de la société. À ce jour, l'IA a offert aux utilisateurs la possibilité de découvrir et d'explorer de nouvelles voies de recherche. Dans ce contexte, le souci de l'utilisateur est comment tiré parti le maximum de ressources et s'intégrer dans ce nouveau mode artificiel.

Dans ce monde, l'accès à la documentation diffère par rapport aux méthodes traditionnelles. Un accès plus personnalisé et calculé en fonction du champ d'intérêt, de la nouveauté et de l'interdisciplinarité de la documentation,…etc. Avec l'IA la recherche et l'accès à documentation collaborative a pris un ascendant via l'approche de filtrage automatique, nous relions chaque document développé aux citations, aux références et aux listes de co-auteurs qui concernent la même thématique ou la même discipline de la recherche suggérée. De plus, l'exploitation de la ressource à grande échelle soit en fonction du temps ou de la quantité d'informations conservées, nécessite un privilège d'accès à l'information sur tous les services fournis par la bibliothèque, tout au long de la journée et de l'année sans interruption. Ceci via des agents numériques programmés avec les différents scénarios possibles. À ce niveau, l'utilisateur aura l'occasion d'accéder à l'information en fonction de sa position et son état d'avancement.

La gestion d'une bibliothèque est devenue un domaine très spécialisé. L'IA offre la possibilité d'accéder à des informations plus approfondies. À ce niveau, l'analyse de la documentation se traduit en fonction des objets et des entités où l'apprenant peut trouver d'autres informations plus précieuses. Avec des techniques d'analyse en profondeur, la source d'information retenue est le point de départ vers des recherches plus approfondies. Dans ce contexte, le diagnostic approfondi sur chaque section, chapitre, partie, sous-partie ou zone du document fournit aux utilisateurs une documentation

personnalisée selon la démarche de recherche suivie. La recherche par objet diffère par rapport à la recherche par domaine ou par discipline. À ce stade, le chercheur développera et enrichira la production scientifique et académique par des modèles et des approches à des fins plus expérimentales.

Abstract

The objective of the research was to study five international and two domestic engine oil brands that compete in the Polish retail market. The study investigates the relationship between past customer's purchase decisions and the customer's characteristics. To this end, survey data were collected from 1060 Polish drivers. The obtained results suggest that the competition between engine oil brands is manifesting itself through attracting varying customer segments. The target customer group for Brand W and Brand X, are drivers up to 35 years of age (Brand W 80%, Brand X 92%). What is more, the users of Brand W clearly favor cars with high engine capacity - 90% of them declared driving cars with engine volume above 1.5 dm^3. The most differentiating criteria, which drivers usually consider when making their purchase decisions, are the OEM specifications, viscosity classification and oil price. From among five sources of recommendations included in the questionnaire, customers strongly rely on those given by car producers, authorized service stations as well as local garages/service stations.The study fills an important gap in empirical research in the context of non-technical properties of engine oils. The results may help researchers and marketers better understand the intricacies and complexities of brand competitiveness leading to consumers' purchase intentions and decisions.

Keywords: engine oil, consumer behavior, role of brands, purchase decisions, choice heterogeneity

Introduction

Producers develop brands as a way to attract and keep customers by promoting value, image, prestige, or lifestyle (Abd Rahman & Hairul Rizad, 2005; Piatkowski, 2012). Many consumers assign high quality to prestigious brands and such brands, therefore, enjoy greater credibility and ultimately greater value (Erdem, Swait, & Louviere, 2002). This is particularly important for the brands whose products have only slight physical differences. Such include a number of products in industrial markets (for example, engine oils) that have comparable physical specifications and performance; yet, some products successfully maintain a high market share, even at a premium price (Mudambi, Doyle, & Wong, 1997). That is why, in the close substitution setting, well-known brands can make products more recognizable for potential consumers (Keller, 2008). But still, the question arises as to what differentiates the successful brand from its competitors in the eyes of the customer. The basic explanation may lie with customer perception of value (Doyle, 1994). However, the processes involved in adding value are complex and interrelated (Porter, 1998). One element of the puzzle may be an effective brand name. Creating one, however, is a challenging task. In the industrial markets one strategy involves choosing a name that has a desirable phonetic symbolism. Also alpha-numeric names are more acceptable for technical products (Labahn & Chiranjeev, 1995). Another element of

the puzzle may be high brand awareness, which is defined in terms of the consumers' ability to associate a brand with its products category (Aeker, 1991). It refers to the strength of the brands' presence in the consumer's mind. Research by Hoyer & Brown (Hoyer & Brown, 1990) demonstrated that brand awareness is a prevalent choice tactic among inexperienced consumers facing a new decision task. This scenario may apply to many engine oil retail customers. This view is also supported by Aaker (Shocker & Aaker, 1993), who points out that when the industrial purchase decision is a "toss-up," the "decisive factor then can turn upon what a brand means to a buyer". This position is also shared by many producers, who believe brand name to be one of the most important factors influencing the success of the product. The opinion is also strengthened by Hoyer & Brown (1990), who argues that in a low involvement decision making settings, a minimum level of brand awareness may be sufficient for product purchase decision. The partially opposite view, however, is demonstrated by (Mudambi et al., 1997), who states that it may be true that "the intangible features of the brand play a less potent role in industrial purchase decisions than in the consumer sector". Consequently, price and hard, tangible attributes of the physical product may not fully explain purchase decisions and the resulting market share but may be more important in industrial than in the non-industrial markets.

The above findings seem to justify the need for more research on the role of brands in industrial products markets. The overall purpose of this article is to study five international and two domestic engine oil brands that compete in the Polish retail market. This study investigates the relationship between different components of brand competitiveness and past customer's purchase decisions. The results may help researchers and marketers better understand the intricacies and complexities of brand competitiveness that lead to consumers' purchase intentions and decisions. In general the subject of non-technical properties of engine oils is not prominently present in the scientific literature. Consequently, this research may partially improve this state of the matter.

Engine oils manufactured by the producers included in the study (Mobil, Shell, Castrol, Elf, Motul, Orlen, Lotos) could be considered part of an industrial products market and should be viewed as close substitutes. The first one is Mobil. Exxon Mobil is one of the largest integrated group of refiners, marketers of petroleum products and chemical manufacturers. Over a period of 125 years, Exxon Mobil has evolved from a regional marketer of kerosene in the United States to become the largest publicly traded integrated oil company in the world (Kumar, 2017). The study also includes engine oils from the second (Shell), third (Castrol) and fifth (Elf) largest petrochemical companies in the world. Shell is a Dutch-British oil and gas company headquartered in the Netherlands and incorporated in the United Kingdom. Castrol is a British company owned by the British Petroleum. Castrol was a longtime supporter of the professional motorsports, which helped to build its brand recognition. Elf is a French company and a part of the Total group. Motul is also an enterprise of French origin. It is a more specialized company focusing on producing lubricants for various kinds of motor engines. This contrasts with the rest of the companies mentioned here, whose main business is related to extracting, processing, transferring the natural gas and crude oil (Ermida, 2014). Motul, through its support of professional motorsports, has built its brand recognition. The last two engine oil producers are Orlen and Lotos. Both of them are the largest companies processing and selling oil and its derivatives in Poland. Orlen, which is a part of the PKN Orlen group, holds approximately 70% of processing capacities of Polish refineries. The company has the biggest network of filling stations in Central Europe, with stations located in Poland, Germany, the Czech Republic and Lithuania (Jonek-Kowalska, 2019). In turn Lotos Oil, which is a member of the Lotos Capital Group, operates in Poland, Norway and Lithuania.

The next sections of the article present literature review, methodology, materials and collected data, as well as the results of data analysis and the discussion.

Theoretical Background

The scientific literature on the economic and marketing aspects of engine oils is rather scarce. One possible reason for this paucity of scientific articles may be that such research is conducted mainly by the private for-profit companies that generally have little incentive to make their research freely available. An in-depth query of international and domestic literature yielded, nevertheless, a few worth mentioning positions.

Iranian engine oil market was studied by (Alavijeh, Fattahi, & Moshfegh, 2019). Their research was conducted to compare the effects of price and brand on the industrial lubricants customers' buying choices. The results indicated the significant effects of brand and price on buying choices. Further, the effect of perceived quality of the engine oil on buying choices was significant, but far less important as compared to that of price or brand. The authors, however, analyzed industrial buyers and as such their results may not be fully applicable for retail markets.

Indian engine oil market was studied by (Srivastava, 2016) and (Srivastava, 2018). The main finding was that the brand positioning of lubricant oils has a positive impact on consumers. Authors define brand positioning as "the act of designing the company's offer so that it occupies a distinct and valued place in the mind of the target customers". In their research, authors also constructed perceptual map using the MDS (multidimensional scaling) technique to map different brands of lubricant oils (Castrol, Servo, MAK Lubricant, HP Lube, Veedol, Superfleet) depending on two attributes - price and quality.

Nigerian engine oil market was studied by (Olanipekun, Rasheed, & Sydney, 2015). The study addressed the challenges of brand recognition as a determinant of customer impulse buying behavior in the automotive lubricant markets in Lagos. The results obtained by the authors imply that there is a significant relationship between brand recognition and customer buying behavior. However, their findings may be of limited general use due to the fact that Nigeria suffers from the influx of fake lubricants into the market and the uncontrolled importation of adulterated lubricants. These reasons may translate into local customers having completely different hierarchy of importance as compared to the customers that do not need to worry about the technical quality of engine oils.

Indian engine oil market was investigated by (Pawar & Khandelwal, 2011). They studied products of Indian Oil, Bharat Petroleum, Hindustan Petroleum and Castrol India. Through their research it was found that very few customers were aware of the changing technology and that customers were influenced by advertisement and information received from car mechanics.

Pakistani automobile lubricant market was studied by (Zakir, 2011). The authors motivated the need for their research by observing that "it is essential for organizations to understand a consumer behavior and attitude towards a particular product as the insights gained through these kinds of research help organizations customize and augment their offering". The authors found out that the important reason behind low customer ratings for some engine oil brands was the fact that the lubricants were quite new to the market, despite the fact that customers had no objections to their technical properties. Another interesting finding was a high importance of the word of mouth in building the trust towards the oil brand among new customers. The findings, however, may not be particularly useful for brands operating in countries (for example, European ones) with markedly different climate, as the authors stress that in Pakistan the diesel engine heavy-duty vehicles play an important role due to the need for traveling through "different climate, road, temperatures, dusty areas and weather conditions".

Research Objective, Methodology and Data

Research Hypotheses

As mentioned before, in the Introduction section, the competition among different brands of products that are close substitutes may manifest itself in many ways. Engine oil manufacturers, however, rarely disclose marketing strategies they undertake and even more rarely they provide any information regarding efficiencies of their marketing efforts. It is also unknown whether the engine oil manufacturers prefer to target broad populations or more focused segments. Consequently, due to the lack of reliable first-hand information, a direct comparison between competing oil brands is problematic. This research study takes an indirect observational approach. It is hypothesized that the competition between engine oil brands will manifest itself through attracting varying customer segments.

To examine the stated hypothesis, a preselected set of indicators was chosen, and the survey data was gathered. If the homogeneity of indicator distributions across brand strata is found, the main hypothesis will be rejected. However, if no such homogeneity is found, it will be taken as an evidence in favor of the hypothesis.

Data Analysis Methods

All variables analyzed in this study are categorical or categorized variables and as such are summarized using relative frequencies. An appropriate statistical method to investigate the presence of a relationships between two categorical variables is a contingency table accompanied by conditional distributions and Pearson chi-square test. Since multiple statistical null hypotheses are tested, the resulting p-values are corrected for multiplicity, which may cause untoward inflation of a false positive rate. Briefly, the more tests are carried out, the more likely erroneous inferences are to occur. In the literature, several statistical techniques have been developed to counteract this. These techniques generally require a stricter significance threshold for individual comparisons to compensate for the number of tests being made (Bretz, Hothorn, & Westfall, 2016). In this study, the Bonferroni method is employed. According to this method, a usual significance threshold of 0.05 should be divided by the number of statistical tests performed. The p-value correction (0.05 divided by 21 tests) yields a new threshold which equals to 0.00238.

Data and Survey Design

The study included a large group of 1060 drivers from Poland. The study was conducted between 1st January and 31st July 2018 and the questionnaire method was used. The questionnaires were submitted online and required providing answers to all questions, which helped to avoid the problem of incomplete or partial data. The questionnaire was addressed to drivers who use fully synthetic engine oils. It was completed by drivers who decide or co-decide about the oil change. The respondents were invited to participate in this study using the snowball sampling (chain-referral sampling). This is a non-probability sampling technique, where a pool of initial respondents nominated - through their social networks (both virtual and non-virtual) - other participants, who met the eligibility criteria and could potentially contribute to the study. This sampling technique is often used in hidden populations, which are difficult for researchers to access, due to the fact that there are no lists or other obvious sources for locating the members of the population.

The questionnaire comprised of three main groups of questions. The first one, the demographic section, allowed for identification of the respondents' sex, age, type of the place of residence they live in. The second group of questions was devoted to the technical properties of respondents' cars. The questions asked about engine type, engine capacity (measured in cubic decimetres, dm^3), year of car production and segment of vehicle. The definition of car segment will be provided in the next section. In the last group of questions, respondents were asked to evaluate the importance of 13 main criteria typically encountered during the process of deciding which engine oil to purchase. Respondents marked each criterion as either *important* or *not important*.

Beside the above-mentioned items, the last question required respondents to reveal the exact brand name of the engine oil they recently purchased to be applied in their car. This item constitutes the main stratifying variable in the statistical analysis. In the Introduction section, seven engine oil brands were briefly introduced. As this study's main purpose is strictly scientific (and not a commercial one), authors decided to partially mask the brand names when presenting the findings. To be more specific, a code name S, T is either Castrol or Mobil, U, V, W is either Shell, Elf or Motul, X, Y is either Orlen or Lotos.

Results and Discussion

Results

Tables 1 to 7 present the results of the data analysis. In each table, to save space, multiple variables are shown. At the bottom of each variable the p-value is placed. As described in the Data analysis methods section, the p-value less than 0.00238 indicates the statistically significant result of the Pearson chi-square test, which can be interpreted as evidence favoring the statistical hypothesis that conditional distributions across brand strata (rows in the tables) are not equal.

Table 1: Distribution of drivers' sex and age across oil brands. Source: own research

Oil brand	Females	Age			
		<25	<25;35)	<35;45)	>=45
Brand S	11%	22%	46%	15%	17%
Brand T	16%	30%	42%	16%	12%
Brand U	17%	11%	42%	33%	14%
Brand V	11%	19%	50%	19%	11%
Brand W	10%	27%	54%	10%	10%
Brand X	14%	35%	57%	5%	3%
Brand Y	27%	21%	46%	13%	19%
	p = 0.00189	p = 0.00001			

Table 1 shows that there is statistically significant relationship between engine oil brand and the sex of the oil buyers; for example, 27% of the Brand Y users declared being a woman. In the case of the remaining brands, women indicated them less frequently (10%-17%). There is also statistically significant relationship between engine oil brand and the age of the oil buyers. A clear outlier is the Brand X, which was strongly favored by the younger customers, as only 8% of its customers were older than 35. On the opposite end was the Brand U with the highest frequency of buyers above 35 y/o (47%). The remaining brands were more similar with regard to the customer age profiles.

Table 2 shows that there is statistically significant relationship between engine oil brand and both the place of residence and the education level. Brand U and Brand T users were most often the residents of large cities (67% and 63%). Drivers who chose any of the examined oil brands usually had a master's degree or high school education with the highest proportion of masters among Brand U and Brand S customers.

Table 2: Distribution of drivers' place of residence and education across oil brands.

Oil brand	Place of residence			Education			
	rural	urban (below 250K)	urban (above 250K)	primary or vocational	high school	bachelor	master
Brand S	19%	34%	47%	2%	24%	17%	57%
Brand T	15%	22%	63%	7%	22%	22%	49%
Brand U	19%	14%	67%	8%	22%	6%	64%
Brand V	11%	47%	42%	0%	39%	8%	53%
Brand W	20%	24%	56%	5%	39%	17%	39%
Brand X	14%	30%	57%	8%	30%	22%	41%
Brand Y	21%	38%	40%	8%	33%	13%	46%
	p = 0.00002			p = 0.00000			

Source: own research

Tables 3 and 4 describe the relationship between engine oil brand and, in succession, engine type, car production year, engine capacity and car segment. The Brand X users most frequently drove cars with the petrol engines (68%) and the Brand V users were the most diesel-oriented group (53%). The Brand U users were typically owners of the newer cars, whereas the Brand Y users typically owned older cars. However, in both cases, for the engine type and production year - the Bernoulli corrected p-value threshold for statistical significance of the relationship with the brand was not reached.

Table 3: Distribution of cars' engine type and production year across oil brands.

Oil brand	Engine type: petrol vs diesel	Production year			
		below 2000	2000-2005	2006-2010	above 2010
Brand S	50%	12%	31%	32%	24%
Brand T	57%	16%	34%	34%	16%
Brand U	61%	11%	22%	44%	22%
Brand V	47%	11%	39%	33%	17%
Brand W	61%	12%	46%	32%	10%
Brand X	68%	16%	30%	30%	24%
Brand Y	62%	23%	37%	21%	19%
	p = 0.01727	p = 0.00752			

Source: own research

The brand W (Table 4) users clearly favor cars with higher engine capacity, as 90% of its users declared driving cars with engine capacity above 1.5 dm^3. In contrast, the users of Brand T and Brand Y would rarely drive cars with engine capacity above 2.0 dm^3, 7% and 8% of the cases respectively. The users of the rest of brands were more, however not ideally, evenly distributed across the engine capacity categories.

The interpretation of the results for a car segment needs to be preceded by a short definition of this term, since it is a first non-self-explanatory variable to be discussed in this study. Typically, passenger cars are divided into 10 groups (segments). Segment A consists of city cars, which are predominantly small sized and require relatively modest maintenance costs. In Europe, good examples of the segment A cars are Citroen C1 and Toyota Aygo. Segment B (small cars, e.g. Citroen C2, Fiat Panda) cars in comparison to segment A have more cargo and passenger space. Segment C (lower-middle class cars, e.g. Citroen C4, Toyota Corolla) are designed to make them better suited for mixed usage (city vs out of the city driving). Segment D cars (middle class and family cars, e.g. Audi A4, Honda Accord) are designed to fully accommodate five adult passengers on the long-haul travel. Segment E (upper-middle class, e.g. Audi A6, BMW 5) cars are usually larger passenger vehicles equipped with non-standard accessories and with additional attention to visual appearance. Less represented in this study are sports cars (segment G), cabrio cars (segment H), off-road cars (segment I) and vans (segment K).

Table 4: Distribution of cars' engine capacity and segment across oil brands

Oil brand	Engine capacity [dm^3]			Segment			
	below 1.5	1.51 – 2.0	above 2.0	A, B	C	D	E, F, G, H, I, K
Brand S	22%	65%	12%	16%	48%	28%	8%
Brand T	31%	62%	7%	21%	50%	21%	9%
Brand U	39%	50%	11%	25%	50%	17%	8%
Brand V	31%	58%	11%	25%	44%	19%	11%
Brand W	10%	68%	22%	10%	41%	32%	17%
Brand X	41%	46%	14%	27%	51%	8%	14%
Brand Y	40%	52%	8%	33%	48%	15%	4%
	p = 0.00000			p = 0.00007			

Source: own research Source: own research

The Brand Y users (Table 4) have the largest subgroup of cars from segments A and B (33%) and the smallest from segments E-K (4%) in comparison to the other engine oil brands in those segments. The Brand W stands out from the rest of oil brands due to its higher presence in the D (32%) and E-K segments (17%) and lower in the A-B segment (10%).

Table 5: Distribution of drivers' perceived importance of various oil related characteristics across oil brands

Oil brand	Oil price	Brand familiarity	Brand loyalty	Radio and TV ads
Brand S	38%	67%	29%	6%
Brand T	39%	69%	35%	5%
Brand U	42%	56%	28%	14%
Brand V	36%	58%	19%	8%
Brand W	32%	63%	41%	5%
Brand X	59%	54%	27%	14%
Brand Y	65%	44%	29%	6%
	p = 0.00000	p = 0.00015	p = 0.05444	p = 0.02691

Source: own research

Customers for whom a low product price is important in the purchasing process dominated among buyers of Brand Y and Brand X oils (domestic oils, seen as cheaper) (tab. 5). Clearly, Brand W has not been built around the idea of a low-price product and among customers who choose it, almost 70% (the vast majority among the surveyed brands), do not attach importance to price. Other brands in this group include: Brand V, Brand S and Brand T. Above 60% of their buyers do not attach much importance to the price.

In the case of brand familiarity, it is interesting to note a particularly high importance of this criterion for users of almost all engine oil brands, except for Brand Y. This may be due to what has been pointed out in the previous paragraph, namely that Brand Y users tend to value competitive pricing above other factors.

In the context of brand loyalty, Brand W and Brand V are worth mentioning as two extreme cases. The first one strongly attracts the customers to its brand, while in the second case the customers are not particularly associated with the brand - only 19% of respondents choosing Brand V believe that brand attachment is an important criterion during the purchasing process. However, the relationship between oil brand and brand loyalty did not reach statistical significance threshold in this study. Another non-significant result was obtained for radio and TV ads (p=0.02691). Nevertheless, it is worth observing that consumers in general believe advertising to be of low importance in their purchase decisions.

Table 6: Distribution of drivers' perceived importance of various technical properties of oil across oil brands

Oil brand	OEM specifications (e.g. VW, MB, GM)	Classification		Scope of information provided on the oil label
		Qualitative (e.g. API, ACEA)	Viscosity grade (SAE J300, e.g. 5W-30)	
Brand S	51%	59%	73%	32%
Brand T	48%	56%	74%	37%
Brand U	36%	61%	78%	28%
Brand V	50%	44%	72%	25%
Brand W	71%	73%	90%	39%
Brand X	43%	49%	59%	43%
Brand Y	35%	56%	56%	23%
	p = 0.00003	p = 0.00992	p = 0.00000	p = 0.02705

Source: own research

Considering the technical aspects of engine oils, the users of Brand W oils stand out in a special way. Drivers choosing Brand W clearly more often than the users of other brands indicate a high importance of the OEM specifications (71%), quality classifications (73%) and SAE classifications (90%). This suggests that they have high expectations and at the same time extensive technical knowledge in the field of oil parameters. The opposite situation is observed for drivers choosing Brand X and Brand Y. In their case, the above-mentioned technical parameters count in the smallest degree (43/35%, 49/56%, 59/56%, respectively).

The results obtained for Brand V and Brand U suggest some inconsistency exhibited by their buyers. In the first case, despite attaching great importance to the OEM specifications and viscosity class, quality classification was rarely indicated as important. In the second case, despite viscosity grade and quality classification being assessed as very important, the OEM specifications were rarely indicated as such. Statistically non-significant result was obtained for the scope of information provided on the oil label (p=0.02705).

Table 7: Distribution of drivers' perceived importance of oil recommendations by various agents across oil brands.

Oil brand	Oil recommended by:				
	supplier	car manufacturer	authorized service station	local garage/car service station	family or friends
Brand S	25%	69%	53%	58%	30%
Brand T	29%	63%	48%	58%	39%
Brand U	33%	53%	56%	58%	44%
Brand V	8%	47%	28%	39%	31%
Brand W	20%	51%	32%	41%	24%
Brand X	38%	54%	32%	57%	49%
Brand Y	31%	50%	40%	48%	40%
	p = 0.00071	p = 0.00013	p = 0.00001	p = 0.00470	p = 0.00262

Source: own research

Of the five sources of recommendations available in the questionnaire (Table 7), those given by car manufacturers and authorized service stations, as well as those obtained at the local garage/car service station are the most important for customers of all analyzed brands. It also seems that Brand S, Brand T and Brand U have the strongest presence in garages and service stations (including authorized ones) among all of the brands examined. Drivers choosing Brand V, much less frequently than the users of other brands, point to the high importance of the recommendations of the oil seller (8%), authorized service stations (28%) and local garage/service stations (39%). This may suggest that in the indicated places, the oils of this brand are not as well perceived as the other brands investigated. Among drivers choosing Brand S, a considerable number (69%) indicated the importance of the car manufacturer recommendations, whereas only a quarter of them pointed to the seller's recommendations (25%). A similar situation was observed for Brand T (63% and 29%, respectively). A narrow range of indications was obtained for drivers using Brand Y and Brand X oils. In the first case (Brand Y), all five recommendations seem relevant to only 30-50% of respondents; whereas, in the case of Brand X, they are relevant to 38-57% of respondents. Among drivers using Brand V oils, the lowest hypothetical importance of the analyzed recommendations was found - more than 50% of respondents (53%-92%) considered that these recommendations were not significant in the purchasing process. On the other hand, among those choosing Brand U oils, between 53 and 58% are of the opinion that the recommendations coming from car manufacturer, authorized service stations and local garage/car service station are the most important ones. In turn, oil supplier recommendations as well as those coming from the family or friends are unimportant for 56-67% of respondents.

Discussion

The research outcomes provide many practical conclusions, directed mainly to marketing departments in companies that introduce new oils to the market or are developing strategies aimed at increasing the sales of oils already available on the market. Some of the petrochemical companies may be especially interested in them because, as Jonek-Kowalska (2019) indicates, even giants from the petrochemical market were systematically incurring losses in the years 2013-2015.

Brand X has a strong market position for spark-ignition cars, while the diesel car owners are in minority, when compared to Brand S and Brand V, where almost equal distribution was obtained for both engine types. Brand Y has a strong position among drivers of cars from the A + B segment. In terms of the E, F, G, H, I, K segments, Brand W seems to stand out. Brand W has built its recognition around sports cars with a focus on providing exceptional protection for the engine in difficult operating conditions. This study confirms that such marketing orientation has been the right choice, and it can serve as a valuable supporting point for competitors that are looking for proven ways to reach specific audiences. In somewhat disparate field similar conclusion was found by Baziana et al. who state that branding in the olive oil market is a key factor in boosting the competitiveness (Baziana & Tzimitra-Kalogianni, 2019). They established that the preference for an olive oil brand is associated with increased brand awareness and higher levels of loyalty.

Interestingly, owners of new cars mainly look for oils among brands such as Brand S, Brand X and Brand U, while owners of older vehicles mostly choose Brand Y. It can be also seen that brands such as Brand S, Brand T and Brand U have established a good cooperation with authorized service stations, local service stations and garages. Respondents indicate a large number of recommendations from these places. It seems that Brand V has yet the most to do in this area – merely a quarter of respondents (28%) make their purchase decision as a result of recommendations obtained from authorized service stations.

Among the information particularly valuable for companies selling engine oils may be the fact that radio and television commercials featuring such products are generally indicated by customers as a criterion very weakly affecting the purchasing process. Hence, other channels for reaching the customer are worth considering, e.g. establishing a closer cooperation with local service stations/garages, where customers change oils in their cars. However, there is a need for additional research to reveal if this is in fact true that radio and television commercials are ineffective or the real explanation is that they are effective but only customers do not realize they have a, possibly subconscious, impact. Similar issue that could be considered by those involved in the sales and marketing of car related products, was highlighted by (Murry, 2018), who found an evidence that dealer and manufacturer advertising are substitutes within the vertical channel. As dealers decrease their advertising budgets, manufacturers can make up for this with their own advertising strategies.

It was also found that Brand Y consumers are very price sensitive. One possible explanation can be found in Fornari et al. which studied inter-brand competition within the FMCG market and, in particular, the market share trade-off between leading national brands (LNB) and store brands (SB) (Fornari, Fornari, Grandi, & Menegatti, 2016). Their results show the existence of a relationship between the increase in the LNB-SB price gap and the switching of market share from the former towards the latter.

Conclusions

Summary of Findings

The research has shown that there is a large range of customer groups opting for individual oil brands. As such, the obtained results confirm the hypothesis presented in the article - the competition between engine oil brands will manifest itself through attracting varying customer segments. The Brand W and X target group of drivers are up to 35 years old (Brand W 80%, Brand X 92%); in contrast to Brand U, with almost 50% of customers being over the age of 35 years. Among the respondents who were below 25 years of age, the least popular is Brand U, whereas Brand X is by far

the most sought-after engine oil of all (it is 3 times more popular than Brand U). Drivers over 45 years of age mostly value Brand Y and Brand S, while they do not particularly trust Brand X. The majority of Brand X users would most frequently drive cars equipped with petrol engines (68%), and the Brand V users were the most diesel-oriented group (53%). Drivers who chose Brand S or Brand V oil had at least high school education. The users of Brand W clearly favored cars with high engine capacity - 90% of them declared driving cars with engine volume above 1.5 dm^3. In contrast, the users of Brand T and Brand Y would rarely drive cars with engine capacity above 2.0 dm^3 (7% and 8% of the cases, respectively). Moreover, Brand W stands out from the rest of oil brands due to its higher presence in the D (32%) and E-K segments (17%) and lower in the A-B segment (10%). Drivers choosing Brand W oils have clear expectations and show great knowledge in terms of the technical parameters that the oil should have. Moreover almost 70% of the respondents choosing Brand W (the majority among the surveyed brands) do not attach high importance to its price.

The most differentiating criteria, which drivers usually consider when making their purchase decisions, are the OEM specifications, viscosity classification and oil price. In all cases, the difference between extreme brands exceeded thirty percentage points. Importantly, the Brand W and Brand Y customer groups differed the most in each of the three cases. These two brands can be considered as the representatives of two different marketing strategies. Moreover, it is worth mentioning that in the case of brands such as Brand X and Brand Y, the above-mentioned technical parameters count the least.

From among five sources of recommendations included in the survey, customers strongly rely on those given by car manufacturers, authorized service stations as well as local garages/service stations. Of less importance were recommendations provided by oil suppliers and family members or friends.

Research limitations

Just like with any research, especially empirical in nature, the analysis presented in this article has its limitations. These are mainly conditioned by the method of the sample selection. Above all, the population was limited to customers buying engine oils in Poland. Another potential limitation of our research affecting the generalizability of the results are slight deviations in the distributions of drivers' place of residence and education from the expected population distributions. There is a slight overrepresentation of drivers from cities and drivers with higher education. The age structure did not cause any particular concerns. Yet, for the reason stated, it was not possible to widely generalize the results. Thus, further in-depth research on this topic (also in other countries) is still needed.

Suggestions for Future Research

An interesting direction of future research may be to focus on drivers who professionally use but also own the vehicle, e.g. taxi drivers, truck drivers or bus drivers. It would be interesting to investigate whether the professional drivers are more or less likely to pay additional attention to the quality of the services provided by the authorized service stations and the engine oils they use or recommend.

Abstract

The purpose of the article is to find out the relationship between the age of employees and their perception of intergenerational knowledge transfer in an organization. The article is based on the assumption that effective knowledge management requires a flow of knowledge between employees. This applies especially to employees from different generational groups, i.e. people with varied professional and life experiences. The first part of this paper presents the importance and limitations of knowledge transfer in an organization. Next, various generations on the contemporary labour market were described. The survey research was conducted among 895 employees, representing 829 business entities. On this basis, the final conclusions were formulated which show that the age of respondents influences their perception of knowledge transfer in organizations. Significant differences in the assessment of knowledge exchange made by the representatives of different age groups based on a clear tendency to more positively assess own generation group have been noticed. The research presented in this article does not allow for a clear conclusion which generation is more involved in the intergenerational exchange of knowledge since the assessment of the openness of employees to share knowledge depends on the age of those who evaluate it. Representatives of the *baby boomers* generation highly assess their readiness to share knowledge, but the perception of younger age groups does not confirm this phenomenon. Due to the limitation of research to Polish enterprises, we treat their results as preliminary and requiring continuation.

Keywords: Knowledge Transfer, Generations, Generational Diversity.

Introduction

Preservation and development of organizational knowledge, which is the basis for shaping the competitive advantage of enterprises, constitutes, at the same time, one of the key challenges of contemporary management. Knowledge transfer is still not a solution commonly and effectively used in many organizations. It is also worth noting that the circumstances and conditions of this transfer are changing quite significantly due to the fact that four different generations of employees cooperating with each other are present on the current labour market.

This creates new opportunities, but also problems in the area of knowledge exchange within an organization. Difficulty of this task is raised by the fact that there are many antagonisms and prejudices based on established stereotypes between age-diverse employees (Amayah 2016, Kunze 2009). Representatives of particular generations are guided in their lives by different values, have different customs and habits, prefer different methods of learning and information exchange, and build their professional and social relationships in different ways. Understanding and intergenerational communication, including the transfer of knowledge, are becoming more and more difficult due to such differences.

Taking into account the value and importance of the above circumstances for development of enterprises, the aim of this work is to find out the relationship between the age of employees and their perception of intergenerational knowledge transfer in an organization. The research, which had the form of a survey, leads to the verification of a research hypothesis assuming that the perception of intergenerational transfer of knowledge depends on the age of the respondents and each age group positively assesses the openness of its own generation to share knowledge and critically evaluates other generation groups in this respect.

Intergenerational Knowledge Flow - Theoretical Analysis

The key role of knowledge in shaping the competitive advantage and development of an enterprise is highlighted by a great number of researchers, including P. Drucker (2002), R.J. Howlett (2012), K. Ichijo and I. Nonaka (2007). Knowledge enables an organization to survive in a turbulent environment; it allows the organization to make more effective decisions and predict their effects, implement innovations and streamline management processes (Krogh 2000).Therefore, it should not be surprising that enterprises more often implement knowledge management systems, which include processes of knowledge acquisition, multiplication, storage and usage (Paulin 2012). In this context, the importance of knowledge for the development of an organization is unquestionable.

However, it is worth noting that according to G. Probst, S. Raub and K. Romhardt knowledge is always associated with a specific person (2000). As a result, the level and usage of knowledge depends on actions undertaken by people, and therefore, is related to their experiences, emotions, motivation and intentions, that is mainly their mental sphere (Sharma 2012). On this basis, it can be stated that acquisition, accumulation and exchange of knowledge in an organization are relatively difficult processes to observe, measure and analyze.

The knowledge management process is determined by many factors, both internal and external to the organization (Harvey 2017, Ichijo 2007, Liebowitz 2019). An important advantage in this respect should be the fact of possessing by the enterprise the age-diverse staff, as it opens the possibility of an extremely valuable knowledge transfer between employees with different competencies and experiences. In this area, every employee can constantly deepen their practical knowledge and acquire new skills, which is a prerequisite for professional development, increase in creativity, flexibility and openness to new solutions (Sujansky 2009). This concerns both older and younger employees. Thus, it has an influence on their work results and, consequently, the results achieved by the entire enterprise (Sung 2012).

On the basis of numerous practical experiences, however, it can be noted that the effective intergenerational transfer of knowledge is a very difficult task to accomplish. It requires goodwill and commitment on the part of employees, their openness and mutual trust, yet these are not frequent phenomena in many organizations. When employees have to convey their knowledge to other employees, they come with great caution or even fear (Renz 2008).

The above restrictions in knowledge transfer result from both personal and organizational reasons (Ichijo 2007, Probst 2000, Renz 2008). The first group of barriers includes: fear of losing the current professional position at the expense of co-worker's development, lack of willingness to listen and respect people from other generations, prejudices as well as deficiencies in the area of knowledge transfer. Among the organizational obstacles to knowledge exchange are: lack of practices promoting work in multigenerational teams, approval of discriminatory behaviour on the grounds of age, failure to prepare older employees to take the role of mentors or lack of formal roles and tasks in the area of knowledge transfer assigned by the managerial staff (Paulin 2012).

The current personnel situation of the majority of organizations is characterized by a large age diversity of employees. This results from the fact that in enterprises can simultaneously work representatives of up to four generations: *baby boomers, generation X, generation Y and generation Z*. The high complexity of managing such diverse staff is influenced by the fact that each of these age groups has different needs, requirements, expectations and attitude to professional and private life. These differences result from both the period in which these people were born and educational

opportunities and socio-economic realities in which they were growing up (Amayah 2014, Becton 2014, Kirton 2010).

It is worth noting here that the division of society into generation groups in terms of the year of birth differs slightly in particular countries and geographic regions. This results from differences that characterize countries in the area of global demographic changes, economic crises or phases of the technological progress (Fishman 2016). *Baby boomers* are representatives of the population growth which followed the Second World War in the years 1945-1960. The motto of this generation is hard work and care not to lose it. *Baby boomers* live to work and are loyal to the employer (De Meuse 2010, Phillipson 2007).Therefore, they seldom change their workplace and position. They believe that only work is the path to the professional success. Representatives of this generation appreciate independence. Their strength at work is commitment, optimism and a global view of problems. *Baby boomers*, however, feel uncomfortable in a conflict situation and may be reluctant towards their peers (Phillipson 2007).

People from generation X were born between 1961 and 1983. They are mature and trustworthy employees. Like *baby boomers*, they are characterized by their loyalty to the employer. They appreciate the following values: personal development, independence, diversity and diligence. Although representatives of generation X use new technologies without any problems (computers, tablets, smart phones, etc.), they prefer direct contacts and paper archives, not the digital ones. They value the importance of good education and recognize it as a “pass” for a professional career. They are responsible and engaged employees, willing to cooperate with different people regardless of their way of work or communication. They appreciate the balance between work and personal life (Moczydłowska 2020, Murphy 2010, Sandeen 2008). However, they are relatively often sceptical and pessimistic. They are distrustful of their superiors and treat their mistakes as personal failures (Twenge 2010). In Polish conditions, in the image of an employee from the 55+ age group, the characteristic attributes of the so-called homo sovieticus: claim, that is, the independent heir to the worst features of a socialist system not adapted to work in free market conditions. The description of their professional attitudes on the Polish labor market uses the motto "I work to survive" (Moczydłowska 2020). They can avoid passing on their knowledge to other generations because they treat knowledge as the source of their strong position in the organization. In turn, the use of knowledge of younger employees is hindered by differences in the ways of communication.

People born between 1984 and 1995 belong to generation Y, often referred to as *Millenials*. People from this age group value partner relationships, tolerance, development opportunities as well as new challenges. They show high and unconventional life aspirations. They are able to actively use digital media almost in every area of their lives. They are perfectly prepared to work in realities of free market and globalization. They are usually well-educated and success oriented people, although work is not a priority for them, but rather a “tool” for self-realization (Sujansky 2009). They expect from their employers a satisfying salary and investment in their professional development. They are often regarded as disloyal employees because occupational stabilization is not the most important thing for them. They prefer task and design work with a great degree of freedom in its implementation and flexible working hours (Bolton 2013, Chillakuri 2018). According to research carried out by the University of New Hampshire, the representatives of generation Y are characterized by high self-confidence, high perception of their skills, conviction of their own uniqueness, high expectations and strong aversion to criticism (Iorgulescu 2016). They often avoid learning from other employees because they think that all professional questions will be answered online. Their task is the master-student relationship is a thing of the past. It was replaced by a student-technology relationship (Moczydłowska 2020).

The youngest people on the labour market belong to generation Z, that is people born after 1995. In most cases, it is a community of times of prosperity. They are people who do not know the world without internet and mobile phones. Therefore, they are perfectly aware of digital technologies. They also highly value the circle of close friends, like friends from social media sites. They care about everything what is “online.” As employees, they gained the name of creative and imaginative multi-taskers, but those who desire a high degree of flexibility and development opportunities leading to success, for which they expect an appropriate reward (Kirton 2010). For this reason, they usually

constitute a challenge for employers who are not always able to provide them with a suitably paid and interesting job. The weaknesses of this age group most often include deficiencies in social skills, problems with concentration and stabilization or superficial analysis and assessment of the situation (Kooij 2011).

Research Methodology

The aim of the study was to diagnose opinions of employees representing various generations on the flow of knowledge between different generation groups in their enterprises. The following hypothesis was formulated: the perception of intergenerational knowledge transfer depends on the age of the respondents. Each age group positively assesses the openness of its own generation to share knowledge and critically evaluates other generation groups in this respect.

The research was carried out in the 2019 year on a group of 997 full-time, part-time and post-graduate students from three universities in Białystok, Warsaw and Łomża. The availability of respondents and their diversity in terms of age, gender and place of residence constituted the selection criterion for the examined sample. Professional activity of students in the enterprise sector constituted the condition to be included in the examined sample. In order to limit the number of variables, owners, members of their families and co-owners of the enterprise as well as students of other nationalities and representatives of the managerial staff have been excluded. Therefore, 895 questionnaires were used for further analysis, including 490 completed by women and 405 by men. The respondents represented 829 business entities. The structure of their age is shown in Table 1.

Table 1: Age of the surveyed employees and age structure in Poland

age	women (n = 490)		men (n =405)		total (n = 895)		total in Poland	generation
	L	% for a group of women	L	%	L	% for a group of men	% (without younger than Z)	
20-25	151	30.9	146	36.0	297	33.2	8.3	Z
26-35	104	21.2	94	23.2	198	22.2	18.6	Y
36-45	97	19.8	66	16.3	163	18.2	19.9	X
46-55	67	13.7	45	11.1	112	12.5	15.4	X
56-60	60	12.2	37	9.1	97	10.8	8.3	BB
above 60	11	2.2	17	4.2	28	3.2	29.5	BB

Analysis of Research Results

The analysis of data (see Table 2) on knowledge transfer between different generation groups in Polish organizations indicates several regularities. Significant differences in the assessment of the situation made by the representatives of different age groups are visible; these consist in a clear tendency to more positively assess own generation group. For employees aged 55+, the statement that in their workplaces "older people are usually reluctant to share their knowledge with younger employees" is false. The younger the responders are, the assessment of this sentence as true increases. Employees from generation Z assessed it as "rather real" with a large internal consistency of answers. A similar tendency, though not so unambiguous, can be seen in the assessment of the readiness of young people to share their knowledge with older colleagues. The respondents from the

55+ group assessed the statement that younger employees are reluctant to share their knowledge as "partly true, partly false" (the average 3.4, but with a large internal differentiation of answers). In the same range are the answers of all other age groups, but here the average is always below 3, and in the case of generation X and generation Z there is a great internal diversity of responses, which indicates large discrepancies in respondents' experiences and perceptions. It is interesting that the younger the responders are, the average assessment of the sentence "We are eager to learn from each other regardless of age." as true increases. The oldest employees assess it as "partly real, partly false" (the average 3.4), and the representatives of the youngest age group as "real" (the average 4.0 with a large internal consistency of answers). Statistically significant differences in assessments made by the surveyed women and men were not noticed.

Table 2: Intergenerational transfer of knowledge in the assessment of employees – the assessment of the truthfulness of the statements on a scale from 1 (definitely false) to 5 (definitely true)

Category of the answer	baby boomers (n = 125)		
	average	SD	SD^2
In our enterprise, older people are usually reluctant to share their knowledge with younger employees.	2.0	1.156	1.338
In our enterprise, young people are usually reluctant to share their knowledge with older employees.	3.4	1.216	1.480
In our company, people are reluctant to share their knowledge, regardless of age.	3.1	1.034	1.070
We are willing to learn from each other, regardless of age.	3.4	0.984	0.969

Source: own elaboration based on the results of the survey

In the light of the research results, the hypothesis that the age of the respondents influences their perception of knowledge transfer in organizations has been confirmed. The tendency to more positively assess own generation group has been recognized.

Summary, Discussion of The Results

The research carried out by B.P. Sharma and M.D. Singh (2012) shows that knowledge sharing significantly limits the existence of competition between employees and their individualism, which may occur at different age; however, these tendencies are more often attributed to the representatives of generations Y and Z. The results published by Polish researchers are ambiguous (Moczydłowska 2020). On the one hand, the attention is paid to the fact that younger employees more often perceive their knowledge as a source of advantage over other employees and, in this situation, knowledge sharing weakens their position. In turn, older employees are less reluctant to share their knowledge. On the other hand, significant barriers of knowledge sharing by the oldest generation of employees and reluctance of this group to teach younger people have been indicated. The research presented in this article does not allow for a clear conclusion which generation is more involved in the intergenerational exchange of knowledge since the assessment of the openness of employees to share knowledge depends on the age of those who evaluate it. The representatives of the *baby boomers* generation highly assess their readiness to share their knowledge but the perception of the younger age groups does not confirm this phenomenon. Research requires continuation and consideration of other variables important in the context of knowledge transfer, especially cultural conditions.

Abstract

The Visegrad Group is an alliance of the four countries: the Czech Republic, Hungary, Poland and Slovakia. This group focuses on cultural, economic, energy and military cooperation. These countries belong to the group of 193 United Nations countries that adopted the EU's 2030 Agenda for Sustainable Development in 2015. There are 17 Sustainable Development Goals and one of them is to provide decent work and economic growth. Since the Visegrad Group should enhance economic cooperation, it is vital to analyze what is the current situation of this particular Sustainable Development Goal in the Visegrad countries. This goal is measured by nine indicators, including: employment rate, inactive population due to caring responsibilities, involuntary temporary employment, long-term unemployment rate, people killed in accidents at work, real GDP per capita, resource productivity and domestic material consumption, and young people unemployment. Each of these measures are presented and then compared with the result of the EU's average. The Visegrad countries have been improving in these indicators, on average, however they still need to work on increasing real GDP per capita and resource productivity as well as decreasing inactive population due to caring responsibilities. This will lead them to catch up with the EU's average.

Keywords: Sustainable Development Goals (SDGs), economic growth, the Visegrad countries (V4).

JEL codes: F63, O11, Q01.

Introduction

The Sustainable Development Goals were presented in the so-called Agenda for Sustainable Development 2030, which was adopted by all 193 UN Member States in 2015. This Agenda includes 17 Sustainable Development Goals and 169 related targets to be achieved by the World by 2030. They deal with 5 areas '5xP': people, planet, prosperity, peace and partnership. Objectives cover a wide range of challenges such as poverty, hunger, health, education, gender equality, climate change, peace, and social justice. They replaced the Millennium Development Goals that were supposed to be implemented by 2015. There are, however, some words of criticism for the SDGs in general. Lomborg (2018) in his book about "prioritizing development" wonders which goals should be above others. Process of collecting data is also costly, even not to mention - analyzing it. Some researchers even question the concept of SDGs saying that it is problematic to achieve a sustainable economic system in Europe when there is an ongoing process of

globalization (Barry et al. 2004). However, the SDGs are widely applicable and standardized so it is very convenient and quite easy to compare performance of different countries.

The aim of the Visegrad Group is to advance cultural, economic, energy and military cooperation. In line with the EU's 2030 Agenda for Sustainable Development, it is vital to analyze the current situation of SDGs in the Visegrad countries (V4). This paper focuses on the analysis of SDG 8: decent work and economic growth. The main objective of this paper is to analyze the performance of the Visegrad countries in the SDG 8. Since one of the pillars of the Visegrad Group is economic cooperation, it is important to see if the Visegrad countries have the same direction in fulfilling the SDG 8. In case their results diverge, then the Visegrad Group should think of some common actions and activities that would get them on the fast track development, at least to catch up with the EU's average. The ongoing scientific discussion on SDGs is mainly devoted to its character and structure. This paper also offers the analysis of a selected SDG in the group of countries and some practical applications.

The paper starts with the description of the SDG 8: decent work and economic growth. It briefly presents some data on the SDG 8, the idea behind it and a short literature review on it. Next part of this paper is devoted to the Visegrad Group. It provides an overview of the Group: its origin and development. Part 4 presents the analysis of nine indicators of the SDG 8 in the Visegrad countries in comparison to the EU's average. In this way, it can be clearly seen in which areas of the SDG 8, the Visegrad countries need to improve in order to catch up with the EU's average. Section 5 includes the discussion of the results. The last part concludes and show some directions of further research on this topic.

Sustainable Development Goal 8: Decent Work and Economic Growth

Table 1 presents important facts and statistics about the SDG 8 in the global scope. Although it should be noted that the lowest results in the SDG 8 are recorded in the least developed countries in the World (and the EU economies are not in that group) the SDGs concept aims to improve sustainable economic growth worldwide. The United Nations (2015) imply that the aim of the SDG 8 is to: "promote sustained inclusive and sustainable economic growth, full and productive employment and decent work for all".

Table 1: Facts and statistics about issues concerning the SDG 8

The global unemployment rate in 2017 amounted to 5.6 %, while it reached 6.4 % in 2000.
Worldwide, 61% of all workers were informally employed in 2016. Besides the agricultural sector, 51% of all employees fell into this category of employment.
Men earn 12.5% more, on average, than women in 40 out of 45 countries with available data.
The global gender pay gap remains at 23 % around the world, and without decisive action, another 68 years are needed to achieve equal pay. The female economic activity rate is 63 %, while it is 94 % for men.
Despite the growing presence in public life, women continue to perform 2.6 times more, on average, unpaid care and homework than men do.
There are at least 470 million jobs needed globally for new labor market participants from 2016 to 2030.

Source: United Nations (n.d.)

The SDG 8 has been considered in many different ways. There is an interesting study on the SDG 8 in the context of gendered analysis. It implies that the SDG 8 does not address the value of social reproductive work. The SDG 8 does not take into account unpaid work, which is still largely done by women, it cannot deal with the decent work program in a comprehensive and gender-sensitive manner. This seems to cause two problems: (1) a significant proportion of social reproductive work remains unpaid and is therefore not

included in GDP; (2) even if paid, in the labour market - work is in general gender segregated: insecure and undervalued regarding the wages and working conditions (Rai et al. 2019).

Rosa (2017) underlines that approximately half of the world's population lives for the equivalent of about $1 to $2 per day. It affects men, women and children of all ages. This may be called as an endless cycle of poverty, in which finding a job may not mean being financially secured to survive, and available quality jobs require education and necessary qualifications that is very often unaffordable for many people. All these can have harmful and negative lifelong health implications. Other scholars confirm that people with a low socioeconomic status need to face with a higher level of both physical and mental challenges resulting in not meeting basic psychological needs. It then causes emotional exhaustion and a growing level of stress (González et al. 2016).

In addition, Poshen (2015) suggests that decent work should be connected with environmental and social development – which are the so-called green jobs. Jobs that produce green goods and services tend to involve higher qualifications, better work conditions in terms of safety and health at work and higher salary in comparison to other jobs (as evidenced from the US, China, Germany and Spain). However, the problem of greening economic activities needs to be addressed in: agriculture, building and construction, waste management and recycling. All these sectors are run by many employers but working conditions for workers are very often far from what it should be required. Apart from hazardous work conditions, workers need to face with a low level of salary that in some cases bring them to poverty.

Economic growth and sustainable development have been a subject of numerous scientific publications (e.g. Balisacan et al. 2014; Filho et al. 2016; Hess 2016; Higgins 2014). There has also been a discussion that achieving economic growth regardless the environmental concerns seems to be impossible. This is because, trying to achieve only the highest level of economic growth may end up with the lack of water, forest and land. On the other hand, trying to preserve the environment without paying attention to economic growth is considered as utopia. As population grows, there is also an increasing demand for a better living so more and more resources are used. Therefore, one should note that promoting economic growth should be in line with environmental concern (Munier 2006).

The Visegrad group: An Overview

The Visegrad Group was formed on February 15, 1991 by Poland, Hungary and Czechoslovakia under the name of the "Visegrad Triangle". As a result of the break-up of Czechoslovakia in 1993, the Czech Republic and Slovakia took its place, so the name changed from the Visegrad Triangle to the Visegrad Group. The initial goal of the Visegrad Group was to support the process of European integration through economic, social and political cooperation. Over the years, cooperation has been extended to include further areas of activity. Currently, the Visegrad Group has an established position in Europe, which has been achieved through a series of actions and aspirations based on mutual cooperation and implementation of the set goals. The Visegrad countries are situated in Central Europe. Interestingly, the very notion of "Central Europe" is not unequivocal, so the term itself cannot define a group of countries belonging to it. The concept of Central Europe is so controversial that the French political scientist of Czech origin, Jacques Rupnik, wrote the following statement: "Tell me where Central Europe is, and I can say who you are" (Johnson 1996). Le Rider (2008) believes that Central Europe is a term that does not directly correspond to any geographical reality, and in turn is a kind of "mental map". Many sources indicate that it is only the countries of the Visegrad Group that make up Central Europe (e.g. Gorzelak, 2012; Samson, 2009). As noted by Czyż (2018), in many documents of the World Bank and the Organization for Economic Cooperation and Development (OECD) Central Europe is considered as the countries of the Visegrad Group and Slovenia e.g. Borish (1996). Johnson (1996) adds that Central Europe is also sometimes extended to include Germany and Austria. In turn, according to Ágh (1998), Central Europe covers the following countries: the Czech Republic, Poland, Slovakia, Hungary, Slovenia, Croatia and Austria. Regardless of the perception of the concept of Central Europe, it can be assumed that the states in the Visegrad countries are in it.

In terms of real GDP per capita, the countries of the Visegrad Group fall behind the EU's average. Figure 1 clearly shows that the Czech Republic scored the highest value of GDP per capita from the Visegrad Countries, which accounted for 17 640 euros per capita in 2018, while the EU's average GDP per capita was 28 210 accordingly. Then, there was Slovakia with the GDP per capita 15 560 euros, and Hungary and Poland with the results: 12 560 and 12 430 euros per capita, respectively. That clearly shows that the V4 need to work on their economic growth so as to catch up with the EU's average.

Figure 1: Real GDP per capita in the EU countries in euros, 2018

Source: Based on data from Eurostat

Decent Work and Economic Growth in The Visegrad Countries

The Eurostat has prepared a set of data for the EU countries in order to monitor the performance of each country in the 2030 Agenda for Sustainable Development. There are nine indicators of the SDG 8 and the data for them are very often incomplete. Therefore, some data for those indicators are estimated, provisional or not available (n/a). Below, there is a descriptive analysis of each indicator from the SDG 8.

Figure 2 presents real GDP per capita in the Visegrad countries. Out of all V4, the biggest economy is Poland in terms of real GDP, however, concerning real GDP per capita, the Czech Republic was a leader in this statistic from the V4, with the value of € 17200 per capita in 2017, which is still over € 10000 less than the EU average. Although, all V4 have improved their performance in real GDP per capita, they are still lagging behind the EU's average, Poland and Slovakia even more than two times in 2017. Here, all V4 might consider investing in human capital as its concept confirms a positive relationship between education and economic growth (Altinok, 2007). In addition, Kubík (2013) notes that the number of academic years done per capita has a greater positive impact on economic growth in countries with higher education quality.

Figure 2: Real GDP per capita in the Visegrad countries, chain linked volumes (2010), euro per capita

Note: Since the data for Hungary overlap in most years with the data for Poland, full data for Hungary are presented below:

geo\time	2000	2004	2008	2012	2013	2014	2015	2016	2017	2018
Hungary	7900	9490	10500	10010	10230	10690	11130	11410	11930	12560

Source: Own elaboration based on Eurostat data

Another indicator of the SDG 8 is investment as a share of GDP and the data are presented in figure 3. All V4, except for Poland (data not available), had higher share of investment than the EU's average. Poland in the last five years when statistics were available noticed a lower level of investment than the EU's average. It is quite interesting that the Czech Republic spent as much as 30,59 % of its GDP for investment in 2000, and in 2017 it was 24,77 and remains as a leader in this indicator from all V4.

Figure 3: Investment share of GDP in the Visegrad countries, % of GDP

Source: Own elaboration based on Eurostat data

Resource productivity, shown in figure 4, is the next indicator of the SDG 8. It is measured in euro per kilogram in chain linked volumes (2010). The V4 need to work on this indicator since there are not even close to the EU average which is 2,04 euro per kilogram in 2017, while in the best-performing country of the V4 – the Czech Republic, it amounted to around 1,1 euro per kilogram. However, one should note that, in general, the V4 had improved in this indicator considering year 2000 and 2017, but it is still not enough to catch up the EU's average.

Figure 4: Resource productivity in the Visegrad countries, in euro per kilogram, chain linked volumes (2010)

Inactive population due to caring responsibilities as a percentage of inactive population aged 20 to 64, is also considered under the SDG 8 (figure 5). Among caring responsibilities, the United Nations perceive the following ones: looking after children, incapacitated adults as well as other family or personal responsibilities. Hungary with the score of 21,6 % had the lowest share in this indicator in 2017 out of all V4, however it was slightly higher than the EU's average. All V4 need to improve in this statistics, especially Poland with a result of 29 %. However, the trend for all V4 and the EU average is rising, what might be alarming, considering the fact that the Western EU countries scored much less, e.g. Denmark 5 %.

Figure 5: Inactive population due to caring responsibilities in the Visegrad countries, as a % of inactive population aged 20 to 64

Note: Data for the EU 28 in year 2000 are not available
Source: Own elaboration based on Eurostat data

Young people cannot be omitted when considering decent work and economic growth. Therefore, the SDG 8 measure the case of young people neither in employment nor in education and training as a percentage of population aged 15 to 29. Only Slovakia with the score of 16 % was behind the EU average (13,4 %). The leader from the V4 in this indicator is the Czech Republic with a score of 10 %. It is worth noting that the situation improved in all V4 considering year 2000 when some of those countries scored even more than 20 %.

Figure 6: Young people neither in employment nor in education and training in the Visegrad countries, as a % of population aged 15 to 29

Note: Data for the EU 28 in year 2000 are not available
Source: Own elaboration based on Eurostat data

Employment rate in the V4 as a percentage of population aged 20 to 64 is shown in figure 7. All V4 have the employment rate above 70 %, the Czech Republic and Hungary scored 78,5 % and 73,3 % respectively, which was above the EU average (72,2 %) in 2017. Only Poland and Slovakia had a slightly lower share of employment than the EU average but the difference was not that high. All V4 improved their employment rate over time as from 2000 until 2017.

Figure 7: Employment rate in the Visegrad countries as a % of population aged 20 to 64
Note: Data for the EU 28 in year 2000 are not available
Source: Own elaboration based on Eurostat data

After analyzing employment, the SDG 8 continues with the data on long-term unemployment rate, which is shown in figure 8. When considering long-term unemployment rate in the V4, one can notice that the Czech Republic, Hungary and Poland are perfuming quite well in this measure, scoring not more than 1,7 % in 2017 while the EU average amounted to exactly 3,4 % in 2017. Only Slovakia has some issues with that aspect, however, the trend goes into a right direction. Slovakia manged to decrease its long-term unemployment from 10,1 % in 2000 up to 5,1 % in 2017. All the V4 has significantly improved in this measure over time.

Figure 8: Long-term unemployment rate in the Visegrad countries, as a % of active population
Note: Data for the EU 28 in year 2000 and 2004 are not available
Source: Own elaboration based on Eurostat data

Next measure of the SDG 8 deals with people killed in accidents at work, calculated by 100 000 employees (figure 9). The safest country in the V4 in terms of the lowest number of people killed in accidents at work is Poland with a number of 1,54 in 2017 while the EU's average is 1,71. In the rest of the V4, this number was above 2,0 in 2017.

Figure 9: People killed in accidents at work in the Visegrad countries, in number per 100 000 employees

Source: Own elaboration based on Eurostat data

Last but not least measure of the SDG 8 concerns people that have jobs but their disposable income is below the risk-of-poverty threshold. Figure 10 presents data on people in such a situation as a percentage of employed persons aged 18 or over. The Czech Republic with a result of 3,5 % in 2017, had been dealing with this problem extremely well in comparison to other V4 and the EU average (9,4), and then there was Slovakia with a score of 6,3 %. Hungary and Poland had a slightly worse situation than the EU average. In Hungary, this problem arose from 8,7 % in 2000 up to 10,2 % in 2017, while the situation in Poland improved.

Figure 10: In work at-risk-of-poverty rate in the Visegrad countries, % of employed persons aged 18 or over

Note: Data for the EU 28 in year 2005 and 2008 are not available

Source: Own elaboration based on Eurostat data

There is a lack of common strategy of the V4 towards SDGs. Therefore, when analyzing the data of the V4 in the SDG 8, one may notice that sometimes there are quite large disparities in individual performances of the V4. Being under one umbrella called the Visegrad Group, these countries could join their forces and come up with a common action plan for tackling some of the "burning" problems of SDG 8.

Discussion

Although the Visegrad countries joined the EU in 2004, there are still considered as the new EU member states. They still need to make a significant progress to catch up with the old EU member states (as well as with the EU's average) in terms of economic growth. Although concepts of SDGs in general and the SDG 8 in particular are very problematic (since the indicators used to define them, are selected mainly based on data availability criterium) there is a need to take them for granted in the point of departure in this analysis. In total, there are nine indicators used to assess the SDG 8 and the situation in the V4 seems to be far from general expectations. They do seem to have an economic potential as there are more than 60 million people and more than € 900 thousand GDP. If the V4 were a single country, then it would be ranked as the 4th most populated EU country and the 6th wealthiest EU economy. However, the V4 do not seem to be successful in fulfilling the SDG 8 since they are lagging behind the EU's average in the following indicators: real GDP per capita, resource productivity, and inactive population due to caring responsibilities. In addition, some of the V4 need to improve, at least towards the EU's average, in employment, dealing with young people unemployment, and decreasing or even eliminating fatal accidents at work. There are only three indicators that the V4 are above the EU's average level: investment, dealing with long-term unemployment, and tackling the problem of employed people being at-risk-of-poverty. Having discussed an overview of the V4 performance in the context of the SDG 8, there is room for substantial improvement. Therefore, the V4 should join their forces and act together by establishing some common policy towards the 2030 Agenda and addressing problems connected with not only the SDG 8, but also other SDGs.

Conclusion

Although the concept of Sustainable Development Goals is criticised, it is still one of the complex and comprehensive tools for tackling the problem of sustainable development worldwide. It does concern more than 190 countries and has universal indicators and the way of measurement. The Visegrad countries are quite good at investment, tackling long-term unemployment, and the problem of employed people being at-risk-of-poverty. However, some of them need to improve in rising an employment level, deal with young people unemployment, and solve the problem with relatively high number of people killed by accidents at work. All the Visegrad countries do need to work on improving their real GDP per capita, resource productivity, and inactive population due to caring responsibilities.

The Visegrad Group should therefore focus on some common activities or tools that would allow them to improve their results in the SDG 8, at least, in the areas lagging behind, to catch up with the EU's average level. Having in mind all possible restrictions of the concept of SDGs, the future research on this topic might include a set of indicators composed to describe decent work and economic growth for the Visegrad countries, in addition to those which are included in the 2030 Agenda for Sustainable Development.

Abstract

The purpose of the paper is to measure the perception of the phenomenon of burnout among medical, educational and higher education workers in Poland. Professional burnout was treated as a psychological syndrome resulting from chronic stress experienced by employees, as a result of impaired balance between work environment and individual capabilities. The conceptualization of empirical research was based on the acceptance of the syndrome as a universal phenomenon, occurring among various professions, but above all in the field of professions related to helping others. Two types of questionnaires were used for the measurement. The first was the LBQ Professional Burnout Questionnaire, which is an adaptation of the Italian Link Burnout Questionnaire. This tool enables diagnosis of four aspects of burnout, i.e. psychophysical exhaustion, lack of involvement in client relationships, lack of professional effectiveness and disappointment professional. The second is an author`s questionnaire designed to assess the probability of the phenomenon among Polish workers. The study was conducted in June and July 2017 as part of the transnational cooperation project, which aims to develop an effective prevention tool for burnout. The article presents the results of using two methods of econometric modelling to identify differences between employees in terms of main predictors of occupational burnout (logistic regression) and to evaluate the level of experienced burnout symptoms (classification method - two-steps cluster analysis). The obtained results show that burnout is a problem in each of the occupational groups covered by the research, which is the justification for a deeper exploration of this phenomenon, especially in the sector of higher education. There are some universal predictors of burnout for all occupational groups, but some are specific to a given profession and burnout area.

Keywords: Professional Burnout, Predictors of Burnout, Econometric Modelling.

JEL Classification: C59, M54.

Introduction

The aim of this paper is to make an initial estimation of the perception of the phenomenon of burnout in Poland and to generate a discussion about an issue that is both important and difficult but often overlooked. The article provides insight into some of the research findings that are the result of the activities undertaken in an international research project dedicated to the prevention of burnout. The inspiration to undertake presented empirical research in the field of occupational burnout, with particular emphasis on professional groups such as teachers, academic teachers and healthcare representatives, was the analysis of the literature on the subject and the specific situation of these

professional groups in Poland. The authors of the publication have practical experience concerning cooperation with presented professional groups due to the implementation of an innovative EU project: Time2Grow (a transnational cooperation project POWR.04.03.00-00-W300/16, implementation period April 2017 – December 2019, cooperation between Belgium and Finland). It's worth to underline, that especially in Poland academic teachers are a professional group generally omitted in empirical research concerning organizational pathologies such as burnout (Lubrańska 2012, Majchrzak, 2011, Świętochowski 2011). In higher education, such factors as: experiencing role conflict, ambiguity of tasks, pressure to achieve scientific results, lack of greater support from universities are very common on the way of building career paths. A high level of expectations and a complicated and very often unclear procedure determining the promotion process influence the motivation of employees to invest in their professional development. Additionally academic teachers are working with very specific clients, representing various types of studies, which can generate a lot of challenges as well as professional burdens. Taking into account the burnout process among academic teachers, potential consequences have a negative impact on the quality of research and also influenced creativity of researchers and decrease the level of delivered teaching at universities. It can be explained though greater professional disappointment and lowered self-efficacy as well as lowered organizational engagement. Similar to the area of education and health care, relatively low salaries can generate additional frustration for employees. Among Polish teachers, apart from organizational factors (such as the level of salaries, difficult working conditions - overcrowded school classes, a lot of educational changes caused by the political reforms), very stressful factors are: relationships and contacts with students, their parents, guardians and colleagues. Despite the fact, that teachers are one of the best described professional group, when it comes to diagnose of occupational burn out process (Cherniss, 1980, Cherniss, 1995, Cieślik, 2012, Gavish, Friedman, 2010) there is still a gap concerning the practical, but empirically verified solutions of effective burnout prevention.

Health care employees have always been associated with emotional overload and high level of stressful situations at work. Predictors of burnout in this professional group are connected with direct contact with patients, their pain, emotions, and their general situation. Primary research carried out as part of the Time2Grow project confirmed, that Polish health care employees work in several places at the same time for financial reasons. The low level of salaries cause growing tendency to take up an additional part tome job, what definitely influence private social and family life. Lack of free time, psychophysical overload and generally permanent physical and emotional effort at work are additional factors burning this professional group. The course of building an accurate and useful model (which is to prevent burnout and minimize its effects), the authors have carried out a primary research which addressed the problem of how the phenomenon of burnout is perceived and how its symptoms are experienced among the representatives of three groups: healthcare professionals, education professionals and – what seems to be particularly innovative – higher education professionals (for the purpose of this article the aforementioned professional groups will also be referred to as "sectors"). To meet the objective of the research two research questions must have been asked:

1. Do the employees in Poland perceive (are aware of) the phenomenon of burnout (and to what extent)?
2. Are there any differences in the perception of burnout and its symptoms among the representatives of the three professional groups that, as the subject literature suggests, might be especially vulnerable to the syndrome?

The article presents the results of using two methods of econometric modelling to identify differences between employees in terms of main predictors of occupational burnout (logistic regression) and to evaluate the level of experienced burnout symptoms (classification method - two-steps cluster analysis). It should be pinpoint, that selected professional group were considered as those, where the risk of occupational burnout is the highest in comparison to other branches in Poland. For more than forty years the phenomenon of burnout has been generating a great interest among psychologists and management professionals. The literature concerning this subject delivers many studies and a lot of research concerning the diagnosis of burnout and its predictors, especially among the professionals who are engaged in helping relationships with their patients, clients or pupils. The contemporary theories of burnout define this phenomenon as a "disordered professional relationship" between an individual and his/her job, environment, external expectations etc. (Maslach, Leiter, 2007, 2008, 2010,

2011). What is more, the spectrum of the symptoms of burnout includes the understanding of work disappointment as an existential-axiological issue that embraces work dissatisfaction, lack of self-realization and failure in meeting one's expectations (Santinello, 2003, 2008, 2014). It is worth emphasizing that the problem of coping with the consequences of long-term occupational stress was brought to attention by a legislative action that had been taken by the European Union. The legal framework for the discussion about workers' health and safety (as well as about the possible prevention measures) was set by Council Directive 89/391/EWG of 12 June 1989 on the introduction of measures to encourage improvements in the safety and health of workers at work (Dz. U. L. 183 of 29 June 1989, hereafter referred to as Framework Directive), with the last modification dating 2008. In the Article 5 (1) the Directive defines a wide scope of employer's responsibility, who is excepted to "ensure the safety and health of workers in every aspect related to their work". Each member state of the European Union is responsible for setting its own "basic" framework for actions necessary to reduce psychosocial risk at work. The Belgian legislation remains an undisputed leader in this respect. Due to legal changes, in force from 1 September 2014, not only did it introduce a definition of psychosocial risk to the domestic legal system but also imposed a number of obligations on the Belgian employers which aim to prevent their occurrence.

The research material and analytical tools used during the research

The research was conducted on June and July 2017 on the group of 153 people working in the following areas: healthcare (mid-level staff, mostly nurses, 64 people), education (teachers, 46 people), higher education (academic teachers, 43 people). Table 1 groups the respondents on the basis of the survey demographic questions.

Table 1: The division of the sample by the characteristics included in the demographic questions

Workplace			
Healthcare	Education	Higher education	
64	46	43	
Place of residence			
Countryside	City of less than 50 000 inhabitants	City of 50 000 – 200 000 inhabitants	City of over 200 000 inhabitants
13	28	30	82
Type of institution			
Private sector	Public sector	Mixed capital	
36	112	5	
Sex			
Male	Female		
25	128		
Age			
35 years or less	36-45 years	46-55 years	56 years and more
20	46	67	20
Seniority			
Under 5 years	6-15 years	16-25 years	Over 25 years
8	42	51	52

Source: own calculations

Most of the respondents are residents of cities of more than 200 000 inhabitants. 112 people work in the public sector, 36 in the private sector and 5 in mixed enterprises. This structure derives from the fact that the considerable number of schools and bigger universities are public institutions. There was a significant prevalence of women over men in the sample (128 *versus* 25), which clearly reflects the extent to which the teaching and nursing profession are female-dominated. The sample is divided by age as follows: the respondents aged 46-55 (67 people) and those aged 36-45 (46 people) form the most numerous groups; the other two groups, i.e. "35 years and less" and "55 and more" involved 20 participants. 52 respondents have been working in their profession for over 25 years, 51 people have gained the seniority of 16 to 25 years, 42 respondents declared 5 to 15 years of professional experience and 8 people have been working in their profession less than 5 years. Most of the respondents – due to the formal requirements in the analysed professions – received higher education (115 people); others got secondary education (that includes 14 people who graduated from Further Education College). It should be underlined, that in this presented research authors didn't take into detailed analysis the seniority of researched groups. As it has been presented most of the researched group are very experienced professionals (about 145 people from the sample). Many research (Maslach, Leiter, 2010, 2011, Sęk, 2011) suggest that, paradoxically very often younger employees are experiencing higher level of burnout. It is caused by their approach to work, often it's not adequate to the real requirements of the job positon. Additionally they didn't gather as much experience to effectively deal with stress and difficult situations as older employees. Two types of questionnaires were used for the purpose of this research. The first was a LBQ Burnout Questionnaire, which is an adaptation of an Italian Link Burnout Questionnaire (Santinello, 2008, 2014), which enable to measure the level of experienced burnout and which has standardized normalization for Polish population of researched groups (made by Polish Psychological Association). In 2013 a team from the Psychological Test Laboratory of the Polish Psychological Association conducted standardization and validation studies among five professional groups who are engaged in helping other people (teachers, nurses, medical professionals, uniformed services, in total N=995 people with at least one year of seniority, aged 19-65, from all around Poland). The psychometric properties of the questionnaire for the Polish sample were characterised by high reliability. The estimated reliability of the measurement carried out with the use of Cronbach's alpha measure was sufficiently high, which proves the adequacy of the research tool to national conditions. We based the likelihood of our research in the field of a test assessing the level of occupational burnout on the results of reliability assessment conducted by the Polish Psychological Association. The other questionnaire has been originally devised by the authors to assess the perception of the phenomenon among Polish employees. The LBQ questionnaire allows to diagnose four key aspects of burnout, i.e. psycho-physical exhaustion, lack of involvement in relationships with clients (patients, pupils, etc.), lack of sense of professional self-efficacy (effectiveness) and career disappointment. The psycho-physical aspect includes the self-assessment of one's own psycho-physical resources like stress level, mental pressure and fatigue. The aspect concerning relationships with recipients raises the issue of the quality of the relationships (with patients, pupils, clients, etc.) and helps to study an individual and subjective attitude towards social environment at work. The aspect of professional effectiveness refers to how an individual assesses his/her professional competence, while the aspect regarding career disappointment concerns the existential expectations that an individual holds for their work, job satisfaction, enthusiasm for work and the sense of professional fulfilment. The tool possesses a satisfactory psychometric characteristics. It consists of 24 positions – statements that describe the feelings of a subject towards his/her work. Respondents answer the questions using the six-level frequency scale (the scope of which is: "never", "seldom", "once or a few times per week", "roughly once per week", "a few times per week", "everyday").

The original questionnaire was to assess the extent to which the phenomenon is recognized among the Polish employees. It comprised 26 questions, 22 of which were closed, 4 questions were open and 6 questions were demographic ones. The closed questions were twofold: they either determined the occurrence of a given factor (when a respondent answered one or more questions from the cafeteria) or assessed the level of occurrence of a given factor (on a 11- level scale, from 0 to 10). This measurement wasn't psychometrically tested yet. It's original scale, during the statistical description. The collected materials will be used to study the psychometric properties of the obtained results based on the factor analysis and reliability assessment, but this will be the topic of another article. In the presented article, we focus on individual questions and assessment of specific work and life characteristics as predictors of occupational burnout.

The part of the original questionnaire used in the article has been included in the appendix.

The results of the research with the use of LBQ Burnout Questionnaire

The results of the LBQ survey are presented as sten scores, which enables faster and more accurate interpretation for psychologists. The LBQ tool diagnoses the level of burnout in reference to three states experienced by subjects: low (1 – 3 scores), average (4 – 7 scores) and high (8 – 10 scores). It enables to analyze four aspects (dimensions) of burnout. If any of the dimensions of the questionnaire receives high scores it means – according to the subject matter – that there is a potential threat of burnout in this particular area. Nevertheless, it is important to stress that even average results are an alarming sign indicating problems with functioning at work. That originates, among others, from the dynamics of the burnout process which is known to intensify with time, together with its symptoms. The process deepens unless there have been some interventions or significant events in an individual's professional or private life (Cherniss, 1992, Golembiewski i in. 1993a, 1993b). The results of the conducted survey with the aid of LBQ questionnaire allow to confirm the hypothesis stating that the phenomenon of burnout is omnipresent among the Polish employees working in healthcare, education and higher education sector. From the perspective of emotional depletion (understood as psycho-physical and emotional fatigue, sense of helplessness, being overwhelmed with work) each of the three groups achieved similar results. In the healthcare sector 75% of subjects experience the average level of emotional exhaustion, while only 8% of them highly developed this symptom. Among the group of teachers 72% respondents report being moderately fatigued with their work and 13% declare that their level of fatigue is high, which suggests a very high level of stress and strain. Among the higher education professionals 77% is moderately affected and 14% is highly affected by exhaustion. Psychological studies confirm that emotional depletion, which is sometimes viewed as a consequence of excessive occupational stress, is the first and the most common symptom of burnout. It is those factors that discriminate between "healthy" occupational functioning and behaviours that are an imminent threat to the well-being of an individual and his/her closest socio-professional environment.

As much as 19% of academic teachers report that their involvement in occupational relationships is highly disordered, and 72% of them is declaring the average level of involvement, which is still an alarming figure bearing in mind how dangerous the issue in question is. This means that the professionals dissociate themselves from their working environment, draw away from social relations and let the quality of working relations deteriorate. Furthermore, this area of burnout clearly exposes a cynical and hostile attitude towards service recipients, which leads to difficulties in interaction between a subject and his/her working environment. The findings conclude that academic professionals who are expected to demonstrate professional and educational competences (thus expected to hold high educational standards and share their knowledge with students) are having serious problems with functioning in this area effectively. It is evident that this professional group could suffer from a deficiency in interpersonal skills, which would help them overcome challenging situations involving their students or co-workers. While healthcare workers and teachers attend trainings and seminars quite often, it is not so when it comes to higher education. There is still no qualitative support that would develop teaching and mentoring skills, which are essential to succeed as an academic teacher.

An interesting finding emerged while analysing the level of lowered professional self-efficacy, a combination of low self-confidence and a sense of effectiveness in handling day-to-day working obligations. Only 7% of the academic teachers report a high level of this indicator of burnout; 19% of the respondents declared a belief that their level of professional effectiveness is high. By comparison, 11% of the subjects from the healthcare sector received a high score and 20% received a low one. In the group of school teachers 13% is facing a high sense of ineffectiveness at work, while 24% reported being satisfied with their effectiveness and performance. One possible explanation is that, although they had been asked to assess their work in general, the surveyed academic teachers concentrated only on the effects of their research work (which seems quite implausible given their range of responsibilities). It may also be that the findings illustrate a narrow perspective of the academic teachers (when it comes to assessing professional effectiveness) and a tendency to overestimate one's results during the interview. The highest score according to the job satisfaction and the least positive results were observed among the higher education professionals. While as much as 93% of the academics are

disenchanted with their work at a moderate level (12% at a high level), the figure is lower among the healthcare workers (70%) and the school teachers (78%). This dimension of burnout puts emphasis on the negative feelings of subjects, which are closely related to their experiences and existential beliefs. These are aroused when a person experiences a dissonance between the realities of work and aspirations combined with values that simply cannot be satisfied in a particular workplace environment.

By using the results of LBQ Questionnaire an attempt was made to classify the homogenous groups on the basis of experiencing the phenomenon of burnout in the four analysed areas. In this regard a two-step cluster analysis was used. TwoStep Cluster Analysis is to be found, among others, in SPSS v. 24.0. On the one hand it is a method which allows to include categorical and continuous variables, on the other hand it is proof against not meeting the assumptions of normal distribution and the independence of the input data (Kwiatkowska, Załuska, Dziechciarz 2007, SPSS 1999). After applying a procedure with automatic selection of number of clusters, with a condition concerning changes in the likelihood ratio (BIC change), five groupings were filtered out (see Table 2). In the next sixth step, the change in the likelihood ratio was not significant (BIC change at the level – 15, BIC change ratio below 0,1). In the opinion of the authors a further analysis of the results reveals an interesting classification. The classification is statistically reliable due to the fact that the criteria of cohesion and separation are fulfilled. Figure 1 shows the results of the classification quality assessment. Using the thresholds adopted by the authors of this assessment method, it is assumed that up to 0.2 the classification is poor, from 0.2 to 0.5 it is medium, and above 0.5 - good. For the results presented in this article, one obtained the result of 0.58, indicating good quality classification.

Table 2: TwoStep Cluster Analysis – an evaluation of the quality of the classification

No. of clusters	Bayesian information criterion (BIC)	BIC change	BIC change ratio	Distance measure ratio
1	1050,145			
2	888,587	-161,558	1,000	1,230
3	764,760	-123,826	0,766	1,195
4	667,672	-97,088	0,601	1,491
5	615,838	-51,834	0,321	1,637

Fig. 1: Two-step Cluster Analysis – an evaluation of the quality of the classification
Source: own calculations

Three clusters out of five turned out be very cohesive (compare Figure 2): one of the clusters grouped the respondents with high scores in every area and virtually with no low scores (cluster no 1). Another cluster aggregated the respondents with mostly low scores and with no high scores (cluster no 4). There was also a cluster which grouped only the respondents with middle scores on the burnout scale. In order to verify whether there are some differences between the professional groups in terms of burnout further analysis included the respondents that had been classified to two very contrasting clusters (cluster no. 1 and no. 4). Figure 3 displays the deviations from the expected representation of respondents in particular professional groups. It has been assumed that the expected participation of the respondents in a cluster is proportional to its size and reflects the representation of a given cluster (value = 1). A

situation when there is more respondents from a given professional group than expected is called overrepresentation (value > 1). Underrepresentation is the exact opposite of overrepresentation (value < 1).

It is worth noting that there are significant deviations regarding the higher education sector professionals – the overrepresentation in the cluster no. 1 (+ 26%) and the underrepresentation in the cluster no. 4 (- 35%).

This means that the representatives of higher education participating in the study are more often exposed to occupational burnout than the representatives of other professions. At the same time, taking into account the results of the answers to the remaining questions, this occupational group find it most difficult to admit that they experience problems causing the risk of burnout and the first symptoms of this phenomenon. According to the authors of the study, this is a clear signal for deepening research in this occupational group in the field of burnout predictors, the possibility of counteracting this adverse phenomenon, as well as the dissemination of the topic of burnout in the group of decision-makers at universities.

At this stage, without conducting any detailed research, only preliminary hypotheses can be made concerning the reasons for such a high risk of burnout in the group of academic teachers. It seems that one of the reasons is the fact that they belong to the group of the so-called high-skilled occupations, where one has to perform several different types of activities. In Poland, the vast majority of academic teachers are employed in scientific and didactic positions, which means that they are evaluated for the results of their work in the area of didactics, scientific research and, additionally, organisational and management tasks. D. Prediger, researching various occupations and their specificity, formulated the concept of the World of Work Map (1993, 1999). The Map refers to two dimensions of occupational tasks: Data & Ideas and People & Things. According to its author, one dimension is sufficient for a good description of most occupations, e.g. social occupations (People). However, taking into consideration the assumptions of the Prediger concept and analysing the position of the academic teacher, one can assume that due to the complexity and specificity of the work they perform, this group can fall into the category of Ideas & Data (scientific activities requiring scientific research, data analysis, interpreting research materials) as well as the category of People, taking into account didactic duties, i.e. work in direct contact with students, mentoring and tutoring, conducting MA, doctoral and diploma seminars, etc. Due to their diversity and level of difficulty, the responsibilities and functions of academic teachers may result in experiencing a kind of “conflict of occupational roles” (Borucki 1988, 1994). According to Z. Borucki's approach, an employee experiences stress when he or she evaluates external requirements as exceeding their capabilities, whereas the environment (work environment) - as insufficient to meet the needs.

Main Predictors of Burnout

With an aim to identify the key factors that determine the level of burnout in its particular dimensions a logistic regression was used (SPSS, ver. 24.0). The results of the LBQ that were related to the level of burnout in a given dimension served as dependent variables. The results were aggregated into two categories: 0 – a respondent is characterized by a low level of burnout (scores 1-5), 1 – a respondent is characterized by a high level of burnout (scores 6- 10). The set of the potential explanatory variables included two demographic characteristics (namely age and seniority) and the answers to the questions from the original questionnaire (see Table 3).The demographic characteristic „sex" was not included in the analysis given the small number of men among the survey participants. The answers to question no. 5 were grouped into two categories: 0 – a respondent never or rarely engages in activities other than professional and domestic responsibilities, 1 – a respondent regularly engages in activities other than professional and domestic responsibilities. In order to find a model that would be significant in terms of F- statistics (the Wald test), the method of stepwise logistic regression was employed. The critical value of the F-statistics was at the significance level $\alpha = 0{,}05$ during forward selection, and $\alpha = 0{,}10$ during backward elimination. To validate the goodness of fit two tests were used: the Nagelkerke R^2 and the Hosmer-Lemeshow test. The latter compares the used model and the null model (with an intercept parameter only) in terms of the relevance of classification (cf. e.g. Gruszczyński, 2002; Heckman, Leamer, 2001).

Table 3: The selected questions of the original questionnaire

No.	Question
	Type of work
3a	High emotional stress
3b	Great physical strain
3c	I am mostly responsible for my work results
3d	My work involves contact with others
3e	A stressful relationship with a supervisor
3f	Stressful relationships with co-workers
3g	Too much bureaucracy
3h	A dynamic environment/ a necessity to adapt
3i	An adequate remuneration for work
3j	Little success at work
3k	I feel that my work suits me

3l	I maintain a work-life balance
3m	I am satisfied with my work
3n	I would like to change my job
3o	I wish I could take some time off work
3p	I can influence the way I do my work
Hobby	
5	Leisure and personal development activities (hobby)
A subjective assessment of the knowledge of burnout	
7a	I have sufficient understanding of burnout

Figures 4 – 7 present the received models for the particular dimensions of burnout and for the professional groups in the form of graphs. The explanatory variables are displayed from top to bottom, in the order they were being added to the model. Under each graph, which represents a combination of a dimension of burnout and a factor (factors) that has (have) influence on it, there are two other parameters. The value of the parameter B is attributed to a given independent variable. The value of the parameter exp(B) measures how the increase of a predictor by one point will change the probability of transition from category 0 (a low level of burnout) to 1 (a high level of burnout).

Fig. 7:The factors influencing the level of burnout - disappointment

Source: own calculations

Stress was a factor that played the biggest role as a predictor in the logit models (question no. 3a). It occurred three times in healthcare and two times in education, whereas it did not occur in higher education at all. The model for disappointment in healthcare, apart from revealing a variable referring to high stress, also showed a variable that measures the level of work satisfaction (question no. 3m). An important factor in education was whether a respondent feels that his/her job suits him (question no. 3k). In higher education the highest importance was attributed to maintaining work-life balance (question no. 3l) and the level of understanding of burnout.

The measured parameters could be interpreted as follows: the dimension of exhaustion, the model for healthcare, question no. 3a: the values of B = 0,512 and exp(B) = 1,668 mean that a growth of the stress level by one measure results in 67% higher risk of transferring from the category of the low level of burnout to the category of the high level of burnout. The dimension of involvement, the model for higher education, question no. 5: the levels of parameter B = 2,199 and exp(B) = 0,111 mean that the probability of experiencing a high level of burnout is lower by 90% among the people who have got “a regular escape” from the daily work and domestic routine, i.e. hobby.

Concluding Remarks

The conducted research was of a pilot nature. The conclusions formulated below are a preliminary evaluation of the situation and constitute the basis for further research steps.

The present research on the phenomenon of burnout that has been simultaneously carried out in healthcare, education and higher education is an attempt to identify similarities and differences between three professional groups. It provides the answers to the initial research questions. The following points can be made:

— The phenomenon of burnout is widely perceived in all of the analysed professional groups. This claim is supported by the high LBQ Questionnaire results.
— The used of logit models worked well to determine the impact of various factors on individual areas of burnout. It should be emphasized that this method gave good effects differentiating the impact of factors depending on the industry and the area of burnout. It turned out that some of the factors are universal and strongly affect most burnout areas regardless of the occupation (e.g. stress), while some are specific to the industry or burnout area (e.g. work-life balance).
— In addition to the predictors listed above, it is worth paying attention to the fact that stress is the main and basically the only factor significantly affecting the level of occupational burnout in health care. In the group of teachers, apart from stress, the sense of being suitable for a

given profession and assessment of the need to remain in a professional relationship with other people also play a similar role. In the case of academic teachers, the main predictors of occupational burnout in individual areas are very diverse.

— The outcome of the two-step cluster analysis additionally support a conclusion that burnout is a common issue among the surveyed professionals and provides justification for deeper exploration of the phenomenon, especially in higher education. Academic professionals experience the typical symptoms of burnout. What is more, the results of the analyses demonstrate that the group is distinctly different from other groups. It achieved high scores in most of the areas (the LBQ Questionnaire).

— Despite the noticeable differences in the perception of burnout among the professional groups subjected to the survey, the adoption of the automatic selection procedure revealed three cohesive clusters that included respondents of diverse occupations. This means that the employees of the analysed professions probably share traits that influence the shape of the process of burnout in a similar way. Undoubtedly, a direct contact with another person is one of those shared traits. Given the aims of the international research project that has been a framework for this paper (building an useful model for the prevention of burnout) what seems to be particularly important is to conduct a longitudinal research that would illustrate the dynamics of the respondents burnout before and after taking the preventive action.

It should be underline, that despite the great amount of interesting research results, it's not possible to present all findings in this article. The authors decided to concentrate on particular aspects of their project, based on presented research questions. More demographical findings and their connections with burnout syndrome are presented in another publication (Załuska, Ślazyk-Sobol, Kwiatkowska-Ciotucha, 2018).

Acknowledgments

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

- **Appendix. Selected questions from the original survey questionnaire.**

3 Firstly, let us ask you some general questions about your work. Please asses to what extent each of the questions describes your current job. Use the scale of 0 to 10, where 0 – definitely inadequate, while 10 – definitely adequate.	a. High emotional stress _____ b. Great physical strain _____ c. I am mostly responsible for my work results _____ d. My work involves contact with others _____ e. A stressful relationship with a supervisor _____ f. Stressful relationships with co-workers _____ g. Too much beaurocracy _____ h. A dynamic environment/ a necessity to adapt _____ i. An adequate remuneration for work _____ j. Little success at work _____ k. I feel that my work suits me _____ l. I maintain a work-life balance _____ m. I am satisfied with my work _____ n. I would like to change my job _____ o. I wish I could take some time off work _____ p. I can influence the way I do my work (e.g. way of working, selecting tasks) _____
5 Do you take part in any leisure or personal development activities, other than your professional and domestic duties?	Yes, regularly 1 Yes, although sporadically 2 No 3
7 Please think about „burnout" for a moment. How would you describe your level of understanding of this phenomenon? Please describe to what extent you agree with the following statements using a scale of 0 – I completely disagree to 10 – I completely agree. a. I have sufficient understanding of burnout _____ b. I could recognize the symptoms of burnout if they affect me personally _____ c. I am able to tell whether somebody else shows the symptoms of burnout _____	

Institutionalizing Strategic Communication through CSR Initiatives: The Effects on Corporate Reputation, Legitimacy, and Culture

Abstract

Has strategic communication been institutionalized in Southeast Asia particularly in Malaysia? The purpose of this paper is to identify the importance of corporate social responsibility (CSR) initiatives as a projection of corporate identity of the organization. The study also aims to examine the impacts of CSR on corporate reputation, legitimacy and culture to the organization in building a favorable relationship between the organization and its environment. A survey questionnaire was administered to 285 practitioners in Malaysia. Results indicate that CSR initiatives are imperative in institutionalizing strategic communication. A greater focus on corporate reputation, legitimacy and culture can improve the favorable relationship between the organization and its environment. An empirical understanding of CSR initiatives as distinctive corporate identity projection is explicitly addressed by making reference to strategic communication literatures.

Keywords: Strategic communication**,** Corporate social responsibility, legitimacy, reputation & culture.

Introduction

The importance of professionalization and institutionalization of strategic communication has been debated vigorously since 1980s (Grunig & Hunt, 1984) and 1990s (Cameron, *et al*., 1996; Sallot, *et al.*, 1997 & 1998) predominantly in the US. In the early 2000s, more studies were conducted by Elmer (2000), Parkinson (2001) and Rawel (2002) to name a few to challenge the debates on public relations professionalism in the US and Europe. However, little relevant studies were conducted in an Asian country (see Chay-Nemeth, 2003; Park, 2003). Only after mid 2000s, the institutional theory has been substantially influenced a study of public relations profession or strategic communication predominantly in Europe (Tench, *et al*., 2009a; see Hallahan, *et al*., 2007). This becomes more interesting with the discussion from the outcomes of research projects such as EBOK and ECM (Tench, *et al.,* 2009b; Van Ruler & Vercic, 2004).

The term "institutionalization" is inspired us to look further the importance of emerging profession of strategic public relations or corporate communication in a Southeast Asian region particularly in Malaysia. Many scholars use the term "strategic public relations" as synonym to "strategic communication" or "communication management" to institutionalize the role of communication managers in managing formal communication activities to attain their organizational missions and visions (Tench, *et al*., 2009a; see Hallahan, *et al*., 2007). Although the use of terms suggests a fruitful meaning to the profession, changing terms may confuse practitioners and community at large. The term "corporate communication" is widely used in Malaysia when referring to institutionalizing strategic communication activities at the managerial level while "public relations" always refers to the specific technical tasks such as media relations and event management. In fact, there are

continuous debates to differentiate between corporate communication (strategic) and public relations in Southeast Asia.

Although the current practice of strategic communication is universally practiced in the US, Europe and Asia, there is lacking of empirical research in Southeast Asia with regards to institutionalizing strategic communication. Specifically, in practice, strategic communication always is related to corporate social responsibility (CSR) and corporate reputation (CR) in Southeast Asia. However, none or little empirical research have done to bridge a link between institutionalizing strategic communication and the key concepts of CSR, CR, legitimacy and culture in Southeast Asia. Thus, this study will close the gap. We aim to examine the relationship between aspects of CSR, CR, legitimacy and culture, and its importance to strategic communication.

One must see institutionalization as a process. Institutionalizing strategic communication requires a considerable attention to the strategic role of communication managers (Tench, *et al*., 2009a) such as public speaking skills, team's communication skills and so forth (Baninajarian and Abdullah, 2009). Importantly, projecting corporate identity of the organizations considers as strategic and managerial skills for competent managers. Selznick (1957, p. 16-17 in Scott, 2008, p. 22) argued that "to institutionalize is to *infuse with values* beyond the technical requirements of the task at hand". Scott (2008, p. 22) extended his argument by noting that "by embodying a particular set of values, the organization acquires a 'character structure', *a distinctive identity*". Thus, excellent organizations need to be infused with values to project a distinctive identity which lies in the strategic role of strategic communication. Thus, this paper aims to answer the question "can institutionalizing CSR initiatives be one of core roles of strategic communication to position the essential practice at the dominant coalition?". This work is supported by Abdullah and Seman (2018) that Korean companies perceived the importance of building a unique corporate identity virtually.

The concept of institution refers to a degree of normative structure within the societies (Parsons, 1960) which requires examining the relationship between the organization and its environment. Sandhu (2009, p. 87) argued that there is a dire need to emphasis on a wider lens of cultural and social embeddedness of all organizations rather than focusing on a single organization. This will lead us to study the reflection of the CSR initiatives to the notions of reputation, legitimacy, and culture.

The purpose of this paper is to identify to the importance of CSR initiatives as a projection of corporate identity of the organization. The study also aims to answer the importance of corporate reputation, legitimacy and culture to the organization in building a favorable relationship between the organization and its environment. In this paper, we aim to make two contributions to the literature on institutionalizing strategic communication in Malaysia. First, on the basis of an overview of the existing literature, we provide the empirical research in Malaysia to enrich the debates on institutionalizing strategic communication universally. Second, we argue the significant relationships between CSR, CR, legitimacy and culture will expand the role of strategic communication in strengthening its contribution to a societal environment.

The paper is structured by describing a broader perspective on CSR and Malaysian CSR scenarios to give an overview of strategic communication practice in Malaysia. Then, the notions of CSR, CR, legitimacy and culture are theoretically discussed in the context of institutionalization of strategic communication. Next, evidences from a survey on Malaysian companies are presented. Discussion and implications of study are addressed.

Literature Review

Perspectives on CSR

Previously, behaving irresponsibly is seen as harming the organizational performances, but now, ignoring environmental, social and governance issues can be very risky. With the recent development of CSR, today's organizations face several challenges to satisfy stakeholder's increasing expectations (Freeman, 1984; Beckman *et al.,* 2006; Jamali, 2008), society (Szekely & Knirsch,

2005) and public (Gower, 2006; Holshausen, 2000). This situation has led to the high adoption of CSR practices among multinational companies (Vives, & Peinado-Vara 2004). While the study done by Szekely and Knirsch (2005) revealed that, many large companies and small medium enterprises (SME) have ventured into entrepreneurship challenges (Ekpe et. al., 2015) and also have introduced numerous sustainable development initiatives to address the stakeholders' demands and expectations.

In broader perspectives, social responsibility is also regarded as how the economic and legal duties of the companies can be prolonged by certain responsibility to public (McGuire, 1963). Both Carroll (1999) and Wood (1991) agreed that, producing goods and services which has social impacts should be the main social responsibility of companies. McWilliams *et al.*, (2006, p. 4) pointed out that CSR ''should be considered as a form of strategic investment'' which ''can be viewed as a form of reputation building or maintenance". Brown and Dacin (1997) described CSR as a company's "status and activities with respect to its perceived societal or, at least, stakeholder obligations".

Despite gaining a greater attention from various groups of practitioners and academicians, the practice of CSR is much debated and criticized, especially on the CSR's relationship between purpose and nature of business as well as the motive for engaging in CSR (Friedman, 1970). Few Scholars have emphasized the need for a substitution, and the need for new critical CSR research agenda (Fox, 2004; Utting, 2003, 2005). Companies are continuously arguing the potential and restrictions of CSR efforts (Reed & Reed, 2004). Specifically, companies will also gain benefits from CSR initiatives financially, and the employees and communities enjoy great benefits socially and environmentally (Prieto-Carrón, *et al*., 2006). What is clear here is that, CSR becomes increasingly important and interesting in studying the CSR theory and practice (Visser, 2008). It also signifies a great prospect for researchers to enhance their knowledge and understanding about CSR rigorously.

Malaysian CSR Scenarios

Raslan (2007), chairman of CSR Malaysia was concerned with CSR noting firmly:

> "*On the 16th of November 2006, we saw the birth of CSR Malaysia, a unique network of corporate and academic institutions, committed to advancing responsible business strategy and practices that will have a triple bottom line impact - people, environment, and economies*".

Over the years, Malaysia suffers from severe environmental issues such as deforestation which triggered the loss of pollution, biodiversity, and erosion (Boon, 2007; Ahmed, 2008). This country has fought these great challenges of the increasingly needs of energy and managing fragile ecosystems (Yakcop, 2004). The awareness of social issues has also been growing up to various areas such as the needs for affordable housing, fair labour, employee safety, welfare, and access for the disabled as well as aboriginal people rights (Staples, 2004; Sen & Bhattacharya, 2001). Since then, Malaysian companies have expanded their annual reports by integrating the key aspects of social, environmental, product and workers information (Zulkifli & Amran, 2006).

Furthermore, based on the corporate governance studies, it is argued that there are plenty of opportunities for advancement for Malaysian companies in this CSR area (Salleh, 2009). In a Government Link Corporations (GLC) transformation program, Khazanah Nasional Berhad has released the Silver Book which contains CSR guidelines for GLCs in Malaysia. This "Silver Book provides a strategic framework for GLCs to establish effective contributions and mitigate the cost of any social obligations" (Silver Book, 2006, p. 15).

With the current development of CSR in Malaysia, there are tremendous contributions of CSR literatures from various aspects of social and environmental issues. According to Zulkifli and Amran, (2006), Teoh and Thong (1984) studied the early development of Malaysian CSR studies. Interestingly, they focused their study on three key issues of CSR which are the concept of CSR, the corporate involvement in CSR and finally, the corporate social reporting.

Recently, Amran and Siti-Nabiha (2009) indicated that there are substantial advancement in company reporting that indirectly may emulate the abundant enhancement in social performance.
While Newel and Manaf (2008) have proved the significance of sustainability practice by the Malaysian property investment companies, and Dusuki (2006) explained the importance or CSR practices in the Islamic banking institutions in Malaysia. Aini and Sayce (2010) examined a number of property investors who has implemented environmental and social practices. This rapid growth has raised the tremendous awareness amongst corporate Malaysia in improving its capacity and competent to fight against environmental and social issues. Seriously, it is dire needs for companies to prioritize social responsibilities towards society for the real solutions towards sustainable development. As such, this effort lies in the institutionalization of strategic communication through building a coherent and planned CSR initiative for an excellent organization.

Operational Definitions

Corporate Social Responsibility

Corporate Social Responsibility is "a commitment to improve community well-being through discretionary business practices and contributions of corporate resources" (Kotler & Lee, 2005). According to European Commission (2001), CSR is "a concept whereby companies integrate social and environmental concerns in their business operations", means that companies have a strategic focus on its contribution to public growth over the long terms. Robert (2003) pointed out that, economic, social and environmental issues are frequently referred to as "triple bottom line", and either by necessity or invention, CSR has become a form of ethical accountability. Hopkins (2003) added that, although the acronym CSR is now well established, what the term actually means remains a subject of much debate.

Established in the early 1950's and 1960's, CSR has become a popular topic to be discussed and numbers of publications pertaining to CSR issues in local and international journals are also high. However, Ebner and Baumgartner (2006) argued that, there is no common definition of CSR. Since then, there have been significant developments in the various fields and sub-topics of CSR, such as CSR effects on consumers (David *et al.,* 2005), accounting and financial sector (Dusuki, 2006; Gray *et al.,*1996), corporate brand (Urde, 2009), trust (Ingenhoff & Sommer, 2010; Balmer, 2009), reputation (David, 2009; Fombrun, 2005;), not least within the stakeholder approach (Freeman, 1984; Donaldson & Preston, 1995; Jamali, 2008).

As mentioned by Wood (1991: 695), "the basic idea of corporate social responsibility is that business and society are interwoven rather than distinct entities; therefore, society has certain expectations for appropriate business behavior and outcomes". However, each company has to decide which component to focus on in their social responsibilities such as economic, legal, ethical and discretionary expectations (Carroll, 1979). As a conclusion, CSR is an organizational
obligation and key duties for companies to run their business in sustainable manner economically, socially and environmentally. At the same time, the organization needs to balance their interest of various stakeholders. However, it is still desirable for every Malaysian organization to improve their corporate reputation across industries worldwide.

Reputation

Reputation is "the perception of an organization built over time" (Balmer, 1998), that is why it is frequently understood that reputation is significant and treasured because it may influence the organizational confidence and customers feel good about purchasing products and services. Since corporate reputation is able to provide information about an expected future behavior of a company (Alchian & Demzet, 1972), most of consumers nowadays are rely on firms' reputation since they have limited information than managers do about firms' promise to delivering necessary product features like reliability or quality (Grossman & Stiglitz, 1980; Stiglitz, 1989). Davies et al. (2001: 114) define reputation as "a collective term referring to all stakeholders' views' of corporate reputation including

identity and image", and one of the notable objectives of corporate identity management that mentioned by Van Riel and Balmer (1997) was the development of a desirable reputation among an organization's stakeholders.

Reputation provides a source of competitive advantages (Balmer, 2001). Fombrun notes that, "good reputations increase credibility, making us more confident that we'll really get what we're promised" (Fombrun, 1996, p. 3). Previous consumer marketing studies (Brickley *et al.,* 2002; Jones, 2005; Smith & Higgins, 2000; Varadarajan & Menon, 1988) have highlighted that the influence of CSR and corporate reputation may induce positive brand perceptions of company products.

Legitimacy

Legitimacy theory is the response to the environmental pressures involving social, political and economic forces. According to Patten (1991) the main argument in this theory is that the more social exposure a firm receives by being larger, the greater the need to legitimize its existence to its relevant publics. Based on Branco and Rodrigues's (2006) findings, a legitimacy threat occurs when a company's behavior is perceived as not in accordance with society's norms. Therefore, to be appearing 'legitimate' in the eyes of society, many companies resolve to indulge in 'good news' by reporting only on the positive impacts on society and choose not to disclose the bad news (Atan *et al.,* 2010).

Recent developments have created opportunities and brought legitimacy research into overlap with a variety of other ways of discussing the social assessment of organizations. (Deephouse & Suchman, 2008). Since then, much corporate management have established environmental management systems and progressively adopted environmental reporting within the annual report (Deegan & Gordon, 1996). Previous studies have proved that the legitimacy theory has been extensively applied to discuss the social and environmental disclosure by corporations focusing mainly on social and environmental reports (Suchman, 1995; Deegan, 2002, Gray *et al.,* 1995; Lindblom, 1994; Maignan & Ferrell, 2004). However, Deephouse and Suchman (2008) identified that much of this literature has been highly theoretical, invoking legitimacy as an explanatory concept rather than examining it as an empirical asset. Both Suchman (1995) and Deegan (2002) pointed out that, the perceptions of the society towards the organization are critical which may influence the existence of the business. While Gray *et al.,* (1995) argued that, the organization will only secure their existence if they are perceived as operating within the values and norms of the society.

Culture

Corporate culture has been highlighted in the last decade for the key important role that it can play in a firm's success. Cultural is now widely recognized as a component of corporate identity (Melewar, 2003), since then corporate culture is paramount topic in business and organization (Abdullah, 2010; Sadri & Lees, 2001). It is widely agreed that culture contribute significantly to productivity and performance as well as a company's ability to create sustained competitive advantages. A formal definition offered by Greenberg and Baron (2008, p. 544) includes "culture as a cognitive framework consisting of attitudes, values, behavioral norms, and expectations".

Within the cultural research, Schien's model of culture remains a pivotal influence (Hatch, 1993). According to Abratt (1989), Schien's model has also been the basis of most conceptualizations within corporate identity models to date. Schien (2004) assumes that culture is largely antecedent to behavior; however Hatch (1993) argues that not everything that happened within the organization can be contributed to culture. Rather, culture has significant effects on behavior and other sources of influence apply (Vella & Melewar, 2008).

Barney, 1986; Dutton *et al.,* (1994) described that managers' perceptions and motivations are influenced by corporate culture, that is why managers are required to be concerned about their organization's culture and its alignment with the corporate values. Ignoring this notion, they would

face inconsistent behavior and adversely affect stakeholders' perceptions of the organization. Furthermore, Bettencourt and Brown (1997) argued that, corporate culture can be representing a source of companies' competitive advantages, but the culture is required to be attentive, adaptive, and appropriate to the expectations of all stakeholders (Kotter & Heskett, 1992).

In relation with CSR and corporate culture, Haniffa and Cooke (2002) extended the literature by examining the impact on culture the structure of governance on CSR. Findings from the survey conducted by Adam (2002) also indicated that country of origin, corporate size and corporate culture are likely to have an impact on CSR. This reflects that managers should be focused in internalizing the CSR culture into the companies. In the section, research method is addressed to provide empirical data of this study.

Research Method

Research Objectives

This quantitative research project aims to achieve the following objectives:

RO1: to determine the importance of CSR initiatives to Malaysian companies.
RO2: to examine the importance of corporate reputation to Malaysian companies.
RO3: to identify the importance of culture and legitimacy to Malaysian companies.
RO4: to examine the correlations between CSR initiative dimensions and corporate reputation and its associated outcomes.

Sample and Procedures

We conducted a survey to identify to the importance of CSR initiatives as a projection of corporate identity of the organization. Empirical data were also collected to answer the importance of corporate reputation, legitimacy and culture to the organization with regards to favorable relationships between the organization and its environment.

Study respondents were 300 volunteered practitioners enrolled in the executive programs of Master of MBA and Corporate Communication at one reputable research Malaysian university. All respondents involved directly in implementing CSR initiatives in their respective companies. Out of 350 questionnaires distributed, only 300 questionnaires were usable. Due to missing values, 15 were eliminated. With a response rate of 95%, therefore, the final sample size is 285.

Measures

Based on the past studies, we obtained the multiple-item scales. Mainly, survey questionnaire was designed by adapting David *et al.*'s (2005) CSR initiatives which consist of three underlying constructs: discretionary practices, moral/ethical practices, and relational practices. Questionnaire items were also adapted from Helm's (2005) formative measure of corporate reputation. The data for this study were gathered using the structured questionnaire consisting of five parts covering underlying elements of CSR initiatives, reputation, legitimacy and culture.

Results and Discussion

Importance of CSR Initiatives

Table 1 discusses some respondents' perceptions about the CSR initiatives that include "*moral/ethical practices", "discretionary practices"* and, *"relational practices"* of the company. This section is crucial to the overall study as it provides important issues that respondents felt companies in this industry should be aware of, when dealing with their stakeholders.

The study reveals that, majority of the respondents agreed that "*moral practice*" is important for company CSR initiatives. This can be seen in the column 4 (important), where the score are given in between 54.7% to 56.5%. Most of the respondents are perceived that "my company compete fairly with its competitors" are important with the highest score of 56.5%, while "company treats employees fairly" and "my company honors human rights of those employed in foreign countries" were given 54.7% and 52.8% respectively.

Surprisingly, most of the respondents in the current study were not recognizing "responsibly toward the environment" and "being honest and upfront about telling the truth" as an important CSR initiative for the company since the score for both are given below 50%. Similarly, with regards to "*discretionary practices",* all four items were rated below 50%. This could be happened due to a lack of awareness level of art and cultural programs in the community, very low social awareness of issues such as domestic violence and hunger, not aware of family conflict and a lack of information about the supports through public health programs, such as the fight against AIDS, cancer and other severe diseases. Nevertheless, among 285 participants, there were 54% of respondents who believed that "company strives to build long-term relations with its consumers" and 56.1% of respondents supported the company strives to promote satisfactory relationships with its internal stakeholder are an important factor in CSR initiatives.

TABLE 1: Importance of Corporate Social Responsibility Initiatives

No	Construct/ Items	[1] Not at all Important	[2] Less Important	[3] Slightly Important	[4] Important	[5] Extremely Important
CSR INITIATIVES (%)						
CSR: Moral Practices						
1.	My company treats employees fairly	**0.7**	**3.9**	**19.3**	**54.7**	**21.4**
2.	My company honors human rights of those employed in foreign countries.	**1.4**	**4.2**	**28.8**	**52.8**	**13.0**
3.	My company competes fairly with its competitors.	**2.1**	**56.5**	**23.2**	**15.1**	**3.2**
4.	My company acts responsibly toward the environment.	**0.4**	**3.9**	**23.5**	**49.5**	**22.8**
5.	My company is honest and upfront about telling the truth when something goes wrong.	**1.8**	**3.9**	**31.2**	**43.5**	**19.6**
CSR: Discretionary Practices						
6.	My company contributes resources to the art and cultural programs in the community.	**3.2**	**9.5**	**30.9**	**41.8**	**14.7**
7.	My company contributes resources to raise social awareness of issues such as hunger and domestic violence.	**1.8**	**11.2**	**26.7**	**44.9**	**15.4**
8.	My company supports children and family issues, such as adoption and foster care.	**3.2**	**14.0**	**30.2**	**36.1**	**16.5**
9.	My company supports public health programs, such as the fight against AIDS, cancer and other diseases.	**3.5**	**8.1**	**33.3**	**40.0**	**15.1**
CSR: Relational Practices						
11.	My company strives to build long-term relations with its consumers.	**1.4**	**3.2**	**18.2**	**54.0**	**23.2**
12.	My company is willing to listen to its consumers and other stakeholders and is open to constructive criticism about its business practices.	**1.4**	**4.2**	**23.5**	**48.1**	**22.8**
13.	My company strives to promote favorable relationship with employees.	**2.1**	**4.2**	**20.0**	**56.1**	**17.5**
14.	My company appears to be trustworthy.	**1.1**	**3.2**	**23.5**	**49.8**	**22.5**
15.	My company is concerned with aligning its value and belief with the stakeholders' interest.	**2.1**	**4.2**	**26.0**	**48.8**	**18.9**

Importance of Corporate Reputation

Respondents were shown a list of benefits for having good corporate reputation. From that list, they were asked to rank those benefits according to their importance from the respondents' perspectives (1 = Not at all Important, 5 = Extremely Important). Table 2 shows the overall findings for this question.

By judging from the Table 2 particularly in "corporate reputation" section, it can be seen that different respondents have different sets of expectations and preferences. Therefore, the only way to rationalize this data is by looking from a wider perspective and thus, may derive some conclusions using the aggregated results. Referring to the scores column, as suggested by the majority of the respondents, the most extremely important influence of corporate reputation was "my company has the credibility of marketing communication claims (77.9%)". Interestingly, "my company strives for corporate success (57.9%)" only came second, then followed by "company focuses on customer oriented (52.3%)" and "my company is very well organized (51.2%)" being ranked third and fourth respectively. The importance of companies to be recognized in this list suggests an indication of how to make full use of their good corporate reputation, and from there they could achieve certain competitive advantages.

TABLE 2
Importance of Importance of Corporate Reputation

No	Construct/ Items	[1] Not at all Important	[2] Less Important	[3] Slightly Important	[4] Important	[5] Extremely Important
CORPORATE REPUTATION (%)						
1.	My company strives for corporate success.	**0.4**	**3.9**	**10.2**	**57.9**	**27.7**
2.	My company focuses on customer oriented.	**0.0**	**1.4**	**15.4**	**53.7**	**29.5**
3.	My company provides high quality products.	**0.4**	**1.8**	**14.4**	**49.8**	**33.7**
4.	My company provides value for money for its products and services.	**2.1**	**3.9**	**20.7**	**44.2**	**29.1**
5.	My company has the credibility of marketing communication claims.	**0.4**	**4.9**	**24.2**	**29.5**	**77.9**
6.	My company has a commitment to protect the environment.	**0.7**	**4.6**	**28.1**	**42.8**	**23.9**
7.	My company has a commitment to charitable causes.	**0.4**	**6.7**	**27.0**	**48.1**	**17.9**
8.	My company is very well organized.	**1.1**	**2.5**	**23.9**	**52.3**	**20.4**
9.	My company recruits top talents	**1.1**	**4.9**	**19.3**	**51.2**	**23.5**
10.	My company has a good standing financial performance.	**0.4**	**3.2**	**19.6**	**50.5**	**26.3**

Importance of Culture and Legitimacy

Both culture and legitimacy have becoming important and talked about. Culture is concerned with the impact of the employees' activities that related to value and beliefs, multi-ethnics and cultural sensitivity among diverse employees. While legitimacy tried to fulfill the legal principle and expectation.

In this section, all the respondents were asked to review, and provided feedbacks on the importance of culture and legitimacy. Based on the result in the Table 3, majority of the respondents agreed that all cultural issues are "important" to the company, where "multi-ethnic employees work in harmony in this company" represents the highest score of 56.1%. "company policy on equal opportunities among the diverse employees" is rated the second highest with total score of 55.8%. Furthermore, the perception on "company uses local values to articulate its company brand", and "employees share the same values and beliefs" are rated as third and fourth place with total score of 53.3% and 53.0% respectively. However, only 44.6% of the respondents gave a rating of 'important' for respecting cultural sensitivity among diverse employees.

Referring to the legitimacy score, 54.4% respondents gave a rating an "important" to "company always submits to the newest legal principle as soon as possible". Followed by 53.3% for "company products and services are compliant with the legal expectation". Under the same issues "company works with regulators to formulate and develop the regulatory standard" were rated as important with total score of 51.2%. Nonetheless, the rest of two items that related to law, social and environmental disclosure were rated below 50% (47.0% and 41.4%).

TABLE 3: Importance of Culture and Legitimacy

No	Construct/ Items	[1] Not at all Important	[2] Less Important	[3] Slightly Important	[4] Important	[5] Extremely Important
***CULTURE & LEGITEMACY* (%)**						
Culture						
1.	Multi-ethnic employees work in harmony in this company.	**0.7**	**2.1**	**13.0**	**56.1**	**28.1**
2.	My company is concerned about respect for cultural sensitivity among diverse employees.	**0.0**	**3.2**	**23.4**	**44.6**	**28.8**
3.	Employees share the same values and beliefs.	**0.4**	**3.2**	**21.4**	**53.0**	**22.1**
4.	My company has a policy on equal opportunities among the diverse employees.	**0.4**	**2.1**	**20.0**	**55.8**	**21.8**
5.	My company uses local values to articulate its company brand (e.g. HSBC local bank).	**2.1**	**4.1**	**22.5**	**53.3**	**17.9**
Legitimacy						
6.	My company products and services are compliant with the legal expectation.	**0.0**	**1.4**	**21.8**	**53.3**	**23.5**
7.	My company always submits to the newest legal principle as soon as possible.	**0.0**	**2.5**	**27.7**	**54.4**	**15.4**
8.	My company is only allowed to do what is explicitly permitted by law.	**0.0**	**1.8**	**23.9**	**47.0**	**27.4**
9.	My company works with regulators to formulate and develop the regulatory standard.	**0.0**	**3.2**	**22.1**	**51.2**	**23.5**
10.	My company emphasizes on voluntary social and environmental disclosure.	**1.1**	**3.9**	**32.3**	**41.4**	**21.4**

Correlation between CSR Initiative Dimensions and Corporate Reputation and its Associated Outcomes

Based on the Table 4, it is found that all variables are significantly correlated. There was a strong positive correlation between all CSR initiative dimensions with the CR construct where the ethical dimension shown the strongest correlation (*r=.604*), which then, followed by the relational dimension (*r=.590*), and the discretionary dimension (*r=.504*). Similarly, an inspection on the CSR initiative dimensions with culture also showed a significant positive correlation between all the dimensions. The ethical dimension reported the highest and strongest correlations among all dimensions. It is significantly correlated at .524. On the other hand, the discretionary dimension reported lower correlation at .391 suggested weaker relationships. Relational suggest a moderate correlation with culture at .474. It was also found that all the CSR initiative dimensions are significantly correlated with legitimacy where relational showed the highest impact at .551, then followed by ethical at .506 and relational at .495. An examination of correlation between corporate reputation and culture has evidence a strong positive correlation between the two constructs. It was found that corporate reputation and culture are significantly related at .624. Similarly, the Table 4 also suggests a strong positive relationship between corporate reputation and legitimacy at .686.

TABLE 4: Correlation between CSR Initiative Dimensions and Corporate Reputation and its Associated Outcomes

	TMoral	TDiscretionary	TRelational	TCR	TCulture	TLegitimacy
TMoral	1					
TDiscretionary	.527**	1				
	.000					
TRelational	.606**	.512**	1			
	.000	.000				
TCR	.604**	.504**	.590**	1		
	.000	.000	.000			
TCulture	.524**	.391**	.474**	.624**	1	
	.000	.000	.000	.000		
TLegitimacy	.506**	.495**	.551**	.631**	.686**	1
	.000	.000	.000	.000	.000	

**. Correlation is significant at the 0.01 level (2-tailed).

Overall, majority of the respondents confirmed that any corporate responsibility areas that have been classified as extremely important, very important or important, companies should be dealt with these items seriously. Any slackness could be harmful to their long-term corporate reputation. They should lead by practicing good ethics, assuring that explicit and implicit promises to stakeholders are met, setting directions for obtaining good corporate reputation in general, and being the first line of defense to protect the companies' reputation when challenged. Indeed, a strong positive relationship between all CSR initiative dimensions with the CR construct, and also with its related constructs shows there is a dire need to pay a greater attention to CSR initiatives for Malaysian companies.

Conclusion

The purpose of this paper is to identify to the importance of CSR initiatives as a projection of corporate identity of the organization. Thus, building distinctive corporate identity leads us to seek the importance of corporate reputation, legitimacy and culture to the organization in building a favorable relationship between the organization and its environment.

Despite enormous efforts from the US and European scholars to institutionalize strategic communication, the profession is still lacking recognition at the dominant coalition especially in Asian country in general and Southeast Asian country in particular. Findings of this study suggest that institutionalizing CSR is vital today in understanding the role and contribution of strategic communication to the organization, away from window dressing activities. The findings also suggest that a greater focus on corporate reputation, culture and legitimacy is central to today's organization. This implies that CSR initiatives as the projection of corporate identity of organization (a behavioral perspective) ties with the key concepts such as corporate reputation, culture and legitimacy in strengthening the favorable relationship between the organization and its environment.

Practical implications imply that competent strategic communication managers should capable of developing strategic planning and implementation based on CSR initiatives to look a broader aspect of macro-level analysis of environment in order to detect any issues and opportunities in the context of corporate reputation, culture, and legitimacy. This might create competitive advantages to project distinctive corporate identity of organization which is essential at the meso and micro levels of analysis as suggested by Sandhu (2009).

Furthermore, the notion of institutionalized strategic communication not only lies in discussion on established theories and renowned practices in Europe and the US but also should look at whether the profession is institutionalized worldwide in general and Southeast Asia in particular. Indeed, the paper contributes imperative evidences of institutionalized CSR within strategic communication in Malaysia.

Abstract

With the rapid expansion of Information and Communication Technologies (ICT) throughout almost all aspects of tourism and hospitality industries, the task of integrating technology into higher education curriculum is a need. This paper analyzes the relevance given by the various Portuguese and Spanish institutions of higher education to ICT in their degrees. The analysis carried out was done in degree courses operating in academic year 2018/2019, in Portuguese and Spanish universities and polytechnics. A comparison was also made with the reality of 2012/2013.

Keywords: Tourism, Information and Communication Technologies (ICT), Higher Education.

Introduction

The tourism sector is one of the most important economic sectors, both for the developed countries and developing countries. This sector has features such as globalization of tourism market, mobility of tourists and abundance of information. Also, all these features characterize an information society.

Tourists could be from all nations, social classes, and professions. The tourism sector is diverse, because the size of the companies that make up this sector ranges from micro, medium, to global companies (Buhalis & Jun, 2011).

Tourism is acknowledged to be very information intensive. Tourists need information before going on a trip to help them plan and choose between options, and also increasingly need information during the trip as the trend towards more independent travel increases. But for this it is necessary that the information be available and the tourism professionals with the capabilities to solve the problems.

Information and communication technologies (ICTs) have been transforming tourism globally. The ICT driven re-engineering has gradually generated a new paradigm-shift, altering the industry structure and developing a whole range of opportunities and threats.

The introduction and increased proliferation of technologies has had a significant impact on many industries, especially the tourism sector (Ukpabi & Karjaluoto, 2016); (Morais, et al., 2016). Technological advancements have impacted and disrupted all tourism organizations (Sigala, 2018). The increased awareness and use of innovative technologies, have changed travel behaviours, revolutionizing the way in which tourists search for information, make decisions (Wang, et al., 2016), purchase tourism products and services, find and explore reviews (Ukpabi & Karjaluoto, 2016). In addition, Sigala (2018) identified tourism technologies have had an impact on the way tourists select, evaluate, pay, share and experience tourism.

People, are a critical dimension within the successful delivery of tourism services. ‘‘The story of successful tourism enterprises is one that is largely about people - how they are recruited, how they

are managed, how they are trained and educated, how they are valued and rewarded, and how they are supported through a process of continuous learning and career development'' (Fáilte, 2005).

This paper aims to analyze the relevance given by the various Portuguese and Spanish institutions of higher education to ICT in their Tourism degrees. The analysis carried out was done in degree courses operating in the school year 2018/2019, in Portuguese and Spanish universities and polytechnics, public and private. It was made a comparison to a study carried out in the school year 2012/2013 (Morais, et al., 2013) in order to see the evolution.

Tourism Education and ICT

The adoption and diffusion of educational technologies that leverage ICT and the Internet has provided an unprecedented opportunity for improving higher education around the world (Davis & Wong, 2007). Educational technologies must become more popular among developing nations which seek economic improvement (Khasawneh, et al., 2011). In fact, the educational technology is becoming more universal at an increasing rate as most firms recognize the needs to prepare the ICT professionals for the global environment (Margavio, et al., 2005).

People are critical assets within the tourism industry for sustaining and enhancing competitiveness and quality. The involvement of the training and education sectors to industry is vital. Good management in service organizations and tourism enterprises certainly qualify as strategic success factors of the industry (Heskett, et al., 2008).

Higher education drives, and is driven by globalization. Higher education institutions train the highly skilled workforce and contribute to the research base and innovation capacity that increasingly determines competitiveness in a knowledge-based global economy. With their central role in cross-cultural encounters, Higher education institutions foster mutual understanding and helps to build global networks for the future. At the same time, cross-border flows of ideas, students, faculty and financing, coupled with developments in information and communication technologies, as well as the emergence of new players are changing the environment for higher education. Globalization implies both increased collaboration and competition between countries and institutions on a global scale (OCDE, 2009).

In all the discussion forums of tourism jobs, Informatics and use of Information Technology appears as one of the most desirable skills for the future professional. Ramos et al (2009) argues that competitiveness and exploitation of the tourism industry increasingly depends on the ability of professionals and managers take advantage of the emerging ICT to increase competitive benefits, since ICT allows adding value by facilitating the differentiation of the tourism product and increasing efficiency.

One of the fundamental challenges facing tourism professionals is the need for continuous adaptation to changes, due to the dynamism of the sector (Pilar, 2007). It is through the training of human resources in the tourism industry, especially in ICT, which improves their ability to adapt and consequently is increased flexibility and interactivity productive processes which result to be increasingly complex, due to the competitiveness and globalization currently existing (Buhalis & Law, 2008). The improvement in the training of professionals will greatly increase both the quality of services provided to customers, and the level of quality of information provided to customers.

At the present moment, the basic objective is the formation of a quality specialist in the field of tourism, able to adapt quickly to the environment changes, ready for practical activity, able to use modern technologies, to find flexible and optimal solutions, to identify influences of the external environment on the company's work and be able to forecast the demand (Lungu, 2017). We agree with this and also that without training in ICT these goals will be difficult to achieve.

Joaquim Majó (2004) does, for some time, highly relevant considerations regarding higher education in Tourism and particularly on ICT.

Even before the Bologna process there were authors who argued that degrees in tourism beyond the pure ICT content should contain other topics, such as: Information Systems; Database Systems; Use of CRS (Central Reservation System) and GDS (Global Distribution System); Systems to promote

tourism (multimedia environments); Telematics networks: Internet (both as a source of information as a mean of promotion and marketing through web pages); Local networks, use of intranets and extranets; Analysis of the main management programs of tourist companies (both at the front-office and back-office); Geographic Information Systems.

(Buhalis, 1998) and (Majó, 2004) argue that this type of training should cover between 15-30% of the dedication of the student.

People are often a critical dimension within the successful tourism service businesses. The history of successful businesses in the tourism sector resides above all about people, how they are recruited, how they are managed, trained, educated, the way they are valued and rewarded and how they will be supported through a process (Fáilte, 2005); (Baum, 2007).

The impact of ICT on tourism has altered the way tourist services are accessed and consumed. Thanks to increasingly ubiquitous and innovative ICT, new channels have been created for consumers (Liburd & Christensen, 2013). This new reality has made it much more demanding for tourism professionals to master the use of these new tools. Preparing students for trainings in the area of higher education tourism is, in our view, more and more important, as ICT innovation has increasingly technologically strengthened the profile of travelers. Projects such as INNOTUR and the use of Web 2.0 technologies are an example of a concern to prepare students, from training in the area of higher education tourism, to an increasingly global and technologically demanding work reality (Morais, et al., 2018).

Methodology

The nature of the objectives led to a methodology of quantitative research, descriptive and interpretative eminently possible that characterizes the object of study. The study focused on the analysis of ICT training courses in tourism, because we believe ICT, especially in the context of the Bologna process, as basilar course units in curriculum structure, and are fundamental to the development and innovation of tourism.

The research of the courses for this study was based on the website of the Directorate General of Higher Education (http://www.dges.gov.pt/) in the case of Portugal and the State Department of Education for Spain (http://www.mecd.gob.es). We considered only the courses that had “Tourism” or “Tourist” in their name or derived (e.g. “ecotourism”, “touristic”). After collecting the courses available in the academic year 2018/2019, the remaining data were obtained through the consultation of the information available on the websites of the different institutions. For each tourism course, we considered the course units with a name and/or content (the latter not always available) that suggested references to ICT, like “information systems”, “computer”, “technology”, “electronic”, “digital”, among others. We did not consider non-ICT related course units that, eventually, could promote the development of students’ ICT skills by indirect means, since the available data don’t allow inferring that.

It was also made a comparison with a similar study developed in 2012/2013.

Analysis of Data Obtained

From the analysis carried out it was found that exist in the Portuguese higher education 50 degrees in tourism (in 2012/2013 there were 39), with 16 different designations (in 2012/2013 there were 10), distributed by 36 higher education institutions (15 on Private Higher Education and 21 on Public Higher Education). In 2012/2013, of the 39 degrees, 3 were after working hours and the remaining 36 had normal arrangements. In 2018/2019, of the 50 degrees, 6 are after working hours.

When analyzed data from the Spanish higher education it was verified that there are 73 degrees in the area of tourism (in 2012/2013 there were 67), with 10 different designations, distributed by 50 Higher Education institutions. The term "Tourism" is predominantly utilized (there are 62 degrees with that designation). When analyzed the education subsystem in Spain it was found that 61 degrees are on the Public subsystem and 12 degrees are on the Private subsystem (in 2012/2013 there were 53 on the Public subsystem and 14 were on the Private subsystem).

The geographical distribution of courses by NUTS II, to Portugal, and communities, to Spain, are represented in Table 1 and Table 2, respectively.

We can verify that in Spain the changes were not significant. In Portugal there was an increase of degrees in the North region and in the Center region.

Table 1: Degrees distribution in Portugal, by NUTS II

	2012/2013	2018/2019
Azores archipelago	1	1
Algarve	5	2
Alentejo	3	3
Center Region	7	14
Lisbon and Tejo Valley	10	12
Madeira archipelago	1	0
North Region	12	17

Table 2: Degrees distribution in Spain, by communities

	2012/2013	2018/2019
Andalusia	9	9
Aragón	1	1
Asturias	2	2
Canarias	6	7
Cantabria	1	1
Castilla y León	5	6
Castilla-La Mancha	1	1
Cataluña	12	16
Extremadura	1	1
Galicia	2	2
Islas Baleares	3	3
La Rioja	1	1
Madrid	13	11
Murcia	3	4
País Vasco	2	2
Valenciana	5	6

Table 3 shows the different designations and number of respective degrees, for the school year 2012/2013 and 2018/2019 both for Spain and for Portugal.

It is interesting to note that Portugal, despite having fewer degrees, has more different designations. However, in both countries the predominant designation is "tourism", as it would be expected. In both countries there is a higher concentration of degrees in areas where the population is more abundant.

Table 3: Number of degrees in Tourism scientific area (2012/2013 and 2018/2019)

Degree	Number of Degrees in Spain		Number of Degrees in Portugal	
	2012/2013	2018/2019	2012/2013	2018/2019
Ecotourism	0	0	1	0

In the Portuguese case, it has been verified that in a relatively short space of time there have been significant changes, particularly in degrees whose designation is not only "Tourism", which proves that it is a dynamic area, and intends to respond to a market that has come growing.

Figures 1, 2, 3 and 4 shows the number of ECTS (European Credit Transfer System) in the ICT area, and the number of degrees with the corresponding ECTS in Portugal and Spain for the school year 2012/2013 and 2018/2019.

Figure 1: Comparison of Number of ECTS by Degree in Portugal and Spain (2012/2013)

Figure 2: Comparison of Number of ECTS by Degree in Portugal and Spain (2018/2019)

Figure 3: Evolution of Number of ECTS by Degree in Portugal between 2012/2013 and 2018/2019

Figure 4: Evolution of Number of ECTS by Degree in Spain between 2012/2013 and 2018/2019

In 2012/2013 Spain had 22 degrees without any curricular unit of the ICT area, while Portugal had only 6. This trend has reversed in 2018/2019. Spain has reduced the number of degrees without ICT curricular units to 10, while Portugal has increased this number to 13. With 6 ECTS, Portugal had 18 degrees in 2012/2013, also decreasing this number to 7. In contrast, Spain had 23 degrees with 6 ECTS, increasing this value to 47. There is a positive trend in the adoption of curricular units of the ICT area in Spain, while in Portugal the number of ECTS in the area of ICT in the degrees of the Tourism area has been decreasing.

Tables 4 and 5 show the curricular units of the ICT area existing in the school years 2012/2013 and 2018/2019 for the two countries.

It was verified that in Spain there were significant changes in the curricula with regard to ICT, and there was a concern with emerging issues in technology, namely in terms of digital promotion, digital marketing, Web, Internet and Social Networks. In Portugal there were no major changes in curricula since 2012/2013.

Institutions have their study plans available on their websites; however, when someone intends to analyze the detailed contents of the program curricular units that are part of the curriculum, in many cases the institutions do not have that information available. It was a problem detected in the analysis carried out in 2012/2013 and after six years this failure persists.

From the information we were able to collect from the institutional websites we could verify that, as expected, there is a great diversity of ICT contents in the courses, with different subjects addressed and with different levels of specialization. For example, there are courses with 18 ECTS of ICT curricular units, of which 12 are exclusively for Geographic Information Systems, while in other

courses with the same name (Tourism) that topic does not even seem to deserve a topic on the syllabus.

Some of the most frequent topics are related to the main management programs of tourist companies, like Central Reservation System (CRS), Global Distribution System (GDS) and Property Management Systems (PMS), as well as topics related to e-commerce and e-business.

Curiously, being the smartphones an essential tool of today tourists it is worthy to mention that mobile systems and technologies is not one of the most referenced topic.

The table 6 shows an overview of the ICT related topics found in the analysed tourism curses. The data is showed without any particular order and some of the topics are only mentioned in a few courses while others are more frequent.

Table 6: ICT related topics in tourism courses

ICT fundamentals	Hardware Software File handling and storage Operating Systems Mobile systems and technologies Communication networks
Internet	Internet architecture (including servers, DNS) WWW Online communication (including e-mail, instant messaging) Social Media (including blogs, wikis, podcasts) Online searching and information sources (including engines, tools, portals, databases) E-learning SaaS Online storage Security (including network security, digital certificates) Touristic portals

Discussion and Conclusions

This paper shows values related to ICT, and the weight that the curricular units of ICT have in the plans for undergraduate studies in the tourism sector in the Iberian Peninsula (Portugal and Spain), and concluded that on average, curricular units of ICT has an insignificant representation of the ECTS in Tourism degrees, and not 15% - 30% as some authors argue that it should be (Buhalis, 1998; Majó, 2004).

The maximum number of ECTS in Portugal was 14 in 2012/2013 and 15 in 2018/2019 (around 8%). In Spain in 2012/2013 it was 18 and 24 in 2018/2019. However, they are isolated cases and still far below desirable.

In most cases the courses have a curricular unit in the ICT area, where practically address office tools. In 2012/2013 some courses do not have any curricular unit of ICT area (6 in Portugal and 22 in Spain, which corresponds to 15% and 33%, respectively, of the courses). In the hope that the data for the 2018/2019 school year would be more prosperous with regard to ICT, we have seen that in Portugal the situation has not improved and it has also worsened. There were 13 degrees without any curricular unit of the ICT area, which corresponds to 26% of the total of degrees. Spain had 22 degrees without any UC for the school year 2012/2013 from the ICT area and decreased to 10 in 2018/2019, although the number of degrees has increased.

Increasingly ICT plays a critical role for the competitiveness of tourism organizations and destinations becoming a key factor (Bethapudi, 2013). "A profession, no less than a craft, is shaped by its tools" (Farkhondehzadeh , et al., 2013). When we find that the evolution of the tourism industry has been principally on the ICT, in our opinion, the courses should be redesigned in order to enhance professionals with more and better skills in ICT. According to Adeyinka-Ojo (2018), ICT skills are among the necessary skills to improve graduate employability. Also Kim et. al (2017) refers that specific competencies of the work indicate the student's ability to apply and use information in a specific context and their knowledge about ICT. This emphasizes the need to align the graduated ICT know-how with the increasing technology wave that is flowing into the tourism industry.

With ICT, it is possible to reduce the direct costs of operation, as well as to increase the flexibility, interactivity, efficiency, productivity and competitiveness of organizations, and this situation is valid both for companies and for tourist destinations. The advantages that ICT have brought to the area of Tourism are widely recognized. To train professionals in the area of Tourism with skills and abilities in the field of ICT, it seems to us urgent. However, due to the analysis of the degree programs in this area, we found that many institutions are not training professionals with these skills. This will conduct to ICT less prepared tourism-professionals, that will embrace the tourism industry, which is very demanding in the use of ICT and, in our opinion, even worst, will tendentiously lead to professionals less capable to create value through innovation in a very information demanding market, where the target (i.e. tourists) are requiring for new tools and innovative approaches in the before, during and after their trips process.

Most of the courses do not prepare their students in order to acquire skills in the area of Geographic Information Systems, Multimedia, Augmented Reality, Digital Marketing, Social Networks, among others, especially in Portugal. In Spain, emerging themes in the ICT area, began to be addressed in the degrees analyzed in school year 2018/2019.

Given to the recent, and expectable continuous, introduction of ICT on tourism industry, tourism related courses must improve their curricula on ICT skills. This can be achieved changing the current mandatory ICT curricular unities, increasing the optional ones related to ICT and even increasing the seminars dedicated to ICT and how can they boost graduated capabilities to improve organizations through their ability to manage information as organizational critical success factor.

A Spatial Analysis of The Concentration of Population and Income Potential Using the Example of The Opolskie Voivodeship In the Years 2000-2018

Katarzyna WIDERA
Opole University of Technology, Opole, Poland
k.widera@po.edu.pl

Abstract

The aim of the present study was to analyse and evaluate the concentration of income and population potential of communes (municipalities) in the Opolskie Voivodeship in the years 2000-2018. The study involved the application of the physical potential theory in a spatial study of territorial units on the commune level. Statistical spatial analysis tools used in the present work included the spatial autocorrelation coefficient and the related Global Moran's index as well as Local Indicators of Spatial Association (LISA). The analysis of the concentration of potential enabled the assessment of financial self-sufficiency of the communes of the Opolskie Voivodeship.

Keywords: population potential, income potential, potential concentration, Global Moran's, LISA - Local Indicators of Spatial Association, spatial analysis.

Introduction

Regional studies on the commune/municipality level (NUTS 5) are an important part of local analyses. The use of the potential theory coupled with the tools of spatial statistics offers a new perspective on the idea of the potential of the commune as a territorial unit. A total of 71 communes of the Opolskie Voivodeship were subjected to spatial analysis in the years 2000-2018. To determine distance between communes (objects), the study used straight line distance data (without taking the road network into consideration) between towns in which commune offices were located. Distance information was retrieved from the Office of the Marshal of the Opolskie Voivodeship, Department of Regional and Spatial Policy, Land Surveying and Cartography Office. Statistical data concerning the communes analysed in this study were retrieved from the Local Data Bank of the Statistical Office (www.stat.gov.pl). The data was analysed in the Open GeoDa software by Luc Anselin as well as the software Statistica PL 13.1.

Identifying spatial relations between investigated objects at any territorial level involves primarily the selection of the matrix of spatial weights. The matrix presents the internal structure of their mutual connections [Łaszkiewicz, 2014, Kuc, 2015], and such connections have a significant effect on the investigated phenomena [Klaassen, 1988]. At this point we should mention publications by Kooijman [1976] and Openshaw [1977], who regard Moran's measure as the criterion of weight matrix selection. Deriving from Griffith's work [1996], Getis and Altstadt [2010] claim that the adjacency matrix should result from the distance between analysed units or geographical adjacency. When weight matrices have been defined, global Moran's is applied to identify the overall nature of spatial relations [Sikora, 2009; Suchecki, 2010], while local indicators of spatial autocorrelation (LISA) statistics are used to evaluate the local character of the relationship of the phenomenon of interest [Anselin, 1995; Janc, 2006].

Applications of the model of potential in regional studies include: economic potential assessment of a selected voivodeship by Müller–Frączek, Pietrzak [2009], financial independence assessment of communes in studies by Głowicka-Wołoszyn, Wysocki [2014, 2015, 2016], financial independence assessment of local government in a study by Surówka [2013], and a measurement of unit's and

organisation's economic potential by Mastalerz- Kodzis [2018b]. Werner, Korcelli, Kozubek [2014] described changes in Poland's metropolitan areas through the use of the potential theory. Yang X, Cai, Wang [2015] discussed the potential of urban population in Jiangsu province in China, and Klobučník, Máliková [2016] analysed the potential of population in Stredne Povazie region in the Slovak Republic.

Methodology of the Study

As a category in this study, potential is defined as a measure of spatial availability of a specific territorial unit. Literature of the subject describes potential also as a measure of the effect of regions comprising a given territorial division system on the unit (Mastalerz-Kodzis, 2018a). Potential determines the intensity of the effect between regions, taking into account e.g. economic quantities as well as distances between them. Therefore, the assumption that spatial objects exert mutual influence on one another is the essence of the potential theory. This study utilises population potential and income potential categories based on the physical potential theory (Mastalerz-Kodzis, 2018b). These research categories are considered spatial distribution functions of every population unit in a given area (Chojnicki et al., 2011). The communes of the Opolskie Voivodeship are population units (objects) in the present study. The first category analysed is the population potential for a specific commune (object in space), which is given by equation (1). The i-th commune's own population potential corresponds to the amount of its inhabitants. The sum in equation (1) shows that the potential of a specific territorial unit is made up of its component potentials: the i-th object and all the remaining j-th spatial units (Müller-Frączek and Pietrzak 2009).

$$\text{The population potential of the i-th commune} = l_i + \sum_{j \neq i} \frac{l_j}{d_{ij}} \tag{1}$$

where:

l_i – the i-th commune's own population potential,
l_j – population of the j-th commune (from the surroundings of the i-th commune),
d_{ij}– distance between the i-th commune and the j-th commune.

Income potential is the second category subjected to spatial analysis (Chojnicki et al., 2011). The income potential of a given commune is a measure of available income in the system of communes as spatial objects. It is defined as a function of income generated in the commune (object) and income in other communes (objects), taking into account the distance between them. The income potential of the i-th communes is given by equation (2).

$$\text{Income potential of the i-th commune} = w_i + \sum_{j \neq i} \frac{w_j}{d_{ij}} \tag{2}$$

where:

w_i – i-th object's own income,
w_j – j-th object's own income (from the surroundings of the i-th object),
d_{ij}– distance between the i-th and the j-th object.
The third category in the analysis is the ratio of income potential to population potential of a specific commune defined by equation (3) or, after transformation, by equation (4):

$$\text{i-th commune's ratio of potentials} = \frac{\text{income potential}}{\text{population potential}} = \frac{w_i + \sum_{j \neq i} \frac{w_j}{d_{ij}}}{l_i + \sum_{j \neq i} \frac{l_j}{d_{ij}}} \tag{3}$$

$$\text{i-th commune's ratio of potentials} = \frac{w_i + \sum_{j \neq i} \frac{w_j}{d_{ij}}}{l_i + \sum_{j \neq i} \frac{l_j}{d_{ij}}} = \frac{1 + \frac{\sum_{j \neq i} \frac{w_j}{d_{ij}}}{w_i}}{1 + \frac{\sum_{j \neq i} \frac{l_j}{d_{ij}}}{l_i}} \cdot \frac{w_i}{l_i} \tag{4}$$

where: $\frac{w_i}{l_i}$ — own per capita income of the i-th commune

The ratio of income and population potentials corresponds to the per capita income quotient. Its advantage as a measure of the i-th object's development level is that it takes into account the effect of the relationship between objects on the level of development (Głowicka-Wołoszyn, 2017).

Equations (3) to (4) will be used later on in analysis of potentials. They demonstrate the relationship between the ratio of potentials and the concentration of potentials of the i-th commune, i.e. the fourth category analysed in the present study and given by equation (5):

$$\text{Concentration of potentials} = \frac{\text{ratio of potentials}}{\text{own per capita income}} \tag{5}$$

The value of the concentration of potentials in equation (5) is compared to 1 (Chojnicki et al., 2011). This provides the basis for the assessment of the role played by surroundings (i.e. communes which surround a specific commune) in generating its population or income potential. The assessment involves a diagnosis of the commune's financial self-sufficiency. A value lower than 1 for the commune (object) indicates a greater role played by its surroundings in creating its population rather than income potential. This means that income potential has a higher concentration than population potential, hence the greater financial self-sufficiency of the commune.

The present analysis also uses the spatial autocorrelation coefficient to determine the degree to which the value of the investigated variable in a specific location (commune) is correlated with its values in other locations (communes) (Sikora, 2009). The presence of a statistically significant autocorrelation enables us to capture the spatial correlation between objects (communes). The verification tool to test this relationship is Global Moran's I (Suchecki, 2010) provided by equation.

$$\mathrm{I} = \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} w_{ij} (x_i - \bar{x})(x_j - \bar{x})}{\sum_{i=1}^{n} (x_i - \bar{x})^2} \tag{6}$$

where:

$n -$ number of communes (objects),
$x_i, x_j -$ value of the analysed category of potential of communes (objects) in locations i, j,
$\bar{x} -$ mean value of the analysed category of potential x_i,
$w_{ij} -$ weight matrix element determined on the basis of the coordinates of the commune (object) on the basis of which the distance between them was calculated.

Selection of weight matrices can be defined e.g. on the basis of the neighbourhood criterion (Głowicka-Wołoszyn et al., 2017, Kopczewska, 2006) as in the case described. The presence of a statistically significant spatial correlation indicates clustering or dispersion of objects. Otherwise, we may speak of the lack of any significant spatial correlation. Local Indicators of Spatial Association - LISA (Suchecki, 2010, Anselin 1995) were also used, which helped determine whether a commune (object in space) was similar to other communes (objects) and assess the statistical significance of the relationship. The following items were identified in the procedure:

- ✓ hot spots (High-High) – communes with a high value in a particular category surrounded by communes with a high value in the same category,
- ✓ cold spots (Low-Low) – communes with a low value in a particular category surrounded by communes with a low value in the same category,
- ✓ outliers (Low-High) or (High-Low) – communes with a low value in a particular category surrounded by communes with a high value in the same category or vice versa,
- ✓ not significant – without statistical significance.

The present study assumed the level of statistical significance corresponding to $\alpha = 0.05$.

Research Results

The presentation of changes in investigated potentials and their concentration in the communes from 2000 to 2018 comprised the analysis of data from the years: 2000, 2010 and 2018. Chart 1 and Table 1 show changes in population potential of the communes of the Opolskie Voivodeship given by equation (1).

Chart 1: Changes in the distribution of population potential

Table 1: Descriptive characteristics of communes' population potential

Years	Median	mean	minimum	maximum	lower quartile	upper quartile	standard deviation	coefficient of variation
2000	42063.8	45365.4	26726.2	161133.6	36104.8	48763.7	18605.5	41.01 %
2010	39797.3	43059.3	25333.7	151643.5	34548.7	46478.6	17554.3	40.77 %
2018	38728.6	41806.6	24072.3	155724.2	33342.9	44932.1	17756.8	42.47 %

Source: Author's own work

Looking at Chart 1 and data in Table 1, we may notice a decreasing population potential in communes of the Opolskie Voivodeship over the period investigated in this study. Both the median for the potential and the values of its quartiles have dropped relative to their level in the year 2000. This tendency demonstrates the decrease of the communes' own potential, i.e. their population, which is a symptom of depopulation (Dybowska et al., 2015), as well as the increasingly weaker mutual effect the communes exert on one another in creating population potential in each of them (the second part of the sum in equation 1).

Map 1 below shows spatial similarity of the communes of the Opolskie voivodeship in terms of population potential. Red colour signifies communes which have high population potential and which are surrounded by communes with a similar level in this category. This circle comprises the communes surrounding the capital of the voivodeship, i.e. Opole. They are the so-called 'hot spots' (High-High). Blue colour stands for communes with low population potential, surrounded by communes of equally low potential in this category, the so-called 'cold spots' (Low-Low). One of the communes is an outlier (High-Low), which means that it is has a high population potential, but it is surrounded by communes with a low level of such potential.

Map 1: Local similarity of communes' population potential

Source: Author's own work

Communes shown in grey did not display any statistically significant similarity to adjacent objects in terms of the level of the population potential category. The difference in the area of the voivodeship capital is due to the expansion of its administrative territory in the year 2017. The subsequent stage of the study included the analysis of changes in the category of income potential given by equation (2). Chart 2 and Table 2 show changes in the level of potential.

Chart 2: Communes' income potential

Source: Author's own work

Table 2: Descriptive characteristics of communes' income potential

Years	Median	mean	minimum	maximum	lower quartile	upper quartile	standard deviation	coefficient of variation
2000	27166217	31313973	14673642	167225041	22568668	33492767	19490593	62.24 %
2010	54732022	62792790	30493872	357228751	45470838	66598959	41488726	66.07 %
2018	84561807	98364427	48616708	616501056	71114413	106786109	69335357	70.49 %

Source: Author's own work

Chart 2 presents the increasing level of income potential in the communes. An analysis of Table 2 indicates an increase both in the median and quartiles but also greater diversification in the level of the category (the range of variability expands over the years). In subsequent years we can also see a growing spread of income potential values (the difference between the minimum and the maximum). Map 2 shows spatial similarity of income potential of the communes.

Red colour signifies hot spots – communes which have high population potential and which are surrounded by communes with a similar level in this category. The area is almost identical to the area of the similarity of the population potential presented in Map 1. A comparative analysis of the year 2000 and 2018 reveals changes in local similarity of income potential consisting in a statistically significant difference in income potential of two communes. The first one, marked with yellow, was a hot spot in 2000, whereas in 2018 its income potential fell radically and it was classified as an outlier (Low-High), a commune with a low income potential surrounded by communes with a high level in this category. Another commune, highlighted as orange, has undergone the opposite process: in 2000 it was a cold spot, and its income potential rose markedly in 2018, and it was classified as an outlier (High-Low).

Map. 2: Local similarity of communes' income potential

Source: Author's own work

The next stage of the study involved a spatial analysis of the ratio of potentials given by equation (3). Chart 3 and Table 3 present significant changes in the level of the category over the investigated period.

Chart 3: Population-to-income potential ratio

Source: Author's own work

Table 3: Quantitative characteristics of communes' ratio of potentials

Years	Median	mean	minimum	maximum	lower quartile	upper quartile	standard deviation	coefficient of variation
2000	646.3	667.6	541.4	1037.8	629.5	690.6	75.9	11.36 %
2010	1361.4	1402.9	1167.5	2355.7	1298.9	1458.2	179.3	12.78 %
2018	2216.3	2270.8	1878.5	3958.9	2075.8	2349.5	323.7	14.25 %

Source: Author's own work

Chart 3 presents the increasing level of income potential in the communes. An analysis of Table 3 indicates an increase in both median and quartile values, albeit in subsequent years the dispersion of the ratios of potentials (the difference between the maximum and the minimum) also rises. The category of the ratio of potentials of the objects (communes) will be used at a subsequent stage of the analysis of potentials.

The next step involved an analysis of a statistically significant spatial autocorrelation for the ratio of potentials and changes in the strength of the correlation. The presence of a statistically significant autocorrelation makes it possible to capture changes in the spatial distribution of the ratio of potentials. Chart 4 shows the dispersion of the ratio of potentials in the test for statistically significant spatial autocorrelation in subsequent years.

Chart 4: Dispersion of empirical points for the calculation of the coefficient of spatial autocorrelation for the ratio of potentials

Source: Author's own work

Table 4 contains values of Global Moran's (I) and values by means of which the presence of a statistically significant spatial autocorrelation was verified. All p-values were smaller than the significance level 0.05 assumed at the beginning of the test. Therefore, in the investigated period there was a statistically significant spatial autocorrelation between the levels of the ratio of potential of the analysed communes.

Table 4: Global Moran's I values and their verification

Variable	Moran's statistic (I)	E(I)	$\sqrt{Var(I)}$	Z(I)	p-value
Income potential / population potential (2000)	0.3764	-0.0143	0.0827	4.6415	< 0.05
Income potential / population potential (2010)	0.4530	-0.0143	0.0813	5.7125	< 0.05
Income potential / population potential (2018)	0.2897	-0.0143	0.0788	3.8872	< 0.05

Source: Author's own work

Statistical significance of Moran's I for the variable corresponding to the ratio of potentials in each selected year demonstrates a significant degree of correlation between the value of the ratio of potentials of a specific commune (object) and values of the same ratio in other locations (communes). An analysis of spatial autocorrelation revealed an increase of the autocorrelation coefficient value in the year 2010 over the year 2000. This is a symptom of progressing convergence in 2010. In terms of space, this signifies convergence (attraction) between communes with similar ratios of potentials. In contrast, lower autocorrelation coefficient value in the year 2018 relative to other years investigated in this study suggests divergence between the communes, i.e. a reverse process.

Map. 2: Spatial similarity of communes' ratio of population and income potentials

Source: Author's own work

The last stage of this study was the analysis of the concentration of communes' potential given by equation (5). Chart 4 and Table 5 present the distribution of the values of this category over the analysed period.

Chart 4: Concentration of potentials of the analysed communes

Source: Author's own work

Chart 4 displays slight alterations in the concentration of potential of investigated communes. This is confirmed by a test verifying the existence of statistically significant differences across the values in the category (Table 4).

Table 4: Results of Friedman's ANOVA, a non-parametric test

$\chi^2 ANOVA\ dla\ n = 71, df = 2$	p-v□lue
0.789	0.674 > 0.05

Source: Author's own work

The results of the above test indicate statistically insignificant differences over the investigated period, as p-v□lue equal to 0.6749 for the value of the test statistic $\chi^2 ANOVA$ equal to 0.789 was greater than the assumed level of significance.

Table 5: Descriptive characteristics of communes' concentration of potential

Years	median	mean	minimum	maximum	lower quartile	upper quartile	standard deviation	coefficient of variation
2000	1.308	1.320	0.658	2.245	1.086	1.564	0.337	25.50 %
2010	1.289	1.339	0.654	2.493	1.093	1.562	0.342	25.57 %
2018	1.271	1.300	0.552	2.167	1.113	1.474	0.286	22.03 %

Source: Author's own work

Table 5 presents values of descriptive characteristics which indicate that the values of potential concentration are decreasing. This shows a drop in the variability coefficient as well as decreasing values from the upper quartile, with a growing value in the lower quartile. The median displays a decline in the category over the investigated years.

Map 3 presents changes in the concentration of potentials in the communes in the analysed period.

Map 3: Comparison of concentration of potentials in communes

Source: Author's own work

A concentration of potentials (5) higher than 1 means that the concentration of income potential is below that of population potential. This signifies a greater role of the commune's surroundings in creating its income potential than the population potential, and hence lower financial self-sufficiency of the commune. Otherwise, if the value of the concentration of potentials is lower than 1, the concentration of income potential is higher than population potential. Consequently, the surroundings of the commune have a greater role in creating its population potential rather than its income potential, which implies its greater financial self-sufficiency.

An analysis of Map 3 shows the direction of changes in the concentration of potentials in the communes of the Opolskie Voivodeship. The number of financially self-sufficient communes falls over consecutive years. In 2000 there were 14 of them, of which 8 are communes containing towns which are capitals of *poviat* (an administrative unit in Poland; the Opolskie Voivodeship has 11 *poviats*). In 2019 there were 9 such communes. The last year covered in the analysis saw the number of financially self-sufficient communes go down to a mere 5 (of which 2 *poviat* towns).

Table 6 below lists changes in the concentration of potentials by commune type, with figures indicating the number of financially self-sufficient communes. Values in parentheses stand for the number of all communes of a specific type.

Table 6: Changes in concentration of potentials in communes by commune type

Years	Urban Commune	Urban-Rural Commune	Rural Commune	Number of Communes
2000	3 (3)	7 (31)	4 (37)	14
2010	2 (3)	3 (32)	4 (36)	9
2018	2 (3)	1 (33)	2 (35)	5

Source: Author's own work

Conclusions and Discussion

A spatial analysis of the potential of the communes of the Opolskie Voivodeship in the years 2000-2018 revealed a decreasing population potential, which is a sign of the ongoing depopulation process affecting many regions. The next part of the study, in which communes' own income potential was analysed, showed the opposite tendency: the level of this category of potential increased over the investigated period. An increase in this category of potential expressed as the commune's own income as well as the income of ifs surroundings, given the decreasing population, indicates and improvement in this component determining the financial condition of communes. Global Moran's I statistical tool was subsequently applied to analyse whether the communes have a tendency to form groups with a similar level of investigated categories as well as to study changes in the process.

Last but not least, an analysis of the changes in the concentration of potentials was performed. This was the central part of the study, and its results demonstrate a growing number of communes with a higher concentration of population potential in comparison to their own income potential. This phenomenon leads to adverse changes in the communes' financial self-sufficiency, whereby the surroundings of a commune play a greater role in generating its income potential rather than its population potential. Therefore, there are fewer and fewer communes in which the concentration of own income potential is higher than that of population potential, i.e. communes' surroundings have a greater role in generating population potential than income potential. The conclusions of this study clearly indicate a drop in financial self-sufficiency in the communes of the Opolskie Voivodeship. Such adverse changes were reported for all types of communes: urban, rural and urban-rural (mixed).

An analysis of the potential of the Opolskie Voivodeship communes using the potential theory and spatial statistical analysis tools is an example of their application in regional research. The application of the physical potential theory in regional research made it possible to examine interactions between objects in spatial terms on the basis of mutual influence of the communes. Spatial statistical analysis tools enabled the assessment of statistical significance of relationship between selected categories. The relationship was investigated between the level of a given category and its level in other locations or only among the neighbours of commune.

The study reported spatial and temporal diversification of population potential, own income potential, ratio of potentials and consequently the concentration of such potentials across the communes of the Opolskie Voivodeship. The most important conclusions which can be drawn from the above analyses is the determination of the influence that the communes have on their surroundings or the influence that the surroundings may exert on the communes. The present work provides the basis for further regional analyses.

Abstract

We are witnessing a technology revolution (referred to as Industry 4.0 or I4.0) that has transformed the way we live, work and socialize. As a result, global labor markets have undergone major transformations that require different kinds of competencies and skill sets to work with complex, fast and smart machines. Several comprehensive studies have been published by leading think tanks and advocacy groups on future skills and competencies. The purpose of this paper is to identify the I4.0 core non-technical skills recommended by the leading think tanks and advocacy groups.
The research used suggested core skills by the International Labor Organization, reviewed all relevant reputable studies, and summarized them to identify the key core skills. Reports from McKinsey Global Institute, Deloitte, Boston Consulting Group, Ernst & Young, QS Intelligence Unit, Burning Glass Technologies, Pearson, PWC, World Economic Forum, Universities of the Future, OECD, LinkedIn, and Manpower Group were reviewed, a summary of key core skills were developed, and several practical recommendations were made to help higher education equip their graduates with these essential skills of the future.

Keywords: Industry 4.0, Think Tanks, Skills Gap, Transferable Skills, and Core Skills.

Introduction

The speed, size, and scale of Industry 4.0 have been quite profound, and we have not yet fully comprehended and harnessed its benefits. Deployment of Artificial Intelligence, Machine Learning, Interconnected Sensors, Internet of Things (IoT), Cloud Computing, Augmented Reality, and 3D Printing Technologies have had a tremendous impact on growth and productivity. It has not only released humans from repetitive jobs, but also helped organizations to be more efficient, expand quickly globally, and gain an exceptional competitive edge. Manyika et al. (2019), in a report published by the McKinsey Global Institute, estimated that the impact of the Internet of Things (IoT) applications on the global economy could be as high as $11.1 trillion per year by 2025 ().

However, while I4.0 has generated tremendous opportunities, it has also created new challenges, especially in terms of skills and competencies. I4.0 demands a trained, creative, and adaptable workforce which can deploy technology to improve productivity and competitiveness. Employees are now required to use complementary robotics in the workplace, interpret data collected by cameras and sensors to accurately forecast future demand, deploy machine learning mechanisms to optimize performance and plan predictive maintenance, utilize smart whiteboards to communicate with team members, and use augmented reality glasses to perform assigned tasks perfectly.

The Industry 4.0 revolution has broadened the present skills gaps in the workplace as it has required further upskilling and reskilling. After an extensive global survey of 20 countries and 30 industries, Manyika et al. (2017) in another McKinsey Global Institute report projected that by 2030 between 75 million to 375 million employees (depending on different possible scenarios) may need to change their occupational categories (). McKinsey also stated that even though only 5% of occupations will be eliminated due to automation, more than 30% of activities in 60% of occupations will be automated by 2030. This certainly would change the landscape of the workplace and should alarm businesses, policymakers, and higher education institutions to re-examine their workforce training and education systems.

McKinsey is not the only think tank that has tried to predict future skills requirements. There has been a wide range of studies conducted by other think tanks, leading international HR companies, and advocacy groups on I4.0 skills and its required competencies, where each suggested several skills. It would, however, be interesting to examine what has been recommended as the most common skills. Shortlisting necessary future skills would be beneficial to higher education in narrowing future skills gaps.

The main goal of this study is to list the core non-technical skills of the future as suggested by the 20 think tanks, HR and advocacy groups' reports. It should be noted that the technical skills were not included in this study as they are specifically industry-based.

Literature Review

Present Skills Gaps

Before reviewing future skills requirements, we need to have a thorough understanding of the present status of workforce skills. Unfortunately, the global economy in recent years has suffered from an increasing skills gap, a phenomenon that has had adverse effects and caused major financial loss. The Open University (2018) reported that the direct cost of skills gaps to the UK economy is $8.4 billion each year. The skills gap has been a global syndrome. In Europe, the European Centre for the Development of Vocational Training, Cedefop (2019) stated a skills mismatch that resulted in unemployment in several countries. In the USA, the National Network of Business and Industry Association (2019) that represents a wide range of business sectors including manufacturing, transportation, hospitality, construction, retail, information technology, and health care Claimed that 5 million jobs are not being filled due to skills gaps.

The alarming news is the gaps are getting wider. A 2018 global survey of 40,000 employers in 45 countries by the Manpower Group (2018) reported the skills shortage was at a 12- year. The main drivers of this skills shortage included the absence of applicants, lack of experience, and a shortage of hard and soft skills according to the Society for Human Resource Management (2018).

There has also been a new development in the job market. The traditional employer-employee system has been replaced with the gig economy which has an impact on the required skills. According to Deloitte (2018) Global more than 40% of the USA workers are now employed in part-time and freelance work arrangements. Mercer (2019) suggested that 79% of executives believe that freelance workers will replace full-time workers in the future.

Impact of Industry 4.0 on Future Skills Gaps

Adoption of I4.0 digital enablers such as the Internet of Things, Cloud Computing, and Big Data has already impacted the job market and will have further drastic effects. Korn Ferry (2018), a multinational human resource firm, predicted that by 2030 there will be a shortage of 50 million high-skilled laborers, yet at the same time, more than 200 million people globally continue to be out of a

job. The company also claimed there will be a shortage of 85.2 million workers globally, which is equivalent to $8.452 trillion in unrealized annual revenue. Thomas et al. (2018) in a report published by the Deloitte estimated from 2017 to 2028 the cost of unemployment and mismatched skills to the US economy will be $454 billion.

The nature of work is already changing. Deloitte reported that the workplace of the future demands diversity, collaboration, agility, innovation, creativity, and emotional and digital intelligence that are based on contingent labor (Thomas et al. 2017). McKinsey Global Institute stated that the major workplace changes are in tasks and roles and predicted that 30% of tasks in 60% of occupations will be automated (Manyika et al. 2017). Employees of the future should understand, monitor, and improve systems, learn quickly, and solve real-world problems.

A machine operator's role, for instance, will be different in the future. Currently, he presently needs to possess specific technical skills, works with a single machine, monitors machine performance, assures the quality of output, and adheres to the required standards and maintains the machine. However, in the future, his job will most likely involve the supervision of several machines, responding to the quality issues that digital monitors display, and deploying augmented reality technology to resolve issues. These changes call for flexibility, agility, independence, and digital literacy. Future jobs will be less about what people know and more about what they can do. In a nutshell, in the future "the science of the job" will be done by intelligent machines, but "the art of the job" will be performed by humans (Pring et al., 2019).

The Core Skills of the Future

The next obvious question is what kinds of skills are needed to be agile, flexible, and independent. What kinds of hard skills (technical skills) and non-technical (human skills, soft skills, or transferrable skills) are required? Although some technical skills are required for each specific occupational category, most published reports point to the importance of human and soft skills as the core skills of the future and rated soft skills as being much more significant than technical skills.

In its 2018 global survey, IBM suggested that top global executives believe behavioral skills are becoming more critical than technical skills (Fig. 1) (LaPrade et al., 2018). LinkedIn made the same observation in its survey of talent professionals where 92% stated that soft skills matter as much or more than technical skills. Besides, 80% stated that soft skills are increasingly important to the success of the company (Lobosco, 2019).

2016	Skills Shift	2018	Skills	Type of Skills
1		1	Willingness to be flexible, agile, and adaptable to change	Behavioral
1		2	Time management skills and ability to prioritize	Behavioral
3		3	Ability to work effectively in team environments	Behavioral
4		4	Ability to communicate effectively in business context	Behavioral
5		5	Analytics skills and business acumen	Technical
5		6	Technical core capabilities for STEM	Technical
7		7	Capacity for innovation and creativity	Behavioral
8		8	Basic computer and software/application skills	Technical
9		8	Ethics and integrity	Behavioral
10		10	Foreign language proficiency	Technical
11		11	Fundamental core capabilities around reading, writing, and arithmetic	Technical
12		12	Industry- or occupation-specific skills	Technical

Figure 1: Behavior Skills Become More Important - Inspired by IBM Global and Country Survey (Laprade et al., 2018)

Manpower Group has further supported this concept. They claimed that by 2030, the demand for human skills will grow by 22% and 26% in Europe and the U.S respectively (Manpower Group, 2019). Deloitte reported, as the future jobs will be augmented by technology, more human skills are needed (Schwartz et al., 2017). Ernst & Young stated in its report that adaptive learning and "human skills" are essential for future workforces (Ernst & Young, 2018).

A report published by the World Economic Forum in 2018 also rated transferable skills as the most essential skills of now and the future (Table 1) (World Economic Forum, 2018). McKinsey Global Institute listed transferable skills such as leadership, communication and negotiation, critical thinking, empathy, creativity, project management, entrepreneurship, adaptability, teaching and training, and digital literacy as the skills of the future (Bughin et al, 2018).

Table 1: Top Ten Skills Demand of 2018 versus 2022 (World Economic Forum, 2018)

A leading HR company, Cognizant, echoed the same thing. They claimed 93% of senior executives believe interpersonal relationships will be needed and valued more senior executives believe as future tasks become more automated, work will become faster and more strategic. Greater technical expertise will be required, and skills will undergo significant change, but interpersonal relationships will be more valuable (Brown and Satyavolu 2019).

Other aspects of future jobs are that there will be more contracts and temporary jobs than permanent ones due to digital transformation, globalization and Millennials' approach to careers. According to the Foundation for Young Australians, Millennials will likely change between 17 employers across 5 different careers in their lifetime (Foundation for Young Australians 2017). Similar statistics are reported by others. Ernst & Young claimed that by age 38, the average college senior will have changed job 10-14 times (Ernst & Young, 2018). Visier, a company specialized in creating workforce analytics, reported in 2018 that Millennials resigned three times as often as non- Millennials and changed jobs inside the company twice as often (Visier, 2018). This makes transferable skills more important than technical skills for employees of the future.

Hybrid jobs are new and relevant development in the job market that amplifies the importance of transferable skills as core skills. It refers to possessing interdisciplinary skills in certain jobs. For instance, a sales manager is required to have expertise in CRM software; a technical recruiter must possess strong communication, interpersonal skills, data-mining skills, marketing abilities, and expertise in statistical analysis; or administrative staff not only need to answer calls and organize files

but also must be responsible for social media and web presence of companies. Burning Glass Technologies, a workforce analytics company that utilizes artificial intelligence to analyse one billion job advertisements from millions of companies, reported the importance of transferrable skills as essential skills for hybrid jobs (Sigelman, 2019).

In summary, digital transformation augments and automates workplace tasks and frees employees from repetitive tasks so they have more time to apply their human and behavioral skills such as collaboration and interactivity. Nurses, for instance, are expected to apply their soft skills such as empathy and emotional support as well as spend more time on patient care than on administrative tasks; researchers should possess better communication skills as they are expected to spend more time sharing and selling their research than in labs; and machine mechanics are expected to use their analytical skills and technology to predict future failures rather than fixing machines when they break down.

Methodology

Before reviewing the deployed methodology, we need to define core skills. The core skills include work readiness skills such as literacy, numeracy, and technology; conceptual skills such as collecting and organizing information; problem-solving; lifelong skills such as thinking innovatively and creatively; systematic thinking; and people skills including negotiation, teamwork, collaboration, etc. (International Labour Organization, 2015).

The criteria framework employed in this study adheres to the International Labor Organization Framework (International Labour Organization, 2015). They found that core skills should:

a. be non-technical
b. be learnable and assessable
c. be essential, especially for graduates to get entry-level positions irrespective of any specific occupation or industry
d. ease the effective participation of individuals in workplaces and adult life

To gather a comprehensive list of future core skills, an extensive search was conducted in four popular academic databases including Google Scholar, Elsevier's database (Scopus), Web of Science, and ERIC database. A conscious attempt was made to include only leading global organizations that published reports on future skills. Renowned think tanks include McKinsey, Deloitte, Boston Consulting Group, Ernst & Young, Brookings, Pew Research Center, Bricks, QS Intelligence Unit, Burning Glass Technologies, Pearson, Universities of Future, Accenture, and PWC, as well as not-for-profit international organizations including World Economic Forum, Universities of the Future, and OECD. In addition to the aforementioned think tanks, recent reports from the leading HR firms of LinkedIn, SHRM, Manpower, and Mercer were also reviewed and summarized in this study. Snowballing and qualitative exploration of citation networks were among strategies that were used to identify other relevant sources to core skills. As specific technical skills vary for different professions, only the core behavioral and transferable skills were included in this study.

Analysis

The review of more than 20 recent reports (within the 2016-2019 period) indicated that creativity, critical and analytical thinking, complex problem solving and communications (oral expression, reading comprehension, and writing expression) are by far the most significant skills of the future. The irony is that the same set of skills has been the root cause of skills gaps for more than two decades, yet the higher education system has not lived up to the task and has not made sure that their graduates possess these core skills.

Cognitive abilities such as creativity and cognitive adaptability are quite vital in the uncertain and complex workplace of the future. Creativity was recommended in 80% of the publications that were

reviewed in this study (Appendix 1). Most faculty members do not know how to promote creativity in their lessons. Drapeau (2014) suggested that to promote creativity in classrooms, faculty should provide a safe environment that encourages unusual ideas, offer learning alternatives, apply creative strategies and techniques, support multiple solutions, embed originality, and provide personal and constructive feedback.

According to Tempelaar (2006), critical thinking and solving complex problems are the other two significant core skills that many faculty struggle to practice in their lessons. The main hurdle, according to him, is the absence of focus in the learning process as the emphasis of most lesson delivery is on content which encourages memorization. This needs to be replaced by a system that focuses on the process of learning and assessments that measure students' intellectual abilities rather than their memory recall skills (Snyder and Synder, 2008).

Deploying project-based and case-based learning are among the possible approaches to enhance critical thinking and solving problem skills. Another suggestion is encouraging students to question assumptions and analyse situations from different perspectives. Other possibilities include cultivating decision making by practicing the path from awareness to making decisions independently or jointly and exposing students to other disciplines by offering interdisciplinary programs are some suggestions for achieving these ends.

Communication skills such as presentation skills, business writing, and reading skills usually are covered in universities but instead of being integrated across the curriculum, they are mostly being taught as a standalone course that is referred to as a bolt-on approach. Effective inclusion of communication skills and embedding communication skills across the curriculum is a daunting task that demands institutional approaches and collaboration between disciplinary academics and the general education department. Offering integrated and real-time projects where students are expected to apply their communication skills in their discipline-related courses should be a priority in higher education.

Assessing soft skills is also quite challenging as most higher education systems apply summative assessment to measure student's skills. Since interviews, group interactions, case studies, role plays, and presentations are popular methods of soft skills assessment by the employers (Cook, 2016), higher education should follow the same suit. It also should be noted that formative assessments should be the preferred mode of transferable skills assessments.

The importance of lifelong learning is among the findings of this study. As digital transformation evolves, there will be an increasing demand for employees who can develop new skills quickly and independently. One way to do this is through MOOCs and online courses where students could develop the skill of independent learning as well as a habit of learning continuously. Self-reflection should be an integral part of teaching and learning strategies as it ensures continuous development at the workplace.

Conclusion and Recommendations

Lack of collaboration and trust between the higher education system, employers, and policymakers is perhaps the main cause of the skills gap. Employers have repeatedly expressed their concerns about the failure of the higher education system in equipping students with the right workplace skillset. In addition, graduates have confessed that they are not confident about the suitability of their skills. Further, and policymakers have asked for drastic changes in the higher education system.

Close examination of the education system and workplace demonstrates how differently they define the same competencies. An OECD survey in 12 countries that include seven European countries and the United States disclosed that there are major differences between how the education system and employers interpret eight competencies (OECD, 2002). While the employers mainly defined competencies in the context of the workplace, the education sector trains and educates students on cognitive and theoretical levels. For instance, the self-management competency was defined by

educators as a learner being autonomous and having meta-cognitive competencies, whereas to employers, self-management means being an action-oriented, responsible individual who assesses the possible course of actions and the associated risks, has resource management skills and is flexible. This discrepancy is due to a lack of collaboration between education and industry. A good example of collaboration between employers and higher education is the Automotive Manufacturing Training and Education Collective (AMTEC) curriculum that was designed with 110 core competencies through input from high-performing technicians (Automotive Manufacturing Training and Education Collective).

The higher education sector around the world has to revisit its significant role in preparing students for the future workplace. Universities should place employability as a top priority.

The role of the career service department presently is limited to securing job placements and offering career counselling, but it has to be extended to what is defined by Dey and Cruzvergara (2014) as connected communities. They defined connected communities as communities that foster strong partnerships with employers in different sectors, promote experiential learning, industry mentoring, and establish a community of learners, alumni, and employers.

Developing a competency framework that assists higher education to minimize skills gaps and improve core employability skills is quite essential. Cole and Tibby (2013) suggested a four-step process that could help higher education institutes to design and deliver a curriculum that adheres to the world of work. The Business-Higher Education Forum (BHEF) recommended a systematic approach to establish a strategic alliance between higher education and industry. The approach includes analysing required jobs in the local market, developing a competency map that identifies the skills, knowledge, abilities, and attributes.

Another possible approach to prepare students for hybrid jobs is offering STEAM (Science Technology, Engineering, Art, and Mathematics) interdisciplinary programs that offer opportunities to develop STEM skills along with art and design which helps students to be more creative while analysing and resolving problems. A large number of universities, including Yale University, offer interdepartmental programs between computer science and art departments. For example, a computer major could be exposed to the challenge of creating a robotic conductor, while an art major gets a more comprehensive understanding of existing computing tools for artists (Yale University, 2019).

Assessing soft skills is another challenge for higher education, but recently a few innovative approaches have been introduced. One of the popular approaches in assessing soft skills is the Collegiate Learning Assessment (CLA) that has been endorsed by several national higher education systems. CLA is an open-ended computerized assessment that measures students' ability to think critically, solve problems, reason analytically, and communicate clearly (Council for Aid to Education, 2019). The criterion-sampling nature of the test, which is real-world scenario-based, assesses properly what a person knows and can do. Governments, too, should play their role. Creating an online knowledge base that provides insights and guidance on jobs could not only help job seekers, but also bring employers and the education system closer to each other.

The suggested core skills in this study are not region or country-specific. Perhaps a consortium of higher education, government authority, and business should be prioritized core skills in each country and ensure they are included in the curriculum and measured throughout the higher education system.

Appendix 1: Core Non-technical Skills Predicted by Advocacy Groups, Think Tanks and Leading HR Companies

Core Non-technical Skills		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	Sum

Abstract.

The aim of the paper is application of Nominal Response IRT (NR-IRT) polytomous measurement model (Bock 1972) within the framework of conjoint analysis of banking product on Polish market. Proposed approach links the tradition of conjoint measurement of dominance structures in attitude measurement with the preference analysis. Incorporating the explicit measurement model within the conjoint analysis allows for error - in variables effect and controlling for downward bias in estimates of the parameters. Additionally, it combines the fundamental conjoint measurement of Rasch tradition with the preference - oriented conjoint analysis.

Keywords: conjoint analysis, nominal model, banking products, R software.

Introduction

Conjoint analysis and discrete choice models are well known method of preference measurement in marketing research (Szymańska 2007, Szymańska, Dziedzic 2005). Usually, in order to model part-worth utilities, the ordinary least-squares regression is used assuming the interval - level of measurement of overall preferences of product profiles. However, the ordinal categorical 1-5 or 1-7 point Likert-type scales are commonly used and no measurement model are incorporated within the framework of preference measurement (Walesiak 2000, Walesiak 2001). Also, in discrete choice models estimated by multinomial logistic regression, no measurement model is taking into account. This gap in conjoint analysis studies opens the opportunity to introduce IRT measurement models into the conjoint framework and utilize classic regression - based conjoint approach, without referring to ordinal MONANOVA and especially choice-based techniques in conjoint studies.

The lack of measurement models of stated (or revealed choice-based) overall preferences of products profiles in conjoint analysis implies the lack of knowledge concerning reliability of preference measurement and strength and direction of possible bias and attenuation of the estimated regression parameters. Additionally, in classic OLS conjoint analysis, the assumption of interval level of measurement of Likert-type scales are taken for granted.

The approach used in the paper is related to the integration of IRT-based measurement model (Nominal Response Model) of overall preferences of product profiles and classical regression-based conjoint analysis stemming from the fact, that conjoint measurement in IRT model and conjoint

analysis of the preferences are conceptually related. There is still limited number of research related to such integration (Neubauer 2003; Sagan, Rybicka and Brzezińska, 2017; Caughey, Katsumata and Yamamoto, 2018).

Conjoint Measurement and Conjoint Analysis

Conjoint Analysis in SDL

Marketing inherited a model of exchange from economics, which had a good dominant logic based on the exchange of goods, which usually are manufactured output. The good dominant logic focused on tangible resources, embedded value, and transactions. Over the past several decades, new perspectives have emerged that have a revised logic focused on intangible resources, the co-creation of value, and relationships. The new perspectives are converging to form a new dominant logic for marketing, one in which service provision rather than goods is fundamental to economic exchange.

Service Dominant Logic proposes that all exchange is the exchange of service and that products are simply mechanisms for service provision. A major implication is that the transfer of ownership may not be necessary, nor desired by consumers. Assumption in Service Dominant Logic (SDL) approach in marketing (Vargo, Lush 2004) says that product offer is evaluated by consumers perception and evaluation. Product value is always co-created and not simply delivered by the firm. It provides the This provides the rationale to include conjoint analysis and measurement studies in SDL approach.

Conjoint Measurement and Conjoint Analysis

Conjoint measurement is simultaneous scaling (transformation) of the two variables, together with the response variable to obtain an additive structure. Additive conjoint measurement in Rasch model assumes that an item response probability is an additive function of two independent variables - (1) person ability and (2) item difficulty. Specific objectivity is that person abilities do not depend on specific items and item difficulties do not depend on given persons. This property is given by logistic response function. When the data fits Rasch model, item difficulties and person abilities are weakly ordered and weakly canceled:

$$\Pr(X = x) = \phi(B_n, D_i), \tag{1}$$

where: B_n - ability of person n, D_i - difficulty of item i. Within Coombs theory (Coombs, Dawes, Tversky 1970) of data that is Object $\times$ Person comparison.

Conjoint measurement is a nominal-response based method in comparison to classical conjoint analysis. However, in conjoint analysis there is no measurement model for preferences.

Conjoint analysis originated in mathematical psychology and was developed since mid-sixties also by researchers in marketing and business. Conjoint analysis is a statistical method for finding out how consumers make trade-offs and choose among competing products or services. It is also used to predict (simulate) consumers choices for future products or services.

$$Y_{i,j} = \phi(C_i, D_j), \tag{2}$$

where: C_i - evaluation of attribute i, D_j - evaluation of attribute j.

According to Coombs theory of data that is Object $\times$ Object comparison. The problem that may occur is that Y_{ij} is often measured on ordinal scales (i.e. Likert - type) without any assumptions concerning measurement model.

IRT Models

Item Response Theory (IRT) is a statistical theory that distinguishes the latent trait (ability) of a participant from the difficulty of a set of item with well-correlated response patterns. It was formally presented by Lawley (1943) who introduced IRT as a measurement theory and later developed by Rasch (1960) to measure the ability and to devise tests for the military. Fumiko Samejima (1969) developed graded response models in IRT for polytomous IRT models that deal with Likert-scale data and other tests with ordered multiplie response option for each item (DeMars 2010). Gerhard Fischer extended Rasch`s binary or dichotomous model so as to handle with polytomous data in the linear logistic latent trait model. IRT models are often referred to as latent trait models. The term latent is used to emphasize that discrete item responses are taken to be observable manifestations of hypothesized traits, constructs, or attributes, not directly observed, but which must be inferred from the manifest responses. Latent trait models were developed in the field of sociology, but are virtually identical to IRT models.

IRT is a psychometric theory and family of associated mathematical models that relate latent trait of interest to the probability of responses to items on the assessment. It is very general method, permitting one or more traits, various (testable) model assumptions and the analysis of binary or polytomous data. The mechanism of IRT can be presented most easily in term of a dichotomous model, that is, a model for item with only two response alternatives. Such items require responses that are either correct or incorrect. In dichotomous IRT models, the item category that represents a positive response (and is subsequently coded 1) is described as indicating a correct response on an item; the alternative category, coded 0, indicates incorrect response. Moreover, the item location parameter is commonly referred to as the item difficulty parameter. The IRT function is a function reflecting probability of selecting a positive response on an item. The IRT function requires the estimation of two parameters. One is location parameter, which describes where along the trait continuum the function is centered. The second parameter is estimated to give an information on of how well an item discriminates among people along the trait continuum and shows how well an item can tell people apart with respect to the amount of a trait that they have.

Nominal Response Model

Assumptions of NRM

Nominal Response Model (NRM), also called the Nominal Categories Model (NCM), was introduced by Bock (1972) as a way to model responses to items with two or more nominal categories. A standard example of such an item is a multiple-choice item where the distractors are chosen with no particular order in mind in terms of the trait being measured. Clearly, there is explicit ordering with respect to the correct alternative in a multiple-choice item. This item category represents the highest category, in terms of the trait being measured, for the item.

NRM model is based on the following assumptions:

- modeling responses to items with two or more nominal categories (multiple-choice item's response alternatives),
- probability of responding in any given category is modeled directly by multivariate generalization of the logistic latent trait model,
- NRM is an extension of multinomial, fixed-effects, logit-linear models to the mixed-effects setting of IRT,
- the implicit purpose of the NRM is to find the unobserved ordering within unordered categorical data,
- all of the polytomous models for ordered data are special cases of the NRM,
- NRM is an approximation to Thurstone (normal) models, and the multivariate version of the BTL model,

- extension to multidimensional IRT (MIRT) model (Item Factor Analysis with Nominal Responses) is also possible.

NRM is ideal for items with no ordering of any kind. Response options don't have to be same across items. Such model is a direct model (probability of response given directly). In NRM we measure the probability of one response category against all others.

Model Parameters

Modeling responses to items with two or more nominal categories are multiple-choice item's response alternatives (Bock1972). Probability of responding in any given category is modeled directly by multivariate generalization of the logistic latent trait model. NRM is an extension of multinomial, fixed-effects, logit-linear models to the mixed-effects setting of IRT. The implicit purpose of the NRM is to find the unobserved ordering within unordered categorical data. All of the polytomous models for ordered data are special cases of the NRM. NRM is an approximation to Thurstone (normal) models, and the multivariate version of the BTL model. Extension to multidimensional IRT (MIRT) model (Item Factor Analysis with Nominal Responses) is also possible.

Conditional probability is given as (Bock 1972) :

$$P\left(Y_{ij} = k \middle| a_i, b_i, \theta_j\right) = \frac{e^{a_{ik}(\theta_j - b_{ik})}}{\sum_{h=1}^{K} e^{a_{ih}(\theta_j - b_{ih})}} . \tag{3}$$

Nominal response model reparametrization is given as:

$$P\left(Y_{ij} = k \middle| \lambda_i, \varsigma_i, \theta_j\right) = \frac{e^{\lambda_{ik}(\theta_j + \varsigma_{ik})}}{\sum_{h=1}^{K} e^{\lambda_{ih}(\theta_j + \varsigma_{ih})}} . \tag{4}$$

Model parameters are: ς_{ih} - intercept, overall popularity of alternative h ; $\frac{-\varsigma}{\lambda} = b$ is ratio of the slope and intercept parameters that is location of the item category response function (ICRF); $\lambda_{ih} = a$ - slope, item discrimination of ICRF. Identification constrains should be added (Bock 1972) : $\sum a_{ih}, b_{ih} = 0$ or $a_{i1} = 0$, $b_{i1} = 0$.

Conjoint Analysis of Banking Products with NR Measurement Model

Data File

The research on banking products and bank account preferences was conducted in cross-sectional studies in southern part of Poland. The product analyzed was bank account choices of bank customers. Attributes and levels were: (a) Yes, (b) No. The questionnaire consisted of the following questions:

1. Bank account access via mobile devices (X_1),
2. Bank account commission (X_2),
3. Credit card payment return (X_3),
4. Fee for withdrawal in foreign ATM machines (X_4),
5. Credit card free of charge (X_5).

Profiles: respondents were asked to make a choice between 28 pairs of profiles (fractional factorial design prepared with R software). Full factorial design contained 32 profiles, fractional factorial design was 8 profiles. In the research NMR model was built, as well as conjoint analysis of banking products.

NRM Measurement Model of Customer Preferences

The nominal response model (NRM) is the most general divide-by-total item response theory (IRT) model. It allows researchers to estimate a slope parameter for each response category within a polytomous item with ordered categories. The nominal response model is available if the data type is multiple choice or graded. Each option of each item has two parameters, the threshold and the slope, and no order is forced on the options. If the data type is graded, then the value of the options is used only for the initialisation and to compute the item characteristic curves. Nominal response models have received relatively limited application to real-world measures and applications.

In this article NRM measurement model will be applied for customer preferences based on own research. Item characteristic curves of NRM is presented in Fig. 1. Each category represents the ICC of particular profile of banking product. The greater increase in latent preferences (latent trait) the higher probability of choosing particular profiles, except profile 1, where the higher probability appears at lower score of the latent trait. The position of ICC curves reflects the "difficulty" of particular item (item location parameter) and therefore the preferences of particular profiles.

Estimated NRM model-based latent trait (latent preference scores - Theta) are treated as quantitative (metric) measure of overall consumer preferences of the profiles (as dependent variable) for regression-based conjoint analysis.

Fig. 1: Category characteristic curves of NRM

Source: Own calculations.

Having the model-based item characteristic curve parameters, the amount of information and thus standard error of measurement of measurement of overall preferences along the latent trait can be estimated. The non-linear item characteristics curves assumes also the non-constant standard error of measurement across latent trait continuum. The total information curve of the preference scale is depicted on Fig 2.

Fig. 2: Test information curve of NRM

Source: Own calculations.

Fig. 2. shows that the measurement of the latent preferences by NRM model is reliable (having high information and low standard error of measurement) in the area of weaker consumer preferences of banking product. The stronger overall preferences, the smaller value of information, and the higher standard error of measurement and thus lower reliability of measurement. Therefore the part-worth utilities in conjoint model may be strongly downwardly biased (attenuated) especially for the respondents with the higher overall preferences score.

Conjoint analysis of banking products

Conjoint analysis is a research technique developed in early 70s, first applied in psychology and marketing. The main aim of the conjoint measurement is to determine (measure) the influence of two or more independent variables (that are nominal) on one dependent variable (that can be ordinal, interval or ratio). Conjoint analysis is based on the following assumptions:

- the number of attributes taken into consideration in the research is usually limited to 6,
- profiles presented to respondents to assess are described by using all attributes,
- profiles are generated on the basis of orthogonal factor system,
- profiles generated on the basis of orthogonal systems which are maximally, mutually varied,
- main effects and also the effects of an attribute interaction can be incorporated into the conjoint analysis model,
- all respondents assess the same set of profiles,
- the conjoint analysis model represent so called decomposition approach, which means that on the basis of empirical usages of full profiles, it is possible to assess partial usages of attribute levels,
- different methods of gathering data from original, primitive sources can be used,
- each stage of conjoint analysis procedure is separated (namely: preparing profiles, gathering data, assessing parameters, simulating market shares).

Conjoint models with nominal dependent variable (consumer choices from the list of profiles) are usually estimated using discrete choice models. However, in this analysis the response variable is continuous as a result of NR preference model. Therefore, the classical conjoint analysis were adopted in part worth estimations.

Profiles importance ranking is presented in Table 1. The most attractive profile was the 6-th profile with the following characteristics: bank account with access via mobile devices, with some commission, but with returns for credit card usage. This account does not allow to withdraw money for free from foreign ATM machines and credit card is not free of charges.

Tab. 1: Profile importance ranking

Profile	Bank account access	Bank account commission	Payment return	Fee in foreign ATMs	Free of charge	Ranking
1	No	No	Yes	Yes	Yes	6
2	Yes	Yes	No	Yes	Yes	3
3	No	Yes	Yes	No	Yes	4
4	Yes	No	No	No	Yes	5
5	No	Yes	No	Yes	No	8
6	Yes	Yes	Yes	No	No	1
7	Yes	No	Yes	No	No	7
8	No	No	No	No	No	2

Source: own calculations.

Fig. 2 presents the attribute importance ranking. We can see that the greatest importance of attribute is achieved for factors: X_1 - bank account access via mobile devices (Access) and X_3 - credit card payment return (Return). The smallest importance can be observed for factors: X_5 - credit card free of charge (Cards) and X_4 - fee for withdrawal in foreign ATM machines (Fees). Last factor with average importance is X_3 - credit card payment return.

Fig. 3: Attribute importance ranking.

Source: own calculations.

For full profile generation the `AlgDesign` of **R** software is needed. Usually full profile design is not used in conjoint analysis due to high number of profiles. When the number of profiles is relatively small (up to 16) all profiles can be used in the conjoint analysis. Otherwise partial profile design has to be prepared.

Part worths utilities of attributes levels for whole sample are presented in table 2.

Tab. 2: Parth worths utilities of attributes levels for whole sample

No.	Attribute	Level	Parth worth utilities
1	Bank account access via mobile devices	Yes	-0.0272
		No	0.0272
2	Bank account commission	Yes	0.0117
		No	-0.0117
3	Credit card payment return	Yes	-0.0318
		No	0.0318
4	Fee in forting ATMs	Yes	-0.0017
		No	0.0017
5	Credit card fee of charge	Yes	-0.0073
		No	0.0073

Source: own calculations.

Evaluations were applied in package `conjoint` and part-worth utilities were estimated. Obtained part-worth utilities were used to calculate attractiveness (total utilities) of individual profile and average attribute importance.

Average importance of attributes are presented in table 3.

Tab. 3: Average importance of attributes for whole sample

Attributes	Parth worth utilities
Bank account access via mobile devices	34.05
Bank account commission	14.23
Credit cant payment return	39.07
Fee in forting ATMs	3.38
Credit card fee of charge	9.27

Source: own calculations.

Conclusions

The most important attribute is the access to bank account via mobile devices and the payment return. The most attractive profile was the 6th profile: bank account with access via mobile devices, with some commission, but with returns for credit card usage. This account does not allow to withdraw money for free from foreign ATM machines and credit card is not free of charges. Measurement models of consumer preferences (Rasch, PCM, RSM, NRM) may overcome the problems with evaluation of overall preferences for product's bundles (profiles). It possible also to introduce multidimensional preference vector as a dependent variable. Further comparative simulations between model-based and model-free conjoint analysis is needed to test the size of attenuation. The next research goal is to incorporate multilevel analysis (on households level).

Abstract

Purpose and research questions. Entrepreneurial orientation is typically analysed at the firm level, There is not much attention paid to analyse micro-foundations of the entrepreneurial orientation, that could act as explanation for the firm level of entrepreneurship. The purpose of this paper is to fill this gap by indicating that applying the micro-foundation perspective could broaden the understanding of strategic entrepreneurship processes. The aim has been realized by answering the following research question: How might the micro-foundations concept in strategic management develop the understanding of the entrepreneurial orientation? **Design/Methodology/Approach**. The method that has been used is a systematic and critical literature review of the entrepreneurial orientation concept as well as a critical literature review on the micro-foundations concept. **Findings.** The overarching findings are as follows. Firstly, the micro-foundational perspective significantly complements both OMT (organization and management theory) and the strategic management field. Secondly, considering the entrepreneurial orientation under a constructivist perspective enables to implement the micro-foundational programme in this field. Moreover, incorporating multi-level conceptualizations and multi-level methodology as well as the micro-foundational programme it might be possible to examine the following linkages: an individual entrepreneurial attitude determines individual entrepreneurial behaviour which as such influences organizational entrepreneurial orientation, which, as a result, has impact on organizational performance and growth. **Research implications**. The findings fill the research gap in the strategic management field concerning a lack of specific micro-foundations of the entrepreneurial orientation as an organizational (macro) phenomenon and revise the current knowledge in this realm.

Keywords: Strategic Entrepreneurship, Entrepreneurial Orientation, Micro-Foundations.

Introduction

One of the contemporarily explored research fields in strategic management is strategic entrepreneurship (e.g. Hitt *et al*., 2001). Many factors at micro and macro levels—including, amongst others, individual, organizational, and inter-organizational ones - facilitate activities that makes entrepreneurship strategic One of the most predominant construct of interest in strategic entrepreneurship research is entrepreneurial orientation comprehended as a firm's strategic posture towards entrepreneurship (Anderson *et al*., 2015). Notably, the entrepreneurial orientation is also considered as one of the strategic orientation types, besides market orientations and learning ones (Hakala 2011, Schweiger *et al*., 2019). However, despite the considerable growth of strategic entrepreneurship research over the past 30 years (since Miller's (1983) seminal paper), there is a need to develop the theoretical lens of this field by implementing new perspectives that allow a deeper understanding of how firm strategies are reflections of their managers. As such, a promising view emerges from the 'micro-foundations' concept (ontologically and epistemologically) and the micro-foundational analysis (methodologically).

Management literature indicates that here are various approaches to conceptualizing organizational entrepreneurship (Acs and Audretsch, 2003), but in significant number of research (e.g. Covin and Wales, 2012; Lumpkin and Dess, 1996) it is described as innovativeness, proactiveness, risk taking, competitive aggressiveness, and autonomy. Although the operationalization of entrepreneurial orientation is commonly used in management research, there is not much attention paid to exploring the micro level of entrepreneurial orientation which would act as an explaining power on the organizational and strategic levels. Our paper seeks to fill in this vein of reasoning, applying the idea of micro-foundations to the conceptualization of entrepreneurial orientation as a reflection of the firm's strategic entrepreneurship.

Entrepreneurial orientation is typically analysed at the firm level, as a strategic orientation of the firm. Some research presents the individual entrepreneurial orientation concept. However, there is not much attention paid to analyse micro-foundations of the entrepreneurial orientation, that could act as explanation for the firm level of entrepreneurship. The purpose of this paper is to fill this gap by indicating that applying the micro-foundation perspective could broaden the understanding of strategic entrepreneurship processes. Specifically, the following research question has been formulated: RQ. How might the micro-foundations concept in strategic management develop the understanding of the entrepreneurial orientation?.

The method that has been used is a systematic - critical literature review. First, the review was made with 'entrepreneurial orientation' keyword on the basis of 2 journals (excluding the date publication criterion): *Strategic Management Journal* and *Strategic Entrepreneurship Journal*. Second, after analysing seminal papers in the field of entrepreneurial orientation and implementing the snowball method, additional papers have been considered. Third, the seminal and overarching papers concerning the micro-foundations concept in strategic management have been added as well.

The structure of the paper is four-fold. The first section presents the micro-foundations concept in strategic management. The theoretical background of the entrepreneurial orientation concept has been presented in the next section. Then, the insights on a micro-foundational perspective of entrepreneurial orientation have been posed. Finally, the conclusions, encompassing the most salient findings, limitations and future research directions have been presented.

Micro-foundations – a Concept in Strategic Management

The 'microfoundations movement' (Winter, 2013) has appeared in the management theory landscape over the past decade (Foss and Linder, 2019). The micro-foundations project 'seeks to advance our understanding of phenomena by ensuring that analysis explicitly considers (…) multilevel nature by locating (theoretically and empirically) the proximate causes of the phenomenon one seeks to explain at one or more levels of analysis lower than that of the phenomenon itself' (Felin and Foss, 2019, p. 7). Selective and not exhaustive conceptualizations of the 'micro-foundations' have been presented in Table 1.

Table 1: Basic conceptualizations of the 'micro-foundations' concept

Conceptualization	References (selective, not exhaustive)
Micro-foundations of a given phenomenon constitute its main elements and processes.	Lippman and Rumelt (2003)
Micro-foundations refer to aggregated phenomena and/or relationships between aggregated variables.	Barney and Felin (2013)
A micro-foundational approach concern collective phenomena. Specifically, it refers to the processes of creating, developing, reproducing the phenomena analysed. As such, it requires explanation of lower level phenomena such individuals or processes in organizations as well as the interaction between them.	Felin *et al*. (2012)

Micro-foundations constitute cognitive fundamentals in strategic management rooted in individual actions and interactions between individuals.	Abell *et al*. (2008); Barney and Felin (2013)
An individual level (micro) is a key for explaining phenomena at the organizational level (macro) such as routines, capabilities, organizational performance.	Foss and Pedersen (2014)
The main aspect of the micro-foundations concept refers to consider the constructs at the individual level, collective constructs, and the constructs at strategic organizational level. Aggregation is not a primary premise of micro-foundations. It ought to just bond the constructs aforementioned.	Devinney (2013)
Micro-foundations are responsible for explaining a mediating character of influencing individual level (micro) phenomena and/or interactions between them on the relationships between organizational level variables.	Abell *et al*. (2008); Foss and Pedersen (2014)
A micro-foundational analysis is multilevel (ontologically, epistemologically, and methodologically).	Molina-Azorin (2014); Foss (2016)
The explanation how individual level factors as a result of aggregation contribute to occur collective phenomena and constitute *sine qua non* the micro-foundational analysis.	Barney and Felin (2013)
The 'micro-foundations' concept does not refer to individuals and theirs characteristics *per se*, but also to additive and emergent forms of aggregation.	Barney and Felin (2013); Felin *et al*. (2015)
The 'micro-foundations' concept refers to methodological individualism and the search for causality mechanisms (at the individual level) as well as it reflects how intentional activities and/or interactions between individuals constitute phenomena in the strategic management field.	Abell *et al*. (2014); Molina-Azorin (2014)
The purpose of micro-foundations is to explain (*via* seeking causality) how higher level constructs emerge from constructs that reside and interact at lower levels of analysis.	Devinney (2013); Felin *et al*. (2015); Molina-Azorin (2014)
Micro-foundations constitute a research programme with the main aim of understanding collective/aggregated macro level phenomena by means of actions of and/or interactions between lower level constructs (not necessarily concerning individuals).	Foss (2016)
'Microfoundations as a theoretical explanation, supported by empirical examination, of a phenomenon located at analytical level N at time *t* (N*t*). In the simplest sense, a baseline micro-foundation for level N*t* lies at level N - 1 at time *t* - 1, where the time dimension reflects a temporal ordering of relationships with phenomena at level N – 1predating phenomena at level N. Constituent actors, processes, and/or structures, at level N - 1*t*-1 may interact, or operate alone, to influence phenomena at level N*t*. Moreover, actors, processes, and/or structures at level N - 1*t*-1 also may *moderate* or *mediate* influences of phenomena located at level N*t* or at higher levels (e.g. N + 1*t*+1 to N + n*t*+*n*)'.	Felin *et al*. (2012, p. 1353)
A micro-foundational analysis needs specifying the components of the micro-foundational construct, interactions between those components, causative mechanisms contributing to emerge a collective phenomenon from micro-foundational components. The boundary conditions are necessary.	Felin *et al*. (2012)

Micro-foundational studies (mainly theoretical) have been evidenced in many research fields. Referring to the recently published systematic review on micro-foundations made by Foss and Linder (2019), besides such *explanandum* as, amongst others, dynamic capabilities, routines, value creation,

absorptive capacity, etc., which are present in the papers analysed, there is just one paper revealing a significant research gap in examining entrepreneurial orientation. Specifically, authors (Dai *et al*., 2016) consider and strongly call for the need of explaining organizational entrepreneurial orientation by means of implementing the micro-foundational programme what is in line with the recent studies on the entrepreneurial orientation concept (i.e. Wales *et al*., 2020).
Consequently, the following proposition have been formulated:

P1. The micro-foundational programme constitutes a significant premise for exploring the entrepreneurial orientation concept.

Entrepreneuarial Orientation – Theoretical Background

The entrepreneurial orientation involves 'strategy making practices, management philosophies, and firm-level behaviors that are entrepreneurial in nature' (Anderson *et al.,* 2009, p. 220; Anderson *et al.,* 2015). Moreover, the entrepreneurial orientation captures a firm-level strategic posture (Covin and Wales, 2012) / an organizational attribute (Wales *et al*. 2020) / a fundamental organizational orientation (Li *et al*. 2010, Wiklund and Shepherd, 2003; 2011) toward the pursuit of new opportunities for organizational growth and renewal (Covin and Wales, 2012).

There are three components of the entrepreneurial orientation the most frequently examined, namely innovativeness (the introduction of new products, processes, and business models, novelty, experimentation, and creative processes), proactiveness (actively entering new product/market spaces and seeking market leadership positions, creating a first-mover advantage), and risk taking (a willingness among strategic decision makers to contribute resources to projects with uncertain outcomes, a willingness to commit large amounts of resources to projects where the cost of failure may be high) (Anderson *et al*., 2009, Anderson *et al*., 2015, Baird and Thomas, 1985, Covin and Slevin, 1989, 1991, Lumpkin and Dess, 1996, Miller, 1983, Miller and Friesen, 1978, Wiklund, 1999, Wiklund and Shepherd, 2003).

Notably, there are slight conceptual differences between Miller / Covin and Slevin and Lumpkin and Dess in understanding the entrepreneurial orientation constituents and how each characterizes organizational entrepreneurship based upon a set of dimensions such as innovativeness, proactiveness, risk-taking, competitive aggressiveness, and autonomy. In the view of Miller / Covin and Slevin, a subset of three co-varying dimensions are critical for the entrepreneurial orientation to exist (innovation, proactiveness, and risk-taking), whereas Lumpkin and Dess emphasize the assumption of co-variance amongst a broader set of dimensions (introducing competitive aggressiveness and autonomy (Wales *et al*. 2020)[1]. The five-constituent conceptualization is also called strategic entrepreneurial orientation (McKenny *et al*., 2018).

Significantly, entrepreneurial behaviour and managerial attitude toward risk highlight the entrepreneurial orientation concept under a constructivist perspective (Anderson *et al.,* 2015, Eshima and Anderson, 2017). An advantage of this approach is to allow a potential antecedent to relate differentially to the entrepreneurial orientation's lower order dimensions, while still allowing the researcher to embed the antecedent within the entrepreneurial 's broader nomological network (Anderson *et al.*, 2015, Eshima and Anderson, 2017) what gives the green light to the micro-foundational exploration in this field.
Consequently, the following proposition have been formulated:

P2. Embedding the entrepreneurial orientation concept in the constructivist perspective (in terms of methodological issues) would enable to implement the micro-foundational programme in the research on entrepreneurial orientation.

[1] The specific differences between Miller / Covin & Slevin and Lumpkin & Dess have been widely presented in (Wales *et al*., 2020).

Insights on A Micro-Foundational Perspective of Entrepreneurial Orientation

While there are no doubts that the entrepreneurial orientation is depicted as an organizational-level phenomenon, there are still debates whether the entrepreneurial orientation is an attitudinal construct or a behavioural one, or both (Covin and Lumpkin, 2011; Miller, 2011) and what might constitute the antecedents of this phenomenon at lower epistemological levels. In general, the entrepreneurial orientation had been evidenced as a second-order, firm-level construct comprised of two lower-order dimensions, namely entrepreneurial behaviour (encompassing innovativeness and proactiveness) and managerial attitude towards risk, inherent managerial inclination (risk taking) (Anderson *et al.*, 2015, Eshima and Anderson, 2017). It is worth noting that "attitudes towards risk are usually pictured as stable properties of individuals, perhaps related to personality development or culture" (March and Shapira, 1987). Moreover, taking into account a top management style, Miller and Covin and Slevin regard risk-taking as "the degree to which managers are willing to make large and risky resource commitments" (Miller and Friesen, 1978, p. 923).

There are also no doubts that the entrepreneurial orientation relates to some extent to other macro level phenomena as entrepreneurial firms grow faster (Penrose, 1959, Rauch *et al.,* 2009) as well as behaving entrepreneurially places the firm in new domains that facilitate expansion – for instance, organizational performance (Anderson *et al.* ,2015, Balasubramanian *et al*., 2020, Gupta and Wales, 2017, Putninš and Sauka, 2019, Rauch *et al.,* 2009 (in this case the entrepreneurial orientation is treated as an advantage view), Schweiger *et al*., 2019, Wiklund and Shepherd, 2003) or firm growth (Eshima and Anderson, 2017, Miller, 1983, Wales *et al*., 2013). As Schweiger *et al*., 2019 state, prior research on the performance effects of the entrepreneurial orientation has yielded double-edged results: whereas most studies report positive effects, some have obtained negative or insignificant results (Rauch *et al*., 2009) - for example in terms of the entrepreneurial orientation as an experimentation view (Patel *et al*., 2015). Interestingly, researchers explain the variation in the entrepreneurial orientation - performance relationship by the moderating role of environment (e.g. Wiklund and Shepherd, 2005) or by the need to align the entrepreneurial orientation with other organizational capabilities (Schweiger *et al*., 2019)

The links between micro- and macro-level phenomena involved in the entrepreneurial orientation concept reveal the necessity of a multi-level conceptualization (see Wales *et al*., 2020). Wales *et al*. (2015) propose a new path that synthesizes the alternative Miller and Covin and Slevin and Lumpkin and Dess perspectives on the entrepreneurial orientation. They propose three distinct, yet complementary ways in which the entrepreneurial orientation is manifest as an organizational attribute at and across different levels of analysis: entrepreneurial top management / TMT style (an individual / team level), organizational configuration (an organizational level), and new entry initiatives (a market level). The entrepreneurial orientation as top management style captures the top managerial goals, beliefs, dominant logics, mindset decisions, and communications which demonstrate organizational commitment to the entrepreneurial orientation. They also convince that their proposal is consistent with upper echelons theory (Hambrick, 2007, Hambrick and Mason, 1984) since the entrepreneurial orientation as the top management style recognizes that organizations are often reflections of their top managers. Indeed, Covin and Slevin (1988, p. 218) observed early on that "entrepreneurial firms are those in which the top managers have entrepreneurial management styles, as evidenced by the firms' strategic decisions and operating management philosophies".

Therefore we propose to consider individual-level entrepreneurial orientation (see Hughes *et al.,* 2018, Kollmann *et al*., 2017) as the one of main individual level antecedents of the entrepreneurial orientation on the whole as it 'has never quite found a footing within research exploring entrepreneurial organizations. While it is generally recognized that individuals throughout organizations can be entrepreneurial actors, the concept of individual-level EO has not been widely embraced, largely because EO was introduced to the literature as a firm-level construct by definition' (Wales *et al*., 2020). Hence, the following proposition have been formulated:

P3. Incorporating multi-level conceptualizations and multi-level methodology as well as the micro-foundational programme it is proposed to examine the following relationships:

An individual entrepreneurial attitude determines individual entrepreneurial behaviour which as such influences organizational entrepreneurial orientation, which, as a result, has impact on organizational performance and growth.

Significantly, individual-level entrepreneurial orientation (both an attitude and behaviour) in terms of innovativeness, proactiveness, and top managerial preferences for risk-taking (Anderson *et al*., 2015) is dependent on lower order phenomena such as collective top managerial cognitions favouring entrepreneurial activity (Wales *et al*. 2020) and individual entrepreneurial proclivity (top managerial beliefs) (Matsuno *et al*. 2002), etc. Beliefs, cognitive maps and shared cognitive maps (Wales *et al*. 2020) develop a shared cognitive schema amongst top managers characterized by an enthusiastic support for the pursuit of new entry initiatives, innovations, and value creation opportunities, even when the outcomes of such experiments are unknown (Covin and Slevin, 2002; Wales *et al*. 2020)

Conclusion

The systematic and critical literature review allowed us to organize the current knowledge and findings referring to the micro-foundational perspective of the entrepreneurial orientation and present them in this paper. Specifically, it has been stated that the micro-foundational perspective significantly complements both OMT (organization and management theory) and the strategic management field. Secondly, considering the entrepreneurial orientation under a constructivist perspective enables to implement the micro-foundational programme in this field. Moreover, incorporating multi-level conceptualizations and multi-level methodology as well as the micro-foundational programme it might be possible to examine the following linkages: an individual entrepreneurial attitude determines individual entrepreneurial behaviour which as such influences organizational entrepreneurial orientation, which, as a result, has impact on organizational performance and growth

The research proposed is the answer for the Wales *et al*. (2020) call for "the need to consider top management style as a key phenomenon within the manifestation of entrepreneurial orientation. Viewing entrepreneurial orientation as a top management style provides a conceptual lens to develop theory pertaining to how and why organizations become entrepreneurial actors and with what effects". Our findings fill the research gap in the management science concerning the lack of investigating entrepreneurial orientation under multi-level studies and the micro-foundational programme.

Our paper is just the illustration of our research in progress and our next step will be connected with formulating research design. As well as this, we perceive a wide range of research directions and realms in that field. Certainly, besides managerial cognition and beliefs, it is necessary to take into account an adaptive capability (individual and organizational) as the predictor of entrepreneurial orientation as well. Eshima and Anderson (2017) proved that organizational growth influenced the adaptive capability that in turn had impact on entrepreneurial orientation. Moreover, it is proposed to examine the role of entrepreneurial orientation as a moderator in the relationship between absorptive capacity and firm performance (Wales *et al*. 2013) as well as in the relationship between a bundle of knowledge-based resources and firm performance (Wiklund and Shepherd, 2003). Prior research shows that absorptive capacity might be a moderator in the relationship between entrepreneurial orientation and sales growth with the mediator in the form of innovation variations (Patel *et al*., 2015). Furthermore, CEO core self-evaluation seems also to be a direction in exploring individual-level entrepreneurial orientation as a predictor of organizational-level entrepreneurial orientation (Simsek *et al*., 2010).

Abstract

Eco-innovation and green technologies are the key to Europe´s future and they are at the heart of the European Union (EU) policies. As the numerous practical examples demonstrate, eco-innovation is a powerful instrument that combines reduced negative impact on the environment and the positive impact on the economy and society. Emphasizing eco-innovation as a means for achieving sustainable development requires information on the performance of main actors, in particular, countries. Measuring country´s performance of eco-innovation has started via indices or scoreboards, which come with indicators and scores and help with benchmarks across countries. Policy and innovation actors can thus learn about diagnosing different areas of eco-innovation and drawing lessons about the strengths and weaknesses across countries. The aim of this paper is to assess the eco-innovation performance during the last three years in Slovakia by means of eco-innovation index, to analyse and assess the components and indicators of eco-innovation index for Slovakia in the year 2018 and to compare them with those of EU 28–average. Identified and discussed will be the areas in which the main weaknesses and strengths are evident. Based on the research results formulated will be the main implications for managers and policy makers in Slovakia to improve the state in mentioned area. Our study is qualitative and descriptive in nature and is based on secondary sources of data coming from the Eurostat and Eco-Innovation Observatory. The methods used in the paper are the method of casual analysis, deduction, abstraction, comparison as well as the synthesis.

Keywords: Eco-Innovation Index, Eco-Innovation Performance, Assessing Eco-Innovation Performance.

Introduction

Europe´s economic growth over many decades has been fuelled by the intensive use of resources. However today it faces multiple challenges of stimulating the growth, while ensuring that this growth is economically and ecologically sustainable. Energy use, water scarcity, land shortages, the depletion of materials and the management of waste are among the most discussed issues posing sustainability challenges.

The EU´s economic prosperity and well being is linked to its natural environment and the global demand for renewable energy and resource-efficient solutions will be a source of jobs and economic growth in the years to come. To secure (reaching) the environmental protection and economic growth, eco-innovations have a central role. Eco-innovation becomes an emerging priority of EU policy relating to different aspects of almost all industries.

A significant step forward for eco-innovation is the Eco-Innovation Action Plan (EcoAP) launched by the European Commission in December 2011. Eco-innovation Action Plan is an important element of the European policy framework for sustainable consumption and production. It aims to transfer Europe into a more competitive resource-efficient economy and acknowledges the key role of eco-innovation in the context of job creation, growth and competitiveness, as well as environmental protection.

At the macro level it is necessary to understand environmental, economic and social dimensions in which eco-innovation strategies may develop. The new global economy is not only a knowledge economy, but also an economy based on responsible behaviour. In the knowledge-based development, the key to growth and prosperity relies on the issues of acquiring, creating, developing, storing and applying knowledge for a sustainable economic, social and environmental development.

To step towards the sustainable economic growth, there is a need for much more eco-innovations to appear in all sectors of EU.

The aim of the article is to assess the eco-innovation performance in Slovakia by means of eco-innovation index. To fulfil the main aim of the paper we formulated three partial aims:

1. To assess the overall eco-innovation performance of Slovakia during the last 3 years, to analyse and assess all the components and indicators of eco-innovation index for Slovakia in the year 2018 and to compare them with those of EU 28 – average.
2. To identify main strengths and weaknesses of eco-innovation performance for Slovakia.
3. To formulate main implications for managers and policy makers in Slovakia to improve the state in mentioned area.

The methods used in the paper are the method of casual analysis, deduction, abstraction, comparison as well as the synthesis.

Theoretical Background

Eco-innovation is a concept that is difficult to define because of the complexity of the subject. Fussler and James (1996) define eco-innovation as “new products and processes which provide customer and business value but significantly decrease environmental impacts”. Hillebrand and Driessen (2002) state that green innovation “does not have to be developed with the goal of reducing the environmental burden” but it “does however, yield significant environmental benefits”. Kemp and Pearson (2007) extend the view on eco-innovation from products and processes to the “assimilation or exploitation of a (...) service or management or business method” and include the consideration of the life cycle aspects. Arundel and Kemp (2009) emphasize that eco-innovation “can be motivated by economic or environmental considerations”.

Rennings (2000) perceives eco-innovations as new approaches that help reduce environmental burdens or achieve ecological targets and differentiate between technological, organizational, social, and institutional ones.

Originally, the concept of eco-innovation focused on progress in the field of technology and processes, with an intention to reduce environmental impacts of economic activities (Terjesen and Patel, 2017; Del Rio Gonzales, 2009). In time, eco-innovation´s awareness has essentially broadened, particularly where the following aspects are concerned (Azevedo et al., 2014):

- Eco-innovation does not only apply to clean and resource-efficient technologies that are specifically aimed at reducing environmental harm (Horbach, 2008). Every product or service generating an environmental benefit (reduced use of natural resources and lower use of emissions and waste) in relation to relevant alternatives should be recognized as an eco-innovation (Kemp and Pearson, 2007).

- Eco-innovation encompasses all environmental improvements across the whole product life cycle, concerning the way they are designed, produced, used, reused, and recycled (Eco-innovation Observatory, 2011).
- Eco-innovation, in a broader perspective, also embraces environmentally oriented organizational and marketing approaches, including eco-innovative business models, which can have effects on the consumer behaviour (Eco-innovation Observatory, 2013).

Concentrating on most of these additional aspects, the expert group of the Eco-Innovation Observatory defines eco-innovation as the following. Eco-innovation is the introduction of any new or significantly improved product (good or service), process, organizational change or marketing solution, that reduces the use of natural resources (including materials, energy, water and land) and decreases the release of harmful substances across the whole life-cycle (Eco-innovation Observatory, 2011).

Emphasizing eco-innovation as a means for achieving sustainable development requires information on the performance of main actors, in particular, countries (Kemp, 2010; León-Ledesma and Satchi, 2019). Measuring country´s performance of eco-innovation has started via indices or scoreboards, which come with indicators and scores and help with benchmarks across countries. Policy and innovation actors can thus learn about diagnosing different areas of eco-innovation, monitoring trends and directions and drawing lessons about the strengths and weaknesses across countries (Park et al., 2017).

Measuring eco-innovation enables to assess the progress of the components of eco-innovation (Cheng and Shiu, 2012). In practice it helps policy makers to understand the overall trend of eco-innovation, its drivers and barriers and to design effective policies and framework conditions especially encouraging for companies to increase their eco-innovation efforts (Wagner, 2008).

Eco-innovation can be measured at different levels: firm, national, regional and international (Hammond, 1995). Measuring eco-innovation at the national level provides information on which countries are leaders, followers, loungers or laggards (Jang et al., 2015).

Various stakeholders including governments, enterprises, investors, NGOs, etc. exist in the field of eco-innovation. The results of measuring eco-innovation can be meaningful and useful to multiple stakeholders (Phillips, 2003). The role of the government is crucial for implementing and diffusing eco-innovation at the national level. Governments can develop a national system that enables the production of eco-friendly goods and services. Governments can establish and implement policy instruments for eco-innovation, such as environmental regulations, financial schemes and programs for supporting R&D and fostering eco-markets (Jang, 2015). Business and industry play a crucial role in reducing impacts on resource use and the environment, through more efficient production processes, preventive strategies and cleaner production technologies and procedures (Kogan et al., 2017; Wagner, 2008). Citizens as consumers have demands on eco-products, and may become involved in innovation activities. Consumer behaviour contributes to building green markets (Rogge, Reichardt, 2016). NGOs set the environmental issues in the society and collaborate with other actors to create sustainable life. Investors can influence eco-innovation through green investment (Inderst et al., 2012). Therefore, the eco-innovation index can be used by multiple stakeholders. It provides useful information for all stakeholders to encourage further actions.

Methodology of Research

To measure the eco-innovation performance in all EU member states the Eco-Innovation Observatory has developed a composite index, so called “Eco-innovation index” (EII). The Eco-innovation index demonstrates the eco-innovation performance of a country compared with the EU average and with the EU top performers. It is equated in scores and shows how well individual member states perform in different dimensions of eco-innovation compared to the EU average (EU EII is equated with 100, EU EII=100). Eco-innovation index is a composite index that is based on 16 indicators which are aggregated into five components: eco-innovation inputs, eco-innovation activities, eco-innovation

outputs, resource efficiency outcomes and socio-economic outcomes. The composition of eco-innovation index offers the insight in eco-innovation performance of a country and enables the eco-innovation assessment.

According to a technical note from the Eco-innovation Scoreboard (Giljum and Lieber, 2016), country-specific figures of the single indicator are weighted with the share of population to calculate an EU average which corrects for the bias of smaller member states. Therefore, the EU average of a sub-indicators presents the weighted mean of all country specific data of the EU member states. The EU average of indicators that display absolute numbers is built directly by summing up the underlying data.

The index presents the situation of eco-innovation at the national level. The value of the index can influence decision-making in the field of eco-innovation. Considering for applicability, the eco-innovation index helps to assess the status of eco-innovation performance, identify areas for improvement as needed, to facilitate comparison of countries´ eco-innovation performance over time and to motivate eco-innovation activities (Park et al., 2017).

The study is qualitative and descriptive in nature and most of the date is based on secondary sources of data coming from Eurostat and Eco-Innovation Observatory.

Results and Discussion

The Eco-Innovation Observatory is publishing (starting the year 2010) the eco-innovation index for all EU member states. In the year 2018 all EU countries were clustered into three groups (Eco-innovation Observatory, 2018a):

1. Eco-innovation leaders, with score significantly higher than the EU average (a score of > 114);
2. Average eco-innovation performers with scores around the EU average (a score between 85 and 114);
3. EU countries with performance around 85 % or less compared to the EU average (with a score < 85).

Fig. 1: EU 28 Eco-innovation index 2018, composite index.
Source: https://ec.europa.eu/environment/ecoap/scoreboard_en/

According to the Eco-Innovation Index in the year 2018, Luxembourg leads the ranking of all EU countries with an aggregated score of 138. Germany (137), Sweden (132) and Finland (121) follow the Luxembourg. Eleven EU member states obtained scores around the EU average of 100 and were labelled as average eco-innovation performers. The aggregated eco-innovation scores in this group

range from 112 (France and Italy) to 88 (Croatia). Eleven countries in the last group of countries represent countries catching up in eco-innovation. Aggregated scores in this group of countries range from 83 (Belgium) to 45 (Cyprus).

Slovakia with an overall score of 68 in 2018 is on the 23th place among 28 EU member states. The score of 68 means, that Slovakia´s overall eco-innovation performance is 32% below the EU average. The country´s performance has improved compared to 2010 when the overall score was only 43; in the year 2015 the eco-innovation index has increased to 72 and in the year 2016 was 85, but during the last three years the index has decreased every year and with the score 68 in 2018 Slovakia belongs to the last group of countries with low eco-innovation performance (Lesáková, 2018).

The eco-innovation index is an aggregated index giving a general overview of the overall eco-innovation performance across the EU and it does not allow to identify strong or weak areas. It offers the disaggregation of the composite index into five components – sub-indices (Table 2).

Tab. 2: Scores in the five components of the eco-innovation index in Slovakia (2016-2018)

Year	Eco-innovation inputs	Eco-innovation activities	Eco-innovation outputs	Resource efficiency outcomes	Socio-economic outcomes	**Eco-innovation index**
2016	29	91	28	121	142	**85**
2017	27	90	33	87	124	**74**
2018	25	71	57	99	82	**68**

Figure 2 illustrates scores of the five sub-indices (components) in the eco-innovation index 2018: eco-innovation inputs, eco-innovation activities, eco-innovation outputs, resource-efficiency outcomes and socio-economic outcomes.

Fig. 2: Components of the Eco-innovation index for Slovakia 2018.
Source: Own elaborating based on EIO data.

Critical may be viewed that Slovakia is below the EU average in all components of eco-innovation index. In order to illustrate the diversity across the EU countries, the minimum and maximum scores as well as the overall score range is illustrated for each of the five components and also for the aggregated index (table 3).

Tab. 3: Scores in the five components of the Eco-Innovation Index 2018 Slovakia

	Eco-innovation inputs	Eco-innovation activities	Eco-innovation outputs	Resource efficiency outcomes	Socio-economic outcomes	**Eco-innovation index**
Slovakia	25	71	57	99	82	**68**
Minimum-EU	0	10	9	5	1	**45**
Maximum-EU	175	179	224	190	177	**138**
Range-EU	175	168	216	185	176	**94**

Source: Eco-innovation Observatory. EU Eco-Innovation Index 2018.

As the weakest component of the Eco-innovation index appear the *Eco-innovation inputs*. Eco-innovation inputs show to what extent the government gives the priority to investments in support of environmental and energy R&D. It also gives information about R&D human resources in this area. This component is composed of three sub-indices: government environmental and energy R&D appropriations and outlays (as share of GDP), total environmental and energy R&D personnel and researchers (as a share of total employment) and total value of green early-stage investments (in USD/capita).

The eco-innovation input component had a score of 25 in 2018 in Slovakia (compared to a score of 29 in 2016). Government environmental and energy R&D appropriations and outlays, as a share of GDP, were 0.01% in 2017 (compared to 0.04%, the EU average). The performance was slightly better for the share of R&D personnel and researchers out of total employment, with 0.72% in 2014 compared to an EU average of 1.32% (Eco-innovation Observatory, 2018b). The value for green early-stage investments was during the last three years very low (1 USD/capita) (SBA, 2018).

Eco-innovation activities include indicators to monitor the scope and scale of eco-innovation activities undertaken by companies. This component shows to what extent companies in Slovakia are involved in material and energy efficiency eco-innovation, as well as in observing environmental

management. The indicators include: a) enterprises that introduced an innovation with environmental benefits obtained within the enterprise (% of total firms); b) enterprises that introduced an innovation with environmental benefits obtained by the end user (% of total firms); c) ISO 14001 registered organisations (per mil. population).

Overall component index is 71 for the year 2018, which is the third highest (after resource efficiency outcomes and socio-economic outcomes) among the rest of the sub-indexes. Enterprises that introduced an innovation with environmental benefits obtained within the enterprise and those obtained environmental benefits by the end user are almost the same 0.23 and 0.22 (it is twice lower as EU average 0.53 and 0.50). The third indicator of this component is the number of ISO 14001-registered organisations per million inhabitants. Slovakia is doing well in this indicator. There were 427 ISO 14001 registered companies per million inhabitants in 2016, which gives an index score of 0.76, which is well above of EU average 0.30 (Eco-innovation Observatory, 2018b).

Eco-innovation outputs are used to monitor the extent to which knowledge outputs generated by businesses and researchers relate to eco-innovation. Eco-innovation outputs quantify the outputs of eco-innovation activities in terms of patents (per mln population), publications (per mln population) and media coverage (per numbers of electronic media).

Eco-innovation outputs reached an index score of 57. Slovakia´s low score in eco-innovation outputs is explained by the relatively low performance in all three dimensions of EI outputs (eco-patents, EI publications and EI media coverage). The number of eco-patents obtained in 2014 was 2.09 eco-patents per million people. In comparison to the EU average, number of EI patents obtained per million populations amounted to 15.34 in the same year (Eco-innovation Observatory, 2018b).

Resource-efficiency outcomes relate to wider effects of eco-innovation on improved resource productivity. This component measures material, water and energy productivity and greenhouse gas (GHG) emissions intensity.

The overall component score for Slovakia was 99 in 2018, what was a slight improvement since 2015 when it was 78, but it is a decrease to the year 2016, when it was 121. Material productivity amounts to 1.76 EUR/kg in 2015, which is below the EU average of 2.25 EUR/kg, while energy productivity is 7.85 Eur/toe (the EU average of 9.66 EUE/toe) in 2015 (SBA, 2018). The GHG emissions intensity is slightly higher in comparison to EU average, amounting to 0.34 CO2 emissions generated per unit of GDP.

Socio-economic outcomes of eco-innovation represent effects of eco-innovation activities for society and the economy. This includes changes in employment turnover or export that relate to broadly understood eco-innovation activities. The indicators for this component include: export of products from eco-industries (% of total exports); employment in eco-industries and circular economy (% of total employment); revenue in eco-industries and circular economy (% of total revenue across all companies).

The overall component score for socio-economic outcomes for Slovakia in 2018 is 82. This is a rapid decline since 2016, when Slovakia scored 142 for this component. Employment in eco and circular economy industries was at 2.93% of total employment in Slovakia in 2016 that is slightly above the EU average of 2.69%. Eco-industries´ revenue has achieved 4.73% of total revenue across sectors, which is higher in comparison to the EU- average 2.30%. The share of products from eco-industry in total export was 0.40% in 2016, which is below the EU average of 0.60% (Eco-innovation Observatory, 2018b).

It can be stated that the eco-innovation performance has decreased during the last three years and Slovakia faces many challenges from wide range of environmental and economic problems.

Eco-innovation inputs and outputs are *the weakest components* in overall eco-innovation index. Eco-innovation inputs account only 14.3% of EU average for 2018. This is mainly due to low public funding in environmental and energy R&D. Government budget appropriations and outlays for R&D

(usual public funding in Slovakia) lag far behind the EU´s average (they are twice lower than the EU average). The public funding is supplemented by the EU funds (mainly the European Structural Funds and Horizont 2020). There is also evident a lack of human resources in research and development. Highly educated persons in the field of engineering and science present a very low share in the national workforce of population, partly due to a tendency of a "brain-drain" in Slovakia (MŽP, 2019a). Better conditions, international exposure, and a creation of a more competitive environment could improve this situation. As the indicators show, the green early-stage investments are in Slovakia very low.

As the result of low financial support into the environmental and energy R&D as well as low percentage of workforce in research and development, the eco-innovation outputs related to eco-innovation (eco-patents, EI publications and EI media coverage) is very low (26% of EU average).

What concerns the resource-efficiency outcomes, there are many challenges for Slovakia. The big challenge is to increase the energy and material productivity as well as the green gas (GHG) emissions intensity. Slovakia is committed to the goals of the EU 2030 Agenda and to the 2020 climate and energy package. Share of renewable energy is coming closer to 14% target for the year 2020 and is mostly covered by Slovakia´s traditional clean energy sector based on large hydropower plants and supplemented by a small hydro power biomass and solar. Air protection represents one of the main challenges (the largest sources of such pollution are the transport sector and the residential heating) (MŽP, 2019b). In October 2017, an amendment to the Air Act was approved. This deals with specific measures to combat the air pollution such as reducing nitrogen oxide emissions to comply with currently applicable national emission ceilings reducing nitrogen dioxide and ozone concentrations as well as with reducing transport and energy related emissions.

The rapid decline is seen for the component socio-economic outcomes (it was 82 in the year 2018 to 142 in the year 2016). Employment in eco and circular economy industries was 9% more in 2016 than the EU average and what concerns the eco-industry´s revenue it was twice more than EU average; the decline of this component in the year 2018 is the result of decrease in employment in eco- and circular economy as well as in the decrease of total revenue across all sectors in the country.

At the same time there is only one *strength* to be mentioned; Slovakia outperforms many EU countries in a number of companies with ISO 14001 certification demonstrating aspiration to higher environmental standards in business sector (index Slovakia : EU average = 2.53) (SBA, 2018). This contributed positive to the average score in the Eco-innovation activities.

Thought Slovakia has implemented many of EU policies and measures in the area of environmental policy and eco-innovations to the SR legal system, the progress is slow (Lesáková, 2019). Insufficient approximation of the EU directives to the SR legal system in relation to environmental protection and eco-innovation has been criticized by the European Commission. Environmental policy stringency in Slovakia has been assessed as above average compared to OECD countries. According to the World Bank, we lag behind other countries in the quality or regulations and law enforcement.

The need for a new, modern environmental strategy which reflects the actual situation and urgent problems of the whole system of environment has resulted at the new "Envirostrategy 2030 for Slovakia" (MŽP 2019a), which was approved in February 2019. The strategy identifies basic system problems, sets 2030 targets, proposes framework measures to improve the current situation and contains also basic performance indicators for verification of achieved results. The strategy underlines the role of eco-innovations.

Conclusion

It can be stated that eco-innovations in Slovakia face many challenges. Based on the above analysis, the main implications for policy makers and managers in Slovakia may be formulated as follows.

Policy makers in Slovakia should place greater emphasis on sufficient approximation of EU directions to the legal system of the SR. They have to create effective policy programs and measures supporting eco-innovation and helping to establish a stable platform for eco-innovation´s development.

Public funding and expenditure in the eco-research and development is still low in Slovakia. To tackle with this issue both state as well as public and private institutions have to be more involved in the financial support.

It is necessary to raise firm´s awareness about eco-innovations and green business as business with a high added value in relation to the corporate responsibility concept as well as to raise firm´s awareness about the necessity to implement stabile and continual environmental business strategy.

In cooperation with central government authorities and professional organizations, academia and non-governmental organizations, the more efficient system of formal and informal environmental education and training for sustainable development has to be implemented.

Eco-innovations call attention to the positive contribution that the companies can make to sustainable development and a competitive economy (Jaffe et al., 2005). Hence, eco-innovation is understood as the combined improvement of economic and environmental performance of society.

The findings of our study contribute to the theory of using the eco-innovation index as a mean to assess the eco-innovation performance of the country. The results of this study give insights into the key areas of eco-innovation index and can help to understand the scope of eco-innovation performance. Measuring eco-innovation enables to monitor the changes in eco-innovation performance and helps with benchmarks across countries. Policy and eco-innovation actors can learn about diagnosing different areas of eco-innovation, monitoring trends and indicate strengths and weaknesses. The results of assessing eco-innovation can be thus a meaningful and useful to managers and policy makers to encourage further actions.

As the main limitation of this study may be viewed the absence of benchmarks in assessing the eco-innovation performance across EU countries. For the future we aim to spread our research also to benchmarks across some neighbouring countries (V4 countries). Despite the limitations, our paper contributes to extending the scope and scale of eco-innovation studies. It offers insights into the application of eco-innovation index.

Multivariate Item Response Models in Questionnaire Research

Justyna BRZEZIŃSKA

University of Economics in Katowice, Katowice, Poland
justyna.brzezinska@ue.katowice.pl

Abstract

Item response theory (IRT) is widely used in educational, psychological research to model how participants respond to test items in isolation and in bundles, however there is still existing gap in socio-economic area. Nowadays, due to availability of computer softare, we are able to analyse large datasets and it is possible to use multivariate IRT models as well. This study investigates the application of multidimensional item response theory (MIRT) models to validate test structure and dimensionality. When the items measure two or more latent traits, the test structure is referred to as multidimensional. Multidimensional item response theory provides an ideal foundation for modeling performance in complex domains, taking into account multiple basic abilities simultaneously, and representing different mixtures of the abilities required for different test items. In this paper we present the theory, application and the use of multivariate IRT models for the analysis of socio-economic phenomena. We also present model selection criteria and graphical presentation of results using Item Characteristic Surface (ICS) and Item Information Curve. All calculations will be conducted in R available from CRAN.

Keywords: item response model (IRT model), measurement theory, survey research, multidimensional IRT models, R software.

Introduction

The measurement of human properties has been a long-lasting quest that originated in the Ancient China and Zhou Dynasty. Chinese imperial examinations were a civil service examination system that enabled to select candidates for the state bureaucracy. Such way of examining potential candidates served to ensure a common knowledge of writing, literature, archery, horse riding, and diplomacy. Exams played a significant role in tempering the power of hereditary aristocracy, as well as military authority. It lasted for a very long time in unchanged form.

The second breakthrough was the 19th century, where the origin of psychological measurement called psychometry took place. In the beginning of the twentieth century Binet and Simon (1908), were the first to develop and use what we would nowadays call a standardized intelligence test, and in the same era Charles Spearman (1904) developed the concepts and methodology of what would later be called classical test theory (CTT) and factor analysis (FA).

The classical test theory and the item response theory (IRT) are two commonly used psychometric theories in conducting item selection and reduction for measures; however, these two theories work based on different assumptions and statistical approaches, and both have shortcomings. Although CTT was the dominant statistical test model in the first half of the 20th century (Guilford, 1936, Gulliksen, 1950), other developments were also taking place. In England, Walker (1931) set the stage for what later was to become known as Guttman (1944, 1950) scaling, by introducing the idea that if a respondent can answer a harder question correctly then he or she should be able to answer easier questions on the same topic correctly as well. Walker also introduced the idea of a quantitative index measuring deviation from this deterministic model in real data (Loevinger, 1948). This was a deterministic approach without a random error component to the analysis of data collected by a set of items that are assumed to measure one psychological property in common. A little earlier, in the 1920s, Thurstone (1928) developed his statistical measurement method of comparative judgment.

Thurstone's work may be viewed as the most important probabilistic predecessor of item response theory (IRT).

In the decade of the 1970s, item response theory became the dominant topic for study by measurement specialists. But, the genesis of item response theory (IRT) can be traced back to the mid-thirties and early forties. In fact, the term Item Characteristic Curve (ICC), which is one of the main IRT concepts, can be attributed to Ledyard Tucker in 1946. Despite these early research efforts, interest in item response theory lay dormant until the late 1960s and took a backseat to the emerging development of strong true score theory. While true score theory developed rapidly and drew the attention of leading psychometricians, the problems and weaknesses inherent in its formulation began to raise concerns. Such problems as the lack of invariance of item parameters across examinee groups, and the inadequacy of classical test procedures to detect item bias or to provide a sound basis for measurement in tailored testing, gave rise to a resurgence of interest in item response theory. Impetus for the development of item response theory as we now know it was provided by Frederic M. Lord through his pioneering works (Lord, 1952, 1953). The progress in the fifties was painstakingly slow due to the mathematical complexity of the topic and the nonexistence of computer programs. Interest in Lord's work spread quickly, as evidenced in the increase in publications in this area. Allen Birnbaum wrote a series of technical reports on logistic test models and model parameter estimation in 1957 and 1958. George Rasch (1960) published his book proposing several models for item responses. Nowadays, IRT models and procedures are no longer the main instruments only in the educational testing industry but are becoming increasingly popular in psychological testing as well. In addition, they have also become very popular and applicable in many scientific areas such as socio-economic research, medical diagnosis and marketing research.

According to Bartholomew (1987) there are different types of latent variable models, depending on the type of manifest (observed) variable and latent variable.

Table 1: Classification of latent variable models

Manifest variable	**Latent variable**	
	Continous	**Discrete**
Continous	Factor analysis	Latent profile analysis
Discrete	Item response theory models Latent trait analysis	Latent class analysis

Source: Bartholomew (1987).

In this paper we focus on the analysis for continuous latent variables and discrete manifest variable where latent variable is multidimensional. In multidimensional IRT, item characteristic surface (ICS) is used to represent the probability that an examinee with a given ability composite will correctly answer an item. This terminology is valid for two dimensional items only. The term of "item response hyper surface" should be used if more than two latent traits are necessary for an item. ICS is limited for two dimensions because of the graphical representation restrictions for more than two dimensions in multidimensional latent space (Ackerman, Gierl and Walker, 2003, Ackerman, 2005). Multidimensional IRT are models which explain the relationship between two or more unobservable variables, conceptualized as constructs or dimensions, and the probability of the examinee who is correctly answering any particular test item by the mathematical model (Ackerman, Gierl and Walker, 2003). Like unidimensional models, multidimensional models have some assumptions. These are monotonicity and local independence. Monotonicity means, as the examinee ability level increase, the probability of the examinee correctly answering any particular test item increase (Smith, 2009). Local independence is defined as the probability of solving any item i is independent of the outcome of any other item, controlling for person parameters and item parameters (Embretson and Reise, 2000).

Item Response Theory (ITR) is an extension of Classical Test Theory (CTT) (Lord and Novick 1968; Birnbaum 1968; Baker 1985; Bock and Lieberman 1970; Bock 1972; Lord 1980 and Wright 1992; 1997). The mathematical foundation of IRT is a function that relates the probability of a person

responding to an item in a specific manner to the standing of that person on the trait that the item is measuring. It means that the function describes, in probabilistic terms, how a person with a higher standing on a trait is likely to provide a response in a different category to a person with a low standing on the trait. This mathematical function has a pre-specified form (usually a logistic ogive) and is referred to as an item response function (IRF).

The main advantage of IRT models is the fact that the item location parameter (b) and the person trait level (θ) are indexed on the same metric. Therefore, when a person`s trait level is higher than the item location on the trait continuum, that person is more likely than not to provide a trait-indicating (positive or true) response. The converse is true when a person`s trait level is below the item location. IRT models are well suited to cope with dichotomous and polytomous responses, where the response categories may be unordered as well as ordered. The incorporation of linear structures allows for modeling the effects of covariates and enables the analysis of repeated categorical measurements.

In the literature the most common IRT models are models that are dichotomously scored. Test items have a polytomous format when the responses are scored in more than two categories. Such models have a response function for each different category. Although the response categories of dichotomous items typically have a fixed order (e.g., correct–incorrect; true–false), this does not necessarily hold for polytomous items. Polytomous items have a nominal response format if their response categories can be classified but an a priori order between them does not exist. The nominal response model below is appropriate for items with this format. If an a priori ordering of the categories does exist, a graded response model or partial-credit model should be chosen. The two models differ in the problem-solving process that is assumed to lead to the responses. Models for a graded-response format are more generally known as cumulative models in ordinal categorical data analysis. The partial-credit models below are known as adjacent-category models. These two options do not exhaust all possibilities, a more comprehensive review of different polytomous response formats and IRT models is given in Mellenbergh (1994).

Multivariate IRT Models

Unidimensional IRT models are appropriate for analyzing examinees' responses to items measuring a single latent trait or ability. However, for complex items that measure multiple latent traits simultaneously, item responses should not be modeled using a unidimensional IRT model because the probability of a correct response would not be a function of a single latent trait anymore. When item response data do not satisfy the unidimensionality assumption, multidimensional item response theory (MIRT) should be used to model the item-examinee interaction. MIRT enables one to model the interaction of items that are capable of discriminating between levels of several different abilities and examinees that vary in their proficiencies on these abilities. In this article graphical MIRT analyses designed to provide better insight into what individual items are measuring as well as what the test as a whole is assessing are presented and discussed.

Multidimensional item response theory (MIRT) provides an ideal foundation for modeling performance in complex domains, taking into account multiple basic abilities simultaneously, and representing different mixtures of the abilities required for different test items. MIRT models explain the probability of a correct response to a given item as a function of a vector of latent traits, instead of a single latent trait. Although MIRT can be used for various purposes, this modeling framework is particularly useful for modeling the item response data when one or more items measure multiple latent traits simultaneously (Reckase, 2009), and for improving measurement precision when there are individual tests or subtests measuring correlated latent traits (Wang, Chen, & Cheng, 2004). MIRT models can be categorized into two groups based on the test structure. These are between-item models and within-item MIRT models (Adams et al., 1997; Wang et al., 2004). In a between-item MIRT model, each latent trait is measured by a unique set of items. In other words, each item is associated with only one of the latent traits measured by the test. This type of test structure is also known as simple structure, as with a factor analytic solution where items load onto a single factor. Between-item MIRT models are typically used for estimating subscores from subtests measuring correlated latent traits (e.g., Bulut, Davison, & Rodriguez, 2017; de la Torre, Song, & Hong, 2011;

Wang et al., 2004). In a within-item MIRT model, each item can be associated with two or more latent traits measured by the test. This type of test structure is known as a nonsimple or complex structure. A good example of within-item multidimensionality is the bi-factor test structure from cognitive ability assessments, where all items are associated with a general latent trait (i.e., general intelligence) and each item is associated with a secondary latent trait (i.e., specific cognitive abilities).

Fig. 1 presents the between-item and within-item MIRS models for a measurement of two latent characteristics.

Figure 1: Between-item (left) and within-item (right) structure.
Source: own calculations.

Figure 2 illustrates the between-item and within-item MIRT models for a test measuring two latent traits. In the between-items item model, items from 1 to 3 are associated with the first latent trait θ_1, while items from 4 to 6 are associated with the second latent trait θ_2. Latent traits θ_1 and θ_1 are not correlated and do not share any common traits. The test structure becomes multidimensional, while each latent trait is defined by a set of unidimensional items while the overall structure becomes multidimensional. In the other type of MIRT, within-item model, the terms are associated with both θ_2 and θ_1 latent traits, and thus the test has a nonsimple structure. In MIRT models the correlation between the latent traits becomes larger, the estimation results are likely to become less reliable (Bulut et al., 2017). As in IRT analysis, there are several types of MIRT, depending on the number of parameters included in the model.

As we have discussed earlier, uni-dimensional IRT models are appropriate for analyzing examinees' responses to items measuring a single latent trait or construct. However, for complex items that measure multiple latent constructs simultaneously, item responses should be modeled using multi-dimensional approach, as the probability of a correct response would be a function of a multiple latent trait. MIRT models explain the probability of a correct response to a given item as a function of a vector of latent traits, instead of a single latent trait. Although MIRT can be used for various purposes, this modeling framework is particularly useful when we:

1. model the item response data when one or more items measure multiple latent traits simultaneously (Reckase, 2009),
2. want to improve measurement precision when there are individual tests or subtests measuring correlated latent traits (Wang, Chen, and Cheng, 2004).

Multidimensional Item Response models can be categorized in several ways. They can be categorized based on whether the weakness (or deficit) in one dimension (i.e., latent trait) can be compensated by the strength in another dimension. In addition, MIRT models can be grouped based on whether each

item is associated with a single latent trait or multiple latent traits.

Two-parameter multidimensional IRT model

First, we present the two-parameter multidimensional model (M2PL), which is an extension of the unidimensional Birnbaum model. This M2PL model is a compensatory MIRT model including item difficulty and item discrimination parameter from a multidimensional test. The M2PL model is defined as:

$$P\left(u_{ij}=1\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},d_i\right)=\frac{\exp(\mathbf{a}_{\mathbf{i}}\boldsymbol{\theta}_{\mathbf{j}}^{`}-d_i)}{1+\exp(\mathbf{a}_{\mathbf{i}}\boldsymbol{\theta}_{\mathbf{j}}^{`}-d_i)}, \tag{1}$$

where: $\boldsymbol{\theta}_{\mathbf{j}}$ is a $1\times M$ vector of latent traits for examinee j $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, $\mathbf{a}_{\mathbf{i}}$ is a $1\times M$ vector of slope (i.e., item discrimination) parameters for item i $\left(\mathbf{a}_{\mathbf{i}}=\left(a_{i1},a_{i2},\ldots,a_{iM}\right)\right)$, and d_i is the intercept term for item i. The intercept in M2PL model is not similar to the difficulty parameter in 2PL model, because it cannot be considered a unique indicator of the difficulty of the item (Reckase, 2009). To obtain a multidimensional difficulty parameter for item i we can use a transformation formula:

$$B_i=\frac{-d_i}{\sqrt{\sum_{m=1}^{M}a_{im}^2}}. \tag{2}$$

The higher the value of B_i gets, the more difficult the item becomes. Similarly, we can obtain the discrimination parameter using the transformation presented below:

$$A_i=\sqrt{\sum_{m=1}^{M}a_{im}^2}, \tag{3}$$

where A_i is the multidimensional discrimination parameter representing the overall discrimination power of a multidimensional item. For unidimensional IRT models with a single latent trait the difficulty parameter would contain only one non-zero element.

Multidimensional Rasch model

Multidimensional Rasch model was introduced by Adams (1997). This model can be used for estimating item parameters from a test measuring multiple latent traits. The general form of the Rasch model is (Adams 1997):

$$P\left(u_{ij}=1\middle|\boldsymbol{\xi},\boldsymbol{\theta}_{\mathbf{j}}\right)=\frac{\exp(\mathbf{b}_{\mathbf{ik}}^{`}\boldsymbol{\theta}_{\mathbf{j}}^{`}+\mathbf{a}_{\mathbf{ik}}^{`}\boldsymbol{\xi})}{\sum_{k=0}^{K}\exp(\mathbf{b}_{\mathbf{ik}}^{`}\boldsymbol{\theta}_{\mathbf{j}}^{`}+\mathbf{a}_{\mathbf{ik}}^{`}\boldsymbol{\xi})}, \tag{4}$$

where $\mathbf{b}_{\mathbf{ik}}$ is a score vector for category k of item i across the M dimensions, $\mathbf{a}_{\mathbf{ik}}$ is a design vector for score category k of item i across that defines the relationship between the item difficulty parameters, $\boldsymbol{\theta}_{\mathbf{j}}$ is a vector of latent traits $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, and $\boldsymbol{\xi}$ is a vector of item difficulty parameters for item i. In multidimensional Rasch model presented above $\mathbf{a}_{\mathbf{ik}}$ and $\mathbf{b}_{\mathbf{ik}}$ do not refer to item discrimination and item difficulty parameters. In multidimensional case of Rasch model they refer to weights derived from the test structure based on the researcher`s hypothesis. Parameters that are estimated under multidimensional Rasch model are $\boldsymbol{\xi}$ and $\boldsymbol{\theta}_{\mathbf{j}}$.

Multidimensional Graded Response model

Now we present multidimensional IRT model that is used for polytomously scored items. This model is an extension of unidimensional Graded Response Model (GRM) and presents the probability of examinee j selecting response category k in item i:

$$P\left(u_{ij}=k\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=\frac{1}{1+\exp\left[-\sum_{m=1}^{M}-\left[a_{im}\left(\theta_{jm}-\delta_{ik}\right)\right]\right]}, \tag{5}$$

where $\boldsymbol{\theta}_{\mathbf{j}}$ is a $1\times M$ vector of latent traits examinee j $\left(\boldsymbol{\theta}_{\mathbf{j}}=\left(\theta_{j1},\theta_{j2},\ldots,\theta_{jM}\right)\right)$, a_i is a $1\times M$ vector of slope (i.e., item discrimination) parameter for item i $\left(\mathbf{a}_{\mathbf{i}}=\left(a_{i1},a_{i2},\ldots,a_{iM}\right)\right)$, and δ_{ik} is the category boundary location for the response category k of item i. As we compute the probability of responding on the kth category of item i, $P\left(u_{ij}=0\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=1$ and $P\left(u_{ij}=K+1\middle|\boldsymbol{\theta}_{\mathbf{j}},\mathbf{a}_{\mathbf{i}},\delta_{ik}\right)=0$.

In the further part of this paper we present the application on multidimensional item response models using R software.

Model Selection Methods

The goodness of fit of a given latent class model to the observed data can be assessed using a chi–square test based on observed and expected frequencies. We can use Pearson‘s χ^2 statistic based on the differences between observed and expected frequencies:

$$\chi^2=\sum_{s=1}^{2^v}\frac{\left(n_s-\hat{n}_s\right)}{\hat{n}_s}. \tag{6}$$

Another widely used test is likelihood ratio G^2 based on the logarithm of the ratio of observed and expected frequencies (Agresti 2002):

$$G^2=2\sum_{s=1}^{2^v}n_s\cdot\ln\left(\frac{n_s}{\hat{n}_s}\right). \tag{7}$$

When $\hat{n}_s=0$, the corresponding term in G^2 is set equal to 0. The degrees of freedom (df) for both of statistics are equal to 2^v-m-1, where m is the number of independent parameters. When expected cell frequencies are small (smaller than 5), both statistics χ^2 and G^2 tend to be distorted and may fail to follow appropriate chi–square distribution. When the difference between the computed values of χ^2 and G^2 are large, there are often one or two response vectors where small expected frequencies are causing the discrepancy.

There is a wide range of another criteria for model selection called information criteria. The Akaike information criterion (AIC) (Akaike 1973) is a measure of model fit based on concepts derived from information theory. There are two equivalent ways to implement the AIC for a set of competing latent class models. As originally proposed by Akaike, the AIC is defined as:

$$\ln\left(L_h\right)=\sum_{s=1}^{2^v}n_s\ln\left[P_h\left(\mathbf{Y}_s\right)\right], \tag{8}$$

where: $P_h\left(\mathbf{Y}_s\right)$ is the probability for an observed response vector based on maximum-likelihood estimates for the h–th model.

Another Akaike information criterion is defined as:

$$AIC_h = -2\ln(L_h) + 2m_h, \tag{9}$$

where: m_h is the number of independent parameters that are estimated when fitting the h–th model to the data. For model selection we can also apply Bayesian information criterion (BIC) (Schwarz 1978):

$$BIC_h = -2\ln(L_h) + \ln(N) \cdot m_h. \tag{10}$$

The AIC and BIC are mostly used for comparison across several plausible models where the lowest value of a given information criterion indicates the best fitting model.

Applications in R

Mirt package of R

A common characteristic of the IRT models are well known and used in education and psychology research, where there is a single latent trait underlying the items. In other words, the test structure is assumed to be unidimensional. However, most educational and psychological assessments tend to measure two or more latent traits or dimensions. When the items measure two or more latent traits, the test structure is referred to as multidimensional. To estimate item parameters and latent trait levels from multidimensional assessments, multidimensional IRT (MIRT) models should be used.

Now we present the application of multidimensional IRT models in R using mirt package. The mirt package is capable of estimating various MIRT models, although there are other R packages available for estimating some MIRT models, such as flirt (Jeon, Rijmen, and Rabe-Hesketh, 2014), TAM (Kiefer et al., 2016), eRm (Mair and Hatzinger, 2007), and sirt (Robitzsch, 2017).

Using the mirt package there are many flexible parameter estimation features:

- Mixe ed (dichotomous and polytomous) IRT model estimation with flexible specifications for uni-dimensional and multidimensional patterns,
- linear and nonlinear parameter constraints and bounds,
- prior parameter distributions,
- item- and group-level covariates,
- user defined item types for on the fly estimation,
- nonlinear latent traits and interaction term.

The mirt package contains five primary estimation functions, all of which support mixed item formats for multidimensional response models, and each with their own special purpose. They are:

- mirt() - single group estimation using quadrature (EM) and stochastic MML (MH-RM) estimation,
- bfactor() - single/multiple group bi-factor or two-tier estimation by using a dimensional reduction EM algorithm, useful when there are multiple packets of independent specific factors (e.g., testlets, longitudinal models),
- mdirt() - latent class model estimation (fairly experimental, as there are better packages for such procedures).

Multidimensional IRT analysis for the dataset from R

Now we apply mirt{mirt} function for the analysis of Science dataset from mirt package (Chalmers 2012) 4 items: Comfort Work Future Benefit, and 392 respondents. First, we compute parameters for items and we compute 1 and 2 factor models. Using coef() function extracts the maximum-

likelihood parameters and item facilities (i.e., average number of correct responses). We build uni-dimensional and two-dimensional IRT model and then we compare goodness of fit using information criteria (AIC and BIC statistics).

Descriptive statistics present proportions for each level of response (categories) for all variables on the sample 392 respondents. We also obtain frequencies of total scores for all responses, as well as Cronbach`s alpha value for items.

Sample:
7 items and 392 sample units; 0 missing values

Proportions for each level of response:

	strongly disagree	disagree	agree	strongly agree
Comfort	0.0128	0.0816	0.6786	0.2270
Environment	0.0740	0.2296	0.3699	0.3265
Work	0.0842	0.2500	0.5255	0.1403
Future	0.0357	0.1837	0.5357	0.2449
Technology	0.0459	0.2321	0.4005	0.3214
Industry	0.0255	0.1199	0.4413	0.4133
Benefit	0.0536	0.2551	0.4923	0.1990

Frequencies of total scores:

	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28
Freq	0	0	0	1	0	0	1	0	5	13	24	38	43	43	70	56	28	27	21	15	4	3

Cronbach's alpha:

	value
All Items	0.5082
Excluding Comfort	0.4467
Excluding Environment	0.4880
Excluding Work	0.5129
Excluding Future	0.4474
Excluding Technology	0.4791
Excluding Industry	0.4394
Excluding Benefit	0.4726

Now we run item response analysis for one latent dimension. Results of the analysis for uni-dimensional model are presented below.

Log-likelihood = -1608.87
Estimated parameters: 16
AIC = 3249.739; AICc = 3251.19
BIC = 3313.279; SABIC = 3262.512
G2 (239) = 213.56, p = 0.8804
RMSEA = 0, CFI = NaN, TLI = NaN

Residuals of uni-diemensional IRT model are as follows:

	Comfort	Work	Future	Benefit
Comfort	NA	-0.147	-0.101	0.152
Work	-25.512	NA	0.088	-0.141
Future	-12.002	9.208	NA	-0.122
Benefit	27.321	-23.235	-17.461	NA

From the analysis we can see, that information criteria for uni-dimensional IRT model are: AIC=3249.739, and BIC=3313.279. Now we present results for two-dimensional model.

Log-likelihood = -1601.969
Estimated parameters: 19
AIC = 3241.938; AICc = 3243.981
BIC = 3317.392; SABIC = 3257.106
G2 (236) = 199.76, p = 0.9583
RMSEA = 0, CFI = NaN, TLI = NaN

Residuals of two-dimensional IRT model are as follows:

	Comfort	Work	Future	Benefit
Comfort	NA	-0.143	-0.096	-0.116
Work	-23.892	NA	-0.087	-0.131
Future	-10.943	-8.899	NA	-0.121
Benefit	-15.793	-20.286	-17.157	NA

From the analysis we can see, that information criteria for uni-dimensional IRT model are: AIC=3241.938, and BIC=3317.392.

Using plot() function we can present graph of expected total score for uni- (left, fig. 1) and two-dimensional model (right, fig. 1).

Fig. 1: Graphical presentation of expected total score for uni- and two-dimensional IRT model

Source: own calculations using R.

As one-dimensional model is presented for one latent variable, the plot presents relation between latent construct (θ) and the total score (T(θ)). For two-dimensional latent space we obtain plot in three dimensions: for two latent constructs (θ_1 and θ_2) and for the total score (T(θ)).

To compare one and two-factor IRT model we can use anova() function. We obtain statistics of goodness-of-fit for models that are compared (uni- and two-dimensional).

	AIC	AICc	SABIC	HQ	BIC	logLik	X2	df	p
1	3249.739	3251.190	3262.512	3274.922	3313.279	-1608.870	NaN	NaN	NaN
2	3241.938	3243.981	3257.106	3271.843	3317.392	-1601.969	13.801	3	0.003

In the summary we obtain all possible statistics of goodness-of-fit based on the chi-square statistics, as well as information criteria. The smaller information criterion, the better model, however the differences between one and two-factor model are very little. From the study of goodness of fit statistics we choose model 2 as fitting best. The BIC criterion BIC=

We can also present test information function graph, as well as test standard errors for two latent traits using two-dimensional latent space. We present graphically test information function (left) and plot for the test standard error function (right) (Fig. 2).

Fig. 2: Test information function (left) and plot for the test standard error function (right) for two-dimensional IRT model
Source: own calculations using R.

Having chosen two-dimensional IRT model we can provide great visualizing tools in three dimensional space.

Using plot() function we can present graphically information in different intervals of latent variables.

Fig. 3: Test information function (left) and plot for the test standard error function (right) for two-dimensional IRT model in interval (-3,0) (left) and (0,3) (right)
Source: own calculations using R.

Fig 3. presents the surface of information values for two intervals: (-3,0) and (0,3). We observe the values and changes of information depending on the values of two latent constructs (θ_1 and θ_2).

Summary

Item response models are widely used in assessment and evaluation research to explain how participants respond to item level stimuli. Several R packages can be used to estimate the parameters in various IRT models, however these packages have limitations because they can focus on one-dimensional latent space only. In this paper we present the theory, methodology and application of IRT models for multidimensional latent space.

We presented the mirt package of R software. This package was created for estimating multidimensional item response theory parameters for exploratory and confirmatory models by using maximum-likelihood method. The analysis conducted on real-life data based on Science dataset provides parameter estimates, residuals and graphical presentation of multidimensional IRT model. Using multidimensional latent space we prove that there is a great advantage of additional latent space in describing latent variable.

Sylwia PANGSY-KANIA
University of Gdansk, Poland
E-mail: sylwia.pangsy-kania@ug.edu.pl

Abstract

The article focuses on the importance of economic socialisation with particular emphasis on its impact on the processes of developing a proper model of economic culture conducive to economic growth. In the first, theoretical part of the article, selected concepts relating to the subject of socialisation are presented, including the issue of economic socialisation and its significance for economic culture as well as the related categories. The second part reviews the research conducted on the discussed issues. The research results obtained thereby enabled laying down guidelines for selected initiatives that may stimulate the process of economic socialisation in order to strengthen and develop such a model of economic culture that fosters economic growth. The main research objective was to examine and determine the current level of awareness concerning economic life and how it affects the respondents' behaviour.

Keywords: Creativity, Economic Socialisation, Economic Culture

Introduction

The interest in culture as the primary source of changes taking place in the world is becoming the basis for explaining and interpreting the phenomena occurring in the socio-economic space. Its importance was particularly emphasised as one of the factors contributing to the economic success of Asian countries considerably different from European countries in terms of culture. The intensification of this phenomenon was first observed in the last decade of the 19th century, when as a result of second industrial revolution, urbanisation and the emergence of mass society it was necessary to find conceptual categories that would describe the meaning of the changes taking place (precursors M. Weber, A. de Tocqueville, E. Banfield, K. E. Boulding (Michalski, 2014). As a result of these processes, economic culture is gaining in significance and is increasingly perceived by economists as an important aspect affecting numerous phenomena occurring in the domain of economics. Therefore, in order to present a certain research area and analyse it, the article distinguishes two trends. The first one is of cognitive nature and focuses on the analysis of the source literature. The study investigated foreign and Polish literature which provided the basis for the critical analysis and the research framework. It concerned concepts related to economic socialisation and its significance for the process of creating economic culture. The descriptive and cognitive considerations formed the basis for the analytical considerations. The second, research-oriented, trend focuses on the research conducted in the form of focus group interviews concerning the impact of economic socialisation on the process of economic culture formation. The interviews were carried out with working young students of the Institute of Management, Faculty of Economics, Finance and Management, University of Szczecin. The main research objective was to: examine and determine the current level of awareness concerning economic life and how it affects the behaviour of the respondents, using research procedures and appropriate methodology. The considerations provided the basis for the formulation of the research hypothesis: *The higher the level of the respondents' awareness of economic life, the more correct the model of economic culture conducive to economic development*.

The Concept of Economic Socialisation

Socialisation (*Latin socialis – social*) is a process of change which consists in the acquisition by an individual of knowledge, communication competences, psychosocial skills and a system of values, norms and patterns of behaviour resulting from the influence of the social environment (Encyclopedia PWN, 2020). In other words, it is a process in which an individual adapts themselves to life in society. Hence, it is so important in the formation of culture.

Traditionally, the basis of socialisation was the family and the process itself meant inheritance of a stable hierarchy of values and was functional under conditions of stability of cultural values and invariability of norms and principles of social life. Such an understanding of socialisation lasted until the mid-18th century. Subsequently, the industrial revolution contributed to rapid social change. The inevitable technological changes that accompany contemporary social and cultural conditions may undermine the individual's belief in the traditional hierarchy of values (Juszczyk-Rygałło, 2016). In recent years, the issue of social maladjustment has become particularly important. This is due to the faulty process of socialisation and the greater prevalence of social problems (Skuza, 2011).

Socialisation, due to the influence of social factors on people at every stage of their lives, lasts from birth to death (Checkel, 2017). This process reaches its peak at the stage of early childhood, as this is when life in society begins. Through the social and cultural processes taking place in the child's environment, elements of their personality and value system are formed. The changes also concern the problems of economic life. The turbulent economic environment significantly influences the socialisation process. The process of acquiring knowledge, skills, behaviours and values leading to the comprehension of the principles governing the economic system and taking actions in the surrounding economic reality is defined as economic socialisation.

The history of economic socialisation, which is a part of economic psychology and combines psychology, sociology and behavioural economics, dates back to the 1950s. Research in this area was carried out by Strauss (1952), who distinguished the stages of growing understanding of the concept of money, and Danzinger (1958), who conducted research on a sample of 41 Australian children aged 5-8 years involving a questionnaire of 10 standard questions about various economic processes. The 1980s saw a boom in research on economic socialisation (e.g. research of Berti and Bombi (1988) on the sources of money). In Poland, research on economic socialisation began with the transformation of the economy, when a period of rapid adjustment shock was followed by stabilisation in new economic, political and social conditions (Trzecińska 2012; Harmacińska, Szmelter, 2015).

Economic socialisation concerns both children, youth and adults. However, in the source literature it is predominantly discussed in the context of the childhood period. The concept of economic socialisation includes all the processes by which a child acquires the ability to understand the economic world that surrounds them (Roland-Lévy, 2004; Zaeri, 2016, Otto, Serido, 2017). In sociology, this process is divided into two stages which differ in terms of the intensity of socialisation. The first one, referred to as primary or early, includes infancy and early childhood. The second (secondary, permanent) extends to further years of life (Giddens, 2006). As a result of economic socialisation, the child gains the ability to understand the surrounding world of economy and to function in it (Trzcińska, 2012). In the mind of children and young people, in response to objectively existing phenomena, processes and economic institutions, a subjective image of the world of economics is created, influencing their emotions and behaviour (Goszczyńska, Kołodziej, Trzcińska, 2012). The analysis of economic socialisation of children cannot be considered without reference to Piaget's theory of cognitive development (1966) and Bandra's theory of social learning.

Contemporary economic changes strongly affect the process of economic socialisation of children and youth, including financial (Piageta, 1966) and consumer socialisation (Kołodziejczyk, 2020). However, economic socialisation applies to adults as well. For example, the studies of Moreno, Salcedo, Rebellon, Anzelin (2018) deal with the use and importance of money in students' lives. Its importance is growing especially in the process of developing economic culture.

Children's knowledge of the economic world has a great influence on their perception of the world and the hierarchy of values also when they enter into adult life. Therefore, the role of education (economic socialisation) of children and young people will be crucial as well as the role of school and family to provide children with such knowledge of economics which will allow them to find their place in everyday reality of the modern economy and acquire the ability to understand the economy in its various dimensions. It should be kept in mind that a properly conducted process of economic socialisation creates such a model of economic culture that fosters the development of the country.

Economic socialisation as a component of economic culture

Economic culture as a concept was developed in the early 1980s by P. Berger. The author was inspired by works of G.A. Almond and S. Verby who described civil culture. According to P. Berger, the concept of economic culture does not ultimately include a unidirectional causal relationship. This is to say that it does not assume that culture determines the economy, just as it does not assume that economic factors are always determinants of culture (Berger 1986). In his opinion and in the opinion of the authors of this article the concept of economic culture only directs attention to the existence of such relationships.

According to M. Marody and J. Kochanowicz (2007), economic culture is understood as a system of values, cognitive schemas and patterns of behaviour that are associated with business management. Value systems define what is perceived as good or bad, desirable or undesirable, acceptable or unacceptable, beautiful or repulsive in a society. Cognitive schemas include the categories through which people interpret reality (especially economic reality) and its causal relationships. Behavioural patterns are a set of internalised norms and habits that structure human behaviour. Furthermore, “the concept of economic culture does not include any unidirectional causality, that is to say, it does not assume that culture determines the economy or, vice versa, that economic factors always determine culture. These specific causal relationships may be subject to empirical research in each individual case” (Kochanowicz 2012).

In addition, broadly interpreted economic culture is a part of culture, encompassing behaviours, actions and attitudes related to economic life and human material existence. Economic culture is sometimes understood as the result of actions related to natural phenomena, however somehow contrary to nature, i.e. as an order imposed by man, and simultaneously as a tool for satisfying human needs and a method of achieving goals in the area of material existence (Kozera, 2007).

According to A. Sokół (2018), economic culture is one that refers to the national context in which value systems, patterns of behaviour (not necessarily conscious) of social groups or individuals relevant for their economic activity are characteristic, taking into account their cognitive and adaptive abilities in this respect. It individualises the characteristics of those nations which use this cultural category effectively enough as to create added value in the economy, thus contributing to economic growth. Therefore, the analysis of economic culture conducted in this article allows the identification of two intertwining areas that produce value as a result of mutual interaction. These include the general dimension of national culture and economic culture. Thus, the proposed research category is primarily a broadly defined interdependence at the level of the nation, including economic aspects, which by means of appropriate tools influences the behaviour of all business entities (figure 1).

Figure 1: Elements of national economic culture

Source: The author's own work.

To sum up, economic culture may be defined as a category of phenomena related to the economy, specific values, cognitive schemas and patterns of behaviour, as well as views on how economic life should be organised (Krzeminiewska, 2013). Economic culture may be interpreted from two angles. The first one refers to a catalogue of all these values, cognitive schemas and behaviour patterns relevant to economic activity. The second one distinguishes the main factors affecting the evolution of cultures, standardising them on several dimensions or around the central points of analysis, each of which may be crystallized in terms of more concrete problems or questions (Marody, Kochanowicz, 2007 after: Krzeminiewska, 2013).

Therefore, in the light of the discussion above, it seems appropriate to include certain areas in the definition of economic culture. The aim of the applied concept is to seek appropriate representations of the cultural context relating to economic characteristics, also allowing research of a nomothetic nature as well as the inclusion of cultural "multidimensionality" – a simultaneous analysis of many cultural characteristics.

The analysis of the components affecting the model of economic culture included the following categories: economic socialisation, attitude to money and saving, consumption, economic aspirations, evaluation of social reality, value system, skills, economic knowledge, attitude to work and entrepreneurship (Krzeminiewska, 2010). On the basis of the already existing papers on the subject and by modifying the above model, the following components will be taken into account in this article: economic socialisation, attitude to money, saving and investment, consumption, economic aspirations, evaluation of social and economic reality, value system, competences, economic knowledge, attitude to work and entrepreneurship, attitude to law and property, attitude to wealth and inequality, business ethics, attitude to creativity and innovation. Having regard to the aim of the article, it seems interesting to indicate the importance of economic socialisation in the development of economic culture.

Material and Method

The empirical verification of the hypothesis formulated in the article about the level of the respondents' awareness of economic life and its influence on the proper model of economic culture conducive to economic development. This phenomenon is definitely of a qualitative nature and therefore difficult to measure. In addition, any attempt to assess it is (or may be) subjective, depending on the degree of maturity and the ability of participants to objectively assess the phenomenon. Despite these limitations, an attempt was made to study the respondents' awareness of economic life in relation to the phenomenon of economic culture on the basis of focus group interviews. The interviews were carried out with working young students of the Institute of Management, Faculty of Economics, Finance and Management, University of Szczecin.

Research Results

The article presents the scope of issues related to own research. The area of research on the presented subject matter includes the analysis of the discussed issues both on the theoretical (literature studies) and empirical (focus group interviews) basis (figure 2).

Figure 2: The scheme of aims and research tasks

Source: The author's own overview.

Based on the application of appropriate research methods and procedures, the concept of economic socialisation and its impact on the model of economic culture was defined. This means that specific

methods were used in the research: analysis, synthesis, induction and deduction. The answer to the following research questions will conclude the conducted research: *does, in the opinion of the respondents, economic socialisation affect the formation of a proper model of economic culture? What improvements should be made if economic socialisation were to support the process of development of economic culture in Poland?*

Therefore, the following hypothesis has been formulated: *The higher the level of the respondents' awareness of economic life, the more correct the model of economic culture conducive to economic development.*

As part of qualitative research, focus group interviews (FGI) were conducted. A discussion was held in which phenomena related to the issue of economic socialisation and its impact on developing processes were analysed. Focus group interviews were conducted in a group of working young students in December 2019. The group consisted of participants between 19 and 30 years of age. The group consisted of 8 people (6 of whom were women).

As part of the focus study, at the beginning of the discussion participants were asked about the definition and role of economic socialisation in the process of developing economic awareness of citizens. Unfortunately, only 3 respondents were able to indicate what socialisation, including economic socialisation, is associated with. One of them believed (they gave the most precise answer) that "it includes different kinds of processes taking place in an individual's environment which make it easier for them to understand and navigate through the economic space. This makes such a person more or less susceptible to influence, especially an adverse influence in this area". This particular person was then asked how they learned about the concept of socialisation, including economic socialisation. It turned out that this person graduated in sociology and is interested in psychology, currently is attending studies in the field of economics. The remaining two persons who also answered the question about the concept of economic socialisation, defined it as a process of adaptation of an individual to the surrounding conditions. Taking into account the above answers, it may be concluded that, unfortunately, the remaining participants have not often come across this concept or considered aspects related to these terms. It is difficult to assess this situation as negative or positive for Polish society. However, it is worth noting that these were students in the fields related to economics. This indicates that Polish higher education institutions fail to provide complete knowledge about economic socialisation.

Then, after the respondents were informed how to understand the concept of economic socialisation, they were asked who in the society, in their opinion, affects the understanding of economic life to the greatest extent. They were requested to include the period of early childhood (up to 5 years) and the current period. The answers obtained indicated that the economic attitudes and perception of economic life by the respondents in the early years of their lives I predominately determined by the family. Thus, this space influences the life goals and level of aspirations and values of the individual in the future. The level of economic socialisation at this stage takes place rather unconsciously, according to the respondents, the child, observing the behaviour of those around them, attempts to adopt the models considered by the family as appropriate. However, in the later and current period, the media, school and friends are of particular importance to the respondents. In particular, the respondents pointed to the high position of the media which affect current attitudes towards economic life and its related processes.

Then the participants were asked *where they obtain their economic information from and what economic topics they are especially interested in.* The answers included: economic websites, newspapers, conversations with family and friends, including information derived from work (this source of information was indicated by 4 respondents). Then, to further explore the topic, the respondents were asked *what economic issues are important to them.* Three persons indicated that they were primarily interested in financial information, two persons were interested in economic trends and the remaining persons stated that they looked for economic information when they needed it to carry out their official tasks. Moreover, the respondents are particularly interested in foreign exchange markets and economic trends in Poland.

The participants were also asked *if, in their opinion, the process of economic socialisation during childhood and later period was conducted properly and if economic issues were frequently discussed in their families.* Only 2 respondents out of 8 considered that they could discuss the topic of economic socialisation in their families. Their interests and current activities in the family, especially in the financial sphere, have allowed them to have greater knowledge of the economy.

Therefore, another aspect addressed in the discussion related to the factors that the respondents would include among the most important determinants of economic socialisation. According to the respondents, one of the factors that could particularly raise the economic awareness is the introduction of classes on economic basics and entrepreneurship regardless of the field of study. This, in their opinion, would contribute to a more informed society that understands these kinds of processes taking place in the country.

When asked *whether, in their opinion, economic socialisation influences the model of economic culture,* the majority of respondents replied that economic socialisation determines the model of economic culture. The respondents were asked to justify this opinion. They responded that economic socialisation forms the basis for many other factors that affect the model of culture (the respondents were provided with the definition of the components of economic culture adopted by the authors of this article and the meaning of these terms). Namely, it is closely related to and significantly affects, according to the respondents, economic knowledge, attitude to money, saving and investment, consumption, economic aspirations, assessment of social and economic reality, the system of adopted values, competences, attitude to work and entrepreneurship, attitude to wealth and inequality, business ethics, attitude to creativity and innovation.

In the summary of the study, the participants noted that the analysis of and discussion about the phenomenon allowed them to recognise diversified aspects of economic culture as one of the most important distinguishing features of its development in economic socialisation. Therefore, the panel participants (8 persons) had no doubt that economic socialisation exerts a significant impact on the proper model of economic culture. Thus they support the hypothesis that *the higher the level of the respondents' awareness of economic life, the more correct the model of economic culture conducive to economic development*.

Summary

Economic socialisation as a research category is becoming increasingly popular. There are more and more studies presenting the new context of the issue. In spite of that, the concept is still poorly recognised in economic sciences in the theoretical and empirical terms. Detailed analyses which examine the impact of economic socialisation on the model of economic culture are rare. The conclusions reached in this study allow the authors to indicated and support the hypothesis that *the higher the level of the respondents' awareness of economic life, the more correct the model of economic culture conducive to economic development*. It should be noted that socialisation is achieved through specific social teaching which engages the individual in a culture of work based on economic knowledge and its technical and technological forms in the professional environment and everyday life. In addition, the study showed that a modern educational institution, which is the carrier of economic socialisation, is able to realise the idea of a learning economic community in which every student represents fairly well what they do, how to do it and why.

Considering the development of economic socialisation and its impact on economic culture in a given space, whether urban or regional, local authorities should pay particular attention to the aspects mentioned above, as they form important components contributing to the development of a proper economic culture model that promotes economic growth. Attention to the development of these key aspects also leads to the improvement in the life of the inhabitants of a given territory. By intensifying the process of economic socialisation through various initiatives, the authorities ensure long-term economic development.

Researches on The Recovery of Aquatic Productivity in The Basins Located in The Southern Region of Moldova

Mihaela MUNTEANU PILA and Silvius STANCIU

„Dunărea de Jos" University of Galați, Romania

mihaela_pila@yahoo.com; sstanciu@ugal.ro

Abstract

This paper presents research regarding the exploitation of the fishing potential in the Southern region of the Republic of Moldova. The aim of this document is to assess the productivity of five ponds from the Southern region of the country, namely the determination of phytoplankton, zooplankton biomass and the evolution of growth and development of fish species. An important task for increasing the productivity of fish farms, is to populate the pond with broods of fish species of high economic value, to provide the pond with generations of breeders of these species, as well as to maintain the highly productive characteristics of the pond, (detritus, phytoplankton, zooplankton), essential food for indigenous fish species. Fish production in natural reservoirs is an essential part of the biological productivity related to the formation and maintenance of the aquatic biomass. Therefore, the issues affecting the effectiveness of aquaculture development in the Republic of Moldova can be conditionally grouped into external and internal factors. External factors include low investments, insufficient level of technical material and scientific support. The internal factors depend directly on: the level of the anthropogenic damage to the pond, the optimal use of the material to populate, water resources and the natural reserves of the pond.

Keywords*:* Productivity, Republic of Moldova, ponds.

Introduction

The efficient development of fisheries in the southern region of the Republic of Moldova, ensures the achievement of a quality production, indigenous and safe products for the population of this region. The productivity of a pond is often hampered by pollution due to the uncontrolled entry of manure, pesticides, fertilizers from the agricultural land, as well as of the industrial wastes, where the insufficient self-cleaning leads to a negative impact as well as to risk factors over the reservoir ecosystem. In this respect, it is relevant to apply and improve a systematic water control, taking into account the rules and requirements of worldwide standards. In the last decades, due to the anthropogenic factors that influenced directly and indirectly the ichthyofauna, related to which, there have been significant changes in the structure of ichthyocenosis, the proportion of species such as carp, avat, bream, has decreased significantly, and the dominant species are the mullet, Aspius and the crucian carp. By the end of the 70s of the last century, the ponds represented 55-65% of the surface, at the end of the 90s it decreased to 30-40%, and in 2005 the surface of the ponds from the southern region of the Republic represents 15-20%. Due to the drought from the last years for which many ponds have dried up or are used for other uses (agricultural land), or have been abandoned, where no measures have been taken in order to rehabilitate the wetlands in the area.

Short Literature Review

A feature that represents damage to the "pond" is the intensive development of algae *(Aphanizomenon flos-aquae)*, causing "water bloom". Algae decomposition causes significant fish death and inhibition of zooplankton development, essential feed for carp *(Cyprinus carpio)*, Bighead carp *(Aristichthys nobilis),* and other indigenous fish species, leading to decreased productivity or extinction of the wetland for fish recovery - sloughing, (Prusevich, Egorov, 2013). The most significant factors hindering the development of aquaculture in the Republic of Moldova include: reduced investments

and insufficient level of technical material and scientific support (Condition and perspectives of freshwater aquaculture development, 2013). Certain individual characteristics are significant for each hydrobiont, which allows us to assess the ecosystem to the extent that it has been directly or indirectly affected by anthropogenic pollution. In order to assess the ecological status of the natural aquatic ecosystems in the southern area of the Republic of Moldova, analysis is being carried out annually, in order to determine the status of each ecosystem. This step is carried out by the National Integrated Water Monitoring System, in accordance with the provisions of the Water Framework Directive 2000/60 / EC and other water directives (Annual Report, 2015).

Material and Methods

This paper was drafted based on a research of the functional state of the natural reservoirs (ponds), of production, growth, capitalization and potential, in the southern region of the Republic of Moldova. The objects of study of this paper consisted in the research and differentiation of the productivity of ponds located in different localities (Taraclia, Pelinei, Taraclia de Salcie, Libidenco, Bucuria) of the Southern region of the Republic of Moldova. Some data were collected from books and specialized papers and compared with real data (research) for a proper interpretation. Data collected were sorted, differentiated and statistically processed.

Productivity of ponds in the Southern Region of the Republic of Moldova

In the Republic of Moldova most of the aquaculture production (over 85%) is destined for ponds, with the growth of several species of fish (polyculture). Fish production in natural reservoirs is an essential part of the biological productivity related to the formation and maintenance of the aquatic biomass. The qualitative and quantitative aspects of this process depend on the characteristics of the reservoir, including the behavior and structure of the ichthiocenoses. Out of the total number of ponds in the Republic of Moldova, the eutrophic type predominates, where the ichthyofauna is dominated by cyprinids (crucian carp, silver carp, Bighead carp, carp, bream, mullet). In terms of nutrition for fish in the natural environment, benthos and zooplankton predominate, which are a specific food for young brood (until passing to the specific feed). The zoobentos resources (oligochaetes, chironomid larvae and some insects) are consumed completely by the indigenous fish. The main natural reserves represented by macrophytes, debris and phytoplankton allow to increase the productivity of a pond with 25%. The case study proposes the assessment of 5 fishing ponds, located in the southern region of the Republic of Moldova.

For pond 1 (Taraclia) the average annual fish production varies 50 tons fish / 50 ha
For the pond 2 (Pelinei) the annual fish production varies 10 tons fish / 2ha
For pond 3 (Libidenco) the average annual fish production varies 800 kg fish / 1.2 ha
For pond 4 (Taraclia de Salcie) the average annual fish production varies 8 tons fish / 6 ha
For pond 5 (Bucuria) the average annual fish production varies 700 kg fish / 0.43 ha

Fig. 1: Productivity of each pond in the southern region of the Republic of Moldova.
Source: Own research

The catch structure of each fish pond is made up of 5-7 species of fish from the Cyprinids family. Of the fish species the carp *(Cyprinus carpio)* 11%, the mullet *(Rutilus rutilus)* 6.2%, the silver carp *(Hypophthalmichthys molitrix)* 27%, the bighead carp *(Aristichthys nobilis)* 23%, the crucian carp *(Carassius gibelio)* 12%, the bream *(Abramis brama)* 1.7%, and the Aspius *(Aspius aspius)* 1.2% (figure 2).

Fig. 2: Types of catch fish from ponds in the southern area of the Republic of Moldova
Source: Own research

In the ichtyofauna of the ponds where the bream *(Abramis brama)* predominates, a species of fish from the Cyprinids family, and the bentofag proportion fluctuates between 57.9% and 88.4%, with an average of about 72%. This suggests that in some ponds from the Republic of Moldova zoobentos from the natural environment is very necessary for many species of fish, since many ponds are foddered in a smaller proportion or the abandoned ones do not fodder at all.

Currently, the increase in the costs related to feed, vitamins, the maintenance of filtration and water supply systems, amendments to capitalize the pond potential limit the possibility of increasing the large volumes of fish production through traditional methods of growth. As a result, the fish farm cannot provide, upon the consumers'request, quality fish for a low price.

One of the real ways to increase productivity in ponds is the annual popularizations with fish species, usually being used grass carp, bighead carp, carp. In addition to achieving a valuable production, herbivorous fish fulfill a significant function of pond recovery, using as food phytoplankton (bighead carp) and macrophytes (grass carp).

The phytoplankton biomass in some ponds from the southern region of the Republic of Moldova, such as those from the city of Taraclia, is quite high, which means a significant reserve that can be used as food for growing the grass carp. On average, in the research area, the phytoplankton biomass during the spring period can reach up to 3.81 g / m3 with fluctuations between ± 0.72 - 3.24 g / m3. In summer, biomass and abundance of phytoplankton, as a rule, grows: as part of the increase in phytocenosis, namely blue-green algae. During the period July-August, the phytoplankton biomass reaches the maximum values, in an average value of 3.86 g / m3 (determined by analysis in 2018, by the Water Quality Monitoring Directorate, Cahul), represented in figure 3.

As a result, the complete use of phytoplankton in natural reservoirs can ensure fish productivity of the grass carp up to 21- 99 kg / ha.

Fig. 3: Phytoplankton biomass determined in the pond from Taraclia locality.
Source: Own research

In this sense, the introduction of the grass carp in the pond represents a significant ecological function for the ecosystem. The natural nutrition of this fish determines a high trophic plasticity, namely the ability to restore the trophic chain in the ecosystem. This property, which is significant from the improvement point of view, allows the growth and use of this species in order to clean the ponds, water self-filtration mechanism, and a positive process for the growth of other valuable fish species.

Research on some eutrophic ponds in the southern region of the Republic of Moldova, (pond from Bucuria, Libidenco and pond from Pelinei), on biological production and the level of development of fish farming has determined a minimum or practically absent nature reserve, which determines the use of higher costs for feed (for herbivorous species).

The pond from Bucuria locality, at certain times of the year, cannot intervene independently, namely in the years with low humidity it has led to the overcrowding of its upper level with aquatic (harmful to fish) vegetation, reporting that the pond has an area of 0 ,43 ha, which led to the decrease in oxygen, light, and volume of water mass, which leads to the superficial and almost complete drying of the area. In recent years (2017-2019), zooplankton and phytoplankton biomass from the pond, from March to the middle of June does not usually exceed 1.0 g / m3, which does not cover the vital needs of the fish, which has led to a low fish surviving population in this area.

Especially for the use of fish farming in several natural water bodies examined, where pond feeding is essential, the coefficient of feed consumption for the pond is achieved by determining the surface area of water and the production we have in the pond, by daily assessing the dynamics of the positive factor of the food ration over each species in the pond, related to the net final product that we want to obtain. A well-developed pond is considered valuable if its aquatic fauna represents a variety for fish breeding. Of which in the water mass the zooplankton should represent 72-100% and the zoobenthos 50-100%. Another significant factor for capitalizing the productivity in the ponds of the country, may be the replacement of species with low economic value, (as for example: mullet) with more productive fish (Aspius, bream, carp).

Because the additional introduction of bentophages with the purpose to increase the productivity of the pond, without a suitable decrease in fish population (with low economic value) will not provide a favorable result. That is why, often in the ponds of the country, the carp is found in smaller quantities. Because not taking into account these factors will give a negative result to the repeated introduction of this species. This process has been proved by (Costousov V, 2013) by the fact that the proper removal of a species of indigenous (non-valuable) fish will decrease the feeding rate of a valuable fish and thus the pond will be considered unproductive.

Conclusion

In the Republic of Moldova most of the aquaculture production (over 85%) is destined for ponds, for polyculture growing of indigenous fish species. The qualitative and quantitative aspects of this process depend on the characteristics of the reservoir, including the behavior and structure of the

ichthiocenoses. The prospect of restoring and developing productivity is determined by the state of the pond, and the level to which it was affected anthropically. decreasing the density of development of harmful algae for fish is possible by: introducing organic and mineral fertilizers, aerating as much as possible the pond (pond bottom), periodically discharging the pond for breeding purposes. In order to capitalize on the productivity of ponds in the southern region of the Republic of Moldova, it is essential to replace species with low economic value, (mullet) with more productive fish (Aspius, bream, carp), as well as the growth of herbivorous fish (considered natural water filters) for plasticity. high trophics, and additional cleaning of the pond.

The EU Enlargement Policy – the EU-28 Extra Trade Issues

Oksana KIFORENKO
Uman National University of Horticulture, Uman, Ukraine, ok.kiforenko@gmail.com

Abstract

Today's European Union, with its 28 Member States (27 nowadays – author.) and a population of approx. 500 million, is the result of an integration and enlargement process of more than half a century, which is continuously evolving. The EU's enlargement policy deals with the countries currently aspiring to become members of the European Union. The European Union's enlargement policy has traditionally been described as the EU's most successful foreign policy. Extra-EU refers to transactions with all countries outside of the EU: the rest of the world except for the European Union Member States. International trade - especially the size and evolution of imports and exports - is an important indicator of the performance of the EU economy, showing how it interacts with other countries and its position. The structure of the EU trade in goods by top 5 partners both in terms of imports and exports was analyzed in the article. The dynamics of the EU-28 extra total trade turnover was analyzed and the trend line of it was built using one of the functions available for the purpose, taking into account the R^2 value. The dynamics of such constituents of the EU-28 extra trade as exports, imports, trade balance and exports to imports ratio were analyzed by the author. The trend lines were built using the appropriate functions, taking into account the R^2 coefficient value. Two periods of time (years) were taken for the projection of the trend line direction of each component of the EU-28 extra trade under analysis.

Keywords: enlargement policy, the European Union, extra trade, total trade turnover.

Introduction.

The European Community for Coal and Steel, the European Economic Community and Euratom, founded in 1951 and 1957 respectively, are at the origin of the European Union. The European Union was founded with the aim to promote peace, security and prosperity throughout Europe and is based on a commitment to common values such as democracy, the rule of law, freedom and human rights and the single market. The enlargement process goes hand in hand with the deepening of the cooperation between the Member States. Successive enlargements have shaped the history of the European Union. Up to now, seven enlargement rounds have taken place: 1973 (Denmark, Great Britain, Ireland), 1981 (Greece), 1986 (Portugal, Spain), 1995 (Austria, Finland, Sweden), 2004 (Czech Republic, Cyprus, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia and Slovenia), 2007 (Bulgaria, Romania) and 2013 (Croatia) (Austrian Embassy in the US, 2020).

The EU's enlargement policy deals with the countries currently aspiring to become members of the European Union. There are strict conditions for membership to ensure that new members are admitted only when they are fully able to take on the obligations of EU membership. This includes compliance with all the EU's standards and rules. For the purpose of accession negotiations, these are divided into 35 different policy fields (chapters) (European Commission, 2020).

Extra-EU refers to transactions with all countries outside of the EU: the rest of the world except for the European Union (EU) Member States. The term is used in the context of external trade, balance of payments, foreign direct investment, migration, transport, tourism and similar statistical areas where goods, capital or people moving in and out of the EU are being measured and where the EU as a whole is considered in relationship to the rest of the world. Extra-EU transactions of the EU as a whole are the sum of the extra-EU transactions of the EU Member States. …the EU has not always had the same composition, due to consecutive enlargements. For this reason, both terms (extra-EU

and intra-EU – author.) are sometimes further qualified as 'extra-EU-15', 'intra-EU-25' etc.; 'extra-EU-15', for instance, refers to the rest of the world apart from the 15 Member States that in the past made up EU-15 (Eurostat, 2020 (1)). International trade - especially the size and evolution of imports and exports - is an important indicator of the performance of the European Union (EU) economy, showing how it interacts with other countries and its position (Eurostat, 2019).

The aims of the paper are: 1) to describe the main stones of the EU enlargement policy; 2) to analyze the structure of the EU trade in goods in 2018 by top 5 partners both in terms of imports and exports; 3) to analyze the dynamics of the EU-28 extra total trade turnover and to build the trend line of it using one of the functions available for the purpose, taking into account the R^2 value. The list of functions to choose from in order to build the trend line of the data mentioned above comprise the exponential, linear, logarithmic, polynomial and power ones. Among the aims of the paper one should state the dynamics of such constituents of the EU-28 extra trade as exports, imports, trade balance and exports to imports ratio analysis. The trend lines of the data mentioned above were built using the appropriate functions, taking into account the R^2 coefficient value. Two periods of time (years) will be taken for the projection of the trend line direction of each component of the EU-28 extra trade under analysis as the EU budget covers a period of 7 years (the Multiannual Financial Framework - MFF) and the most recently approved Multiannual Financial Framework covers the period of 2014 to 2020. Though the United Kingdom of Great Britain and Northern Ireland ceased its membership in the EU at the beginning of the year 2020, the negotiations on the major number of the trade contracts are to be held through the whole year 2020 and the possibility of the negotiations continuation in the following year as well still exists.. More than that, under the given circumstances of nowadays, it is not considered to be scientifically sound to take a longer time frame for making predictions than two periods.

Problem Solution.

Today's European Union, with its 28 Member States (27 nowadays – author.) and a population of approx. 500 million, is the result of an integration and enlargement process of more than half a century, which is continuously evolving (Ministry for Foreign Affairs of Romania, 2020). The European Union's enlargement policy has traditionally been described as the EU's most successful foreign policy because it has managed to trigger the expansion of the democratic ideal across the European continent. The EU's ability to peacefully spread these ideals derives from the political conditionality that defines the accession of any country to the EU, which requires any candidate to converge towards the EU's principles of democracy, open market and protection of human rights (Pérez-Solórzano N., 2015). Candidate countries must prove they will be able to fully assume the role of Members of the Union. To this end, they must obtain citizens' support and meet strict European standards and rules of a political, legal and technical nature. Countries wishing to join the EU can cover the various stages of the integration process only when all conditions for each stage have been met. The complex procedures for being admitted into the EU guarantee that the new Member States only join the Union when they fulfill all requirements and when all EU institutions, the governments of Member States and their own governments have actively expressed their consent. The prospect of integration therefore serves as an incentive to promote reforms. The EU's enlargement policy guarantees that this process is thoroughly managed so that accession can be beneficial to both parties involved, the EU and the acceding countries (Ministry for Foreign Affairs of Romania, 2020).

Europe is the world's largest exporter of manufactured goods and services, and is itself the biggest export market for around 80 countries. Trade is an important indicator of Europe's prosperity and place in the world, and the bloc has become deeply integrated into global markets both for the products it sources and the exports it sells. Because the 28 Member States of the European Union (27 nowadays – author.) share a single market and a single external border, they also have a single trade policy. Both in the World Trade Organization, where the rules of international trade are agreed and enforced, and with individual trading partners, EU Member States speak and negotiate collectively (Eurostat, 2019). For example, in 2018, the United States (€674 billion, or 17.1% of total extra-EU trade in goods, i.e. the sum of exports and imports) and China (€605 bn, or 15.4%) continued to be the two main goods trading partners of the European Union (EU), well ahead of Switzerland (€265

bn, or 6.7%), Russia (€254 bn, or 6.4%), Turkey (€153 bn, or 3.9%) and Japan (€135 bn, or 3.4%) (Eurostat Newsrelease, 2019). To illustrate the last paragraph, let's follow the structure of the EU trade in goods by top 5 partners in terms of imports in Figure 1.

Source: based on the data from Eurostat (Eurostat, 2020) (1).

Figure 1. The EU Trade in Goods (Imports) by Top 5 Partners in 2018, %

As we see from the figure given above, the main trade partner of the European Union in terms of goods imports in 2018 was China, which accounted for about 20% of the overall amount of the goods imported into the EU. The second place was taken by the United States of America with their 13% and the third place was taken by Russia, from which the European Union imported 8% of the goods. The forth and the fifth places, in terms of the amount of goods imported into the EU, were taken by Switzerland and Norway respectively. To proceed with the research, the structure of the EU trade in goods by top 5 partners in terms of exports can be followed in Figure 2.

Source: based on the data from Eurostat (Eurostat, 2020 (1)) .

Figure 2. The EU Trade in Goods (Exports) by Top 5 Partners in 2018, %

As it can be seen from the figure given above, the main partner of the European Union in terms of the goods exports in 2018 was the United States (21%). After the US, China (11%) and Switzerland (8%) came followed by Russia and Turkey (4% each). The analysis of two figures given above confirms once more the statement that China and the US were the most important trade partners of the European Union in 2018 in terms of the international trade. What is also worth paying attention at is Turkey – though it comprises "only" 4% of all the goods exported from the EU, its aspirations to become the EU-member could benefit the EU in the direction of the continuing enlargement of the

goods exports thanks to the economic benefits of being inside the EU market, meaning – the simplification of the border crossing, customs clearance, currency exchange and payments procedures, etc.

If we look at the main destinations of the EU exports in terms of the continents, we'll see, that the main destination for the EU exports in 2018 was Asia accounting for about one third of the total, followed by North America (28 %) and other European countries (22 %) (Eurostat, 2020 (1)) .

To see how the EU enlargement policy influenced the EU-28 extra trade, let's follow the data in figures given below as well as their analysis presented. The dynamics of the EU-28 extra total trade turnover can be followed in Figure 3.

Source: author's own elaboration on the basis of the data from the (Eurostat, 2020 (2)).

Figure 3. The EU-28 Extra Total Trade Turnover, bln EUR

The data in Figure 3 point to the fact that the largest amount of the EU-28 extra total trade turnover can be observed in 2019 and the smallest – in 2014. The biggest increase of the said total trade turnover is observed in 2018 and the biggest decrease – in 2016. There is no one clear trend in the said trade turnover either as we can see the increase of the trade turnover mentioned above in 2015 followed by the decrease in the amount of the total trade turnover of the EU-28 in the next year. The downward tendency didn't last during the next year and was changed with the upward one in 2017, which, in turn, last till the end of the time frame under analysis. The trend line was built using the polynomial function, taking into account the R^2 value. The said line is upward during the whole time frame under research and continues to be of the kind during two more periods of time, that is years, taken for the projection. As the beginning of the time frame under analysis is the year 2014, that is the first year after the last EU enlargement, the dynamics of the data under analysis shows us the impact of the EU enlargement policy on the trade relations and the result of the said relations, that is the amount of the total trade turnover of the extra-EU trade. The upward trend of the total trade turnover mentioned above testifies to the fact that the EU enlargement policy has a positive economic impact on the EU as a whole and its extra trade turnover in particular. To continue the research, let's follow the dynamics of the EU-28 extra trade (exports) in Figure 4.

Source: author's own elaboration on the basis of the data from the (Eurostat, 2020 (2)) .

Figure 4. The EU-28 Extra Trade (Exports), bln EUR

The dynamics of the exports in the EU-28 extra trade is very much like the one of the EU-28 total trade turnover, that is an increase in 2015, followed by the decrease in the next year plus the increase of the exports amount in 2017 continued during the whole time frame under analysis. The biggest increase of the amount of exports in the EU-28 extra trade can be observed in 2017 and the biggest decrease (and the only one) – in 2016. The trend line of the dynamics of the said exports was built using the polynomial function, taking into account the value of the R^2 coefficient. The trend line is upward during the whole period of time under analysis and continues to be like that during two periods of time, that is years, taken for the projection. The next step of the research is the analysis of the EU-28 extra trade in terms of the imports, which can be followed in Figure 5.

Source: author's own elaboration on the basis of the data from the (Eurostat, 2020 (2)).

Figure 5. The EU-28 Extra Trade (Imports), bln EUR

As we see from the data depicted in Figure 5, the general dynamics of the EU-28 extra trade (imports) is not homogeneous, that is there is an increase in the amount of imports mentioned above in 2015 which was substituted by the decrease in the next year, that, in turn, was changed in 2017 with another increase and the latter tendency continued till the end of the time frame under analysis. The biggest increase in the amount of the EU-28 extra trade (imports) can be observed in 2017 and the biggest (and the only) decrease – in 2015. So, we see that the general dynamics of the EU-28 extra trade in terms of imports is like the ones of the total trade turnover and of the exports mentioned

above. The trend line of the imports amount dynamics mentioned above is built using the polynomial function taking into consideration the R^2 value. The trend line built is upward during the whole period of time under analysis and continues to be of the kind for two periods of time, that is years, taken for the projection. As we see, thanks to the EU enlargement policy with the establishment of the new commercial, trade, logistics, etc. relations and the expansion of the existing ones, the general trend of the EU-28 extra trade in terms of imports through the whole time frame under analysis is upward showing us the positive impact of the said policy on the EU benefits from the trade relations.

The dynamics of the EU-28 extra trade balance can be followed in Figure 6.

Source: author's own elaboration on the basis of the data from the (Eurostat, 2020 (2)).

Figure 6. The EU-28 Extra Trade Balance, bln EUR

When we cast a look at the figure given above, we'll see that the dynamics of the said trade balance is not one and the same during the time frame under research, that is we see the increase of the balance mentioned above in 2015, followed by the decrease in the year 2016, which continued til the end of the time frame under research. The biggest decrease of the said balance can be observed in 2018, that is in this year there was the biggest difference between the exports and the imports of the trade under analysis. The only increase of the said balanc can be seen in 2015. The trend line was built using the polynomial function. It should be added here that there was not such a big number of functions avalable for the trend line building in this case as two values are negative. The trend line is downward and continues to be of this kind during two more time period of time (years) taken for the projection. This fact can be explained in the following way – the difference between the exports and the imports of the EU-28 extra trade would be decresing to the direction of the imports prevailing over the exports. The dynamics of the exports to imports ratio of the EU-28 extra trade can be followed in Figure 7.

Source: author's own elaboration on the basis of the data from the (Eurostat, 2020 (2)).

Figure 7. The EU-28 Extra Trade Exports to Imports Ratio

If we look at the figure given above, we won't observe one clear tendency in the EU-28 extra trade exports to imports ratio – it increased 0.03 points in 2015 but in the next year we can see the decrease of the said ratio of 0.02 points. The downward tendency, written about in the latter sentence, continued during two following years as well being changed only in 2019 as in this year the said ratio had the same value as in the previous year. The biggest decrease of the ratio mentioned above is obseerved in 2016 and 2018 and the only increase was in 2015. The trend line of the data dynamics depicted in Figure 7 was built using the ploynomial function taking into account the value of the R^2 coefficient. The said trend line is downward after the year 2016 and remains of the kind during two time periods, that is years, taken for the projection.

Conclusions.

European integration has been one of the fundamental goals of the European Union since its establishment (Ministry for Foreign Affairs of Finland, 2020). Enlargement is widely hailed as the EU's most successful foreign policy tool. Over the past four decades, the European Community (which became the European Union in 1993) managed to transform itself from a club of six Western European democracies to the world's largest economy, encompassing 28 countries (27 nowadays – author.) and half a billion people (Brunet L.A., 2013). Legal matters and fighting organised crime and corruption must remain at the core of the EU's enlargement policy. Economic matters, such as growth, competitiveness, and management of general government finances as well as a well-functioning public administration belong to the three pillars of the enlargement process (Ministry for Foreign Affairs of Finland, 2020).

Europe is the world's largest exporter of manufactured goods and services, and is itself the biggest export market for around 80 countries. Trade is an important indicator of Europe's prosperity and place in the world, and the bloc has become deeply integrated into global markets both for the products it sources and the exports it sells. Because the 28 Member States of the European Union (27 nowadays – author.) share a single market and a single external border, they also have a single trade policy (Eurostat, 2019).

If we talk about the EU-28 extra trade, then it should be pointed out that there is no one clear trend in the EU-28 extra trade turnover as we can see the increase of the total trade turnover mentioned above in 2015 followed by the decrease in the amount of the total trade turnover of the EU-28 in the next year. The downward tendency didn't last during the next year and was changed with the upward one in 2017, which, in turn, last till the end of the time frame under analysis. The trend line was built using the polynomial function, taking into account the R^2 value. The said line is upward during the whole time frame under research and continues to be of the kind during two more periods of time,

that is years, taken for the projection. As the beginning of the time frame under analysis is the year 2014, that is the first year after the last EU enlargement, the dynamics of the data under analysis shows us the impact of the EU enlargement policy on the trade relations and the result of the said relations, that is the amount of the total trade turnover of the extra-EU trade. The upward trend of the total trade turnover mentioned above testifies to the fact that the EU enlargement policy has a positive economic impact on the EU as a whole and its extra trade turnover in particular.

The dynamics of the exports in the EU-28 extra trade is very much like the one of the EU-28 total trade turnover, that is an increase in 2015, followed by the decrease in the next year plus the increase of the exports amount in 2017 continued during the whole time frame under analysis. The trend line of the dynamics of the said exports was built using the polynomial function, taking into account the value of the R^2 coefficient. The trend line is upward during the whole period of time under analysis and continues to be like that during two periods of time, that is years, taken for the projection. The further enlargement of the EU either in the Balkan or East direction will benefit the EU extra trade in terms of its goods exports thanks to the acquirement of the new markets for goods exports as well as the simplification of the logistics, customs and currency exchange and payments procedures. Among the greatest beneficiaries of the further EU enlargement in terms of the goods exports one should mention such export oriented EU members as Germany, the Netherlands and France.

The general dynamics of the EU-28 extra trade (imports) is not homogeneous, that is there is an increase in the amount of imports mentioned above in 2015 which was substituted by the decrease in the next year, that, in turn, was changed in 2017 with another increase and the latter tendency continued till the end of the time frame under analysis. The trend line of the imports amount dynamics mentioned above is built using the polynomial function taking into consideration the R^2 value. The trend line built is upward during the whole period of time under analysis and continues to be of the kind for two periods of time, that is years, taken for the projection. The major beneficiaries of the further EU enlargement in terms of the goods imports are supposed to be the countries which took the first three places concerning the amount of the imported goods in 2018, namely – Germany, the United Kingdom and France. The fact that those countries are placed among the major beneficiaries of the EU enlargement in terms of the goods exports as well means that those countries are the EU's major players in international trade.

The dynamics of the EU-28 extra trade balance is not one and the same during the time frame under research, that is we see the increase of the balance mentioned above in 2015, followed by the decrease in the year 2016, which continued til the end of the time frame under research. The trend line was built using the polynomial function. The trend line is downward and continues to be of this kind during two more time period of time (years) taken for the projection.

We don't observe one clear tendency in the EU-28 extra trade exports to imports ratio – it increased 0.03 points in 2015 but in the next year we can see the decrease of the said ratio of 0.02 points. The said downward tendency continued during two following years as well, being changed only in 2019 as in this year the said ratio had the same value as in the previous year. The trend line of the EU-28 extra trade exports to imports ratio was built using the ploynomial function taking into account the value of the R^2 coefficient. The said trend line is downward after the year 2016 and remains of the kind during two time periods, that is years, taken for the projection.

The European Union (EU) today stands at a crossroad. Recent times have been difficult for the EU, where member states have been facing challenging situations and questions regarding European integration. These challenges have arisen in many fields and policies, with one of them being the enlargement policy. Consequently, views of not expanding the EU borders further have been growing, and enlargement fatigue has been used to describe the current situation towards further expansion (Jónsson S. D., 2019).

Some specialists in politics think, that " Enlargement should remain an active element of the future of European integration. The EU is not only about free trade; it is a community of values for establishing democracy and the rule of law in a growing number of European countries" (Ministry for

Foreign Affairs of Finland, 2020). Though, the others "As N. Piers Ludlow explains, enlargement was never part of the initial European project when it began in the 1950s, yet it eventually became one of the EU's most important and successful policies. While the first enlargement of 1973 welcomed other Western European democracies (the UK, Ireland and Denmark), no long-term strategy for enlargement was developed. Only with the Greek accession in 1981 did the strategy of democratisation enter into the enlargement process" (Brunet L.A., 2013).
To fix the problem of dysfunctional enlargement, the EU should make the process political and reversible. As Macron mentioned in his recent Economist interview, the EU has to remember that it is, most of all, a community rather than an ever-expanding market. France's new approach to the EU accession process is largely based on the so-called horizontal method: candidates would make reforms in various areas, gaining access to select EU programmes and gatherings along the way, before attaining full membership. By reforming enlargement methodology in this way, the EU would also help address democratic backsliding and rule of law problems in Western Balkans countries (ECFR.EU, 2020).

Applying IRIS Attendance Management System (AMS) on college of Shareeah and Islamic studies in Ahsa, Kingdom of Saudi Arabia

Maath A. ALMULHIM

Imam Mohammed Bin Saud Islamic University, Riyadh, Kingdom of Saudi Arabia,
maalmolhem@imamu.edu.sa

Abstract

Education is one of the most important aspects of daily lives to many countries around the world. For the students who attend the classes full or even part time, attendance is an important measurement that shows the student's care in gaining the highest knowledge and highest marks in courses, as well. This paper will represent some problems associated with current attendance systems in College of Shareeah and Islamic Studies in Ahsa city at the eastern province of the Kingdom Saudi Arabia and suggest a solution to it. This will assist in improving the college performance to the level that supports the achievement of Saudi Arabia 2030 vision(Web Ref).

Keywords: Student, Attendance, Iris, Database.

Introduction

It is strongly recommended to illustrate the importance of attendance system in general. It is stated that the attendance process is vital for clarifying the organization's overall performance. (Kadry and Smaili, (2007), Khatun et al (2015)).

Discussion about the aimed organization

The college of Shareeah and Islamic studies has been established at First of February 1981 and it is a branch of Imam Mohammad Bin Saud Islamic University, which is one of the first and oldest universities in Kingdom of Saudi Arabia. It was established with five basic Departments: Shareeah(Islamic Law), Religion Principles, Arabic Language, Geography, and Management. In 2009, another two departments were opened, which are English Language and Computer sciences.

Numbers about the organizations

Number of current students: 7723 (including 5937 males and 1786 females)

Number of academic staff: 310

Number of classrooms: 145

Literature Review

Some reasons behind the iris method proposal for some organizations.

Khatun et al(2015) claimed that the iris identification method is introduced in order to eliminate the time spent on calling the students' names or writing each student's name when marking the attendance in any educational firm.

It is claimed that the iris technology can be easily integrated into other systems. 'IrisAccess system incorporates other system-designed elements. 'The IrisAccess system offers integration flexibility found in few other biometrics. Designed for easy integration with standard security infrastructure, the IrisAccess has been successfully integrated to most of the leading access control panels as well' (Web ref). Khaw (2002) stated that the iris system is useful for organizations where the systems are manually programmed with financial identifications, like credit card number, which can be stolen. The iris replacement of these cards will minimise these cases(Web ref).

Khatun et al (2015) stated that the Eye Recognition (Iris) identification method is considered one of the best biometric realization systems because it has the advantages of distinction, stability, unchanged through the time. 'The iris is a circular diaphragm which is punctured by the pupil and lies between the cornea and lens'. Iris identification was an alternative approach to fingerprints due to the advantage of its uniqueness. This means that it is impossible for two people to have the same iris. Moreover, each person's iris identity can be taken from either the left or the right eye, unlike the fingerprint where there are ten fingers for taking fingerprints. With the iris identity, it will be faster for large database searches to keep accurate results. In addition, the accuracy of the iris is because it deals with 240 reference points for matching. Such biometric systems will be used in large percentages by organizations in the future, because it is the only method for ensuring the presence of employees.

How the Iris Recognition System Work

Segmentation step

Abo Zanona and El-Zaghmouri (2013) argued that after capturing the IRIS, first thing to do is to specify the iris region as the main focus. This region, can be identical to two circles, interior and exterior. The 'eyelids and eyelashes' usually close the top and bottom areas of the iris region. The accuracy of iris dividing depends on imaging quality and the early processing of the eye image. The best type of database that does not have any effect of regularly reflection is the one that uses the infrared light. Moreover, persons with dark painted iris (Usually those who use lenses) will cause more difficulty in the iris segmentation. The segmentation step is vital for the success of iris identification system because any error in data representation will lead to corrupted biometric template generation which will, in turn, cause the poor recognition average.

Morphology

The operation that effects the image is called morphology. These 'morphological operation applies a structure element to the image, the output resulted image will be the same size. Each pixel' value in the output image is based on a comparison of the corresponding pixel in the input image with its neighbors'.

The basic morphological operations are opening in and closing. These two operations change the pixel set identification based on the neighborhoods pixels and structure element. The most basic operation are 'dialation and erosion'. The first one put on pixels to the objects limits in an image, while erosion deletes pixels on these limits.

Captured Image pixels role

The pixels' numbers that are edited in the image depends on the structuring element size and shape that is used to make the image processing. To clarify more about structure elements, it is helpful to know that they are the basics of any operation in the morphological system. Two types of them are called liner and disk. The liner type is similar to the sequence of zeros and ones in the following example:

0 0 0 0 0 0 0 1

0 0 0 0 0 0 1 0

0 0 0 0 0 1
0 0

And so on.

Radom or Hough transform

Inside the image, there is further consideration for the projections of cycles and lines through a specific algorithm called Radon transform or sometimes Hough transform. It is used to identify the shadows and centres of the circular or bend areas which make it vital in line detection. The Hough algorithm is used in calculating two dimensional gradient mathematical equation.

$$\lim_{h \to 0} \frac{\|f(x+h) - f(x) - \nabla f(x) \cdot h\|}{\|h\|} = 0$$

System Working Modes

Such system is working in two modes; enrolment mode and identification mode. In the first one, the 'templates will be taking and the iris copies are stored in the database' while the second one runs normally to get the recognition. Both modes will run as a serious of similar steps except in one step where the database is used in the enrolment mode only. Otherwise, the stages will be:'eye image input, segmentation, normalization, feature encoding, iris code and noise mask, and the matching step in which the match can or cannot be found'.

IRIS Code:

To talk a bit about the iris code, the process is considered a template of the encoding process and will be divided into multiple phases. Generally speaking, the template contains the bit number that carry the iris information with the noise mask areas that are considered corrupt in the template. The areas of zero amplitude are meaningless to the information phase and mask noise as well.

Demarcated zones of analysis and illustration of a computed iris code.

Matching Step

In the matching step, there is depending on a form of calculation aimed to find the number of similar bits between two patterns of bits. This calculation will lead to a decision whether two patterns were extracted from different irises or from the same one. This calculation form is called Hamming Distance(HD).

Steps summarizing

To summary, the process flow will be clarified from iris image till pattern isolation. The original iris image must be gray or transferred to gray image.

The first pre-processing is the extraction of edge map that aimed to identify the pupil and its centre that can be used in gradient calculation at later steps.

The radon transfer projection representation is not enough for isolating the pupil due to the consistent effect of eyelashes.

Rebuilding the image after conversion will lead to an image with clear position of eyelashes. So, the cooperation between Hough transform, morphology, and mathematical calculations will localize the IRIS in the best way.

The morphology will lead to a dilated image.

After that, a process is done to identify the centre of the pupil. This is usually done through centralizing the pupil as rigid object so that the vertical gradient will be easy to measure.

After that, there is a try to identify the iris through Hough conversion and gradient to replace its error. The Hough conversion will be a red colour surrounding the iris radius. Next, the morphology will calculate the gradient initially from centre of the pupil to its boundary. After that, a further calculation of gradient will be between the pupil limit to the eye end. Such cooperation is aiming to minimize the error or Hough conversion. This gradient calculation is shown in blue and green circles.

After locating the iris, the process of isolating it is done through a Mathematical circle equation in geometry. This equation is aiming to return every pixel that is out of the iris circle to the zero value. A further morphological operation will be taken place to clarify the limits of eyelashes and eyelids.

Finally, the step of complete isolation of the iris and determining of pupil centre and boundary is taken place.

Daugman has added a methodology of taking 2048 pixel from any part of the circle of the iris as the initial reorganization part.

How to try to Implement an IRIS Recognition System

Khatun et al (2015) claimed that a proposed system will use the MATLAB software for calculating the radius of the iris by using specific code algorithm, and match each person's iris with the stored data. It is argued that the proposed system will send the attendance report to an email without human intervention using 'SMTP (Simple Mail Transfer Protocol)' which is an Internet principle offered by Gmail to 'send emails from any network to an email address'. This principle is accessed in MATLAB through one of its built-in functions (Web ref).

Analysis Phase of current system

This phase will describe the current system and its problems in order to suggest a proposal to them. Moreover, it aims to analyze, specify, and define the system to be built.

Current IT (Information Technology) systems

The main system that formulates the IT work is the banner system: it is an online system with three sub-systems. This proposal is related and integrated in-scope with two of these sub-systems and out-of-scope with the third one.

Project Scope

Development of an attendance system which will help in managing and controlling the database for storing and retrieving required information on students' attendance actions, and to manage courses' scheduled plan during each semester. The system will have a friendly user interface, which will make the database management system easy to use by common users.

Motivation

Attendance system is the Link between the student and the collage. The attendance system can understand all the problems that face its user and solve these problems to give them better services using the internet that is now the link between the whole worlds.

In-scope subsystems

Student Registration sub-system

Here, the IT department registers the data of the newly-accepted students and assigns them to each department that the students were accepted at. I refer this system in the database as the Student and Major entities.

Course Schedule Registration Sub-System

In this sub-system each department creates the schedule for its courses (including sections), arranges and sends it (as an MS Word printed copy) physically to the IT department. Currently, each department has its own classrooms for different levels of the degree according to the level, the year and the semester that the student is studying. After that, the IT staff inserts these course sections into the system. Then, the students register their courses through the website with their credentials. Normally, the students register for their courses at the first week of the academic year. Registration is done by inserting the section number in the system.

When the minimum number of students needed in each section registers, the IT will send the attendance sheets (printed from the system) to the departments' heads and their assistances. This step is a formal confirmation for the department that the section of each course has opened and that this course will be taught. Otherwise, the section closes and gets deleted from the system. I refer this system in the database as the Registration, Section, Course, PreRequirement, Room, Department, and Lecturer entities.

Entity Relationship Model (ERM) for current system.

Figure 1 : ERD for current system

Entities Definitions

The current database diagram shows that it holds entities of all the data that are in the student registration sub-system and the course schedule registration sub-system. These data are presented as entities and attributes for each entity (object). We have the following entities:

Student Entity

Because all the students are Saudis in the college, I assumed that each student's national identity number is enough to be the primary key.

Table 1: Student entity

Column Name	Data Type	Constraint	Note
NationalNo	Char(10)	Primary Key	10 Digits
Surname	varchar(30)		
Midname	varchar(30)		
FirstName	varchar(30)		
Gender	varchar(6)	Male or Female	Restricted by special SQL
City	varchar(40)		
P.O.Box	Char(4)		
Street	Varchar(20)		
Mobile	Char(10)		
Major-ID	Number	Foreign Key	From Major Table

Course Entity

This is a subject that is taught throughout the semester. Credit hours are the quantity of the course worth in the overall scale for the required degree.

Table 2: Course entity

Column Name	Data Type	Constraint	Note
CourseCode	Char(6)	Primary Key	
CourseName	varchar(50)		
Credit Hours	Tinyint		Between 2 and 3

Lecturer Entity

This is the person who is teaching the courses to the students.

Table 3: Lecturer entity

Column Name	Data Type	Constraint	Note
Lecturer-ID	Char(4)	Primary Key	
FullName	varchar(50)		
Gender	varchar(6)	Male or Female	Restricted by special SQL
City	varchar(40)		
P.O.Box	Char(4)		
Street	varchar(20)		
Mobile	Char(10)		
Email	varchar(50)		
Start Date	Date		
Qualification	Varchar(40)		
Experience	Varchar(40)		
Major-ID	Char(2)	Foreign Key	From Major Table

Room Entity

This is the place where the lectures will be taught.

Table 4: Room entity

Column Name	Data Type	Constraint	Note
RoomID	Char(4)	Primary Key	
RoomLocation	Varchar(50)		
RoomSize	Varchar(50)		

Section Entity

This is the group of a course. In many college, there are courses that have a high number of students, which should be divided into many groups. Section opening date means the date when the section was announced to the students.

Table 5: Section entity

Column Name	Data Type	Constraint	Note
SectionID	Char(5)	Primary Key	Primary Key
Semester	Varchar(6)		
StartTime	Time(7)		
EndTime	Time(7)		
SectionOpenningDate	Date		
CourseCode	Char(6)	Foreign Key	From Course Table
RoomID	Char(4)	Foreign Key	From Room Table
Lecturer-ID	Char(4)	Foreign Key	From Lecturer Table

Department Entity

This is like the (school) that contains many majors in each one.

Table 6: Department entity

Column Name	Data Type	Constraint	Note
DepartmentID	Char(4)	Primary Key	
DepartmentName	Varchar(50)		
DepartmentHead	Char(4)	Foreign Key	From: Lecturer table

Major Entity

This is the specialty of each department just like the majors of information systems abd data studies in computer science department.

Table 7: Major entity

Column Name	Data Type	Constraint	Note
MajorID	Char(2)	Primary Key	
MajorName	varchar(50)		
DepartmentID	Char(4)	Foreign Key	From Department table

Pre-Requirement Entity

(Combined Primary Key): These are the courses where students should have pass or study other courses previously in order to enroll in them.

Table 8: Pre-requirement entity

Column Name	Data Type	Constraint	Note
[Pre-Requirement-ID]	Char(6)	Primary Key	Combined PK(one of them is the FK)
CourseCode	Char(6)	Foreign Key	From Course Table

Users Entity

These are all the people who will use the system through the credentials. Username and password means that they are not including students. In this case, users are lecturers assuming that there is only one system administrator.

Table 9: Users entity

Column Name	Data Type	Constraint	Note
UserID	Char(6)	P.K	No need to relate it to any table
Password	Varchar(15)		
Type	Varchar(40)		

Registration Entity

This entity has the combined primary key from the Student and the Section entities beside the date. It is clearly stating the date that each student registers in the sections during the registration week.

Table 10: Registration entity

Column Name	Data Type	Constraint	Note
SectionID	Char(5)	Foreign Key	From Section Table

NationalID	Char(10)	Foreign Key	From Student table
Date	Date	Primary Key	

Current Data Model Missing Part

It is clear that the current system is missing an important part and further attribute. They are the attendance entity and student iris in the database.

Current Attendance System Problems

The current process of attendance has many disadvantages. Reading the students' names and checking attendance, can be exhausting for the lecturer's eyes and mind, as it takes time, especially for the courses that have high number of students and are taught in large classrooms. Sometimes, the students are changing their voice or raising hand when their absent friends' names are called which is difficult to distinguish or remember by lecturer. Moreover, there is a possibility of losing or damaging the attendance sheet. In such case, then the lecturer will face problems as he or she will be unable to know who has exceeded the maximum attendance percentage. Sometimes lecturers with a high number of students in their classes are distributing blank pages to students to write their names and signatures. This saves some time for explaining the lesson instead of checking attendance. In these cases, some students write also their absent friends' name and signature in order to help them maintain the minimum percentage of presence. Then, the paper is given back to the lecturer before the end of the lecture. Following this, the lecturer has to write the names of all the attending students at the official attendance sheet.

Another serious problem can occur when a student enters accidentally the wrong classroom during an exam, and find out later that he / she is in the wrong classroom throughout the attendance process.

At the end of the semester and before the final exams, students who fail to meet at least 75% of their attendances rate and provide absence excuses for some of these absences, will be prevented from attending the final exams. This decision is made manually and posted at the advertisement board.

Activity Diagrams

Bell (2003) claimed that activity diagrams illustrate procedural control flow among two or more class objects within activity processing.

Table 11: Activity Diagram for write student attendance (First Scenario)

Table 12: Activity Diagram for write student attendance (Second Scenario)

Table 13: Activity Diagram for updating attendance information with proof of absence

The previous process takes longer time and can be exhausted for the lecturers.

Research Questions

Due to these mentioned problems, this paper aims to answer the following questions:

1- What is the solution to the current attendance system problems?
2- Does the solution include enhancing the existing attendance processes? Or Launching a new idea?
3- Is the solution will work independent? Or through linking with current system?
4- What are the costs for the solution implementation? Is there any competition in applying the solution?
5-Is the solution aims only to minimize the time that the attendance take? Or there are further objectives?
6-Does the solution work for the students only? Or there are other stakeholders will be affected by the solution?
7- Is there any future suggestions in case of achieving the solution objectives?

Research Methodology

Wahyuni (2013) claimed that the methodology means a model to execute a research within a context of specific model. It consists of sets of beliefs that guide the researcher to choose certain research methods among others. So, it can be imagined that the methodology is a map and a method is a group of steps to travel between two places on it. Based on the research questions mentioned above, I will proposed that the research method will be a mixed method that combine both qualitative and quantitative methods This is because it focuses in numbers in some areas and the quality of output on

other areas. It have been gone through measurements like interview in some areas and focus group in other areas. Mixed research methods is growing in popularity as claimed by Heyvaert et al(2013).

Feasibility Phase

Problem Solution

All the above mentioned disadvantages led me to make this proposal for the iris attendance management system. The problems will be solved by keeping the attendance process electronically instead of manually.

After mentioning the ERM and the current attendance system problems, the system will be created, updated and improved in order for it to become more efficient, easier and accurate.

Solution Objectives

1. The system allows the students to check-in at the eye scanner system in any classroom they are assigned for and in proper time.
2. The system allows the Lecturer and administrator to view all students' information (attendance date and time, status)
3. The system allows the administrator to manage and control the schedules of each room, lecturer and the student.
4. The system allows the lecturer to produce several reports on his or her students.

Hardware and Software Requirements

SQL Server Management Studio, IRIS Scanner.

Requirements Definition

The first step in capturing the requirement is to specify the type of requirements (functional or non-functioning requirements). (Web Ref)

Functional And Non-FunctionRequirements.

Functional Requirements

A. Student requirements

- Check-in (create an attendance record) at the eye scanner machine.

B. Administrator requirements

- The administrator can add new user information, update, and delete user information.
- The administrator can view, or delete student attendance information.
- The administrator can view course's information.
- The administrator can search courses, and students.
- The administrator can generate reports (attendance report).

C. Lecturer requirements

- The lecturer can view all student attendance information at his or her class.
- The lecturer can update, delete any student attendance information in his or her class (there will be a choice to give the absent student an excuse for emergency cases, always agreed with the lecturer).

- The lecturer can view several attendance reports related to his or her students in each classroom.
- Lecturers must be able to view the students' final exam elimination list at the end of the semester.

D. System requirements

- The system provides several attendance reports.
- The system is integrated with a student registration sub-system and a courses schedule plan sub-system. Each iris scanner must be programmed to a specific classroom, courses, lecturers, and students who are registered in these courses. This means that the functions of each device will more complicated than the default specifications it came with. The specifications of the scanner's functions are demonstrated in the process of identifying each student's irises and detect if the specific student was scanned on the right day, time, classroom, and course followed by the confirming step in which the student's attendance is added to the course's electronic attendance table in the database. Otherwise, then the whole proposal idea will be useless, since it will only detect student's irises and give it an identification code. Furthermore, there must be an ability to reprogram the device in case of changing the class for a different course.

- The system will affect the student registration sub-system by adding student eye scanning information. To clarify it more, the iris scanner comes with a software. This software is the process of identifying any iris that is detected and recognized. When recognising the iris, the software process it and gives it an ID (digitalized form). Then, the system administrator adds this ID to the related student record in existing database where all students' information is kept.

- The system will provide the lecturers with sufficient time to make sure that every student absence had no excuse.

Non-Functional Requirements

These requirements deal with the attributes that are not described specifically in the functional requirements but recognized as properties of any system. (Web Ref)

A. Usability
The AMS provides the student and the lecturer with easy use, consistent and friendly interface, and coherent user documentation.

B. Reliability
The AMS is able to address frequency and severity of failure, recoverability, predictability and accuracy.

C. Performance
The AMS must implement the system with high performance on functional requirements such as the transaction rate, the speed, the availability, and the accuracy of information.

D . Supportability
The AMS will support maintainability[1], testability, and the other qualities to keep the System up-to-date after its release.

E. Security:
The AMS has to be secured from being physically damaged or electronically hacked by hackers. This involve credentials for lecturers and administrator for giving accesses only to the authorized persons
.

Important Features Definition

Here, and based on my reading of each device, the most important selection features are summarized in the table below except about API (Application Programming Interface).The API each device come with is an important factor effect the implementation of each selection. Sometimes it is mentioned generally as SDK. 'SDK is a ('Software Development Kit) that provides several commands that allow the developer to operate the iris scanner for capturing or matching iris images. Set of those commands is call API of the SDK. Basically, API is the interface that the developer can communicate with Iris scanner SDK and device'(Web ref).

Features Table:

Table 14: Features summary for selective IRIS machines

Brand	***Model***	***Response Time (For student check in)***	***Users storage (How many IRISes)***	***Capturing distance***	***Health Assurance***	***Is it movable? (For different student heights)***	***API***	***Cost***
Panasonic **(Web ref)**	*BM-ET200*	*0.3 Second (less than a second)*	*10.000*	*0.508 Meter*	*A laser that does not affect the eyes at all*	*No*	*No*	*£ 2050*
IRIS ID (Web ref)	*iCAM D1000*	*Less than 3 Seconds*	*32GB*	*1 Meter*	*Certified for eye safety and ISO standards*	*Yes, the camera is movable between 1.5 and 2 Metres height*	*Yes (As SDK)*	*£ 20000*
IriShield **(Web ref)**	*BK2121U*	*0.750 second (less than a second)*	*1000 and can be extended till 10000*	*0.14 Meter*	*Eye safety standard (IEC 62471:2006-07)*	*No*	*Yes*	*£385*
Aditech *(Web ref)*	*Iris ID iCam7000*	*Less than a second*	*100.000*	*0.355 Meter*	*IEC 62471 certified*	*No*	*Yes*	*£ 2000*

Best Recommendation

In this study, I will provide a recommendation for the "best solution" in terms of the best business process and associated technology implementation taking relevant costs into account.

If I would like to choose the best solution, I will find that the selection of IriShield will cost £55825 only (multiplying the device cost into rooms number). This machine comes with a basic data security infrastructure that minimizes any further costs for security software. It support the API as needed.

This selection API is provided in 'C++. .NET or Java languages'(Web ref) Such diversity in programming languages options offered for API add simplicity in the implementation step. 'When building computer applications, an API allows a software developer to perform basic functions and define the proper way for programs to interact'(Web ref).

Software architecture applicable styles and the selected style

The solution can be applied in several different styles. The most efficient, cost effective, and time consuming one is through linking each device to the existing database: This means that all the devices will be connected to the attendance management system, which is an addition linked to the overall university students' system. With this solution, any change in the scanners positions will be automatically changed in the database and this will save a lot of time and budget.

It is important to mention that when the student is trying to attend a class, the iris scanners are only linked to the database and the comparison process will be done in the database. Based on the comparison results, the device will give the acceptance or refusal message to the student. Then, the result of this check will be sent back to that scanner in order to give the student the acceptance or refusal message.

Required System Specification

Activity Diagrams

Add New User

Proposal Data Model

Proposed System Entity Relationship Model(ERM):

Bellow, the added entities and attributes are shown in the ERM:

Figure 8: ERM- Diagram for Proposed AMS

Proposal Entities and Attributes Definition

At this point, the proposal will update the student entity with the IRIS attribute.

Table 19: Proposed entity attributes

Column Name	Data Type	Constraint	Note
NationalNo	Char(10)	Primary Key	10 Digits
IRIS	Varchar(5000)		
Surname	varchar(30)		
Midname	varchar(30)		
FirstName	varchar(30)		
Gender	varchar(6)	Male or Female	Restricted by special SQL
City	varchar(40)		
P.O.Box	Char(4)		

Street	Characters		
Mobile	Char(10)		
Major-ID	Number	Foreign Key	From Major Table

Added Proposed Entity: Attendance Registration Entity

This table has combined primary key. It is come from the section table (where the sectionID, and NationalID are combined primary keys), besides having the attendance date, attendance (either 0 or 1 based on attendance).

This is the most important entity in the database once the attendance management system mainly exist, attendance actions are recorded, and several reports will be taken from. That's why the following attributes are combined primary key.

Table 20: Attendance Registration entity

Column Name	Data Type	Constraint	Note
SectionID	Char(5)	Foreign Key	From Registration Table
NationalID	Char(10)	Foreign Key	From Registration Table
AttendanceDateandTime	DateandTime	Primary Key	This table has combined PK
Attendance	Char(1)	Primary Key	Either 0 or 1

Results

In case of successful implementation of this project, we will obtain the following benefits:

1-Minimise the time that attendance take.

2-Eliminate the cases of attending the absent students by their presence colleagues.

3-Encourage the students to attend the classes regularly and not exceeding the maximum absence percentage.

4-By attending more, the students will be able to gain more knowledge and understanding about the courses they are learning. This assists in gaining higher marks at college as argued by Newman et al (2008).

5-Prevent the lecturers from being responsible of the attendance sheet once it will be in an electronic form.

6-Allow the lecturers to view several reports about the course easily.

7- Allow the administrator to create, update, or delete information regarding courses, students, classes, or even lecturers.

Future Suggestions

Further ideas and research can be done based on this project are:

1- Linking the IRIS machines to doors of classes where door opens when recognizing the proper student IRIS and closed after it.

2- Adding further privilege to the lecturer in order to set up the time that students are allowed to register their attendance from the start time of the lecture and refuse any attempt after it.

3- Linking the final exams classes to the AMS.

4- Extending the AMS to the employees in the university for a better employee attendance management.

5-Giving the lecturer privilege to make some students who are not able to use the IRIS machine (like blind students) present based on their physical existence.

6- If the solution is implemented and works in the best scenario, it can be further implemented to all the other branches and institutes of the same university which are now 18(Web ref). Further extension may be executed to all state universities in the country which reaches now 30 universities(Web ref).

7-Implementing such technology in all the organizations that focus on attendance and eliminating the need for paper attendance sheet. This is importance because in these organizations , the attendance sheet is importance in annual and urgent vacations beside the monitoring departments work whether within the organization or from outside it.

[1]Maintainability: Software Maintenance is the modification of a software product after delivery to correct faults, to improve performance or other attributes, or to adopt the product to a modified environment. [IEE 1993]

Acknowledgment

I would like to thank Dr. Marwan for his help and support.

I would like to thank our close friends for their help and support.

For all whom stand beside me and for all whom gave me the hope, for everyone feel my fear and remove our tears.

Special thanks for my faculty team of college of Islamic Studies' doctors, teachers and employee staff.

Abstract

The contemporary agriculture facing not only challenges in the form of higher efficiency, productivity or consolidation, but also it should fulfill certain criteria, related to sustainable development concept. In these days the management of agriculture sector should take into account, not only the economic, but also the ecological aspects. Taking account that agriculture is one of the most important activities in EU countries, the purpose of the article was to outline the present management of agriculture from sustainable development point of view. The methodology used adopted the form of comparative analysis conducted for chosen agri-environmental indicators. Based on Eurostat statistics and own calculations, it can be concluded that the level of agriculture sustainable if very differentiated between selected countries in EU.

Keywords: Agriculture, Sustainable Development, Management, Sustainable Agriculture.

Introduction

Agriculture in EU countries continues to be a very important sector of the economy, next to the food, fisheries and forestry industries, it is one of the most important elements of broadly understood agribusiness (Skowron-Grabowska, 2010). Agriculture and rural areas play a key role in the economic and social development of developing countries (Brzozowska, 2014). The basic task of agriculture is to provide food for worldwide population, but in present times, reducing the environmental impact and preserving natural resource for the future generation also is a major task (OECD, 2020). Consequently, there is a need for a conscious agricultural policy aimed not only at the further development of agriculture, ensuring the continuity of food supply, but also guaranteeing adequate financial profits for farmers, reducing poverty but also ensuring food security (Wspólna polityka rolna…, 2014). However, in agriculture, not only food production is important. In all EU Member countries, there are farmers who care about rural areas and traditional lifestyles. Farmers need equipment, energy and fuel, buildings, fertilizers and veterinary care for animals (Kalinichenko, Havrysh, Perebyynis 2016). And the competitiveness of agricultural enterprises management is inextricably linked to the state of the other agribusiness links and the level of development and modernization of the economy (Starostka-Patyk, 2016).

In Poland, until 1989, agriculture management was completely incapacitated by full dependence on the state, in terms of production, supply and disposal and on social grounds as well. This caused that the collision with the realities of the market economy become a challenge to which Polish farmers

were completely unprepared, and the state policy in fact hindered their adjustment process of proper management.

The principle of sustainable development was adopted during the Earth Summit in Rio de Janeiro in 1992, under the most well-known definition: „Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Our common future, 1992). Since then, it has been incorporated into all EU policies, including agriculture, which meant new obligations for farmers to provide public goods in the interests of all of us, in the form of well-maintained rural areas, high biodiversity, wise use of natural resources and cultural objects (Fidlerova et al., 2014). This concept is even more important for agriculture and rural areas that directly affect the natural environment (Adamowicz, 2000), as today the concept of sustainable development has strongly affected the agriculture sector (Latruffe et al., 2016). Agriculture has a great impact on the natural environment – its negative effects increase the pollution and lead to soil's, water's and air's degradation, but its positive effects can cause greenhouse gases decrease or mitigate the flood risks by the adoption of certain practices (OECD, 2020).

Due to the close link between the agriculture development and the development of rural areas, it is impossible to talk about the sustainable development of these areas without sustainable agriculture (Żmija, 2011). Sustainable agriculture development, which is a key element of sustainable rural development, as defined by the FAO Food and Agriculture United Nations in 1987, is the use and conservation of natural resources and the orientation of technology and institutions to meet human needs and future generations (Sydorovych and Wossink, 2008).

Awareness of the close development of agriculture with the concept of sustainable development manifests itself in emphasizing the essence of this concept in many documents related to the development of agriculture and rural areas (Velten et al., 2015). Reference to the concept of sustainable development can be found in the CAP (Common Agriculture Policy) (Wspólna polityka rolna…, 2012). Sustainability appeared in the Agenda 2000 reform, which established the second pillar of the CAP and formulated agri-environmental programs and started to support sustainable development activities (Jambor, 2011). The present CAPis structured around two pillars: first pillar focuses on greening and a more equal distribution of support, while second pillar focuses on competitiveness, innovation, climate change and the environment (Dunay, 2011). The Europe 2020 Strategy document, which also includes references to the concept of sustainable development, in one of its headline targets: sustainable growth (A European strategy…, 2020) . The main goals of "Sustainable growth" are connected to climate, energy and efficiency targets, such as using renewable energy, building low carbon economy, improving energy efficiency (Vida and Illes, 2014). In, 2019, a new document "Annual Sustainable Growth Strategy 2020" has been released with the new term "European Green Deal" as a new growth strategy for all UE countries (Annual Sustainable…, 2020).

Sustainable agriculture as one of the fields of sustainable rural development and an alternative to intensive industrial farming, should rationally manage the land resources, so that they can benefit from it and meet their needs for future generations of producers and consumers as well (Marsden and Sonnino, 2009). Its essence is to strive for a stable and, at the same time, economically viable and socially acceptable production in a way that does not harm the natural environment (Pretty, 2008).

Sustainable agriculture in European Union Countries – the purpose of the research

Bearing in mind all of the above, an analysis, which outcomes may be response to the extent to which agriculture of EU countries is sustainable, have been conducted. To find an answer, the values of selected agri-environmental indicators were measured. To perform an analysis, chosen Eurostat statistics have been used and own calculations as well. The selected indicators were adopted to the study as its volumes present the actual level of sustainability in agriculture. The obtained data and

appropriate calculations made it possible to present the current state of agriculture in the aspect of sustainable development. The following issues have been analyzed:

- Basic information regarding the agriculture in EU including: the number of farms, their total area, the amount of income earned, the number of employees and the level of production (crops, milk and meat) in order to present the current state of agriculture in EU countries,
- then, the overall farms' efficiency was calculated based on the chosen indicators,
- productivity: the income generated by single farm, the production level generated by single farm, the income generated by farm's single employee, the average size of farm and the income generated by 1 hectare. These indicators were chosen as the production is one of the four major components of sustainable agriculture,
- the values of adopted agri-environmental indicators for agriculture in all EU countries such as: the share of UAA under agri-environmental measure, the average annual expenditure on agri-environmental measures per hectare, the total public expenditures for environmental trainings, information and advisory services and the total public expenditures for environmental trainings, information and advisory services in 2010 per employee in agriculture.

The conducted analysis present the state from the year 2016, as the most current year, because the majority of statistical data obtained for the analysis came from this year as the most up-to-date.

The Research Results

General Data

The first stage of the analysis was the presentation of basic figures characterizing agriculture in all EU countries. These values were: the number of farms, their total area, the amount of income earned, the number of employees and the level of production (crops, milk and meat) presented in Table 1.

The yellow fields indicate the first five countries with the highest values for a given category, and the countries are being sorted by the number of farms. As shown in the table above, the first five countries with the largest number of farms are: Romania (3.6 mln), Poland (1.4 mln), Italy (1.0 mln), Spain (0.9 mln) and Greece (0.7 mln). For the total area of agricultural land, Spain is on the 1st place, with more than 30 million hectares of agricultural land, on the second is France, with less than 30 million hectares of agricultural land. On further places, the following countries have been found: Poland (16.4 mln ha), Germany (18.3 mln ha) and United Kingdom (18.6 mln ha), in which the area of agriculture land is similar. In the case of revenues generated by farms, France is on 1st place, when in 2013 farms generated a total of more than 56 billion Euros. On the further places are Germany (46 billion Euros), Italy (43 billion Euros), Spain (35 billion Euros) and United Kingdom (21 billion Euros). It is worth to add that, right after the United Kingdom, Poland was located, whose farms in 2013 generated over 21 billion euro revenue. In the case of number of employees in agriculture, on the first four places are the countries with the largest number of farms: Romania (1.5 mln employees), Poland (1.9 mln employees), Italy (0.8 mln employees) and Spain (0.8 mln employees). Whereas France is on the last place (0.7 million employees). But, in contrast, France is on the 1st place in the case of total production, being an undisputed leader, since French farms in 2013 have produced over 75 million tons of products. Germany, which produced nearly 20 million tons less – 57 million tons of products, are on 2nd place. Poland is on the 3rd place, whose production is less than half of the French farms production – 31 million tons. The next is Spain, whose production is one third the size of French farms and is hovering around 25 million.

Table 1: The main volumes of EU agriculture

Country	Number of farms	Total farms' area (ha)	Standard output (euro)	Labour force directly employed (per person)	Total production of crops, milk and meat (in tons)
Romania	3 629 660	14 661 380	11 989 578 640	1 552 630	20 926 360

Luxembourg	150 871.08	87.14	88 898.54	66.25	2 277.46

In general, looking at the tables 1, 2, it is clearly visible that Romania, Poland, Italy, Spain, France, Germany and United Kingdom are characterized by the largest values. On the other hand, Greece is on the 5th place in terms of the number of farms, but the remaining values are far from the first five. Based on the calculations, to the most efficient agricultures the following countries can be selected: Netherlands, Denmark, Belgium, Czech Republic, Germany and United Kingdom. The following

conclusions can be drawn for the individual indicators:

1. The income generated by single farm (in euro) – In this case, farms in the Netherlands were the most efficient, one farm from 67 000 was able to generate revenues of more than 300 000 Euros. The next two places included farms from Denmark and Belgium, generating 250 000 euro and 222 000 euro respectively. On the last two places Czech Republic and Germany have been found, with the 169 000 euro and 162 000 Euro generated revenues. While among all these countries, this is Germany with the largest amount of farms – over 285 thousand so four times more than Netherlands.
2. The production level generated by single farm (in tons) – here farms from Czech Republic are on the first place, when in the years 2013 the production volume per one farm estimated around 321 tons per farm. The next is Denmark, with a production of 259 tons per farm, and Germany – 201 tons per farm. On the last places are France and United Kingdom, whose production volume per one farm was 159 tons and 158 tons respectively.
3. The income generated by farm's single employee (in euro) - on the basis of the calculations, it is clear that Denmark is the leader - the work of one employee in agriculture brought the effect of 180 thousand euro. On the 2nd place was Belgium, where the work of a single employee translated into 148 thousand euro revenue. In this set up, again the Netherlands, with the income generated by a single employee at 133 thousand euro has appeared. On the last place is Germany again and Luxembourg, where the work of one employee brought the effect of 88 thousand euro. But in Germany, 522 thousand people are employed in agriculture, and in Luxembourg - 3,500 employees only.
4. The income generated by 1 hectare (in euro) – again Holland is on 1st place - where revenues from one hectare in 2013 amounted to 10 thousand euro. Malta ranked second, for the first time in this ranking, with a revenue of one hectare of 8,000 euro. While Netherlands has more than 2 million hectares of agricultural land and Malta has 11,000 hectares only. On the further place are Belgium, Cyprus and Denmark, with the revenues: 6 thousand euro, 4 thousand euro and 3 thousand euro. While Denmark has 3 mln hectares of agricultural land and Belgium 1,3 mln hectares, the area of agricultural land on Cyprus does not exceed 125 thousand hectares.

Thus, it can be concluded that the number of farms, the area of agricultural land, the volume of production and employment, and the volume of revenue generated is practically unimportant in terms of agricultural efficiency. While in the case of basic volumes, where the following countries have been characterized by the highest values: Romania, Poland, Italy, Spain, France, Germany, United Kingdom, in the case of the indicators above, the highest volumes were noted for the countries such as: Netherlands, Denmark, Belgium, Czech Republic and Germany and Malta, Cyprus, Luxembourg, France and United Kingdom as well. Only Germany, France and United Kingdom are present in both groups. But none of these countries in efficiency analysis got the first three places.

In addition, based on the calculations made in relation to the analysis of the level of efficiency of individual agricultural economies, it was also possible to identify countries where the level of efficiency of agriculture is similar to Polish agriculture (figure 1).

Fig. 1: The graphic presentation of similar values for selected countries

In terms of indicators such as:

- the income generated by single farm,
- the production level generated by single farm,
- the income generated by farm's single employee,
- the income generated by 1 hectare.

we may assume that agriculture in Italy, Portugal, Croatia and Slovenia in quite similar to Poland. That is why in the further analysis, in regards to describe the sustainability level in polish agriculture, for these countries calculations will be conducted as well.

Agri-Environmental Indicators

Having in mind that almost 40% of the EU's land area being farmed, can be concluded that agriculture has a very important impact on the natural environment.

The above and the Common Agriculture Policy's adoption caused that new indicators, called Agri-environmental indicators (AEI's) have been developed, in order to track and measure the integration of environmental concerns into the Common Agricultural Policy (CAP) at EU, national and regional levels (ES, 2017). According to data from Eurostat, unfortunately the year 2009 is the latest year, no further statistics are available, the following can be concluded (in division to chosen sub-indicators):

1. Expenditures on agri-environmental measures -the differences in the agri-environmental expenditure per hectare among various countries, give indication of the importance they attach to the implementation of agri-environmental measures across their own agricultural area (table 3).

Table 3: Average annual expenditure on agri-environmental measures per hectare of UAA supported (EUR per ha)

Country	Average annual expenditure on agri-environmental measures per hectare of UAA supported (EUR per ha)	Country	Average annual expenditure on agri-environmental measures per hectare of UAA supported (EUR per ha)
Malta	615	Czech Republic	190
Cyprus	610	Italy	190
Netherlands	460	Germany	180
Estonia	375	Lithuania	140
Austria	350	Denmark	130
Luxembourg	330	Belgium	120
Slovenia	275	Ireland	115
Hungary	210	Latvia	110
Sweden	205	Romania	90
Portugal	202	Spain	80
Slovakia	200	Poland	75
		France	60
		Bulgaria	50
		United Kingdom	45
		Finland	10

As we can see from the table above Malta is on the first place with average annual expenditure on agri-environmental measures per hectare with 615 euro. On the second place is Cyprus, whose average annual expenditure on agri-environmental measures per hectare, was 610 euro in the year 2009. But it is worth to bear in mind, that Malta and Cyprus are characterized by the smallest area of agriculture land, 11 980 hectares and 123 810 hectares respectively. Thus, it can be assumed that even a little area of agriculture land makes it possible for such a high expenditure to be made by both countries. But on the 3rd place is Netherlands, whose average annual expenditure on agri-environmental measures per hectare was 460 euro, but total farms area is more than 2 mln hectares. Poland, on the other hand, is in the final part of the statement, amounting to 75 Euros, which accounts for only one-eighth of the expenditure incurred by Malta and Cyprus. Also among countries like Italy, Slovenia, Hungary and Croatia, Poland has the lowest level of average annual expenditure on agri-environmental measures per hectare. And on the first place is Slovenia with 275 euro. In the remaining, selected, countries – the level of these expenditures is far above 150 euro, Only in Poland, the level of these expenditures is below 100 euro. While lowers expenditures of average annual expenditure on agri-environmental measures per hectare have the following countries: France, Bulgaria, United Kingdom and Finland, while in Finland the expenditure level in the year 2009, was 10 euro only.

2. Total public expenditures for environmental trainings, information and advisory services – according to the data from Eurostat for 2010, Sweden, Ireland, Spain, France and Austria had the highest number of participants to environmental training, and Sweden represents more than 50% of

the total participants among all UE countries (Kalinichenko and Chekhlatyi 2017). The highest numbers of applications for environmental advisory services were registered in Italy, Hungary and the Czech Republic – these three countries were accounted for 79% of the total number of applications. In relations to public expenditures the most important sub-indicator was number and share of participants in vocational trainings sub-indicator (table 5).

The above table presents the outcomes of expenditures of vocational trainings, applications for advisory services and economic actors in trainings. The unquestioned leader of this list is Sweden, whose spending in 2010 amounted to over 36 635 thousand euro, and 92% of that expenditure was related to the vocational trainings. On the 2nd place is Austria, which in the year 2010, spent 6 882 thousand euro on this kinds of trainings, and 5 392 thousand euro on economic actors in trainings (78%) only. On the 3rd place in France, which spent 4 506 thousand euro on that purpose, almost all expenses went on vocational trainings. On a further place Belgium can be found, with the expenditure level of 4 132 thousand euro and with the significant share of vocational trainings (68%). Poland, allocating 34 thousand euro on this kinds of trainings in the year 2010, is located on the one of the latest places. But at the very end, Slovenia can be found, which designated only 1 thousand euro for vocational trainings in the year 2010 (table 4).

Table 4: Average annual expenditure on agri-environmental measures per hectare of UAA supported (EUR per ha)

Country	Number and share of participants in vocational trainings (thousand Euro)	Number and share of applications for advisory services (thousand Euro)	Number and share of economic actors in trainings (thousand Euro)	*TOTAL*
Austria	1 490	0	5 392	**6 882**
Belgium	2 810	967	355	**4 132**
Czech Republic	408	867	423	**1 698**
Denmark	898	0	116	**1 014**
Estonia	23	32	0	**55**
Finland	244	0	338	**582**
France	4 486	0	20	**4 506**
Germany	660	30	302	**992**
Hungary	147	909	0	**1 056**
Ireland	1 449	0	295	**1 744**
Italy	1 967	1 291	0	**3 258**
Latvia	107	0	0	**107**
Lithuania	775	0	0	**775**
Luxembourg	10	0	0	**10**
Poland	0	34	0	**34**
Slovakia	933	0	0	**933**
Slovenia	1	0	0	**1**
Spain	1 789	0	0	**1 789**
Sweden	33 763	0	2 872	**36 635**
United Kingdom	585	41	183	**809**
TOTAL	**52 545**	**4 171**	**10 296**	**67 012**

Checking the level of expenditure on environmental training per capita in agriculture, we will get slightly different results. In this case, Sweden is on the 1st place, where the level of expenditure per employee in 2010 amounted to 617 Euros. Belgium, on the 2nd place in the list above, and fourth in previous ones, in the year 2010 allocated 70 Euros for training courses. Austria, which in the first ranking, was on the 2nd, occupies the 3rd place, but the difference in spending is huge - because the level of expenditure per employee in Austria is almost 10 times lower than in Sweden.

Table 5: Average annual expenditure on agri-environmental measures per hectare of UAA supported (EUR per ha)

Country	*TOTAL*	Country	*TOTAL*
Sweden	617.58	Italy	3.99
Belgium	72.84	United Kingdom	2.95
Austria	61.91	Luxembourg	2.83
Denmark	19.07	Estonia	2.49
Slovakia	18.44	Hungary	2.43
Czech Republic	16.16	Spain	2.20
Ireland	10.65	Germany	1.90
Finland	10.11	Latvia	1.30
France	6.22	Poland	0.02
Lithuania	5.35	Slovenia	0.01

The biggest difference, however, is in the case of France, where in the first ranking it was third in the list with expenditure of EUR 4 506 thousand, in the case of the amount of expenditure per employee in 2010 - amounted to 6 Euros only. This is due to the fact that among the countries mentioned earlier, France has the highest amount of employees in agriculture – more than 700 thousand. Poland, again, can be found on the further place, with the expenditures level per employee 2 eurocents only. Such a low cost level is connected with the fact, that in the year 2010, Poland allocated 34 thousand euro on trainings only but the number of employees in agriculture is more than 2 mln people.

Conclusion

Based on the conducted analysis one major assumption can be made - the number of farms, the area of agricultural land, the volume of production and employment, and the volume of revenue generated is practically unimportant in terms of agricultural efficiency. For example, in Poland the agriculture sector plays a major role in the national economy, because Poland has the highest values for the number of farms, total farm's area, standard output, people working in agriculture and the total production of crops, milk and meat. But taking account the indicators such as: the income generated by single farm, the production level generated by single farm, the income generated by farm's single employee, the average size of farm and the income generated by 1 hectar, it is clearly visible that polish agriculture has one of the last places. Thus, it can be concluded that the efficiency of polish agriculture, being the determinants and major element of sustainable agriculture, is at a very low level. But having in mind that the main purpose of this article was to check the level of sustainability of EU countries agriculture, it is possible to assume that:

- In case of agricultural area enrolled in agri-environmental measures - Luxembourg, Finland, Sweden and Austria more than two-thirds of the UAA were enrolled in agri-environmental commitments, while in countries such as: Portugal, Cyprus, Malta, Romania, Lithuania, the Netherlands, Poland, Bulgaria this share was below 10%,

- In case of expenditures on agri-environmental measures - Malta is on the first place with average annual expenditure on agri-environmental measures per hectare with 615 euro. On the second place is Cyprus, whose average annual expenditure on agri-environmental measures per hectare, was 610 euro in the year 2009,

- In case of total public expenditures for environmental trainings, information and advisory services - the unquestioned leader of this list is Sweden, whose spending in 2010 amounted to over 36 635 thousand euro, and 92% of that expenditure was related to the vocational trainings. On the 2nd place is Austria, which in the year 2010, spent 6 882 thousand euro on this kinds of trainings, and 5 392 thousand euro on economic actors in trainings (78%) only. On the 3rd place in France, which spent 4 506 thousand euro on that purpose, almost all expenses went on vocational trainings,

- In case of the level of expenditure on environmental training per capita in agriculture - Sweden is on the 1st place, where the level of expenditure per employee in 2010 amounted to 617 Euros. Belgium, on the 2nd place in the list above, and fourth in previous ones, in the year 2010 allocated 70 Euros for training courses. Austria, which in the first ranking, was on the 2nd, occupies the 3rdplace, but the difference in spending is huge - because the level of expenditure per employee in Austria is almost 10 times lower than in Sweden.

Based on the above we can conclude that the sustainability level in agriculture is the highest for Sweden – taking account the above indicators, Sweden has the highest places in three of them. We can also conclude that agriculture in Austria and France is characterized by quite high level of sustainability. Unfortunately polish agriculture is quite far away for the "sustainable agriculture" description. But in comparison to selected countries (Italy, Hungary, Croatia and Slovenia), polish agriculture seems to be more sustainable. On the other hand, in this paper, the size of the indicators for only one group defining the level of sustainability was examined. It would be useful to also examine the levels of environmental spending, environmental taxes, innovation expenditure, as well as the level and type of waste and greenhouse gas emissions and pollutants generated by UE countries agriculture, in order to fully assess which agriculture of UE countries is a sustainable agriculture. Therefore the above issues will be the subject of further research in this field.

Abstract

The use of historical experience is an important component of the modern economy reforming in Ukraine. The reforms of the second half of the 19th to early 20th century are of particular importance. As their immediate result was the creation of an extensive credit system for agricultural producers, which was very effective at that time. The article describes the main types of financial resources used by agricultural producers in Ukraine at the turn of the 19th and 20th century. The analysis of statistical data confirms the idea of the extraordinary vitality of small family-owned agricultural enterprises. In such places there has always been the possibility of replenishing a modest budget through both economic activity and handicraft industries, as well as loans of different origins. The use of historical experience can be extremely useful for increasing the competitiveness in both domestic and foreign markets.

Keywords: Agricultural Sector, Agricultural Goods Producers, Budget, Financial Resources.

Introduction

The era of deep and comprehensive economic reforms in Russia, the beginning of which goes back to the period of the abolition of serfdom in 1861 is of considerable public interest. At least, because that's when these elements of market relations, without which it is difficult to imagine any modern, improved in every respect country, began to function successfully. This includes wage labour, extensive system of credit relations, and diverse State support for agricultural producers and many other activities of central and local authorities. These activities are aimed at improving the competitiveness of the country's agricultural sector in both the domestic and foreign goods and services markets.

In the works of domestic and foreign researchers socio-economic standards of life for agricultural producers of Ukraine during the period of capitalism are very widely represented. There is every reason to call this period the era of free enterprise. Another matter is the coverage of the problem related with analysis of the financial resources of business entities of Ukraine's agricultural sector in the aforementioned historical period. From this point of view, we should recall the fundamental work by P. Kovanko, professor at Kyiv University, which was published in 1914 (Kovanko 1914, pp.1-77). It dealt with the performed detailed analysis of the financial aspects connected to the form and content of the production relations between the State, landowners and former serfs in accordance with the Tsarist Manifesto of February 19th, 1861. However, the specificities of the Ukrainian area in general and the state of finances of its agricultural producers in particular are not reflected in the mentioned research. Characteristics of the peasantry's redemption payments at State level are found in the works of P. Golubev (1905), A. Lositsky (1906), N. P. Oganovsky (1917) and some other authors from the late 19th and early 20th century. Soviet researchers paid much more attention to the financial aspects of the

Emancipation reform of 1861 in the context of specific regions including the Ukrainian provinces of the Russian Empire. First of all, the authors of the article consider the works of such agrarian historians as P.A. Zaionchkovsky (1958, 1968), P.A. Teplytsky (1959) and A.V. Bondarevsky (1961). In those works not only the content of the redemption operation was analyzed, but also its consequences, including Ukraine as its constituent part. Anglo-American researchers such as H. Rogger (1983), D. Macey (1984), S. Hamburg (1984) and a number of other, less outstanding authors roughly described the financial aspects of the farms of Ukraine's landowners and peasants in their works. Meanwhile, the present-day historians have an appropriate documentary base at their disposal. It enables them to disclose the main sources of financing for business entities in the agricultural sector of Ukraine with sufficient completeness. At the end of the 19th and the beginning of the 20th century those business entities mainly consisted of the so-called unprivileged estates of the realm – peasants of all categories and the so-called MaloRussian Cossacks[1]. From this point of view, the most valuable group of sources consists of various statistical compendiums on both the All-Russian (1866, 1907) and regional (1916, 1917) scales. It also includes the documents of the Russian State Historical Archive (holding No. 577 – Main Redemption Board).

The aim of this study is to analyze the financial resources of business entities in the agricultural sector of Ukraine at the turn of the 20th century, which in some cases ensured the sustainable and progressive development of the corresponding farm business and in others – did not.

The Findings of the Study

Both privileged and unprivileged segments of the population took part in agricultural production within the territory of the Ukrainian governorates of the Russian Empire in the second half of the 19th and early 20th century. While the State and local statistics gathered a huge information base regarding the latter ones, the agricultural activity of the former feudalist landowners at the turn of the century was much less covered. This is evidenced, in particular, by the currently most comprehensive study by N.R. Temirova. She has never been able to establish the total number of landed estates in any given region of Ukraine due to the lack of necessary information in the relevant sources (Temirova 2003, pp. 26-211). The statistics of 1905 well-known to researchers of the agrarian history of Russia reports the total number of private landowners. About 90% of them belonged to the privileged categories of the population. Based on this, it is possible to establish an approximate number of farms within 32 thousand, with a total land area of about 16 mln dess.[2] (Statistics of land ownership in 1905, p. 12). In the historical literature there is a perception that land tenure by nobles was large as a rule. The fact that this was not the case is evidenced, in particular, by the materials of the 1910 household census in the Poltava Governorate. Out of 1,458 farms of privileged classes: 15.8% had less than 3 dess. of land; 15.4% – from 3 to 6 dess.; 1.2% – from 6 to 9 dess.; 12.6% – from 9 to 15 dess.; 10.6% – from 15 to 25 dess.; 11.5% – from 25 to 50 dess. and, finally, only 23,1 % of farms of this agricultural producers category had 50 or more dess. of land (Statistical yearbook of the Poltava 2012, p. 47). On the other hand, we acknowledge that there were the nobles who had dozens (dukes Sanguszko, Romanovs, Kochubey) and even hundreds (counts Branicki and Potocki) thousand dess.of land in the Ukrainian governorates after 1861. Although about half of the agricultural land of Ukraine was in the hands of the privileged classes after the agrarian reforms of the 1860s, not them, as some authors believe (Zhuk 2005, p. 120), but the rural inhabitants produced the lion's share of agricultural products. It was due to the fact that the noble landlords in most cases did not keep their own farms. They considered it more profitable to lease the land possessed by them to the mentioned peasants or Cossacks. According to the official statistics, there were 5,401,277 former state peasants in Ukraine in 1866. They included the above mentioned "Little Russian" Cossacks of the Poltava and Chernigov Governorates (the former Hetmanate). Another 4,231,579 people, or 40.93%, previously belonged to landlords' peasants, and 705,436 (6.83%) were under the jurisdiction of the specific department. That is, they were the property of the royal family until 1863 (Statistical Timeline of the Russian Empire 1866, p. 50-51). The first to feel the change in their financial situation were the landlords' peasants, whose situation reforming

[1] Cossack – historical terms, (formerly) any of the free warrior-peasants of chiefly East Slavonic descent who lived in communes, esp, in Ukraine, and served as cavalry under the tsars

[2] A *dessiatin* or *desyatina* (dess.) is an archaic land measurement used in tsarist Russia. A dessiatin is equal to 2400 square sazhens and is approximately equivalent to 2.702 English acres or 10,926.512 square metres

began in accordance with the same Manifesto of February 19, 1861. The specific conditions for the release of this agricultural producers category in Ukraine were governed by three laws. Each of them concerned correspondingly: Chernihiv, Poltava and partly Kharkov Governorates; Kiev, Podolian and Volhynian Governorates; Yekaterinoslav, Kherson and Taurida Governorates. The three groups had their regional specificities. In general, the content of the 1861 legislation came down to the fact that the peasants who received land for permanent use, were obliged to buy out their land for the price set without their consent. The basis for the relevant calculations were not the market prices of land or its profitability, but the size of overall monetary obligations. The appropriate amount was set for each governorate separately, and its size was determined by the annual quitrent multiplied by $16^2/_3$. Such an approach of the tsarist bureaucrats made it possible to significantly exceed the real market price in the left-bank and steppe governorates of the South by 84.7%. Whereas in the Right-Bank Ukraine[3] the amount calculated in accordance to the mentioned above formula was reduced by 20% under the influence of the Polish uprising of 1863. To ensure the practical implementation of the plans outlined by the legislation of 1861, the State granted a loan up to 80% of the redemption amount to the peasants. It was given not to them, but to the landlords in the form of securities (Kovanko 1914, p. 479). The peasants were supposed to repay this loan in the next 49 years, together with the traditional for the State Bank 6% per annum. The peasants had to pay the remaining redemption amount in person or work off for the same landowner for 9 years (Russian State Historical Archive, sheet 6). As of January 1, 1907, the day the redemption payments were canceled under the influence of the revolution, the former serfs in the Ukrainian governorates paid to the state not only the loan amount (166.8 million rubles[4]). They also paid 215.2 million rubles of interest for it (Agriculture, factory industry … 1918, p. 508). The total amount is 382 million rubles, which is more than twice the real value received by the peasants as a result of land reform in 1861. No wonder that the redemption payments were financially unbearable for the majority of former landowners' peasants. As so-called Valuev Commission officially recognized in the early 70s of the 19th century, it was because they exceeded the incomes of peasant farms. Therefore the rural classes were forced to seek additional resources outside their own farms (Kaufman 1873, p. 4).

In the 1860s, the financial condition of not only former landlord peasants, but also of a number of other rural groups deteriorated significantly. And if the redemption of land tenure by former landowners and crown peasants could somehow be explained, the requirement for the redemption of land to the State peasants cannot be called anything other than legalized State robbery. It was not by chance that some contemporary public figures spoke quite frankly about this, as far as the tsar's censorship allowed. In 1905 in "State peasants" P. Golubev, well known a lawyer, wrote: "There have always been free, people everywhere who have lived on the lands brought to the desired level by their own hands and means. These lands could be considered the property of the Russian state on the same basis as all the other landlords' or crown lands, like any other real estate within Russia" (Golubev 1905, p. 37). V. Boiko investigated the course of issuing the so-called "owner's records", a receipt which the tsarist government demanded from the former State peasants. He made a reasonable, from our point of view, conclusion of increase in the State peasants' payments for the use of their own land due to that measure, which caused their natural resistance (Boiko 1999, p. 69).

A lot of generations of professional historians had performed the analysis of the essence of the 1860s agrarian reforms. It gives us every reason to state the obvious, as we see it, fact of their direct influence on the acceleration of the development of commodity and money relations in the Russian Empire in the following decades up to the well-known social upheavals of 1917. The part of population mostly in the need of finance ware, of course, the underprivileged classes who were forced to redouble their efforts in the search for the vital financial resources. As evidenced by the relevant statistical data collected by economists of the Poltava governorate zemstvo[5] during the household survey of 1910, these were revenues not only from their own households, but also funds earned outside (tab. 1). An analysis of relevant statistics enables to trace certain regularity in the formation of the budget of the peasant and Cossack farms: the smaller the arable land the farm had, the higher was the percentage of

[3] Right-bank Ukraine is a historical and territorial name for a part of Ukraine on the right (west) bank of the Dnipro River

[4] *Ruble* or *rouble* – monetary unit in old and modern Russia

[5] *Zemstvo* was an institution of local government set up during the great emancipation reform of 1861 carried out in Imperial Russia by Emperor Alexander II of Russia

their income from outside earnings (local, seasonal and handicrafts). It is quite natural that among those who had arable land, the income from a personally cultivated land included 68% of financial revenues, whereas livestock raising was slightly less than 30%. The leased land brought only about 2% of the profits. As for the receipt of money from other sources, almost half (48%) of the profits came from crafts and artisanal products. The second place in this list was occupied by local earnings (40%), while seasonal ones gave a little more than 11%. As we see from table 1, there was a direct dependence of the landholding area on the corresponding profit. In the farms, where the size of land did not exceed 3 dess., the profit from local handicrafts and seasonal works exceeded the amount the householder received from crop production and animal husbandry by almost 40%. As for middle-income peasants (6–9 dess.), the profit from agriculture was almost ten times higher than the income from cottage industries and seasonal works. The relevant indicators of the well-to-do farms (25-50 dess.) engaging in no seasonal work and handicrafts (pottery, wood or iron processing, as well as basket weaving) for obvious reasons stand out. Revenues from the so-called local earnings meant profits from the mills or small enterprises to manufacture building materials.

Table 1: Sources of financial income into the peasant and Cossack farms of Poltava region at the beginning of the 20th century

Farms with arable land	**Earnings per household (RUB)**							
	From agriculture				From cottage industries and seasonal work			
	From the personally cultivated land	From the land leased	From livestock and poultry	Total	Local handicrafts	Seasonal works	Cottage industries	Total
under 1 dess.	28.90	0.04	19.83	48.77	48.81	32.22	107.50	188.53
1 to 3 dess.	97.29	9.17	80.04	186.65	39.58	6.53	213.92	260.03

Based on Statistical yearbook of the Poltava governorate zemstvo for 1915, p. 107

Sales of the goods resulting from agricultural activities took place, as a rule, at local marketplaces, fairs or agricultural exhibitions. They were organized by the local agricultural societies with the assistance of zemstvos and the government. For instance, it was possible to earn 81 to 86 kopecks[6] for a pood[7] of rye, 100 to 107 kopecks for a pood of wheat, 64 to 68 kopecks for a pood of barley, 53 to 57 kopecks for a pood of oats, 66 to 76 kopecks for a pood of millet; 77 to 83 kopecks for a pood of buckwheat, and only 14-17 kopecks for a pood of potatoes in Kharkiv region in the autumn period during 1906-1910 (Agriculture, factory industry … 1918, p. 63). The prices of the main crops in Chernihiv region, Poltava region and Right-Bank Ukraine were approximately the same in the aforementioned period

[6] *Kopeck* (*copeck*, *kopek*) – monetary unit in old and modern Russia (100 kopecks equal 1 ruble)
[7] *Pood* – unit of weight, used in Russia, equal to 36.1 pounds or 16.39 kilograms

(Agriculture of Ukraine 1923, Table 11-12). If the above prices in 1881-1885 are taken to mean 100 %, than they accounted for 71% in 1886-1890 (period of agrarian crisis) and for 84% in 1901-1905. They certainly grew significantly during World War I (Agriculture of Ukraine 1923, p. 224). Let's assume that the average yields of rye within Ukraine in 1907-1914 were 58 poods per dessiatin (Agriculture of Ukraine 1923, p. 168). Then it turns out that the seller could get 46 rubles for it and at least 58 rubles for the same amount of wheat from each sown area of the respective crop. We should not forget about the possibility to receive profits from other, less common types of crop production by the both privileged and unprivileged estates. For example, one pound of straw could be paid with a certain amount of money in 1909-1910, namely: a pood of oat straw cost an average of 8 kopecks; barley – 9 kopecks; wheat – 7 kopecks; millet – 10 kopecks; rye – 6 kopecks; buckwheat – 7 kopecks. 18 kopecks were paid for a pood of buckwheat chaff and 14 kopecks for a pood of chaff of other cereals (Review of agriculture … 1913, p. 65).

At the turn of the 20th century, the agricultural commodity producer in Ukraine could also obtain certain financial resources from an industry such as animal husbandry. For instance, the cost of a working horse within Ukraine was on average 37 rubles in the autumn during 1881–1885, 51 rubles during 1901-1905, 69 rubles in 1909-1913. The cost of a cow was about the same: 29 rubles in 1881-1885 and 62 rubles in 1909-1913 (Agriculture, factory industry … 2018, p. 225-226). One sheep could be sold for 3 rubles in the autumn of 1913 (Agriculture of Ukraine 1923, pp. 123-124). On average, 166 kopecks were given for a well-fed gander, 60 kopecks for a duck and 55 kopecks for a chicken. A dozen of eggs could be sold for 20 kopecks (Review of agriculture 1913, pp. 166–167). And yet, overall, the livestock industry was unprofitable in financial terms even in medium-income farmsteads. It is evidenced by quite convincing budget surveys carried out by A. Matisen, a member of the Poltava Agricultural Society, on behalf of the zemstvo (Matisen 1914, p. 14). However, not only small but also large farms of local landowners could only dream of great profits from animal husbandry. For example, in the Karlivka estate of counts Mecklenburg-Strelitz with the land area of 54 thousand dess., the profit from crop production was up to 675,854 rubles on average over five years (1906-1913). On the other hand, livestock production gave only 5,796 rubles, or 0.8% of the total amount. A similar situation could be seen in Duke L.V. Kochubey's estate (2,700 dess.) in village of Zhuky, in landowner A.M. Varshavsky's estate in Pavlivka village (4,105 dess.) of the Poltava Governorate (Poltava Society of Agriculture 1883, pp. 107, 133).

Analyzing the financial resources of business entities of the agricultural sector of the economy of Ukraine in the late 19th and early 20th centuries, it should not be forgotten about the loans, the amount, forms and origin of which were very diverse (Brzozowska et al. 2017). Only limited amounts of loans from the fellow villagers were available to the farms run by peasantry for a long time. They were usurious in its form, as the annual interest on it often reached a giant 1,200% (Katajew 1902, p. 1). In an effort to rid the peasants of this kind of enslaving loan conditions, in 1840 the tsarist government decided to open the so-called "volost[8] auxiliary funds" and "rural banks" in some localities. They existed in a somewhat reformed form until 1917 inclusive. The next step in this respect was the permission to start savings and credit cooperative-type partnerships at the request of the local population. Banks were approved somewhat later, in the 1870s and 1880s: joint-stock banks (Kharkov, Poltava, Kiev and Bessarabia-Taurida Land Banks) and then state-run Peasants' Land Bank (1882) and Nobles' Land Bank (1885). However, it soon became clear that the aforesaid institutions did not meet the needs of population in credits. It resulted in the extension of the related rights of the State Bank in 1894 that was established as early as 1860. And then, in 1904, the extension of the population's rights to receive credit from the Zemstvo budget was legalized. In general, as of 1909, there were about 1.5 thousand institutions that somehow lent money to agricultural producers in Ukraine. The generalized data on financial resources of the privileged and unprivileged classes to be used by representatives of the agricultural sector of Ukraine at the turn of the 20th century are shown in Table 2.

The most active institutions in terms of lending to agriculture in Ukraine were joint-stock land banks; the specific weight of their loans was in general 38%. The 2th place on this list belonged to the Nobles' Land Bank that, as we know, credited the nobles exclusively. The periodic benefits provided by the bank to that population category sometimes reached even the full debt forgiveness. This gave grounds for Witte, former finance minister, to qualify the above bank as a "semi-charitable institution"

[8] *Volost* was a traditional administrative subdivision in Eastern Europe

(Remarks by Witte … 1957, p. 155). The Peasant Bank that, as of 1909, provided its clients from the unprivileged classes with loans totaling 128,620 thousand rubles, remained on the 3th place in the list of creditors.

Table 2: Financing the agricultural sector of Ukraine by various credit institutions at the turn of the 19th - 20th century

Number	Governorates of Ukraine	Credit issued (mln RUB)								
		Mutual loan partnership	Savings and credit partnerships	Credit societies	Volost funds	Zemstvo funds	Joint-stock banks	Nobles' Bank	Peasants' Land Bank	State loans
1	Kharkov	7,627.6	626.9	311.5	2,201.6	18.6	17,981.4	35,783	12,454	12,410.6

Based on Statistical Yearbook for the South of Russia. Poltava, 1910, pp. 17-18, 37-38, 42.

As for the State Bank that received the right to grant loans including the rural classes in 1894, it occupied only fourth place in this rating. Though it should be noted that with the entire amount of loans of 104,293.6 million rubles issued by this bank, as of 1909, most of the funds were directed not to the agrarian, but to the industrial sector of the country's economy (State Bank 1916, p. 264).

Conclusions

1. At the turn of the 20th century, Ukraine's agricultural producers were not economically in equal conditions. It was due to the traditional for the Russian Empire division of the population into privileged and non-privileged categories, the latter being defined by the legislation as "rural classes". They were the ones who constituted the bulk of the business entities in the agricultural sector of the country. The peasant and Cossack farmsteads set in an exceptionally difficult financial position by the government during the 1860s agrarian reforms persistently searched for and in most cases found sources of financing for their needs. This once again confirms the idea of the extreme survivability of the peasant economy, regardless of the area of its land.

2. Government support of an extensive system of crediting the agricultural goods producers played a significant, and in some cases decisive, role in the successful functioning of both large and small business entities in the agricultural sector of the country's economy at the turn of the century. Whereby over one billion rubles were channeled to the agricultural sector. It was a huge amount of funds at that time, which certainly contributed to the intensification of both crop production and livestock production.

3. The conclusion about the crucial significance of private capital in the form of joint-stock land banks in financing the agricultural sector of Ukraine within the period under study is of the utmost importance, both in purely theoretical and practical terms. While bearing in mind that the banks can successfully develop, as domestic historical experience has shown, only if there is a market land, which many Ukrainian (and not only) politicians unfortunately oppose today.

Participatory Budget at The Regional Self-Government. Participation of Citizens as An Element of Intraregional Policy of Voivodeships In Poland

Abstract

The article addresses the issue of regional participatory budgets in Poland. Despite the functioning of the PB in Poland for several years, participatory budgets are not common at the regional level and the adopted solutions are not uniform. The analysis was to identify the most commonly used solutions, which may lead to the unification of future regional PBs in Poland, and be a comparative material for researchers analysing the possibility of introducing regional PBs in other countries. The results of the analysis clearly indicate that regional PBs can complement the activities of lower-level local governments. It is important to indicate a number of restrictions resulting from the scope of competences (including regional self-government subsidiarity), financial conditions (low-income potential) and the specifics of the participatory budget (local nature of activities).

Keywords: Participatory Budgeting, Regional Self-Government, Public Services

Introduction

The participatory budget (referred to as civic in Poland) is becoming a more widely used innovative solution of the citizens' consultation process all over the world (Dias, 2018). Among the benefits resulting from its use, the most frequently mentioned ones in the literature are the improvement in efficiency and transparency of public money spending, adjustment of the goods and public services provided to the requirements of residents, activation of the society and strengthening of social ties(Cabannes, 2004; Sintomer, Herzberg and Rocke, 2008, p.174; Sintomer et al., 2010; Yang and Pandey, 2011; Speer, 2012; Mkude, Pérez-Espés and Wimmer, 2014; Cabannes and Lipietz, 2018). On the other hand, there are also pointed disadvantages and weaknesses of the use of mechanism of citizen participation in the activities of local authorities who point to flaws and imperfections in the processes of citizen engagement (Irvin and Stansbury, 2004; Filner, 2006; Papadopoulos and Warin, 2007; Fuji-Johnson, 2015, p.120). Nevertheless, both individual countries and international organisations, such as the World Bank(Mansuri and Rao, 2013), European Union(European Parliment, 2016), OECD(OECD, 2011) or United Nations (UNDP and UN Habitat, 2016) indicate the need to involve local communities and citizens in the actions of the authorities. While such activities occur at the local level in many countries, they are mostly absent at the regional level. The few countries where the occurrence of the participatory budget (PB) at the supralocal level can be noted include Peru, Ivory Coast, Russia, Poland, Portugal, Colombia, Ecuador and several other countries with isolated cases of such solutions (Dias, Enriquez and Julio, 2019). The question, therefore, arises as to the reasons for such significant differences in the use of the PB at the regional level. In addition to such obvious reasons as, for example, the lack of a regional level of local government or the scope of competence of regional authorities in individual countries, associated with the inability to use the PB, it should be also noted that there is the existence of the political will of regional authorities and the possibility of cooperation with governments of lower levels. This article will present the operating conditions and adopted solutions

in PBs implemented in local government regions in Poland. The approximation of these conditions and the solutions used should be important for future decisions of regional governments in other countries, constituting a significant contribution to the analysis of the PB development opportunities at the regional level, primarily in unitary countries.

Objective and Research Methods

The main purpose of the work was to analyse and evaluate the manner and scope of use of the participatory budget by voivodeship (regional) self-governments in Poland. Based on the results of the research, the areas and forms most often used by regional self-governments will be identified, which will enable determination whether evolution has developed a homogeneous PB model at the regional level in Poland. This analysis is also aimed at showing researchers and practitioners from other countries acceptable (after taking into account the specificities of individual countries) solutions in the field of regional PBs. The analysis will cover 5+1 out of 16 regions of Poland, i.e. all five regions that employed solutions with features similar to those of the PB in 2018. Regions in which the full PB procedure was not carried out or where the procedure was of a pilot nature were omitted, excluding the Silesian Voivodeship, as an example of a PB deriving from the solutions used in individual voivodeships. The analysis covered ten main issues determining the shape of a PB. The following were included to them on the basis of an analysis of resolutions: the method of defining the amount of expenditure (source of law), main and optional financing objectives under a PB, the structure of the distribution of funds in the region (division into pools), funding limits for individual tasks and areas, restrictions in scope/specificity of the tasks, rules for submitting task proposals to a PB, existence of relations between the applicant and contractor, method of substantive supervision over projects, rules for the selection of tasks (voting), selection of the contractor. As it can be seen, some of the issues mentioned will determine the transition between the regional level and the local dimension of the task. By its nature, the participatory budget is local, which means that its implementation by the regions will face the indicated divergence. Therefore, regions will be forced to use various tools/solutions adapting their PB to the local dimension.

Self-Government in Poland

The structure of public administration in Poland is characterised by high complexity since it includes central (government) administration, units of central government administration at the regional level, and three-level of self-government administration – i.e. regional(voivodeship), supralocal(poviat) and local government administration(gmina). As it can be seen, regional self-government operates independently of the government administration. This structure of public administration in Poland is a consequence of the system reform of 1998 and the assignment to local governments of 16 new voivodeships of competences and own tasks in the field of intra and interregional policy. Self-government at the voivodeship level is elected, like other supralocal and local self-governments, by way of general and direct elections by the inhabitants of a given region. Self-government voivodeship means a self-government unit created by law by the inhabitants of the voivodeship. It is the largest unit of the main territorial division of the country for the purpose of performing public administration (Act of 5 June 1998 on voivodeship government - Journal of Laws of 2013, item 596). The voivodeship self-government performs voivodeship public tasks that have not been assigned by law to other government administration units. It does not have a superior and control function in relation to the supralocal and local (municipality) government. The basic tasks of the voivodeship self-government include matters in the field of:

1) public education, including higher education;
2) health promotion and protection;
3) culture and protection of monuments and care for monuments;
4) social assistance;
5) supporting the family and foster custody system;
6) family-friendly policy;
7) modernisation of rural areas;

8) spatial development;
9) environmental protection;
10) public transport and public roads;
11) physical culture and tourism;
12) protection of consumer rights;
13) defence;
14) public safety;
15) counteracting unemployment and activating the local labour market;
16) activities in the field of telecommunications;
17) protection of employee claims in the event of the insolvency of the employer.

It is indicated in the literature that the types and categories of tasks assigned to the self-government voivodeship in many points overlap with the tasks of the municipality and poviat. The basic criterion distinguishing what belongs to the tasks of a municipality, poviat, and voivodeship is most often the territorial scope of tasks – local, supralocal or regional (Dolnicki, B., 2012). Therefore, it can be seen in the tasks of the voivodeship self-government that there is room for using a PB formula in relation to similar tasks taken up by the PB in local governments. It should also be noted that the voivodeship self-government carries out a voivodeship development policy, which consists of:

1) creating conditions for economic development, including creating the labour market;
2) maintenance and development of social and technical infrastructure of voivodeship importance;
3) acquiring and combining funds: public and private, in order to implement tasks in the field of public interest;
4) supporting and conducting activities aimed at raising the level of citizens' education;
5) rational use of natural resources and shaping the natural environment in accordance with the principle of sustainable development;
6) supporting the development of science and cooperation between the area of science and the economy, supporting technological progress and innovation;
7) supporting the development of culture and the care of cultural heritage and its rational use;
8) promotion of values and development opportunities of the voivodeship;
9) supporting and conducting activities for social integration and combating social exclusion.

Thus, from the point of view of the objectives of PB implementation, most areas of the strategy may also be areas of citizen participation within the PB, in particular the area of infrastructure, natural environment, culture or social integration.

Participatory (civic) budget at the Regional Level

The first forms of participatory budget in Poland appeared before 2010 and concerned the participation of rural residents in planning budget expenditure under village funds. At the same time, it should be pointed out that the possibility of the existence of forms of consultations with residents in local governments similar to the PB functioned in Poland since the 90s(Wójcik, 2014; Olejniczak and Bednarska-Olejniczak, 2019; Feltynowski and Rzeńca, 2019). The next stage of PB development in Poland was the introduction of the first PB in Sopot in 2011(Kębłowski and Van Criekingen, 2014), which initiated an avalanche increase in interest in the PB in cities and contributed to discussions on the scope and forms of PB that could be used in Poland (Bednarska-Olejniczak, Olejniczak and Svobodova, 2019; Bednarska-Olejniczak and Olejniczak, 2018). Due to the lack of detailed legal regulations, the PB in Poland has evolved adequately to the needs of residents or authorities of individual local governments, which resulted in a significant diversity of the scope, scale and form of a PB in individual local governments(Bednarska-Olejniczak and Olejniczak, 2017). The changes in the regulations regarding municipalities, poviats and voivodeships, introduced by the Act of January 31, 2018, refer to the civic budget as a "special

form of public consultation."(Local Government Act, 1990) Pursuant to the provisions of the Act, as part of the civic budget, the inhabitants of a given local government unit may directly vote in order to decide about a part of the budget's expenses. The tasks selected under the civic budget are included in the budget resolution of the local government unit. A very important issue ensuring the credibility of the process is the regulation that in the course of work on the draft budget resolution, the tasks selected within the civic budget cannot be removed or significantly changed. This means that selected projects should be implemented. In addition, regulations for large cities (with poviat rights), where the creation of a civic budget is mandatory, were introduced. The guaranteed minimum amount of funds to be spent under the PB should not be less than 0.5% of the municipality's expenses included in the last budget implementation report submitted. It is left to the powers legislative bodies of local governments to determine by a resolution the requirements to be met by a draft civic budget. This means that it is the local government authorities that determine the formal requirements to be met by submitted projects; the required number of signatures of residents supporting the project, rules for assessing submitted projects as to their compliance with the law, technical feasibility, compliance with formal requirements and the procedure for appealing against decisions of not allowing the project to voting, as well as rules for voting, determining results and making them public, given that voting rules must ensure equality and directness of voting.

In recent years, five regions have implemented participatory budgets in various forms (usually self-developed) in Poland. It should be noted that as a result of the abovementioned lack of legal regulations there was a relatively large freedom as to the scope and form of the PB in the regions. The analysis of resolutions establishing participatory budget mechanisms indicates that an analogous form to the one used in cities - consultation with residents - was adopted as a basis. Thus, it can be stated that in the absence of mandatory requirements for the existence of the PB, only a relatively small part of voivodeship governments decided to allow residents to participate in the choice of the spending direction. These are voivodeships in which GDP per capita ranges from 80% of the national average (Opole Voivodeship, West Pomeranian Voivodeship) to over 100% (Lower Silesian Voivodeship, Silesian Voivodeship). The spatial arrangement is dominated by the voivodeships of western and southern Poland (bordering Germany, the Czech Republic and Slovakia). The exception here is the Łódź Voivodeship in the central part of Poland. It is difficult to indicate significant similarities between individual regions because both their size, specialisation, structure, scale of income as well as the structure of the population are varied.

Analysis of differences in the construction of the participatory budget at the regional level

The previously mentioned main issues determining the differences between the regionals' participatory budgets are shown below (fig. 1).

Fig. 1: Differences in regional PB regulations in Poland

The first area analysed is the definition of the amount of funds allocated to the PB by individual voivodeship self-governments. As the funds allocated to the PB constitute an integral part of the budget of individual voivodeship self-governments, it is important to include them in the financial plans for subsequent years - which results in a provision indicating the need to specify them in the budget resolution. At the same time, only in one voivodeship (West Pomeranian Voivodeship) the level of these funds was defined in advance for subsequent years. This means that in most voivodeships, the size of the PB may depend on the financial liquidity of the voivodeship in the following year.

However, a very diverse category is the purpose of spending funds under the PB. While in most voivodeships, "a project submitted under the Budget may be a regional citizens' initiative that will contribute to the development of the voivodeship" the specification of this goal varies significantly in different units. In the Lower Silesian Voivodeship, the PB areas are usually established every year, in the Opole Voivodeship, the implementation of, in particular, a civic, health, cultural,

educational, sports or tourist task can be a citizens' initiative, and in the Lesser Poland Voivodeship it can be also an ecological task. In the West Pomeranian Voivodeship, "the main goal is to build the identity and cohesion of the region by supporting and promoting the initiatives of the inhabitants of West Pomerania, strengthening trust and ties between citizens (social capital), the ability to cooperate in the immediate environment to achieve common goals and strengthen convergent values," while in the Łódź Voivodeship, for general-regional tasks there is no defined scope, and poviat tasks can only be allocated to the implementation of "non-investment" tasks of a sports nature, regarding public safety, tourism, ecological education, protection environment, health-related rehabilitation, the dissemination of folklore related to the Voivodeship, disseminating culture in relation to the history of the voivodeship and historical memory. As it can be seen, this is a closed catalogue of tasks, in contrast to the first group of listed voivodeships.

There is also the problem of the territorial scope of financed tasks. In addition to the presented division into regional and poviat (also occurring in the West Pomeranian Voivodeship), voivodeship governments accept, as an alternative to poviat division, the division into subregions (covering several poviats) as a criterion for the distribution of funds. This is primarily caused by the desire to maintain balanced distribution funds within the voivodeship (regardless of the number of inhabitants) while enabling communities to cooperate across the administrative boundaries of municipalities and poviats in order to implement joint ventures relevant to residents.

To ensure that the desired number of tasks within the civic budget is implemented, local governments set funding limits, with funding limits for regional projects typically up to 50% higher than for other projects. In addition, it should be noted that there was a large variation in the value of funding limits (even a tenfold difference) and in the case of the West Pomeranian Voivodeship the own contribution of the entity obtaining funding was required. In some cases, the funding restriction concerned the maximum number of projects under the civic budget in individual poviats.

At the same time, each of the voivodeship governments indicated a list of activities that cannot be financed from the civic budget. The most common provision was the inability to finance as a task consisting only in the preparation of project documentation, financing the implementation of a task already financed from the funds of the voivodeship government, organisation of mass events and tasks involving the purchase of land.

The above restrictions are important as the framework within which the participatory budget projects will be created and implemented, however, for the participation of residents, the following elements of the resolution on the participatory budget are important: specification of the applicant, the formal form of the application and accompanying documents, as well as persons entitled to vote. The essence of the participatory budget is the active participation of residents in as much of the works on it as possible. Thus, by nature, the most favourable situation would be the one in which both at the stage of coming up with ideas and preparing proposals, voting and partly implementing the idea (e.g. through participation or supervision), the inhabitants would actively participate in it. It can be pointed out that the Polish village fund is the solution which is the closest to this concept. In the case of Polish regions, we deal with a very diverse approach to the issues discussed. In most voivodeships, the inhabitants of a given region or a subregion/poviat have the exclusive right to submit projects. This means that they are required to prepare the project together with the cost estimate and to promote the project before voting. More importantly, at this stage there is usually no possibility to indicate the entity to implement the project, as in the case of most non-infrastructural or non-investment activities of the contractor, the winning projects will be implemented by non-governmental organisations as part of open competitive tenders for public tasks announced on the basis of the Act of April 24, 2003 on public benefit activities and volunteering. Thus, even the applicant related to a given social organisation wishing to implement a given project does not guarantee the implementation of a given project to that organisation. In turn, in the West Pomeranian Voivodeship, the applicant may be, apart from a natural person (informal group) represented by the Guardian (usually an NGO entity), also an entity having its registered office/branch in a given voivodeship/subregion. In this case, the applicant is not

separated from the implementer and the participatory budget itself takes the form of a grant competition for the creation of a concept and implementation of public tasks. Residents, like in other voivodeships, are entitled to vote for projects located in the area adequate to their place of residence. It is worth noting that in the case of projects submitted by residents, the voivodeship offers support in project preparation.

In most voivodeships, "lists of support" are required which show residents' interest in a given idea; however, the limits set by individual voivodeships are often very low compared to the number of inhabitants of a poviat, subregion or region, and range from 50 to 150 signatures. Also the minimum support limits during voting at the level of 200 votes as qualification for possible implementation are very low. This demonstrates the expected low interest of residents in this form of participatory budget.

Conclusions - participatory budget model at the regional level - an attempt to synthesise experiences

Based on the analysis of existing solutions, an attempt can be made to define the general framework for the construction of regional participatory budgets in Poland. The solutions that allow the greatest involvement of citizens in the processes of co-governance have been chosen. It is worth noting that in the case of one of the analysed regions, there are significant differences in some areas, while these differences may reduce the importance of citizen participation in creating the civic budget. So in the synthesis of solutions they were omitted. This framework covers the following issues:

First of all - the main determinant of the regional PB will be the scope of competences of a given region and the subsidiarity of its activities with local and supra-local governments. Thus, it should be assumed that the regional PB will be a complement to the lower-level local governments.

Second of all - the scope of the PB will be determined by the development strategy of a given region in close relation to the strategy of the state and the strategies of other local governments within a given region. Therefore this means a restriction of freedom in terms of submitted and implemented initiatives of residents.

Third of all - the projected financial stability of the voivodeship and the existence of free funds possible to be allocated to the PB in the region will be a significant limitation here. This is a significant limitation because in Polish conditions regional governments have a significantly limited income base, which affects the relatively low possibilities of financing optional tasks, which include the regional PB.

Fourth of all - the choice of task areas is a consequence of the three points mentioned above. Limited resources, subsidiarity and being part of strategies determine the preference for "soft" (non-investment, non-infrastructure) projects. Therefore, it seems that pro-social activities will be prioritised here.

Fifth of all - despite the regional nature of the voivodeship participatory budget, the allocation of funds takes place mainly at the local level - which reflects the idea of a participatory budget as a budget for the local community. This results in the need to allocate funds and select projects in the layout of individual subregions/poviats and a significant deviation from general regional tasks.

Sixth of all - both the submission of projects by residents, their support (list of support) and voting for them, mainly become actions of local/supra-local nature, as the people entitled to participate must be residents of a given area (poviat/subregion). It can therefore be concluded that the use of the regional participatory budget formula will be more justified for projects covering the area of more than one lower-level administrative unit. Otherwise, it will only complement the activities of individual units.

Seventh of all – the dominant solution in the selection of the entity implementing projects that won the vote is a competitive tender for the implementation of a public task by NGOs, but the requirement to provide "own contribution" as a supplement to the project funds by these entities seems to be problematic. Another issue is the fact that we may often be dealing with a situation when the applicant is also a person closely related to the entity that is applying for the opportunity to complete the task.

The above studies also encountered significant limitations. It should be noted that due to the differences between the regions in Poland it is hard to unify the regional PBs. The research did not use methods of statistical analysis because it was not intended to indicate the factors determining the use of PB institutions but only to discover and underline possible main directions of creating PB at the regional level. Yet another important limitation in the analysis is the lack of qualitative research – interviews with the regional authorities representatives who implement PBs in their regions. Such interviews would allow assessing the premises and barriers in making decisions about the introduction of regional PBs.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme
"Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Personal and Contextual Factors Affecting The Intentions of Commercialization of Research Results Among Academic Teachers of Technical Universities - Concept of Model and Research Process

Urszula KOBYLINSKA

BIALYSTOK UNIVERSITY OF TECHNOLOGY
Bialystok, Poland, u.kobylinska@pb.edu.pl

Abstract

The article presents the issues of the entrepreneurial intentions of scientists and includes such elements as: literature review, research assumptions, a proposal for a model of intention of commercialization of knowledge by scientists and the method of its verification. In addition, a discussion of the usefulness of the model for University leaders and scientists is undertaken.The main goal of this paper is to develop a new model of causal shaping the intention to commercialize knowledge and its empirical verification among scientists. Using the methodology of structural equation modeling (PLS), the results will verify which personal variables (i.e. professed beliefs, values, etc.) initiate a chain of effects affecting variable activities (i.e. self-confidence, self-efficacy, etc.) and to what extent the context affects for such behavior (i.e. completed training, support ecosystem, quality of inter-organizational relationships, etc.).

Keywords: Academic Entrepreneurship, Personal And Contextual Factors, Entrepreneurship Intention, Theory Of Planned Behavior (TPB)

Introduction

To understand what mechanisms govern the entrepreneurial intentions of individuals, usually different researchers use a well-established psychological concept, initiated in the mid -1980s - namely the Theory of Planned Behavior (TPB) developed by Ajzen (1987, 2011). According to this theory, entrepreneurial intentions depend on three predictors i.e.: (i) attitudes, (ii) perceived control of one's behavior and (iii) social norms that shape the perception of such behavior. Entrepreneurial intentions largely determine entrepreneurial behavior, so studying these intentions and the factors that affect them is an important area of research. Insofar as entrepreneurial intentions are the subject of research of many groups of respondents (i.e. youth, students, immigrants, the unemployed, women, etc.) or interest in them touches the context of research (research at local, regional, international level, in developed and developing economies) little is in the literature on the subject of research results analyzing the intentions of scientists in the commercialization of the results of their research (de facto entrepreneurial intentions). Intentions and, as a result, entrepreneurial behavior of academic teachers can be equated with the intention of their commercialization of their research results, and consequently specific entrepreneurial behavior manifested in varying degrees of involvement in business activities (in the form of: spin-offs or spin-outs, sold licenses, involvement in the sale and transfer of technology, in the development of patents, utility models, consultations, commissioned works, reports, etc.). In this paper, the author assumed that the entrepreneurial intentions of scientists are synonymous with the intention of commercializing the knowledge they create. Research into the entrepreneurial intentions of scientists in this paper is justified due to the fact that there is still a gap in the literature on the subject in explaining individual and contextual conditions affecting the entrepreneurial attitudes of this group of respondents and their exemplification in the form of commercialization of research results. The mechanisms that stimulate scientists to engage in commercialization of research results are still not explained. In particular, we feel unsatisfied in comprehensive national surveys, which are simply not on this subject on such a large scale. The article addresses this gap and, based on theoretical considerations, own empirical research and

available foreign research results, an identification of the model for measuring these intentions was identified, which is the subject of verification.

The theoretical analysis in this paper has been limited to the level of groups of factors recognized in the literature of the subject as important for the development of academic entrepreneurship, while not being explored on a large scale in national studies.

The goal of this paper is to develop a new model of causal shaping the intention to commercialize knowledge and its empirical verification among scientists. Using the methodology of structural equation modeling (PLS), the results will verify which personal variables (i.e. professed beliefs, values, etc.) initiate a chain of effects affecting variable activities (i.e. self-confidence, self-efficacy, etc.) and to what extent the context affects for such behavior (i.e. completed training, support ecosystem, quality of inter-organizational relationships, etc.).

An analysis of foreign and domestic literature in the field of management sciences indicates the lack of a clear concept and model explaining the determinants and predictors of the intention to commercialize research results in the activities undertaken by academic entrepreneurs. The author believe that statistical verification of the intention model for commercializing research results is a contribution to the development of management and quality sciences, and will contribute to national policy makers to develop effective strategies to stimulate entrepreneurship among researchers. The developed model will be verified in terms of the importance of individual (personal) or contextual variables in the intention to commercialize knowledge.

The results of research will have several implications for both the academic community and university managers. First of all, this project contributes to the literature on intentions in the commercialization of scientists' knowledge, because the research covers the academic context and enriches the existing model of entrepreneurial behavior (TPB) with new factors, both individual and contextual. Secondly, it shows the particular importance of predictors of entrepreneurial attitudes of scientists (i.e. values, creativity) and environmental factors (quality of relationships in the ecosystem of entrepreneur support, contact with the business environment, previous experience in commercialization).

The proposed model takes into account and complements previous constructs described in the literature. It will be able to be verified in various areas of the higher education sector and by institutions involved in supporting academic entrepreneurship.

Theoretical Background

The concept of academic entrepreneurship has been making a career all over the world in recent years - also under other names, including technological, innovative and intellectual entrepreneurship, and technostarters. The term "academic entrepreneurship" was originally conceived as referring to the extension of business entrepreneurship towards the academic environment and only to distinguish enterprises based on academic knowledge from others (Obschonka 2015, p. 687). The dominant definitions in English-language literature then changed from the idea of creating profit-oriented enterprises at universities and focused on the fundamental role of university spin-offs (Shane 2005; Wright et al. 2017). Later, other authors promoted the views of academic entrepreneurship as a way of transferring knowledge from the university environment to the market. This broader interpretation of academic entrepreneurship encompassed all academic contacts with business entities that underpin the creation of market value. In a different approach, academic entrepreneurship is presented as: all activities that go beyond the traditional academic roles of teaching and / or research, are innovative, carry a risk element and lead to financial benefits for individual academic employees or their institutions (Abreu, Grinevich 2013). Finally, some authors consider academic entrepreneurship to be focused on creating social value (Botes, 2005). In simpler terms, academic entrepreneurship is defined as the synthesis and integration of scientific, academic and commercial activities (Botes 2005, Kingma 2011). It is often

characterized by formal arrangements for the commercialization of intellectual academic property through knowledge (e.g. consultation or contracted research), technology transfer (e.g. patent or licensing), and transfer of products or services, e.g. spin offs. Academic entrepreneurship occurs at the level of individuals or groups operating independently or as part of faculties or other university units that create new organizations or initiate innovation inside or outside the university (Tijssen, 2006).

Academic entrepreneurship in Poland, as in foreign literature, is interpreted very differently. In the national literature, the most common approaches define it as "all kinds of involvement of scientific institutions, academics, support and administration staff, doctoral students and students in business activity". In a different approach, also as: "business activity of people from the academic community, which consists in the establishment by academics, PhD students and students of activity at or around the university" (Guliński, Wajda 2005, pp. 77-78). In a narrower sense, academic entrepreneurship is limited to the involvement of researchers in the creation of new enterprises, the so-called spin-out or spin-off (Szara, Pierścieniak 2015, pp. 32-33). Is also identified, among other as educating students for entrepreneurship and promoting entrepreneurship; with support for entrepreneurs who are students, PhD students and academics; with support for the transfer of knowledge and new technologies to the economy (Development of the model ... 2006, p. 61). The Polish legal system even imposes on universities the obligation to educate all students of social studies in such a way that they are ready to "think and act in an entrepreneurial manner" (Moczydłowska 2017, p. 50). In addition to the traditional teaching and research functions, universities are increasingly involved in technology transfer, establish contacts with industry and engage in the creation of innovative infrastructure, i.e. research laboratories, science parks and industrial clusters (Bednarczyk 2013; Plawgo 2011, Szara, Pierścieniak 2011). There is no consensus in the literature on the definition of an academic entrepreneur (Plawgo, 2011). It was assumed in this project that an academic entrepreneur is a person (student, graduate, doctoral student, research, teaching, research and teaching, administrative university): engaged in business activities or creating new enterprises, the so-called spin-out or spin-off, or commercializing knowledge in the form of patents, licenses, utility models, consultations, commissioned works, reports, or involved in the sale and transfer of technology or being the author of innovative works for public use, where the university and its nearest sphere the environment is the territorial area of entrepreneurial initiatives (Kobylińska, 2019). This definition is crucial from the point of view of subsequent analysis of research results carried out among the respondents of the project, which will take into account such control variables of the respondents (academic teachers) as academic entrepreneur (scientist with experience in commercializing their research results) and scientist (without experience in commercialization).

Efforts to promote academic entrepreneurship have already been the subject of empirical and theoretical research, recognizing the high potential of academic entrepreneurship mechanisms as beneficial to both the economy and society (Feldman and Desrochers 2004; Shane 2004; O'Shea et al., 2005; Wright et al. ., 2007). The undertaken research in the discussed issues most often focus on the best practices in public support of academic entrepreneurship (Rothaermel et al., 2007), analyze factors facilitating the commercialization of research results in the form of external and internal support (Perkmann et al., 2013) or relate to specific mechanisms / forms of transfer, such as spin-off or spin-out companies (Djokovic, Souitaris, 2008). The literature on the subject also includes several literature reviews: Feliu and Rodriguez (2014), Mustar et al. (2006), Rothaermel et al. (2007), Djokovic and Souitaris (2008), Mars & Rios-Aguilar (2010) and Yusof & Jain (2010). While early work in this area focused on measuring the university's knowledge transfer activity (licenses, spin-offs) and analysis of initiatives that could affect the effectiveness of this activity (Siegel & Wright, 2015), in recent years the number of publications analyzing factors that lead scientists to entrepreneurial behavior (Nyeko, Sing 2015, pp. 1050-1055). In literature, mainly in English, one can find publications with research results that approximate the empirical analysis of individual factors influencing the intentions of entrepreneurial activities (Obschonka et al. 2012; Goethner et al. 2012, Huyghe, Knockaert and Obschonka, 2012) and contextual (see e.g. Moog et al. 2015, Obschonka et al. 2015; Guerrero & Urbano, 2014), however, none of these studies were conducted on a large scale in the academic world. Among other studies, there are those that are

focused on academic promotion (Foo, Knockaert, Chan and Erikson, 2016), the entrepreneurial identity of scientists (Obschonka, Silbereisen, Cantner and Goethner, 2015), scientific productivity (Erikson, Knockaert and Der Foo, 2015) and social identity in the academic community (Obschonka, Goethner, Silbereisen and Cantner, 2012).

Entrepreneurial behavior is a type of planned behavior (Miranda et al. 2017). Intention models are most appropriate for explaining and predicting this behavior. Various models have been developed to analyze the factors influencing the decision to start an entrepreneurial career. Examples are the entrepreneurial event model (Shapero, 1982), planned behavior theory (TPB) (Ajzen 1991, Ajzen 2001) and the entrepreneurial potential model (Krueger and Brazeal, 1994). Entrepreneurial intentions are the key to understanding the entrepreneurial process and can be considered as the first step in a long and complex process of understanding academic entrepreneurship. If entrepreneurial intention models are the strongest predictor of entrepreneurial behavior, studying their determinants is particularly important for understanding entrepreneurship among academic teachers. As the theoretical basis of study, the TPB model was chosen because of the advantages that have been demonstrated in using this concept in the academic environment (Goethner et al., 2012, Obschonka et al., 2012, Obschonka et al., 2015). In short, in the TPB model, a person's behavior is immediately determined by the person's intention (or not). In turn, the intention to behave depends on three basic elements: first, entrepreneurial attitude (EA); secondly, subjective norms (SN), which are the most social component of the model, and thirdly, perceived behavioral control (PC) in a situation in which they have to make decisions and act. Earlier applications of TPB in the entrepreneurial literature suggest that (EA), (SN) and (PC) usually explain 30-45% of the variance of intentions (Miranda et al. 2017). Unlike previous studies, proposed research assumes that a deeper look at the individual characteristics of academic entrepreneurs (professed values, creativity, etc.) and explanation of the importance of relationship quality in the academic support ecosystem (and within it such variables as trust, commitment, no conflict of interest, etc.), affecting the explanation of this area supporting entrepreneurial intentions. The support environment recently referred to as the university's ecosystem also plays an influential role, but there is a lack of in-depth research in this area to confront and statistically explain its importance in the entrepreneurial intentions of scientists. Therefore, the research indicates the need for further analysis of entrepreneurial intentions in the context of technical universities, especially in the national field, where there are no models explaining such behavior. It is important in this project to combine in the model the intrapersonal features of scientists and contextual factors of the work environment (Foo et al., 2016, Miranda et al., 2017), with particular emphasis on the support University ecosystem.

Model Proposal and Research Methodology

Methodological assumptions of the entire research process are as follows:

1. updating and systematizing knowledge about determinants, predictors and forms of commercialization of research results among scientists and networks of entities supporting them in Poland and in the world;
2. adaptation and modification of the TPB model (Theory of Planned Behavior) for the purposes of researching the intention of commercializing research results among technical university teachers;
3. systematization and description of model variables, including personal and contextual factors;
4. development and validation of theorems for independent and dependent model variables (factors);
5. determining base variables (factors) and strengthening the intention to commercialize research results;
6. identifying the strength and direction of the impact of individual personal and contextual variables (factors) on the intention to commercialize research results among technical university teachers.

Based on the literature review (described in the previous section) and previous own research, main research hypothesis was developed that will be verified in the research process:

H: PERSONAL AND CONTEXTUAL FACTORS POSITIVELY AFFECT THE INTENTION OF COMMERCIALIZATION OF RESEARCH RESULTS AMONG ACADEMIC TEACHERS FROM TECHNICAL UNIVERSITIES

Eleven specific hypotheses were also developed and will be verified during the research (Fig. 1).

Realization of the main goal requires answering research questions: What are the relationships between the intention to commercialize research results and individual (personal) and contextual factors of teachers of technical universities? Which factors have a stronger impact on the entrepreneurial intentions (in terms of commercializing research results) of scientists? What are the differences in the perception of personal and contextual factors among academic entrepreneurs and scientists of technical universities who have not yet commercialized research results?

In connection with the main theoretical and empirical currents discussed in intorduction taking into account the literature review on the intentions of academic entrepreneurship, we propose a model explaining the intentions of commercializing research results of teachers of technical universities in Poland based on three main explanatory factors (Fig. 1):

- entrepreneurial attitude of scientists (EA),
- perceived control of entrepreneurial behavior (PC) and
- subjective norms.

The general assumption we made in the project is that: the intentions of commercialization of research results by scientists are influenced by both personal (EA), (C), (V), (SC), (PU), (CE) and contextual (PC), (SN), (QRE), (T), (BE) verified in the literature on the subject (e.g. Obschonka et al. 2012; Obschonka 2016; Goethner et al. 2012; Alonso-Galicia et al. 2015; Erikson et al. 2015; Foo et al. 2016; Huyghe and Knockaert 2015; Guerrero and Urbano 2014; Moog et al. 2016; D'Este et al. 2011; Miranda et al. 2017).
Based on the review of the literature, the results of the available empirical research we consider 4 personal variables of the unit - creativity of academic entrepreneurs (C), professed values (V), perceived usefulness as the basis for constructing entrepreneurial attitudes of researchers in the direction of commercialization of research results (EA). The other two elements of the construct are (PU) and self-confidence (SELF).

As the background to the variable Perceived control of behavior (PC), we adopted factors such as: completed entrepreneurship training (T), Previous experience in business (BE) and Quality of relations in the ecosystem of support entities (QR), as well as previous experience in the field of commercialization of knowledge (CE).

The model has also been supplemented with the inclusion of several variables as predictors of (PC) design: previous experience in business (BE) and three context variables: training in academic entrepreneurship (T), favorable entrepreneurial environment (ENV) and quality of relationships in the support ecosystem entrepreneurs (QR).

Figure 1: Model of intention to commercialize research results among technical university academic teachers

Source*: own study*

Modeling using structural models will adopted as the main method of hypothesis verification. Modeling is to help fill the scientific cognitive gap in terms of key variables in the entrepreneurial intentions of scientists. The project plans to use statistical techniques such as descriptive statistics, discriminant analysis and AMS analysis for many groups.

Based on the concept of planned behavior theory (TPB), model will enrich the literature related to the entrepreneurial intentions of academic teachers with such aspects as:

- extension of predictors included in individual and contextual factors affecting intentions;
- demonstrating the special importance of entrepreneurial attitudes (AE) of academic teachers (individual factors) and their relationship with the following predictors: values, creativity and self-confidence;

- demonstrating the importance of perceived control (PC) (contextual factor) and its relationship to the quality of relationships in the support ecosystem, as well as training policies and previous business experiences of researchers.

Discussion and Conclusions

The planned study is innovative due to the context of its implementation. There are no national studies available to verify the entrepreneurial attitudes and behavior of technical university teachers. Technical universities in Poland employ a considerable number of academic teachers (almost 19 thousand) with a high potential for commercializing research results, covering the disciplines of technical, natural and social sciences. Most domestic universities, especially technical universities, have in their structure Technology Transfer Centers that can support the process of commercialization of research results. The way from the results of scientific research to their practical application, and therefore commercialization, is quite complicated. It requires not only time and resources, but also knowledge of the economy and its needs. A very important condition of success is also a very good knowledge of the realities of scientific work, as well as the determinants of the entrepreneurial intentions of scientists referred to in this project.

The research will also have important implications for practitioners. First, for policy makers who, in addition to incorporating results commercialization into many of their assessment processes, should also promote entrepreneurial culture creation at the university and shape high-quality relationships across the entire academic entrepreneurial support system. Therefore, the author believe that it is worth comprehensively identifying the main determinants of the intention to commercialize knowledge among teachers of technical universities in the context of Polish conditions. Secondly, the model suggests that managers of technical universities must be aware that the best way to promote entrepreneurship in their institutions is to create the conditions necessary to increase the entrepreneurial attitudes of their employees through various projects (training, study, cultural) aimed at strengthening creativity and shaping entrepreneurial values.

Completed research will contribute to the development of the knowledge for Univeristy leaders - regarding key factors affecting the entrepreneurial intentions of technical university teachers. The theoretical model developed shows the key elements shaping the entrepreneurial intentions of scientists and explains the relationship between personal and contextual variables important for the intention of commercializing research results. From the research point of view, it will be important to identify key factors shaping entrepreneurial attitudes to the greatest extent.

Abstract

The paper addresses the problems related to financial stability and exposure to poverty risk of senior citizens in European countries. The aging population trend is now becoming a global challenge, which is being made worse by the inevitable retirement of the so-called baby boom generation over the coming decades. The development of aging population will cause a series of problems to the elderly, including increasing instability of financial situation of elderly households. The budgets of senior citizens may considerably shrink because of low disposable incomes and overburden expenditures (e.g. expenses on health care services). The purpose of the paper is to identify and evaluate the main factors affecting the financial situation of elderly households, especially in the context of their exposure to poverty risk. In the analysis the selected external variables, such as: GDP, inflation index, saving rate, unemployment rate and old-age dependency ratio were included, in order to indicate the impact of economic environment, demographic trends and the existing pension schemes on the elderly financial stability. Moreover, specific variables corresponding to income and expenses of seniors were also examined. With the use of multiple regression analysis an attempt of comparison and evaluation of the poverty risk of elderly households in the selected European countries in 2007-2017 was made. The obtained results may be useful for policymakers in the area of pension systems and they indicate the need for the further analysis of detailed reasons for similarities and differences in the seniors' financial stability across Europe.

Keywords: Elderly Household, Poverty Risk, Europe, Multiple Regression.

Introduction

Despite the great progress in reducing financial inequities in populations, made in the past few decades, poverty still remains a broad and comprehensive global problem. Nowadays, more than 700 million people subsist on extremely low incomes, therefore research focused on the measurement of poverty and identification of possible ways of reducing it in the long run often represents a direct response to practical challenges of national, regional and local policymakers, especially in developing countries.

The importance of the problem of poverty and how to deal with it, is evidenced by the fact that the 2019 Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel has been awarded to Abhijit Banerjee, Esther Duflo and Michael Kremer "for their experimental approach to alleviating global poverty". The above-mentioned researchers have introduced a new approach to obtaining reliable answers about the best ways to fight global poverty by dividing this issue into smaller, more manageable questions, e.g. the most effective interventions for improving child health. It is worth mentioning that the research conducted by the 2019 Economic Sciences laureates has considerably improved the ability to fight global poverty. In just two decades, their new experiment-based

approach has transformed development economics, which is now a flourishing field of research (more in: Nobel Prize Committee (2019)).

With respect to elderly people the risk of poverty is of particular importance. Many countries have experienced aging population trend causing that the poverty among the elderly has remain a global concern (Khan et al. 2017). Also in Europe, an increasing lifetime in combination with relatively low replacement rate from the public pension systems and little pension savings or even a lack of them are the main factors causing that a growing number of senior citizens in European countries can be exposed to the risk of poverty. According to Eurostat (2019), in 2017 in the EU member states people aged 65 and over were faced relatively lower risk of poverty or social exclusion than the overall population with 18.2% compared to 22.4% for the whole population. However, significant differences can be observed among the share of older people exposed to the risk of poverty in particular European countries. The share of seniors being at risk of poverty was the highest in Bulgaria, Estonia, Latvia and Lithuania (more than 40% of 65+ age group). These differences depend on a number of factors, including above all, the characteristics of pension schemes for current pensioners as well as the age and gender structure of the population of older people in a given country.

It is important to emphasize that for the elderly households specific changes in consumption and savings profile can be observed, typical for this stage of a household financial life cycle. In European countries, the amount of pension benefits received from the public systems usually constitutes the main component of an individual's income, possibly supplemented by an additional private income available at retirement period. With respect to the senior citizens, a characteristic change in the consumption structure can be noted. Elderly people usually spend relatively more money on health care, long-term care services and rehabilitation services. Moreover, they usually use savings accumulated earlier, so they are less likely to accumulate new savings. All the above-mentioned aspects contributing to the potential exposure of elderly people to the risk of poverty require examination from both the social policy and market perspective.

The purpose of the paper is to identify and compare the main factors influencing the financial stability of elderly households in selected European countries, in the context of their exposure to the risk of poverty, with the application of multiple regression. The conducted analysis was aimed at answering the following research problems:

- What are the main factors affecting the poverty risk for the elderly?
- What are the differences in these factors and their impact among the examined European countries?

In the study selected external variables, such as: GDP, unemployment rate, inflation rate, old-age dependency ratio and the share of expenditure on pensions in GDP, were included in order to indicate the impact of economic environment, demographic trends and the existing pension schemes on the elderly financial stability in terms of their exposure to poverty risk. Moreover, specific variables corresponding to the seniors' budgets main components were also examined.

The main contribution of the paper is that we not only tried to measure and compare the exposure to poverty risk among elderly people in European countries, but we also made an attempt to identify the main factors causing the poverty of seniors in the examined states. This study contributes to the development of the silver economy and constitutes a part of a greater research on the financial standing of elderly people in Europe. We do hope that the results of the research can be useful for both scientists and practitioners interested in the implementation of social policy solutions as well as financial services addressed to the elderly.

The remainder of the paper is organized in the following way. Section 2 briefly reviews the literature on the poverty meanings, its indicators as well as the previous research concerning the trends and determinants of poverty among elderly people. In section 3 results of correlation analysis as well as multiple regression analysis are presented. Section 4 draws some concluding remarks.

Literature Review

Living in poverty can be defined in a number of ways. In simple words, a household is being in poverty when its resources are insufficient to meet the household's members basic needs (risk of poverty) and also to allow them to take part in the society (risk of social exclusion) (Joseph Rowntree Foundation 2016). As Drewnowski (1977) points out, poverty occurs when it is not possible to meet the needs at a level deemed satisfactory. This definition of poverty is ambiguous, because the feeling of satisfaction in meeting the needs is subjective and it is very difficult to determine what the desired level of satisfying these needs should be. In the scientific literature, in general two ways of understanding poverty are distinguished, i.e. absolute poverty (also called extreme poverty) and relative poverty. The first one – absolute poverty – occurs when the satisfaction of living and consumption needs is at a very low level, while consumption below this level leads to biological destruction of a human being. With respect to relative poverty, the level of satisfaction of needs of individuals (or households) refers to the level of satisfaction of these needs by other members of the society. This type of poverty is identified with excessive spreads in the level of meeting the needs in society and it is not possible to eliminate it entirely, but only to reduce it by limiting inequalities in the level of covering the needs. It is worth mentioning that in the case of the poor, there is often a limited possibility of their participation in economic, social and cultural activities, what can lead to social exclusion.

Poverty and low income can be measured in various ways. For the purpose of scientific research the indicators of poverty and social exclusion are applied. These indicators are designed to monitor the phenomenon of poverty and can be used in comparable household surveys conducted around the world. In Europe, the most commonly used approach uses poverty indicators which are one-dimensional (monetary) and relative (based on a threshold defined in relation to the distribution of income within each country) (Khan et al 2017). According to the widely-used concept, individuals being at risk of poverty are those living in households where equivalised disposable income is below the risk-of-poverty threshold, which is set at 60% of the national median equivalised disposable income after social transfers. (Antczak and Zaidi 2016; Eurostat 2019). The equivalised income is calculated by dividing the total household income by its size determined after applying the following weights: 1.0 to the first adult, 0.5 to each other household members aged 14 or over and 0.3 to each household member aged less than 14 years old (Eurostat 2019). This relative poverty measure enables comparisons between examined countries, however it has limitations related to the fact that the thresholds as defined above are country-specific (Zaidi 2010).

It is worth mentioning that there are also other ways to measure the risk of poverty based on the following main concepts (see more in e.g.: Eurostat 2019; Joseph Rowntree Foundation 2016):

- material deprivation – indicating if people lack access to certain goods or services, such as being able to pay regular bills, to face unexpected expenses or to keep their home adequately warm;
- minimum income standards – this approach focuses on the costs of goods and services required by different households in order to achieve acceptable standard of living;
- self-reported measures – in this approach people are asked how well off they evaluate themselves.

Recently, research problems related to the financial stability of senior citizens and their exposure to risk of poverty are getting more and more attention. One can distinguish the different directions of conducted research. From a household perspective issues related to income level and possibilities of accumulation of savings during retirement period were examined, among others, by De Nardi, French, and Jones (2010), Ishikawa and Haji (2009), Jin (2009), Palumbo (1999), Rank et al (2014). For example, Jin (2009) investigated the impact of out-of-pocket health care expenses on elderly household allocation decisions in the U.S. and found that because of volatility of the health care expenses elderly households were less likely to invest in risky financial assets. In turn, in the study written by Rank et. al. (2014) the life course approach was applied in order to understanding poverty among American elderly. Next, Khan et. al (2017) consider poverty as multidimensional issue

depending not only on income, but also other factors, such as health, education and labor market opportunities. They indicated the general causes of poverty at old age in the following areas: financial planning (income, savings), social demographic (employment, education), government support (retirement age, social security benefits) and social support (family and community support).

There are also comprehensive studies in the area of household financial situation comprising states from different European regions. Tai and Treas (2009) conducted cross-national research comprising 22 countries (Southern European, post-communist European and East Asian states) in order to examine the exposure to the risk of poverty from both the macro-level state approach and micro-level composition of households. The risk of poverty among elderly people in European Union countries was broadly investigated by Zaidi (2010), who distinguished the profiles of poverty among senior citizens in European countries and analyzed the trends in elderly people poverty risk in 2004-2008. In the next study Antczak and Zaidi (2016) examined the stability of elderly pension benefits taking into account the negative impact of the financial crisis. Moreover, Perek-Białas (2012) in her research discussed possibilities and limitations of the analysis of the elderly households material situation in Central and Eastern European (CEE) countries based on data from the EU-SILC (European Union – Survey of Income and Living Conditions). Borda and Kowalczyk-Rólczyńska (2018) examined the similarities in financial situation of elderly households in CEE states with the application of classification methods. The challenges for the economic situation of elderly people living in different European countries were also investigated by Buber et al. (2010) and Stula (2012). Another important issue is the relatively higher exposure of older women to the risk of poverty with their markedly higher longevity projections and notably lower average pension benefits compared to men. Ahonen and Bach-Othman (2010) analyzed differences in the poverty rate among elderly men and women in eight EU countries, with the objective of finding explanations for why the poverty risk of women is considerably higher than that of men in some countries but not in others. In the above-mentioned studies, one dominant research method can not be identified. Various research methods were used depending on the type and availability of data as well as the assumed research goals and hypotheses.

Summarizing, the provided literature review shows that although many researchers deal with problems related to the financial situation of elderly people (households) and their exposure to the risk of poverty, comprehensive studies on the identification and comparison of the factors affecting the financial situation of elderly households living in different European countries are still missing. In view of the demographic trends (aging societies), observed in practically all European countries, one can expect that further changes in the age structure of populations will lead to an increasing number of elderly households. Ageing society and related problems, such as poverty and social exclusion of the elderly, require continuous examination from both the social policy and market perspective.

Research and Results

The deterioration of the financial situation of the elderly, which, as a consequence, can lead to life in poverty, has been influenced by many factors. The literature survey has resulted in a list of variables that can be deemed potentially significant in the context of poverty risk in elderly households (see Table 1).

Table 1: Variables representing selected factors in the context of poverty risk in elderly households

Symbol of variable	Variable
Y	At risk of poverty or social exclusion rate for elderly (65+) (in %)
X_1	GDP per capita (in PPS)
X_2	Median equivalised net income 65+ (in PPS)
X_3	Housing cost overburden rate 65+ (in %)
X_4	Household saving rate (in %)

X_5	Old age dependency ratio (per 100 person of working age (15-64))
X_6	Inflation rate (in %)
X_7	Unemployment rate (in %)
X_8	Expenditure on pensions (as % of GDP)

Source: own study.

The study was conducted based on data from Eurostat for the period of 2007-2017, for the eight European countries: Germany, France, Spain, Italy, Poland, Romania, Hungary, Latvia. These countries represent both Western European countries (developed countries) and Eastern European countries (developing countries). The period selected for the study is dictated by the availability of comparable data. The objective of the study was to identify and verify whether the same factors significantly affect the risk of poverty rate for elderly in the different countries. Of the selected countries, the highest values of risk of poverty rate were registered in Latvia and Romania, the lowest – in France, in whole analysed period (see Appendix 1). Furthermore, median equivalised net incomes of elderly people in Western European countries were definitely higher than in Central and Eastern European countries. The highest value of housing cost overburden rate were noticed in case of elderly households in Germany, the lowest values for elderly who live in Spain. Values of this factor decreased between 2007 and 2017 in almost all countries, except for Germany (here similar level of this factor was observed).

In this study, for every country, the dependent variable is at the risk of poverty or social exclusion rate for elderly, and the potential independent variables are X_1 to X_8, that were submitted for verifications. At the risk of poverty or social exclusion rate for elderly is defined as the sum of elderly (65+) who are: at-risk-of-poverty or severely materially deprived or living in (quasi-)jobless households (i.e. with very low work intensity) as a share of the total population in the same age group.

In the first step, a variation coefficient was calculated for every independent variable in order to reject these variables for which $V < 0.1$ (see Appendix 2). Next, correlation coefficients were calculated between independent variables and the dependent variable; and a significance evaluation of the correlation coefficients was carried out, using a non-parametrical test for *p-value* 0.05. The statistically significant correlation coefficients that were obtained; were also exposed to substantive evaluation, which allowed for identification of these correlation coefficients for which the sign was illogical. Results of this part of the study are presented in Table 2, where statistically significant level of correlation coefficients was marked in bold type.

Table 2: Correlation coefficients of the risk of poverty or social exclusion rate for elderly and eights independent variables

Symbol of variable	Germany	France	Spain	Italy	Poland	Romania	Hungary	Latvia

Source: own study using Statistica software.

The correlation results suggest that, for all Central and Eastern European countries under study and for France, a significant impact of the housing cost overburden rate upon at the risk of poverty and social exclusion rate can be observed. The remaining variables – depending on the country – were found to be either significant or non-significant. It should be noted that:

- median equivalised net income is found to significantly affect at the risk of poverty and social exclusion rate in France, Poland and Romania,
- inflation rate is significantly correlated with at the risk of poverty and social exclusion rate in Italy, Poland, Latvia and Romania,
- expenditure of pensions is found to be significantly correlated with at the risk of poverty and social exclusion rate in Spain and Latvia.

It is worth pointing out that in the majority of countries under study, a statistically significant relationship between household saving rate and at the risk of poverty and social exclusion rate has not been found. Moreover, in case of Germany, almost all variables under study turned out to be statistically insignificant in correlation with at the risk of poverty and social exclusion rate.
Following of the correlation analysis, variables for further research for each country are presented in Table 3.

Table 3: A list of potential variables

Country	Germany	France	Spain	Italy	Poland	Romania	Hungary	Latvia
Symbol of variable	no variables	X_2, X_3	X_8	X_6	X_2,X_3,X_6	X_2,X_3,X_6	X_3	X_3,X_6,X_8

Source: own study.

In the next step, the variables listed in Table 3 were used to build multiple regression models. The general form of the linear multiple regression function for k independent variables X_1, X_2,…,X_k is (Hamburg 1970; McClave et al 2008):

$$Y = a_0 + a_1X_1 + a_2X_2 + \cdots + a_kX_k$$

$a_0, a_1, \ldots, a_k$ – coefficients.

Next, some variables were eliminated using the backward elimination method (Kotu and Deshpande 2015), until models with only statistically significant variables remained. For every regression model a determination coefficient was calculated; also the normality of the residual distribution, using the Shapiro-Wilk model, was verified (with *p-value* 0.05). The final forms of every model are presented in Table 4.

Table 4: The final form of regression models

Country	Variable	coefficient	p-value	Adjusted R^2	p for Shapiro-Wilk test
Germany	no model				
France	*constant*	27.368	0.000	0.913	0.415
	X_2	-0.001	0.000		
Spain	*constant*	62.210	0.000	0.973	0.307
	X_8	-3.792	0.000		
Italy	*constant*	21.099	0.000	0.395	0.641
	X_6	1.019	0.023		
Poland	*constant*	35.881	0.000	0.996	0.939

Source: own study using Statistica software.

Results of multiple regression allow to indicate that in case of Germany no variable affects poverty in the elderly group. Moreover:

- in France, Poland and Romania: the level of income affects poverty in the elderly group,
- in Spain: the level of expenditure on pensions affects poverty in the elderly group,
- in Italy and Poland: the level of inflation affects poverty in the elderly group,
- in Romania, Hungary and Latvia: the level of housing cost affect poverty in the elderly group.

It is worth pointing out that the level of housing costs play important role in the case of elderly who live Eastern European countries.

Conclusions

The problem of poverty in elderly households is a multifaceted problem requiring continuous examination from both practical and theoretical sides. The level of poverty depends on many factors, both measurable and difficult to measure. In the study we took an attempt to identify quantitative factors that affect the risk of poverty in the case of elderly living in selected European countries. We found that among the analysed countries, Latvia and Romania were characterized by the highest values of at risk of poverty rate, the lowest level of this measure was noted in France.

Moreover, the results of multiple regression analysis indicate that the main factors causing the poverty of the elderly in the examined countries are: level of income, expenditure on pensions, inflation rate as well as housing costs. One can observe the essential role of variables corresponding to the seniors' budgets main components – income and costs. It is also worth emphasising that the level of housing costs mainly affects the risk of poverty of seniors in Romania and Latvia, these are countries in which the elderly exposure to the risk of poverty is much higher compared to other examined countries. Future directions of research on factors leading to poverty of elderly people should be extended taking into account intrafamily relationship as well as sociological factors, as they may play an increasingly crucial role. In the further research, depending on the type and quality of data, more advanced research methods can be implemented.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

A Comparative Study of Social Representations on Euthanasia in Medical Students of Two Different Cultures

Evgeni NIKOLAEV

Ulianov Chuvash State University, Cheboksary, Russia
E-mail: pzdorovie@bk.ru

Laziz NIYAZOV

Bukhara State Medical Institute named after Abu Ali Ibn Sino, Bukhara, Uzbekistan

Abstract

The paper presents the results of comparative study of social representations on euthanasia in 140 medical students from Russia and Uzbekistan. Social perceptions of euthanasia were studied using the 19-point Attitude to Euthanasia Questionnaire (Nikolaev, 2017). The key differences are determined by legal, ethical and spiritual representations. There are trends towards differences, related to gender, age, faith, level of urbanization. The study establishes the closeness of social representations on euthanasia of Russian and Uzbek students in medical, sociocultural and personal aspects of their attitude to euthanasia.

Keywords: Medical Students, Social Representations, Euthanasia, Russia, Uzbekistan.

Introduction

The topic of conscious death in a situation of a serious incurable disease, designated in the modern world as euthanasia, is one of the main problems of bioethics (Thomas, 2017; Burger et al., 2018). Medical students in the years of study at the university should form an adequate attitude to the problem of death, since its immaturity can reduce their psychological well-being (Chistopolskaya et al., 2017) and directly affect the effectiveness of their future professional activity. Issues related to the attitude of medical students to death and suicide are the subject of cross-cultural research (Chistopolskaya et al., 2016), which helps to better understand the sources of social representations of tomorrow's specialists and to influence them. Comparative studies of social representations on euthanasia are no less relevant. Today social representations of euthanasia are used in medical and religious practice to protect professional identities and to justify their expert knowledge of death and dying (Jylhänkangas et al., 2014). It is important that new experience in the study of social representations of medical students' on euthanasia already exists both in Russia (Nikolaev et al., 2018) and in other countries with a predominant Christian culture (Pomfret et al., 2018; Santos et al., 2019). Religious beliefs are known to play an important role in shaping attitudes toward euthanasia (Zaccaria et al., 2019). In this connection, it seems to us important to compare social representations of the Russian medical students on euthanasia with similar views of their peers of a different culture, in particular, Muslim. A reasonable platform for such a study could be Uzbekistan, which has a modern level of education and medicine development, as well as rich historical experience of bioethical doctrines (Mukhamedova, 2014; Mukhamedova, 2015).

Method

The survey involved 140 medical students studying at universities in Russia and Uzbekistan. The Russian sample is represented by 84 students of Ulianov Chuvash State University (mean age 19.10±1.98; 58.33% women), the Uzbek sample - 56 students of Bukhara State Medical Institute (mean age 20.11±1.63; 57.14 % women). These groups did not differ in age and gender, but they

differed in cultural status (language, religion, traditions). Among Russian students Orthodox Christians predominated (89.29%), among Uzbek students, Sunni Muslims (96.30%).

Social perceptions of euthanasia were studied using the 19-point Attitude to Euthanasia Questionnaire (Nikolaev, 2017) which was structured into five modes (medical, legal, ethical, sociocultural, spiritual and personal) to reveal specifics of social representations on euthanasia.

Statistical processing was carried out by calculating basic statistics, comparison of means and standard deviations, comparison of rates, correlation analysis at significance level of $p < 0.05$.

Results

At the first stage of the study, the characteristics of the respondents were compared by faith factor, which to a greater degree reflects not professional, but cultural representations about death and dying. Thus, among Uzbek students, significantly more ($p=0.02$) believers were identified (92.86%) than among Russian students (76.19%). There were no atheists or non-believers among Uzbek students. Among Russian students there were 4.76% and 7.14% of such respondents respectively. The self-esteem of faith in Uzbek medical students (93.39%) is one third higher ($p = 0.0001$) than that among Russian students (62.55%).

At the second stage, the attitude of medical students of two cultural groups to various aspects of euthanasia was evaluated. As the analysis showed, Russian and Uzbek students have both similar social representations on euthanasia ($p < 0.05$) and significantly different ($p > 0.05$).

The similarity of attitudes toward euthanasia is determined at the level of medical, socio-cultural and personal representations. Half of Russian and Uzbek medical students are equally often sure that euthanasia is more a medical problem (46.43% and 60.00%), and their countries are not ready for euthanasia legalization due to organizational specifics of healthcare system (44, 05% and 50.94%).

As part of sociocultural perceptions, two-thirds of Russian and Uzbek students have a similar opinion on fear of possible abuse if euthanasia is legalized (76.19% and 69.23%). Two-thirds of respondents believe that such a risk may arise due to possible insufficient control over the implementation of the law in their countries (30.96% and 39.62%).

In the personality context of social representations of euthanasia, one in ten Russian and Uzbek students report that they already have experience of situations in which euthanasia could be used (10.71% and 9.09%). Every third is ready to apply it to himself /herself (32.15% and 42.31%), a slightly smaller number of those who allow euthanasia in relation to their loved ones (29.76% and 28.85%).

According to the survey, if in Russia the share of opponents of euthanasia (58.33%) significantly ($p=0.045$) exceeds the share of its supporters (41.67%), then in Uzbekistan the share of opponents (51.85%) and supporters (48.15) %) are statistically indistinguishable ($p=0.84$).

Significant differences are observed at the legal level of social perceptions of E. Uzbek students to a greater extent ($p=0.0001$) consider E. as a legal problem (64.81%), unlike their Russian peers (28.53%).

Russian students see the problem of euthanasia to a greater extent (70.24%) than Uzbek students (50.00%), moral content, which corresponds to differences in social representations at the ethical level ($p=0.025$).

Differences are also identified on the spiritual level of euthanasia representations. Medical students from Uzbekistan are significantly more likely (76.47%) than Russian peers (57.14%) to believe that a person should not die at will, because comes to this world not of his own free will (p=0,030).

At the third stage, the correlation relationships between the obtained parameters were studied. The following reliable relationships were obtained in the Russian sample. Men are more likely to agree with the legalization of euthanasia (r=0.26), relating it with the humanization of society (r=0.25). The willingness to legalize euthanasia increases with the age of the respondents (r=0.21) and with the increasing degree of urbanization of the settlement in which they live (r=0.29). Urban residents are more likely to associate euthanasia practice with a high level of humanism in society (r=0.24), less prone to abuse opportunities (r=-0.21), and they also more welcome the experience of countries that have already legalized euthanasia (r=0.28).

More religious Russian students do not see euthanasia as a legal problem (r=-0.19) and as a manifestation of humanism (r=-0.22), and more as a violation of the fundamental divine order (r=0.24).

Russian medical students, who are more inclined to rely on their own strength in difficult situations than to turn to others for help, are less afraid of the risk of abuse during euthanasia (r=-0.20). Persons who prefer less frequent use of official medicine more often agree to the hypothetical use of euthanasia in relation to themselves (r=0.21). Students who are more approving of suicide practice have a more positive attitude to legalizing euthanasia (r=0.19), recognizing it as one of the manifestations of high humanism (r=0.19).

In the Uzbek sample, other relationships are identified. Men are more likely to consider euthanasia as a legal problem (r=0.30) and to a greater extent agree with the use of euthanasia in relation to themselves (r=0.29). Older students are less likely to support euthanasia legalization (r=0.29).

Believing students do not consider euthanasia as a sign of humanism in society (r=-0.31), but rather as a contradiction of the divine essence of man (r=-0.29). The more faithful Uzbek students consider themselves to be believers, the more they consider euthanasia a question of moral character (r=0.27), the legalization of which indicates a high level of spirituality of society (r =0.23).

Uzbek medical students, who mostly rely on their own strengths in difficult situations, are sure that everyone has the right to make decisions regarding his/her own life only (r=-0.40). The less healthy the respondent considers himself/herself, the less likely he/she is to blame the low moral level of medical professionals (r=-0.32). Students who are more likely to seek help from official medicine are less likely to find an imperfect legal framework in connection with euthanasia (r=-0.31).

Conclusion

In this research, a comparative analysis of social representations of medical students from universities in Russia and Uzbekistan, presenting differing in language, religion and traditions cultures, is carried out. It is revealed that the key differences in attitudes toward euthanasia between Russian and Uzbek students are determined at the level of legal, ethical and spiritual representations. There are certain trends towards differences between the two groups of students, related to their gender, age, faith, level of urbanization, and other factors. The study establishes the closeness of social representations on euthanasia of future Russian and Uzbek medical doctors in context of medical, sociocultural and personal aspects of their attitude to euthanasia. The sources of these similarities and differences should be the subject of a new larger study.

Abstract

Matching and multi-criteria multi-alternative problems are two well-known problems in decision science. Over the years, many solutions, tools, and techniques have been developed to solve each problem. When a situation arises where both problems intersect, then one may use approaches developed for each to tackle it. Given the competitive and dynamic business environment, problems with such attributes are bound to take place. Hence, this research paper extends the Gale-Shapley algorithm, which is a well-known algorithm that solves matching problems with the analytic hierarchy process (AHP), weighted-product model (WPM), and weighted-sum model (WSM). The extended Gale-Shapley algorithm is dubbed the Extended-GS (E-GS) algorithm and is referred to as E-GS. The basic idea of the E-GS algorithm is feeding the preference lists to the Gale-Shapley algorithm to produce an optimum match using the WSM, WPM, and AHP models. E-GS combines the powers of all four algorithms to provide an optimum solution.

Keywords: Gale-Shapley, Analytic Hierarchy Process, Weighted-sum Model, Weighted-product Model, Multi-criteria Decision-making, Operations Research, Decision Support Systems.

Introduction

A matching problem is a well-known problem in decision-making. The idea is to match two sets in an ideal manner; hence, the solution was nicknamed a “stable marriage” by the mathematicians D. Gale and L. Shapley. As the name suggests, a stable marriage is one where none of the two partners want out of the relationship. A multi-criteria multi-alternative problem is also a well-known problem in decision-making. Multi-criteria decision-making (MCDM) is a discipline that addresses problems in decision-making that involve selecting the best alternative for a decision from multiple potential candidates using multiple criteria or attributes that may be concrete or ambiguous (Pavan & Todeschini, 2009). Such problems have many suggested solutions, such as the analytic hierarchy process (AHP), weighted-product model (WPM), and weighted-sum model (WSM).

Decision-makers (DMs) should always try to select the optimal solution when making decisions. Unfortunately, an optimal solution exists only in cases with a single criterion, whereas decisions almost always involve some conflicts or dissatisfaction in real decision-making situations (Asghar, 2009). A decision problem is typically a situation in which an individual must select one of a number of alternative courses of action without prior knowledge of which one is the best (Abbas Mardani, et al., 2015). The decision process can be organized into three phases: problem identification and structuring, model development and use, and the development of action plans. The first step consists of defining the aims of the decision, recognizing the issue to be solved, diagnosing the cause-effect relationships for the situation of the decision, and determining the criteria of the judgment. The

second phase is comprised of the development of the DM preferences, formal models, trade-offs, values, and the objectives for comparing the alternatives or actions being considered with each other transparently and systematically. The third phase includes the development of action plans since the decision is not reached by analysis (Pavan & Todeschini, 2009). The decision-making process results in the selection of the best solution and is considered effective if the solution procedure is optimal in that the positive results outweigh possible losses (Asghar, 2009). The decision process aims at generating information on the decision problem from the available data, developing effective solutions, and providing a good understanding of the nature of a decision problem (Brans, et al., 1986).

The MCDM methods that support DMs in making the best decisions are multi-criteria decision analysis (MCDA), but they cannot make the final decisions themselves. MCDA's primary goal is to help DMs in synthesizing the information to feel confident and comfortable about making a decision. MCDA integrates objective measurements with value judgments and makes subjectivity explicit (Løken, 2007).

Several MCDM methods have been suggested over the years. These methods have been in various fields with different theoretical contexts and have been faced with multiple types of questions and various types of results. While some of these methods have been designed to address the need for specific problems, there are other methods that are more general for use in different areas. MCDM methods are similar in their goal of creating a formalized and better-informed decision-making process, the need to identify alternatives to be considered, the criteria to guide the assessment, and the relative importance of the various criteria. However, MCDM methods are distinguished from each other by the model's nature, the information required, and how the model is used.

This research paper proposes an optimum solution for multi-criteria multi alternative problems. Problems with many alternatives are not as simple as one may imagine. Carrying out the responsibility of comparing alternatives is a difficult task. Hence, "criteria" comes into play, where one is seeking justice in evaluating all the alternatives (according to one criterion or many criteria). Actually, building a scenario with alternatives and criteria to reach a sound and realistic decision is time-consuming and consequently, costly. Another type of problem involves matching different alternatives, for example, matching the right project manager with the right project or matching the right car to the right buyer. The suggested solution marries three methods analytic hierarchy process (AHP), weighted-product model (WPM), and weighted-sum model (WSM) to the Gale–Shapley algorithm, also known as the deferred-acceptance algorithm. Such a marriage will allow the AHP, WPM, and WSM to calculate alternatives according to criteria (a preference list) then feed these results to the Gale–Shapley algorithm, therefore, producing an optimum match. Hence, the major contribution of the E-GS is to automate the development of the preference list then use the list in the Gale–Shapley algorithm, producing an optimum match. Furthermore, E-GS creates an interface between methods that develop a preference list (WSM, WPM, AHP) on the one side and the Gale–Shapley algorithm on the other side.

The paper presents the suggested E-GS method in six sections as follows: In Section **Error! Reference source not found.**, a literature review is presented about MCDM. In Section 0, AHP is reviewed. First, AHP and ExpertChoice are discussed, then the process of AHP, pair-wise comparison in AHP, and finally, the AHP algorithm. In Section 0, WSM and WPM are presented and reviewed. Both WSM and WPM are outlined mathematically, and their respective algorithms are presented. Next, all three models (AHP, WSM, and WPM) are compared in accordance with six axioms. In Section 0, the original Gale-Shapley algorithm is presented. First, an abstract view of the Gale-Shapley algorithm is presented, then the pseudo-code of the algorithm is discussed. In Section 0, E-GS, the suggested extended Gale-Shapley algorithm is discussed. In Section 0, the implementation of E-GS on Projects-PM is presented along with a basic data structure to be used in the implementation.

Literature Review

MCDM is one of the most important and fastest-growing subfields of operations research (OR) science since it started in the 1970s (Koksalan, et al., 2011). MCDM provides strong decision making in areas where it is highly complex to select the best alternative (Koksalan, et al., 2011). The main

concern of MCDM is structuring and solving planning and decision problems in the existence of multiple conflicting criteria. "Solving" can be interpreted in various ways: one interpretation corresponds to the selection of "best" alternative from a set of available alternatives." Another interpretation could be the selection of a small set of good alternatives. An interpretation could be to find all "efficient" or "non-dominated" alternatives. A large number of decision-makers use MCDM in conjunction with decision support systems (DSS) in various fields, such as flood risk management, financial analysis, customer relationship management, disaster management, and housing evaluation (Asghar, 2009).

The aim of the MCDM methods is to help a decision-maker in selecting the most suitable alternative from many alternatives, considering a multitude of criteria characterizing the acceptability of individual variants of the decision. The criterion can also determine the quality of the variants when all choices are available, and the challenge is to select the best one subjectively. In this case, subjectivity refers to the value of specific criteria, as some factors are generally more relevant for decision-makers than others. Also, the inaccuracy and uncertainty of the data identifying alternatives influence the subjectivity of the evaluation (Roy, 2005).

The MCDM method generally involves doing the same set of steps that can be expanded or reduced depending on the size of the projects. These steps are not necessarily done in a fixed order. According to Roy, the decision-making process consists of four steps (Roy, 1996): (I) defining the subject-matter of the decision and the set of potential alternatives for the decision, as well as deciding the reference problems; (II) the analysis of consequences and the development of a coherent set of criteria; (III) modeling comprehensive preferences and aggregating performances operationally; (IV) developing and investigating the recommendation. Roy argues that the steps are not serial. For example, some of the step I elements can involve performing elements of step II. Similarly, one cannot simplify the decision-making process by removing individual steps. In addition, one must apply a properly chosen method to achieve a "good" solution to the problem.

Interest in MCDM has led to the development of many methods of MCDM within the operations research field. According to (McGinley, 2012) (Weistroffer, et al., 2005) (Rezaei, 2015) (Sałabun & Piegat, 2016) and (Buckshaw, 2010), there are more than 40 methods of MCDM in the literature. These methods are broadly classified into three groups: outranking models, value measurement models, and goal, aspiration, or reference level models (Løken, 2007). Choosing the best MCDM method varies depending on the source and nature of the information used to inform decision making and, on the model, the decision-makers believe match their ability. A general feature of any MCDM is a performance matrix or consequence table, which is comprised of rows describing options and columns describing the performance of the options against each criterion (Adunlin, et al., 2015).

MCDM methods have been applied to diverse applications. The widely used MCDM methods have been described in Table I. Apart from the MCDM methods which are listed, many other MCDM methods are available in the literature.

Table 1: Summary of MCDM methods

Abbreviation	Method	Description	Ref.
AIRM	Aggregated Indices Randomization Method	AIRM solves the complex problem where uncertainty occurs, which has incomplete information for the problem to be addressed.	(Aruldoss, et al., 2013)
AHP	Analytic Hierarchy Process	This method uses pair-wise comparisons, which are used to compare the alternatives and to estimate criteria weights.	(Saaty, 1980)
ANP	Analytic Network Process	The general form of AHP and is more concerned with network structure.	(Horenbeek, 2014)
BJT	Bayesian Junction Tree	A decision framework based on Bayesian networks (BN) and influence diagram (ID).	(Watthayu, 2004)
CBR	Case-Based Reasoning	A new method for predicting financial distress in companies one year before	(Li, 2008)

		actual distress using case-based reasoning.	
DEA	Data Envelopment Analysis	This method is used to find the efficiency of the combination of multi inputs and multi outputs of the problem	(Hermans, 2009)
FST	Fuzzy Set Theory	The fuzzy set theory allows using uncertain data as trapezoidal fuzzy numbers or fuzzy triangular numbers.	(Khadam, 2003)
ELECTRE	Elimination and Choice Translating Reality	An outranking method based on concordance analysis.	(Roy, 1968)
GP	Goal Programming	GP is a division where it has more than one objective conflicts with each other, and by arranging the goals have to be achieved by minimizing the irrelevant information.	(Mukherjee & Bera, 1995)
GRA	Grey Relational Analysis	The multi-criteria weighted average is proposed in the DM process to rank the materials with respect to several criteria.	(Chan & Tong, 2007)
MAUT	Multi-Attribute Utility Theory	An expected utility theory that decides best course of action in a problem by assigning a utility to all possible consequence.	(Fishburn, 1967)
PROMETHEE	Preference Ranking Organisation Method for Enrichment Evaluation	PROMETHEE is like ELECTRE in that it also has several iterations and is also an outranking method.	(Brans, et al., 1986)
SAW	Simple Additive Weighting	A function is established based on a simple addition of scores that represent the goal achievement, multiplied by the weights	(Qin, et al., 2008)
SMART	Simple Multi-Attribute Rating Technique	This method requires two assumptions: utility and preferential independence.	(Chen, 2010)
TOPSIS	Technique for Order of Prioritization by Similarity to Ideal Solution	An approach to identify an alternative which is closest to the ideal solution and farthest to the negative ideal solution in a multi-dimensional computing space.	(Qin, et al., 2008)
WPM	Weighted Product Model	Alternatives are compared by the weights and ratio of one for each criterion.	(Miller & Starr, 1963)
WSM	Weighted Sum Model	Evaluating several alternatives in accordance with the different criteria which are expressed in the same unit	(Miller & Starr, 1963)

In recent years several studies have employed MCDM tools and applications to solve area problems (Abbas Mardani, et al., 2015). Up to now, there are 36 software packed to automate the work of such algorithms & methods: @RISK, 1000Minds, PEERForecaster Excel Add-in, AgenaRisk, Analytica 4.2, Promax 2010 Standard, DecideIT, Decision Advisor¬Æ, RICH Decisions Decision Explorer, DecisionTools Suite, RPM-Decisions Doctus, DPL, TreePlan, DTrio, Equity3, Vanguard Business Analytics Suite, ForeTell-DSS, Frontier Analyst 4, GoldSim, Portfolio NavigatorÀô Value Optimization Software, IDS (Intelligent Decision System), QMms (Quantitative Methods for Management Science), Logical Decisions Portfolio, HiPriority 3 SE, RiskSim, Logical Decisions for Windows v6.2, Hiview3 v6.2, SensIt, MakeItRational, MindDecider, TreeTop, OnBalance 3 SE, OWL, Vanguard System.

In the following sections, Analytic Hierarchy Process (AHP), Weighted Sum Model (WSM), Weighted Product Model (WPM), and Gale-Shapley Algorithm will be explained in detail in their respective sections. In section 0, AHP is reviewed. First, AHP and ExpertChoice are discussed, then the process of AHP, next pair-wise comparison in AHP, and finally, the AHP algorithm. In 0 4, WSM and WPM are presented and reviewed. Both WSM and WPM are outlined mathematically, and their respective algorithms are presented. Next, all three models, AHP, WSM, WPM, are compared in accordance with six axioms. In section 0, the original Gale-Shapley algorithm is

presented. First and abstract view of the Gale-Shapley algorithm, then the pseudo-code of the algorithm is discussed. In section 0, E-GS, the suggested Extend Gale-Shapley algorithm is discussed. In part 7, the implementations of E-GS are discussed with a Projects-PM is presented along with a basic data structure to be used in the implementation.

Analytical Hiearchy Process (AHP)

The Analytic Hierarchy Process (AHP) was developed in the 1970s by Dr. Thomas L. Saaty and defined as a decision based on mathematics and human psychology algorithm (Chauhan, et al., 2008), (Saaty, 2004).

AHP process is used when a decision is to be taken based on multi-criteria with many alternatives. Thomas Saaty defined AHP "The Analytic Hierarchy Process (AHP) is a theory of measurement through pairwise comparisons and relies on the judgments of experts to derive priority scales" (Saaty, 2008).

Based on AHP, the software was developed named ExpertChoice (ExpertChoice, 2012). ExpertChoice was developed in 1983 by Dr. Saaty and Dr. Ernest Forman. In China alone, more than 900 papers were released on AHP (Sun, 2005).

The AHP and ExpertChoice software help decision-makers in structuring a decision into smaller parts, proceeding from the goal to objectives to sub-objectives down to the alternative courses of action. Decision-makers then make simple, pair-wise comparative judgments across the hierarchy to arrive at overall alternatives priorities. The decision problem may involve social, political, technical, and economic factors.

Analytical Hierarchy Process (AHP) Process

The process of conducting AHP is straightforward and explained in (Saaty, 2008) as follows:

1. Define the problem and determine the kind of knowledge sought.
2. Structure the decision hierarchy from the top with the goal of the decision, then the objectives from a broad perspective, through the intermediate levels (criteria on which subsequent elements depend) to the lowest level (which usually is a set of the alternatives).
3. Construct a set of pair-wise comparison matrices. Each element in an upper level is used to compare the elements in the level immediately below with respect to it.
4. Use the priorities obtained from the comparisons to weigh the priorities in the level immediately below. Do this for every element. Then for each element in the level below, add its weighted values and obtain its overall or global priority. Continue this process of weighing and adding until the final priorities of the alternatives at the bottom-most level are obtained.

AHP Pair-wise Comparison

The pair-wise relative importance allows the user to compare each criterion to the other without looking at the importance of the rest of the criteria. Pair-wise relative importance is interpreted as [1: Equal, 3: Moderate, 5: Strong, 7: Very strong, 9: Extreme]. According to Saaty (Saaty, 2008) the importance and ranking to scale is the Scale of Relative Importance, where the intensity of importance ranges from 1 to 9, 1 is of Equal importance, and 9 is absolute importance. The fundamental scale is shown in table 2.

Table 2: The fundamental scale of absolute numbers (Saaty, 2008)

Intensity of Importance	Definition	Explanation
1	Equal importance	Two activities contribute equally to the objective
3	Weak importance of one over another	Experience and judgment slightly favor one activity over another
5	Essential or strong importance	Experience and judgment strongly favor one activity over another
7	Demonstrated importance	Activity is strongly favored, and its dominance demonstrated in practice
9	Absolute importance	The evidence favoring one activity over another is of the highest possible order of affirmation
2,4,6,8	Intermediate values between the two adjacent judgments	When compromise is needed

AHP Algorithms

The AHP algorithm is composed of two functions 1) Eigenvector 2) AHP. The first function Eigenvector, figure 1, will be called with AHP. Eigenvector successively squares a matrix and then normalized its rows. In figure 2, The AHP is carried out: first, compare each criterion to another, then call the Eigenvector. Next, compare all alternatives to each other according to each criterion and call the Eigenvector for each matrix. After, multiply the alternatives matrix with the criteria vector, as shown in figure 2.

```
Function Eigenvector (input M: Matrix NXN, output Vector N X 1)
        Iterate
                Take successive squared powers of a matrix
                Normalize the row sums
        Until the difference between consecutive row sums is less than a pre-specified value
```

Fig. 1: The function Eigenvector.

```
Function Build AHP_preference-list (input: Criterion, alternatives; output: ordered-
preference)
        Build a pair-wise comparison matrix of Criterion
        call Eigenvector (Criterion Matrix, Criteria-Vector)
        Build comparison matrix alternatives according to each criterion
        For each c in Criterion
                call Eigenvector (Alternative matrix of criteria, Alternative Vectors)
        Build Alternative matrix according to criteria using Alternative Vectors
        Alternatives Vector=Multiply Alternatives matrix (NXN) by Criteria-Vector
        ordered-preference =Sort Alternatives Vector in descending order
```

Fig. 2: The suggested Algorithm AHP.

Weighted Sum Model (WSM) and Weighted Product Model (WPM)

In this section, WSM and WPM are presented and reviewed. Both WSM and WPM are outlined mathematically, and their respective algorithms are presented. The Weighted Sum Model (WSM) is similar to Weighted Product Model (WPM); the only difference is that the WSM adds the products while WPM multiplies the products. Both models relatively weigh the criterion such that, given m alternatives and n criterion. The sum of all weight must add up to 100%, as shown in (1).

$$\sum_{j=1}^{n} weight\ of\ C_j = 1, where\ n\ is\ the\ number\ of\ criteria \quad (1)$$

WSM calculates the alternative Aj, as shown in (2):

$$A_i = \sum_{i=1}^{m} W_j a_{ij}\ for\ i = 1\ to\ m\ \ number\ of\ alternatives\ \ \&\ j\ is\ the\ index\ of\ criterion \quad (2)$$

WPM calculates alternative Ak, as shown in (3):

$$A_k = \prod_{i=1}^{m} a_{kj}^{w_j}\ \ for\ k = 1\ to\ m\ of\ alternatives\ \&\ j\ is\ the\ index\ of\ criterion \quad (3)$$

When comparing an alternative to another AK & AL, the calculation is conducted, as shown in (4):

$$P(_{A_K/A_L}) = \prod_{j=1}^{n} (a_{Kj}\ /a_{Lj})\quad ^{wj}\ for\ K, L = 1\ to\ m \quad (4)$$

In both WSM and WPM the best alternative is the one with maximum Ai.

WSM & WPM Algorithms

In this section, the paper presents the algorithms of WSM and WPM. In figure 3 the WSM algorithm is shown with two nested loops. In the first loop, the user enters the weights of criteria, and in the second nested loop, the user enters the weights of the alternatives. In 5th line of the algorithm, the score of the alternatives is calculated. The algorithm returns a list of alternatives where the head of the list is the best option, according to WSM.

In figure 4, WPM algorithm is presented. The algorithm is similar to WSM with one difference in 5th line. In WSM the score is summed, while the score in figure 4 is multiplied, and the weight of alternative is raised to the power of weight of criteria.

```
For j=1 to n (n: number of criterion)
        Enter w[j] (w: is weight of criteria)
        For i=1 to m (m: number of alternatives)
            Enter a[i,j] ‘ value of alternative
            A_ WSM _score[i]=w[j]*a[i,j]+ A_ WSM_score[i]
Return Sort A_ WSM _score[i] descending ‘highest score is best
```

        Enter W[j] (w: is weight of criteria)
        For i=1 to m (m: number of alternatives)
            Enter A[i,j] ‘ value of alternative
            A_ WPM _score[i]= a[i,j] ^ w[j] * A_ WPM_score[i]
Return Sort A_ WPM _score[i] descending ‘highest score is best
```

Fig. 4: Weighted Product Model (WPM) Algorithm.

Compare AHP, WSM, WPM

To further explain, all three methods AHP, WSM, WPM, are compared in this section. The three methods are compared according to 6 axioms, seen in table III: all three have the same goal, which is ranking alternatives according to criteria. Second, running time (RT) where both WSM and WPM have M * N running time where N is the number of Criteria, and M is the number of alternatives. Regarding the implementation complexity, WPM uses Powers while WSM is only addition and AHP relays on matrix multiplication. The fourth axiom of comparison is the criteria. The criteria in AHP can be multiuser; on the other hand, in WSM and WPM can be single user. Criteria pair-wise comparison is available only in AHP, while WSM and WPM lack such a trait. The 6th axiom of comparison is available on all three AHP, WSM, and WPM.

Table 3: Comparison of AHP, WSM, WPM

Comparison Criteria	AHP	WSM	WPM
1. Goal: Rank alternatives according to criteria	Yes	Yes	Yes
2. Run Time	M X N	M X N	M X N
3. Implementation complexity	Matrix multiplication	Straight forward sum	Multiplication and use of power
4. Criteria	Many Users	static	static
5. Criteria Pair-wise comparison	Yes	No	No
6. Alternatives pairwise comparison according to criteria	Yes	Yes	Yes

Gale and Shapley Algorithm

In this section, The Gale–Shapley algorithm is discussed with detail. First, an overview is given about the algorithm, and the algorithm is shown and explained. The Gale–Shapley algorithm(Deferred Acceptance algorithm) is to solve a matching problem named the stable marriage problem (stable matching problem or SMP). The SMP is to find a stable match between two sets that are equal in size, and each set ordered their preference to the opposite set. The match is stable if the following two conditions:

1. There is an element A of the first matched set which prefers some given element B of the second matched set over the element to which A is already matched, and
2. B also prefers A over the element to which B is already matched.

In other words," Given n men and n women, where each person has ranked all members of the opposite sex in order of preference, marry the men and women together such that there are no two people of the opposite sex who would both rather have each other than their current partners. When there are no such pairs of people, the set of marriages is deemed stable" (Gale & Shapley, 1962), (Cseh & Heeger, 2019). The runtime complexity of the Gale–Shapley algorithm is O(n2), where n is the number of men or women.

In figure 5 and abstract view of the Gale–Shapley algorithm environment. Matching between two sets of men and women are being matched according to their preferences to each other. Each woman and man each have a preference list; further women "a" is to be matched with man 'B" according to her preference list. When a match is challenged, if two women matched to the same man, then the man's preference list is used to either approve or disapprove the match. In figure 6, the original algorithm suggested by Gale–Shapley is presented.

Fig. 5: an abstract view of Gale and Shapley

Function stableMatching (input m,w; output: matched-pairs)
Initialize all m ∈ M and w ∈ W to free
while ∃ free man m who still has a woman w to propose to
*w = first woman on **m's list** to whom m has not yet proposed*
if w is free
(m, w) become engaged- add to matched-pairs
else some pair (m', w) already exists
*if w **prefers** m to m'*
m' becomes free
(m, w) become engaged – add to matched-pairs
else
(m', w) remain engaged

Fig. 6: Original Gale and Shapley algorithm.

(Berkeley, 2019).

Uses of Gale- Shapley Algorithm

The algorithm of (Gale & Shapley, 1962) was introduced to solve a matching problem abstracted as a stable marriage problem, to solve College admissions. The algorithm was published by the researchers in Journal named The American Mathematical Monthly. The algorithm stresses the stability condition "A matching is stable if there is no pair of agents who would be mutually better off by forming a new pair, perhaps after abandoning their previous partners." The algorithm was applied in many variations and forms to solve the matching problem. The same algorithm in the year 2012 was awarded by the Royal Swedish Academy of Sciences, the Nobel prize of economics for Lloyd Shapley and Alvin Roth (NobelPrize, 2012). (Biró, 2017) listed more than 25 applications for the algorithm; all applications were related to matching two entities: student-college, doctors-hospitals, teacher-school, lawyer-firm, project-supervisor, refugees-camps, dating, dormitory-match, course-teacher, paper-reviewer, and contract-contractors. In the next section 0, E-GS, the suggested Extend Gale-Shapley algorithm is discussed.

The Suggested Algorithm Extended-GS (E-GS)

The suggested algorithm is based on WSM, WPM, AHP, and Gale-Shapley Algorithms hence named Extended-GS (E-GS) for short. E-GS is shown in figures 7 and figure 8. In figure 7 the E-GS is written in pseudo-code, and in figure 8 the algorithm is shown in the flowchart.

The first section of the E-GS is called Build-WSM_WPM_preference-list; the function's input is alternatives and criteria, and the output is ordered-preference-list-WPM and ordered-preference-list-WSM. The function has two nested loops that calculate the scores of each alternative, according to criteria. The calculations are conducted in lines 5-6.

The second section of E-GS is a function that produces a preference list according to the AHP method named Build-AHP-preference-list. The input of the function are alternatives and criteria, and the output is the ordered preference list. Function first builds a pair-wise comparison of the criterion matrix and conduct Eigenvector, explained in figure 1. Then the function builds a comparison matrix for alternatives according to criterion. Again, calls Eigenvector. Then produces an alternatives vector, which is multiplying an alternative matrix with criterion vector. The function returns a list of alternatives ordered in accordance with criteria.

The third function inputs are two preference lists applied to projects and project managers, and the output is a matched pair of projects to project managers. This section behaves like the Gale-Shapley algorithm of matching the project to the project manager according to criteria. In the main body of the E-GS, the functions are called, first three preference lists are built for projects according to criteria: list using WSM, list using WPM, and a list using AHP. Next, three preference lists are built for managers: one list for managers using WSM, a list using WPM, and a list using AHP. The last step is to call E-GS and conduct the matching using Automated preference stableMatching.

In the next section, the implementation of E-GS on Projects-PM is presented along with a basic data structure to be used in the implementation.

Implementation of E-GS

There are many implementations of E-GS. In fact, wherever there is a matching problem, E-GS can perform. As discussed before, the uses of the original GS student-college, doctors-hospitals, teacher-school, lawyer-firm, project-supervisor, refugees-camps, dating, dormitory-match, course-teacher, paper-reviewer, and contract-contractors. In the next section, E-GS is implemented on Assigning Project Manager (PM) to an IT project is presented.

Implementing E-GS On It Project Management Problem

Assigning the right personnel to an IT project is an art rather than science; the idea depends on the competence and skills of the personnel and the needs of the project itself. To match the right workers

with the right project is the essence of this problem. Personnel may have many skills required for a project; hence each personnel is related to a list of skills of knowledge: programming, security, hardware, operating system. The IT project, on the other hand, also requires skills of knowledge. Which makes matching the right skills of personnel with the needed skills of IT project a dilemma. Mismatching causes delays, frustration, over cost. Hence, the process of assigning the right project to the right person relay on the wets of the manager and how much does s/he knows about the different needs of the IT project and on how much s/he knows about the personnel.

Basic Data Structure

The data structure of the solution is composed of 4 suggested tables (table 4). The first table is for all criteria a manager will work with, as suggested in a database table named Criterion. The second table suggested is the preference's database table that holds all preferences codes with preferences name. The third table is the database table named personnel, which a database table that holds all data about the employee with the preference list. The fourth table is the project database table, which is a table that holds a project ID and name with a preference list pertaining to the project.

Table 4: Data structure of the solution

Criterion	Data Type
Criteria Code	Number
Criteria Name	string

Preferences	Data Type
Preference Code	Number
Preference Name	string

Personnel	Data Type
Emp. No	Number
Emp. Name	string
List of preferences	list
Projects Assigned limit	Number

Project	Data Type
Project ID	Number
Project Name	string
List of preferences	list

The Gale–Shapley algorithm requires that both matching sets are equal in numbers, as shown previously. Hence the number of women must equal the number of men, as shown in figures 5 and 6. Thus in the project management example, the number of projects must equal the number of project managers (personnel). To rectify such a dilemma, the structure above was suggested. The structure suggests having multiple copies of project managers (personnel). Hence the field Emp_No is not a primary key in the database.

Contribution and Analysis

The contribution of E-GS is to interlink two sides of decision making. The first side is the Gale–Shapley algorithm which, when given a preference list, will produce an optimum match between two sets. The second side is methods that build a preference list of alternatives, according to criteria. In Gale–Shapley algorithm preference list is the most critical element and is developed according to the user's feelings mostly. Hence, the preference-list is generated by the user without any criteria. The criterion in decision making is essential and structures the decision-making process. Having the preference-list built around criterion-alternative methods like WSM, WPM, AHP is more structured, fair, and logical. Henceforth, the researchers used the models WSM, WPM, AHP to build a preference-list made of alternatives in accordance with criterion. E-GS utilized the work of both sides and developed a much-needed step that liaison between the two sides.

Conclusion

E-GS is a proposed multi-criteria & multi-alternative algorithm that automates the process of building preference lists using three methods Analytic Hierarchy Process (AHP), Weighted Product Model (WPM), Weighted Sum Model (WSM). Then, E-GS feeds the preference lists to the Gale-Shapley algorithm to produce an optimum match. The automation process will save time, money, and effort.

Hence, a user can examine many scenarios before deciding. No known study has previously interlinked AHP, WSM, WPM methods with the Gale-Shapley algorithm to produce an optimum match. This study, therefore, contributes to the literature by interlinking two sides of decision making. The first side is the Gale–Shapley algorithm which, when given a preference list, will produce an optimum match between two sets. The second side is methods that build a preference list of alternatives, according to criteria. E-GS has been implemented on assigning a project manager to an IT project problem.

Function Build WSM_WPM_preference-list (input: Criterion, alternatives; output: ordered-preference-WPM, ordered-preference-WSM)

```
For j=1 to n (n: number of criterion)
        Enter w[j] (w: is weight of criteria)
        For i=1 to m (m: number of alternatives)
                Enter a[i,j] ‘ value of alternative
                A_ WSM _score[i]=w[j]*a[i,j]+ A_ WSM_score[i]
                A_ WPM _score[i]= a[i,j] ^ w[j] * A_ WPM_score[i]
Return Sort A_ WSM _score[i] descending ‘ordered-preference-WSM
Return Sort A_ WPM _score[i] descending ‘ordered-preference-WPM

Function Build-AHP-preference-list (input: Criterion, alternatives; output: ordered-preference-AHP)
        Build a pair-wise comparison matrix of Criterion
        call Eigenvector(Criterion Matrix, Criteria-Vector)
        Build comparison matrix alternatives according to each criterion
        For each c in Criterion
                call Eigenvector (Alternative matrix of criteria, Alternative Vectors)
        Build Alternative matrix according to criteria using Alternative Vectors
        Alternatives Vector=Multiply Alternatives matrix (NXN) by Criteria-Vector
Return ordered-preference-AHP =Sort Alternatives Vector in descending order

Function Automated preference StableMatching (p: projects, Emp: personnel, matched-pairs:p-emp)
        Initialize all p ∈ projects and Emp ∈ personnel to free
        while ∃ free project who still has a Personnel to propose to
                emp = first Emp on p's list to whom p has not yet proposed
                if emp is free
                        (p,emp)become matched – add to matched pairs
                else some pair (p', emp) already exists
                if emp prefers p to p'
                        emp' becomes free
                        (p, emp) become matched – add to matched pairs
                else
                        (p', emp) stay matched
%Build the Preferences list of the Project according to criterion
        Call Build WSM_WPM_preference-list (Criterion, personnel-alternatives-WPM, personnel-
alternatives-WSM)
        Call Build AHP_preference-list (Criterion, Personnel-alternatives-AHP)
%Build Preferences list of the Personnel according to criterion
        Call Build WSM_WPM_preference-list (Criterion, Project-alternatives-WPM, Project-alternatives-
WSM)
        Call Build AHP_preference-list (Criterion, Project -alternatives-AHP)
%Apply E-GS
        Call Automated preference stableMatching (Project-alternatives-WPM, personnel-alternatives-WPM,
return matched pair-WPM)
        Call Automated preference stableMatching (Project-alternatives-WSM, personnel-alternatives-WSM,
return matched pair-WSM)
        Call Automated preference stableMatching (Project-alternatives-AHP, personnel-alternatives-AHP,
return matched pair-AHP)
```

Abstract

The aim of the article is to identify the information content, being the product of the accounting system, of the integrated report with a division into financial and non-financial information. The aim of the study was realized on the basis of an analysis of integrated reports published in 2013-2018 by companies listed on the Warsaw Stock Exchange. In 2013-2016, the number of companies publishing integrated reports both in traditional (in pdf) and interactive form increased. The number of companies publishing integrated reports decreased in 2017. The integrated reports contained mainly non-financial information. In most cases, the share of financial information in the integrated report did not exceed 20% of the total report length.

Keywords: Integrated Report, Financial Information, Non-Financial Information, Accounting System

Introduction

Information is an essential resource in an organisation that needs to be identified, processed and delivered in an appropriate form and on time to specific recipients. Information together with other elements, for example technology, form the so-called information system. The key information system used in business is accounting. Modern accounting system processes both financial and non-financial data and enables their presentation, and thus communication in the form of reports. A special form of reporting has recently been integrated reporting, which mainly refers to large organisations. The aim of the article is to identify the information content of the integrated report (IR), which is the product of the accounting system, with a division into financial and non-financial information. Discourse on the IR is conducted in science all over the world and it is essential also for business practice. Therefore, it is worthwhile to introduce this subject on the basis of the practice of a specific country, for example Poland, whose economy is relatively young, which is the contribution of knowledge to the studied issues.

Information as an essential resource of the organisation

Information is an important foundation of societies, economy, and therefore business. It should be treated as a resource that creates a dimension of the organization and shapes the course of its activities in the present and future (Adeoti-Adekey, 1997). Information, like other resources, requires appropriate registration, processing, storage, distribution and use. Therefore, information should be properly managed in order to benefit the business. However, it is not easy to define 'information'. It is indicated that it is an abstract phenomenon that is revealed between material objects. In such an approach, information can be treated as an idea analyzing it under various contexts, i.e. concepts related to: data, human understanding, communication, decision-making and human behavior, moreover to content and interpretation of information, and document and message for its

transmission (Palmius, 2005). A similar view is presented by Zorkoczy (1981), who perceives information "as the meaning that a human expresses by, or extracts from, representations of facts and ideas, by means of the known conventions of the representations used". In business, information is considered as a specific commodity most often in the form of reports. The content of this ‘intangible commodity’ is differentiated by certain criteria (e.g. expressed by source: internal and external information or by form: numeric and nonnumeric information) (Adeoti-Adekey, 1997). Information can have different meanings depending on its place in the organisation and the individual's function. Therefore specialists (e.g. bookkeepers and management accountants) will perceive information as data and managers as reports, and in both dimensions there is a third perspective on information, i.e. technology. These areas form a comprehensive information system. It consists of elements capable of obtaining and storing information (financial and non-financial), channels (IT systems) that disseminate it and units operating according to the information provided to them and responding to it taking into account the operational and strategic perspective of the organisation's functioning (Leek, 1997).

Accounting as an information system in an organization

Accounting can be defined as a subsystem of an information system covering the process of creating a specific range of information (Andrzejewski, 2006). Another definition that reflects more clearly the information function of accounting in business indicates that it is a system that provides quantifiable information, i.e. financial information about business units that serve to make decisions, including rational choices between alternative directions of action (Belkaoui, 2004). The indicated explanation mainly emphasizes the essence of financial information, which, taking into account economic trends (social and environmental responsibility), is not sufficient to manage modern business. Accounting is not only financial accounting, but also management accounting, which creates and provides non-financial information alongside financial information. In this connection, the so-called unity of the accounting system is emphasised. It is particularly visible in large organisations, which are often obliged to comply with International Financial Reporting Standards and have management accounting systems in place (Sobańska, 2012). Such a state of the art means the extension or integration of tasks for accounting professionals, including those typically of an operational nature and focusing on financial data processing and reporting, with activities of a strategic nature that take into account qualitative data and translate into integrated reports (Belfo and Trigo, 2013). Therefore, the modern accounting system differentiates between financial and non-financial information, which is created for specific needs of its users and then integrated into reports. Financial information is slightly easier to define than non-financial information, although sometimes the boundary between them is blurred. The former includes 'information in verbal or numerical form that presents the process, the economic phenomenon, including information necessary for an understanding, the process, the economic phenomenon and any other information in the financial statements about the reporting entity, its environment, the facts and factors affecting the reporting entity and its operations'. (Błażyńska, 2015). Non-financial information, on the other hand, is any information - descriptive or numerical, not necessarily expressed in a monetary measure - published (whether mandatory or voluntary) as part of the company's annual report, other than the financial statements and the auditor's opinion and report (Krasodomska, 2014).

Reporting as a part of communication of information from the accounting system

Reporting is the most frequent activity carried out by accounting specialists. They have to not only prepare reports in real time but also interactively. Reporting information as a form of communication of the accounting information system in an organization is becoming more and more important but also a complex task (Belfo and Trigo, 2013). So far, financial (external) reporting has been identified as an effect of financial accounting and internal reporting, the so-called management reports for internal needs of the organisation (Nita, 2015). In recent years, however, the organisation's reporting has become more complicated - both financial and non-financial. There has been a proposal to combine some social and environmental disclosures with financial disclosures in the form of collective reports, so-called integrated reporting. It is defined as "a process that ultimately ensures

maximum transparency in the organisation's communication in the form of a periodically published IR (...); the IR therefore provides a concise communication on the company's strategy, corporate governance, business performance and development prospects, in the context of the external environment, to create value in the short, medium and long term" (The International <IR> Framework, 2013).

Research Methodology

The IRs of 12 companies (for 2013-2016) and 10 companies (for 2017-2018), which are listed on the Warsaw Stock Exchange (WSE) in Poland, were studied. The companies under analysis operate mainly in the energy and mining sector, but also in the fuel and gas, banking, telecommunications and construction sectors. The research process included the following stages: (1) identification of the form of IRs and guidelines, constituting the basis for their preparation in 2013-2016 and 2017-2018, (2) verification of the information content (financial - non-financial information) of traditional IRs (in pdf) in 2013-2018.

Presentation of Findings

In 2013-2016, IRs were prepared by 12 companies listed on the WSE and in 2017-2018, 10 companies respectively. In 2013-2016, 27 IRs were published, including 19 in the traditional version (in pdf) and 20 in the interactive version. Moreover, 12 IRs were presented in both versions, while 8 reports were available only in an interactive version (Walińska et al., 2018). Between 2017 and 2018, 19 IRs were published, including 15 in the traditional (in pdf) and 17 in the interactive version. In both approaches, the IR appeared 13 times, and only 4 times in the interactive version. The IRs may be published by the analysed companies in Polish (according to the Global Reporting Initiative - GRI standards: most often G4 standard, while in individual cases they were G.3.1. or G5 standards) and English (according to the guidelines of the International Integrated Reporting Council - IIRC). In 2013-2016, the analysed companies published 23 IRs in both languages, while only 4 reports were available in Polish. In turn, between 2017-2018, 17 IRs in both languages (Polish and English) were separated, and 2 reports were presented only in English. In the next stage of the study, due to difficulties related to the analysis of the information content of IRs prepared in an interactive form, only reports prepared in a traditional form, i.e. pdf (if researchers also had access to these reports) were taken into account. In terms of report structure, i.e. identification of financial and non-financial information, 20 IRs for the years 2013-2016 and 13 IRs for the years 2017-2018 were analysed. Three models were distinguished in this respect, i.e. model 1 - (integrated report as a place of presentation of non-financial information, up to 20% of financial information), model 2 - (integrated report as a place of presentation in a similar proportion of financial and non-financial information, over 20% share of financial information), model 3 - (integrated report as an information area containing only non-financial information, from 0 to 3% share of financial information) (see Table 1).

Table 1: Three models of the Integrated Report of companies listed on the WSE in 2013-2018

Year	***Financial information - financial statements (full or simplified) and financial data prepared on its basis*** *in pages*	***Non-financial information*** *in pages*	***Total information*** *in pages*

ING BANK ŚLĄSKI			
2016	0 stron	215 stron	215 stron

Verifying the structure of IRs published by the surveyed companies for the analysed period, it can be pointed out that, from the point of view of their information structure, there were most reports compliant with model 1, i.e. an advantage in their structure of non-financial information over financial information. Separated model 2 of integrated reporting occurred less frequently in business practice, while model 3 of the integrated report appeared only in one case.

Conclusions

The analysis of the collected data indicates that from 2013 to 2016 the number of companies publishing the IR has been growing. A significant change occurred in 2017, when the number of

companies publishing the IR decreased. A vast majority of companies published the IR in two language versions - Polish and English. In 2018, two companies only published the IR in English. The reports were prepared according to GRI and IIRC guidelines. Most of the surveyed companies prepared their IR both in traditional (in pdf) and interactive form. Moreover, the reporting practice of companies listed on the WSE indicates that the IR is primarily a non-financial report. The financial information presented in the reports includes only fragments of the financial report and additional financial data prepared on its basis. In 2017-2018, there is a clear change in the information structure and reporting form. The IR becomes a report in which the share of financial information is significantly reduced - only in two companies (three reports) do they account for more than 20% of the total report content. Moreover, the results of study indicate that the reporting practice in the area of publication of the IRs in Poland was significantly influenced by Directive 2014/95/EU of the European Parliament and of the Council amending Directive 2013/34/EU as regards the disclosure of non-financial information and diversity information by certain large entities and groups. In the case of some companies, the IRs were replaced by a statement on non-financial information, less extensive as compared to the IR. Thus, the literature's predictions as to the direction of changes in integrated reporting were confirmed (e.g. Walińska et al., 2016).

Abstract

The aim of this paper is to analyze the influence of brand and ecological awareness on electric car purchasing intentions and to determine whether there are differences in ecological awareness and brand importance according to the different consumers' characteristics. Correlation analysis shows strong correlation between brand and ecological awareness in the process of purchasing the electric car in Croatia. Therefore, if customer has the higher level of ecological awareness then the car brand will have more impact on electric car purchasing process. On the other side, the regression analysis concluded that none of independent variables are significant for the customer when purchasing an electric car. That means neither brand nor ecological awareness has a significant impact on the customer when purchasing an electric car in Croatia. Considering that the research sample was relatively small, results of this research can be viewed only as an indicative. Recommendations for future researches should include the price, risk and value as variables, since it could potentially be the crucial aspect in electric car purchase decision making.

Keywords: Ecological Awareness, Brand Influence, Purchasing Intention, Electric Car.

Introduction

Today's consumers are increasingly aware that their buying behavior can greatly affect the environment (Wahid et al., 2011), so it is important to explore the impact of ecological awareness on consumer buying behavior regarding different product categories. Last couple of years, more and more authors have been writing about and analyzing consumer ecological awareness and its influence on purchase decision-making. The results of some research have shown that an eco-conscious customer is more likely to purchase environmentally-friendly products and that price and brand awareness image significantly impacts their decision to purchase environmentally-friendly products (Hussain et al., 2014). Lesser number of research focuses on understanding the customer awareness of environmental initiatives in the automotive industry and their perception toward buying environmentally friendly cars (Sharma and Maheshwari, 2014). The results of these surveys show that most of customers are familiar with the benefits of environmentally friendly cars and that the level of ecological awareness affects their car purchase. In addition to ecological awareness, the car brand is also significant determinant of

the car purchase decision-making. In various researches, it was concluded that the car purchase decision is strongly impacted by the car origin country (Wu, 2011), the brand of the manufacturer (Anisimova and Mavendo, 2010), and the attractiveness of the car brand as well as the level of loyalty of the car brand (Muhammad and Butt, 2012).

In this paper, research focus is finding out, how much car brand and ecological awareness impact on electric car purchase decision making in Republic of Croatia. Correlation analysis of customers' ecological awareness and car brand has been conducted. Following, it was analyzed the impact of car brand and the ecological awareness on car purchase.

Theoretical Framework

Analysis of brand impact on customer during the car purchase

The brand represents a key element that characteristically wise differentiates the product, whether it is the quality that characterizes that brand, some specific features which brand possesses, or perhaps connectivity or familiarity with that brand. According to Shamsudin et al., (2016), brand of the car plays a key role in the automotive industry and thus becomes the subject of numerous academic and professional researches. Despite the conducted researches, Wu (2011) concluded that customers make the ultimate purchase decision based on their own opinion, choice, preference, taste and personal demands. The same author raises the question of whether the brand is actually the decisive factor during the car purchase process.

Wu (2011), in his paper, emphasizes country origin of the brand and collectivism, that is, individualism as well as the car brand itself as an extremely important and significant factor when purchasing a car. Yet the results have shown that the car brand and brand loyalty do not present a decisive factor during car purchase process in the United States of America. By contrast, the research conducted in Japan and in Europe has shown that customers perceive brand loyalty highly during car purchase process. According to Narteh et al. (2012), automotive industry researches have shown that brand awareness, brand identity, brand image, availability, emotional link toward the brand, price, quality and brand relationships and ratios and car features have a significant impact on car purchase and a positive correlation with the customer car purchase intention as well. The results also suggest that consumers are willing to pay for the car brand where there is a certain level of familiarity present and when they have specific information and knowledge about the car, compared to the cars they do not know, or are unfamiliar with. The general conclusion is that the car brand, as well as everything that determines it, like brand image, country origin image, car quality, impacts costumers' car purchase. Setting up a positive relationship between customer and the car brand depends on the positioning the car brand deep into the consciousness of the customer. In a way, it is like trying to link customers' lifestyle with the brand identity and brand meaning (Nareth et al., 2012).

According to research conducted by Benoit-Moreau and Parguel (2011), ecologically themed communication, involving some brand cars, had positive impact within the automotive industry. Joining the car brand and ecological awareness strengthens the value of the car brand, but also customers' propensity toward the car brand. Following, Letchumanan and Sam (2016), conclude, that the customers will show higher level of propensity toward a more familiar car brand if there is a higher level of brand awareness and enterprise reputation connected to the observed car.

Analysis of the ecological awareness impact on the customer car purchase

According to Carrigan and Attalla (2001), ecologically aware customers, are mostly educated customers, which, from the beginning emphasizes their awareness in comparison to less educated customers. The common assumption is that without necessary awareness level, customers do not possess enough motivation for purchase of ecologically acceptable products. Because of that exact reason, authors such as Ginsberg and Bloom (2004), Meyer (2007) and Ottman (2008), think that companies should inform their customers and keep them aware of market trends through their own practices, which would automatically impact customer awareness level, and therefore purchasing intention. Sharma & Maheshwari (2014), consider Indian automotive industry to be one of the most

promising global automotive industries when it comes to ecological awareness. Accepting and adopting the ecologically labeled technology, as one of many marketing strategies Indian automotive industry managed to scale up their numbers which still grow on daily basis. Main cause of this results is differentiation and filtering of ecologically aware customers.

Previously mentioned authors came to conclusion that 15% of customers are willing to purchase ecologically acceptable car, and they are also willing to pay more for purposes of ecological contributions. Also, they discovered that 52% of customers declared themselves as ecologically aware and friendly oriented toward the environment. Those 52% would be ready to purchase ecologically acceptable car, but they simply lack the purchasing power. On the other hand, 25% of participants already owns ecologically acceptable car. Those 25% of participants have already paid for additional costs as an ecological contribution. Customers, expectedly, consider the ecologically acceptable car price to be the biggest issue and barrier when intending to purchase a car. Following, there are some other barriers involved, such as lack of critical infrastructure, unattractive car design, lack of ecologically acceptable products information and lack of service centers. Sharma and Sharma (2013) conclude that ecologically aware customers consider important ecological questions when making a car purchasing decision. Their criteria during decision-making process is based on ecological and natural sustainability. Results, also support hypothesis that ecologically aware customers have higher level of propensity toward electric car purchase. Sharma and Kesherwani (2016), emphasize that ecological awareness can be strengthen through educations, intrinsic motivation, change of attitude and customers' value perception. Also, customers that possess previously mentioned characteristics have positive electric car intentions, as well as other ecologically acceptable products. Research conducted by Suki (2013) shows that great responsibility lies in building a positive and ecologically aware corporate image, which should make customers to behave ecologically and environmentally responsible. Same author also believes that customers prefer ecologically acceptable product purchase if they are familiar with the company that offers those products. Fine example is Toyota where the company launched various series of ecologically acceptable cars using their environmentally friendly technology, which resulted in production of hybrid, electric and plug in electric vehicles (Delafrooz et al., 2014).

Higher level of ecological awareness and knowledge of ecological and environmental issues have direct influence on purchase intention, and ecologically acceptable car purchase as well (Afroz et al.,2015). Previous findings were confirmed in research conducted by Cheah and Phau (2011), where it was emphasized how important behavior of every individual is when it comes to resolving ecological and environmental issues, and how awareness and consciousness influences on willingness to pay and purchase intention of ecologically acceptable products. Research conducted by Afroz et al. (2015) imply that customers with high level of ecological awareness possess higher intention of purchasing the ecologically acceptable car, in comparison with customers which had low level of ecological awareness. Results provided in research by Egbue and Long (2012) show that electric car perception is correlated with the gender, age and education level of a customer. Same authors conclude that ecological sustainability and environmental preservation have strong impact on acceptability of electric cars, right after price and car performance constructs, which were perceived as most impacted variables. Also, the electric car batteries technology and energy source sustainability are considered to be biggest barriers and challenges toward electric car usage.

Lane and Poter (2006) analyzed two research projects which identify customers' behavioral issues toward ecologically 'pure' cars. First project was 'The Low Carbon Vehicle Partnership by Ecolane Transport Consultancy' which observed behavior and attitudes of customers toward cars with low CO2 emission, and the authors found that customers have low knowledge level of new technologies, environment impact and costs of owning such car. 'Open University's Design Innovation Group' researched key factors which impact customers' adjustments on 'pure' cars. Contrary to other researches, results of this study showed that environmental preservation issues had small impact on both B2B and B2C segment during car purchase decision making.

Research of car brand and ecological awareness influence on electric car purchasing intentions

Research Goals and Methodology

Goal of this research paper was to determine the influence of car brand and ecological awareness on electric car purchasing intention in Republic of Croatia, and analyze if there were any statistically significant differences in ecological awareness and car brand importance between various characteristic of research participants.

In order to achieve previously mentioned goals, quantitative research using questionnaire instrument was conducted. Questionnaire was distributed through various channels such as e-mails and social networks. Some of e-mail addresses was gathered from car saloons in Zagreb. Beside demographic information, other information such as hybrid and electric car usage experience, electric car purchases intention, ecological awareness and car brand toward car purchase (car brand on social status impact and car brand on car purchase impact) were collected.

Questionnaire used in this research was constructed using other relevant literature. For assessing ecological awareness of customers, Sharma and Mahesmaris' (2014) and Hussain et al. (2015) researches were used. Car brand impact on customers was taken and adjusted from researches conducted by Shamsudin at al. (2016) and Wu (2011), and determination of ecologically acceptable car purchase intention was taken from Henning and Karlsson (2011). Five degrees Likert scale was used to evaluate participants' level of agreement and disagreement with statements regarding car brand influence, ecological awareness and electric car purchase intention. The questionnaire was divided in four sections. First section contains socio-demographic aspects (gender, age range, education level, region, household size) and financial aspects (monthly household income and potential electric car purchase budget). Second section of research addressed statements regarding ecological awareness influence, while the third section include the influence of car brand during car purchase process. The fourth section examined the car purchase intention perception.

Data normalization was conducted using Levine test and graphical data, as well as skewness and kurtosis check, to insure the usage of parametric tests in data analysis process. All variables performed within allowed deviation limit, which provided enough support for conducting parametric tests according to Byrne (2016).

Sample

In this research participated 105 people from Croatia. There were 60,4% of female and 39,6% of male participants in the sample. The most participants were under 30-year-old, with income between 1.000-2.000 EUR and the budget for electric car 10.000-20.000 EUR (Table 1.)

Table 1: Socio-demographic sample characteristics

Gender	**Percentages**	**Cumulative %**
Male	40,0	40,0
Female	60,0	100,0
Age	Percentages	Cumulative %
Less and equal to 25	38,1	38,1
25 – 30	29,5	67,6
30 – 40	17,1	84,7
40 – 50	8,6	93,3
50 and more	6,7	100
Education	Percentages	Cumulative %
High school	31,4	31,4

Higher expertise	16,2	47,6
University education	37,2	84,8
MBA/PhD	15,2	100,0
Household budget	Percentages	Cumulative %
Less and equal to 1000 EUR	19,0	19,0
1000 – 1500 EUR	23,8	42,9
1500 – 2000 EUR	21,9	64,8
2000 – 2500 EUR	17,1	81,9
More than 25000 EUR	18,1	100,0
Electric car budget	Percentages	Cumulative %
Less and equal to 10000€	19,0	19,0
10000 - 15000€	30,5	49,5
15000 - 20000€	30,5	80,0
20000 - 30000€	17,1	97,1
More than 30000€	2,9	100,0

Research Results

Factor Analysis

The factor analysis was conducted to determine and define validity and reliability of observed constructs. Following, the reliability of ecological awareness scale was highly supported by *Cronbach alpha* coefficient level of 0,932 (eliability coefficient of 0,70 or higher is considered to be acceptable in most social science research) (Table 2). To conclude, the factor analysis of the ecological awareness construct was formed without first item, due to low saturation level on observed factor (0,375), and such construct was used in further data analysis.

Table 2: Factor analysis of ecological awareness construct

Item	**Factor saturation**	
	% variance extracted = 60,01	**Cronbach α= 0,932**
Ecological awareness of individual can highly contribute to environment preservation	0,375	
In general, I take care of environmental issues and energy preservation	0,624	
I am often worried about ecological issues	0,823	
I consider myself quite ecologically aware person and buy only ecologically acceptable products	0,683	
I consider myself ecologically aware person because of my own attitudes and believes	0,865	
I consider myself ecologically aware person because it makes me feel useful and satisfied	0,833	
I rather buy products which are known to be ecologically acceptable	0,575	
I often discuss ecological problems with my friends	0,614	
I support solving ecological problems, even if I have to give up some traditional daily activities	0,478	
I consider usage of electric cars is able to contribute environmental preservation	0,466	

During conducting factor analysis of brand impact construct, two factor structure was formed. Saturation of items, after first rotation points out the necessity of two factors existence. Therefore, items saturated on first factor indicate that newly formed construct measures brand influence on car purchase, and second factors' items measure car brand as a social status symbol. After first construct measurement, reliability score of *Cronbach alpha* coefficient was high (α=0,906) (Table 3). Similar results were present during reliability measurement of second construct (α=0,898) (Table 4).

Table 3: Factor analysis of car brand influence construct

Item	Factor saturation	
	% variance extracted = 52,98	**Cronbach α= 0,906**
I always purchase well known car brand	0,651	
It is important that I own a car which country of origin is well known for elite car production	0,650	
During car purchase I always look for car country origin	0,651	
I intend to buy only specific car brands	0,665	
I actively search specific car brands during car purchase	0,647	

Table 4: Factor analysis of car brand as a social status symbol construct

Item	Factor saturation	
	% variance extracted = 56,87	**Cronbach α= 0,895**
Extremely famous car brand represents a symbol of social status	0,677	
Owning a famous car brand improves my social status	0,747	
Car brand logo represents who I am	0,526	
Car brand ensures the quality of car itself	0,433	
Well known and expensive brand represents symbol of status for me	0,822	

After analyzing validity and reliability of purchase intention construct, results show one factor structure with 62,30% of variance explained. Reliability analysis of purchase intention construct resulted in high *Cronbach alpha* coefficient (α=0,934) (Table 5). To conclude, during data analysis process, all construct items were used.

Table 5: Factor analysis of electric car purchase intention construct

Item	Factor saturation	
	% variance extracted = 62,30	**Cronbach α= 0,934**
There is a high probability that I'll purchase an electric car in the future	0,752	
I would purchase an electric car if its' price would be the same as traditional car prices	0,483	
In comparison with other (traditional) cars, there is a higher probability that I will purchase an electric car	0,780	
I would purchase an electric car even if its' price is higher than traditional car price	0,676	

I would purchase an electric well known car brand even if its' performances were not as good as traditional cars' performances	0,655
I would purchase an electric well known car brand even if its' design isn't as attractive as traditional car design attractiveness	0,641
I intend to purchase electric car	0,721
It is very certain that I will search for information regarding electric cars during my next car purchase	0,625
I will probably support a friend and recommend him to purchase an electric car	0,587

Analysis of ecological awareness and car brand impact on electric car purchase

In order to determine correlation between observed variables, correlation analysis was conducted (Table 6). Correlation analysis points out that the strongest correlation is between ecological awareness and car brand influence (r=0,95; p<0,05). Correlations between other variables vary around moderate and weak intensity. Electric car purchase intention will be higher for the participants who perceive car brand as an extremely important factor during car purchase. Car brand as a social symbol will have moderate correlation with electric car purchase intention (r=0,46; p<0,05). Participants who have higher ecological awareness will also have higher car purchase intention level (r=0,44; p<0,05). Participant who expressed high level of ecological awareness will have less interest in purchasing car just as social status symbol (r=-0,27; p<0,05), which means that high ecological awareness correlates negatively and linearly with car brand as a social status symbol. Participant which perceive car brand as a social status symbol will correlate negatively with electric car purchase intention, which indicates that those participants won't be interested in electric car purchase.

Table 6: Correlation matrix of observed variables (p<0,05; **p<0,01)***

	Ecological awareness	**Car brand as a social status symbol**	**Car brand impact**	**Electric car purchase intention**
Ecological awareness	1	-,268**	,945**	,439**
Car brand as a social status symbol		1	-,295**	-,201*
Car brand influence			1	,461**
Electric car purchase intention				1

After the correlation analysis, the regression analysis was conducted (Table 7 and Table 8), which came up with the conclusion that there were not statistically significant impacts detected on electric car purchasing intention.

Table 7: Regression analysis of the electric car purchase model

Regression summary				
Model	*Multiple R*	*R-Square*	*Adj R-Square*	*Standard Error*
1	,467[a]	0,22	0,19	7,56

According regression summary analysis, it is concluded that electric car purchase model is not representative (*Adj R-Sq*<0,9), which points out that it is not possible to predict electric car purchasing intention using observed independent variables (Table 8).

Table 8: Regression coefficient table and coefficient significance

Regression coefficient table						
Model		Unstandardized coefficients		Standardized coefficients	*T*	*P*
		Beta	*SE*	*Beta*		
1	(Constant)	15,95	4,12		3,87	
	Ecological awareness	0,04	0,24	0,04	0,16	1,002
	Car brand as a social status symbol	-0,13	0,16	-0,08	-0,81	0,103
	Car brand influence	0,73	0,50	0,40	1,46	0,670

Testing the independent variables in the electric car purchase intention model resulted in insignificant impact of all independent variables.

Analysis of subsample differences regarding the ecological awareness level and car brand perception level

Additionally, analysis regarding various subsample differences were conducted. Participants' intentions, ecological awareness and car brand preferences were tested between gender, potential electric car budget and previous electric car experience. Series of *F-tests* and *Scheffe tests* were conducted. Testing results point out that women have higher average ecological perception than men, while men are more likely to show higher average brand importance perception than women, which means that brand car impacts more on man's car purchase intention than woman's. Mean scores also indicate that women have higher average purchase intention level than men. Statistically significant differences were found at construct of economical awareness, which concludes that women are statistically significant more aware when it comes to ecological issues than men (Md=-8,09; t=-4,59; p<0,05). Also, other empirical researches show that women are more sensitive on environmental issues and tend to support ecological problems in comparison to men (Ahmad et al., 2012).

Discussion and Conclusion

Conducted research has shown that there is a strong correlation between ecological awareness and car brand influence on purchasing intentions. Also, there is moderate correlation between car brand and electric car purchasing intention. These findings indicate that if customers with higher level of ecological awareness purchase car according to their beliefs (ecologically aware), it is more likely that these customers will also perceive a car brand as a very important factor during car purchase intention. Also, can be concluded that purchase intention will be more emphasized within customers which consider car brand very important. Correlation analysis detected moderately strong correlation between ecological awareness and electric car purchase intention constructs, which means that higher level of ecological awareness among customers could affect higher level of electric car purchase intention. To conclude, customers that consider brand as a social status symbol will consequently have lower level of ecological awareness, and therefore lower electric car purchase intention. The analysis of differences in ecological awareness and brand importance according to the different consumers' characteristics

point out that women have higher average ecological awareness than men, while men are more likely to show higher average brand importance perception than women, which means that brand car influence more on man's car purchase intention than woman's.

Regression analysis detected no significant influences of independent variables toward electric car purchase intention. Even though this analysis did not provide positive results, most of other relevant literature indicate that there is positive correlation between ecological awareness, car brand importance and car purchase intention. Following, some research conclude that high level of ecological awareness indicate ecologically acceptable car purchase, and also ecologically aware customers have higher chances of purchasing ecologically acceptable cars in comparison to those customers that are not ecologically aware (Afroz et al., 2015). Sharma and Mashesmari (2014) conclude that customers with high ecological awareness during purchase decision making process think about environmental issues and their purchasing criteria is based on ecology and natural sustainability. Thogersen and Ebsen (2019) find out that Danish car owners' intention to buy an electric cars increases with their attitude towards those cars and felt moral obligation to buy an eco-friendly car and decreases with increased perceived difficulty in use and feeling uncertain about electric cars.

Considering other product categories, it can be concluded that higher customer ecological awareness will impact to more positive environment oriented behavior in general (Gadenne et al., 2011). One of the most important challenges within customers' perception, when considering ecologically acceptable products is higher product price range. Marketing experts claim that the customers are, despite their beliefs and level of ecological awareness, still very sensitive when purchasing ecological products (Čut and Pandža Bajs, 2016). Previously mentioned authors (2016) conclude that customers' key criteria when purchasing ecological products is price, which is compared with similar and marginally satisfying brands. The study of Tarigan (2019) shows that individuals tend to support the eco-friendly cars when the technologies meet their expectations towards cost and safety, but the cost expectation is the most significant factor that results in the decision to purchase the eco-friendly cars. Also, some of the recent studies (Sefora et all, 2019) showed that the intentions to use electric cars were influenced by perceived usefulness, risk and value.

Cross branding and ecological awareness strengthens the values of brand itself and customers' loyalty toward that same brand as well, which can be partially linked with this research, where higher ecological awareness level within customer has positive correlation with brand importance and car purchase intention. This research emphasizes the importance of price sensitivity within customers during car purchasing process. Participants claim that they would be interested in electric car purchase if there was a significant price decrease. Following, they would purchase electric car if the price range was in the domain of traditional car price. Conclusion could be made, that electric car purchasing price and expected costs potentially have more influence on electric car purchase decision making than ecological awareness and car brand.

Considering that the research sample was relatively small, results of this research can be viewed only as an indicative. Recommendations for future researches should include pricing and costs variable, perceived risk and value, since it could potentially be the crucial aspect in electric car purchase decision making. Research conducted in other sectors indicate on price importance as one of the key factors influencing decision making. Those research also support ecological awareness and brand influence to have significant but not crucial impact on purchasing behavior.

Abstract

The level of requirements for thermal resistance of structures in Kazakhstan is significantly lower than the requirements imposed in EU countries with similar climatic conditions. The average data on heat consumption in the residential sector in Central Asia countries (230-270 kW * h / m^2) exceed this indicator in Europe (100-120 kW * h / m^2) and are comparable with Russia (210 kW * h / m^2). In general, the level of our lag in the degree of thermal protection of newly constructed buildings is 15-20 years. It is important to use the correct rating to obtain a complete and objective picture of energy efficiency indicators in the field of buildings and structures. This article provides an overview of indicators and rating categories for energy efficiency projects. Based on a study of best practices, the authors propose common and relevant rating assessment techniques that can be successfully applied in the economy of Kazakhstan. Assessment is based on rating systems, of which the following are most known: LEED (USA); BREEAM (UK); DGNB (Germany), each of which has a specific specificity and identifies various priorities.

Keywords: Energy Efficiency, Rating, Energy Savings, Environmental Management.

Introduction

In conditions of fierce competition in the world market, any country aimed at economic growth and development should take thoughtful and consistent steps to create optimal conditions for the development of the industrial sector. As the experience of developed countries shows, for the harmonious development of industry it is necessary to take into account energy efficiency indicators. Today, the energy intensity of industry in Kazakhstan is 4-5 times higher than in European countries. The energy intensity index of Kazakhstan's GDP in the world ranking is 1.9, while the indicator of Japan, for example, is 0.1, and that of Germany is 0.16.

As you know, to reduce the energy intensity of GDP of the Republic of Kazakhstan by 40% by 2020, a comprehensive energy efficiency plan was developed and adopted. The implementation of this plan will make it possible to obtain positive shifts in this area and obtain additional advantages and benefits in the form of financial resources due to more efficient use of energy in industry. The potential is comparable to the increase in production of all primary energy resources and is estimated at 20-30% reduction in energy demand in Kazakhstan and 35-40% in Kyrgyzstan.

An important part of this plan is the implementation of standards for assessing energy efficiency of projects, including in the field of construction. Such a measure is necessary because the concept of energy efficiency is associated with a large number of diverse and rather complex factors and processes, which determines the need for analysis of the definition itself, which could fully reflect all the necessary aspects of this phenomenon. It is important to distinguish between the concepts of energy efficiency and energy conservation, which are often mistakenly identified.

According to the Law of the Republic of Kazakhstan "On Energy Saving and Energy Efficiency Improvement" dated January 13, 2012 No. 541-IV ЗРК, these concepts indicate:

- energy efficiency (energy efficiency) - characteristics that reflect the ratio of the beneficial effect of the use of energy resources to the costs of energy resources produced in order to obtain such an effect;

- energy saving - the implementation of organizational, technical, technological, economic and other measures aimed at reducing the amount of energy resources used.

The creation of a better regulatory framework for energy conservation is one of the main mechanisms for improving energy efficiency. At present, Kazakhstan has several dozen state standards for industrial equipment, machinery, and appliances that can be attributed to energy efficiency standards. A number of regulatory documents on energy audits and energy certification have been developed, which reflect energy performance indicators.

In Kazakhstan, energy saving and improving energy efficiency in all sectors of the economy are currently a priority task, the solution of which will solve a complex of problems - energy, environmental, economic and social.

On January 13, 2012, No. 541-IV ЗРК, a new Law of the Republic of Kazakhstan "On Energy Saving and Improving Energy Efficiency" was adopted. The law was adopted in place of the previous Law on Energy Saving. The new law defines the concept of the State Energy Register - a systematic collection of information on business entities consuming more than 1,500 tons of fuel equivalent per year, or 2 MW of installed capacity.

So, following the global socio-economic trends, Kazakhstan, like many countries of the West and East, has joined the international environmental movement and is now taking its first steps on the road to sustainable development. Confirmation of this is the Strategic Development Plan of the Republic of Kazakhstan until 2020. According to this document, which as a whole does not change the general trend, Kazakhstan seeks to reduce the energy intensity of the economy (according to the Strategic Plan by 25%) and carbon emissions (in accordance with the obligations under the Kyoto Protocol - by 15% by 2025 and by 25% by 2050).

Today, the energy intensity of Kazakhstan's industry is 4–5 times higher than in European countries. The energy intensity index of Kazakhstan's GDP in the world ranking is 1.9, while Japan's indicator, for example, is 0.1, and Germany's is 0.16. In this direction, the experience of developed countries, that already have positive experience in energy efficiency management, is very interesting.

We believe that Central Asia countries need to adopt a national standard in the field of energy efficiency. As example, the countries of the Eurasian Economic Union adopted a technical regulation on energy efficiency of energy-consuming devices in 2019. A national standard for energy efficiency is necessary to establish a universally recognized scheme for integrating energy conservation into their management practices for organizations and it can be based on a number of standards from different countries.

In the field of energy saving and energy efficiency in buildings, the republican building standards "Energy Consumption and Thermal Protection of Civil Buildings" are in force SN RK 2.04-21-2004, SN RK 2.04-04-2011 "Thermal Protection of Buildings".

The classification and standard values of the specific characteristics of the consumption of thermal energy for heating for residential and public buildings, the form of the energy passport of the building in SN RK 2.04-04-2011 are identical to Russian standards.

The European Union is a leader in environmental standards applicable in Kazakhstan. In the practice of technical regulation of energy efficiency in the EU, two main methods are used - labeling energy efficiency and establishing requirements for eco-design of products (environmentally-friendly design).

On the basis of financial, technical, environmental and social indicators, methodologies for environmental assessment of building construction have been developed in various countries, of which the following are best known: LEED - a guide to energy and environmental design (USA); BREEAM - environmental impact assessment method (United Kingdom); DGNB - certificate of sustainable construction (Germany), Standard STO NOSTROY 2.35.4-2011 - Residential and public buildings. Rating system for assessing the sustainability of the environment (Russia) and others. The financial indicators for assessing the construction of a building are described in the cost-optimal methodology concept, which became widely used after the adoption of Directive 2010/31 / EC on the energy performance of buildings. This methodology is discussed in various studies: Araujo et al. (2016), Ascione et al. (2016), Atanasiu et al. (2013), Ballarini et al. (2017), Becchio et al. (2015), Hamdy et al. (2017), Hamilton B. A (2010), Enseling and Loga (2013), Gurgun A.P. and Arditi D. (2018), Leutgöb and Rammerstorfer (2013), Miller (2014), Ortiz et al. (2016), Pikas et al. (2015), Tadeu et al. (2016), Tabunshchikov et al.(2013), Tleppayev (2019). Based on previous standards and studies, a rating metodology for Kazakhstan's practice was developed to assess the attractiveness of energy efficiency projects.

Materials and Methods

As a study of the best practices in the field of improving energy efficiency shows, the investment attractiveness of energy efficiency projects depends on the use of various assessment tools that contribute to the formation of objective and relevant forecasts for investors. The current practice of development of the economy of Kazakhstan indicates the need to develop this issue and apply project evaluation methods that take into account the particular development.

In world and Russian practice, several methods and indicators of economic and financial evaluation of energy efficiency projects in buildings are widely used: simple payback period or rarely used inverse of the average annual income per unit of capital investment; an indicator of the net present value and its derivative characteristics: profitability index, internal rate of return, payback period simple when discounting costs, etc .; energy saving cost; life cycle cost of a building. Each of these indicators has its own advantages and limitations on its use. The first two indicators are widely known and are often used to justify measures to improve energy efficiency, including and in buildings.

The life cycle cost of a building is the total discounted cost of owning, operating, repairing and disposing of a building or complex of buildings over a period of time. The concept of life cycle costs has been known for a long time. However, in relation to buildings, it has become actively used relatively recently - after the adoption of the EU Directive 2010/31 / EC on the energy performance of buildings, which requires EU members to set energy efficiency requirements not lower than economically optimal levels. To determine such levels, states are obliged to use a framework methodology that is fully based on the concept of the costs of the building's life cycle.

In addition to assessing the initial costs of building the building, all future costs associated with its operation, repair and subsequent demolition are taken into account. The sum of all costs associated with the construction and operation of buildings is "the cost of the building's life cycle". Optimization is carried out according to the criterion of minimizing the total life cycle costs of the building for the builder, owner and society, including the requirements to reduce environmental damage and reduce greenhouse gas emissions. Analysis of the life cycle cost of a building can be carried out for buildings of any type - existing and new, residential and public, individual and multi-unit.

The discount factor significantly affects the indicators of economic efficiency of projects. Its high value leads to a rapid depreciation of future income and underestimates the positive cash flow, and hence the economic effect of the project. A package of measures is cost effective if the net present value of the revenue stream calculated with a given discount factor is greater than zero, or the discounted income is greater than the discounted cost. In substantiating investment projects, two approaches are used: calculating cash flow at current prices and at comparable prices. In the first case, the refinancing rate is often used as a discount coefficient in economic analysis, and in the financial analysis, the market interest rate on long-term loans. In comparable prices - the interest rate taking into account the level of inflation.

Along with financial indicators, many non-economic variables are used in assessing the construction of a building. So, the green building assessment is based on rating systems, of which the following are best known: green building certification programs LEED - The Leadership in Energy & Environmental Design (USA); BREEAM - Building Research Establishment Environmental Assessment Method (United Kingdom); DGNB - certificate of sustainable building (Germany), etc.

Results

The methods LEED, BREEAM, DGNB are based on a rating system and are applicable to various types of buildings. Certification by this system allows you to evaluate and determine the "rating of environmental friendliness and energy efficiency." As you know, with a rating score, points are summed up subject to certain engineering and organizational as well as organizational measures, while points are grouped into certain sections.

BREEAM evaluation includes the following criteria:

- management (construction process management, building management after commissioning, etc.);
- energy (reduction of CO2 emissions, use of renewable energy sources, etc.);
- water efficiency (use of gray and rainwater, meters, leakage control, etc.);
- efficient use of the building site and the environment (taking into account the ecological value of the territory, the use of previously contaminated lands, etc.);
- health and environmental well-being (natural ventilation, comfortable thermal conditions, etc.).

The following categories are subject to LEED assessment:
- sustainable development of the territory,
- water efficiency
- energy and atmosphere,
- materials and resources,
- the quality of the internal environment,
- application of innovations in design.

Summarizing the above, we can describe characteristics of the green building assessment system, which is shown in the table 1 below.

Table 1: Example of assessment according to the system of green standards

Element	Content
Sections	Adjacent territory, Water use efficiency, Energy and microclimate of the building, Materials and resource base, Indoor air quality, New project strategies and innovations
Evaluation Techniques	Sections contain a different number of requirements - according to compliance with these requirements, the evaluated project receives credit points. The system is designed so that even one missed requirement does not allow certification of the object. The final certificate is determined by the total amount of these points on a flexible certification scale and has several gradations.
Evaluation Schemes	New construction; Maintenance of already constructed buildings; Commercial space Interior design; Fine finishing of buildings; Schools Trading areas; Healthcare facilities; Residential Properties; Development of suburban housing construction (cottage villages); Offices Integrated Residential Areas
Categories	Ensuring environmental sustainability of projects; Efficient use of water; Energy and the impact of energy use on the atmosphere; Materials and resources; Creating a favorable atmosphere inside the building; Application of innovation in design

Source: Gurgun A.P., Arditi D. (2018), Hamilton B. (2010)

When evaluating energy efficiency, rating categories are also taken into account, which allows a more complete and objective assessment of the energy efficiency of projects: “Energy Saving and Energy Efficiency”, “Alternative and Renewable Energy”, "Economic efficiency".

Table 2 shows a comprehensive approach to assessing energy efficiency of Kazakhstan’s projects, which allows to obtain significant cost savings when implementing a whole set of measures aimed at improving the identified indicators. As can be seen from the table, an integrated approach to assessing energy efficiency allows you to get positive results, which vary significantly depending on the parameters and evaluation criteria.

Table 2: Rating criteria for evaluating energy efficiency projects

Criterion	Parameter
Energy Saving and Energy Efficiency	
Thermal energy consumption for heating and ventilation of building	Saving thermal energy is achieved through energy-saving measures in the heating system.
Power consumption	Specific energy consumption for lighting common areas relative to the standard indicator and the use of energy-efficient lighting
Primary energy consumption for engineering systems	Energy efficiency of equipment according to EU standards
Consumption control	Availability of an automatic heat station and individual control and regulation of heat consumption
Sustainable and ecological development	
Use of recycled resources	Use of recycling systems (ventilation with heat recovery, etc.)
Use of renewable resources	Application of a heat transfer system for hot water supply
Automation of flow control processes	Application of automatic lighting, humidity and air exchange control systems
Conformity to norms of light comfort (building insolation) and humidity	Conformity of insolation to normative coefficients of natural light and observance of distance between buildings according to Kazakhstan's standards
Quality of waste collection and recycling organization	Availability of separate waste points within a quarter
Cost effectiveness	
Life cycle cost of the building per m^2 of the building at NPV>0	Total discounted cost of ownership, operation, repair and disposal of the building over a period of time to the corresponding value for the analogue or benchmark facility
Cost per annum operating costs per m^2 of building	Ratio of the average annual cost of a residential building operation to the cost of a similar object or benchmark
Payback period	Comparison of the payback period in relation to an object-analogue or benchmark

Source: Authors research based by Miller (2014), Tabunshchikov et al.(2013), Standard STO NOSTROY 2.35.4-2011

According methodology, great weight should be given to energy efficiency indicators, since they are directly related to environmental criteria, since saving heat and electricity leads to a reduction in emissions of combustion products into the atmosphere. Depending on the number of points summarized in the analysis of the project, it should be assigned a class of energy and environmental efficiency by analogy with the European energy efficiency labeling system for buildings A – G.

This methodology can defines a rating system for assessing the sustainability of the human environment that meets the goals of the present generation in meeting its needs in a comfortable living environment and performing public functions through the use of residential and public buildings without reducing the level of such an opportunity for future generations. The requirements of the rating system are aimed at reducing the consumption of energy resources, the use of non-traditional, renewable and secondary energy resources, rational water use, reducing harmful environmental impacts during the construction and operation of the building, including the local area, while ensuring a comfortable human environment and adequate economic profitability of architectural , design and engineering solutions.

The requirements of national standards, construction and sanitary norms, rules and methodological documents, as well as the main provisions of foreign rating systems for evaluating LEED (USA), BREEAM (Great Britain), DGNB (Germany) and HQE (France) should be also considered.

Conclusions

A rating methodology allows to:

1) Allow, based on the data obtained, to plan measures to eliminate the most inefficient indicators;

2) Reflects the multidimensionality of the measurement of the project energy efficiency indicator

The use of an integrated approach in matters of rating assessment of energy efficiency indicators is based on the following provisions:

- at the present stage, considerable foreign experience has been accumulated in the development and practical use of rating systems for energy efficiency of projects, which allow taking into account features and specifics, based on a complete and relevant assessment;

- assessment of green construction is based on rating systems, of which the following are most known: LEED (USA); BREEAM (UK); (Germany), each of which has a specific specificity and identifies various priorities. That is why it is important to fully understand the specifics of the application, as well as the results that can be obtained and used in the future to achieve the set goals depending on the project.

At the present stage, there is a large list of energy efficiency indicators for buildings, which includes 5 main groups, within which indicators are distributed into subgroups.

Using an integrated approach to assessing energy efficiency allows you to get significant returns in accordance with a variety of parameters and criteria. What is especially important in conditions when obtaining some data may be difficult or distorted as a result of various phenomena and circumstances.

With the harmonization of various standards, as in the case of this study, it is justified to use an integrated approach, which allows, in the absence of some data, to vary and get the big picture, in which you can compare rating indicators by common standards.

In Kazakhstan, the relevance of the proposed approach is especially felt when working with residential facilities. This is due to the fact that usually such buildings have a large number of owners, and decisions are taken for a sufficiently long period.

The authors see the solution of issues and problem situations in the field of housing in an effective rating system, which could clearly show the main problems in terms of indicators. And this in the future allows us to offer effective solutions with an optimal price-quality ratio to increase the energy efficiency of a residential property. This can be the basis for the development of project work that is fully justified and has evidence of high economic return.

The economic return on projects in existing and new buildings, in our opinion, depends on the creation of energy efficiency programs for overhaul and subsidies from the budget for the overhaul of energy-efficient projects; creation of revolving funds for energy conservation and business development of energy service companies; developing standardized banking products to finance energy efficiency programs.

Abstract

We suggest a new approach to assessment of institutional quality - the institutional option concept. It's based on modern institutional theory principles and new problem-oriented research paradigm. This viewpoint reveals the role of institutions in decision making of economic actors. We assume that institutions help actors to find different de jure or de facto variants of problem solving. It allows us to implement problem-oriented approach to institutions quality assessing. We develop new quantitative assessing model, based on matrix methods and conclude with practical value of the concept to show its advantages.

Keywords: Institutions; Institutions Quality; Institutional Option; Institutional Environment; Institutions Assessment.

Introduction

Currently, a quantitative assessment of the institutions quality is one of the most methodologically complex problems in the institutional economy. At the same time, the significance of such assessments cannot be overestimated; the institutional factor is recognized as key in the development system of both national economies in general and individual sectors. The existing gap between the methodological capabilities of modern institutional research and the objective requirements of the economic reality determines the high relevance of the search for possible solutions to this problem.

As you know, sociologists are of the opinion that institutions are stable patterns of social interactions that structure a society, they determine the behavior of individuals, and in terms of philosophy they are identified with necessity (Kirdina, 2001, 2008). Economists, on the contrary, adhering to the principle of methodological individualism, believe that the whole owes all its properties and patterns of behavior to its parts (individuals), and does not have any independent properties (Platonov, 1997; Olejnik, 2005; Nureev, 2010; North, 2010). From this point of view, institutions are the result of free choice of an individual or freedom in terms of philosophy. In this light, the conclusions of scientific studies made by the famous Nobel Laureate Huerta de Soto (2008) are interesting in which he claims that the principle of objectivity is limited, since economic phenomena do not exist outside the subjective interpretation and subjective knowledge of specific individuals. The theory of institutional

coercion proposed by him reflects the presence of institutional aggression against individual freedom in scientific research.

An attempt of a scientific search for a compromise between the identified opposing principles of the modern institutional research was the original concept of an institutional option, proposed by us to the scientific community in (Podshivalova, 2014a, 2014b). This article presents its economic and mathematical modeling, which allows attributing this concept to empirically feasible.

Problem Formulation

The purpose of this study is the development of methodological tools for assessing the institutions quality and the institutional environment of various carriers, based on the original concept of an institutional option. Let us briefly outline its main points.

1) The concept is based on a problem-oriented research paradigm, which suggests that the analysis of the institutional environment of a carrier is carried out through the prism of the problems it faces. Institutions and tasks relate to each other as plurality to plurality - one institution for many tasks and one task can be solved using several institutional technologies. An institutional option manifests itself in the second case.

2) Along with the institution, there is an opposite technology for solving the task - non-institutional behavior. Therefore, methods for solving tasks by individuals are institutional by nature and non-institutional. In the case of an institutional option, we mean only the first type. The second technology for solving the problem - non-institutional behavior. It is due to the fact that along with the necessity (in our context, institutions), there is always freedom of choice at the individual level. And this freedom can ultimately lead to the emergence of new institutions through evolutionary means.

3) The concept is based on two main categories, i.e. “institutional option”. This is a set of alternative options for the institutional solution of the task that are available to the economic agent and used by him to coordinate his actions. “Institutional link” is a set of interconnected formal and informal institutions, which is used by economic agents to solve a specific task, achieve a specific goal. In other words, an institutional option characterizes the possibility of a choice for an economic agent from a variety of options for institutional links.

We are going to define the initial limitations of the mathematical modeling of an institutional option.

1) The setting of a carrier task affects the breadth of the option. The wider the task is, the wider the option is. This dependence must be taken into account during the initial “tuning” of the mathematical model.

2) To expand the possibilities of a mathematical modeling of the option, we introduce the concept of a homogeneous link into the model. A homogeneous institutional link consists of one institution, and includes cases when actors use the “clean” version of the institution without combining it with other formal or informal rules.

3) Institutions cannot be analyzed without semantic content, thus it complicates the process of their quantitative assessment. Despite this, the mathematical model of the option cannot ignore the semantics of the original institutions-elements.

4) When assessing the quality of an option, it is also necessary to consider its sufficiency. It is important to separate the de jure sufficiency of the option from the de facto sufficiency. The latter is the actual choice of actors, realistically observed behavior, reflecting the significance of existing institutional links for the environment carrier. The de jure sufficiency of an option describes the demand for institutional links expected by lawmakers, which they put into the established formal institutions. If we are talking about links with the participation of informal institutions, then the de

jure sufficiency of an option will reflect the demand for such links, which legislators would like to see.

5) The hierarchy of institutional systems imposes one more requirement on the mathematical model of an institutional option. It should include links consisting of institutions of the same order. For example, the institution of tax regulation is an institution of the first order, specific tax regimes and benefits are of the second order.

Thus, a mathematical model that takes into account all the basic properties of the option — breadth, hierarchy, relevance (sufficiency) and semantics — can quantify its quality as a whole.

Economic and Mathematical Model of An Institutional Option

An institutional option as a structural element of the institutional environment cannot be described in isolation from its carrier; therefore, we define small firms as an example of this.

Mathematical modeling of an institutional option taking into account the presented requirements is possible in the categories of linear algebra. This implies the construction of the matrix S of the size mxn, where m is the number of possible links from n institutions-fillers. Each element of the institutional option matrix s_{ij}, i=$\overline{1, n}$; j=$\overline{1,m}$ can take only two possible values: in the absence of the institution i in the link j - 0, in the presence - 1.

Then the j institutional link, subject to the given order of numbering of institutions, can be written by the vector s_j:

$$s_j = \begin{cases} 1, \text{if i institution is present in the link} \\ 0, \text{if i institution is absent in the link} \end{cases}$$

Accordingly, the institutional option S can be described by the matrix:

$$S_{m\times n} = (s_{ij}), \tag{1}$$

where $s_{ij} = \begin{cases} 1, \text{if i institution is present in the j link;} \\ 0, \text{if i institution is absent in the j link.} \end{cases}$

The number of possible links m for the case of coherent institutions - there are no restrictions on the combination of institutions among themselves - is determined by the formula (2):

$$m = 2^n - 1 \tag{2}$$

A graphic and tabular version of the option description is possible if it is described by the distribution law of a discrete random variable, because the number of links m is finite and can be predetermined according to (2). For this, it is necessary to determine the distribution of small enterprises among m possible institutional links that they used to solve a specific task. In this case, the option can be described by the tabular method, in which the frequency $p_j$of the institutional link $s_j$is determined according to (3). And the resulting vector $P_m = \{p_1;\ p_2; p_3 \dots p_m\}$ is a quantitative description of the *de facto option sufficiency*.

$$\mathrm{p_j}=\frac{\mathrm{W_j}}{\mathrm{W}},\ \ \sum_j^m p_j = 1,\ \ 0 \le p_j \le 1 \tag{3}$$

where w_j is the number of small firms that use the j link to solve the problem,
W is the number of surveyed small firms that are solving this problem.

To describe the *de jure option sufficiency* mentioned above, we propose using the vector of significance assessments (expected demand) of the institutional links of the option from the position

of public authorities - $V_m = \{v_1;\ v_2; v_3 \dots v_m\}$, with $\sum_j^m v_j = 1,\ 0 \le v_j \le 1$, the limit on the bit depth of the vector elements is up to thousandths.

The specific values of the de jure option sufficiency depend on the goals of the state policy in the area under study or the strategic objectives set for the near future. From our point of view, they can be determined by expert assessment method. The role of experts may be taken by civil servants of ministries and departments directly in contact with the problematic "field" of the option in question. The establishment of zero significance is permissible (for example, for links with institutions of a shadow orientation).

Assessment of the quality of institutions and institutional environment

Knowing the matrix of the institutional option of the studied problematic "field" described in accordance with (1), as well as the vectors of two types of sufficiency $V_m = \{v_1;\ v_2; v_3 \dots v_m\}$ and $P_m = \{p_1;\ p_2; p_3 \dots p_m\}$, you can solve the problem of assessing the quality of specific institutions, the option as a whole and the institutional environment of a particular carrier. We propose to consider a measure of quality the degree of the gap between the de facto sufficiency and de jure one of the corresponding level of analysis object - the element institution, option, institutional environment.

To assess the quality of the institution, it is necessary to "switch" the level of analysis from the institutional link to its constituent elements, as the elements of each of the vectors $V_m = \{v_1;\ v_2; v_3 \dots v_m\}$ and $P_m = \{p_1;\ p_2; p_3 \dots p_m\}$ describe the significance of the option link rather than a separate institution. For this purpose we propose to form new matrices $Q_{m\times n}$and $U_{m\times n}$ based on the original matrix of the institutional option $S_{m\times n}$ and the vectors $V_m$and P_m. The first matrix $Q_{m\times n}$ should reflect the demand for the de facto institution. Its elements are determined by the formula (4) for the cases when the absolute number of small firms using the j link is known:

$$q_{ij} = \frac{s_{ij} \cdot w_j}{\sum_j^m s_{ij} \cdot w_j} \tag{4}$$

or (5) - for the cases where the frequencies of links use are known:

$$q_{ij} = \frac{s_{ij} \cdot p_j}{\sum_j^m s_{ij} \cdot p_j} \tag{5}$$

An important addition to the elements definition of the matrix $Q_{m\times n}$ is the restriction on bit depth: the elements q_{ij} must be rounded to the hundredths, so that using the institution in a link of less than 5 cases per 1000 is logically considered to be zero.

The second matrix $U_{m\times n}$ is designed to take into account the de jure sufficiency of the institution. The de jure elements of the matrix $U_{m\times n}$are determined by the formula (6):

$$u_{ij} = \frac{s_{ij} \cdot v_j}{\sum_j^m s_{ij} \cdot v_j} \tag{6}$$

It should be noted that for the formation of the matrix $U_{m\times n}$ it is necessary to comply with the condition of the denominator of formula (6) inequality to zero. This means that when determining de jure demand for institutional links, experts need to use values less than 0.005 for situations of undesirable combinations of institutions.

One of the options for the mathematical assessment of quality, both of a separate institution and of the option as a whole, can be a measure of the gap between the two types of sufficiency described by the de facto $Q_{m\times n}$ and de jure $U_{m\times n}$. matrices. To measure the gap measure, we suggest constructing a new matrix $R_{m\times n}$ according to (7):

$$R_{m\times n} = (r_{ij}), \text{ where } r_{ij} = \begin{cases} \left(1 - \frac{q_{ij}}{u_{ij}}\right), u_{ij} \neq 0; \\ 0,\ u_{ij} = q_{ij} = 0; \\ q_{ij},\ u_{ij} = 0, q_{ij} \neq 0. \end{cases} \tag{7}$$

Based on the obtained gap matrix R, one can calculate the quality coefficient of an individual institution QI_i according to (8):

$$QI_i = \frac{\sum_j^m r_{ij}}{m} \quad (8)$$

As it can be seen from the formula, this coefficient measures the average value of the gap between de jure and de facto demand for a particular institution-element of the option.

To assess the quality of an institutional option, we propose using the QIO coefficient, which shows the average measure of the gap between the sufficiency of the de jure and de facto option according to (9):

$$QIO = \frac{\sum_j^m \sum_i^n r_{ij}}{m \cdot n} \quad (9)$$

Both quality coefficients - QI_i and QIO can take any values in the range from – ∞ to + ∞. Moreover, 0 is a critical value, because it means no gap. The measure of removal from zero is a measure of the gap, respectively, the higher the value of the coefficient to modulo is, the lower the quality of an individual institution or an option as a whole is. We offer the following gradation of the institutional option quality assessments according to the values of both coefficients, which is valid in the model limitations indicated above:

a) from 0 to 1 - high quality, as the gap measure of de jure and de facto is minimal or absent, the existing institutional links are in demand by business according to their significance for the government, the state of “synergy”;

b) from 1 to 3 - satisfactory quality, in particular, typical for the situations when the gap in the option is significant, but the number of such links is less than 30%;

c) from 3 and above - low quality, for example - a significant gap of de jure and de facto, observed in most links and the higher the measure of discrepancy is, the lower the quality of the option is, the state of "destruction".

The problem-oriented paradigm laid in the basis of the assessment approach assumes that the assessment of the institutional environment quality is determined within the framework of a specific problem “field” of a particular environment carrier. Accordingly, this allows you to:

1) compare in time the quality of various institutional options, the composition of which changes over time due to the natural evolution of the institutional environment - the emergence of new institutional technologies for solving problems on the background of the old ones’ withering away;

2) evaluate the quality of the whole set of institutions through the quality of individual institutional options corresponding to the key problems of the research object development - a specific environment carrier.

According to this logic, the quality of the institutional environment of a particular research object can be described mathematically: a) through a vector which elements reflect the quality of institutional options of a finite number M of an environment carrier problems: $QIE_m = \{QIO_1; QIO_2; \dots QIO_m\}$, where QIO is the quality coefficient of the institutional option of the i problem “field” of the M studied according to (9); b) through a change in the QIE vector in time $\overrightarrow{QIE = \{m; t\}}$. Moreover, the quality of the institutional environment is determined by the quality of individual institutional options - the higher the proportion of quality options is (such as “synergy”), the higher the quality of the environment as a whole is. Conversely, with the predominance of destructive options, the institutional environment as a whole should be recognized as low-quality or destructive.

Testing the Institutional Option Model

Consider conditional examples of the links formation from three coherent institutions to explain the method of assessing the quality of individual institutions, institutional options and the institutional environment as a whole.

According to formula (2), the total number of an institutional option links from three coherent institutions is seven options. Assuming that the results of a survey of 1000 small firms on the use of links (w_j) are known, we compiled the vector $p = \{p_1; p_2; p_3 \dots p_m\}$ according to formula (3). As a result, the initial data are the matrix S and the vector P of the following form, to the left of which the numbers of option s_j links are indicated:

	I_1	I_2	I_3	P_j
s_1	1	0	0	0,05
s_2	0	1	0	0,05
s_3	0	0	1	0,30
s_4	1	1	0	0,05
s_5	0	1	1	0,20
s_6	1	0	1	0,15
s_7	1	1	1	0,20

Using formula (5) and taking into account the limitation on bit depth, we obtained the de facto matrix $Q_{m\times n}$:

	I_1	I_2	I_3
s_1	0,11	0,00	0,00
s_2	0,00	0,10	0,00
s_3	0,00	0,00	0,35
s_4	0,11	0,10	0,00
s_5	0,00	0,40	0,24
s_6	0,33	0,00	0,18
s_7	0,44	0,40	0,24

Having assumed the expert assessments condition of being known of the importance of institutional links – the vector $V_m = \{v_1;\ v_2;\ v_3 \dots v_m\}$, using formula (6), we calculate the de jure matrix $U_{m\times n}$ for three different cases.

Variant 1. Weak measure of the gap in the option sufficiency of de jure and de facto. To the right of the matrix $U_{m\times n}$ the conditional values of the vector V_j for this case are shown.

	I_1	I_2	I_3	V_j
s_1	0,20	0,00	0,00	0,10
s_2	0,00	0,13	0,00	0,06
s_3	0,00	0,00	0,30	0,25
s_4	0,02	0,02	0,00	0,01
s_5	0,00	0,38	0,22	0,18
s_6	0,33	0,00	0,20	0,17
s_7	0,45	0,48	0,28	0,23

According to the formula (7), the gap matrix $R_{m\times n}$ is determined:

	I_1	I_2	I_3
s_1	0,43	0,00	0,00
s_2	0,00	0,20	0,00
s_3	0,00	0,00	-0,17
s_4	-4,67	-3,80	0,00
s_5	0,00	-0,07	-0,08
s_6	0,00	0,00	0,14
s_7	0,01	0,17	0,15

Knowing the elements of the gap matrix $R_{m\times n}$, we can determine the quality of individual institutions and the option as a whole, according to formulas (8) and (9):

	I_1	I_2	I_3
QI_i	-0,6027	-0,5002	0,0046
QIO	- 0,37		

In accordance with the assessment scale described above, this case of an institutional option can be recognized as high-quality or synergetic. Moreover, all three institutions-elements are of equally high quality (have values close to zero) with minimal discrepancies of the de jure and de facto demand.

Variant 2. A significant gap in the option sufficiency of de jure and de facto. To the right of the matrix $U_{m\times n}$ the conditional values of the vector V_j for this case are shown.

	I_1	I_2	I_3	V_j
s_1	0,09	0,00	0,00	0,06
s_2	0,00	0,13	0,00	0,06
s_3	0,00	0,00	0,41	0,29
s_4	0,28	0,38	0,00	0,18
s_5	0,00	0,02	0,01	0,01
s_6	0,27	0,00	0,24	0,17
s_7	0,36	0,48	0,33	0,23

According to the formula (7), the gap matrix $R_{m\times n}$ is determined:

	I_1	I_2	I_3
s_1	-0,19	0,00	0,00
s_2	0,00	0,20	0,00
s_3	0,00	0,00	0,15
s_4	0,60	0,73	0,00
s_5	0,00	-18,20	-15,47
s_6	-0,25	0,00	0,27
s_7	-0,24	0,17	0,28

Knowing the elements of the gap matrix $R_{m\times n}$, we can determine the quality of individual institutions and the option as a whole, according to formulas (8) and (9):

	I_1	I_2	I_3
QI_i	-0,07	-17,10	-14,77
QIO	- 1,52		

This variant of an institutional option, as it can be seen, can serve as an example of satisfactory quality, with the smallest gap of de jure and de facto demand, and therefore the institution I_1 possesses the highest quality, the other two have a significant gap in one of the links and can be characterized in general, as institutions of satisfactory quality.

Variant 3. A significant gap in the option sufficiency of de jure and de facto in most links. To the right of the matrix $U_{m\times n}$ the conditional values of the vector V_j for this case are shown.

	I_1	I_2	I_3	V_j
s_1	0,41	0,00	0,00	0,400
s_2	0,00	0,01	0,00	0,004
s_3	0,00	0,00	0,14	0,004
s_4	0,58	0,97	0,00	0,568
s_5	0,00	0,02	0,36	0,010
s_6	0,01	0,00	0,36	0,010
s_7	0,00	0,01	0,14	0,004

According to the formula (7), the gap matrix $R_{m\times n}$ is determined:

	I_1	I_2	I_3
s_1	0,73	0,00	0,00
s_2	0,00	-13,65	0,00
s_3	0,00	0,00	-1,47
s_4	0,81	0,90	0,00
s_5	0,00	-22,44	0,34
s_6	-31,73	0,00	0,51
s_7	-108,11	-57,60	-0,65

Knowing the elements of the gap matrix $R_{m\times n}$, we can determine the quality of individual institutions and the option as a whole, according to formulas (8) and (9):

	I_1	I_2	I_3
QI_i	-138,3	-92,79	-1,27
QIO	- 11,07		

This variant gives an example of a low-quality (destructive) institutional option, as the gap measure is significantly larger than the borderline value - 3. Moreover, as you can see, two of the three institutions can be characterized as low-quality due to a significant gap of de jure and de facto demand.

Results and their Discussion

Let us define some features of the mathematical model for assessing an institutional option:

1) the significance of a particular link directly affects the significance of a particular institution for an option: it will be higher for those institutions of which these links consist;

2) the higher the gap measure, and hence the level of the QIO coefficient to modulo, will be, the higher the average level of excess of values for two de facto and de jure sufficiency assessment vectors is, not only the excess level itself is significant, but also the number of links according to which there is a gap;

3) there may be situations in which options different in strength of the gap and the number of links with the gap will have the same QIO coefficients, which means the same level of quality; in such cases the assessment may be supplemented by expert assessments;

4) the matrix $S_{m\times n}$ changes its quantitative and qualitative composition over time, therefore a systematic assessment of the option in dynamics is necessary.

The scientific value of the mathematical model of an institutional option proposed by the author is as follows.

1) The method provides a quantitative assessment of the quality of institutional support for tasks relevant to any carrier of the institutional environment, which characterizes the model as universal.

2) A quantitative assessment of the quality of a particular option institution allows to isolate the institutions, the adjustment of which is necessary in the first place, as they have a significant impact on the solution of the problem under study. Changing these institutions-elements will improve the quality of the institutional option and the environment as a whole. The method also allows you to identify the so-called "institutional traps", first identified by D. North (1997).

3) The model takes into account the gap between de facto institutions - the real institutional choice of actors and de jure institutions - the value of institutional links for authorities (expected, desired significance). This makes it possible, firstly, to take into account the semantics of the option, and secondly, to determine institutional quality in terms of a synergetic approach: “synergy” - “destruction”.

4) The comparability in time of options that are different in semantics is observed due to the problem-oriented analysis paradigm, when the option is considered as an instrument for solving a specific problem of an environment carrier.

Abstract

Being the most commonly used language, English has impact on almost every field of work. More and more universities value the practicability of English incorporating courses of English for Specific purposes in their educational programmes. The purpose of this paper is to study the efficiency of the Insurance English course delivered at Moscow State Institute of International Relations in order to gain some insights into the possible gaps in the current syllabus which may contribute to future modifications and higher quality of the course. To collect data, the study used an anonymous questionnaire distributed among the alumni and current students doing a Master's degree course in International Insurance and Risk Management. The findings have revealed that most respondents are satisfied with the quality of the course, but they consider it necessary to study more practical materials, which would enable them to practice Insurance English terms in authentic contexts. The results suggest that the course extension will give the teachers more room for maneuver granting an opportunity to choose more specific emphasis and focus on learning pathways tailored to students' needs.

Keywords: Insurance English, ESP, Foreign Languages, Risk Management.

Introduction

In our increasingly globalized and internationalized world, the knowledge of foreign languages has become a crucial competitive advantage when applying for a job and seeking career progression. The status of English as a global language has been firmly established, and English as a foreign or second language is a core aspect of education in the majority of non-English speaking countries. However, as Bracaj (2014) emphasizes, education in general English may often be too general.

Undoubtedly, knowledge of English is determined by the opportunities of its study and the frequency of its application in practice, which is often connected with a profession or field of expertise. Over the years, various industries have demonstrated a growing need for specialists who do not just possess a good command of English, but also have in-depth knowledge of collocations and co-occurrence patterns as well as appropriate terminology, in some studies referred to as phraseological competence (Grabowski, 2015), which allows participating in negotiations, conducting business correspondence and drawing up contracts.

English for Specific Purposes (ESP), as a sub-field of English language education, has evolved to address this concern (Hyland, 2007). Following the Second World War, when English became the international language of technology and commerce, the demand for English courses tailored to specific needs has been on the rise (Hutchinson and Waters, 1987).

ESP is focused on meeting the needs of a group of learners who require English skills related to a specific non-language discipline (Dudley-Evans and St. John, 1998).

Since early 1960s, there have been developed such ESP courses as English for Engineers, English for Aviation, English for Advertising, Legal English, and Medical English to name just a few. The language used by specific professional groups has become of critical importance, with Business English being a recognized area of ESP (Bargiela-Chiappini and Zhang, 2013).

Higher education undergoes continuous transformation in most countries (Tikhonova and Raitskaya, 2018).

In an attempt to study the development of language for specific purposes (LSP) in Russia, Zakharova, Bogdanova and Netesova (2018) have revealed that the concept of LSP is relatively new in this country. Nevertheless, the status of LSP is gradually increasing, with a wider range of universities complementing their syllabus by LSP courses.

Among the leaders in developing and teaching ESP courses in Russia, there is Moscow State Institute of International Relations (MGIMO-University) whose undergraduate and postgraduate degree programmes include ESP. The presence of many large international insurance groups in Russia and the need to purchase additional reinsurance capacities abroad increase the need for insurance specialists who have advanced Insurance English skills. This paper is focused on an innovative module on Insurance English introduced within the compulsory ESP course aimed at students of MGIMO-University doing a Master's degree course in International Insurance and Risk Management.

This course was first introduced in 2013, and since then it has been delivered in 1-2 groups of no more than 9 students during 17 weeks of the spring semester of the first year of a Master's degree course in International Insurance and Risk Management. The course is designed to develop the communicative performance of future insurance professionals in their dealings with clients, other insurers and other contacts in the insurance industry, in an international context. The course is intended to enable students to use standard insurance terminology with appropriateness of linguistic context and style.

The course is based on the textbook "English for Insurance Business" produced by the author of the article and published by MGIMO-University publishing house in 2015. The textbook includes mostly authentic materials published in contexts designed specifically for native-speaker consumption. Such materials have rich cultural and linguistic components that the average native speaker uses (Jernigan, 2017), which increases student's motivation.

The textbook consists of 7 sections, revealing the role, functions and types of insurance:

1. History and basic principles of insurance.
2. Classification of insurance risks.
3. Intermediaries of the insurance market.
4. Types of insurance.
5. Insurance claims.
6. Reinsurance and retrocession.
7. Solvency.

Each section is accompanied by a list of active vocabulary, exercises, and role-play tasks aimed at enhancing the development of professionally significant competencies, including communicative, analytical and socio-cultural competencies.

The methodology underlying the Insurance English course is Content and language integrated learning (CLIL), which is content-based language teaching (Wolff, 2003) referring to "any educational situation in which an additional language and therefore not the most widely used language of the environment is used for the teaching and learning of subjects other than language itself" (Marsh and Langé, 2000).

The term "CLIL" was coined in the 1990s in Europe for programmes that require teaching of non-linguistic subjects through the medium of a foreign language, which implies integrating both content and language in the curriculum (Ruiz de Zarobe, 2017).

Every year, the Insurance English course is updated by means of including mainstream articles, analytical reports and research papers on topical issues in insurance and risk-management.

The research topic under consideration is the field of teaching a foreign language in higher professional institutions.

The aim of this paper is to obtain a retrospective feedback on the Insurance English course delivered at MGIMO-University with the view of revealing the encountered problems and improving teaching effectiveness.
The paper is arranged as follows. The following section describes data and research methodology. The major results are revealed and discussed in section 3 which is then followed by conclusions and suggestions in the final section.

Data and Methodology

The data were collected using an anonymous questionnaire survey conducted during the last week of the spring semester of 2019 with first- and second-year students doing a Master's degree course in International Insurance and Risk Management as well as alumnus. The questionnaire was to be completed on paper or online. In accordance with ethical considerations in collecting research data, confidentiality of the research data was maintained (Seliger and Shohamy, 1989).

The questionnaire included 10 questions which mainly focused on a wide range of aspects of the Insurance English course offered at the University: they enquired whether the contents, length, and the structure of the course met the participants' needs and requirements, whether the skills acquired were used in practice, what skills the participants consider to be lacking and would like to practise to a higher extent.

The first three questions were rather general asking about participant's gender, field of expertise and year of study. The answers are required to see the differences in results for female vs. male respondents; their occupation; current students and alumni. The analysis is conducted by comparing basic statistics: minimum, maximum, median, mean, and standard deviation. The 4-5th questions aimed at figuring out whether there is a need to have an Insurance English course at the end of the BA and MA studies. The 6th question asked to specify what the course is necessary for. The 7th question sought the participant's opinion on the advantages of the course compared with other English courses. The 8-9th questions were focused on revealing whether the course matched students' expectations and was relevant for their further career development. The questionnaire was concluded with the open question asking the respondents to evaluate the course, provide their comments and recommendations for future implications.

In total, 56 respondents took part in the survey. Participants of the present study consisted of 9 first-year students (in the spring semester of 2019 there was just one group as fewer students enrolled in the Master's degree course in International Insurance and Risk Management), 10 second-year students and 37 alumni.

Results and Discussion

The findings of the first three questions are as follows: there are 31 females (55%) and 25 males (45%) among the respondents. The major share of the respondents is alumni (66%), with first- and second-year students accounting for 16% and 18% respectively. As demonstrated by Figure 1, most respondents (71%) are involved in their degree field, i.e. Insurance/Reinsurance (39%) or Risk Management (32%), with a smaller share specializing in Audit (4%), Equity Trading (5%), and Banking and Finance (20%).

Fig. 1: Field of study or work.

Source: compiled by the author on the basis of survey results.

The result of question 4 (*In your opinion, is there a need to have an Insurance English course at the end of the BA studies?*) shows that most participants consider that the course would be useful at the end of their bachelor degree studies, whereas a fifth expressed some doubt answering "perhaps", and 13% of the respondents gave a negative answer.

Compared to this, the results of question 5 (*In your opinion, is there a need to have an Insurance English course at the end of the MA studies?*) are significantly different (Table 1). The majority of the participants believe that MA programme should include Insurance English course, with 14% expressing doubt and only 5% answering negatively.

Table 1: Questions 4-5: In your opinion, is there a need to have an Insurance English course at the end of the BA/MA studies?

Option	Number		Percent	
	BA	MA	BA	MA
Yes	38	45	68%	80%
Perhaps	11	8	20%	14%
No	7	3	13%	5%
Total	**56**	**56**	**100%**	**100%**

Source: compiled by the author on the basis of survey results.

These findings prove that the respondents adhere to the opinion that students doing their master's degree course may have gained work-related experience, participated in in-depth research projects, demonstrate increases in confidence and knowledge of subjects of their field of expertise; therefore, it would be more beneficial to include Insurance English course in the postgraduate programme rather than in the undergraduate programme.

The 6th question (*What is the Insurance English course necessary for?*) provided a list of 8 options (Figure 2). More than 80% of the respondents suppose that the course of Insurance English is of critical importance for reading professional literature (86%) and conducting insurance market research (84%). Almost 70% of the survey participants believe that the course may contribute to getting further education in insurance and risk management (68%) and speaking with confidence in face-to-face and telephone conversations (68%). 64% of the respondents consider the course to be vital for drafting insurance and general documents, followed by 63% of those who think that the course enhances their skills of writing business e-mails. Half of the respondents opted for the advantage of dealing with claims, with just 18% choosing job interviews. The results let us assume that the majority of the survey participants are convinced that the Insurance English course is essential for future studies and career development in insurance and risk management.

Fig. 2: What is the Insurance English course necessary for?

Source: compiled by the author on the basis of survey results.

The result of question 7 (*Compared with other language-related major, what do you think the advantage of Insurance English course is*?) demonstrated in Figure 3 below shows that most respondents (89%) believe that the primary benefit of the course lies in combination of language and business knowledge, whereas 9% hold the opinion that the course has international strategic vision. Only 1 respondent (2%) sees no obvious advantage in the course.

Fig. 3: Compared with other language-related major, what do you think the advantage of Insurance English course is?

Source: compiled by the author on the basis of survey results.

Similarly to question 6, answering question 8 (*Did the course match your expectations?*), the respondents were expected to select one or more than one option from the multiple answer options (Figure 4). 42 survey participants (75%) share the opinion that the course should be prolonged throughout the studies or later. The course completely met the expectations of 23 respondents (41%). More than one third of the participants (34%) expected to practise more insurance and risk management vocabulary. 5 respondents (9%) would like the course to include more interactive materials. Only 1 person (2%) considered the course to be rather complicated, whereas 3 individuals (5%) think it is too easy.

Fig. 4: Did the course match your expectations?

Source: compiled by the author on the basis of survey results.

Question 9 (*Do you think the current teaching materials match with your career development?*) investigates participants' overall satisfaction with the provided materials based on a Likert (Likert, 1932) 5 Scale (Table 2). Most respondents (54%) replied that the course materials fully met their expectations in respect to career advancement, followed by 30% considering that they are significantly satisfied with the teaching resources. 7 respondents (13%) expressed slight dissatisfaction with the materials, while 2 persons (4%) think that the materials barely matched their career development. As demonstrated by basic statistics in Table 2, the survey revealed no respondents who consider that the materials completely mismatched their career progress. The median, which is the number located directly in the center of the data set, is equal to 5. The mean is slightly lower and amounts to 4.34, which shows that the 'average' respondent thinks that the materials completely match his/her career development, which demonstrates high quality of the textbook and extra materials.

In order to reveal how much, on average, each of the values in the distribution deviates from the mean of the distribution, it is necessary to calculate standard deviation. According to the three-sigma rule (Cornejo, 2018), the value of 0.83 means that 68% of the responses are plus or minus 0.83 from the mean. With a small standard deviation which we have, most responses are clustered around the mean.

Table 2: Question 9: Do you think the current teaching materials match with your career development?

Answer Choices	Responses	
	Number	**Percent**
Completely match – 5	30	54%
Significantly match – 4	17	30%
Moderately match – 3	7	13%
Hardly match – 2	2	4%
Completely mismatch – 1	0	0%
	56	**100%**
Basic statistics		
Minimum	2	
Maximum	5	
Median	5	
Mean	4.34	
Standard Deviation	0.83	

Source: compiled by the author on the basis of survey results.

For more in-depth analysis of the questionnaire results, I decided to study the differences in results for respondents of different genders, years of study, and fields of study/work. As evidenced in Table 3, there was no significant difference in responses of their respondents and both their gender and year of study. However, the mean for the first-year students doing a Master's degree course (1MA) is slightly higher than that for the second-year students (2MA) and almost equal to the mean for the alumni, which demonstrates that on average 1MA and alumni have given preference to option "Completely match", while 2MA have ticked "Significantly match". The value of standard deviation highlights that the responses of 2MA were spread more to the extremes of the answer options.

As for the field of study or work, the divergence in the results is more obvious. The mean value is higher for those involved in Insurance/Reinsurance or Risk Management, which is sufficient proof of the fact that on average the course almost completely matches the needs of students working in the field of their studies. Judging by the standard deviation values, the responses were all bunched around

the mean responses with some slightly higher variation for equity trading, banking and finance, and risk management.

Table 3: Question 9: divergence in respect to gender, year of study and field of study/work

Gender	**Basic statistics**				
Female	*Minimum*	*Maximum*	*Median*	*Mean*	*Standard Deviation*
Male	2	5	5	4.29	0.85
	2	5	5	4.40	0.80
Year of study	*Minimum*	*Maximum*	*Median*	*Mean*	*Standard Deviation*
1MA	3	5	5	4.44	0.68
2MA	2	5	4	4.00	1.00
Alumni	2	5	5	4.41	0.79
Field of study or work	*Minimum*	*Maximum*	*Median*	*Mean*	*Standard Deviation*
Audit	3	4	3,5	3,50	0.50
Equity trading	2	4	3,0	3,00	0.82
Banking and Finance	3	5	4,0	3,91	0.79
Insurance/Reinsurance	3	5	5,0	4,68	0.55
Risk Management	2	5	5,0	4,50	0.76

Source: author's estimates.

The final question given in the questionnaire was open (*What would you suggest in order to enhance the efficiency of the course?*). This type of open question was not used any more as its interpretation requires more complex analysis. To improve the course, a large number of students asked to increase an interaction between the course and practical issues by means of adding more real insurance related documents/articles/research brochures and best practices. Almost 70% of the respondents suggest increasing the number of hours for the course, extending it for at least to 2 terms. If these suggestions were followed, teachers would have an opportunity to cover a wider range of types of insurance, provide more detailed feedback on students' questions, and arrange business simulation games so that students could learn more about real business processes.

Conclusion

The conducted research is the first attempt to explore the efficiency of the major ESP course developed and delivered at MGIMO-University within the Master's degree programme in International Insurance and Risk Management. The study complements earlier literature by considering both students and alumni who have gained enough professional experience to be able to provide unbiased evaluation of the course. The survey conducted by means of an anonymous questionnaire has revealed the weaknesses and strengths of the current Insurance English course.

First, it is shown that most respondents consider the course should be included both in their bachelor and master degree studies.

Second, the majority of the survey participants think that the Insurance English course is beneficial for their current and future studies as well as career advancement in the industry of insurance and risk management.

Third, almost 90% of the respondents have replied that the course is advantageous in comparison to other language-related university courses thanks to well-balanced combination of language and business knowledge.

Fourth, according to the questionnaire results, the course absolutely met the expectations of 45% of the respondents, with 75% of the survey participants suggesting extending it for two semesters.

Fifth, it is revealed that 84% of the respondents find the course appropriate to either completely or significantly match with their career development expectations. The additional study on the influence of gender or year of study on the obtained results has found no significant difference, whereas the similar study on the impact of the field of study or work has demonstrated that the course almost completely matches the needs of students working in the field of Insurance and Risk Management rather than audit, equity trading, banking and finance.

Finally, the findings of the research prove that more practical materials and real-life business situations should be incorporated in the course, which will improve the students' acquisition of knowledge of the subject. Such course modifications can be possible and would be more ambitious provided that the course is prolonged up to 2 semesters. This would enable the teacher to facilitate learning process by means of vocabulary extension, role-plays, case studies, and simulations; therefore, give ground to further research.

Diplomatic Academy of the Russian Foreign Ministry, Moscow, Russia, an2495@yandex.ru

Abstract

This paper examines structure and geographical distribution of Venezuela's international trade by means of applying basic and extended gravity models to the country's exports to 35 partners in 2000-2018. Model testing revealed that better performance of the extended gravity model was achieved thanks to higher qualitative characteristics secured by additional variables. GDP, participation in the same integration block, membership in Petrocaribe program, and import of crude oil made positive contribution to bilateral trade. Whereas, distance, access to the open sea, the economic policy of developed countries, and sanctions had negative impact. It is assumed that trade flows were affected by dire economic crisis and western sanctions, which led to a sharp decrease both in exports and imports in 2014-2018. Owing to strong influence of political factors, the models failed to perform effectively. Finally, the study provides some suggestions on measures which could benefit Venezuela's foreign trade given the circumstances.

Keywords: gravity model, bilateral trade, exports, sanctions.

Introduction

Venezuela is a one of the typical monocultural Latin-American countries, developing on the periphery of the global capitalism. Possessing the richest oil reserves in the world, it is highly dependent on oil exports revenues. Crude and its derivatives, which predominate in the trade basket, only enforced their positions in the first two decades of the XXI century, which gives evidence of the progressing "Dutch disease". Apart from oil products, the country supplies the global market with iron ores, concentrates, ferrous products, fertilizers, and fish. Its top imports are basic foodstuffs, medicaments, light crude, and equipment. In 2018, export and import quotas were equal to 19.8% and 7.8% respectively. These figures prove the vital role of external trade for the country's economy, developing on the basis of rent-seeking and export-oriented model. Given these facts, the objective of this study is to investigate external trade policy of Venezuela by applying a trade gravity model.

Since 2003, trade volumes were gradually growing and reached their pick in 2008 (USD 149 billion) when the upward trend was interrupted by the global financial crisis resulting in a slump in oil prices. In 2010, foreign trade turnover rebounded reaching all-time high in 2012 (USD 157 billion). However, due to severe economic crisis and external factors, Venezuela's volumes of foreign trade have been decreasing since 2012. The country experienced a sharp drop in foreign trade in 2014-2018, with exports and imports declining by 57% and 76% respectively (Figure 1).

Fig. 1: Dynamics of Venezuela's Foreign Trade in 2000-2018, USD millions

Source: compiled by the authors on the basis of IMF Direction of Trade Statistics

Trade exchange plays a key role in a small open economy, serving as an instrument for national industrial development and sustainable economic growth (Chen, Yang and Liu, 2008). Since 1960s, the trade gravity model has gained its popularity, and it has been considered as a leading empirical tool implemented to analyze commercial exchange on the international scale (Anderson, 2011). Further studies largely contributed to improving the model's performance, which was mainly achieved by introducing additional exogenous and dummy variables, representing integration blocks (Shi, Gu and Qin, 2005), cultural factors (Kogut and Singh, 1998), exchange rates, and time effects (Stender, 2018), trade facilitation (Batra, Kaufmann and Stone, 2003; Wilson, Man and Otsuki, 2003; Engman, 2005), policy influence on trade (Srivastava and Green, 1986) and others.

In recent years, there has been an increase in the number of studies dedicated to trade potential within integration blocks in Latin America. The majority of them dealt with the Southern Common Market (Mercosur), with Venezuela participating therein in 2012-2017. Ghosh and Yamarick (2004), Moncarz and Vaillant (2010), Urata and Okabe (2014), Martin-Mayoral, Morán Carofilis and Cajas Guijarro (2016) are among the authors who examined tariff eliminations and trade potential of the customs union. As for the studies dedicated to particular Latin-American economies, Cáceres (1995) investigated Panama's membership in Central American economic integration. Chili's trade liberalization effects were considered by Fuenzalida-O'Shee, Valenzuela-Klagges and Corvalán-Quiroz (2018). Ahcar Olmos (2018) studied Colombia's potential to trade with the European Union and found that it could bring mutually beneficial results. This study compliments the previous literature by analyzing Venezuela's foreign trade pattern by means of combining quantitative and qualitative research techniques and approaches.

The structure of the paper is as follows. Section II presents data analysis and explains methodology of the mathematical model. Section III describes and discusses the obtained results; final conclusions are given in Section IV.

Data and Methodology

Trade Statistics Analysis

The study covers the period 2000-2018. The bilateral trade data was taken from the IMF Direction of Trade Statistics (DOTS) (Direction of Trade Statistics, 2019), GDP figures come from the World Economic Outlook Database (2019) and World Bank (Open Data, 2019).

The geographical structure of trade has changed dramatically for the past 20 years. In unfavourable conditions, the country was forced to accelerate diversification of its export destinations. Although the USA has topped the ranking for the whole studied period, their share has significantly decreased from 55% in 2000 to 35% in 2018 (Table 1). The main factor which contributed to this reduction was aggressive politics of the American administration towards its much weaker trade partner. Big businesses from the USA could not resign themselves to the lost access to the lucrative oil sector they controlled before 1999. External pressure started to aggravate since 2014 when the USA imposed economic sanctions on Venezuela. After being toughened, the sanctions currently include a large variety of measures from personal sanctions to temporary embargos, arrest of assets on foreign banks' accounts and prohibition to use the dollar. Meanwhile, trade relations have intensified with China, Russia and India as these economies approve of the current political regime in the country. In early 2000s, China was only the 34th Venezuela's trade partner in exports but in mid-2010s it occupied 2d or 3d position on the list. India increased its share from 4% in 2008 to 20% by the end of the period. As of the end of 2018, the Russian Federation was in top 50.

Table 1: Venezuela's main export partners in 2000, 2008, 2012, 2018, %

	2000		2008		2012		2018	
1	USA	55.1	USA	53.7	USA	44.7	USA	35.1
2	Netherlands	13.5	Netherlands	9.0	China	16.4	India	20.1
3	Brazil	3.9	Cuba	4.6	India	16.2	China	15.2
4	Dominic. Rep.	2.9	India	4.2	Cuba	4.8	Netherlands	8.7
5	Cuba	2.9	China	3.9	Spain	2.5	Cuba	4.5
6	Colombia	2.7	Singapore	2.9	Brazil	2.4	Singapore	3.2
7	Trinidad y Tobago	1.9	Bahamas	2.7	Dominic. Rep.	1.5	UAE	2.3

Source: compiled by the authors on the basis of IMF Direction of Trade Statistics

The commercial exchange with Latin-American countries was on the rise during the first decade owing to economic and social integration development in the region. Being the spearhead of a new stage of cooperation development, Venezuela managed to create Bolivian Alliance for the Peoples of our America (ALBA), a left-wing block based on the principals of solidarity and mutual assistance. Furthermore, during the hike of oil prices, the country supplied poor Central American and the Caribbean countries with fossil fuels with a significant reduction in the cost and even financed their social development programs, but amid Venezuela's crisis these processes have slowed down. The share of interregional trade reduced by 15% amounting to only 10% by the end of the period.

As a sample of the geographical trade pattern, we selected 41 countries among 50 main export partners that accounted for 84% of total exports in 2018. The choice of countries was largely motivated by data availability.

These economies are Antigua and Barbuda, Argentina, Belgium, Belize, Chile, Hong Kong, China, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, France, Germany, Greece, Guatemala, Haiti, India, Italy, Jamaica, Japan, Korea, Malaysia, Mexico, Netherlands, Nicaragua, Nigeria, Panama, Peru, Poland, Portugal, Russia, Singapore, Spain, Saint Lucia, Sweden, Switzerland, Trinidad and Tobago, Turkey, the United Arab Emirates and the USA.

The descriptive statistics are presented in Table 2. Exports, the variable to be explained, appeared to have quite a high level of correlation with GDP (0.77), but it was insignificant with the rest of the variables, which may result in poor performance of the model. No notable correlation of the exogenous factors was detected. The regional structure of the series was as follows: Latin America – 18 countries, Europe – 12, Asia – 9, with North America and Africa being represented by one country each. The obtained data was used to compute a gravity model of external trade.

Table 2: Descriptive statistics

	Exports*	GDP*	Distance**	GDP Venezuela*
Min	0.013001	798	618	83670

Model Specification

The first authors to apply Newton's "Law of Universal Gravitation" to the analysis of trade flows were Tinbergen (1962), Poyhonen (1963) and Linnemann (1966). These early studies were enhanced by Anderson (1979), Helpman and Krugman (1985) who introduced the terms of economy of scale and product differentiation providing strong theoretical grounds for the equations. According to the model, bilateral trade should be characterized by a positive influence of partners' economy size; distance, on the contrary, should be an obstacle in international commercial exchange.

For this panel data study, a basic gravity model in a natural logarithm form was specified by the following equation:

$$\ln(E_{ij}) = \alpha_0 + \beta_1 lnGDP_i + \beta_2 lnGDP_j + \beta_3 lnD_{ij} + \varepsilon_{ij}$$

where E_{ij} is exports of country *i* to country *j*; GDP_i and GDP_j are nominal gross domestic products of counties i and j respectively; D_{ij} is a geographical distance between the capitals of countries i and j; ε_{ij} is a random error; β_1, β_2, β_3 are coefficients.

Traditional log-linear formula of the gravity model is unable to consider zero observations in bilateral trade as the logarithm of zero is undefined. However, our dataset is characterized by zero or missing values. Small economies are expected to have low volumes of trade, especially when trading with remoted partners (Frankel 1997). If zero flows do not occur randomly, disregarding them can result in biased empirical estimation of the coefficients. Omitting zero observations leads to lost information on low flow cases. Santos Silva and Tenreyro (2006) argued traditional specification as well as fixed effects approach are subjects to the presence of biases. To tackle this problem, they suggested that a Pseudo Poisson Maximum Likelihood (PPML) method should be used. PPML estimator has been adopted in various studies and seems to be an extremely strong tool for analysis in models where zero values are frequent (Martin and Pham 2008). As often lost data represents zero or close to zero values and in order to take into account the information from missing observations, we replaced them by zeros in our study. Therefore, Maximum Likelihood function could determine the potential size of bilateral trade.

Anomalies in the time series were revealed with the help of Irving criteria and replaced by the mean of the previous and the next numbers in order to smooth highly volatile trade data.

Fig. 2: Exports' dependence on the distance and GDP size in 2018

Source: authors' estimations

As it is demonstrated in Figure 2, the countries were ranged in accordance with the distance which separates a pair of countries, the size of a bubble is the volume of a country's GDP. The graphical analysis of trade partners' distribution shows that the USA (the biggest bubble) is the most evident market for the country's exports as it overweighs all smaller economies that lie on a considerably short distance. Most exports' destinations are located at a distance of 6,000-10,000 km. However, the second and the third counterparts are rather remoted countries (India and China), with more than 14,000 km separating them from Venezuela.

In reality, not only economic power and cost of transportation determine geographical distribution of a country's trade. Far more factors could have a significant impact, with real GDP, administrative procedures, tariffs and taxes, exchange rate, historical ties, common borders and language, access to the open sea, participation in the same trade union, political and economic barriers being among them. These qualitative variables were considered by Chen, Yang and Liu (2008), Fuenzalida-O'Shee Valenzuela-Klagges and Corvalán-Quiroz (2018), with models also containing diverse time variables.

Venezuela has developed close economic relations with the neighbouring counties, especially those with similar political regimes, and small Caribbean states. Until 2017, it was a member of Mercosur that unites the most developed economies in the continent, but the country was expelled from the customs union due to its internal policy-related reasons. A sharp shift to the right of the Latin-American political landscape since mid-2010s resulted in the deterioration of the countries' relations with Venezuela. However, the most powerful external factors were economic sanctions imposed by the main trade partner and oil prices slump in 2014-2017. Rapid decline in exports in the recent years is also explained by severe economic crisis the country has faced since 2014. It has led to nominal GDP dropping by almost 70% by the end of 2019 as a consequence of a high level of unemployment (34% in 2018), decrease in manufacturing output and problems with electricity supply.

In an attempt to consider the influence of the factors mentioned above dummy variables were added to the basic gravity model. The updated gravity equation is the following:

$$\begin{aligned}\ln(E_{ij}) = {} & \alpha_0 + \beta_1 lnGDP_i + \beta_2 lnGDP_j + \beta_3 lnD_{ij} + \beta_4 Devel_j + \beta_5 Ocean_j + \beta_6 ALBA_j \\ & + \beta_7 Petrocaribe_j + \beta_8 Mercosur_j + \beta_9 Union_j + \beta_{10} Ally_j + \beta_{11} OilImp_j \\ & + \beta_{12} Lang_j + \beta_{13} Crisis_t + \beta_{14} Price_t + \beta_{15} Sanc_t + \varepsilon_{ij}\end{aligned}$$

where E_{ij} is exports of country i to country *j*; GDP_i and GDP_j are nominal gross domestic product of counties i and j respectively; D_{ij} is a geographical distance between the capitals of countries i and j; Develj is true if country *j* is developed; $Ocean_j$ is an access to the open sea; *ALBAj* is true if country *j*

is a member of the ALBA alliance; $Petrocaribe_j$ is true if country j is a member of the Petrocaribe program; $Mercosur_j$ is true if country j is a member of Mercosur; $Union_j$ is true if country j is a member of any integration block where country i participates; $Ally_j$ is true if country j supports country i on the international stage; $OilImp_j$ is true if country j imports crude; $Lang_j$ is true if the spoken languages coincide in countries j and i; $Crisis_t$ is a time variable that represents years 2002-2003, 2009, 2014-2018 (the GDP of country i drops); $Price_t$ is a time variable that accounts for years 2008, 2015-2017 (a slope in oil prices or much lower prices than in previous several years); $Sanc_t$ is a time variable representing 2014-2018 when sanctions against country i were in force; ε_{ij} is a random error; β_1, β_2, β_3 are coefficients.

The variables GDP_i, GDP_j, $Ocean_i$, $ALBA_i$, $Petrocaribe_i$, $Mercosur_i$, $Union_i$, $Ally_i$, $OilImp_i$ and $Lang_j$ are expected to have positive signs, whereas D_{ij}, $Crisis_t$, $Price_t$ and $Sanc_t$ are expected to have a negative impact.

Results and Discussion

Statistics data processing program R was used to compute the coefficients. Table 3 presents the obtained results of equations (1) and (2). The goodness of fit of the basic model appeared to be rather high with an adjusted R^2 of 0.632. All the variables are highly significant. The Durbin-Watson test (Durbin and Watson, 1950) showed no evidence of autocorrelation. The results of Breusch-Pagan test (Breusch and Pagan, 1979) proved heteroscedasticity of the time series. The signs of equation coefficients are the same as expected. However, the model failed to accurately describe the external trade of Venezuela.

Table 3: Correlation matrix

	Exports	GDP	Distance	GDP Venezuela
Exports	1			
GDP	0.77	1		
Distance	0.00	0.10	1	
GDP Venezuela	0.10	0.00	0.00	1

Fig. 3: Graphic Interpretation of Data and Correlation Matrix

Source: authors' estimations

To illustrate the quality of the basic model before applying the Maximum Likelihood function to the data set, we have built Figure 3. The graph on the right-hand side is a correlation matrix that highlights the lack of correlation between the explanatory variable Exports and two exogenous parameters: Distance and GDP of Venezuela. If there is no strong correlation between them, the model will not be able to fit the variation of the time series. The top-right part of the graph on the left-hand side shows to what level the correlation is significant. As we can see, if zero and missing observations were not considered, the model would fail to describe the dynamics of Venezuela's foreign trade. The lower left-hand corner of the graph represents graphical interpretation of mutual dependence in pairs of variables. At least one structural breakthrough was visible in the first column. Therefore, introduction of dummy variables could make the model more well-balanced so that it could better account for the data set behaviour over the defined period of time.

Table 4: Regression results for a basic gravity model and an extended one

	Model 1	Model 2
(Intercept)	-2.2700	5.7201***
GDP	0.8052***	2.1062***

CELAC		-3.8273***
OilImp		1.5640***
Sanc		-0.6097***

Source: authors' estimations

The extended model reported advanced results (Table 4). All the variables included in the final equation were of high significance level. Homoscedasticity and autocorrelation were rejected. However, not all the signs of the coefficients met the expectations. The variables $Devel_j$, $Ally_j$, $Union_j$ and $CELAC_j$ had negative effect. The $Union_j$ and $CELAC_j$ variables were introduced to our model in order to take into account privileged trade within integration blocks. The negative coefficient which was obtained could be explained by the fact that Venezuela's exports destinations mainly depend on oil demand from these countries, and lower barriers in trade hardly can change the situation. The variable $Ally_j$ is an example of the same case. For decades, the USA were the key trade partner of Venezuela despite political and even economic tensions between the two countries. Meanwhile, $ALBA_j$ had a strong positive impact due to the fact that during the period of high oil prices Venezuela suppled the members of the union with cheap crude in exchange for agricultural products as the country has unfavourable natural conditions for developing such economic activities.

We supposed that developed countries consume more oil and as a consequence they are likely to be interested in the country's exports. However, throughout the studied period among top 10 trade partners there were mostly representatives of the developing world, which corresponds with the country's government policy targeted at strengthening 'South-South cooperation'. Another important fact to be mentioned in this regard is that China is considered to be a developing economy. Meanwhile, the variable, that represented the importers of crude, had a very strong positive influence on Venezuela's exports. The sanctions limited the number of the country's exports destinations and led to degradation of traditional trade ties. The variables $Mercosur_j$, $Petroj$, $Crisis_t$, $Price_t$, proved to be insignificant.

When measuring the fit of the logistic regression, different approaches to calculate R^2 can be used and there is no consensus on the best option. Following suggestions on the matter proposed in Allison (2014), in our study we chose McFadden R^2 to estimate the predictive power of the model (McFadden

1974). The basic model appeared to have a lower level of the coefficient (0.632) in comparison with the extended equation (0.828), which makes us prefer the second one.

The improved performance of the model was obtained by means of adding dummy and time variables. The larger number of the variables in the equation is bound to increase R^2, but at the same time they often make a model more complex. Therefore, the aim is to achieve a balance between the model fit and its complexity as stated in Babri, Joernste and Viertel (2017). Other commonly used measures of a model quality were implemented in this study to compare the basic and extended models as demonstrated in Table 5.

Table 5: Quality comparison of models

	Model 1	**Model 2**
Alderich- Nelson R-squared	0.724	0.790
McFadden R-squared	0.632	0.828
Cox-Snell R-squared	0.943	0.977
Nagelkerke R-squared	0.953	0.987
p	0.000	0.000
Likelihood-ratio	2234.725	2925.452
Deviance	1299.006	608.278

Source: authors' estimations

As the deviance of the second model was lower, this model should be chosen. The likelihood ratio also proved better performance of the extended equation. Extra dummy and time variables contributed to better quality of our model. The measures taken managed to increase the quality of the model and helped to obtain a trust worthy estimation. These results are explained by a range of external and internal factors.

Traditionally, economic relations between the United States and Venezuela were characterized by intense trade in goods that goes in line with the gravity model theory. Nevertheless, in 2010s its share was plummeting owing to the trade war campaign the US waged against the current political regime in the country. The variable representing sanctions reflected the changes. Dire political, social and economic crisis almost stopped shipments of subsidized oil to the regional partners and hampered integration promotion in Latin America. Although leading economies in the continent could develop mutually beneficial commercial ties, there are some obstacles to the process. The representatives of Brazil's establishment are well-known for their hostility to Venezuela's president Nicolas Maduro. The confrontation intensified so greatly that a neighboring country planned a military invasion at the beginning of 2019. Argentina's leaders also expressed their support for the opposition. To a great extent, this situation resulted in Venezuela's strengthening commercial relations with remoted China, India and Russia. Russia not only became one of the main destinations of the country's oil exports in 2019 but also provided Venezuela with highly necessary humanitarian assistance, supplied with wheat and medicaments, which allows us to predict further growth in bilateral trade. Given the circumstances, the gravity model may need further adjustments to forecast changes in Venezuelan exports' geographical distribution.

Conclusions

In this study, we used panel data, representing Venezuela's exports dynamics in 2000-2018, to estimate the coefficients of the country's bilateral trade gravity model via Pseudo Poisson Maximum Likelihood function. First, we applied a basic equation. All parameters were significant and the model demonstrated a rather good performance. Then considering severe economic crisis and western sanctions, we extended our model so that it included such parameters as participation in the same integration block, membership in Petrocaribe program, access to the open sea, level of a country's development, oil import and the influence of economic sanctions imposed in 2014. To compare the two equations, R^2, deviance and likelihood ratio were used. We revealed that the extended model was

characterized by improved quality. The second model proved to be an effective tool for description of Venezuela's export flows with R^2 equal to 0.828.

Overall, the findings of the paper provided evidence that economic crisis distorted the geographical structure of the country's exports. As a result, complicated political issues that strongly effected trade dynamics required introduction of dummy variables to reflect the real state of affairs. In the study, we tried to handle limitations to the gravity model caused by the impact of non-economic factors that are highly difficult to predict and estimate. More profound analysis of the findings may give ground to further research.

Meanwhile, the country struggles with a range of serious problems: 1) downward trend of exports and imports due to external economic pressure and a plunge in manufacturing output and crude extraction; 2) deterioration of exports structure with increasing share of commodities; 3) heavy dependence on the conjuncture of the global crude market, which is highly volatile; 4) strong reliance on commercial exchange with the USA; 5) a small share of trade with regional partners.

In order to alleviate these negative factors, Venezuela needs to accelerate the pace of imports substitution, mainly in foods and essential goods, so that it could achieve at least pre-crisis volumes of production. By doing so, the country could enhance its national security. Export diversification would enable it to offer manufactured products with a higher value-added cost. At the same time, freed up foreign exchange resources could be used for purchasing foreign technology being an integral part of industrial modernization which is impossible without higher investment in fixed capital. These measures could reduce dependence on crude prices and oil revenues, make trade benefits more predictable and stabilize external trade dynamics. Economic sanctions are still a very powerful negative factor, contributing to the worsening distribution of trade flows from the theoretical perspective. Venezuela is currently unable to influence the situation, it is only capable of adapting. Nevertheless, the political initiative of the country's government could play a vital role in the relations with intraregional trade partners. To improve the situation, the country needs to revive its industrial output potential and to mitigate the consequences of the devastating economic crisis. Stronger cooperation with Latin-American countries and such big economies as China and India could harmonize Venezuela's external trade and bring it into closer conformity with the traditional gravity theory of trade.

Seemingly Acceptance of Data Processing Agreement In the Context of Regulations Regarding Their Security - Outline of The Problem

DR. Monika SZYLKOWSKA

Faculty of Security, Logistics and Management, Military University of Technology in Warsaw
ul. gen.S.Kaliskiego 2, 01-242 Warsaw, Poland
monika.szylkowska@wat.edu.pl

Abstract

This article covers reflection in the area of protection and data security and processing - in particular with regard to new related regulations with their protection. The main purpose of the considerations is to indicate the threat of "apparent consent" to the processing of data due to the mechanism in which only the prior agreement allows the use of services (e.g. installation of applications / software). Selected services and provisions of regulation Directive (EU) 2016/679 of the European Parliament and of the Council of 27 April 2016 on the protection of natural persons with regard to the processing of personal data by competent authorities for the purposes of the prevention, investigation, detection or prosecution of criminal offences or the execution of criminal penalties, and on the free movement of such data, and repealing Council Framework Decision 2008/977/JHA. In the research process, was made extensive use of qualitative research methods, including in the form of analyses (e.g.: legal and institutional analysis, comparative analysis, system analysis and methods: analysis and logical construction), generalization and implication. The empirical stage of the research also consisted in the assessment of the legal status. The cognitive and utilitarian premises of the problems are the implementation of the adopted hypothesis: existing solutions have been shaped in a way that provides protection only in the processing of *ex post* information, because only materialization of threats even in the form of incidents related to their processing is able to verify the level of security in this respect.

Keywords: Security, Data Protection, Data Processing

Introduction - services

The objective to the deliberations covered by the subject are not only the more frequent events (incidents) related to the transfer and use of user data without their consent and knowledge, or illegal processing of these data, but in particular the implication of these events in the form of a Regulation of the European Parliament and Council (EU) 2016/679 of April 27, 2016 on *the protection of individuals with regard to the processing of personal data and on the free flow of such data and the repeal of the Directive 95/46/EC (general regulation on data protection).*

The analysis of the issue of data transmission is worth starting with the initial comments related primarily to the type of network services (e-services) that the user can use.

The following service groups can be accepted as the general classification:

- searching for information (e.g. websites),
- direct communication – active (Internet communicators),
- indirect communication – passive (discussion groups, forums, lists),
- transfer, exchange or downloading of files,
- digital mass media,

- e-services (banking, shopping, etc.),
- strictly entertainment (e.g. online games),
- processing in the *cloud* [1].

Currently, a special type of network services are those referred to as: *SaaS* (*software as a service*), constituting one of the so-called computational cloud models. Their essence is to offer certain services (programs/applications) by the service provide, run on user devices as pointed out Szyłkowska and Kaczmarek (2017) via a web browser, which eliminates the need to install separate software (e.g. Google application package) in order to use their full functionality. The unquestionable convenience in using such services, however, brings a certain risk: as Richard M. Stallman explicitly stated: *we have no control, we deprive ourselves of freedom using the service on the web. And both in the scope of data entrusted to service providers, but also this freedom provided to the users by the truly free software* [1]. In addition to the lack of control over the data, the functional scope and the way the users use the shared software depend on the service provider.

Lack of control

The issue of control and its lack on the data not only concerns services processed in the *cloud,* but all types of services and applications – in particular, installed on mobile devices, e.g. mobile phones. It is worth paying attention to the latter here. The operating system installed in devices of this type to "provide" the functionality of some (or most) applications, *widgets* (graphic link that, when launched /clicked by the user, provides the assigned functionalities) and services requires providing data – including an e-mail address. The fact whether these data will be partial or fictious is not important, because each device has its own individual number, e.g. IMEI for mobile phones, which after installing the SIM card, enables unambiguous identification of the person using it, taking into account the requirement of registering each type of SIM card. However, when you start using the device, you must first go through the installation process and related declarations (consent). The first one is the software licence agreement attached to the device – consent to its registration is a prerequisite for further processing.

The next stage is the possibility of consenting to sending the device diagnostic data to the manufacturer, e.g. in the form of data from the error log (optional). The next part is giving your name and surname, which allows you to "personalize some applications on your phone" and configure your e-mail account. In this case, the user usually has only three options to choose from: provide a private address, provide a business address or add a postal address later, but already in the dedicated application (e.g. Gmail). The next stage concerns related services, including the location that the user can turn on or off at any time. It is worth noting that if you select the location option – your data will be "anonymously" sent to the service provider. In this set of services, there is also the possibility of allowing applications and services to look for wireless signals even when they are turned off (sic!). However, in the case of consent to the automatic sending of diagnostic data and regarding the use of the device and application – the user allows full profiling of his/her behaviour, despite the manufacturer's assurance of *anonymization* (however, there is no information about the mechanisms of such action). In the last stage, the user is provided with "general information" and the possibility of using the information collected by the manufacturer's partners, but again there are no precise markings, out of which information and to what extent it takes place.

In addition, the manufacturer reserves that the disabling of the indicated function "does not affect the ability of the device to send information needed for the operation of important services, such as operating system updates or security".

In practice, the lack of accurate records means that the manufacturer can freely recognize and assess information as "important" or "crucial" that the device can send. In conclusion of the indicated principles and the mechanism described, it should be stated that the user has absolutely no control over his device. He is also not able to determine at what moment and which data is transmitted by the device he owns and uses. Thus, he only seemingly expresses his *consents* at individual stages of the process, because in their absence – he will not be able to use the device.

Liability for the software

Currently there are no legal solutions in the indicated scope – in particular those related to software responsibility – and *de facto* for its "hidden functionalities" or – installation procedures described above, depriving the end user of knowledge and the ability to disable individual functions. The existing regulations now apply only to the area of copyright and legal protection of software, including in the Council Directive of May 14, 1991 on the *legal protection of computer programs (91/250/EEC)*. Even the recognition of software as a commercial product (digital) and the related manufacturer responsibility are subject – in accordance with the regulations – to the significant restrictions raised by the Council Directive of July 25, 1985 *on the approximation of the laws, regulations and administrative provisions of the Member States concerning the responsibility for defective products* (85/374/EEC). The indicated provisions leave no doubt as to the burden of proof on the user, because in the event of any damage – the aggrieved party must prove its loss, the product defect and the causal link between the defect and the damage. As a rule, it is assumed that the aggrieved party is not burdened by the obligation to show "dangerous features of the product or its defects, i.e. the causes resulting from the dangerous product, which normally resulted in damage". However, the logical consequence is *de facto* the lack of possibilities for the use to identify the undesired sending of information, since he has no knowledge in this respect provided by the manufacturer. This should include both the potential danger and the "dangerous property" of the product. In the case of "digital" devices with a multitude of types of installed software – identifying the one that caused the damage in practice could prove not only extremely difficult for the average user, but in fact – virtually impossible. Nevertheless, the provision of art. 8 par. 2 of the Council Directive of July 25, 1985 (85/374/EEC) quoted allows to limit or exclude the manufacturer's liability: *if, taking into account all circumstances, the damage is caused by both a defect in the product and the fault of the injured person or other person for whom the injured person is responsible.* However, apart from the issue of product liability, the challenge and urgent necessity for legislators, both at the European Union and national level, should be to define the requirements for precisely informing the user about data transmitted from his/her device without his/her knowledge – or legal prohibition of such practices by manufacturers. This fact will be confirmed by the following essential considerations, covered by the regulations on data processing – introduced by the Regulation of the European Parliament and of the Council (EU) 2016/679 of April 27, 2016 on the *protection of individuals with regard to data processing on the free flow of such data and the repeal of Directive 95/46/EC (general data protection regulation).* It is not difficult to notice that the consents granted by the user in the software installation process will fit in and thus be subject to these provisions. In turn, point 7. emphasizes that: *Individuals should have control over their own personal data. Individuals, business entities and public authorities should gain a greater sense of legal certainty and its application in practice,* which is directly related – in accordance with the regulations indicated – to the need not only to strengthen and clarify the rights of data subject, but also – or most of all – obligations of entities processing such data, including provisions related to liability in this respect. In accordance with Article 4: personal data is information about an identified or identifiable natural person. This type of data is information that allows you to identify a person either directly or indirectly. These include:

a.) all information on *identified or identifiable natural persons*,
b.) pseudonymised personal data that can be attributed to a natural person using additional information.

In particular, the identification will concern identifiers, such as: *name and surname, identification number, location data, Internet identifier or one or more specific factors determining the physical, physiological, genetic, psychological, economic, cultural or social identity of a natural person.* In turn, indirect identification takes into account the justified probability of its performance. In this case, the provisions require that any objective factors, such as the costs and time needed for identification, and the available technology. Taking into account the above, it should be assumed that there is a probability bordering with certainty that each user of the software can be identified by the manufacturer of the device, and the lack of precise information contained in the use agreement only confirms the presumption. In the same article, *processing* was defined as automated or non-automated operations or their set *performed on personal data or sets of personal data.* According to the rules included in Regulation of the European Parliament and Council (EU) 2016/679 of April 27 these activities include: *collecting, saving, organizing, ordering, storing, adapting or modifying, downloading, browsing, using, disclosing by sending, distributing or otherwise sharing, matching or combining, limiting, deleting or destroying.*

Returning to the issue of a *declaration of will* in the form of consent it should be pointed out that the provisions in question require the necessity of consenting to the processing of data in the form of an unambiguous confirmation action. The user's behaviour is of key importance, which will unequivocally indicate his acceptance of the data processing and this consent should apply to all processing activities (processing purpose). At the same time, the legislator emphasized that both: *silence, default windows or no action should not mean consent.* And moreover in Point (32): an electronic request for consent should be: *clear, concise and not unnecessarily interfere with the use of the service it concerns.*

Anonymous Information

Another point of the regulation indicates that the adopted protection principles should not apply to anonymous information, i.e. those that *do not involve the possibility of direct or indirect identification of a natural person or personal data that are anonymised in such a way that the persons to whom the data relates, s/he cannot be identified at all or cannot be identified anymore.* However, the greatest danger lies in the sentence stating that the protection rules do not concern the *processing of anonymous information, including processing for statistical or scientific purposes.* It is not difficult to predict that the consequence of such accepted provisions may be the updating of licence agreements, which emphasize not only the fact of full anonymisation, but also the indication of purposes: *scientific and statistical.* The procedure of installing software enabling the use of mobile devices, during which an individual identifier of the device can be clearly identified. Due to the lack of possibility to determine which information is sent when you start using a device – it is difficult to state clearly that such data are not transferred and at what point they are subject to anonymisation.

Conclusions

Concluding the considerations outlined in the subject, it should be stated that despite progress in the area of data processing protection – there is still a very high risk of apparent acceptance by users. This means that existing solutions have been shaped in a way that provides protection only in the processing of *ex post* information, because only materialization of threats even in the form of incidents related to their processing is able to verify the level of security in this respect. An additional effect may be the profiling effect even before the data is anonymised, which no user is able to state at the initial stage of the process. At the technical level, in turn – in particular in the field of software – the problem of the liability of suppliers/service providers/manufacturers still remains. This leads to the conclusion that the identified regulatory gap is similar to the gaps in programs that have "vulnerabilities" that allow their

use, resulting in potential user exposure to damage. In the case of software, the only effective tools is its update. The same type of action should be taken in the case of legal regulations – updating through amendment.

Exploring the Antecedents of Employee Engagement Strategies on Migration Intention of Health Workers in Nigeria: A Conceptual Approach

OJEBOLA, O. O., ADENIJI, A. A., OSIBANJO, A. O., FALOLA O. H., SALAU, O. P & ADEOYE, F. Loveth

[1-5] Department of Business Management, Covenant University, Ota, Ogun State, Nigeria

Abstract

Health care worker's migration to other countries has both short and long-term effect on the adequate health care delivery of the affected countries. Several contemporary issues are confronting Nigeria health sector like work overload, inadequate training and the high rate of migration intention of Nigeria health workers to developed western nations. Recently, it has been acknowledged that the sector is experiencing a shortage of medical doctors, nurses and midwives. The non-availability of adequate health workforce in any country will undoubtedly lead to negative health outcomes as adequate and qualitative health workforce is *sine qua non* to a qualitative healthcare delivery. Extant studies in this context mostly analysed factors accountable for the low level of qualitative health care delivery in Nigeria but limited studies proffered mitigating factors in addressing it in human resource context. This study through the review of extant studies identified the antecedents of employee engagement as a strategy that can propitiate Nigeria health workers to have good behavioural dispositions. To this end, this review looks at the relationship between employee engagement and migration intention of health workers. At the end of the review, a model was developed that can be empirically investigated to determine the extent at which the antecedents of employee engagement influences migration intention of health workers in Nigeria.

Keywords: Employee Engagement, Behavioural Dispositions, Migration, Qualitative Health Care Delivery

Introduction

Recent researchers in Nigeria health context observed that the sector has been characterized by instability, unproductivity and inadequate manpower (Court, Emmanuel, Ann & Nwadukwe, 2018; Oleribe, Udofia, Oladipo, Ishola & Robinson, 2018). The high dearth of health workers in Nigeria is caused by poor remuneration, poor working environment, job related stress and lack of career growth (Butawa, asule, Omole, Yere, Dogo and Gyuro, 2013). For instance, Vanguard (2019) assert that the inadequacy of health workers in Nigeria is so alarming as one doctor is to a population of 5000 Nigerians which is against one doctor to 600 people as suggested by World Health Organisation (WHO).

In a related perspective, Uneke, Ogbonna, Ezeoha, Oyibo, Onwe, & Ngwu (2007) observed that the Nigeria's health sector is in a deplorable condition due to dearth of trained medical workers. Moreso, Nigeria according to Uneke et al (2007) is known to be one a major health-worker exporting nation in Africa due to insufficient health amenities and pitiable compensation packages which makes a sizeable number of health workers migrate to advanced nations in search of sustaining and worthwhile jobs. Oleribe et al, (2018) assert that the consequences of inadequate health workforce cannot be over emphasized as it would negatively impact the health status in the society in terms of ineffectual tackling of infectious endemics, emergence of non-communicable diseases (NCDs), increase maternal mortality and non-achievement of Millennium Development Goals (MDGs) as corroborated by Adebayo, Labiran, Emerenini & Omoruyi (2016). In addition, Adebayo et al, (2016) assert that out of forty-nine nations identified by WHO to be having insufficient healthcare workers, Nigeria is in sixth position.

This challenge of dearth of health workers might also add to the present high infant mortality rate in Nigeria (Adetoro & Amoo, 2014). It is opined that the strength of any country is dependent on the reasonable degree on its efficiency, which is reliant on the welfare of the population (Misua, Al-Sadat & Gerel, 2010). This implies that the well-being of the citizens of a nation is sine qua non to national productivity.

On a broader perspective, the Nigerian public sector is bedeviled with low productivity because of socio-economic management and technological factors (Oshilim & Akpesiri, 2015). However, for this study, emphasis will be on the management factor as scholars believe that the failure or success of any organization hinges to a large extent on the management (Alkhazali & Halim, 2015; Henntschel, Muehlheusser & Sliwka, 2014). Several authors on Nigeria health sector have explored how the sector can be revived through the economic, sociological and technological approach, but limited research has been done on the management approach specifically through the engagement of the health workforce (Osain, 2011; Eme, 2014; Omoleke & Taleat, 2017; Eme, Uche & Uche, 2014).

To this end, the importance of this research work emerges from its objectives which are to:

a) identify the factors responsible for the consistent increase of Nigeria health worker's migration intention to other nations
b) explore the influence of employee engagement on Nigeria health worker's migration intention
c) ascertain the precursors of employee engagement and its strategies
d) Access the theoretical underpinnings of employee engagement and the managerial strategic approach to curb health worker's migration.

Literature Review

Workers Migration

Health worker's migration is the movement of health workers from inadequate income level countries to higher income level countries (Adeloye, David, Olaogun, Auta, Adesokan, Gadanya, Opele, Owagbemi & Iseolorunkanmi, 2017; Misua, *et al,*2010; Ogbuabor, *et al;* 2016; Adeloye *et* al; 2017).

Causes of Nigeria Health Worker's Migration

Misua, et al, (2010) posit that migration of health workforce can also be referred to as brain drain which is the movement of health worker's in quest of an improved standard of living and life value, better earnings, access to innovative know-how and more secured socio-economic environment globally. The rate at which Nigeria health workers migrate to other countries which is an aspect of global mobility is so alarming as over 35,000 doctors out of the 72,000 registered are practicing abroad (Vanguard, 2017). The movement of Nigeria health workers to other countries are occasioned by several factors which are hindering efficient healthcare delivery. It has been observed that the inadequacy of human resources in Nigeria health sector is significantly responsible for the poor population health in the country (Salami, Dada and Adelakun, 2016; International Organisation for Migration, 2014).

WHO (2014) and Stilwell, Diallo, Zurn, Vujicic, Adams & Poz (2004) observed that the movement of health workers around the world is motivated by migrants seeking better working conditions in other countries. The decision of health worker's migration is based on personal circumstances coupled with economic and social circumstances as well as state interventions. (Stilwell et al, 2004). Economic issues in this context underscores good wages and working conditions, social context emphasizes issues like social unrest and deprivations while state interventions like placement of international vacancies, flexible issuance of visas and work permits to intending migrants have a significant influence on health worker's intention to migrate (Stilwell, et al, 2004).

In addition, Medic West Africa (2019) posit that a good number of health workforce are faced with several backlogs of salaries, pitiable welfare, inadequate health facilities and work overload. Moreso, the main factors responsible for human resources inadequacy in Nigeria according to Eriki, Oyo-Ita, Odebo, Udoh, Omaswa & Kadama, (2015) include inadequate personnel planning and management

practices, long working hours, unsafe workplaces, inadequate compensation, and limited access to professional development opportunities. Also, Uneka, et al (2007) posit that Nigeria Health workers earn meager salaries, work in unsafe areas, have substantial workloads and lack the most basic health facilities to work and low prospect for career advancement. Nevertheless, Bello, Ajayi & Asuzu (2015) observed that organisational factors like authoritarian leadership style, lack of goal and role clarity as well as poor remuneration constitute push factors that motivate health workers migrate to developed nations. It also being observed that health workers experience low pay, irregular promotion, abusive supervision, unfriendly job attributes and stress on the job which influence their intention to migrate (Ogbuabor, Okoronkwo, Uzochukwu & Onwujekwe, 2016).

Influence of Employee Engagement on Migration Intention

Ibidunni, Osibanjo, Adeniji, Salau & Falola (2016) assert that success of any firm is reliant on workers' role and commitment which can be fostered through employee engagement. The importance of employee engagement cannot be over emphasized as organisational success depends on employee's productivity which is fostered through employee's commitment and involvement towards his/her organisation (Pratima & Bhagirathi, 2016). Employee engagement is an inevitable managerial tool that management uses to foster productivity, performance and retention as engagement ensures an exploratory state that enables organisation members to involve deeply on their individual selves in role performances (Lailah, Christo & Christoff, 2014).

Organisations today have come to realise that not all personnel are devoted and productive but engaged workers who are mentally and emotionally attached to the organisation, are obligated to achieve its objectives and dedicated towards its values like going extra mile beyond their basic work obligation (Bhavani, Sharavan & Arpitha, 2015). Falola, Oludayo, Igbinoba, Salau & Borishade (2018) opine that engagement entails passion and the disposition of an employee to invest own self and extend his extra effort to assist his organisation accomplish its goals, which is beyond ordinary satisfaction with the employment contract. Thus, employee engagement is the level of commitment and participation a worker invests towards their organisation and its success (Syed, Hussain, Abdul, Zamir & Ali, 2019). The survival of an organisation is dependent on how leaders of firm work hard to engage workers because the sustainability of any organisation is dependent on its workforce (Schrita & Mohamad, 2017).

Engaging employees is now an emerging organisational concept and it has been recognised as one of the major primacies of human resource administrators in any work environment (Bhatla, 2011). The term employee engagement refers to the level of loyalty and engrossment of the employees in an effort to achieve organizational goals. Shuck & Reio (2014) further viewed employee engagement as a holistic motivational theory reflecting the concurrent investment of an individual's behavioural, rational, and emotive energy in productive performance. Thakur (2014) further emphasised the advantage of organisations engaging their employees has it can significantly affect worker retention, efficiency, and dependability as well as positively impact organisation repute and overall stakeholder assessment.

According to Nada & Singh (2016) employee engagement is defined as an employees' sagacity of persistence and intensive vigor that involves the display of personal ingenuity, flexibility, energy, and diligence directed toward the realisation of organization's goals. More so, employee engagement can be described as a discrete and distinctive concept that involves intellectual, emotive, and behavioural components related with individual role performance (Marcus & Namitha, 2017). Passanan, Waiphot, Kwanta, Thaywuse and Patipol (2018) also referred to employee engagement as the extra resources like time, brainpower, and energy employees invest in their work that result in discretionary effort. Shuck and Reio (2014) further term employee engagement as the mental, passionate, and developmental energy an employee display toward positive organisational outcomes. In addition, Wang & Tseng (2019) posit employee engagement the psychosomatic state where workers have a vested concern in the organization's success and achieve to a high level that may exceed the specified requirements of the job. Nevertheless, Deepika & Sampurna (2018) added that employee engagement is the substantial degree of passionate and logical link that an employee has for his/her work, organization, colleagues and superiors which empowers him/her to put in additional extra effort to

his/her work. Additional known outcomes of employee engagement according to Falola, et al (2018) include low workforce turnover, enhanced employee productivity, improved support of the organization, positive influences on health and welfare, increased self-efficiency and receptiveness to innovative dynamism.

It is imperative for hospitals management and administrators to know how to drive employees towards being engaged in their work. It has been observed that health managers are deficient in the motivation and management of health workers, (Adeloye, et al, 2017). This suggest that hospitals or health facilities managers should go for human resources management trainings. How can health workers be engaged and committed? How can they be retained in the health sector? How can be motivated to go the extra mile beyond their employer expectations? This questions if addressed can mitigate the challenge of Nigeria health worker's migration to other countries.

Drivers and Strategies of Employee Engagement

Omer, Qaisar, Talat, Khalil & Aamer (2011) assert that when managers appropriately utilize employee engagement strategies like profession prospects, organisational support, investment on employees, employees' involvement in decision making, recognition and reward, fair treatment and equality and transformational leadership style, employees will be enthused to his organisation. Dorothea (2013) also posit that employee engagement motivations are driven both financially and non-financially as workers are not inspired by money alone as corroborated by Safaa (2018) that employees can be motivated to be engaged intrinsically and extrinsically.

Organisation Reputation

Nigeria health sector is currently challenge with issues that are detrimental to the sector image before its stakeholders, (Adeloye, et al, 2017). Extant studies on employee engagement and corporate reputation shows that both constructs are cyclically linked as one can potentially influence the other. Employee behaviour can drive corporate reputation according to (Friedman, 2009; Helm, 2011 & John, Ogunnaike & Osibanjo, 2014) and also corporate reputation influences how employees behave and perform as posited by (Davies, Chun, Da Silva & Roper, 2004; Helm, 2011). However, in this context, we are concerned with how organisation reputation can motivate employee engagement.

One of the leading researchers on company reputation Fombrun (1996) defined it as a constant depiction of an organisation previous activities and upcoming prospects that describes the firm's whole appeal to all of its main stakeholders when compared with other organisations. This implies that reputation is a replication or an appraisal observed by stakeholders including their employees in the past. Men (2012) also described corporate reputation as the totality of an organisation stakeholder's perception of how sensitive an organisational activities are satisfying the demand and hopes of many organisational stakeholders. In a related context, Gotsi & Wilson (2001) succinctly define organisation reputation as a stakeholder's overall valuation of an organisation over time and this assessment is based on the stakeholder's personal experiences with the organisation, their means of communication that gives information about the organisation actions and/or an evaluation with the activities of other organisations. This definition suggests that when an employee perceives that his organisation is better compared to other competitors, he tends to be engaged.

Job Designing

Job design according to Beliasi & Sklikas (2013) is the means of organizing task and duties into an organizational division of work. Job design always start with a breakdown of task requirements like what should be done? what are the motivating characteristics such as independence, responsibility, freedom of choice and self-control. Garg & Rastogi, (2006) observe that well designed jobs can have a positive influence on employee satisfaction and employee productivity as well designed task will foster motivation, fulfilment and performance of the employees. Osibanjo, Salau, Falola & Oyewunmi (2016) also affirm that it is imperative to design jobs in order to minimize and foster satisfaction of employees because job not properly designed can trigger stress. One of the identified factors pushing

Nigeria health workers to migrate according to (Ogbuabor, *et al,* 2016) is stress. Thus, health regulators and administrators can use job design as a mitigating strategy to minimize stress.

Career Development Opportunities

According to Mutunga (2009) employees' career advancement is process which is a formal, systematized and planned effort to achieve the balance between requirement of organisation's workers and individual career desires. When management provides sufficient prospect for training and support regarding career development, they help foster employee advancement and motivate employees to be engaged. Career advancement opportunities according to Hughes & Rog (2008) is the degree to which workers have the prospects for career growth and advancement. This implies that when workers are satisfied with their prospect for career advancement, the more they are willing to be engaged. Mone & London (2010) also observe that employees will feel more involved if organisations provide motivating job with prospects for career growth. According to Mutunga, (2009) when an organisation ensures that the job given to the employees complements with their career goals, it ensures effective employee engagement and retention. This is also corroborated by Vazirani (2007) that career growth influences engagement and retention of workers. Organisations that engages its workers provide them with prospects to develop their talents, acquire new skills, gain new knowledge and maximize their potential.

Investment on Employees

Perceived investment in employee development according to Omer, Qaisar, Talat, Khalil & Aamer (2011) refers to employee's valuation of their organisations' effort to assist them learn to recognize and get new skills and proficiencies that will allow them attain new and challenging positions. Erasmus, Loedolff, Mda & Nel (2011) further posit that when organisations train their workers, they are modifying their skill, knowledge and behaviour in other to increase their productivity and ability to accomplish organisational aims and objectives. The tangible work experiences acquired during this process build employee's capacity which significantly impacts productivity and fosters commitment (Kai, Altman & Roussel, 2008).

As a result, employees are indebted to show gratefulness for the employer's investment in their growth, showing that they do earn value from the process which will make them more motivated, committed and loyal (Alexandros & Bouris, 2008). This means that the organisation appreciate employees' contributions, care about their relevance and as a result they return back to the organisation in positive ways by exhibiting positive behavioural dispositions that proportionate with the extent they feel the organisation have invested in them (Omer, *et al,* 2011).

Work Environment

One of the core elements in the notion of employee engagement is the strong affective commitment of engaged workers and high involvement in their work. Employee involvement ensures a high degree of affection to the organisation which brings about connectivity and subsequently engagement (Lailah, Christo & Christoff, 2014). In addition, Chitra & Munivenkatappa (2017) assert that giving adequate opportunities for development and advancement to employees and ensuring that they have everything they need to do their jobs including physical or material and information resources foster employee engagement. In another context, Chandrasekhar (2011) assert that most workers spend substantial amount of their time within the internal environment which impacts their mental and emotional states, focus, behaviour, abilities and performance at work. In essence, the nature and value of the physical work environment is assumed to influence how workers interact, execute their roles as well as their mental, physical and emotional states (Oyetunji, 2014).

Compensation

Bibi, Pangil, Johari & Ahmad (2017) opine that employees are the most valuable asset of an organisation and retaining these employees is inevitable for the success of the organizations. Compensation packages entails salaries, bonuses and incentives and these have significant impact on employee satisfaction (Chiekezie, Emejulu & Nwanneka, 2017). According to Ldama & Peter (2017) compensation refers to monetary benefits that accrue to workers both intrinsically and extrinsically like

health care, vacation and leave grant, total salary package and other financial benefits. Extant literature on Nigeria health worker's migration to other countries emphasised inadequate compensation as the major factor for migration (Misua, *et al,*2010; Ogbuabor, *et al;*2016; Adeloye *et* al; 2017). According to Bibi, *et al* (2017) compensation is regarded to be one of the core essentials in workers' retention. Though it is expensive to retain experienced and skilled employees, it is more expensive to let them leave because failure to retain them has serious financial implications on the organisation like recruitment and training cost including the long period to acclimatize (Ldama & Peter, 2017).

Nevertheless, nonfinancial rewards such as recognition and other inherent rewards are unavoidable for job satisfaction which can also lead to high level of employee engagement and satisfaction and retention (Tessema, Kathryn & Abel, 2013). Leadership which is the capability to influence and inspire the actions of subordinates in an inspiring and motivating manner which fosters the achievement of objectives of both the team and the organisation is also intrinsically motivated (Alexandra and Maria, 2015). Alexandra & Maria (2015) further opine that leadership must be able to drive worker's engagement by giving primacy to the personal needs of their subordinates and inspire them to put the collective interests first over the individual interests as a means to accomplish the organizational goals.

This is because one of the main characteristics of effective leadership is the ability to increase the level of subordinate motivation in exhibiting good behavioral dispositions (Alexandra and Maria, 2015). These behaviours when exhibited highlight the principle of reciprocity which influence the subordinates to engage in a process of social exchange with their leaders. This implies that leadership style of the organisation like transformational leadership can motivate workers to be loyal to the organisation as a way to return the favourable treatment received from their leaders (Boerner, Eisenbeiss & Griesser, 2007). Thus, subordinates under a transformation leader will be motivated to reciprocate because of the motivation and self-esteem they might have received from their superiors.

Theoretical Underpinnings of Employee Engagement and the Managerial Strategic Approach

A theory is a form of a notion that explicitly explains a particular concept or phenomenon. Some theories have been developed to provide understanding into what employee engagement is all about. For instance, social exchange theory is among the most influential theoretical models for understanding good employees behavioural dispositions which entails series of interactions that generate obligations (Cropanzano & Mitchell, 2005). Social exchange contextually is a process of social interaction by showing how and someone (employer) behaviour reinforced the other behaviour (employee) and vice versa. Cook & Rice (2003) succinctly describe it as a process that involves the norm that when a party does another a favour, there is a general expectation of some future return and its exact nature is not stipulated in advance. For instance, this implies that when a party like the employer does a favour to the employee, such worker will also reciprocate in positive return and vice versa. It is expected for employees who receive an adequate or satisfactory level of most of all the precursors identified in Fig 1.1 not to reciprocate in good return to their employers including having a negative intention to migrate.

In addition, perceived organisation support theory (OST) according to Baran, Shanock & Miller (2011) is the positive perception by the employee that his/her effort is being appreciated as a result of his/her contributions to the organization. This implies that when the perception is positive, the intention to remain with the organisation will be high (Baran, Shanock & Miller, 2011). Eisenberger, Malone & Presson (2016) opine that it is important for firms to value their committed workers because employee's perception that the organization values their contributions and cares about their well-being will have substantial benefits for both parties. As observed by Colakoglu, Culha & Atay (2010) on of the most important predictors of organisational commitment is job satisfaction which has a positive effect on the dimensions of organisational commitment. If workers perceived organisational support to be positive, they tend to be satisfied on the job. This is further corroborated by Colakoglu, et al, (2010) that one of the most important predictors of job satisfaction is organisational support.

Figure 1: Proposed employee engagement Strategies and Retention Model

As depicted in Figure 1, it is observable that some precursors of employee engagement as identified are what health managers should do to motivate health worker's satisfaction. Extant literature on the challenge of health worker's migration in Nigeria identified inadequate poor human resources planning and management practices. Healthcare administrators and managers both at the private and public sector focus more on motivating their workers to be committed. Policy makers and managers must imbibe 21st century human resources management practices to health administration. Also, measures to retain health workers, encourage the return of migrated ones and ensuring their integration upon arrival is inevitable for adequate healthcare delivery in Nigeria. It is therefore inevitable to empirically investigate the proposed model in Figure 1.1.

Conclusion and Managerial Implication

The behavioural outcomes relating to withdrawal process from an organisation are; absenteeism, unpunctuality, citizenship fatigue and eventually turnover including counterproductive behaviour. It is however assumed that, if an employee receives a favourable treatment from his/her employer, he/she tends to reciprocate in likely manner and vice versa. However, employees should be engaged in order to have a feeling of being valued which will foster their commitment and retention. Nigeria health sector stakeholder are however expected to apply employee engagement as a tool to mitigating the menace of health worker's migration.

Evaluating Factors affecting sentences similarity and paraphrasing identification Using K-means clustering

Marwah ALIAN

Abstract

This research considers Arabic Paraphrasing Benchmark for identifying similar and paraphrased sentences using k-means clustering. The benchmark is constructed based on Arabic transformation rules for sentences and provided by labels for similar/not similar and paraphrased/not paraphrased sentences. K-means clustering is applied to partition the dataset into clusters with similar sentence pairs. Three factors that affect the distribution of similar and paraphrased sentences are tested by conducting several experiments with K-means clustering. By analyzing the resulted clusters, paraphrased sentences achieve a recall of 0.81 with the pre-trained embeddings and a recall of 0.78 with introducing words' weight while labeling by majority provides better recall than labeling with a threshold of similarity score.

Keywords

paraphrasing, sentence similarity, K-means, clustering.

1. Introduction

Paraphrasing identification refers to reframing a sentence using different words and structures to produce a new sentence with the same meaning (Fernando, 2008). Semantic similarity has an important role in detecting paraphrases, as it allows the process to compute the similarity score between texts in order to identify whether they are similar in meaning or not (Srivastava and Govilkar, 2017) (Alian and Awajan, 2018). The approaches to measure semantic similarity between sentences can be categorized into four groups, namely, co-occurrence–based approach, statistical corpus-based approach, feature-based approach, and word embedding-based approach. The co-occurrence–based approach represents texts as a bag of words vector while the statistical corpus-based approach uses Latent Semantic Analysis, which represents texts as vectors in a reduced-dimension space. The feature-based approach focuses on the similarity of words and the order between texts where words that have the same part of speech are aligned. The Word-Net based measure is used to compute semantic similarity between words and overlapping word orders in the two texts. Finally, the word embedding approach has the ability to consider the context of the words when representing words in a distributed space (Alian and Awajan, 2018).

For the purpose of analyzing paraphrased sentences in Arabic, we built a paraphrasing benchmark which consists of Arabic sentence pairs; part of these pairs is collected from Arabic books and lexicons while the other is constructed by experts using words form Arabic lexicons and AWSS dataset. Then, six transformation rules are utilized to generate the transformed form of the collected sentences. The dataset is labeled by Arabic specialists with different levels from Art College from Hashemite University (Alian et al., 2019).

The aim of this research is to analyze the constructed paraphrasing benchmark and use the K-means clustering to analyze and study the factors that affect the results of similarity and the distribution of sentences.

The K-means is considered as the simplest method used for partitioning a dataset into clusters of similar objects. Therefore, it is applied to the dataset after representing the sentences as vectors in a continuous vector space using wrod2vec model.

The main factors that will be studied to show their impact are: embedding method, weight of words and labeling dataset. Two ways are considered to implement the word2vec embeddings; the first one is achieved by training word2vec on the dataset and the second one by using pre-trained embeddings. Introducing the weight that represents the importance of words in a sentence is tested using Tf-idf. The way of labeling the dataset for similarity is another factor that may affects the results of similarity and paraphrasing which is tested through experiment.

This paper is organized as follows: section 2 describes the structure of the Arabic paraphrasing benchmark. Section 3 explains K-means clustering algorithm while in Section 4, we experiment k-means clustering on the benchmark. Finally we conclude in Section 5.

2. Arabic Paraphrasing Benchmark

This benchmark is constructed from Arabic sentences that are collected from several books used for teaching Arabic language such as Jordanian curriculums for Arabic language and other books (Jarim and Ali, 2004) (Omar, 1998) (Omar, 1420 - 1999) (Alkholi, 2001). In addition, Experts in Arabic language create a number of sentences based on words from some Arabic lexicons and words from Arabic Word Semantic Similarity (AWSS) dataset (Almarsoomi et al., 2013).

Arabic Paraphrasing can be reached by two methods; the first is based on paraphrasing hypothesis “two sentences are paraphrased if they consist of identical words except one word in the first sentence and its synonym in the second one”. The second method is based on the language transformation rules (Al-Kholi, 1999). Therefore, the collected and created sentences are transformed into other sentences based on the transformation rules for Arabic sentences. The applied transformations are reflected in a set of rules referred to as “transformation rules” that were constructed by Chomsky (Chomsky, 1957); the creator of the constructional and transformational school.

The transformation rules can be categorized into a number of patterns; permutation, deletion, addition, reduction, expansion, and replacement. Permutation is the process of reordering words in the first sentence to get the new sentence while deletion is removing one item from the sentence. It is also the inverse of the addition rule which adds an item to the structure of the sentence. The expansion is the process of replacing a word by two different words that provide the same meaning while reduction is to represent two words by one word with the same meaning (Alian et al., 2019).

The transformation rules were applied on the collected sentences by two experts in Arabic language to produce the transformed sentences. Both experts have the degree of philosophy in Arabic where they collect and transform the sentences in three months.

Let A, B, and C are words or phrases in the sentence. Then, the transformation rules can be symbolized as in Table 1 as described by Al-kholi (Al-Kholi, 1999). Furthermore, the transformation is a description of the relationship between the deep structure of the sentence and the surface structure of the sentence.

Table 1: Transformation rules **(Alian et al., 2019)**

Transformation rule	Representation by symbols	Example
Permutation	A+B = B+A	تسلم الفائز الجائزة تسلم الجائزة الفائز
Deletion	A + B = […] + B A + B = A + […]	اسألوا أهل القرية عن اللص اسألوا القرية عن اللص
Addition	A=A+B	السماء صافية إن السماء صافية
Expansion	A = B+C	وددت نزول المطر وددت لو ينزل المطر
Reduction	A + B = C	الجو حار بارد الجو معتدل
Replacement	A = B	شارك الأستاذ في الأمسية الأدبية شارك الأستاذ في الأمسية الشعرية

3. Background

3.1. K-means

K-means is a non-hierarchical clustering algorithm which was introduced by Hartigan and Wong (1979) (Hartigan, 1979). It is considered as the most popular and simple approach used for partitioning a dataset (Steinley, 2007) or a number of observations in order to produce k clusters such that the total variation of within-cluster is minimized.

In this algorithm, the data is partitioned into k clusters where each cluster is represented by the mean of its content points and this is where the name of K-means comes from (Berkhin, 2002). However, there is no special equation for determining the number of clusters (k). It is specified by the problem domain or the application Data (Parsian, 2015).

K-means clustering can be used in many scientific and industrial applications (Berkhin, 2002). For example, it can be used in clustering documents into groups according to their content similarity or grouping customers into clusters according to their behavior (Parsian, 2015). It is a prototype-based partitioning clustering technique that attempts to find a user specified number of clusters (K) presented by their centroid (Tan, 2014).

K-means clustering technique is used in partitioning data into K classes (C1,C2,…,Ck) where K is the number of clusters and it is a predefined parameter while Ck is the group of nk objects in cluster k . The data consists of N objects where each object has P features. If Xnxp denotes NxP matrix, K-means generates k clusters by selecting k centroids then starts an iterative procedure by computing the squared Euclidean distance between any object vector and the centroids vectors. Euclidean distance is computed as in Equation (1)

$$d^2(i,k) = \sum_{j=1}^{P} (x_{ij} - s_j^{(k)})^2 \qquad (1)$$

Where
$d^2(i,k)$ is the squared Euclidean distance
i is the ith object
k is the *kth* centroid vector represented by $(s_1^{(k)}, \dots, s_P^{(k)})$.

Then an object is assigned to the cluster with the closest centroid to that object. The centroid is a point in the P-dimensional space which is selected randomly at the beginning then it is updated by computing the mean of the values on each feature over all objects in the corresponding cluster. The centroid for the jth feature in cluster Ck is found by Equation (2) (Steinley, 2006) (Steinley, 2007)

$$\bar{x}_j^{(k)} = \frac{1}{n} \sum_{i \in C_k} x_{ij} \qquad (2)$$

And the centroid vector for the cluster Ck will be:

$$\bar{x}^{(k)} = (\bar{x}_1^{(k)}, \bar{x}_2^{(k)}, \dots, \bar{x}_P^{(k)})' \qquad (3)$$

K-means attempts to find good partitioning by minimizing the error sum of squares (SSE) in the constructed clusters. It is considered as a loss criterion and calculated as in Equation (4):

$$SEE = \sum_{j=1}^{P} \sum_{k=1}^{K} \sum_{i \in C_k} (x_{ij} - \bar{x}_j^{(k)})^2 \qquad (4)$$

3.2. Aravec

AraVec (Mohammad, Eissa and El-Beltagy, 2017) is an Arabic language pre-trained distributed word embedding model where it was produced using the Word2Vec skip-gram technique trained on World Wide Web pages Arabic content with a vector dimension of 300 and a vocabulary size of 145,428. The Aravec

models have been built based on three domains: Web pages, Arabic tweets and Wikipedia with articles of Arabic content. These domains provide building the models with more than 3.3 billion tokens.

3.3. Evaluation measures

Precession and recall are commonly used as measures for evaluating the results in Information Retrieval and Machine Learning experiments (Powers, 2007). In information retrieval, they are used for measuring how well the system retrieves relevant items requested by the user (K.M., 2011).
Recall is called sensitivity and it is defined as the percentage of positive items that are predicted correctly positive as in formula (4) (K.M., 2011):

$$Recall = \frac{TP}{(TP+FN)} \qquad (1)$$

Where
TP is the true positives (items that are positive and they are correctly identified positive)
FN is the false negatives (items that are incorrectly identified as negative)
(TP+FN) is the total number of actual positives.

While Precision is called confidence and it is defined as the percentage of predicted positives that are real positives as in formula (2) (K.M., 2011):

$$Precision = \frac{TP}{(TP+FP)} \qquad (2)$$

Where
TP is the true positive
FP is the false positive (items that are negative but falsely identified as positive)
(TP+FP) is the total number of positives predicted

3.4. Term frequency-inverse document frequency

Term frequency-inverse document frequency (TF-IDF) is considered as a numerical and statistical approach that takes into consideration the importance of a term within a group of documents. As the frequency of a word occurrence increased in a document, TF-IDF is proportionally increased but inversely proportional to the word's frequency in all documents or corpus (Mohsen et al., 2018). The TF-IDF is computed as in the following formula:

$$TFIDF = \frac{n_t}{N_d} \times \log\left(\frac{N_j}{n_j}\right) \qquad (3)$$

Where
N_j is the total number of documents in the corpus
n_j is the number of documents that contain term t.
n_t is the number of times where word t appears in the document.
N_d is the total number of terms in the document d.

4. Experiment and Results

Three factors that affect sentences similarity and paraphrasing identification are evaluated using Kmeans clustering. The first factor is the approach used for providing sentence's embeddings; trained and pre-trained embeddings while the second factor is introducing the weight of words. The third factor is the way of labeling the dataset; by majority or by similarity score threshold. The resulted clusters that contain similar sentences are compared with the labeled dataset using recall and precision measures.

4.1 Self-trained Word2Vec word embeddings vs pre-trained Word2Vec

In evaluating the approach used for representing sentences in the distributional space, two experiments are conducted; the first experiment is based on self-trained of word2vec on the dataset that consists of 2020 sentences with 3145 vocabulary while the second experiment is conducted on pre-trained embeddings using

Aravec that utilizes 77,600,000 Arabic tweets, gathered from different locations, in the training of word2vec. The vector that represents a sentence in both experiments has constructed as the mean of its content words' vectors. Then, K-means is applied to partition the dataset into clusters of similar sentences. The number of clusters (K) is chosen as half the number of sentences which is equal to 1010 clusters. Since we compare each pair of sentences if they are similar, paraphrased or not. Table 2 and Table 3 show the confusion matrix for both experiments for the similarity detection.

Table 2: Similarity confusion matrix for self-trained

Training on the dataset	**Labeled**	
	Similar	not similar
Similar	638	95
not similar	226	51

Table 3: Similarity confusion matrix for the Aravec training embeddings

Aravec training	**Labeled**	
	Similar	not similar
Similar	682	102
not similar	182	44

In Table 4 and Table 5, the confusion matrices for paraphrasing test are shown for dataset training embeddings and Aravec embeddings, consequently.

Table 4: The confusion matrix for paraphrasing identification with self-trained embeddings

	paraphrased	**not paraphrased**
paraphrased	576	157
not paraphrased	188	89

Table 5: The confusion matrix for paraphrasing identification with Aravec embeddings

	Paraphrased	**not paraphrased**
paraphrased	611	173
not paraphrased	148	78

Accordingly the recall will be computed as in as in Formula (1) as (in section 3.3) where the true positive is the paraphrased sentences correctly identified while the false negative is the paraphrased incorrectly labeled as not paraphrased.

While the precision will be calculated as formula (2) as previously mentioned in section 3.3 where the true positive represents the paraphrased sentences correctly identified while the false positive represents the sentences that incorrectly labeled as paraphrased.

The results of recall and precision for detecting similar sentences are shown in Fig.1 while the results for paraphrasing identification are shown in Fig.2.

Fig 1. Recall and precision for both dataset and Aravec embeddings for similarity.

Fig.2. Recall and Precision for both dataset and Aravec for paraphrasing.

The recall achieves better values with the pre-trained Aravec embeddings in similarity detection and paraphrasing identification while the precision with the dataset training embeddings provide better value for paraphrasing identification.

4.2 TF-IDF weight

Each word in the structure of the sentence has its significant importance. In this research, word's importance is expressed as the weight which is computed as the Tf-idf as in formula (3) as in section 3.4.

When we include the weight for each word to produce the embedding of a sentence, the results for paraphrasing identification is little better than the results without taking the weight into consideration. As shown in Table 6.

Table 6: comparing paraphrasing identification results

Experiment	recall	precision	F1 score
K-means TfIDF	0.785166	0.808959	0.796885
K-means	0.779337	0.805007	0.791964

4.3 Labeling Dataset

We used two methods to provide the final label to the dataset. In the first method, we used the label of each sentence pair for similarity by majority of experts' decision about similarity. If more than three experts give a decision of similarity for a sentence pair then this pair is labeled as similar. In the second method, we compute the average of the score of similarity provided by the experts. A sentence pair is labeled as similar if the score average is greater than or equal to 0.50, otherwise the sentence pair is labeled as non-similar.

To evaluate the effect of these two methods on the similarity of sentences, we conduct an experiment by applying the two methods of labeling the dataset with K-means and weighted embeddings. The results of labeling by majority are shown in Table 7 while the results of labeling based on the score of similarity are represented in Table 8. It is shown that choosing the method of labeling a sentence pair has affected the precision and recall measures. From Table 7, it is shown that labeling by majority provides better recall for K-means with Tf-idf weighted embeddings.

Table 7: labeling by majority results

Experiment	Recall	Precision	F1 score
K-means TfIDF	0.87468	0.790751	0.830601
K-means	0.789352	0.869898	0.82767

Table 8: the results of labeling by score >=50%

Experiment	Recall	Precision	F1 score
K-means TfIDF	0.748082	0.80137	0.77381
K-means	0.79863	0.743622	0.770145

5. Conclusion

In this research, k-means clustering is applied for Arabic paraphrasing benchmark that consists of pairs of Arabic sentences with two labels: one for similarity and the other for paraphrasing. K-means is used to explore the dataset as clusters of similar sentences and experiment which pairs are paraphrased and allocated in the same cluster. The experiment includes two ways for producing sentences' embeddings: one way is constructing embeddings by training word2vec on the dataset and the other utilizes the embeddings of Aravec model which provides a pre-trained embeddings. The results for pre-trained embeddings produce a better recall in detecting similar and paraphrased sentences. Applying K-means with introducing Tf-idf weighting for words provides a recall of 0.78 while labeling the dataset for similarity by majority of experts provides a recall of 0.87 which is better than the recall achieved with labeling by similarity score threshold with Tf-idf weighting.

Abstract

Modern approaches to the definition of "hunting tourism" are analyzed in the article. It is proposed to consider hunting tourism as an organized paid trip aimed on satisfying the needs of consumers (hunters) in services of extreme, sports & recreational or cognitive character in the process of their staying in the natural habitat of hunting animals. The main problems of organizational, economic and orientation legal, which hinder the development of hunting tourism in Ukraine, are considered. The resource support of hunting tourism development in Ukraine is analyzed. Organizational and management aspects of hunting economy in European Countries (Germany, Sweden, Finland, Hungary, Czech Republic and Poland) are investigated. The directions for solving of basic problems of organizational and legal support, as well as incentives for further development of hunting tourism in Ukraine are offered. The basic principles on which hunting tourism should be based are formed, in particular: the principle of preservation of biodiversity in the animal and plant life of hunting grounds; the principle of sustainable ecologically balanced of using the hunting resources for tourism purposes; the principle of observance of ethical norms and national traditions in the process of organizing hunting tourism; the principle of preservation of the cultural heritage in the areas, which are reserved for the organization of hunting tourism; the principle of promoting the development of alternative types of hunting tourism; the principle of integration of hunting tourism with hunting, forestry and agrarian enterprises; the principle of state support in the development of hunting tourism.

Keywords: Tourism, Hunting Tourism, Hunting Economy, Hunting Industry.

Introduction

The process of Ukraine's integration with the European community involves conducting a series of political, economic and social measures. Reformation of the national economy is possible only by reviewing existing approaches to the process of using and reproducing the country's resource and raw material potential, as well as finding new ideas for the development of entrepreneurial activity. Formation of regulatory and legal support, stimulation of the development of new areas of entrepreneurship in Ukraine should be reflected in the list of main tasks of the state policy on the development of small and medium-sized businesses (SMBs).

In developed countries, SMBs are considered as the subjects, which are forming the basis for the establishment of democratic relations; it's simultaneously aimed at solving the social employment policy. Significant potential for economic and social growth through the development of SMBs is hidden in one of the priority sectors of the national economy – tourism industry, which was repeatedly noted and considered in various regulatory and legal documents both nationally and internationally levels.

Inherently, modern tourism is defined as a multifaceted phenomenon, which is closely related with economics, history, culture, geography, medicine, ecology etc. In addition, tourism is largely characterized as one of the traditional forms of nature use, which is manifested in the using of natural resources for recreational purposes, including using the resources of hunting fauna.

Insufficient attention of scientists, business entities, governmental and non-governmental organizations to the problems of involvement of hunting fauna resources for tourist purposes is determined the relevance of this scientific research.

Literature Review

Organizational and economic aspects, analysis of foreign and domestic experience of organization, management and development of hunting tourism are highlighted in the scientific works of many scientists. Organizational basis of formation and development of international hunting tourism in the independent Ukraine and in conditions of a market economy are covered in the science works of Bondarenko V. (Bondarenko, 1993). Delehan I. is one of the first scientists who distinguished the hunting tourism as a profitable component of the tourism industry in Ukraine; in particular, based on foreign experience, he indicated that hunting tourism can gives such profits, which in magnitude will be higher than the cost of annual allowable cut wood at the average European prices (Delehan, 1994). The analysis of the main ecological and economic trends in the development of hunting tourism in developed countries, the typical forms of hunting tourism in these countries and their economic role in the national and regional context are reflected in the science work of Kulchytska E. (Kulchytska, 2014).

The main directions of development of hunting tourism at the regional level in Ukraine, the current state of hunting tours and trends in tourism industry are considered in the science works of Banderych V. (Banderych, Pryndak & Khoietskyi, 2011) and Yachniuk M. (Yachniuk, 2010). The main provisions of the ecological and economic assessment and economic incentives for the using, protection and reproduction of hunting fauna resources, as well as the determination of payment standards for the special using of resources of the hunting economy are disclosed in the works of Vovchenko V. (Vovchenko, Malevanova & Domnich, 2005), Dynka P. (Dynka, 1992), Koval Ya. (Koval, Antonenko, & Shadura, 2000), Muraviov Yu. (Muraviov, 2001), Syniakevych I. (Syniakevych, 2000) etc.

The grounded analysis of environmental legislation, studying the problem issues of the property right on the resources of the animal world, their rational using, protection, reproduction, regulation of hunting and the development of hunting tourism at different time periods were researched by such scientists as Muntian V. (Muntian, 1982), Tomyn O. (Tomyn, 2009), Klapchuk V. and Protsiv O. (Klapchuk & Protsiv, 2011), Cherkashyna M. (Cherkashyna, 2011), Tykhyj V. (Tykhyj, 2000) and others.

The international aspects of the sustainable development of hunting tourism in the European countries are reflected in the "European Charter on Hunting and Biodiversity" (Strasbourg, 2007), which was approved at the 27th meeting of the Standing Committee of the Bern Convention. This document combines the main aspects of European and international policy on sustainable realization of hunting, ecotourism, biodiversity conservation in the context of ecological, economic and socio-cultural problems of sustainable development; also it provides three main interrelated directions for the development of hunting economy (http://www.cic-wildlife.org/uploads/media/Hunting_Charter_EN.pdf.): 1) the development of principles and practical

recommendations for the sustainable using of wildlife resources and biodiversity in Europe, especially through hunting; 2) the development of principles and practical recommendations for sustainable hunting tourism in Europe; 3) the assistance in raising awareness of the hunter in the issues of weapons handling, safety and adherence of ethical standards in the hunting process.

Also, the "European Charter on Hunting and Biodiversity" contains 12 principles, 47 practical guidelines for natural resource management bodies and 59 practical recommendations for hunters and tour operators, which take into account existing works in this area, in particular the principles and recommendations adopted in Berne (1979), Rio de Janeiro (1992), Malawi (1998), Addis Ababa (2004).

Using of hunting fauna resources as an object of tourism activity is a fairly widespread phenomenon in developed countries. At the same time, the specificity and individual approaches to the using of hunting fauna resources determine hunting tourism as one of the most expensive and elite types of tourism. Hunting tourism in Ukraine is on the formation stage and requires a grounded scientific substantiation in the order to determine the effective organizational, economic and legal mechanism for its functioning. The issues of definition, economic and legislative regulation of hunting tourism in Ukraine still are unresolved and open.

Materials and Methods

The theoretical basis of this research are the fundamental provisions of tourism science, economics of hunting, tourism and nature management, ecological economics, the theory of sustainable development, normative and legal support of activities in the field of hunting tourism. The methodological basis of the study consists of a set of such methods and techniques: induction and deduction – to generalize the basic theoretical principles of the study, as well as the formulation of conclusions and recommendations; monographic – for studying and generalization of scientific approaches to the definition of "hunting tourism"; institutional analysis, comparative analysis, generalization and abstraction – for studying foreign experience of hunting industry and hunting tourism development; integrated and systematic approaches – for the formation of principles of hunting tourism; economic and statistical methods for analysis the potential of hunting fauna resources, hunting production markets, ecological and economic efficiency of reproduction and using of hunting resources for tourist purposes in the European countries and Ukraine.

The information basis for this research were legal and normative acts: the Constitution of Ukraine, Laws of Ukraine, Decrees of the President of Ukraine, resolutions of the Government of Ukraine, normative acts of the Ministry of Ecology and Natural Resources of Ukraine, State Agency of Forest Resources of Ukraine, international legal documents in the field of environmental policy and environmental protection, adopted at international conferences and laid down in international agreements. The official statistics and information from the State Statistics Service of Ukraine, the Ministry of Ecology and Natural Resources of Ukraine, the State Agency of Forest Resources of Ukraine were used in the work.

The aim of this article is to substantiate scientifically the definition and essence of "hunting tourism" and make an assessment of legal, organizational and economic provision for its development in Ukraine.

To achieve the aim we have solved the following *tasks:*

1. to analyze modern approaches to the definition of "hunting tourism" on the basis of foreign and domestic scientific works, legal & normative support;
2. to investigate organizational and management aspects of hunting economy in European Countries (Germany, Sweden, Finland, Hungary, Czech Republic and Poland);
3. to determine the organizational, economic and legal problems of the formation and development of hunting tourism in Ukraine;
4. to offer the incentives for further development of hunting tourism in Ukraine;

5. to form the basic principles on which hunting tourism should be based.

Results

The hunting tourism originated at the first half of the XIX century. It is the time, when traveling related to the hunting on African exotic animals in the order to receive their trophies become very popular among the wealthy European nobles. The most prestigious in the world, even nowadays, are trophies of the so-called "African Five" (elephant tusks, lion fangs, buffalo horns, leopard skin, rhinoceros horns etc.). Subsequently, this type of trips got the name "safari", and the desire of hunters to get the best trophy formed the basis for the development of international hunting tourism, despite the rather high cost of such events.

Let's consider the most famous approaches to the definition of "hunting tourism" (Table 1).

Table 1: Definitions of hunting tourism

Balysheva (2007)	Hunting tourism: an organized paid trip for trophy hunting, which is provided by a set of specific services
"European Charter on Hunting and Biodiversity" (2007)	Hunting tourism is defined as a form of tourism that is carried out by hunters, who can traveling sometimes at significant distances from their permanent homes and/or from their own hunting grounds for hunting (This definition includes both domestic and international hunting trips. In this case, the destination of hunting is more exotic and unusual)
Shandor & Kliap (2011)	Hunting tourism (outfitter tour): a kind of tourism, the purpose of which is searching, tracing, prosecuting and prey some species of wild animals
World practice	Hunting tourism is considered as one of the directions of international tourism, whose purpose is to satisfy the needs of foreign hunters-tourists

In our opinion, the note of "hunting tourism" (which is followed by the vast majority of scientists) is an integral part of the note of "hunting", which involves a special using of the animal world by obtaining hunting animals that are in a state of natural freedom or are kept in semi-free conditions within hunting grounds; and hunting as a branch of the national economy includes the process of providing services in the conduct of hunting (http://zakon.rada.gov.ua).

As we can conclude, the basis of the above definitions of hunting tourism is the consumer direction of the using the objects of animal world, by the extraction of wild game animals with the help of small arms in the order to obtain a trophy. It is impossible to disagree with this, because in countries with long hunting traditions, the quality and quantity of trophies obtained during the hunting process are the most important indicators for assessing the level of development of both hunting tourism and hunting economy as a whole. But still there is a certain contradiction, which is that in itself trophy hunting can't be laid as a basis for increasing the number of wild game animals and lead to increasing the quality of their population, however, it can stimulate hunting economy in the direction of increasing economic and environmental efficiency of their work (Danylkyn, 2010).

In a broader sense, hunting tourism is both craft and entertainment. This approach determines hunting tourism as one of the most profitable modern types of tourism. Hunters consider hunting as one of the types of leisure or recreation, as a way for communicating with nature, which is based on the process of wild game extraction.

In our opinion, in addition to extreme (extraction of hunting animals, obtaining a trophy), it is possible to identify other alternative types of hunting tourism, namely sports & recreational and

cognitive. These should include the following forms of hunting tourism: walks in the woods for monitoring wildlife, photo and video hunting, trophy case, hunting dog breeding, taxidermy (making stuffed of animals) etc. Thus, hunting tourism should be considered not only from the standpoint of consumption, but also as an activity aimed at satisfying the needs of hunters in the services of aesthetic, moral, recreational and cultural character in the process of their staying in the natural habitat of hunting animals. It should be noted that exactly the alternative types of hunting tourism are becoming more and more popular in the countries of Central and South Africa and in the future can completely replace the traditional safari.

Taking into account the above statements, authors' propose the following definition of hunting tourism: an organized paid trip aimed on satisfying the needs of consumers (hunters) in services of extreme, sports & recreational or cognitive character in the process of their staying in the natural habitat of hunting animals.

Organizational and economic provision of hunting tours in the territory of Ukraine for both foreigners and citizens of Ukraine involves solving a sufficiently large number of problem tasks. Hunting tourism is at the junction of hunting, forest, agriculture, water and tourism industries in general. It is obvious that the closest and interconnected relationship is between hunting tourism and hunting economy, which in perspective may lead to conflict of interests between hunters, users of hunting grounds, the state and private landowners. This is confirmed by the fact that in accordance with the National Classifier of Ukraine DK 009: 2010 "Classification of Types of Economic Activities", tourist and hunting activities are classified in different sections, in particular: hunting industry - section A "Agriculture, Forestry and Fishing Industry", issue 01 "Agriculture, hunting and related services"; tourist activities - section N "Activities in the field of administrative and support services", issue 79 "Activities of travel agencies, tour operators, provision of other reservation services and related activities".

However, it should not be forgotten that hunting tourism for hunters, tourist enterprises (tour operators, travel agencies) is primarily an economic activity related to the provision of services to hunters-tourists in the order to generate income and increase the efficiency of hunting activities. Such an approach was formed due to connection with the specific features of hunting tourism, which unites, on the one hand, the hunting industry features of the organization, management, using, reproduction and protection of hunter's resources, and, on the other, the constituent elements of tourism activity (formation of tourist product, search, reception, transfer and placement of customers and other related services).

Like any industrial or commercial activity that is connected to several branches of the national economy, hunting industry should be regulated by relevant related legal norms. Organizational, legal and economic relations in the field of hunting industry and tourism activities in Ukraine are regulated by a number of legislative acts, the main of which are: the Law of Ukraine "On Environmental Protection", the Law of Ukraine "On the Fauna", the Law of Ukraine "On Hunting Economy and hunting", the Forestry Code of Ukraine, the Law of Ukraine "On the Red Book of Ukraine", the Law of Ukraine "On Tourism" etc.

The analysis of regulatory and legal support in the field of hunting industry and tourism in Ukraine confirms the existence of unresolved and problematic issues regarding the functioning and development of hunting tourism. In particular, in the Law of Ukraine "On Tourism" (1995) (http://zakon.rada.gov.ua), such a notion as "hunting tourism" occurs only in the list as one of the types of tourism. In the Law of Ukraine "On Hunting Economy and Hunting" (2000) (http://zakon.rada.gov.ua), hunting tourism even isn't mentioned in general as a promising area of economic activity, which contradicts the main international agreements in the field of protection, reproduction and using of hunting fauna resources.

Although some normative legal acts in Ukraine operate on this notion, they don't give it a legal definition, since hunting tourism has specific features that distinguish it from other types of tourism. Unlike Ukraine, the economic activity related to the provision of tourist services in the field of

hunting is reflected in the legislation of developed countries and is regulated by a number of subordinate legal acts. For example, you can refer to the experience of Poland. In the Polish Law "On Hunting" (1995) (http://isap.sejm.gov.pl) hunting tourism takes a whole section. According to Polish law, hunting activities related to the provision of tourist services include: 1) hunting conducted by foreigners in the territory of Poland; 2) hunting abroad.

Over the last few years, Ukraine has been intensifying the efforts of academics and NGOs for improving regulatory and legal support and effective management in the area of protection, reproduction and using of hunting economy resources. In particular, problems of state regulation and enforcement, increasing the economic efficiency of hunting economy, including hunting tourism, as well as proposals for their solution were discussed and published in the framework of the Regional Program "European Neighborhood and Partnership Instrument East Countries Forest Law Enforcement and Governance II Program" (FLEG II 2014-2017), which the co-authored of this research was participated in (Myronenko, 2015).

Since the foreign hunters-tourists become as a basis for the development of hunting tourism, another legal problem there is – the regulation of documentary support of foreign citizens in Ukraine. Article 13 the Law of Ukraine "On Hunting Economy and Hunting" (http://zakon.rada.gov.ua). allows foreigners to hunt in Ukraine due to hunting rights documents (hunter's certificate, corresponding permission for using the firearms, passport for dogs hunting breeds etc.) issued by appropriate authorities of other states. However, the norms for determining the equivalence of documents for the right to hunt abroad, which citizens of Ukraine must obtain, are not fully defined. One of the objectives of the adopted resolution of Regional Program FLEG II was to develop measures for the development of foreign hunting tourism, minimizing the number of bureaucratic procedures for the admission of foreign hunters, in particular (Myronenko, 2015):

- to grant the right to the user of hunting grounds independently, without intermediaries, to accept hunters from abroad;
- to eliminate the corruption of users from all kinds of permits from other departments (permissive system of the Ministry of Interior of Ukraine, veterinary service);
- to simplify customs procedures for the export/import of legally acquired trophies and hunting weapons (excessive and unreasonable requirements for the list of documents for customs clearance);
- to streamline and improve licensing systems for foreign hunters in Ukraine: the registration of license for trophies, the lease of local weapons etc.

We should note that except this initiative, significant progress hasn't taken place in this direction over the past few years.

The success in the development of hunting tourism directly depends on the level of organization and management of hunting economy. The centuries-old culture of hunting and forestry management in the European Union countries allows not only effectively protect forest, field and wetlands, but also increase the livestock of hunting fauna and biodiversity as an integral part of improving the wildlife habitat. According to various data, the prices for hunting tours in different countries fluctuate within the limits (Table 2):

Table 2: Prices for hunting tours

Wildlife	Price, USD
Mountain ram	12000-50000
Snow ram	7000-15000
Mountain goat	up to 5000
Chamois	1500-2500
Noble deer	2000-8000
Spotted deer	up to 4000
Wild reindeer	up to 2000
Elk	1000-5000
European roe deer	500-2500
Wild boar	400-2000
Brown bear	1500-8000
Lynx	1500-3000
Wolf	200-1500

**Source: (Danylkyn, 2010).*

Hunting tourism in Europe is particularly popular among hunters in Germany. There are 369 300 hunters in Germany, and it's of the lowest indicator in Europe in terms of population. Despite the fair amount of wild game and the high quality of related services, almost half (48.7%) of German hunters used international hunting tourism services, while 38% use these services once a year or several times a year (Haakana, 2007). In the 2017/2018 season, hunters in Germany gained 1948.95 thousands heads of small wild game and 2182.1 thousands heads of hoof wild game, which is almost in 8 times more than total number and in 140 times more than number of hoofed animals in Ukraine. Basically, hunters in Germany gain: roe deer – 1 199 000 heads, wild boar 837 000 heads, noble deer – 77 000 heads, fallow deer – 63 000 heads, moufflon – 7 200 heads, chamois – 4 900 heads, spotted deer – 2 400 heads. It should be noted that the amount of hunting livestock in Germany is high and grows by 5-10% each year (http://www.jagdverband.de). But, in most European countries, the hunter owns only trophies (horns, skin, fangs), and other hunting products are the property of the hunting economy, the owner of the hunting grounds or local people. From hunting products sales (meat, leather, down) 266.39 million EUR was received in 2018, which is on 47.45 million EUR more than in 2014 (218.94 million EUR) and on 88.59 million EUR more than in 2010 (177.8 million EUR). The largest revenues were getting from sales meat and skin of ungulates – 251.71 million EUR (94%) (http://www.jagdverband.de). We should pay attention on the fact that the cost of meat and skin of ungulates and the cost of small wild game is unchanged over the past ten years, which indicates the stability of the industry and the economy as a whole.

The experience of organizing of hunting tourism in the northern European countries (Sweden, Finland) shows that: the system of hunting management is mainly based on a private ownership form; a rental income from hunting grounds and the organization of hunting tourism are the main part of the income of most landowners (Urszula, Törmä, Kinnunen & Rautiainen, 2015). 37 species of animals and birds are the objects of hunting in Finland. In general, hunters are hunted ungulates animals (elk, roe deer, and white - tailed deer) and a variety of small wild game. The average annual extraction of elk is 38 000 heads, deer – more than 12 000 heads, and roe deer – more than 90 000. In a small amount, they hunt fallow deer, wild pig and moufflon (Khoietskyi & Pokhaliuk, 2014). The fee for the right to hunt small wild game varies from 5 EUR/day to 170 EUR/year. For foreign hunters, the cost can be revised and varies from 7 to 400 EUR (Matilainen & Keskinarkaus, 2010). This money (about 5.5 million EUR per year) is accumulated by the state and is used to prevent the negative impact of hunting animals on the environment and to compensate the damage done by them to forestry and agriculture (Matilainen & Keskinarkaus, 2010).

Almost identical system of organization and management of hunting economy is used in Sweden. The main licensed species of animals are elk and noble deer. Most of all, in Sweden, they hunt such

ungulates animals as a roe deer and elk. In modern conditions, more than 100 000 specimens of elk and about 200 000 individuals of roe deer are extracted in Sweden (Khoietskyi & Pokhaliuk, 2014).

For considering the organizational aspects of organizing hunting tourism and hunting economy, the most interesting for Ukraine is the experience of Hungary, Czech Republic and Poland. Despite the fact that the area of hunting grounds of Hungary is in six times smaller than the Ukrainian ones, annually there are hunting over 250 000 heads of ungulates animals and 800 000 heads of small wild game (http://www.menr.gov.ua). Hunting tourism in Hungary (according to various estimates) brings near 60 million EUR to the state budget every year (Danylkyn, 2010). In the Czech Republic, hunters annually obtain about 300 000 heads of ungulates animals and about 1 million heads of small wild game (http://www.czso.cz). Every year, Polish hunters obtain more than 100 000 wild boars, 30 000-40 000 deer, 120 000-160 000 European chamois (Delehan & Shpilchak, 2008).
The main problem of hunting tourism in the organizational and economic direction in Ukraine is its resource support. Forest-game zoning of the territory of Ukraine is divided into five natural zones (http://zakon.rada.gov.ua/cgi-bin/laws/main.cgi?page=1&nreg=z0771-01):

1. Polissya Zone (Volyn Region, Zhytomyr Region, Kyiv Region, Lviv Region, Rivne Region, Sumy Region, Khmelnytskyi Region and Chernihiv Regions);
2. Forest-steppe Zone: right-bank (Vinnytsia Region, Volyn Region, Zhytomyr Region, Ivano-Frankivsk Region, Kyiv Region, Kropyvnytskyi Region, Lviv Region, Odessa Region, Rivne Region, Ternopil Region, Khmelnytskyi Region, Cherkasy and Chernivtsi Regions); left-bank (Kyiv Region, Poltava Region, Sumy Region, Kharkiv Region, Cherkasy and Chernihiv Regions);
3. Steppe Zone: northern (Dnipro Region, Donetsk Region, Zaporizhya Region, Kropyvnytskyi Region, Lugansk Region, Mykolayiv Region, Odessa and Kharkiv Regions); Southern (Crimea, Zaporizhya Region, Mykolayiv Region, Odessa and Kherson Regions);
4. Carpathian (Zakarpattia Region, Ivano-Frankivsk Region, Lviv and Chernivtsi Regions);
5. Crimean Mountains (Crimea).

According to the statistical data, the area of hunting grounds in Ukraine is 38 779.9 thousands of hectares. The largest part in the structure of Ukrainian hunting grounds is occupied by field lands – 28721.0 thousands of hectares (74.1%), as well as forest lands – 7931.9 thousands of hectares (20.4%) and wetlands – 1796.2 thousands of hectares (4.6%). 1077 users work in the management of hunting industry. There are about 780 000 hunters in Ukraine, but only 300 000-350 000 annually participate in the hunt (http://www.ukrstat.gov.ua/druk/publicat/kat_u/publ7_u.htm). Total expenses from hunting in 2017 amounted 360.75 million UAH and the revenues 160.68 million UAH (http://www.ukrstat.gov.ua/druk/publicat/kat_u/publ7_u.htm). Proceeds from hunting economy are mainly formed due to the implementation by the users of hunting grounds of licenses, shooting cards, products obtained from the extraction of hunting animals (meat, leather, trophies) and the provision of services to hunters in the process of obtaining hunting animals.

One of the main factors in the successful development of hunting tourism is the availability of a sufficient amount of hunting resources. In the category of hunting animals in Ukraine are classified 34 species of mammals, 25 of them are found in the Carpathian forests (Bondarenko, 2011).

The end of XX – beginning of XXI century, is characterized by a steady tendency to reduce the number of most valuable hunting species of animals. 217.1 thousands of heads of ungulates animals, 1716.6 thousands of fur animals and 10388.2 thousands of birds were registered in hunting grounds of Ukraine (http://www.ukrstat.gov.ua/druk/publicat/kat_u/publ7_u.htm). The main indicators of the total number of wild game animals is presented in Table 3 and the dynamics of their extraction are shown the Figure 1.

Table 3: The number of hunting animals and harvested hunting animals in Ukraine, thousands of heads

Years	Number of hunting animals			Number of harvested (removed) hunting animals		
	Ungulates animals	Fur animals	Birds	Ungulates animals	Fur animals	Birds
2011	244,4	2189,2	10592,0	13,3	288,9	1914,0
2012	239,6	2070,8	10523,5	12,8	273,7	1827,7
2013	238,3	1944,2	10202,9	12,8	244,8	1912,7
2014 *	233,6	1747,5	9169,3	13,9	207,6	1479,1
2015 *	231,3	1705,5	9756,2	18,6	198,8	1513,0
2016 *	220,2	1675,4	9888,4	14,7	211,7	1595,3
2017 *	221,0	1728,1	9982,0	13,3	219,0	1627,6
2018 *	217,1	1716,6	10388,2	13,0	213,6	1702,5

* *Data exclude the temporarily occupied territory of the Autonomous Republic of Crimea, the city of Sevastopol and a part of temporarily occupied territories in the Donetsk and Luhansk regions.*

Despite the implementation of some biotechnical and organizational measures, the number of certain types of hunting animals remains without significant changes, the volumes of rendered services by hunting farms is not enough for the fulfilling the needs of the hunters market. Ukraine stands on the one of the last places in Europe in terms of production of hunting products, but has an extremely high potential for the development of hunting tourism, since the density of wild animals in hunting grounds is significantly lower than scientifically based indicators of their optimal capacity. If we compare the indicators of the number and, especially, the extraction of game in Ukraine with the indicators of developed countries, we can state that these indicators are tens, and sometimes hundreds of times larger.

Fig. 1: Dynamics of extraction of hunting animals in relation to their total number

We must admit, that large ecological and economic losses of hunting farms are caused by poaching, which slow down development of hunting tourism. In European countries poaching is considered as a major crime. The detection of cases of violation of the legislation in the field of hunting industry and hunting in Ukraine remains at a rather low level, namely poaching has become a common and

everyday occurrence and doesn't encounter any particular resistance from both law enforcement and society.

As you can see, the development of hunting tourism mainly depends on the effectiveness of hunting. In Ukraine, hunting industry is unprofitable and needs fundamental changes. The ineffective using of the potential hunting grounds, which are not able even for the simple reproduction of wild animals, confirms the neediness of a new model of hunting management that would function on the basis of a market economy.

These and many others organizational and legal problems create obstacles for the successful development of hunting tourism in Ukraine, as it falls into the sphere of regulation of a large number of legal acts and administrative structures.

Despite the existence of a sufficient number of problems, which require immediate solution, hunting tourism has a number of advantages and incentives for Ukraine and especially for the rural population, in particular:

- conservation of biodiversity and natural ecosystems;
- income generation and job creation in poor and deprived regions;
- replacement of potentially devastating forms of nature management on the management of hunting fauna resources, using of which is less environmentally harmful form of nature management;
- cost-effective using of unsustainable natural resources for agriculture or conventional tourism;
- raising the environmental awareness of the local population about the value of the fauna, as a hunting tourism is associated with harm, problems and costs;
- decreasing the level of poaching, thanks to the joint efforts of all sides interested in obtaining incomes from hunting tourism.

Conclusions

Leaving aside the controversy, hunting tourism remains a little investigated, but a perspective area of tourism activity. Despite the great popularity and level of hunting tourism development in the European Union countries, Ukraine possesses a wide array of competitive advantages that can be effectively used in the conditions of modern European integration changes. The problems of the Ukrainian services market in the field of hunting tourism are manifested in the imperfection of environmental protection, hunting and tourism regulatory and law enforcement, as well as in the absence of a clear state policy in this area. For developing effective legal rules in the field of hunting tourism, it is necessary to consider an international experience and historical features of national hunting, taking into account also the principles of sustainable ecologically balanced development.

As a result of our research the basic principles on which hunting tourism should be based are formed, in particular: the principle of preservation of biodiversity in the animal and plant life of hunting grounds; the principle of sustainable ecologically balanced of using the hunting resources for tourism purposes; the principle of observance of ethical norms and national traditions in the process of organizing hunting tourism; the principle of preservation of the cultural heritage in the areas, which are reserved for the organization of hunting tourism; the principle of promoting the development of alternative types of hunting tourism; the principle of integration of hunting tourism with hunting, forestry and agrarian enterprises; the principle of state support in the development of hunting tourism.

The prospects for the further investigations are in the creation of economic instruments and incentives for the effective development of hunting tourism on a market basis in the process of decentralization of the Ukrainian economy.

The Effectiveness of Logistic Processes in Military Supply Chains

Tomasz JAŁOWIEC

Dariusz GRALA

War Studies University, Faculty of Management and Command, Warsaw, Poland,

t.jalowiec@akademia.mil.pl

d.grala@akademia.mil.pl

Abstract

Armed forces functioning in contemporary conditions require effective and efficient logistic support. Both during the implementation of tasks in garrisons as well as during peace support operations or a crisis response operation, forces must be supplied at the right time with materiel in the right quantity and quality and at the right price. Modern military supply chains consist of many elements, both military and civil, implementing logistic processes to meet the needs of the forces and provide them conditions for their tasks. The article, based on performed researches has identified the specifics of military supply chains and characterized the key dimensions of their effectiveness. On the basis of the conducted research categorization and priorities of effectiveness in the military logistic system were determined.

Keywords: Effectiveness, Supply Chain, Armed Forces, Logistic Support, Military Logistics

Introduction

Proper functioning of the armed forces and the level of their implementation of training and operational tasks at the required level is the result of many factors. Of these, operational, technological, social and economic factors certainly play a key role. In addition, it should be noted that the military logistic system responsible for meeting the needs of troops during peace, crisis and war has a major impact on all areas of the operation of the armed forces.

In the process of perfecting the functioning of the logistics system of the armed forces, it is necessary to guarantee the conditions for a comprehensive measurement and a reliable evaluation of the implemented solutions. In the past, the reform of the military logistics support system did not always have a clearly defined purpose, and the nature of the changes prevented them from being transparently verified.

Today, according to doctrinal documents, the main task for all elements of the military logistics system is to ensure maximum effectiveness of logistic support in national, allied and multinational operations. Among the twelve principles (shared responsibility, competence, priority of operations, cooperation, coordination, support, sufficiency, effectiveness, flexibility, transparency of the logistics situation, simplicity, multinationality) (*Bi-SC Joint Operational Guidelines for Logistics*, 2013, p. 2-1), according to which the logistic support of troops in national, allied and multinational operations is currently being implemented, one of the key roles is played by the principle of effectiveness, which states that Logistic resources and capabilities should be used effectively and efficiently. Requirements must be identified and addressed in a timely manner to optimize the efficient provision and effective use of such resources and capabilities (*AJP 4B*, 2018, p. 1-2), what could be understand that:

- the logistic resources collected in the area of operations should be optimized for operational requirements and used in the most efficient and economic manner;
- in order to ensure the continuity of logistic support, the logistic needs should be identified and secured on time;
- cost-effective solutions should be used when implementing logistic support tasks.

The above-mentioned general range of the effectiveness of military logistic processes, determined mainly on the theoretical level, is not entirely satisfactory in practical terms. This is primarily due to the specifics of the military environment, where an economic approach (cost minimization) may not always be a superior value. In many cases, other dimensions of effectiveness (operational, systemic, substantive, etc.) play a dominant role as a guarantee of achieving training and operational objectives by military subunits and units. It should be emphasized that, for example, the increased effectiveness of logistic support of troops assigned to participation in modern operations is achieved primarily through (*Logistic doctrine*, 2014, p. 17-18):

- separation of forces and resources and the support of the Multinational Integrated Logistics Unit (MILU), the Multinational Integrated Medical Unit (MIMU), the Multinational Logistic Unit (MLU), the Multinational Medical Unit (MMU); Multinational Logistics Command (Maritime) - MNLC (M), Joint Logistics Support Group (JLSG);
- taking on the role or using the support of: Host Nation – HN, Logistic Lead Nation – LLN, Logistic Role Specialist Nation - LRSN;
- using support from NATO agencies competent to support allied actions;
- using Contractor Support to Operations (CSO);
- using support from other countries.

In logistic activities carried out to the benefit of the armed forces in all conditions of the state, the most important objective is to guarantee the conditions for carrying out training, operational and combat tasks at the expected level. Achievement of this status is largely determined by the human and material resources available to the armed forces, or those which the armed forces are able to gain. Skilful management of resources does not apply solely to the civilian sphere, but rather to the military environment. The armed forces have specific human and material resources that serve to train and fight. They are used in a specific way, appropriate to the nature and scale of their tasks. It is worth emphasizing that housekeeping in management theory is primarily the well-thought-out (calculated) use of limited resources (so-called rational management, as opposed to customary and traditional) to achieve various competing goals.

The aim of the paper is identification and assessment of key factors and levels of effectiveness of contemporary military supply chains. The material used theoretical studies and the results of empirical studies carried out using expert studies. Supplementing the theoretical research with empirical research allowed to general conclusions indicating the essence of the problem.

Theoretical Aspects of The Effectiveness in Military Logistic Systems

One of the key words in modern management is undoubtedly the term "effectiveness". In the literature of the subject it is defined ambiguously due to its multidimensional nature. In addition, the problem with unambiguous definition of the term "effectiveness" is related to the existence of many synonyms of this term, especially in English-language literature (eg effectiveness, efficiency, efficacy, performance). It is also worth noting that the perception of effectiveness is also dependent directly on the environment in which it is determined. It is under-stood slightly different by economists than managers, or politicians (Jałowiec, 2017, p. 24).

In the theory of organization and management, the effectiveness is considered as the basic condition for the functioning of the entity on the market. There is often used the term economic effectiveness, in which the financial perspective is only one of the planes, in addition to operational, market, dynamic and organizational effectiveness (Kachniarz, 2012, p. 61). It is worth noting, however, that in the traditional view of management sciences (represented by, among others, Frederick W. Taylor and Frank and Lillian Gilberth), the term effectiveness primarily means efforts focused on cost reduction, including reduction of loss and waste of production factors (materials, labour force), as well as activities related to the improvement of technology and better use of time factor (which is achieved mainly through detailed analysis of the system of individual tasks and their components). Consequently, the ultimate goal of the organization tasks is to reduce the consumption of production factors at the input of the production system or to contribute to the increase in results at the output – or to achieve both

goals at the same time . In alternative holistic terms, effectiveness is perceived as a natural feature of an organization. The main attention is directed to achieving goals, assuming that, under favourable conditions, a flexible adjustment effect of rationalization of action will be achieved. It is worth to emphasize a recommendation of not attaching too much importance to enforcing only the effectiveness of individual parts, but creating conditions conducive to the effectiveness of the organization as a whole (M. Witzem, 2002, p. 38–47).

In the literature on the subject there exists many definitions and interpretations of the term "effectiveness" (Blaik, 2015, p. 15–16). In further deliberations, effectiveness will be treated as an expression of the ratio of the obtained effects to the expenditures incurred. Such a general approach allows us to refer it to many planes of contemporary organizations, giving an image of the correctness of its functioning in both a partial and a whole sense. It should be also noted that the effectiveness applies to each case where any expenditures have been incurred, which has resulted in effects, whether they were intended or not. Regardless of the present context of the term "effectiveness", two terms: effects and expenditures play a key role in it.

In the literature on organization and management theory, effects are defined as the result of a deliberate, but not necessarily effective action, deviating more or less from accepted assumptions (expectations, effects of undertaken actions) (Matwiejczuk, 2006, p. 82).

The measurement of effectiveness is a prerequisite for describing and evaluating the state of functioning and development opportunities of various types of organizations, including hierarchical organizations whose specific form is the armed forces. The studies on effectiveness involve a great number of areas that follows directly from the nature of the activity of a particular entity. This certainly implies the need for an interdisciplinary approach to defining and measuring efficiency. This approach is of particular importance today, in times of high dynamics of changes, both within the majority of entities and in their surroundings. It must be borne in mind that effectiveness, which is the basic concept in economics and management, is a measure of activity not only at the level of the whole organization but also in its individual areas.

Defining and measuring logistics effectiveness in the armed forces, due to the specificity of the military sector, and the multiplicity and complexity of the factors affecting the functioning of the military logistics system, are extremely difficult but not impossible tasks. The difficulties encountered by many military logisticians in measuring the effectiveness of tasks carried out as part of the logistic support of troops were the reason for the study of theoretical and practical problems of measuring logistics effectiveness in the armed forces.

In the process of integrated management of elements of the military logistics system, precise goal setting is not only the first task in the planning process of logistic support of troops, but is also a prerequisite for their effective operation.

The clear definition of what we should do (achieve), under certain conditions, and how to select resources, is the basis for defining, measuring and evaluating effectiveness in the military logistics system. It should be emphasized that the special importance in the complex process of determining the effectiveness in the analyzed area is applied to its determination on many different levels. The limitation of effectiveness in the military logistics system only to the economic level (economy) distorts its dimension in a specific military environment in many respects (Jałowiec, 2017, p. 34).

In view of the general theory of effectiveness of processes in the organization, it seems reasonable to consider effectiveness in the military logistics system at least on several levels, ie operational, systemic, material, technological, economic, allied, dynamic (evolutional), social and ecological (Fig. 1.1).

Fig. 1: Essential levels of effectiveness in the military logistics system

Taking into account the specificities of the armed forces and their role in ensuring the security of the state, as well as the nature of the logistic support tasks of the armed forces, the **operational level** should be considered as a priority effectiveness level in the military logistics system. It refers to logistic conditions that guarantee the execution of training, operational or combat tasks by military subunits and units at the expected level.

The **systemic level**, directly associated with the operational level, refers to the state of the organic logistic potential as a system or its subsystems with respect to the long-term goals of the national and allied forces.

The **material level** refers to the genotype function of the logistics system in the armed forces - the effectiveness of the military logistics system is expressed in satisfaction of the specific logistics needs of troops. In this area, it is important to refer the scope of tasks to the tactical, operational and strategic level of the logistics system of the armed forces.

The **technological level** appears very important today. It refers to analyses in terms of the number, the degree of modernity necessary to accomplish logistic tasks of hardware units, equipment, resources. Very important in this respect is the issue of the implementation of innovative solutions in the military sector which are becoming a "driving force" for the development of many armies in the world.

The **dynamic (development) level** is connected with the ability to provide new/innovative logistic services and acquire new skills. Today, innovation is a measure of the level of modernity in societies, economies and the armed forces.

Another area of effectiveness in the military logistics system is the **economic level**. In army, unlike the civilian sector, it should not play a key role in assessing the effectiveness of the tasks. Nevertheless, in today's conditions of functioning of the armed forces which in the economic dimension are one of the subjects of the national economy, it is worth to evaluate the economy of the tasks. In relation to the military logistics system, the so-called "logistics costs" are of particular importance. It should be recalled that the costs, as defined, are the specific expenditures (Tkaczuk, 2001, p. 101), expressed in monetary units, incurred by specific entities, while each expenditure in the general economic sense is any cash outflow.

In the contemporary conditions of the functioning of the Polish Armed Forces, the **allied level** will be of incredible importance in the evaluation of the effectiveness of the military logistic system. It refers to relations between the armed forces and other entities in the framework of partnership or alliance. Its measurable effect in the military logistics system is the level of the so-called logistic interoperability. Interoperability is a feature of a product or a system whose inter-faces work in full compatibility with other products or systems that already exist or may exist in the future, without any access limitation or limited implementation possibilities. Improved logistic interoperability is achieved through established synergies that are a prerequisite for effective, integrated multinational logistics, which requires the use of standard practices, procedures, techniques and common language.

In the light of the deliberations carried out, the particular attention is paid to the fact that the use of the armed forces for providing civilian authorities with support in order to ensure the security of citizens of the state is one of the essential elements of national security organization. In this context, it is worth pointing to the **social level** of the effectiveness of the military logistics system. It refers to the attainment of social objectives by taking into account the social costs of their implementation.

The 21st century brings the growing importance of ecology in the activities of many organizations, including the armed forces. This implies: paying particular attention to the impact of military activities on the environment, and the actions undertaken in this regard are referred to the **ecological level** in the military logistics system.

The indicated areas may serve as a starting point for a large-scale activity aimed at credible (complex) parameterization of logistic tasks in favor of troops during their day-to-day operations or during the implementation of training, operational or combat tasks. They may also be used for evaluation of the effectiveness of the military supply chains.

Current dimensions of military supply chains

Correct implementation of the tasks assigned to the armed forces in all functioning conditions of the state (peace, crisis, war) requires the delivery of a wide range of material supplies. Proper realization of tasks that are imposed today on the armed forces requires providing them with a wide range of material means. Their scale and scope depend primarily on the level of involvement of the Armed Forces to provide the security and territorial integrity of the country, the European Union (EU) and the Euro-Atlantic area (NATO Alliance), as well as keeping peace and stability on the international arena. The material needs of soldiers, units and military institutions are fulfilled by the material subsystem of the military logistic system.

The material subsystem is intended for the planning, organization and implementation of material support projects, including the provision of services, and consists in providing all supplies to the troops on a regular basis – in cooperation with other subsystems of the logistics system. In carrying out the supply tasks, both the use of military and civilian resources are taken into account.

The basic goal of the material subsystem is to meet the needs of troops in the required means of supply and specialized material services, in a place and time that enables the armed forces to function properly, during peace, crisis and war. Material supply tasks are carried out according to the possibilities resulting from structures at all organizational levels for armed forces (tactical, operational and strategic) (Zabezpieczenie materiałowe, 2012, p. 8). In the Polish Armed Forces the elements of material subsystem responsible for direct supply of military units are Regional Logistic Bases (RLB) and Garrison Logistic Units (GLU) and their subordinated units. These is another subsystem: Polish Armed Forces Territorial Logistic Support System (Gromek, 2018, p. 14.).

Means of supply can be delivered by transport from the superior level or can be picked up by the user from the indicated sources (*Logistic doctrine*, 2014, p. 103-104):

- **during peace time and crisis** the supplies are realized in the supply chain of material subsystem, according to the supply plan (distribution board) or *ad hoc* based on reported needs;
- **during war time** the supplies are carried out from stocks gathered at the tactical level, then from stationary depots of a stationary logistic unit responsible for purchase (RLB, GLU), maintaining

and distributing the supply means and performing maintenance tasks in the regional area of responsibility (operating stocks and strategic stocks), as well as from the national economy.

It should be pointed out that in the Polish Armed Forces there are five classes of supply, similarly to NATO: Class I - items of subsistence, e.g. food and forage, which are consumed by personnel or animals at an approximately uniform rate, irrespective of local changes in combat or terrain conditions; Class II - supplies for which allowances are established by tables of organization and equipment, e.g. clothing, weapons, tools, spare parts, vehicles; Class III - petroleum, oil and lubricants (POL) for all purposes, except for operating aircraft or for use in weapons such as flamethrowers, e.g. gasoline, fuel oil, greases, coal and coke. Class IIIa - aviation fuel and lubricants); Class IV - supplies for which initial issue allowances are not prescribed by approved issue tables. Normally includes fortification and construction materials, as well as additional quantities of items identical to those authorized for initial issue (Class II) such as additional vehicles; Class V - Ammunition, explosives and chemical agents of all types (NATO Logistic Handbook, 2012).

The basic requirement for a military logistic system is to secure the needs of the armed forces in the material, technical, transport and movement of troops, military and medical infrastructure during peace, crisis and war. According to the theory and practice of management, the proper organization (including organizational structures, division of competences, etc.) directly affects the proper functioning of each complex mechanism, which is undoubtedly the military logistics system. It is worth noting that its operation is subject to continuous improvement in recent years in accordance with the directions of transformation developed at the central level based on national and allied requirements and experience.

In order to properly implement material security tasks, military logistic chains are created, which in the subjective dimension should be understood as a set of cooperating, structural internal and external elements that meet the logistics needs of troops by providing them with the goods necessary to carry out training, operational and combat tasks. The conducted research indicates that they are characterized by a different specificity than supply chains functioning in a civil environment. Table 2.1 presents key parameters characterizing contemporary military supply chains.

Table 2: Key parameters characterizing contemporary military supply chains

PARAMETER	CHARACTERISTIC
AIM	unambiguously defined - securing the material needs of the troops to the extent that guarantees their current operation, and, above all, the implementation of training, operational and combat tasks for military units and institutions
RESOURCES	repeatedly insufficient; difficulties in obtaining them in the area of operations; very difficult to forecast due to the volatility of the demand and the formalized, extended in time process of their demand
EXTENT MEET OF NEEDS	wide; all means of supply conditioning the correct implementation of training, operational and combat tasks; repeatedly difficult long-term planning regarding the place, type and size of necessary material resources
ENTITIES OF REALIZING THE TASKS	military forces supported by civilian entities; national forces supported by allied and multinational potential
TIME OF OPERATION	time pressure; repeatedly a very short time resulting from dynamic changes in the course of operations and operations
INFORMATION	a significant part of the secret; often insufficient, inaccurate; difficult of using IT systems
CONFIGURATION AND COORDINATION OF SUPPLY CHAIN	complex; difficult to monitor as a result of the presence of many variables and unknowns at every stage of delivery for the troops; high dynamics of changes during the course; difficult coordination due to the large diversity of individual chains
COOPERATION IN THE SUPPLY CHAIN	formalized, regulated by many external and internal rules and procedures

PARAMETER	CHARACTERISTIC
FINANCING ACTIONS	country budget
ORIENTATION OF THE SUPPLY CHAIN	clear priorities; focus on training tasks and operational in peacetime, operational and combat during a crisis or war;
CONTROL AND EVALUATION OF EFFECTIVENESS	Limited; limited possibilities of control and assessment of effectiveness resulting to a large extent from many nonparametric characteristics of the activity of the armed forces

Referring to the specificity of military supply chains included in table 2.1, it should be noted that it is fundamentally different from supply chains operating in the civil sphere. This is mainly due to the nature of the tasks carried out by the Polish Armed Forces and their role in the defence system of the state. In this regard, it should be emphasized that for example the Polish Armed Forces of the maintain their readiness to carry out tasks related to (Jasińska, 2012, p. 90-91):

- Guaranteeing state defence and opposing aggression (defence and protection of the inviolability of Polish borders, participation in anti-terrorism activities in the country and beyond, participation in solving a local or regional armed conflict in the area of NATO responsibility or outside it, participating in a defence operation outside the country in accordance with allied commitments under Article 5 of the North Atlantic Treaty, conducting a strategic defence operation on the territory of the Republic of Poland).
- Participation in the process of stabilizing the international situation and in crisis and humanitarian response operations (participation in peace and crisis response operations conducted by NATO, EU, UN and other operations under international agreements, participation in humanitarian operations conducted by international, governmental and other organizations military cooperation in the area of development and application of confidence and security building measures.
- Supporting internal security and helping the public (monitoring and protection of airspace, supporting land and territorial water protection, conducting reconnaissance and intelligence activities, monitoring of radioactive, chemical and biological contamination in the territory of the country, cleaning the area of explosives and dangerous objects of military origin conducting search and rescue activities, assistance to state authorities, public administration and the public in responding to threats).

It should be noted that today's military supply chains are undergoing major transformations. Due to the dynamics of changes taking place within the armed forces as well as in their surroundings, it is necessary to constantly improve them in terms of improving the relation of the obtained effects to the incurred expenditures. This is particularly important in the international cooperation of armed forces during the implementation of training and operational tasks, which changes the nature of contemporary supply chains from national to multinational.

Management of military supply chains

Supply chain management (SCM) is a broadened management focus that considers the combined impact of all the companies involved in the production of goods and services, from suppliers to manufacturers to wholesalers to retailers to final consumers and beyond to disposal and recycling. The goal of SCM is to seamlessly link all of the activities responsible for bringing goods and services to the market and efficiently manage the flow from start to finish. Basically, no matter how many companies are involved, this process should take place as though there were only one, very well managed company performing the activities. All companies in the supply chain can benefit from sharing information and working closely with the other companies that are within their supply chain. SCM affects all aspects of business. Accounting, inventory control, marketing and ultimately a company’s revenues are all intimately linked to and dependent upon efficient management of their supply chain. Supply chains are systems with a flow of goods from supplier to consumer, made up of

many facilities where communication and intensive coordination are a necessity. As with any system, one malfunctioning node can have major effects on all congruent and subsequent actions along the chain. This being said, supply chain management is perhaps the one area of business where creativity and flexibility are most necessary (Tae, Young, Rajath, 2012, p. 64-65).

The relationships described above are also characteristic for military supply chains. The extremely broad spectrum of tasks carried out by modern armed forces in all states of the state's functioning (peace, crisis, war) directly translates into the structure of military supply chains, each of which may have a different degree of complexity. It results mainly from the functional structure of the military logistic system, including directly from: the number of levels, the type of relationships being formed, the diversity of the entities making up the chain, and in many cases the necessity to involve additional participants, including civil enterprises. Management of such a complex organism is an element of the system of managing the entire armed forces. In this dimension, the management of military supply chains is understood as integrated planning, preparation and use of supplies, as well as the provision of specialized services to keep troops in proper combat readiness in their area as well as functioning of troops performing tasks outside the country. These activities are carried out in a multidimensional way: design and development work, acquisition, storage, transport, distribution, as well as the withdrawal of supplies; transport of personnel and means of supply; acquisition, construction, operation and development work in the field of military infrastructure; acquisition and provision of services; medical logistics (the process of acquiring, collecting, distributing, maintaining and rotating medicinal products, medical devices and medical equipment in order to ensure optimal level of health services during peace, crisis and war).

Figure 2: Dependencies in the supply chain (Dulinger, 2002).

Management of military supply chains is directly related to key decisions concerning logistics, which are (Skoglund, 2012, p. 23):

- The basic supply decision: Where to get the needed products?;
- The stockpile decision: What and how much to stockpile and what to postpone until needed?
- The balance decision between being efficient or effective: How flexible the supply chain needs to be to meet changes in the demands.
- The sourcing decision: How to source the needed products?

In an open systems perspective, one acknowledges that supply chain output depends on all participants directly or indirectly controlling activities and resources necessary for the supply chain (Tore, 2018, p. 512-513).

One of the supply chain strategy is SCM efficiency aimed at creating the highest possible cost efficiency by eliminating non-value added activities, pursuing economies of scale, and optimizing capacity utilization in production and distribution (Parlier, 2011, p. 22).

The big challenge for managing military logistic chains is a specific approach to the perception of effectiveness in the military sector. Characteristic for processes and activities in the military environment is a very wide assessment of effectiveness, in which the economic plane is not a priority. It gives way to other dimensions of effectiveness, determining the fulfillment of conditions for the proper implementation of tasks by the army.

Evaluation of Effectiveness of Military Supply Chains

There are many methods for measuring the effectiveness of supply chains described in the literature. As a supply chain performance measurement (SCPM) (Agami, Saleh, Rasmy, 2012). However, the specificity of MSC described above requires the definition of a new measurement methodology appropriate for their processes.

In order to solve the problem defined in the introduction, apart from theoretical studies, empirical research proved necessary. For this purpose, the method of a diagnostic poll conducted using the expert interview method was used. The research covered 23 experts who are professionally responsible for the functioning of military supply chains at various levels of the Polish Armed Forces logistics system.

As a result of the research, research material was obtained containing expert opinions on planes, which in the opinion of the investigated officers should be a priority in assessing the effectiveness of military supply chains. Obtained expert positions of experts can be generalized for the purposes of this article, indicating that in the opinion of the majority of experts, this hierarchy should look as follows for the three most important areas: operational, systemic, financial.

As the most important level of effectiveness in the military chains, the respondents unanimously recognized the operational plane, referring it directly to the logistic conditions guaranteeing the performance of a training, operational or combat task by sub-units and military units at the level expected from them. Such a position is part of the Strategy for the Development of the National Security System of the Republic of Poland 2022, according to which the armed forces should have operational capabilities for autonomous operation in any fighting environment. The main determinant of operational needs is the possession of weapons and military equipment capable of detecting, identifying, tracking and destroying the opponent's resources. Achieving the assumed operational abilities while providing the necessary (optimal) conditions for survival on the battlefield requires a systemic approach, reflected in five basic systems: command, reconnaissance, destruction, survival and protection of troops, and logistic security of operations. Operational capacity is understood in this case as a potential efficiency, the entity's ability resulting from its characteristics and properties, allowing action to be taken to achieve the desired effects. The functional components of operational capabilities are: doctrine, organization, training, military equipment, personnel resources, leadership, infrastructure and interoperability. With regard to the Polish Armed Forces, operational capabilities define the possibilities of accomplishing their missions and tasks.

The systemic plane directly related to the operational plane has been referred to the status of the organic logistic potential as a system or its subsystems in relation to the long-term goals of the operation of the armed forces in the national and allied dimension and the so-called characteristics of potential systems, such as innovation - is the expression of "system health". It should be noted that the functional system of the Polish Armed Forces' logistics is dynamically evolving in accordance with the adopted development directions, allied requirements and changes in the tasks and organizational structures of the armed forces. Expectations towards him boil down to being characterized by: mobility, flexibility, simplicity and the ability to respond quickly to the changing operational situation. In addition, according to the doctrinal records, the manner of its organization should provide the army with combat capability and the ability to maintain it, and thus the conditions to perform tasks during peace, crisis and war. In this dimension, organizational development of the armed forces logistics system against

the background of the development of the entire army, improvement of relations between all elements of the system and cooperating entities of other functional systems, as well as improvement of the efficiency of the management system of all links of the military supply chains can be considered as crucial.

Another, included in the three most important areas of effectiveness of military supply chains is the economic plane. In the military environment, unlike in the civil sector, it should not, in experts' opinion, play a priority role in assessing the effectiveness of tasks. In their opinion, such a position results directly from the most important task for the Polish Armed Forces in accordance with art. 26. The Constitution of the Republic of Poland is to protect the independence of the state and the indivisibility of its territory and to ensure the security and inviolability of its borders. Nevertheless, the respondents indicated that in the contemporary conditions of the functioning of armed forces, which in the economic dimension are one of the entities of the national economy, it is always worth assessing the economics of the tasks. In this respect, in the case of military supply chains, a special role belongs to the so-called logistics costs. It should be emphasized that from the perspective of public institutions (including in the entire extent of the Polish Armed Forces), expenditures are one of the main instruments of the country's economic and social policy in the phase of distribution of financial resources subject to redistribution made through public finance systems, primarily budget systems. The issues of efficiency measurement outlined by experts in the military logistic system at the economic level (economy) clearly indicate the multidimensional character of this extremely complex phenomenon and the great difficulties in defining and calculating it, which results from the specificity of the economic account in the military sector. In addition, during the research it was repeatedly pointed out that the nature of the tasks faced by the armed forces does not allow to include their dimension and, consequently, to assess them only in economic terms.

In conclusion, the empirical part of the article should be noted that measuring the effectiveness of military supply chains, in the absence of formal methodologies for its assessment, is still more discretionary. The opinions presented in this part of the material constitute only a part of this extremely complex and multifaceted phenomenon, and the presented views can only serve as a contribution to further, extended research. It should be noted, however, that the measurement of the effectiveness of military supply chains is a necessary condition, in many aspects, to improve the process of the physical flow of goods that guarantees the implementation of a wide range of tasks by armed forces during peace, crisis and war.

Conclusions

The results obtained in the research process authorize the following general conclusions.

Firstly. On the one hand, military supply chains show some features similar to supply chains from the civil sphere, and on the other hand they have a number of distinctive features directly resulting from the specificity and nature of tasks assigned to the armed forces during peace, crisis and war.

Secondly. The effectiveness of military supply chains is determined largely by the dynamics and a wide range of tasks carried out by the armed forces in all states of the state's functioning.

Thirdly. The most important plane in measuring the effectiveness of military supply chains seems to be the operational level related to the military sector to the logistic conditions guaranteeing the performance of a training, operational or combat task by sub-units and military units at the level expected from them.

Fourthly. There is a real need to develop in the military sector a methodology for assessing the effectiveness of military supply chains, which will be fully adapted to the specifics of the military environment.

The material outlines only selected aspects of the effectiveness of military supply chains. The adopted restrictions made it possible to achieve the assumed goal, at the same time indicating the directions of further research.

Summing up, with all the firmness, attention should be paid to the need to continue scientific research aimed at solving the problems outlined in the paper. Such actions may contribute to the improvement of the effectiveness of military supply chains, and thus translate into the level of training, operational and combat tasks by military units and institutions.

Abstract

India, the rising economic power, and the second largest country in the world in terms of population, is new to the startup scene. As of 2018, out of 29 states and 7 Union Territories, 21 have created a startup policy to support the entrepreneurial ecosystem and attract more youngsters to take up entrepreneurship. Kerala, in the southern part of the country, is the first state to create its own startup policy in the year 2014. According to the Kerala startup ecosystem report (2019), the state is home to more than 2200 startups and has raised $ 44 million as funding in the year 2019. The purpose of this study is to determine the factors affecting the profitability of the startups in Kerala, India. A personal interview with the founders of 201 startup companies were adopted to collect required information. Following Lussier Model an exploratory model was introduced. Using logistics regression analysis, it is found that the model ($p = 0.000$) is a significant predictor of profitability of the business. The model accurately predicted 74 per cent of the surveyed firms and explained 47 percent of the variance of contributing factors to profitability of the business.

Keywords: Entrepreneurship, Startups, Profitability, Prediction Model.

Introduction

The startup wave has hit almost all parts of the world. According to the latest Global startup ecosystem report (2019), the startup sector across the globe has contributed $2.8 trillion in the period between 2016 -2018, which is double than what it was 5 years ago. Recognizing the contribution made by the sector to the economic growth and the example set by Silicon Valley in the USA, many countries have undertaken reform measures to create a startup ecosystem. India, the rising economic power, and the second largest country in the world in terms of population, is new to the scene. Even though the concept of entrepreneurship was not new to the country, the years 2005-2010 witnessed the startup boom and the birth of the current unicorns from India. Later, the Startup India, Make in India initiatives of the central government have sowed the seeds to create a vibrant startup ecosystem in the country. According to the Ministry of Commerce and Industry, a startup in India is any company which was incorporated in India in less than 10 years and has an annual turnover of less than 100 crore. The state government has caught up with the central government in setting up policy measures to foster the startup culture in the region. As of 2019, out of 29 states and 7 Union Territories, 21 have created a startup policy to support the entrepreneurial ecosystem and attract more youngsters to take up entrepreneurship. Kerala is one such state in the southern part of the country to create its own startup policy in the year 2014. The government has created a nodal agency, Kerala Startup Mission (KSUM) to coordinate the entrepreneurship development activities of the state. The state has also set apart 1 per cent of its annual budget for entrepreneurship development activities. Since then, the state has witnessed an increase in the number of startups incorporated.

Startups In Kerala

Kerala was ranked as the top performer of the country in the State Startup Ranking Exercise 2018 by the Department of Industrial Policy and Promotion, Ministry of Commerce and Industry, Government of India. According to the Kerala Startup Ecosystem Report (2019), the state is home to more than 2200 startups and has raised $44 million as funding in the year 2018-19. The state has also set up 40+ incubators and 10 accelerators to support the startups in the state. This has led to a reverse migration of skilled entrepreneurs to Kerala. The government has earmarked 1 per cent of its annual budget for entrepreneurship development activities of the state.

The government through its entrepreneurship development programs are trying to convert job seekers to job creators. The state provides infrastructural support to startups through incubators in tier II cities. This helps in creating more enterprises and job opportunities for skilled youngsters in tier II cities. This could be a revolution which can change the face of the state gradually. The number of startups registered in the state has increased from 299 in 2015 to 2200+ in 2019.The rapid upsurge, in the number of startups being registered, can be due to the high human development index, entrepreneurial quality possessed by the founders and measures taken by the state government. A few of the startups are already acquired by corporates from other countries. Many of them have scaled up and become profitable within a few years of incorporation. Creating and supporting profitable ventures will contribute to the economic development of the state. Attracting youngsters to entrepreneurship also helps in increasing the job opportunities available in the state. There are a few literature available related to the startups in Kerala. This was the motivation behind doing a research on identifying the factors impacting the profitability of high- tech startup ventures in Kerala, India. Given the importance of startups and the boom in the number of startups registered in the state, research on the factors impacting the profitability of startups will benefit policymakers, budding entrepreneurs, venture capitalists and other stakeholders. Understanding the factors impacting the profitability of the firm helps the prospective entrepreneurs in taking planned risk before starting the business.

Theoretical Background

A startup goes through various stages in the life cycle of the business. The entrepreneurs have to prioritize and give importance to factors that make the business into a scalable venture. Picken (2017) has identified eight steps – "Setting a direction and maintaining focus, Positioning products/services in an expanded market, maintaining a customer/market focus, building an organization and management team, developing effective processes and infrastructures, building financial capability, Developing and nurturing a culture, Managing risks and vulnerabilities"- to transform a startup into a scalable business. To analyse the factors affecting the profitability of a business many researchers has introduced both financial and non-financial methods. Researchers measure the performance and critical success factors of a business using Return on Investment, sales, profit earned etc. But it is difficult to measure the performance of a startup business using these financial outcomes as the data are widely not available. Apart from that, many researchers have criticized the usage of financial models as they turned out poor predictors of success or failure (Gilbert et al, 1990).

Cherukara (2015) has identified the factors leading to entrepreneurial success in Kerala. Demographic factors like formal education and location of the business has an effect on the success of an enterprise. He found that the capital invested in the business influences the organisational success. The competitive aggressiveness of the entrepreneur was also found to be contributing factor to the success of a business. Along with the internal factors, external factors like employee loyalty, availability of finance and dynamic market conditions also influences the success of an enterprise in Kerala. The state provides entrepreneurship development programs to educate and promote entrepreneurship. Prasanth (2018) observed that entrepreneurship development programs are helping the entrepreneurs to develop the personal factors like marketing skills, financial literacy etc. Philip (2008) concluded in his study, educational qualification, size of the enterprise, growth phase and R&D capability influences the performance of enterprises in Kerala. Saleem (2012) identified in his study, experience, business profile, investment and culture influence the profitability of the small business. Broers (2016) identified organizational and operational principles that classifies fast growing startups. Staffing, access to technology and asset management were found to be characteristics of a fast growing startup. Network,

managerial skill, experience, and expertise possessed by the entrepreneur contributes to the profitability and growth of a startup enterprise (Huang et al, 2012).

Lussier (1995) has proposed a success Versus failure prediction model to test whether successful and failed business start with equal resources. He identified 20 journal articles and examined the variables considered by the authors, as the factors contributing to the success or failure of a firm. He identified 15 major variables, after comparing the articles, which includes Capital, Record keeping and financial control, Industry experience, Management experience, Business Planning, Professional advice, Educational qualification, Employee retention, Product/ service timing, Economic timing, Age of the entrepreneur, Number of partners, parents owning business, ethnic minority and Marketing skills possessed by the entrepreneur. He found that there was significant difference among successful and failed enterprises for the variables planning, professional advice, education and staffing. Lussier (1996), then used the model to predict the success or failure of startup business in the retail industry. It was observed that the model could explain 67 per cent of the variance in the outcome variable. Later Lussier and Corman (1996), used the same model to predict the success or failure for entrepreneurs with 0-10 employees. The model showed an overall accuracy rate of 75 per cent. Teng *et al* (2011) has adopted the model and tested it in Singapore. Apart from the 15 variables introduced by Lussier, he also introduced 11 other variables which includes relationship with customers, Niche product/ service area, Cost of running business, technology edge, competition from rivals, leadership of senior management, people bonding in firm, organizational capability, broad access to resources, local knowledge of market and good government policy. Availability of high-quality staff working in the company, good product timings, good relationship with customers and good top management staff were found to be significant among the variables. A three- country comparison using the same model was done by Lussier and Halabi (2010) in United States, Croatia and Chile. Although there is wide geographical and cultural disparity among the three nations, it was observed that the success or failure variables are similar in the three countries. Halabi and Lussier (2014) improves the Lussier 15 variables by adding internet and removing highly correlated variables and tested eight variables - internet, starting with adequate working capital, managing good financial and accounting records, planning, owner formal education, professional advice, having partners, parents owning a business, and marketing efforts to predict the entrepreneurial success in Chile. Except planning and formal education all other variables were found to be significant. Marom and Lussier (2014) tested the validity of the model with small business in Israel. The model was found to be statistically significant and the variables in the model could explain 66 per cent of the variance in success versus failure of a business. The model could correctly classify 85 per cent of the time a business in Israel as successful or failed enterprise. Hyder and Lussier (2015) conducted a study on the small businesses in Pakistan and examined the validity of the model in Pakistan. It was found that 82 per cent of the time the model could correctly classify the business as successful or failed enterprise. The research done on different parts of the world prove the global validity of the model. Thus, variables considered in the Lussier model is considered in this study to examine the factors contributing to the profitability of a startup company in Kerala, India.

Methodology

This section includes the methodology adopted to conduct this study. A structured questionnaire was developed to collect information from the respondents. The information about the startups were collected from the website of Kerala Startup Mission. Out of 2200 startups in Kerala, 565 startups were registered under KSUM in Kerala. The scope of this study was the startups registered under KSUM. Stratified random sampling technique was used in this study. The entire state of Kerala was divided into three regions viz., Northern, Central and Southern. The northern region consists of 6 districts, the central region consists of 4 districts and the southern region consists of 4 districts. From each region one district is selected which has the greatest number of registered startups under KSUM. Calicut district from northern region, Ernakulam district from Central region and Trivandrum district from southern region of the state were considered for data collection. Majority of the startups in Kerala are located in Trivandrum, Ernakulam and Calicut districts due to the availability of infrastructure, human resources and a conducive environment for doing business. In total, there are 53 startups in Calicut, 200 startups in Ernakulam and 194 startups in Trivandrum. 250 entrepreneurs were contacted via email and telephone in the first round to get their consent in the month of April 2019. Startups which has

surpassed the ideation stage were only contacted considering their ability to respond to all the questions. Data was collected by conducting a personal interview in the next round from those respondents who were willing to participate in the research. The time period of data collection was 1 May 2019 to 31 October 2019. Data was collected proportionately from 24 startups in Calicut, 90 startups in Ernakulam and 87 startups in Trivandrum district. 201 useful responses were received which was compiled and analysed in the later stages. The variables considered for analysis includes:

i. Age of the Business (Number of years) – "Younger business have a greater chance of failure than older business". (Reynolds, P. and B. Miller, 1989)
ii. Number of employees- Businesses that cannot employee adequate number of employees has a greater chance of failure than firms that do.
iii. Industry Experience (Number of years) – "Businesses managed by people without prior industry experience have a greater chance of failure than firms managed by people with prior industry experience." (Lussier, 1995)
iv. Management Experience (Number of years) – "Businesses managed by people without prior management experience have a greater chance of failure than firms that are managed by people with prior management experience." (Lussier, 1995)
v. Planning (1 no plan – 7 specific) – "Businesses that do not develop specific business plans have a greater chance of failure than firms that do." (Lussier, 1995)
vi. Professional Advice (1 Not used – 7 Used) – "Businesses that do not use professional advisors have a greater chance of failure than firms using professional advisors." (Lussier, 1995)
vii. Employee retention (1 Difficult – 7 Easy)- "Businesses that cannot attract and retain quality employees have a greater chance of failure than firms that can." (Lussier, 1995)
viii. Customer service (1 Poor – 7 Excellent) – "Businesses that do not provide good customer service have a greater chance of failure than firms that do." (Benzing et al., 2005)
ix. Marketing Skills (1 unskilled - 7 skilled) – "Business owners without marketing skills have a greater chance of failure than owners with marketing skills." (Lussier, 1995)
x. Product Innovation (1 Traditional -7 Innovative)- "Businesses that select products/services that are not innovative have a greater chance of failure than firms that select innovative products/services."
xi. Financial account maintenance and control (1 poor - 7 good)- "Businesses that do not keep updated and accurate records and do not use adequate financial controls have a greater chance of failure than firms that do." (Lussier, 1995)
xii. Capital (1 inadequate – 7 adequate)- "Businesses that start undercapitalized have a greater chance of failure than firms that start with adequate capital." (Lussier, 1995)

Following Lussier (1995), Logistics Regression Analysis was performed using SPSS to identify the factors contributing to the two possible outcomes Viz., Business is profitable or not profitable. Profitability is defined as the business is profitable in any of the previous three years of operation and not profitable is defined as the business not making profit in the last three years.

Non- Response Bias

The non-response bias was tested by comparing response of early respondents with the response of late respondents using t- test following Teng *et al* (2011). There was no statistically significant difference in the response of early respondents and late respondents.

Results

The results of the data analysis are presented in this section. Table 1 shows that, out of the total respondents, 44 per cent have started making profit and 56 per cent are in the early stages of revenue generation and are still on loss.

Table 1: Profitability of the Business

	Frequency	Percent
Profitable	88	43.8
Not profitable	113	56.2
Total	201	100.0

Source: Primary Data

As the data are significantly different from the normal population, Mann Whitney U Test is done to check whether there is significant difference in the mean ranks of profitable and non-profitable organisations for all the variables considered. The hypothesis developed is:

H_1: There is no significant difference in the mean ranks of Profitable and Non- Profitable startups.

Table 2: Mann Whitney U Test Ranks

	Total	201						

P- Profitable; N- Not Profitable
Source: Primary Data

It can be inferred from table 2, that except for the variables Industry experience, Management experience, Professional advice, the Significance value is less than 0.05 for all other variables considered. Therefore, it can be concluded that, there is significant difference in the mean ranks of 9 out of 12 variables of profitable and non-profitable startups.

Table 3 shows the list of the 12 variables and the results of logistics regression analysis conducted on them.

Table 3: Logistics Regression Analysis

	B	S.E.	Wald	df	Sig.	Exp(B)
Age	-.065	.210	.095	1	.757	.937
Staffing	-.038	.016	5.780	1	.016	.963
Industry experience	.123	.065	3.538	1	.060	1.131
Management experience	-.121	.074	2.722	1	.099	.886
Planning	.149	.233	.410	1	.522	1.161
Professional advice	.052	.104	.250	1	.617	1.053
Customer service	-.478	.259	3.401	1	.065	.620
Marketing	-.895	.290	9.532	1	.002	.408
Financial account maintenance and control	.323	.279	1.342	1	.247	1.381
Capital	.002	.173	.000	1	.989	1.002
Product innovation	-.840	.293	8.217	1	.004	.432
Employee retention	-.347	.235	2.175	1	.140	.707
Constant	8.725	2.292	14.487	1	.000	6152.274

Table 4: Omnibus Tests of Model Coefficients

		Chi-square	df	Sig.
Step 1	Step	85.895	12	.000
	Block	85.895	12	.000
	Model	85.895	12	.000

Source: Primary Data

The Omnibus Tests of Model Coefficients table shows that the model is statistically significant at less than 0.01 (p= 0.000) for Chi-square value 85.895 at 12 Degrees of Freedom. Thus, the model has empirical validity as 99% of the time it will be more accurate than random guessing of which businesses are profitable and established.

Hosmer and Lemeshow Test was done to check whether the model is significant. The hypothesis is

H_2: The model adequately fits the data

Table 5: Hosmer and Lemeshow Test

Step	Chi-square	df	Sig.
1	3.343	8	.911

Source: Primary Data

From table 5, Hosmer and Lemeshow Test, Significance value of 0.911 is greater than 0.05, which implies that the null hypothesis is accepted, which means the model is statistically significant.

The Nagelkerke R Square from table 6 shows what percentage of the dependent variable may be accounted for by all included predictor variables. From the table, it is concluded that the model is good and can account 47 per cent variation in the dependent variable by all predictor variables.

Table 6 : Model Summary

Step	-2 Log likelihood	Cox & Snell R Square	Nagelkerke R Square
1	189.633[a]	.348	.466

Source: Primary Data

The classification table shows that the model predicts 68.2 per cent of the profitable startups and 78.8 per cent of the non-profitable startups correctly. In 74 per cent of the cases the model classifies correctly a firm as Profitable or Not Profitable. It is concluded that the model is 24 per cent more accurate than a random guess of producing 50 per cent correct classification of a firm as profitable and not profitable.

Table 7 : Classification Table[a]

Observed		Predicted		
		Profitable or Not Profitable		Percentage Correct
		Profitable	Not profitable	
Profitable or not profitable	Profitable	60	28	68.2
	Not profitable	24	89	78.8
Overall Percentage				74.1
a. The cut value is .500				

At the 5 percent significance level, the statistical outcome of the exploratory model in table 3 suggests that, the factors impacting the profitabilty of startups in Kerala are number of employees in the firm (p= 0.016), Product innovation (p= 0.004) and the Marketing skills (p= 0.002). Human resources are the backbone of any organization. It can be concluded that the firms, especially startups, must take utmost care while hiring a person as it has direct effect on the profitability of the firm. Hiring employees increases the fixed expenses of the firm, in the form of salary. Inadequate availability of suitable labour affects the performance which in turn affects the profitability of the business. It was also found that introducing innovative product by the firm also plays a significant role in the profit-making ability of the firm. Firms making profit were found to have diversified their product portfolio to increase the returns from business rather than concentrating on a single product. The respondents also engage in service projects apart from developing products to meet the working capital requirements of the firm. Marketing skill possessed by the business owner is another significant factor affecting the profitability of the firm.

At 10 per cent level of significance, the statistical outcome of the exploratory model in table 3 suggests that, the factors affecting profitability of startups in Kerala are Industry experience (p=0.06), Management experience (p=0.099) and Customer service (p= 0.065). The experience possessed by the business owner has significant effect on the profitability of the business. Providing good service can add to the expenses incurred by the firm. But it is important for any firm to provide good services to

retain existing customers and attract new customers. Therefore, experience of an entrepreneur and providing good service have an impact on the profitability of the business.

Conclusion

Policymakers in Kerala, India has identified the importance of entrepreneurship and introduced many schemes to support the existing entrepreneurs and attract youngsters to entrepreneurship. Infrastructural and financial support are provided to startups through various schemes which were not available in the state a few years back. This has led to an increase in the number of startups registered in the state. Many of the startups has already become profitable and many haven't attained profitability. Creating more profitable enterprises helps in the economic development of the region. The research conducted on 201 startup entrepreneurs from Kerala, India shows that, the model developed can predict the profitability of an enterprise. It was seen that; the model could predict a firm profitable or not with 74 per cent accuracy level. Number of employees in the firm, product innovation, marketing skills, industry experience, management experience and customer service were found to be the significant factors impacting the profitability of the startup. The entrepreneurs should be given non- fiscal support free of cost via incubators to assist them in decision making. It was seen that the experience of the entrepreneur and marketing skills has significant effect on the profitability of the enterprise. Through business incubators the entrepreneurs must be given training on how to market their product or service, how to attract and retain customers, employee retention techniques and state of the art technology in producing innovative product and services. The government through its nodal agency KSUM, should appoint industry experts as mentors. The entrepreneurs without experience could benefit if the mentors could bring in their experience. Number of employees is another significant factor impacting the profitability of the business. Startups in general finds it difficult to attract and retain qualified employees due to the competition from established enterprises. The government could provide a tax waiver for the employees working in a startup. This might attract talented people to work for startups. Although capital was not found to be a significant factor, availability of finance is a major factor for running a business. New funding schemes can be introduced to help the entrepreneurs in starting the business with enough capital. The authorities must follow up to check whether the existing funding opportunities are reaching the deserved people.

Although there are social, cultural, political and geographical differences among countries, the Lussier model was tested to be significant in United States, Croatia, Chile, Israel, Pakistan. Considering many variables from the Lussier model, the model suggested in the present study were also found to be significant. Thus, it can be concluded that, the variables contributing to the performance of an enterprise are similar regardless of the country in which the business is. As opined by Marom and Lussier (2014), the similarity can be due to the effect of globalization and thus research on global Success Versus Failure Prediction model are important in the current scenario.

Some Aspects of Digital Literacy in The Context of Higher Education

Olga M. KOCHKINA

Moscow State Institute of International Relations (MGIMO-University) of the Ministry of Foreign Affairs of the Russian Federation, Moscow, Russian Federation

olkochkina@yandex.ru

Abstract

The phenomenon of digital literacy, or literacies, has been the focus of research for already several decades. However, it is still unclear whether the competence of operating and creating in the virtual reality should be mastered individually or formed with the assistance of academics. Moreover, the integral components of digital literacy are still subject to discussion. These aspects motivated the author to seek the students' understanding of the notion and the degree of responsibility they believe should be applied when using the materials obtained in the internet. As the initial step in the research that is to be developed further, a group of students, as well as a limited group of teachers, were given a discourse literacies test checking their understanding of the notion and conscientious use of online resources. The results confirmed the author's hypothesis that, firstly, definitions of digital literacy vary from person to person, and, secondly, digital competence for both advanced and medium users mostly implies being able to process the data obtained in the digital area and neglecting the skill of being critical and cautious with regard to online resources. Thus, the problem remains to determine who should make young people aware of online etiquette and how it should be done in the context of higher education, if we presume that growing a fully fledged specialist is the responsibility of an educational institution. This constitutes both food for thought and an incentive for further research.

Keywords: Digital Literacy; Individual/ Social Skills; Competences; Responsible Use.

Introduction

Digital literacy as a concept relevant in the educational process appeared relatively recently and has been causing multiple discussions concerning components that make it up, as well as whether it should be taught at educational institutions or it is a skill that is inherent for the modern youth. In the beginning digital literacy was often equated with computer literacy, thus focusing on IT skills (e.g. in a research study by Williams & Minnian), or, later, network literacy, bringing to the fore effective use of internet resources (e.g. research studies by Hargittai or Kauhanen-Simanainen). The first definition of digital literacy was given as far back as 1997 by Gilster in his book "Digital Literacy", where he describes it as "the ability to understand and use information in multiple formats from a wide variety of sources when it is presented via computers". Actually in the same book he distinguishes four core competences of digital literacy, those of Internet searching, hypertext navigation, knowledge assembly, and content evaluation. Since that time a plethora of meanings have been put into the notion, as it evolved from the ability to use computer into a combination of various skills that cover human activities in the digital environment (visual, cognitive, reproductive, emotional, social, etc.).

What interested us at the initial stage of our study was what components adult students distinguish in the phenomenon of digital literacy. Thus, the aim of the current research is to find out whether students are aware of the variety of indicators that make up the notion of 'digital literacy' and help them operate in the digital sphere conscientiously, make full use of digital resources and not breach the laws that regulate their activity in the digital environment of their country and in the global space.

Before we present the results of the survey, we contend it to be vital to review the existing interpretations of digital literacy. First of all, it should be noted that modern researchers prefer the term 'digital literacies'. Dudeney et al. maintain that these constitute a combination of individual and social skills that help effectively interpret, share and create meaningful material in various communication channels. These literacies are more social practices than individual characteristics as they are in larger part necessary to establish communication and collaboration across social, economic, political and cultural boundaries. In modern literature devoted to this problem the concept of digital literacy has evolved from being a functional characteristic into a general competence. According to Bawden, this general competence embraces the ability to assemble knowledge from various internet sources and to assess it critically, analyse for credibility and follow etiquette patterns accepted in the online community. Researchers generally agree that central to the notion of digital literacy is the ability to synthesize and integrate information from various sources; other components added by different specialists vary. However, Bawden, along with some others, believes that we should not limit the number of its components or devise one fixed model of digital literacy for all, as the digital environment constantly develops and it brings about changes in people's individual competences. Wan NG from University of New South Wales, Australia, also believes that digital literacy as a multiplicity of literacies develops while a person adapts to new and emerging technologies.

Another interesting interpretation of digital literacy is presented in the article of David Buckingham "Defining Digital Literacy". He also views it as a form of education about the media, not as a functional or technical skill or competence, and argues that it includes, besides functional skills, conscious use of software: databases, search tools, etc. But Buckingham stresses the point that is generally neglected: the importance of online safety: users, especially young ones, should be able to protect themselves against harmful content. Furthermore, it is necessary to assess the information not only in the terms of factual accuracy, but also in the terms of bias, purposes underlying the context. We believe these aspects of digital literacy to be vital, especially in the context of education, so his definition of digital literacy looks to us quite comprehensive, and can be accepted for the use of teachers and methodologists.

It should be noted that the concept has also been approached by European educational organizations. For instance, in the British Futurelab's handbook on Digital Literacy Across the Curriculum Hague and Payton define digital literacy as the ability to access various practices and resources, make and share meaning, communicate effectively and make correct choices of digital technologies to support these processes. Another broad definition of digital literacy has been formulated by the European Information Society. In their report Martin states that digital literacy enables individuals to be aware of various digital tools and facilities, form corresponding attitude to them and use them with the aim of identifying, managing, evaluating, synthesizing digital resources, constructing new knowledge, communicating and reflecting upon the process. Summing up all the above-mentioned definitions, it can be said that different specialists regard digital literacies from different perspectives, that is why a universal definition of this phenomenon has not been suggested yet. Still, it is obvious that, first of all, we should regard the notion as 'digital literacies', not 'literacy'; second, the components that are inalienable to the phenomenon are individual skills of processing information and creating new data; social skills of managing online communication; functional competence of being able to master new programs and platforms; responsible behavior in the digital world; knowledge of online etiquette.

It has already been mentioned that the study of existing works on the topic of digital literacy reveals variations in the number of components that researchers outline in the structure of digital literacy. For instance, Bawden in his article "Origins and Concepts of Digital Literacy", basing on the studies of digital literacy conducted by a number of scientists, singles out 4 major components: underpinnings, or literacy in the traditional sense (ability to function in society); background knowledge (understanding of new forms of information and how they correlate with each other); central competences (a vast list of basic competences necessary in the digital environment) and attitudes and perspectives (independent learning and moral, or social literacy), or what is necessary to behave responsibly in the digital environment, being aware of issues of privacy and security. Buckingham, in his turn, defines the field of study of digital literacy in four respective areas: representation, or motivations of those creating material online, bias and ideology; language,

understood as analytical skills, systematic awareness of how digital media are constructed; production, or commercial influence, and, finally, audience, or understanding how media are targeted and diverse ways of utilizing them. The list of components composed by these two scientists seems to us most complete as compared to others as it embraces the areas that are often omitted, those of copyright, evaluation of information found on the internet and understanding that one should always be critical while choosing material as no author can actually be completely unbiased.

One more interpretation of digital literacy is suggested by Dudeney, Hockney & Pegrum, who divide digital skills into four areas with connection to the focus points: language (everything that is connected with text, understanding information, operating it and communicating); information (tagging, using search engines and services, evaluating and analysing material, reducing information overload); connections (shaping online identity, developing reputation, building connections, contributing to collective intelligence etc) and (re-)design, or remix (creating new meanings, or interpreting and building on others' remixes). In another classification given by Eshet-Alkalai, five types of digital literacy are singled out, which give a slightly different picture of the same concept. The first component is photovisual literacy, or ability to use intuitive graphic interfaces; second is reproduction, or ability to create meaningful and authentic pieces; third is information, or critical thinking; fourth is branching, or a sense of multidimensional environment; fifth is socio-emotional, or ability to be analytical, willingness to share knowledge and collaborate. Wan Ng distinguishes three intersecting dimensions of digital literacy: technical (operational skills); cognitive (critical thinking) and socio-emotional (responsible use of Internet).

It should be noted that, along with technical skills of being able to use digital technologies, all definitions of digital literacy, or literacies, comprise the ability to work with the information conscientiously, applying critical approach and creating original product. However, what is generally overlooked is conscious and careful attitude to other people's intellectual property, ethical use of data, respect for copyright. Maggie Fieldhouse and David Nicholas in their article 'Digital Literacy as Information Savvy' call it 'being information wise' as opposed to being 'information savvy', the latter implying just being able to locate and choose information in accordance with your purposes. They consider it important that students be taught to be information wise: learn to acquire and apply critical and analytical skills, discriminate between reputable and misleading data, meet existing information standards.

Likewise, Dudeney, Hockney & Pegrum pose a question of digital copyright, understanding of which has been changing in the times of expanding web 2.0 culture, that is growing blogs and social-networking sites, where users communicate actively and jointly create new culture. In fact, they call digital copyright 'a grey area' as, on the one hand, copyright regulations are being constantly revised and adapted to the changing reality of the virtual environment, but, on the other hand, creativity on-line is developing and transforming into a new culture, and the existing rules often hamper and even stifle this process. It cannot be denied that digital etiquette does exist, and most countries have their own codes regulating authors' rights in the digital sphere. There are also creative environments where both students and educators can make use of various materials, for instance, Creative Commons. But the point here is whether all users realize when they actually breach the rules or can be accused of plagiarism, since such cases are not always as obvious as copying of printed material or oral reproduction of other people's works.

Methodology

Research Design and Procedure

Our study of the students' understanding of digital literacy might be the initial step in the long-term research, so at this stage we set ourselves the goal of finding out what components students generally include into the notion. We also asked some English language teachers to complete the same questionnaire in order to compare the answers and get a general idea of whose understanding of the notion is more profound. This survey was carried out in 2019, and involved fourth-year students (bachelors' program) and first- and second-year students (masters' program) from the Department of

International Economy of the Moscow State Institute of International Relations (MGIMO University), and a limited number of English language teachers of the same department. The overall number of the students – participants in the study was 78; teachers – 17. The average age of teachers was 37 years old, meaning that these should be people belonging to the generation proficient in their use of digital devices and mostly familiar with the new technologies being used by their students. The respondents were to answer the questionnaire, which consisted of two parts. The first part was an open question in which they were asked to continue the list of indicators that make up the notion of digital literacy. They were given one indicator as an example (understanding and using information in different formats) and they were not limited in the number of indicators that they could specify. The second part of the questionnaire constituted four multiple-choice questions where they were to choose one answer out of four. The questions concerned the importance of digital literacy, where it can be acquired, whether copyright should be considered when using digital resources and, finally, in what way they make use of digital materials while doing creative assignments.

The participants' free answers and choice of options allowed us to draw conclusions on whether their use of digital environment is responsible or intuitive and whether the young people who believe to be internet-savvy realize the full implications of communicating, cooperating and creating in the digital world.

Results and Discussion

The results of the survey were processed and systematized and the following considerations can be stated.

First, we would like to present the analysis of the answers given by students to the open question. Actually, the survey revealed rather vague understanding of digital literacy both by students and teachers, so it is impossible to refer their answers to the four areas outlined in the works of Bawden and Buckingham, which we consider to be quite exhaustive. The indicators outlined by students can roughly be subdivided into three major areas: information, or cognitive dimension, also embracing communication; technical dimension; and socio-emotional dimension. It should be noted that the first area, with a varying focus, was mentioned by all the participants of the survey. 42% of the respondents maintain that digital literacy is mainly effective search for necessary information; 24% also include analysis of information from various sources; 20% just claim that this is about using the Internet whenever possible and for various purposes; 15% assert that digital literacy is about knowing where to get the information you need. Some students also single out such indicators as setting connections between different ideas and types of information, mixing various sources of information, communicating and sharing digital content and knowing how to apply the obtained information. Judging by the given definitions, the topic seems rather vague for the participants, as some of the indicators in essence reflect the same idea, hence the total percentage constitutes more than 100%.

The second most popular area mentioned by students was technical. Almost 22% of the participants state that understanding the programs used and the way they might help you with research is a necessary component of digital literacy; 18% mention versatility with different gadgets; 15% include keeping up with the news in the digital sphere; 14% consider ability to use various platforms and systems part of digital literacy; 11% are sure that competent users should be familiar with information theory and coding.

The socio-emotional dimension was mentioned less often than the previous two. The majority of those who distinguish this dimension point out that it is important for a digitally literate person to distinguish between reliable and unreliable sources (15%) or between relevant and irrelevant information (9%) and to know how to protect personal data (10%). Probably, the first two indicators might be referred to the information area, but as they involve conscious use of resources, we decided to refer them to this part of the results. 8% of respondents consider making references to the original source of information as relevant; 7% mention responsible use of digital resources and ability to do your own research based on various sources of information. It should be added that more than 6% specify such an indicator as 'digital hygiene', which is also about critical thinking and respect for copyright. It is interesting to mention that one of the participants gives such a component as

'distinguishing acceptable piracy from unacceptable'; another ingenious indicator – 'teaching other people to be digitally literate'.

Comparing the answers given by teachers, it should be noted that the latter are not so varied in view of the dimensions of digital literacy as those of the students. Mostly respondents of this group outline cognitive skills connected with obtaining information: 52% state that digital literacy is about finding, evaluating and composing information (and doing it fast); 29% point out using various media on different digital platforms. Other components pertaining to the sphere of information and operating with it are: effective use of digital devices, communicating via them, creating material using the Internet, navigating the digital world, knowing how to find reliable sources of information etc. We have to admit that students showed a far more conscientious approach to the survey, and the teachers' answers are rather general and not reflecting any specific skills a digitally literate person should possess.

As far as the technical dimension is concerned, teachers do not take it into consideration, the only indicator approaching it being 'learning fast how to use new devices'.

Responsible behaviour and copyright were mentioned by some respondents in a generalized form of online etiquette, critical evaluation of online resources, respect for IP rights of writers and awareness of cybersecurity.

The second part of our research concerned students' and teachers' answers to multiple choice questions.

According to the results obtained in the survey, 57% of the students who participated in the survey believe that digital literacy is a must in modern society, while 36% are sure that it is as important as other literacies. Although it might look ridiculous, there is a small number of students who believe that digital literacy is not necessary or is only necessary if you work in IT sphere (both choices amount to 3.5%). As for the answers given by teachers, they are divided between digital literacy being a must nowadays (50%) and being as important as reading or writing (46%), with 4% considering it unnecessary.

Furthermore, most students confirm that they can learn digital literacy on special sites in the Internet (46%) or themselves by trial and error (41%). Still, 8% of them think that friends can help them in this, and 5% will seek their university professors for help. As for the teachers, the answers to this question are mostly divided between asking professors for help (47%) and learning themselves by trial and error (43%). The rest will either ask friends or try to find help in the Internet.

As for the issue of copyright, both students and teachers would rather use licensed sources (40 and 50% respectively) or be creative so as not to be liable for breaking copyright (37 and 40% respectively). 12% of students and 0% of teachers wouldn't worry about copyright at all, and 11% of students and 10% of teachers admit that piracy is acceptable if it is for educational purposes.

Finally, when doing a creative task, such as an essay, presentation or research, 58% of students and 50% of teachers will process the materials they find on the net and develop them using their own ideas; 21% of students will make a mix of materials from the Internet; 13% of students and 43% of teachers always give references to materials taken from the net; and 8% of students and 7% of teachers will mostly use their own ideas.

As can be seen from the participants' answers to this part of the questionnaire, they are on the whole aware of the importance of digital literacy, but neither do they realize what competences make up the phenomenon of digital literacy nor have an established opinion concerning where these skills should be obtained and who should teach them. We would consider it a good sign that practically half of both students and teachers are aware of copyright and respect it. However, when performing creative activities, teachers appear to behave more responsibly than students, which could be explained by their experience in carrying out scientific research.

Conclusion

It is obvious that nowadays, with new digital technologies, sophisticated devices and ubiquitous on-line communication pervading all spheres of modern life, educational sphere included, the process of acquiring digital competency cannot be neglected and be left in the care of the users of on-line resources. First of all, state educational programs with no regard to the specialization should include competences in the digital sphere. As of now, Federal Educational Standards of the Russian Federation include the general professional competence of being able to use modern information technologies and software to solve professional tasks; professional standards devised by MGIMO University also comprise the general professional competence of being able to tackle standard problems of professional activity by using information communication technologies with the consideration of information security rules. These competences do reflect the major provisions of digital literacy, but they seem to be rather vague as they do not embrace all the aspects of it discussed above. At the same time, the laws regulating people's activities in the digital sphere in many countries are tightening, and the consequences for irresponsible users might be quite serious, up to a jail sentence. The earlier young people, who are most frequent users of digital technologies, realize it, the better, and it is logical that educators both in the spheres of high school and higher institutions should provide them with this knowledge and teach them to behave responsibly in the virtual world. At the same time, teachers' objective, especially in humanities, is to teach their students creative activities, which, in the age of digital communication, invariably involves re-mix of other people's ideas, and that might turn out to be illegal. As Lessig in his book "Free Culture: The Nature and Future of Creativity" states, "As educators we can't promote products and technology that engage in this form of community expression because, increasingly, to deploy products that enable people to engage in something called copyright violation is to make your own organization liable for a copyright violation." This poses a big problem for all educators, and to solve it educators themselves have to become proficient in the digital environment, which might also present a multitude of problems, as these are in a large part people advanced in age and thus struggling to feel at ease in this fast-changing new reality. As we see it, the only option that remains is continuous process of education for both teachers and students, or life-long learning as the main principle of active life. Besides, higher educational institutions should consider including and developing the program of digital literacy (or literacies) education into their syllabi for all professions as one more mandatory literacy along with reading, writing and doing arithmetic.

Still, these tasks are not easy to approach and demand more research and discussion by the professional community.

Acknowledgment

The author would like to thank Shaun Wilden, a teacher, teacher trainer and materials writer, whose captivating and informative course 'Teaching in a Digital World - Dealing with Digital Literacy' during English Language Teachers' Summer Seminar 2019 at Exeter College, Oxford University, inspired his students to start researching the topic.

Polish Tourism Managers Facing the Phenomenon of *Halal Tourism*- Results of Pilot Studies

Jacek ADAMEK

Abstract

The currently experienced dynamic development of Halal tourism (HT), measured e.g. by the growing number of Muslim tourists and the value of expenses they incur, has its implications for both the global tourism market and also for the local markets. Taking advantage of the potential benefits resulting from this growth by tourism managers operating outside the Islamic world, including Poland, forces them to recognize, understand and accept the expectations presented by Muslim tourists regarding the consumed services and desiring to observe the principles of their religion. The purpose of the article was *to present the opinions of the local tourism sector representatives about the possibilities and determinants of HT development*. Based on the results of pilot surveys, the research hypothesis was falsified as follows: *domestic tourism managers perceive HT as their development niche*. Rejecting the adopted hypothesis was based on the identification of factors/characteristics referring to the managers themselves, their attitudes and activities (internal premises) and also the ones describing space (economic and socio-cultural) in which they pursue their business objectives (external premises).

Keywords: Tourism, Halal Tourism, Local Tourism Market

Halal Tourism – The Essence

It is estimated that at the end of the 5th decade of the 21st century, Muslims will constitute 31% of the world's population (*The Future of* ..., 2015, p. 8). The increase in the number of Muslims and their income is becoming, among others, the driving force of changes at the global and local tourism markets. The dynamically growing number of Muslims traveling for leisure, business, health and religious purposes resulted in the tourism segment, covering their travelling, become one of the fastest growing components of the global tourism industry.

According to the *State of the global Islamic economy report 2019/2020* (2019, p. 76), Muslim spending related to their travelling in 2018 reached 189 billion USD, with the estimated increase in 2024 to 274 billion USD. This amount, in 2018, accounted for approx. 12% of the global expenses incurred by travellers. According to the *Global Muslim Travel Index 2019* report (2019, p. 18), 140 million Muslims made international trips in 2018, with an estimated 230 million travellers in 2026. These figures indicate a certain phenomenon, both in economic and socio-cultural dimensions. On the one hand, the growing importance of the Halal tourism sector (HT) in both the so-called *Halal* economy and global tourism is recorded and, on the other, dynamic changes in the behaviour of Muslims are observed, who following their religion rules, are increasingly active as tourists. Understanding this phenomenon, in the authors' opinion, allows approaching this type of tourism through the prism of its premises, nature and characteristics determining its specificity and place in the modern world.

The idea of HT appeared in the Islamic world as a consequence of the need to define and develop the processes and conditions related to the sphere of this religion members' travelling. Its expression, feature and simultaneously the challenge faced is to create the conditions for implementing the tourist

service (including its elements) remaining in line with the religious and moral imperatives regulating its Muslim consumers' behaviour.

HT and its rules are deeply rooted in Islamic origins (the Koran, Sharia and Sunnah of the Prophet) where the religious rules focused on the Muslims' pilgrimage to Mecca[1] are described (as part of the major pilgrimage – *Hajj*, constituting one of the five pillars of this denomination and the minor pilgrimage – *Umrah*) and to the graves of Muslim saints (*ziyara*) (e.g. Jafari and Scott, 2014; Haq and Wong, 2010; Eid, 2013; Kovjanic, 2014; Zamani-Farahani and Eid 2016). There are also recommendations regarding Muslim tourists' behaviour related to: the migration to imitate the Prophet's life – *Hirja* (Henderson 2003), travel to acquire knowledge, skills or for commercial/economic purposes – *rihla* (Zamani-Farahani and Henderson, 2010), to visit relatives and "admire the beauty of this world" (e.g. Al-Munajjid, 2015; Hussain, 2015). This tourism, like other Muslim activities, subject to the overarching condition of their purposefulness and benefits of their implementation, is perceived as an instrument for realizing and maintaining the value of Islam and a tool for gaining benefits in line with their faith and moral imperatives (e.g. Saad et al, 2010; Scott and Jafari, 2010).

Recognizing the essence of HT is somewhat hampered by the definition and conceptual chaos of this activity type. It is a function of nature description perspective and tourism phenomenon analysis of the Islamic world representatives (e.g. perspective of: motivations, needs and services based on religion, teaching Islam) (e.g. Duman, 2011; Akyol and Kilinc, 2014; Sureerat 2015) and the elements emphasized in these definitions (e.g. Sharia, target customer, location, offered product, destination) (e.g. Carboni et al., 2014; Zamani-Farahani and Henderson, 2010; Al-Hamarneh and Steiner, 2004). Table 1 presents diverse approaches to defining the tourism phenomenon in the Islamic world.

Table 1: Halal tourism definitions - diversity of approaches

Definition	***Source***
Type of religious tourism following the permissible in Islamic teachings: actions, behaviour, dressing code, diet.	(WTM, 2007)
Term for marking and describing tourism products and/or activities fully complying with the principles and guidelines of *Halal* and Sharia concepts.	(El-Gohary and Boğan, 2015)
Tourist facility or activity permitted or used according to Islam by Muslims in tourism industry.	(Battour and Ismail, 2015)
Muslims' trips to places where Islam is the dominating religion. Religious goals constitute the majority of Muslim tourists' intentions.	(OIC, 2008)
Any activity, event, experience or meeting the needs while travelling, in accordance with Islam.	(ITC, 2013)
Islamic tourism, involving Muslims interested in maintaining their personal religious habits while traveling.	(Carboni et al., 2014)
Tourist activity motivated by travelling in line with Islam, focused on spiritual and social goals.	(Din, 1989)

Source: authors' compilation based on; (Battour and Ismail, 2015, p. 2), (Boğan and Sariişik, 2019, p. 89)

In public space, the terms *Islamic tourism* and *Halal tourism* are used independently and interchangeably. The description of such tourism is also supported by the slogans: *Islamic travel, Halal travel, Muslim-friendly travel, Shari'ah travel* (e.g. Vargas-Sánchez and Moral-Moral, 2019; El-Gohary, 2016). Leaving aside the considerations regarding the differences between these terms and the grounds for using them, following their classification adopted by CrescentRating, the publisher of *Muslim Travel Index* reports, the concepts used in this area can be organized according to their content below (*Muslim/Halal travel*…, 2015 p. 7-8);

[1] About 10 million pilgrims visit Saudi Arabia annually. By 2030, this number is expected to increase to 30 million) (*State of the global* ... 2019, p. 75).

- *Muslim travel* – Muslims travelling for any purpose.
- *Muslim tourism* – Muslims travelling for tourism.
- *Halal travel* – Muslims travellers, not wishing to compromise their faith based needs while travelling for a purpose, which is permissible. It can also be defined as Halal conscious travellers, travelling for any purpose, which is Halal (permissible). Halal travel is a subset of Muslim travel. However, since the vast majority of Muslims will at least have some form of a faith-based need while travelling, the majority of Muslim travel will fall into the category of Halal travel.
- *Halal tourism* – Halal travel undertaken for tourism. Halal tourism is a subset of Halal travel.
- *Islamic travel* – Muslims travelling mainly for religious reasons and/or to visit Islamic religious sites. Islamic travel is a subset of Halal travel.
- *Hajj & Umrah travel* – Muslims travelling for performing Hajj or Umrah, Hajj & Umrah travel is a subset of Islamic travel.

The article authors, following the approaches adopted by the selected researchers (e.g. El-Gohary, 2016; Battour and Ismail, 2016; Battour, 2017), present the position that, in practice, the discussed tourism type, including its characteristics and nature, can be referred to using the term – *Halal tourism* – as the brand name and the name of tourist products complying with the principles and guidelines arising from the concept of *Halal* and Sharia. It is worth highlighting that this compliance takes the form of prohibitions and imperatives formulated regarding, e.g.: accommodation, equipment, meals and drinks consumed, principles of organizing recreation, staff providing services, destinations, related services, dress code or, e.g., consumer behaviour (e.g. Henderson, 2010; Battour et al., 2010; El-Gohary, 2015; (*Muslim/Halal travel*…, 2015)

Halal Tourism in Poland

Until quite recently, Poland was absent in numerous Muslim-friendly tourist locations (so-called *Muslim Travel Friendly*). This situation changes gradually[2]. Małopolska, including Cracow and Zakopane, is increasingly frequently visited by Muslim tourists. The main reason for this phenomenon is the daily flight connection between Dubai and Cracow (Łazarczyk, 2018), offered by *Flydubai* since April 2018 (Ziomek, 2018). On the occasion of this connection opening Arab journalists arrived in Cracow and after visiting the city and its surroundings prepared reports praising the former capital of Poland. The Arab influencers, who published films about their stay in Poland, also disseminated a positive image of this region. The presence of tourism industry representatives at the Dubai tourist fairs, supported by the Local Tourist Organization *Made in Zakopane*, was also the tool for Małopolska promotion (Swoboda, 2018). It is interesting that a decade ago the newspaper *Gazeta Wyborcza* published an article entitled *Arab Emirates the example for Cracow*?, comparing Dubai and Cracow in terms of the city marketing effectiveness. It recommended following Dubai in tourism development through implementing effective marketing and using air connections (Romanowski, 2009). Cracow used these hints and as a result of good air communication and efficient marketing, Muslim tourists visit the city increasingly often. R. Rostek, the ambassador of the Republic of Poland to the United Arab Emirates, also informs that an important determinant of Cracow's popularity among Arab tourists is not only the short flight but also the absence of visa requirements (Hajnoś and Kursa, 2018).

A. Swoboda (2018) estimates that approx. 13 million tourists visit Małopolska annually, including 3 million foreign tourists. Muslim tourists constitute less than 1% of this group. They mainly arrive from the Arabian Peninsula: United Arab Emirates, Kuwait, Saudi Arabia, Yemen, Qatar and Oman (Mateusiak, 2019).

When characterizing Muslim clients, Małopolska tourist sector representatives indicate that they require greater attention and care than other guests, however, this approach is reflected in their

[2] See e.g. https://mekher.wordpress.com/, https://www.havehalalwilltravel.com/10-amazingly-affordable-eastern-european-destinations-for-your-next-big-adventure, https://www.halalzilla.com/muslim-friendly-destinations-2020/90954

gratitude, also shown by leaving behind considerable amounts of money (these tourists often manifest their material status by giving high tips) (Osowski, 2018). The discussed clients are not characterized by openness in contacts with the local community and value privacy. Muslims prefer staying in high standard accommodation. They rent luxury apartments or live in reputable hotels. Many of them are very wealthy and perceive Poland as a relatively cheap country providing good standard of services (Swoboda, 2018). It is also recognized as a safe, still undiscovered destination offering an interesting tourist experience. They additionally value local weather, fauna and flora. The country offering four seasons, snowfalls, the abundance of forests and lakes including vast green areas is highly appreciated. These elements are a natural contrast to the desert landscape of the Middle East. Despite no universal access to *Halal* food, these guests praise Polish food products and fruits, which are considered tasty in their culture.

The offer of one of Cracow's hotels, addressed to groups of Dubai clients, is an interesting example of meeting the expectations of Muslim tourists (*Cultural differences* ... 2019). It is for them that the hotel prepared a special menu including *hummus* and Arabic bread, as well as dishes including spices commonly used in the Middle East. Names of pork dishes, apart from English, have their Arabic equivalents. The rooms welcome Muslim guests with a special complementary note and apples, for them an exotic fruit. In addition, following cultural preferences, the drinking water available in the rooms was changed to non-carbonated and non-mineral one. The information about the geographical direction of Mecca and the number of kilometres separating it from the hotel is also provided. All of the above was consulted with the *Guest Experience Manager* employed in Dubai, whose opinion and knowledge of Muslim culture resulted in their proper choice and character.

The increasing number of Muslim tourists in Małopolska has various consequences. It provides the tourism sector with the successively growing revenues, but also increases the costs for other tourists (e.g. in Zakopane the average accommodation price in 2018 increased by approx. 75% against the previous year). According to D. Różańska (2019), this increase also contributes to a certain degradation of the natural and architectural environment (e.g. Zakopane developers taking advantage of the tourism sector prosperity implement many construction projects without respecting the local spatial development plan, which results in the appearance of "architectural horrors").

As reported by podhale24.pl (*Halal na* ... 2018), the inhabitants of Zakopane are appalled by the frequent purchase of live lambs by Arab tourists and their ritual slaughter in a nearby forest. The website informs that Arabs do not pay attention to people witnessing such activities, as they do not find them particularly shocking (in their homelands it is nothing special). It, however, raises concerns and fear among local communities and tourists. In contrast to these events, resulting from cultural differences, M. Klara (2019) reports Muslim tourists' behaviour who, during the Festival of Sacrifice *Id Al Adha* (*Kurban Bajram*), were giving money to children in the streets of Zakopane, which baffled Polish tourists.

Method and Research Results

In the context of the above considerations, the article purpose was to *present the opinions of the local tourism sector representatives about the possibilities and determinants of HT development*. This purpose has become the basis for formulating the following research hypothesis: *domestic tourism managers perceive HT as their development niche*. The survey method, based on a standardized questionnaire containing 32 questions, was used to identify the opinions on HT developmental potential. Its content concerned the essence of HT and the respective attitudes, including the assessment of a Muslim tourist from the perspective of his characteristics and expectations addressed to the local tourism managers and their offer. The survey was conducted in a group of 71 tourism sector employees responsible for managing hospitality facilities (hotels, guesthouses and apartments) located in such tourist resorts as Karpacz, Szklarska Poręba and Świeradów Zdrój. It covered owners, managers, supervisors and employees of these facilities responsible for marketing and customer relations. The interviews were conducted in July 2019. Table 2 shows the research group characteristics.

Table 2: The research group characteristics

Świeradów Zdrój – 35%		Szklarska Poręba – 34%		Karpacz – 31%	

Source: author's compilation based on surveys.

The presented data indicate that the respondents are professionally experienced in tourism industry (almost 80% are 36 or older and 64% have at least 10 years of experience in this sector). The majority hold managerial positions (72%) and are well educated (63% – university graduates). They represent diversified standard tourist facilities (50% represented hotels, guesthouses and high standard apartments).

The first survey part covered HT essence, its perception and the respondents' opinions about Muslim tourists visiting the analysed facilities, located in the most popular tourist destinations of the Karkonosze and Jizera Mountains.
Only 15% of the respondents stated they had knowledge about HT essence and its distinguishing features, whereas 73% had no idea of this tourism form and its attributes. Interestingly, 45% of the practitioners previously indicating their knowledge of HT essence identify this phenomenon on Polish tourism market along with the accompanying service portfolio (see Table 3).

Table 3. Knowledge about: HT essence and attributes and also HT phenomenon of the local market of tourist services

Do you have knowledge about HT essence and attributes		
Yes – 15%	No – 73%	Hard to say – 12%
Do you notice the appearance of HT phenomenon on the domestic tourism market including the accompanying service portfolio or its components? *(the question addressed to persons indication the knowledge of HT essence)*		
Yes – 45%	No – 36%	Hard to say – 3%

Source: author's compilation based on surveys.

The opinion about HT phenomenon perception on the domestic tourism market was supplemented by assessing its market significance. In this case, all the respondents indicated that HT could represent a potentially profitable and promising market niche. Moreover, they observed it as a demanding and problematic type of tourism. Simultaneously, only 6% perceived it as an actual chance for this tourism form emergence and development on the domestic tourism market and as many as 54% have no opinion in this matter.

The natural consequence of assessing HT's development capacity on the domestic tourism market was the desire to recognize individual opinions on the premises allowing such development and/or support (see Table 4).

Table 4: Premises supporting HT development on the domestic tourism market

Premise	***Share of indications (%)***
More Muslim tourists visiting Poland	25
Changed image of Muslims in Poland	25
Cooperation with Islamic tourist organizations	20
Developing an offer dedicated to Muslim clients	17
Certification of tourist services respecting *Halal* rules	4
Other (e.g. more Muslim students, cultural education)	9

Source: author's compilation based on surveys.

The surveyed tourism managers identify three leading factors of HT development: quantitative categories (e.g. more Muslim tourists visiting Poland), qualitative categories (e.g. changed image of Muslims functioning in public space and also strengthening cooperation with Islamic tourist organizations).

An assessment of the potential propensity to develop an offer respecting the requirements of this tourism type or introducing selected facilities to their businesses, supporting this offer selection by Muslim tourists, has become a specific contribution to the analysis of the respondents' attitudes regarding HT phenomenon. In this case, as many as 48% of them declined the possibility of introducing a service package dedicated to such tourists only, whereas 1/3 of the respondents recognize the possibility of adjusting some components to such expectations. The most frequently indicated facilities could include: adequate accommodation equipment, prayer room, *Halal* certified food.

Another area of questions focused on assessing HT development opportunities was analysing the conclusions of the surveyed tourism managers resulting from their contacts with Muslim tourists. It should be emphasized that:

- the opinions expressed result from the relationships with a limited number of such tourists visiting the analysed entities and
- the statistics regarding the religion practised by tourists are not available in the surveyed entities.

In the analysed period (first half of 2019), the surveyed businesses hosted Muslim tourists from: UAE, Egypt, Kuwait, Israel and Albania. Their stay was predominantly organized individually. They were mainly young people, up to 36 years of age, who indicated leisure and sightseeing as the primary reason of their visit. Their visit length ranged from 8-10 days.

Focusing on the subjective assessment of Muslim tourists' characteristics and their requirements regarding the services offered by the surveyed entities, certain findings deserve highlighting. Firstly, in the respondents' opinion such guests manifest their religion and culture, respect nature and care for the natural environment. Secondly, Muslim tourists are mostly determined in their choices, demanding and presenting high self-esteem, however, behaving modestly. They are also reticent and characterized by low communication skills. Thirdly, the majority of surveyed practitioners (57%) indicated that Muslim guests presented specific needs related to the required tourist services, e.g.: separate rooms for men and women, separate swimming pool, covered Jacuzzi or the appropriate gender of staff performing SPA treatments. Fourthly, 45% of the respondents were unable to determine clearly which components of their offer were particularly popular among these tourists. The responses provided by tourism managers, emphasizing, e.g., the relaxing atmosphere, the service

quality or the individualized approach to the client are, according to the authors, too general and protecting the business reputation rather than expressing individualized, objective opinions about Muslim tourists. Fifthly, the final assessment of the discussed tourists, expressed by the respondents, is not unambiguous. After adopting a five-grade rating scale, the distribution of these grades shows a strong polarization of opinions on the studied problem (see Table 5).

Table 5: Assessment of a Muslim tourist by the respondents

Assessment of a Muslim tourist				
Negative	Rather negative	Neutral	Rather positive	Positive
29%	14%	14%	43%	0%

Source: author's compilation based on surveys.

Research conclusions

The conducted studies provided a diversified picture of the HT phenomenon perception and its development determinants. Although they were of pilot nature, the conclusions resulting from their interpretation may identify certain states and processes describing space for the domestic tourist offer development, which meets Muslim customers' expectations. In the authors' opinion, there are no objective grounds to confirm the adopted research hypothesis that HT is perceived by Polish tourism managers as a development niche.

Rejecting this hypothesis is determined by various premises, including those related to tourism managers, their attitudes, activities (internal premises) and the ones describing (economic or socio-cultural) space for their business goals (external premises) implementation.

Regarding the group of internal determinants, it is noteworthy that despite high education level and relatively extensive professional experience, the analysed population showed limited knowledge about the essence and attributes of HT. Interestingly, the respondents do not notice this phenomenon emergence on the domestic market. It results from poor knowledge of the global economic structure, co-created, e.g., by the *Halal* economy and its HT component, and also the consequence of Muslims' minor participation in the structure of tourists visiting Poland. This statement is also supported by the limited knowledge of Islamic culture, religion and adopting Islamophobic attitudes, so common for the members of Polish society, for whom Islam and Muslims are rather associated with threats, poverty and migrations than, e.g., with tourists seeking interesting destinations meeting their preferences.[3]

Rejecting the adopted research hypothesis can also be supported by the respondents' strong polarization in Muslim tourists' assessment. It seems to result from a diversified approach to meeting their specific requirements (the aforementioned limited readiness to cover the individualized needs voiced by Muslim tourist) and the characteristics assigned to them resulting, e.g., from the environment in which they function (e.g. emphasized religiousness, self-esteem, extensive demands, etc.).

Negation of the adopted research hypothesis is also a consequence of interpreting the external factors' impact, determining the possibility of HT development on the domestic tourism market. Although the respondents considered HT sector as a potentially profitable and prospective market niche, they do not actually notice opportunities for this tourism form emergence and development on the domestic market. It is determined, in its external (environmental) dimension, by various factors including: a/limited relations with the Islamic world representing a potential platform for promoting

[3] In the group of fourteen most frequently indicated by Poles connotations with the word "Islam" six were negative, e.g., terrorism, war fanaticism, jihad, assassination and violence. Apart from them the following categories were listed: religion, Koran, Muslim, Allah, Muhammad, mosque or burqa. There is no positive concept in this group (Stefaniak, 2015 p.14).

Poland as a tourist destination, b/our country image functioning in international space, indicating xenophobia and low tolerance towards all differences, c/cultural and mental barrier, which in the respondents' opinions creates space for potential conflicts between tourists from different cultural backgrounds, d/focus of the domestic tourism market representatives on customers from other, than Muslim tourists, target groups.

Conclusion

The development of HT is undoubtedly a global phenomenon. Its understanding and benefiting from its opportunities require, from tourism practitioners, operating outside the Islamic world, to identify the expectations expressed by Muslim tourists observing their religion imperatives. In the case of Polish tourism managers, the above challenge takes on a special significance in view of an increased interest in our country presented by this group of tourists[4]. In the authors' opinion, this fact naturally determines the need to conduct research covering the determinants, possibilities and manifestations of adapting HT and/or its elements on the domestic tourism market.

Abstract

Today's business environment is an unavoidable challenge. Small business success is therefore vital to maintaining the Malaysian economy and the world economy. In addition, Entrepreneurship is a driving force in bringing innovation to the market and creating credible firms that can deliver high growth in the economy. Objective of this study is to investigate relationship customer satisfaction and loyalty in delivery industries. Furthermore, this study to describe the characteristic of customer and to determine the degree to which marketing variables associated and significant relationship. The dimensions for customer relationship management performance factors are technology strategy. The method of this study are applied research and respondent is individual customer from a logistic company. According to finding, the result showed that survey by questionnaire on Likert scale is significant to the study. Lastly this study also conducts by SEM analysis. Measurement for technology strategy on this study about the attitude of customer toward the initiative taken by Logistic service provider on Support information system and information sharing, usefulness, care and help, ease of use, service portfolio, security and update System offered by logistic service provider. However, the emergence of new entrepreneurship initiatives especially small enterprises to create innovative ideas can have an impact on the growth and prosperity of the organization and subsequently transport in SMEs. Through this strategic technology, entrepreneurship can create innovations that provide new businesses, products, technologies, markets, good quality and more to an economy that can improve Gross Domestic Product and the standard of living of the people.

Keywords: Customer Relationship Management, technology strategy, SEM analysis, SME's.

Introduction

Customer service is one of the most important parts of marketing for a product or service. High quality customer service can help build customer loyalty and build trust in new customers. It will also create customer chains when loyal customers themselves promote products or services to their peers (Shah et al., 2018; Shah et al., 2019). Customers today are not only interested in the products or services offered but all the additional elements of service they receive from the speech they receive when entering the market until after-sales service. Customers will be satisfied if the service provided is fast, error-free, easy-to-find, non-burdensome and accompanied by friendly and courteous service and reasonable cost. Unidha (2017) reported that friendly relationships between customers and organizations are essential in providing improved input to provide the quality of the desired product or service. To ensure that an organization is able to maintain its competitive edge and lead the way, technology quality and survival factors are crucial to moving forward. The product or service provided will reflect the quality of an organization, the higher the quality of the product or service

provided, the higher the trust level (Jung and Seock 2017). Efficient and effective Customer Relationship Management will ensure the delivery of services that are responsive to customer needs and requirements. The standard of service offered to the customer should be of high value to the customer's expectations in line with the delighting approach of the customer in technology. In addition to identifying their customers and their needs, Organizations must also identify their target customers, whether internal or external. The Customer Relationship Management guide and understand their needs and requirements can be further enhanced with fifth-generation technology. This is to ensure that the services offered can meet their needs. In this regard, customer feedback and feedback should be taken into account by the organization. Therefore, the core services of the organization need to be identified based on their roles and functions. It can also be determined based on the current focus area. The CRM can also be defined as the standard of service quality. In addition, Raji et al. (2017) observed the identified customer requirements must be translated into a realistic service technology quality standard to ensure that the promise is fulfilled. The best possible service quality technology standards can be measured for example in terms of timeliness or number of outputs. In addition, qualitative features of customer service that cannot be measured such as friendly, considerate, easy-to-understand, secure and so on can also be standardized. Service recovery plan should be provided to ensure the implementation of the mechanism to the customer. Therefore, service recovery can be implemented efficiently and effectively in the event of failure to deliver the service as promised. In fact, the service recovery plan is a plan that contains carefully planned actions to restore service and maintain customer confidence in the service provided.

Literature Review

The business world is closely linked to creativity and innovation. Without creativity and innovation, the business world will remain static without any changes and changes. Thus, entrepreneurs who inculcate creativity and innovation in their business models will be more progressive and successful than entrepreneurs who remain in the traditional business model who are only interested in sales. Creativity and innovation refer to doing something out of the ordinary. Singh (2015) and Raji et al. (2017) highlighted creativity and innovation can also be associated with innovation, improvement, creation and discovery. The concept of creativity and innovation is broad and can be applied in a variety of areas and circumstances, except for business. Customer management planning is crucial to strengthening the organization's ability to understand customer needs and expectations so that the services offered can meet their needs as a whole. Technology strategy in customer focus the customer focus needs to be incorporated into the organization's strategic plan in order to work effectively on customer relationship-based services. Organizational top management needs to define the customer service mission in the form of a specific statement and publicize it so that it becomes a commitment that all managers, owners and shareholders will share in the organization's customer service excellence. Hence, definitely target their customers so that their needs and expectations can be more accurately determined. This is to ensure that the standard service technology offered meets customer satisfaction and is of high value to the customer's expectations (Shah et al.,2016; Shah et al.,2017). The provision of customer service standard technology needs to be set and implemented to ensure consistent service quality to be effective and efficient. This is in line with the efforts to enhance the excellence of the service delivery system. Suki (2014) and Soh et al. (2017) found connections between the service offerings that are intended to be delivered to customers must be through efficient working procedures and delivery processes to ensure fast, easy and convenient service quality. Organization in SME's needs to enhance customer service delivery through strengthening its organizational structure and providing facilities that enhance service offerings. Moreover, technology is a tool used to convey the delights necessary to keep up with current developments. Consequently, Abhishek et al. (2018) also found that careful planning needs to be done to identify the customer's need for the service can be offered through the use of the latest tools and technologies can meet customer requirements. Organizations with numbers high customer service transactions should always be explored fifth-generation new technology in Customer Relationship Management. Therefore, here is aimed at strengthening the internal operations that it offers efficient service through a service-oriented structure (big data). Last but not least premise management is just as important to improve service delivery efficiency and guarantee customer comfort, convenience and office layout

customer-friendly including amenities for the less fortunate efforts should be made to enable them to share their experiences.

Customer Relationship Management Performance

Customer relationship service is one of the most important parts of marketing for a product or service. High quality customer relationship services can help build customer loyalty and build trust in new customers. Shah et al. (2018) and Wahab et al. (2017) identified that the creates a customer chain when the loyal customer itself promotes the product or service to the surrounding consumer. Friendly relationships between customers and organizations are essential in providing improved input to provide the quality of the desired product or service. Customer service is often faced with a wide variety of customers out there. Therefore, it is important for each organization to ensure that they have good skills to ensure that they are always keeping in touch with the customers who come to use the services provided. Moreover, good SMEs are the ones who know and want to impress their customers. It is important for the organization to provide the best service to its customers so that they are happy and comfortable. Moreover, Shah et al., (2016); Shah et al., (2017) defined one of the things SME's can do is create a lightweight organization. If employees often provide the best service for them, it will indirectly make their customers feel valued. The needs of customers need to be met to make them feel valued. In addition to ensuring employees understand and meet the needs of existing customers, the relevant parties must always provide VIP offers for their customers to make them happier and more rewarding. In addition, managers can also conduct surveys to come up with ideas and improve if there are some things that need improvement. No matter how productive a business is, feedback should be given to customers so that they are always rewarded (Zuraimi et al., 2013; Ali et al.,2018).

Technology Strategy

Customer relationship service is one of the most important parts of marketing for a product or service. High quality customer service can help build customer loyalty and build trust in new customers. It will also create a customer chain when the loyal customer itself promotes the product or service to another chain. Customers today are not only interested in the product or service offered but all the added value of the service they receive from the speech they receive upon entering until the after-sale service. Therefore, customers will be satisfied if the service provided is effective and efficient. Friendly relationships between customers and organizations are essential in providing improved input to provide the quality of the desired product or service. While, information technology plays a vital role as supporting tool to the organization (Norsyafiqah Filzah Mohamad Saodi et al, 2018). Lariviere B et al. (2017) and Soh et al. (2017) stated that the tools and technologies used to deliver the services need to adapt to current developments. Careful planning is needed to identify customer needs so that services can be offered through the use of the latest tools and technologies that meet customer needs. Organizations that have a high number of customer service transactions should constantly explore new technologies in Customer Relationship Management. This is aimed at strengthening internal operations and offering efficient services through the appropriate technology-based service-oriented structure. Moreover, Paddeu at al. (2017) and Shah et al. (2017) in another study reported that integral to the magic behind our ability to provide quality products and review-worthy experiences is technology. Some may argue that technology can be a barrier to great customer service, however, behind the scenes, technology is driving efficiencies in SME's operations which assisting communications, providing ongoing training, managing quality assurance and more. For SMEs, the right balance of technology and implementation can help improve operations and development, as well as quantify and create a cohesive brand experience, no matter which location a customer visit. In their study, Thammawimutti et al (2018); Slater, and Shah et al., (2019) examined with technology, logistic provider can quantify the customer experience and provide data on what may be missing. Technology helps to ensure that logistic operations are running smoothly and that SME's can communicate with a customer through a centralized platform regarding questions or actions. Flawless execution can be tough to manage for a logistic that may not be located physically near every single logistic location and a centralized

management platform helps to bridge any communication gaps and set SME's up for success. In another study Zhou et al. (2019) and Miroslava (2013) reported that to ensure all locations are providing the best brand-consistent experience possible, logistic provider should consider an effective field team or solution. If a technology solution is utilized, it should be mobile-centric and include brand-specific surveys with visual documentation capabilities, corporate and franchisee feedback and critical action notification and automated corrective action plans with required follow-up. The most effective review tools will compile historical and trending reports to identify locations heading too strongly off a path of success. Similar to managing logistic provider operations, technology can also be used to capture, qualify and convert SME's leads into sales. Technology can help grow a business by reaching new customers through text messaging, digital signage and social media campaigns (Jamaludin et al.,2017.; Shah et al.,2018)

Customer Relationship Management Performance and Technology Strategy

Managing customer experience can also be referred to as assessing a customer's understanding or perception of a product or service that has been offered or the future that will be offered to customers. Moreover, customer knowledge in evaluating or looking at a product can provide transportation services an opportunity to improve a product in the future. Customer Relationship Management is introduced to enhance organizational and customer relationships and thus meet the increasing demands and expectations of customers. However, Paddeu et al. (2017) and Hazee et al. (2017) points out that Customer Relationship Management is a holistic approach to service delivery through effective management of interactions and relationships between organizations and customers. This approach focuses on delivering service technology that is based on customer needs where customers are treated as individuals rather than as a component of the service delivery process. Other authors Liu et al., (2017) mentioned that customer engagement is also taken into account in designing the services so that the services offered can meet their needs and satisfy them. Furthermore, Customer Relationship Management (CRM) are holistic approach to providing services that meet customer needs and expectations through managing effective interactions and relationships between organizations and customers. Organizations need to identify their target customers so that their needs and expectations can be better defined. This is to ensure that the standard of service technology offered is as high as customer's expectations and high value to exceed customer expectations. Perfecting in terms of facilities, technology, logistics and other relevant and relevant products is essential to enable the organization to implement customer service mission (Shah et al.,2016.; Shah et al.,2017). Customer service is the ability of the organization to improve the delivery of products to the customer, and it is the responsibility of all units in the organization. Leaders and managers can determine the organization's pattern and direction. In order to succeed in the mission of customer service, organizational leaders must be those who understand and practice customer-value-oriented leadership and administration than they need (Shah et al.,2018.; Shah et al.,2019).

Objectives of the study

The objectives of this study are as follow:

1. To investigate the impact of technology strategy in customer relationship management performance of SME's logistic provider.

Methodology

This research is empirical test as well as correlational research in nature. According to Hair et al (2010), the number of respondents in pilot test should be at more than thirty as well as appropriate and acceptable for analyses which are greater than 100 samples as suggested by (Hair, et al. 2010; Sekaran and Bougie 2013).Questionnaire survey was carried out for this research and distributed to the respondents that consume logistic service provider as well as Likert scale questionnaire were apply in this study. Population is a target groups whichever the individual person or the customer on

the logistic service provider. The target population of this study were three hundred and ninety-one respondent from Johor Bharu, Selangor and Pulau Pinang on X, Y, and Z organization company.

Theoretical Background for the Models

Logistic service business is considered as a way of expanding business faster and cheaper. This is because the logistic business is all managed by a systematic automation. It will be affected the customer in their benefit. Logistic service business allows transfer of technology and expertise between companies and local customer (Paddeu et al.,2017). This can be realized when a logistic service provider appoints a local company as the technology strategy for a particular area. So that, Chen and Popovich (2003) proposed the perfect underneath to present and support the impression of numerous authors on the significant of technology strategy in realizing Customer Relationship Management Performance in the organization.

Fig. 1: A CRM implementation model Chen and Popovich (2003)

Theoretical Framework

For this study, prototypical proposed that present research a technology strategy as the determination of Customer Relationship Management Performance models for SMEs in Malaysia. The complete models proposed are as follows.

Fig. 2: Theoretical Framework

Hypotheses Development

Paddeu et al.,(2017), Soh et al.,(2017); Shah et al.; (2019); Shah, et al.,(2018); Shah et al., (2017) and Shah et al., (2016) at past research was investigated the character of provider value in technology strategy. Around is a positive significant relationship between technology strategy and customer relationship management performance. Therefore, we hypothesized that:

Hypothesis

There is a significant relationship between technology strategy factor and Customer Relationship Management Performance.

Result

The SEM model and relevant data are shown in Exhibits Table 1, Table 2 and Figure 3. The model fit parameters were similar to previous SEM analyses. These were considered minimally acceptable for exploratory research focused on scale development (Hair et al., 2010.; Anderson, 1988). Analysis of the data was using SEM analysis which is previously tested for validity and reliability. Results of the examination of goodness is fit for overall model and was in accordance with the analysis result of SEM, in order to determine whether the hypothetical model is supported by empirical data, This section gifts the particulars of data analysis to assess measurement model and structural model concurrently by using SEM analysis. Moreover, measurement instrument are evaluated via CFA dimensionality, reliability and validity of model where indicators are measured by multiple items (Crockett 2012). In this scenario given in Figure 3 as such extended analysis of SEM independent variable model. Numerous knowledgeable specialists thought these results and decided the results were rational, mainly since table regression weight and standard regression weight in this same research confirmed that the relationship is positive and significant. One clarification for the illogical finding of there is relationship between technology strategy and customer relationship management performance was the option of a suppressor effect due to interactive effects of multicollinearity in the SEM analysis. Thus, partial model independent variable is demonstrated and Hypothesis H4 is accepted. Nunnaly (1994) suggest that all of the variables in the model estimated to fulfill the criteria of discriminant validity. Then it can be concluded that all of the variables have a good reliability. Below is analysis for regression weight and standard regression weight.

Table 1: Regression Weights

			Estimate	S.E.	C.R.	P

Based on the results above are providing added predictive validation for the relationship between technology strategy and customer relationship management performance. As discussed in the theoretical framework, technology strategy is viewed as integral to firm performance (FP). Thus, technology strategy is likely to impact firm performance positively. A model representing the relationship between technology strategy and firm performance using SEM-based path analysis was tested next.

Research Findings

Fig. 3: SEM Technology Strategy

According to Figure 3 the outcomes presented that the technology strategy is a leading feature of improving performance straight. Result of confirming analysis of variables showed that measurement model if variables are proper and all numbers and parameters of model is meaningful. Measurements of the highest in reflecting customer relationship management are the reward, followed by technology strategy and customer relationship management performance. The SEM path analysis resulted in a chi-square of 97.900, DF of 14. The relative chi-square was 6.993. Furthermore Good fit Index was .928. More over AGFI was .857. The comparative fit index was .919 and the IFI was .919.NFI was .907.TLI was .878 and last but not least RMSEA was .124 with 80 percent confidence level.AIC was 125.

The outcomes of this study exemplify that the improved technology strategy of customer relationship management performance industries is most significant relationship by how the capability of management to deliver product and service to customers. Application of customer priority also played a role in increasing the customer relationship marketing.

Discussion

In conclusion, customer relationships need to be managed as a whole and integrated as a step towards meeting customer needs and requirements. This Customer Relationship Management guide details the quality of customer service and details the steps that need to be taken under the core of customer relationship management to help organizations improve their customer relationship management. This study emphasizes that customer engagement as a receiving service is a key factor in shaping the organization's form, method and level of service delivery. In addition, customer service performance management is an important component of ensuring that the best services are delivered to customers consistently and in line with the customer's transform approach. An organization with high quality customer service depends on satisfied customers and thus provides support for the organization. It is not solely the responsibility of one section to attract customers but the other part of the organization is also responsible for quality customer service. In addition, customers' perceptions of organizational productivity and services need to be constantly reviewed so that feedback on organizational performance can be obtained to enable institutions to find ways to improve their performance. The services or products provided should be as much as possible based on customer demand and requirements and not solely on the part of the management. In essence, no organization can achieve success without building good relationships with customers. Increasing customer satisfaction by understanding customer requirements is one way to gain customer loyalty and customer retention.

Conclusion

Due to globally technological change with including economic and business conditions such as technological advances. It is essential to implementation of information system throughout organization (Asyraf Mohd Bakri et al, 2017). The need to modify the information system or change of management requirements it may be necessary to change the information system. Technology it plays an important role in Technopreneurship. It is an essential tool for enhancing organizational performance. In order to be flexible in the management of the system quickly and save time. With the evolution of data communications networks through computer systems. This is a system that connects a large structure that can exchange information even if it is located in the opposite hemisphere. Organizations need to set standards, processes, procedures, directives and work culture that ensure excellent customer service in order to achieve and maintain a high level of product delivery) is sufficient for all activities to be carried out in the most efficient manner. Regardless of the processes, procedures, facilities and resources provided, but if the attitude and commitment of the employee is not customer-driven, the organization will not reach the customer service level quality. Furthermore organizations need to adopt an effective monitoring system for every activity in the preparation and delivery of products to customers (Brdiger & Wood, 2017; Shah et al. 2018). Through monitoring of internal processes and activities and external interactions with customers, the organization will always be prepared to correct any shortcomings and errors. Last but not least, innovation is the

specific tool of entrepreneurs, the means by which they exploits change as an opportunity for a different business or a different service.

ARVIANSYAH
Universitas Indonesia, Jakarta, Indonesia
arviansyah@ui.ac.id

Abstract

Project control is an essential task for a project manager. Project control is carried out by comparing the actual project performance in terms of time and cost with the project implementation plan. A typical project control method is the Earned Value Method (EVM). Previous research, overemphasis on EVM and using cost component for schedule performance, could provide misleading information in assessing the schedule. Based on data from one of the largest telecommunication providers in Indonesia, many projects suffer a late completion and have proposed a time extension. The penalty for the project's late completion is a percentage of the project's amount. So in this research, three projects with the most significant amount from a telco company as one of the company's clients are selected. The result of this analysis is a preventive and corrective action to control the project duration.

Keywords: Earn Duration Management (EDM), Project Performance Measurement

Introduction

Project monitoring and controlling are critical for the success of project implementation. It is not an easy task wherein this task contains a process of an observation of risk and uncertainty, which has the potential of becoming a problem and will disturb project objectives to take corrective action when necessary (Arviansyah, Spil, van Hillegersberg, 2013). This risk and uncertainty can cause a delay and budget overrun in project execution. Therefore, project forecasting is a crucial phase in project monitoring and controlling to predict the cost and final duration of the project.

(Patel and Kashiyani, 2017) The earned value management (EVM) technique has been widely used to monitor and control the performance of a project up to a reporting date and forecasting the project's final duration. Earned value management (EVM) and similar techniques help managers to focus on projects or work packages that need the most attention, by measuring and highlighting possible future deviations.

Forecasting using these techniques provides a reasonable and uniform approach for project tracking and control. EVM provides a performance metric of cost and schedule performance based on the cost. Three key metrics used in EVM to measure the project progress is Planned Value (PV), Earn Value (EV), and Actual Cost (AC). Earn Duration Management (EDM) developed by Khamooshi and Golashani to overcome the drawback of EVM that assessed to be not reliable to measure project performance. EDM is a technique that provides a performance metric to measure a project performance base on the duration. The key metrics of EDM are the total planned duration (TPD), total earned duration (TED), and the earned duration (ED), which are all time-based.

Literature Review

Every project needs proper control tools and, therefore, every project manager would use it. (Gershon, 2013) Earned Value Analysis considers as a control tool for managing projects during the execution phase and keeping the project on track, including on the right path. Earned Value considered as an ideal tool that would summarize the project's status with two main components, one for schedule (on-time delivery) and one for cost (over or under budget) status. Besides that, Earn Value also provide a measurement. Earn Value provides a forecast, update in real-time, to predict the eventual cost of the project and delivery date. (Mareels and Martens, 2018) Overview of the different forecasting techniques in project management as given.

Fig.1 : Evolution of different forecasting technique

EVM is an established methodology to monitor projects during execution that uses three key metrics to measure the progress of projects, namely the Planned Value (PV), the Earned Value (EV), and the Actual Cost (AC) (de Andrade, Martens, and Vanhoucke, 2019). EVM defines the Planned Value (PV) (previously known as Budgeted Cost of Work Scheduled (BCWS)), i.e., the planned value that will be spent on executing the work based on the original schedule at any point in time (Wilkens, Tammo T, 1999). EV, previously known as Budgeted Cost of Work Performed (BCWP), defines as progress made (work completed) in terms of the monetary value at a certain point in time (Wilkens, Tammo T, 1999). AC was known as ACWP or Actual Cost of Work Performed formerly; it represents the monetary value of what has been expensed to achieve the progress made at a certain point in time (Khamooshi and Golafshani, 2014). EVM provides various performance measurements that are designed to assist the

project's monitoring and controlling activity depends on the type of information needed. Cost Variance (CV) denotes the difference between how much was actually spent and the value earned (EV) across the work performed (Jack R. Meredith, Samuel J. Mantel Jr, 2011). In that case, CV is defined as below:

$$CV = EV - AV$$

A negative value point means the project has spent more on the executed activities than what it is worth (de Andrade, Martens, and Vanhoucke, 2019). On the contrary, a positive value indicates that the project has spent less to gain the value of the executed work. More specifically, two schedule performance indicators can be constructed using the PV and EV, namely the Schedule Variance

$$SV = EV - PV$$

Schedule Performance Indicator,

$$SPI = \frac{EV}{AC}$$

and the Cost Performance Index

$$CPI = \frac{EV}{PV}$$

Consequently, when the value earned is lower than planned and the project suffers from a delay, the SV and SPI will be lower than 0 and lower than 1, respectively. While the ES is expressed in time units, it is calculated based on the EV and PV and, therefore, still depends on the cost structure of the project. EDM has been developed by Khamooshi and Golafshani (Khamooshi and Golafshani, 2014) to resolve this issue. The key metrics of EDM are the total planned duration (TPD), total earned duration (TED), and the earned duration (ED), which are all time-based metrics. Rather than considering the value of project activities in monetary units, the value of the activities is expressed in work periods. Total planned duration (TPD) represents the cumulative number of planned work periods throughout the project makespan and should thus not be confused with the project planned duration or baseline planned duration (BPD).

$$TPD = \sum_{i=1}^{n} PD_i$$

where PD_i is the portion of the planned duration for activity i that occurs up to the current date, and n is the number of completed or in-progress activities up to the current date. For in-progress activities, only the duration of the activity to the left of the current date counts to determine the TPD. Hence, the TPD can be seen as the time-based equivalent of the PV. Total earned duration (TED) represents the cumulative number of working periods earned throughout the project makespan and is calculated using the following equation:

$$TED = \sum_{i=1}^{n} ED_i$$

where ED_i is the earned duration for activity i up to current date and n the number of completed or in-progress activities up to current date. Thus, the TED is the time-based equivalent of the EV. Earned duration (ED) informs the time at which the current total planned duration (TPD at current date) was planned to be earned and can be considered to be the EDM equivalent of the ES. The ED is calculated using the following equation:

$$ED(t) = t + \frac{TED - TPD_t}{TPD_{t+1} - TPD_t} \times 1$$

where t is the number of integer periods for which TED≥TPDt and TED≤TPDt+1. Using the EDM key metrics, schedule performance indicators can be constructed. The Earned Duration Index (EDI). At any point in time, EDI is a measure of duration earned compared to what was planned to be done up to that point in time.

$$EDI = \frac{TED}{TPD}$$

At any point in time, the project might achieve more, less, or the same amount of work compared with the work planned to be achieved at that time. Thus this measurement can have a value higher than one, less than on, or equal to one, respectively. Duration Performance Index (DPI) are respectively the EDM equivalents for the SPI and SPI(t). DPI represents the overall schedule progress performance in delivering projects compared to the plan toward the completion of the project.

$$DPI = \frac{ED(t)}{AD}$$

The value of DPI will be less than one and perceived as behind schedule, more than one perceived that project being ahead of schedule, and equal to one perceived that project is performing at the same level as planned. Project Performance Index (PPI), at any point in time, is a measure of the overall duration progress of the project. It measures ED(t) against the baseline planned duration.

$$PPI = \frac{ED(t)}{AD}$$

The value of PPI will always be less than or equal to one. PPI's value starts from zero, and as the project nears completion, the value of PPI will approaching one. PPI value will be one upon completion of the project. Adapting directly from EVM, Cost Performance Index (CPI) as:

$$CPI = \frac{EV}{PV}$$

The value of CPI will be less than one if the project is over budget, equal to one when the project is on budget, and greater than one fi the project is under budget. One other potential usage of the progress performance measurement is forecasting the future state of the project. In EDM, one can use an equation formulation to forecast the project's future. The equation defines as Estimated Duration at Completion (EDAC)

$$EDAC = \frac{BPD}{DPI}$$

And, one can use the following formula to estimate the duration to complete: Estimated Duration to Complete (EDTC)

$$EDTC = \frac{BPD}{DPI} - AD$$

Research Method

The EDM in this study will be applied in three telecommunication infrastructure projects in a telecommunication company, which is one of the biggest suppliers in the Indonesian telecommunication technology company. The three projects in this research are the Dense Wavelength Division Multiplexing (DWDM) project, Metro Ethernet (Metro) project, and Optical Line Termination (OLT) project. These three projects are related to the network topology. DWDM is used to connect between METRO. Meanwhile, OLT is below METRO. It receives logical data from METRO to distribute service to customers.

This study utilizes both quantitative and qualitative methods. EDM cover the quantitative part. Based on EDM results, interview with project manager held as qualitative part. Mathematical calculations are done using the EDM method. This research employs an interview as primary data. The progress report also budgets and report data as secondary data. For mathematical calculation, secondary data will be used to get a measurement indicator value. Based on the measurement indicator, a semi-structured interview with each project management had been done. The cut-off date for data used in this research is 28 February 2019. Each project will have five milestones upon the project completion. The milestones are, Material On-Site (MOS), Installation, Integration, Commissioning Test (Commtest), and Acceptance Test Procedure (ATP).

The budgeting process in the company is confidential, so the researchers cannot get the detail process of making the budget. The budget for all projects in the client company accounts is collected in one project code and used together for all projects. Each budget for the project is obtained by using a baseline from the finance department that also confidential. So the finance department can only give the total budget without detail information for each project.

EDM Applied In DWDM Project

DWDM project supposed to be done in 107 days (16 weeks), and 73 days have passed since this project officially begins. Which means the AD is 73 days. This project has a total of 152 sites to complete until ATP. All five milestones in a site can progress parallels with other sites. TPD is a sum of each activity's planned duration. TPD for this project is 292 days. The earned duration is known to calculate how many days are needed for each site to finish each milestone. TED is a sum of the earned duration of each activity. The TED at the current state is 287 days, and TAD at the current state is 339 days. The project was planned to earn this duration on day 72. Thus ED(t) is 72 days. Detail duration of the DWDM project can be seen in the following table.

Table 1: EDM Result for DWDM Project at the status date

Week	TPD	TAD	TED
1	28	28	153
2	56	61	170

3	84	96	170
4	112	131	171
5	140	166	178
6	168	201	186
7	196	236	219
8	224	271	237
9	252	306	254
10	280	333	266
11	304	339	287
12	324		
13	338		
14	351		
15	358		
16	360		

Using information from Table 1, DPI and EDI can be calculated as follows:

$$DPI = \frac{ED(t)}{AD} = \frac{72}{73} = 0.986$$

$$EDI = \frac{TED}{TPD} = \frac{287}{292} = 0.984$$

The result of DPI and EDI show that the project is behind schedule and achieve less than planned. In the first week of project implementation, the project achieves quiet a lot. A pre-sale contract causes this fact, and the results are acknowledged within the project contract's release date. Based on the interview with the project manager, there are several reasons why the project is behind schedule. First, there is an Out Side Plant (OSP) that is not ready, the location is not ready, and the lack of subcontractor's team. The budget for this project is Rp 59.123.769.295,00 and the actual cost until the current date is Rp 3.600.100.945,00. The earned value is known by dividing the budget to all sites equally and then multiply it with total sites that already finish all the milestones. For this project, total sites with five milestones are 760 sites. At the current date, 606 sites are finished all the milestones. Therefore CPI will be calculated as follows:

$$EV = \frac{59.123.769.295}{760} \times 606 = 47.143.419.393$$

$$CPI = \frac{EV}{AC} = \frac{47.143.419.393}{3.600.100.945} = 13.10$$

The CPI value shows that the project way under budget. The project manager believes that a sharing resource with other projects causes this considerable gap, whereas the project manager makes a budget

for a dedicated resource in project budget planning. Considering that AD is 73 days, PPI will be calculated as follows:

$$PPI = \frac{ED(t)}{BPD} = \frac{72}{107} = 0.673$$

This PPI's value shows that the project is 67% nearly a project completion. Have known the current project performance, the project manager can use the forecast equation to estimate the project's future.
Estimated Duration at Completion (EDAC).

$$EDAC = \frac{BPD}{DPI} = \frac{107}{0.986} = 108$$

Moreover, we use the calculation as below to estimate the duration to complete:
Estimated Duration to Complete (EDTC)

$$EDTC = \frac{BPD}{DPI} - AD = 108 - 73 = 35$$

By using the above formula, this project estimated to complete on day 108, 1 day late than the project supposed to be done. To avoid this late project completion estimation, the project manager decides to add more workforce to push the progress. Also, try to finish some milestones together in one day in order to accelerate the project progress and avoid late completion.

EDM Applied in Metro Project

Metro project supposed to be done in 210 days (30 weeks), and 74 days have passed since this project officially begins. Which means the AD is 74 days. This project has a total of 121 sites to complete until ATP.

Table 2: EDM Result for Metro Project at the status date

Week	TPD	TAD	TED
1	5	16	3
2	14	44	3
3	28	72	15
4	48	100	119
5	72	128	216
6	100	163	262
7	128	198	264
8	160	228	276
9	195	256	281
10	226	284	284
11	253	300	284
12	274		
13	290		
14	302		
15	309		
16	316		
17	321		
18	321		
19	321		
20	321		
21	321		
22	321		
23	321		
24	321		
25	321		
26	321		
27	321		
28	321		
29	321		
30	321		

TPD for all activity in this project is 242 days with TED in the current state of 284 days. The project was planned to earn this duration on day 88. Thus ED(t) is 88 days. Thus, we can calculate DPI and EDI as follows:

$$DPI = \frac{ED(t)}{AD} = \frac{88}{74} = 1.189$$

$$EDI = \frac{TED}{TPD} = \frac{284}{242} = 1.175$$

From DPI and EDI value, this project is ahead of schedule and achieved more than planned. These causes of this achievement are that this project is an only insert and expanding module. So there are not many issues in this project implementation. All the capacity of an existing device can be monitored using a network system before doing all the work. The issue of implementing this project is permitted for reengineering; this needs a strict schedule and method of a procedure before executing the planned work. Also, the reengineering needs to be handled by the company's engineer resource. This impact on the cost, since the engineer's cost, is different from the cost when using a subcontractor. The budget for this project is Rp 33.461.287.500,00. The actual cost until the current date is Rp 3.798.043.924,00, and 536 sites for all milestones are finished. Therefore, the CPI can be calculated as follows:

$$EV = \frac{33.461.287.500}{605} \times 536 = 29.645.041.487$$

$$CPI = \frac{EV}{AC} = \frac{29.645.041.487}{3.798.043.924} = 7.81$$

Looking at the CPI value, the project is still under budget. Same as the DWDM project, the reason behind the massive gap between budget and cost is because of the resource allocation with other projects.

Considering that AD is 74 days, the project is 42% toward completion; this is known through PPI calculation as below:

$$PPI = \frac{ED_t}{BPD} = \frac{88}{210} = 0.419$$

If the project performance remains the same, this project estimated will be finished at 177 days, which is 103 days to go from the current date and faster than planned.

EDM Applied in OLT Project

OLT project's BPD is 249 days; this means that the project supposed to finish within 249 days (37 weeks). At the current date, 297 days already passed since this project officially begins. Knowing that the current date already passing the BPD, the project supposed to finish all the work already.

Table 3: EDM Result for OLT Project at the status date

Week	TPD	TAD	TED
1	11	15	107
2	42	43	122
3	77	71	126
4	112	99	134
5	147	127	142
6	182	155	180
7	217	183	199

22	742	649	943

Week	TPD	TAD	TED
23	777	684	962
24	812	719	962
25	841	749	972
26	869	777	973
27	897	805	975
28	909	817	976
29	937	845	976
30	963	871	977
31	976	892	978
32	983	913	978
33	990	934	996
34	997	955	1001
35	1004	976	1001
36	1007	985	1001
37	1012	1006	1002
38	1012	1027	1006
39	1012	1048	1007
40	1012	1069	1008
41	1012	1090	1010
42	1012	1111	1010
43	1012	1124	1011
44	1012	1128	1012

TPD for this project is 1012, and the TED for the current date is also 1012; this means that the project is already finished. With that purpose, DPI and EDI then calculated.

$$DPI = \frac{ED(t)}{AD} = \frac{249}{297} = 0.83$$

$$EDI = \frac{TED}{TPD} = \frac{1012}{1012} = 1$$

The DPI value is less than one, which shows that the project is behind schedule; this also means that the project has a late project completion than it should be. EDI value is one since the TED value is similar to TPD, and all works are achieved as much as planned.

Based on the interview with the project manager, the causes behind the project's late completion mostly are from external. The location and allocation are not precise since the beginning. So there are many changes during the project implementation impact in the project delayed. Unready sites also the reason why the project cannot be done on time. Sites in some severe geographic conditions make teams have difficult access to reach the sites. Other than that, subcontractor quality also needs to be improved.

Conclusion

This study shows that the result from EDM can help the project manager know the project status and performance at any time. For any distortion of actual condition from the plan, the project manager can take preventive action to make the project back in track. Two factors affect the project's late completion; these are the internal factor and the external factor. Internal factor is a factor that comes from the company's side while the external factor is a factor that comes from the user and also geographic condition. For the external factor, the cause for late completion mainly because of site readiness, geographic situation, and change in scope of work by the customer. For the internal factor, the cause of late completion is an inadequate number of subcontractor teams and long lead time of material manufacture. Based on the interview with the project manager of each project, these projects constitute of different products and have different users; this is related to how project managers and users can collaborate to solve the problem that occurred during the project implementation. Project managers and users ought to agree on the scope first, i.e., have reasonably similar perceptions and expectations, so there will be fewer changes during the implementation. Finally, the project manager can use the agreement to continue planning the project and achieve the project objective.

Abstract

The concept of economic security is not new. Knowledge of the fact that the economic factor affects or even constitutes an inseparable element of security has been accompanying the evolution of international relations throughout the entire history. The research aim of this article is to explain the need for analysing the phenomenon of economic security in correlation with the implemented trade policy. The authors adopted, among others, method of critical analysis of the available literature and the method of comparative analysis. The importance of global market shares was stressed as determinant of country's competitiveness which, in turn, confirms the role of export in shaping economic security.

Keywords: Economic Security, Trade Policy, International Relations, Development Dilemmas

Introduction

The issue of security has nowadays become the focus of attention for politicians and scientists alike. This results both from the dynamics of changes in the system of international relations as well as the emergence of new economic powers. The Copenhagen school headed by B. Buzan lists five main areas of contemporary security: economic, social, ecological, political, and military (Leszczyński 2016, 83).

At this time of dynamic changes connected with the construction of the new international order in conditions of hyper-globalisation, it is important to examine both the economic security and one of the factors shaping it, namely trade policy. Yet at present it is difficult to answer the question as to what kind of trade policy should be implemented by countries in order to draw benefits from their economic growth, while at the same time avoiding the risk adherent to that process, and the resulting decline in their economic security.

The research aim of this article is to explain the need for analysing the phenomenon of economic security in correlation with the implemented trade policy. In the article is also focused on accomplishing cognitive and methodological aims. The cognitive aim means defining the position and the significance of trade policy in shaping the new international order in the era of the progressing globalisation processes. The methodological aim is realised with the use of: (1) a method compatible with systemic approach to research and verification of descriptive and statistical material, and (2) procedure of ordering the process of examining the features and determinants of a trade policy and their influence on the issues of growth and economic security. The authors also used the method of critical analysis of the available literature and the method of comparative analysis of trade policies adopted in various countries at their diverse levels of development.

Security and Its Models in Contemporary International Relations

The modern concept of economic security is defined in a variety of ways, although there exists a common conviction that the economic factor determines the possibilities of social and economic growth in conditions of globalisation (Skulska 2010, 145-146). Following on from Stachowiak (2012, 4), it can be said that these are: the resultant of the factors of economic growth and its limitations; the state of the economy and its structure and also economic relations enabling an effective counteraction against negative external actions able to affect the stability of state system, disrupt economic growth or lower its defence potential; a general state of economic dependence defining the degree of effectiveness of external economic interference in internal economic growth; the reflection of the degree to which a given state is prone to the transference through the economic sphere – mostly through the channels and mechanisms of economic dependences – actions of a political nature aimed at weakening state security (energy-supply blackmail, speculation on the currency market and money market); balancing development needs and the possibilities of their satisfaction.

Kłosiński (2006, 41) defines economic security as "the entirety of factors and conditions protecting the independence of national economy, its stability and equilibrium, and also ensuring its capability for constant renewal and self-improvement". The above definition directs attention to the three-element structure of economic security:

- independence of economy;
- stability and equilibrium in economy;
- capability for constant renewal and self-improvement.

On the other hand, the development of globalisation and the deeping interdependences between countries have led to a phenomenon in which concern for sovereignty is delegated to the international level and described as *pooling sovereignty* (Żukrowska 2003, 188-189). An example of this phenomenon can be seen in individual EU member countries which have ceded a part of their prerogatives onto the level of central authority. Legislative acts in the individual countries have to be adapted to EU laws based on the principle of precedence of the Community laws. The phenomenon of *pooling sovereignty* is also connected with the participation of individual countries in international organizations. A transfer of responsibility for one's sovereignty to the international level is, on the one hand, something positive which allows for the acceleration in making difficult decisions, and also advantageous in the long term. On the other hand, it leads to the restriction of the decision-making field for individual countries, which in certain circumstances may bring disadvantages for individual entities. Decisions made on the international level are not always beneficial to all the interested parties. From the viewpoint of a country's economic security, an equilibrium should be maintained between leaving decision-making competences at the level of a given country and delegating them to international bodies. There are several international organisations whose scope of activity is providing economic security in diverse areas, e.g. the IMF, the World Bank Group, the WTO and the OECD (Marzec 2006, 69-83).

The question of what constitutes the model for the formation of security is in fact a question about the existence of the paradigm of international security in the current international relations. The universal paradigm of international security is normally defined as a set of features which are recognised as common in the context of international security, due to the fact that they describe relations between the entities constituting the international community (Gryz 2006, 15-17). This allows for indicating a group of characteristics existing in the field of international security based on which, and in relations to which, the research model is constructed. These include:

- anarchy of international environment which results from changes in the balance of power between the growth-oriented entities, usually as a result of political, economic, socio-cultural and military rivalry (Buzan 1984, 19);
- turbulence in the environment of international security resulting from the evolving nature of threats which, in conditions of deep interdependency, take on political, economic, socio-cultural as well as a military character. Their existence prompts those entities to seek new

forms of relationships, thanks to which they can – in a less or more formalised way – counteract these threats by increasing their own security;
- sensitivity and susceptibility of entities to the negative impulses originating from the international environment result from the growing processes of international influences and interdependences. That sensitivity and susceptibility on the part of the entity are also usually expressed by the ability to adapt, or not, to disadvantageous changes taking place in the international environment;
- normativity of international relations which defines the forms of the activity of entities, including the ways of ensuring their security;
- institutionalisation of international relations which involves all the spheres of activities by entities (usually states and organisations of international stature): political, economic, socio-cultural and security. In effect the institutionalised model of cooperation becomes a particular example for the activity of those entities.

This model can be also accepted as one appropriate for the study of economic security, with a particular consideration for the influence of trade policy on that matter.

The place of trade policy and the world trade system in the theory of international relations and in shaping economic security

The theory of international relations does not provide a clear interpretation of the role played by the world trade system. According to the realistic vision of these relations (Cini 2003, 94-95), foreign policy is an outcome of interaction between states, each of whom is focused on its own interests in the anarchical international environment, which lacks the generally accepted rules of conduct, as well as authority to enforce elementary rule of law. In these conditions, states determine their own goals in a rational way, based on their military and economic position achieved in the world. Their most important goal is to survive in spite of the continuous rivalry in which there is no place for common interests. In its turn, neorealism represents the view that states, even when functioning in such conditions, can be interested in international cooperation and ordering of their mutual relations as far as this will allow them to strengthen the position among their rivals. To this end, the existence of regimes is useful because they facilitate the achievement of international agreements. These are games with a zero outcome, in which a division of the jointly accomplished benefits depends on the strength of individual countries. Due to those clashing interests, it is difficult for them when faced with the need to conduct their own foreign policy and act under the pressure exerted by internal groups of interests, to construct healthy compromises in international relations (Świerkocki 2007, 232-235).

The crises experienced in recent years, especially the last financial and economic crisis, clearly indicate the weakness of public institutions and effective mechanisms of prognosis and control, which leads one to reflect on effective economic policies, and a new interpretation of the relationship between the state and the market. This is especially important when creating the new, or reorganising the already existing, institutions responsible for shaping economic security, that they are equipped with the appropriate functions. Those particularly important include: regulating human behaviour in a way which does not result in mutual damage or at least compensates for it; lowering the cost of transactions through simplifying contract procedures and access to the commodity market, organising the process of information transfer and facilitating a learning process (Stachowiak 2012, 108). Regarding the issue of the role of the state and the relation of state-market, it should be stressed that high mobility of transnational capital imposes a reorientation of the role and functions of the traditionally interpreted nation-state which is gradually evolving into a 'neoliberal' state, while losing its attributes of real influence on economic processes. At the same time, one can notice a paradox based, on the one hand, on the fact that a growing importance of economic security is a result of the ever more widespread rules of the liberal order in the world economy, and on the other, that the liberal economic doctrine and the world order created on its basis are themselves a source of numerous threats to economic security (Haliżak 2005a, 88). The principle of competitiveness is the condition of the market's effectiveness, and at the same time a constant threat to all entities operating in that market. Thus efficiency and effectiveness become the fundamental criteria of survival, and

neglecting them poses a threat of failure by those entities and entire economies. Yet economic security can be achieved as a result of state intervention and the policy of protectionism – in direct opposition to the theory and practice of liberalism. In international relations this is represented by the fact that threats to economic security do not result from the shortcomings of the liberal order but from its development and success, which lead to the growing inequalities in development. Therefore they are the threats which are brought on by the market and free trade (Haliżak 2005b, 78). Thus a particular dichotomy of opinions arises in the current scientific discourse. One group of researchers sees a connection between economic liberalisation and the international order as positive, since in conditions of liberalism there is a smaller number of conflicts occurring between states and it is possible to see the positive effects of globalisation in individual countries, measured with the Globalisation Index (Tures 2004, 423-431). The second group of researchers is critical in regard of the practical implementation of the liberal order such as the functioning of the World Trade Organisation. In their opinion, the international trade system which followed the creation of the WTO, instead of bringing benefits to everyone, in fact has led to the petrification of the differences in development between states, mostly due to the unequal distribution of benefits created by international trade (Stiglitz 2004, 52-55).

The economic security means, above all, the degree of influence on other foreign entities through economic activities which result from the character of the implemented policy, and whose purpose is to weaken the economy and the whole system of national security (Perczyński 1985, 95). This thesis is correct yet it lacks the points of reference to activities carried out by the state in its own territory and within its own socio-economic system. Threats to economic security do not always arise due to external aggression. Frequently, erroneous decisions regarding a location of capital or trade policy lead to the weakening of the economy or its destabilisation. Another element of a state's economic security is shaping the relations with other entities in the international arena and entering into trade relations both with countries and other entities in the international markets. On the one hand, expanding business ties with foreign entities creates new possibilities, and opens up the existing ones for the economic growth through accessing new markets as well as various forms of capital, but on the other, results in the threat of the occurrence of external factors which may have a negative impact on economic security (Sojka and Waloszczyk 2008, 82-83). With a highly developed network of business ties, there is an increased risk of the lack of total control over them, the loss of control over the flow of resources and the imprecise absorption of information about the potential threats or attacks against a given community or economic system. There also arises a problem of an excessive dependence on a single trade partner or a supplier in the case of purchasing raw materials and energy. The unforeseen actions on the part of such an entity may pose a serious threat to the state's security. In the literature on this subject, the problem of an effective impact on the socio-economic sphere of the state from the outside, has been acknowledged as one of the most urgent (Księżopolski 2004, 51).

The place of trade policy in building the competitiveness of economies and their security

In light of the changing conditions in international competition there is a growing importance of policies supporting internal adjustment of national economies to the requirements of the global economy. Tools of the adaptation policy include the macroeconomic, microeconomic and structural tools, which belong to different types of government policies and can be divided into: instruments of trade, industrial and regional policies, and of competition.

The policy of adjustment requires building a comprehensive economic strategy with a high degree of cohesion between the individual types of policies. Some of them can be treated as substitutive (e.g. trade and industrial policies), while others as complementary (policy of positive adjustment and policy of competition). The nature of interdependences between the policies should be decided by the objectives directing the whole strategy. If the strategic aim is the integration with a specific regional grouping, a special importance is given to the set comprising trade policy, industrial policy and policy of competition. When the superior objective is of a social nature, such as fighting unemployment, improvement of the environment, or reducing regional disparities, a decisive set of policies consists in: trade policy, industrial policy, regional policy, and policy of environmental protection. For the

government activity aimed at improving international competitiveness, a dominating set of policies is made up of trade policy, industrial policy, and microeconomic policy, in particular the rate of exchange (Domiter 2008, 79-84).

These three sets of policies overlap if the country realises concurrently all the above mentioned goals. Poland and Hungary provide an example of economies which during the period of market transformation simultaneously liberalised trade and investment, and aimed at EU integration. These objectives in a way imposed a parallel realisation of broadly interpreted social aims, especially the reduction of regional differences, improvement in the condition of the natural environment and raising international competitiveness.

Model assumptions of a pro-export development and its influence on economic security of countries' economies

A pro-export concept of growth can be realised with the use of one of the two possible directions: opening an economy to external influences (adjustment integration) and external expansion of domestic entities (active integration).

A liberal model of the pro-export economic development is based on the reform of trade policy and exchange rate, as well as liberalising the import of capital. In this model, the basis for activating an effective allocation of production factors which then determine the direction of structural changes, is removing distortions from the economy, in particular those of an economic and domestic nature. However, the distortions resulting from the underdevelopment and functioning of market mechanisms are being ignored, while for the countries which are liberalising ties with abroad this also leaves out the results of distortions of an international nature linked to the functioning of the global economy and policies of other countries. Yet it is worth stressing that development trends and the condition of the world economy are of great importance for the effectiveness of the pro-export reorientation in a development strategy. In this way liberalisation tendencies facilitate a clear reorientation of development (e.g. the pro-export type of development in Hong Kong, Singapore, South Korea and Taiwan in the 1960s) (Wziątek-Kubiak 1984, 150-155).

The basis of the liberal model is external liberalisation, above all of the imports of goods. Increased competition on the internal markets leads to the weakening of national monopolies, improves effectiveness and competitiveness of production, and favours developing specialisation. Removing import restrictions brings quick effects in the economy, and results in development of the export sector, mainly through absorbing production factors freed from other sectors. Liberalising imports is also demonstrated by lowering production costs in sectors which were protected in the past, whereas it has an indirect influence on the growth of exports. Its weak influence on the development of this sector can be explained mainly by the creation of the effect of 'pushing out' production from the domestic market abroad, which is not sufficient to trigger a dynamic mechanism of structural changes. Hence the complementary functions in this model are taken over by the exchange rate policy (Rosati 1990, 208-254).

The liberal model of pro-export development takes on two forms:

- ultraliberal, i.e. devoid of direct support for export. Export stimuli are contained exclusively in the policy of liberalising imports and devaluing the real exchange rate. This form of model was temporarily realised by countries in Latin and South Americas (Krugman and Obstfeld 2007, 363-374),
- moderate, involving different forms of active pro-export policy (Wziątek-Kubiak 1996, 69-73).

The basic assumption of the interventionist model of the pro-export strategy is acknowledgement of the structural heterogeneity of weakly developed economies and of the global market, and their poor integration as well as the fact that market mechanisms alone, in the conditions of underdevelopment and distortions, do not ensure the effective allocation of production factors.

The interventionist model underlines the need to protect domestic commodity markets in the period of redirecting their development strategy. The functioning of these markets can be gradually liberalised. These assumptions originate from the acceptance of the thesis about the imperfect functioning of international markets. In effect the international market does not generate strong mechanism of 'suction' of the production in weakly developed countries, and its distortions disturb the functioning of such economies. Their pace of external liberalisation of these countries, slower than in the liberal model, is explained by the existence of distortions in competition in the world markets. The pro-export policy is meant to neutralise the consequences negative for the development of exports, protection of their own and foreign markets.

Moreover, in this model there are strong arguments for the need of developing the newly created production. In the conditions of strong international competition and weak domestic production there are only slim chances for the creation of new, effective (in terms of international standards) types of production. This leads to the demand for conducting industrial policy which is supposed to stimulate accumulation, induce the improvement of quality and availability of production factors, and channel the available means to achieve the intended aims. In this model a significant role is played by the policy of stimulating savings both at home and internationally, policy of investment including technological and educational; administrative means of control are also applied (Acocella 2002, 286-288).

In the liberal model, the quick external liberalisation of the commodity markets means that only the most effective segments of the economy are able to survive. As a result, the companies that were growing due to the state protection, go bankrupt, and thus the domestic sector shrinks both in the relative and absolute approach, while at the same time exports are growing. Thus the liberal model is also the model of drastic selection on the micro level. The effectiveness of its functioning has its origin in microeconomics.

In the interventionist model, development of the export sector is not accompanied by the falling volume of production of the domestic sector. Its production is also growing, although not as fast as that of the export sector. The pro-export restructuring is an outcome of the differentiation of the dynamics of growth between these sectors (Wziątek-Kubiak 1996, 108). The general principles of the interventionist model were realised, albeit somewhat differently, by South Korea and Brazil. The differences were mostly connected with the policy regarding production factors, especially the import of capital. In South Korea the market of production factors was controlled by the state, and there was also the anticipation of the liberalisation of the commodity markets, in particular the import of foreign capital, in relation to which a selective policy was conducted. In Brazil there prevailed a liberal approach to importing foreign capital which was treated as an element of realisation of the externally-oriented option of development, as well as a source of capital and technology. Moreover, foreign companies were the direct beneficiaries of the export policy because they obtained export subsidies. The interventionist pro-export model was realised starting from the 1960s, i.e. during the time of favourable international conditions (Kim 1991, 33; Coes 1991, 20; Stiglitz and Charlton 2007, 35-37).

In reference to the eternal discussion on the advantages of the liberal concepts over the interventionist ones, and vice versa, one should mention those economists who in the theoretical framework of international economic policies rejected the assumption of the advantages of free market available to all subjects of the global economy. R. Prebisch thought that international trade is the outcome of trade policies pursued by the most developed countries, defined as the centre, and in his opinion two processes are potentially possible. In the first one, the countries of the centre, through the high level of their own imports create a high import demand for their own products among the other subjects in the world economy. This brings an increase in trade links between countries which remain outside the centre. In another, diverse situation, when countries of the centre demonstrate low import indicators, it is the countries from outside the centre which have to restrict their own imports from there and reduce its volume in their mutual relations.

Prebisch also rejected the thesis about benefits from free trade for all subjects in the world economy. In his opinion, the theory formulated by D. Ricardo restricts the possibilities of obtaining benefits from technological progress by less developed countries. In effect, within the centre-periphery system there exists unequal trade exchange, which in the periphery countries results in structural unemployment, lower domestic revenues, lack of equilibrium in the balance of trade and worsening of the terms of trade (Prebisch 1959, 266).

The concept of Prebisch contributed to the still ongoing discussion which searches for an answer to the question whether in fact developing countries are losing the basis for their own economic security as a consequence of the world trade and the current form of the global economy. This discussion also concerns justification for the policy of protectionism or liberalism. The neoliberal paradigm has become the main ideological force for managers and economists in the global economy, and also for politicians in the centre countries, yet it turned out to be unable to solve the economic and social problems of peripheral economies (Stiglitz 2004, 23-32).

Conclusions

This article showed the relations between trade policy and security of a country. The concern about the shortage of goods, or in other words the psychosis of the fear about the lack of goods, have always constituted the premise for seeking to ensure economic security for countries and for individuals. These factors made the entities in the world market determined to strive for obtaining benefits from trade exchange, and thus for the best possible access to the structures of the global market. This, in turn, is linked to the comparative advantages which define the competitive position of individual countries in respect of other entities in the global market. International competitiveness of a country signifies its ability to defeat competitors not only abroad but also in the domestic market. Market shares which describe the participation of a country in the global export market provide a synthetic measure of competitiveness. This is the reason why countries attach (or should do) such great importance to exports and factors of its growth as to the factors which create their development and shape their economic security.

Treasury Bond Yield Curve as Verification Tool for Equity Us Market Bubbles Valuation Before Recessions

Mikhail DOROFEEV

PhD, associate Professor of the Public Finance Department, Financial University under the Government of the Russian Federation, Moscow, Russia
dorofeevml@ya.ru

Abstract

The concept of a price bubble in the financial market is rather complex and contains many nuances. Measuring of price bubbles and identification of market tops is very sophisticated activity even for professional portfolio managers. Methodology of measuring bubbles contains plenty of various indicators, ratios and statistical models, but nonetheless it is still difficult to forecast timing of equity market top. In this work, we review and classify the definition of a financial market bubble and research its nature via specific financial metrics. Valuation metrics show that at the start of US recession equity markets are not extremely overvalued, that is why according to our research and calculations price bubbles usually start deflating before a recession. During this research we found that yield curve could be a useful methodological support tool for US equity market bubbles identification.

Keywords: Equity Market, Recession, Price Bubble, Financial Bubble, Treasury Bond Yield, Yield Curve, SPX500.

Introduction

The modern market economy develops in a cyclical manner. During periods of economic growth are followed by declines in business activity and financial crises with sharp declines of stock market prices and macroeconomic indicators (GDP, unemployment industrial production). Rather often stock market creates a price bubble, before long-term financial crisis, and economy falls into recession after the bursting of this bubble.

The nature of a price bubble is closely related to the hypothesis of financial markets informational efficiency, formulated by E. Fama (1970). The content of the efficient-market hypothesis lies in the fact that on an efficient market asset prices instantly and completely assimilate all available information, reaching a state of equilibrium over time. The consequence of the information cascade leads to specific collective behavior of market participants and make the prices deviate from their fair value. Determination of this particular fair value and concrete timing of market top formation is a rather complicated task.

In this paper, we exploit the prospective of treasury bond yield as a tool for identifying market tops and as a filter to potential equity market bubbles. To do so, we analyzed NBER recessions data for USA, historical pool of SPX500 traditional valuation metrics (such as D/P, P/E, CAPE10 etc.) and compared them to the data with US treasury bond yield inversion facts.

Literature Review

One group of authors believes that the bubble is an unnatural and irrational phenomenon, mainly associated with a sharp increase in asset prices and having negative consequences for the economy and financial markets (Dorofeev M. and Samarskiy G., 2016; An J., Dorofeev M., 2019; An J. et al, 2019a; Mikhaylov A. et al, 2018). Two subgroups can also be classified in this group: authors who do not have clear criteria for “sharp price increases” and authors who recommend to use different specific financial indicators concerning with the price growth rate and indicating the presence of a price bubble and risks

for an economy. Basing on the first group of authors we conclude that the overall idea of a financial bubble is the following “The financial bubble is a sharp and irrational increase in prices, followed by the collapse of the market and the economy”.

The other group basically interprets the financial bubble as a natural regularity, which is part of the economic system and does not always lead to destructive consequences, i.e. relatively neutral phenomenon for the economy (Garber P., 2001). Some authors from this group suppose that the bubble is a rational phenomenon, and some even believe that such a concept does not exist (Fama E, 1970). Consider each group of "financial bubble" definitions in details. According to our research data we found that second group of authors define financial bubble as a “Rational and natural economic and behavioral phenomenon that is an inseparable part of the financial system and is not always accompanied by devastating consequences for the economic system” (Sornette, 2003; Blanchard et al, 1982; Detken and Smets, 2004).

To summarize our review of the scientific sources about financial bubbles, we must admit that we did not find a comprehensive, concise and universal definition of this term. Firstly, because from a practical point of view, it is not so easy to identify the top of bubble. Secondly, it is also difficult to predict the duration of price bubble development stages. Thirdly, we found different opinions concerning the degree and economic nature of financial bubbles impact on the real economy and financial markets. One group of authors, apparently, connects the concept of a bubble with large-scale phenomena that affect the state of the economy as a whole. Another group considers this concept more broadly and notes that price bubbles are not always a negative phenomenon with devastating consequences for the economy. In addition, there are also opinions that financial bubbles do not exist at all.

There are many approaches to identification of a financial bubble regarding to equity markets. All methods are concentrating on assessments of valuation fundamentals via use of different ratios and financial indicators to measure the fairness of current market price levels (Garber P., 2001; Dorofeev M. and Samarskiy G., 2016; An J. and Dorofeev M., 2019; An J. et al, 2019a; Alwaelya S. et al, 2020; Dayong N. et al, 2020).

Also, there is a group of authors, who use intermarket analysis and measure bubbles in oil prices, implying that energy markets participate in creation of financial market bubble for last turn (An J. et al, 2020; An J. et al, 2019a; An J. et al, 2019b; Mikhaylov M., 2018; Mikhaylov M., 2019; Meynkhard A., 2020; Nyangarika A. et al, 2018; Nyangarika A. et al, 2019a; Nyangarika A. et al, 2019b).

With the development of cryptocurrency markets researches got rather interesting and promising datasets for research the nature of price bubbles. Most methods there are upbuild on modern economic and mathematical models and mainly statistical approaches to identification of bubbles, because there are certain problems with valuation of cryptocurrencies via, for example, DCF-methods are inapplicable in such case (Denisova V. et al, 2019; Dorofeyev M. et al, 2018; Meynkhard A., 2019a; Meynkhard A., 2019b; Mikhaylov A. et al, 2019).

Concept Headings

In our work, we applied methods of traditional fundamental valuation and measurement of equity markets. We used economic database of Federal Reserve Bank of St Louis to give specific financial characteristics for a typical equity market bubble. To make the picture clear enough we took the official dates of recessions in USA (version of NBER) and collected commonly used financial ratios for these particular dates. In our research, we used the following indicators: Dividend-to-Price (D/P); Price/Earnings (P/E) and the reverse ratio (E/P); R. Shiller Price/Earnings ratio (CAPE 10).
Particularities of usage treasury yield curve as special tool for finding equity market bubbles is basing on the following principles.

1. We used three types of curve spreads: 10-year treasury constant maturity minus 3-month treasury constant maturity (T10Y3M), 10-year treasury constant maturity minus 1-year treasury constant

maturity (T10Y1Y) and 10-year treasury constant maturity minus 2-year treasury constant maturity (T10Y2Y).
2. Each curve spread moves in a cyclical manner, according to the certain phase of US credit cycle, and also has its own typical upper and lower boundary, reflecting changes of term premiums for US treasures investors. For T10Y3M yield spread this range is [0%; 3.5%]. For T10Y2Y yield spread the range was set as [0%; 1.6%]. Finally, the range for T10Y2Y the range was set as [0%; 1.5%]. Reaching the lower boundary corresponds with a peak of FED's interest rate normalization policy (rate hiking). When spreads intersect their upper boundary, the picture becomes the opposite – easing phase of monetary policy comes to the end and finishes there.

Calculations of equity valuation metrics are made with the use of SnP500 index open monthly prices for the starting date of a recession and close prices for the its ending date.

Discussion

We understand financial bubble as a sharp, steady and rapid increase in the asset price (over 10%, depending on the type of the market) over a certain period of time. It develops from one to three years in equity market in conditions without adequate and proportional change of asset fundamental metrics and in most cases caused by irrationality of investors' behavior or by specific monetary policy of a country. In all cases price usually reverses on the top of financial bubble and market makes a meteoric decline to the price levels where this bubble starts.

Table 1 contains information with calculations of key statistics for SnP500 equity index valuation financial metrics averages and extremums, produced with the use of data of the 1873Y-2019Y period.

Table 1: Key statistics for SnP500 equity index valuation financial metrics in 1873-2019 YY

	D/P	E/P	P/E	CAPE10
Maximum	13,84%	18,82%	123,73	44,20
3-rd quartile	5,38%	8,73%	18,07	20,56
Average	4,33%	7,35%	15,76	16,99
Mean	4,27%	6,77%	14,77	16,22
3-st quartile	3,14%	5,53%	11,45	11,84
Minimum	1,11%	0,81%	5,31	4,78
Standard deviation	1,71%	2,70%	8,39	6,83

Our own calculations based on monthly data from https://fred.stlouisfed.org and http://www.econ.yale.edu/~shiller/data.htm

This information is useful for valuation and measurement of SnP500 bubbles. According to basic rules of asset valuation, long term mean or average reflects the level of fair market value. Potential price bubbles usually occur in higher than the 3-rd quartile range of metrics.

Table 2 shows the picture of SnP500 equity index financial metrics only during the periods of US recessions from 1873Y till 2009Y.

Table 2: Statistics for SnP500 equity index financial metrics during US recessions. The period of observation is 1873-2009 YY

Our own calculations based on https://fred.stlouisfed.org and http://www.econ.yale.edu/~shiller/data.htm

We measured out that US recessions timing is usually suits the occasion when yield spreads move from the lower to the higher boundary and cross its middle. US economy overcomes a recession before yield spreads come to their higher boundaries.

Visualization of SnP500 bubbles valuation metrics is shown on figure 1. We can see there, that treasury yield inversions precede recessions in US economy, at the same time they arise at local tops of CAPE10 chart and in most cases before SnP500 tops before recessions.
The key finding of this work is that the idea of the usage yield spreads in combination with SnP500 valuation metrics is an effective filter of identification price bubbles, giving rather accurate timing for long-term investors and monetary authorities.

Fig. 1: SnP500 valuation metrics; dates of recessions start, SnP500 tops; yield curve inversions. Monthly data for the period of 1873-2020 YY.

Our own calculations based on https://fred.stlouisfed.org, http://www.econ.yale.edu/~shiller/data.htm and https://www.gurufocus.com/yield_curve.php

Results

Stock market price bubble is rather complex matter. It is difficult to make at the same time laconic and comprehensive definition for this phenomenon. The key feature of a bubble is the speed of movement and a significant change in price and fundamental metrics of a particular asset.

The comparison of the SnP500 statistics for equity index financial metrics at the start of a recession with averages and extremums calculated for the general sample of monthly data of the period 1873-2019 shows that equity market is usually in a relatively adequate valuation levels at the start of a recession.

The use of treasury yeild curve in pair with a number of commonly-known valuation financial metrics is useful methodological support tool for identification equity market bubbles.

Impact of Urban Transport Innovation on The Quality of Life: What Do Passengers Say?

Abstract

City authorities are taking action to increase public transport attractiveness. More and more innovative solutions are being introduced. Therefore, the research was aimed at answering the question: have innovations improved residents' quality of life in their opinion. The research was conducted in one of the Polish cities due to the number of introduced innovations. Surveys were carried out, which showed that the introduced innovations improve the quality of life of residents. In their opinion, innovations most influencing their quality of life are connected with security and travel comfort. Innovations connected with the environment and availability of information play also an important role.

Keywords: Quality Of Life (QOL); Public Transport; Innovations; Management.

Introduction

The literature indicates that the increase in the wealth of the Polish society affects the greater accessibility of individual transport to the users. Thus, the demand for public transport services is decreasing. Cities are becoming increasingly crowded with cars, which may lead to their transport paralysis. At the same time, the inhabitants bear the costs related to the negative impact on their health and natural environment (Barcik and Jakubiec, 2014), (Proost and Van Dender, 2012). The key to reversing this trend may be the introduction of innovative services and solutions that meet the needs of public transport passengers (Tsafarakis *et al.*, 2019), (Trippner-Hrabi and Podgórniak-Krzykacz, 2018). It should be emphasized that the improvement of the residents' quality of life may be the consequence of reversing the trend of increasing the share of individual transport in mobility within cities.

The issue of quality of life is widely discussed in the literature on the subject (Pukeliene and Starkauskiene, 2011). Some researchers express the opinion that no other topic is so frequently discussed (Shek, Chan and Lee, 2005). This concept is considered from the perspective of various sciences (Shek, Chan and Lee, 2005), e.g. medicine (Kane, 2003), ecology (Ims, 2018), or economic sciences (Vargas-Hernández, 2016). Moreover, specialised journals are dealing with the quality of life, such as "Quality of Life Research" or "Applied Research in Quality of Life". Due to the differences between scientific disciplines, it is not possible to develop a commonly accepted definition of quality of life. However, there is a consensus in the literature on the subject, with some reservations (Shek and Lee, 2007), that quality of life can be understood as “as the set of factors which contribute to the general well-being of people in terms of personal satisfaction with happiness, health, safety, intellectual and cultural preferences, financial security, family life, job satisfaction, etc. Quality of life has been defined as the level of satisfaction with an individual´s conditions,

relationships, and surroundings relative to the available alternatives" (McGregor and Goldsmith, 1998), (Wallander, Schmitt and Koot, 2001).

Quality of life is also important from the perspective of sustainable development (Eusuf *et al.*, 2014). By integrating the natural environment into the socio-economic development of a region, country, or in the global perspective, the whole world, it is possible to improve its condition and thus the quality of life of people (Skowroński, 2006). The quality of human life cannot be considered in isolation from the quality of the natural environment in which humans live (Khasaev *et al.*, 2019).

Within the framework of European Union policy, the importance of improving quality of life and pursuing sustainable development can also be noticed. This is expressed, inter alia, through the European Mobility Week campaign. In fact, "since 2002 it has sought to improve public health and quality of life through promoting clean mobility and sustainable urban transport. The campaign gives people the chance to explore the role of city streets and to experiment with practical solutions to tackle urban challenges, such as air pollution"(*The campaign*, 2019). Moreover, at the strategic level, there are documents such as the Europe 2020 Strategy, which in its assumptions determines the need to support innovation, intelligent and sustainable development and counteracting social exclusion (*EUROPE 2020 A European strategy for smart, sustainable and inclusive growth*, 2010).

Schumpeter pointed out that innovation affects the quality of life. There are publications confirming the opinion of that author (Woodside, Bernal and Coduras, 2017). Therefore, it can be presumed that innovations related to sustainable urban transport can also improve the quality of life.

In the literature, studies are linking the quality of life to transport, e.g. on transport policy in ageing society (Metz, 2003), or generally on the impact of urban public transport on the quality of life of urban residents (Ciobanu, Bugheanu and Ciobanu, 2015), (Wann-Ming, 2019), (Ismail *et al.*, 2012). It is indicated that appropriate solutions in public transport, responding to the needs of residents, may contribute to the improvement of their quality of life (Przybyła, Kulczyk-Dynowska and Kachniarz, 2014). So, we should know the importance of innovation for residents (Tsafarakis *et al.*, 2019). At the same time, it should be emphasized that the comprehensive improvement of the quality of life only through the development of sustainable transport is insufficient (Wann-Ming, 2019).

In the authors' view, the impact of public transport innovation on the quality of life of passengers should be investigated, as it is an area that requires in-depth analysis. There are papers which try to rank innovation in public transport (Nalmpantis *et al.*, 2019), (Tsafarakis *et al.*, 2019), and are based on people's opinions. However, they are not investigating the quality of life and are not focused on passengers who are using those innovations on an everyday basis. This paper closes this research gap.

The results of the local government elections in Poland in 2018 proved that issues related to public transport are important for voters. They occupied the central positions in the programs of candidates for mayors. Those of them, including the former mayors, who cared about systematic and planned development of urban transport, usually either won in the first round or were elected in the second round (Gromadzki, 2018).

There are examples of cities in Poland where efforts have been undertaken to make public transport more attractive. For example, 198 electric buses were registered in Poland in July 2019. Most of them were registered in the following cities: Zielona Góra 43 buses, Warsaw 31 buses, Kraków 26 buses, Jaworzno 24 buses, Inowrocław 10 buses, Stalowa Wola 10 buses, Szczecinek 10 buses, Rzeszów 10 buses ("E-bus counter in Poland" 2019). Electromobility is, at present, a subject of particular interest among leading world economies (Altenburg, Bhasin and Fischer, 2012). Therefore, it is not surprising that also in Poland, steps are being taken to increase the share of electromobility in urban transport.

Zielona Góra may be considered the city with the highest number of introduced innovations in the context of urban transport and sustainable development.

The electronic boards informing about the actual departure time of buses were introduced in 2005. It was the first city in the country where this solution was applied. The interchange station was opened in 2019. The first electric buses appeared in Zielona Góra in 2018. From amongst the fleet of 100 vehicles in Zielona Góra, 43 buses are electric. They performed about half of the transport work in August 2019. 2018 was also the first year when free rides for students up to 20 years of age were introduced. Furthermore, the buses are equipped with video monitoring and some of them with defibrillators. Passengers can also use an interactive map indicating the position of the vehicles, the type of vehicle (electric) and the availability of a defibrillator on the bus. Additionally, it is possible to purchase tickets via mobile applications. The residents have also been provided with an option if an electronic ticket, the so-called e-card. All of the above changes are innovative solutions in the area of public transport in Zielona Góra.

The aim of the research was to identify, analyse and evaluate the impact of the introduced innovative public transport solutions on the passengers' quality of life. The research was conducted in Zielona Góra due to the diversity and number of introduced innovations.

Materials and Methods

Based on the analysis of the literature, the factors which theoretically influence the quality of life in the context of urban transport innovation were identified. The factors were also selected on the basis of the objectives to be achieved by the introduced innovations in urban transport in Zielona Góra. The analysis of the documents related to the introduced innovations showed that the undertaken actions were to reduce the noise level, to improve the air quality, to improve the safety and to facilitate the use of public transport. The list of factors was supplemented by the following elements related to the quality of life:

- safety (Pukeliene and Starkauskiene, 2011), (Cummins, 2000);
- material well-being (Pukeliene and Starkauskiene, 2011);
- accessibility of urban transport information for older adults (Hounsell et al., 2016);
- reduction of the negative impact of transport on the environment (Nosal and Starowicz, 2010);
- noise (Duarte and Tamez, 2009);
- comfort (Fellesson and Friman, 2012), (Putra and Sitanggang, 2016).

Due to the similarity criterion, it is possible to combine noise and reduction of the negative environmental impact of transport into one factor, which has been done.

As it was mentioned in the introduction section, there are nine types of innovation in the analysed city.

The survey was conducted among public transport passengers between 21.08 and 07.09.2019. The information about the survey was published on the website of the Municipal Department of Communication (MZK) in Zielona Góra and in the social media of the carrier. The respondents filled in an online form. The formulas in the questionnaire were consulted during trial tests. As a result, the decision was made to change the content of some of the questions in order to make them more understandable for the recipients.

The questionnaire consisted of 23 research questions covering factors influencing the quality of passengers' lives. A metric examining demographic data was also included. In the first part, the respondents were asked about the impact of introduced innovations on their quality of life. The 5-point Lickert scale was applied, where 1 meant a very negative impact on the quality of life, whereas 5 meant a very positive impact on the quality of life. For example, passengers were asked about the impact of electric buses on their quality of life. In the second part, the respondents were asked to link an appropriate statement relating to a given factor (eg. safety). For example, they were asked do the bus defibrillator affect their safety? The 5-point Lickert scale was also used here, where 1 meant that it did not improve at all, and 5 meant that it improved to a very large extent.

More than 400 people took part in the survey. If we take as our confidence level 95%, with unknown faction size (assuming 0.5) and a maximum error of 5%, knowing the population size - 60,000 users of public transport per day, then the minimum number of people in the study should be 382. Therefore, it should be assumed that the research sample, with the given assumptions, is representative, and the results obtained on the sample can be extended to the whole population. It should also be emphasized that only questionnaires completed in full and correctly were accepted, those with gaps or errors were rejected. We gained 400 questionnaires and used IBM SPSS to all statistical analysis.

Since the questionnaire was the researchers' original concept, its reliability was analysed by calculating the coefficient alpha. The questionnaire consisted of two types of scales. Scale1 included questions concerning the impact of the applied innovations on the quality of life, Scale2 measured the change in the level of quality of life indicators after the introduction of innovative changes in urban transport.

Table 1: Cronbach's Alpha for Sale 1 and Scale 2

Scale	Cronbach's Alpha	Number of items
Scale 1	.740	7
Scale 2	.740	7

Source: own work.

Cronbach's alpha is a measure of internal consistency, that is, how closely related a set of items are as a group. It is considered to be a measure of scale reliability. The results presented in Table 1 indicate that an acceptable level of statistics of Cronbach's Alpha was obtained (reliability coefficient of .70 or higher is considered "acceptable" in most social science research situations), and therefore the questionnaire can be considered reliable.

The study involved 231 women and 169 men, whose age ranged from 18 to over 65 years, as shown in Table 2.

Table 2: Age of the respondents

Age	Number of respondents
18-30	230
31-45	94
46-65	59
over 65	17

Source: own work.

The majority of respondents, 343 out of 400, indicated Zielona Góra as their place of residence. The level of education is presented in Table 3.

Table 3: Level of education of respondents

Level of education	Number of respondents
Elementary	3
Lower secondary	26
Vocational	22
Secondary	171

Source: own work.

Results

Literature studies have indicated that there are factors linked to innovation in urban transport that can improve the quality of life of the users. The performed theoretical analysis resulted in the formulation of the main research hypothesis: H1: *There are statistically significant relationships between groups of innovative factors and measures of the quality of life of urban transport users*.

We have nine introduced innovations: 1. electric buses, 2. integrated interchange station, 3. surveillance system on city buses, 4. availability of a defibrillator during travel, 5. option to buy tickets through mobile applications, 6. free rides for students up to 20 years of age, 7. information about current GPS positions of buses via the website, 8. electronic bus stop boards, 9. introduction of an electronic ticket (e-card).

Aggregation of these innovations (factors) using factorial analysis with Varimax rotation was proposed. So there is need to check if conditions for factors analysis are fulfilled. Kaiser-Meyer-Olkin Measure of Sampling Adequacy and Bartlett's test of sphericity should be done.

Table 4: Kaiser-Mayer-Olkin's and Bartlett's tests

KMO measurement of sample selection adequacy		.794
Bartlett's test for sphericity	Approximate chi-square	551.138
	Df	36
	Relevance	.000

Source: own work.

The Kaiser-Mayer-Olkin's test with high values (close to 1.0) indicates that factor analysis may be useful with provided data. If the value is less than 0.50, the results of the factor analysis probably won't be beneficial. Bartlett's tests with small values (less than 0.05) of the significance level indicate that factor analysis may be useful with provided data. Results in Table 4 show that conditions for factorial analysis are fulfilled.

Factor analysis is used to identify variables called factors that explain correlation patterns that occur within sets of observed variables. Factor analysis is often used in data reduction to identify a small number of factors explaining most of the variance observed in a large number of variables. Varimax method allows minimizing the number of variables with high factor loadings by orthogonal rotation. This simplifies the interpretation of the factors.

The applied factor analysis with Varimax rotation showed the existence of 2 new bundles of factors. The first bundle of factors include: the surveillance system introduced on the buses, availability of a defibrillator, introduction of electronic tickets (e-card), electronic bus stop boards and the possibility to buy tickets through mobile applications. The second bundle of factors is burdened with the following variables: the integrated interchange centre, electric buses, free rides for students, information about the current GPS position of buses via a website.

In conclusion, the conducted factor analysis with Varimax rotation resulted in the aggregation of nine factors into two factor beams. According to the method of main-factors components identification, the first one consists of 5 factors, and the second one consists of 4 factors. The statistical analysis and the results of Kolmogorov-Smirnov's test with Lilliefors correction for n=400 amounted to 0.161 and 0.111 for Component1 and Component2, respectively. The α value in both cases was lower than 0.05. That indicates that the distribution of new variables is not similar to the regular distribution.

In order to verify the primary research hypothesis H1: *There are statistically significant relationships between groups of innovative factors and measures of the quality of life of urban transport users*, four auxiliary hypotheses were formulated and then subjected to statistical tests. The first and second auxiliary hypotheses referred to the relationship between Component1 and the quality of life aspects

studied: HpP1: *There is a relationship between Component1 and the improvement of the quality of life of the population*, HpP2: *There is a relationship between Component1 and the improvement of the quality of life in the four areas of the standard of living*. The results of the rho-Spearman correlation test for an alternative hypothesis to the studied hypothesis indicate that there are statistically significant monotonous relationships between all the variables studied. The values of correlation coefficients are shown in Table 5.

Table 5: Correlation test for Component1

	Value R	Relevance at the level of 0.01	Interpretation
Component1 Level of security improvement	0.613	0.000	Correlation high-dependence high
Component1 Level of environment improvement	0.371	0.000	Low correlation - clear dependence
Component1 Level of availability of information improvement	0.424	0.000	Moderate correlation - significant dependence
Component1 Level of travel comfort improvement	0.370	0.000	Low correlation - clear dependence
Component1 Level of quality of life improvement	0.558	0.000	Moderate correlation - significant dependence

Source: own work.

When interpreting the rho-Spearman ranks' correlation coefficients, it should be noted that the strongest correlation occurs between Component1 and the level of safety improvement. The relationship between Component1 and the general level of improvement in the quality of life of the inhabitants is considered to be significant. The second and third auxiliary hypotheses referred to the relationship between Component2 and the quality of life aspects studied: HpP3: *There is a relationship between Component2 and improving the quality of life of the population*, HpP4: *There is a relationship between Component2 and improving the quality of life in four areas of the living standard*. The results of the rho-Spearman correlation test for the alternative hypothesis with respect to the hypothesis under investigation indicate that there are statistically significant monotonic relationships among all the variables studied. The values of correlation coefficients are shown in Table 6.

Table 6: Correlation test for Component2

	Value R	Relevance at the level of 0.01	Interpretation
Component2 Level of security improvement	0.319	0.000	Low correlation - clear dependence
Component2 Level of environment improvement	0.501	0.000	Moderate correlation - significant dependence
Component2 Level of availability of information improvement	0.524	0.000	Moderate correlation - significant dependence

Component2 Level of travel comfort improvement	0.576	0.000	Moderate correlation - significant dependence
Component2 Level of quality of life improvement	0.670	0.000	Correlation high-dependence high

Source: own work.

When interpreting the rho-Spearman ranks' correlation coefficients, it should be noted that the strongest correlation occurs between the Component2 and the level of improvement in the quality of life in general. The relationship between Component2 and the level of safety improvement is considered to have a low degree of correlation. The link between the examined component and the other measures of improvement in the standard of living level is considered a significant relationship.

In the course of the survey, the respondents were asked to determine the degree of improvement in the quality of life in the following areas: the improvement of the security level, the improvement of the environmental conditions level (natural environment), the improvement of the availability of information level, the improvement of the travel comfort level. The appropriate measures were assigned to the above mentioned areas. The respondents were asked to assign an appropriate statement to a given measure in a particular area. Answers were marked on the 5-point Likert scale.

Table 7: Scale

Answer code	Meaning
1	Has not improved in any way
2	Has slightly improved
3	Has moderately improved
4	Has improved to a large extent
5	Has improved to a very large extent

Source: own work.

Surveys showed that the highest average value was achieved in the level of improvement in the travellers' safety. The average of the responses amounted to 4.45, which means that safety had improved significantly since the introduction of the innovations in public transport. The area of the improvement in a natural environment, at the time of the survey, was determined at the level of 3.14, which implies that respondents moderately feel the level of improvement in air quality or noise reduction. After the introduction of innovative solutions in the field of transport services, the level of accessibility to information improved significantly, which was estimated at the level of 4.27. The level of travel comfort, according to the respondents, improved on average at the level of 3.58. The analysis of the obtained answers indicates that in general the level of improvement in the quality of life of the inhabitants after the introduced changes was estimated to be 3.93, which means that the users of public transport experienced improvement in the quality of life level to a large extent.

Discussion

There are other studies that assess innovations in public transport. For example, (Tsafarakis et al., 2019) show that the most important innovation is “Real-time travel information at Public Transport stops”. In turn, (Nalmpantis et al., 2019) show that “enabling a seamless journey, using the best possible connections and the most suitable transport modes, provided through one interface, such as a platform that brings together different types of transport options and the provision of real-time transport information” has the highest score in terms of utility. In our research “availability of information” is also significant. Passengers in Zielona Gora are happy with electronic boards

informing about the actual departure time of buses. In their opinion, it is one of the most important innovations.

There are other similarities too. One of the most important innovation is connected with tickets. People appreciate special prices for commuters (in our research: free rides for students) and advanced e-ticket system.

We have found additional innovations connected with the environment and with safety. Respondents say that the surveillance system and defibrillator have a positive impact on their quality of life. They think electric buses reduce noise and increase travel comfort.

It seems that other cities authorities when buying new buses should focus on buying electric ones with the surveillance system and provided with a defibrillator. That will increase the quality of life. In their mind should be advanced e-ticket system, with the possibility of mobile payments. Passengers will appreciate real time traffic information at bus stops too.

Further research should focus on conducting it on a larger sample, e.g. national or in comparison with other countries. This may be problematic as different cities have implemented different numbers of innovations in public transport. Other factors, i.e. those not examined by the authors of this article, may also be taken into account.

It should be noticed that the survey was based on the opinions of respondents. So there are some limitations. Hence, it is possible that respondents could give opinions without thinking more deeply about the questions. It is also essential that the respondents may not have had the same experience level as the introduced innovations. For example, some use them every day, others occasionally. The circumstances in which the subjects filled in the form were also significant.

Acknowledgments

The authors would like to thank Barbara Langner and Anna Chaberska for help in carrying out the research, and Ewelina Hajlasz for the guidance in the construction of the questionnaire. This research was funded by the Ministry of Science and Higher Education core funding for statutory R&D activities.

Abstract

India is the largest milk producer in the world, but faces a lot of challenges in the form of dropouts from the farming activity, high cost of milk production and meagre returns. All this is due to the inefficient use of the inputs. Efficiency signifies a level of performance that describes using the minimal values of input to achieve the highest amount of output. The study was conducted to estimate the allocative efficiency of dairy farms in Kerala, India, by applying stochastic cost function methodology. Allocative efficiency estimates are generated for 300 dairy farms in Kerala. The results of the study communicates the allocative efficiency of milk production by the dairy farms in Kerala is between 70-79 per cent levels of efficiency. The mean efficiency is only 61.3 per cent, where the farms could increase efficiency by 51.3 per cent. There is a statistically significant difference between the farm sizes concerning allocative efficiency. To enhance farm efficiency, there should be a proper awareness and education regarding how to reduce the cost of production

Keywords: Milk production, dairy farms, Allocative efficiency, stochastic cost functions, Kerala India.

Introduction

Dairying is an essential activity in the Indian economy, contributing to 4.6 per cent of the national Gross domestic product (GDP) by Datta (2018). The Milk production in India has increased from 55.6 million tones (1991-92) of output per year (1991-92) to 176.3 million tones (2017-18) of production per year (Basic Animal Husbandry Statistics-2019). The country is now self-sufficient in milk and exports dairy products. The dairy sector has a very crucial role in ensuring food security by reducing poverty at the same time and involvement in dairying activities creates many employment opportunities. The Indian economic survey for the financial year 2017-2018 showed the fall in the growth rate of agriculture and its allied sectors by 2.1 from 4.1 per cent by Datta (2018). This is because many farmers exit from this sector, due to the high cost of production. Kerala is a state in India, famous for its eco tourism and back waters. It's situated to the west of Arabian Sea.

The Cooperative systems in India have a long history. They have been supported majorly by the government and international donor agencies as a way to improve the income of the farmers. Especially Dairy Cooperative Societies (DCS) have been promoted by the Government of India (GOI) since the 1960s. The dairy cooperative in India is known as the Anand Pattern Co-operative society, which is popularly known as APCOS. It functions mainly as a collection point of milk produced in villages (National Dairy Development Board, 2017). At the DCS level, the milk poured by the farmer is tested for fat percentage and payment is made accordingly at a weekly or fortnightly basis through bank transfer, which was a recent development as part of Digital India. At the second tier, DCS are linked to district cooperative unions which are engaged in processing of milk and packaging of final products. The cooperative society usually provides subsidy services to the

producers, such as cattle feed, artificial insemination and veterinary services (Department of Dairy development Kerala)

The liquid milk represents the most prominent product segment in Kerala, accounting for more than 71 per cent of the entire market share. (Dairy Industry in Kerala: Market Size ,2020). The milk production in Kerala is not showing a static growth; it's increasing in a very slow phase. In 2006-2007, the production was 21.9 million metric tons per year, and in 2017-2018 it rose to 25.70 million metric tons. (Basic Animal Husbandry Department, 2019). The cost of milk production in Kerala is very high compared to other states of India, mainly due to non-availability of feed, high price for feed and non-availability of hired labours for engaging in this activity. This affects milk productivity. The annual hike in feed, animal health issues and weak and inefficient marketing systems are contributing to these productivity problems.

In developing countries like India, it is useful for policymakers to estimate the efficiency of agricultural production. The notion of economic efficiency brings out a theoretical base for such estimations (Russel & Young, 1983). Measurement of efficiency in any industry is to analyse the relative performance of plants or firms within the industry and thereby to give a structural picture of the sector (Farrell, 1956). An inefficient firm is one which is not reducing its average cost and misusing all the inputs, because it is not producing the maximum attainable output from the given quantity of inputs by Bauer et al (1998).

Frontier cost functions have been applied to farm level in many developing countries, to estimate their cost efficiency of milk production. These results have yielded many useful results and suggestions for improvement (Coelli, 1996).

The stochastic cost function is a parametric stochastic approach, which is used to measure allocative efficiency.

In spite of the efforts made by the Kerala Government and Kerala Dairy Development Board for the improvement of milk production in the country, the dairy farmers still face high input cost in the milk production coupled with low milk procurement price offered by the dairy cooperative society. The problems mentioned above will reduce profit margins. There is a need to estimate the allocative efficiency of milk production in Kerala.

The primary purpose of this study is to estimate the allocative efficiency of milk production in Kerala by applying the stochastic frontier methodology. The study aims to test the following hypothesis

H1= Allocative efficiency is the same across the different farm sizes.

Materials and Methods

The study is conducted among the Kerala dairy farmers, who are registered under Kerala Co-Operative Milk Marketing Federation (MILMA). A sample survey of 300 commercially dairy producers was selected. Out of 14 districts in Kerala, six districts were selected randomly. From each district, 50 dairy farmers were interviewed. The farmers were divided into small (1 to 4 milch animal) medium (5 to 6 milch animal) and large (greater than six milch animals) farmers based on a number of milch animal holdings by Binita et al 2016). Following table shows the number of dairy farmers interviewed for the study based on their milch animal holding.

Table 1: Farm groups depending on the number of milch animals

Farmer Group	Number of Milch Animal	Number of Sampled Framers
Small Farmer	1 – 4	273
Medium Farmer	5-6	9
Large Farmer	Greater than 6	18
Total		**300**

Source: Prepared by the author

The survey was conducted during the month of September to December 2019. Through personal interviews, data's were collected. For the collection of socio-economic characteristics, input prices, amount of milk produced and other related aspects, a structured questionnaire was designed.

Based on Farrell's theory, there are two methods to use for the estimation of efficiency; one is stochastic production frontier method (Meeuseen and van den Broeck, 1977) and the data envelopment analysis by Charnes et al (1978). The paper has used stochastic cost function and one way ANOVA tests to run the hypotheses.

Theoretical Framework

The efficiency is considered as one of the most critical issues in agricultural production economics. It is always measured by comparing the actually attained production value against what is attainable at the production frontier. The economic efficiency or overall efficiency is divided into two forms technical and allocative efficiency (Farrell, 1957). Technical efficiency is considered as the production function, in terms of maximum output that can be obtained from a specified set of inputs using the existing technology available to the farm by Battese et al. (1995). Allocative efficiency is the ability of the firm to allocate its input bundle at a given level of output in the most cost minimizing way. Thus an allocatively efficient level of production is where the farm functions at the least cost combination of inputs. Estimation of allocative efficiency is fundamental due to the increasing cost of production. This has been estimated using a Cobb-Douglas stochastic cost function. The study considers the value of milk produced as the dependent variable and all other inputs as the independent variables which work for the production of milk.

The model specified in this study is expressed as

$C = f(X_1, X_2, X_3, X_4, X_5)$

The empirical form of the model was expressed as:

$C = f\,(X_{green\ feed\ costs}, X_{dry\ feed\ costs}, X_{concentrates\ costs}, X_{labour\ \mathrm{cost}}, X_{veterinary\ cost})$

The Cobb-Douglas stochastic cost function was elucidated as follows:

$C = \beta 0 X_1^{\beta 1} X_2^{\beta 2} X_3^{\beta 3} X_4^{\beta 4}\ X_5^{\beta 5}\ e^{v-u}$

Taking the natural logarithms of both sides, the log linear form of the cost function used becomes:

$\ln C = \beta 0 + \beta 1 \ln X1 + \beta 2 \ln X2 + \beta 3 \ln X3 + \beta 4 \ln X4 + X5\beta 5 + (vi - ui)$

Where:

lnC = natural logarithm of the value of milk production

lnX1 = natural logarithm of the total cost of green fodder used in each farm

lnX2 = natural logarithm of total cost of dry fodder used in each farm

lnX3 = natural logarithm of total cost of concentrates used in each farm

lnX4 = natural logarithm of total cost of labours

lnX5 = natural logarithm of total veterinary cost

($\beta 0$, $\beta 1$, $\beta 2$, $\beta 3$, $\beta 4$and $\beta 5$= are unknown parameters to be estimated

(vi - ui) = e = stochastic error term

Results and Discussion

The main characteristics of the sampled dairy farms average characteristics shown in Table No 2.

Table 2: Average statistics of the characteristics of sampled dairy farms

Variables	N	Minimum	Maximum	Mean	Standard Deviation
Value of milk production	300	21.54	10440	940.2911	1174.20
Milch Animal (Number)	300	1	18	2.58	2.492
Experience of farmer (years)	300	1	50	17.31	10.360
Age of Farmer (Years)	300	27	80	55.37	9.344
Education of farmer(Years)	300	0	17	9.35	4.18
Green fodder Cost	300	0	3600	120.40	281.23
Dry Fodder Cost	300	0	1450	60.68	122.47
Concentrates cost	300	0	16915	499.46	1112.94
Veterinary Cost	300	1500	51500	7918.4	4932.71

Source: Computed from primary data

The average age of the sampled farmer is 55 years with average education is nine years and of 17.31 years of experience. The average value of green fodder, dry fodder, concentrates and veterinary cost are 120.40, 60.68, 499.46 and 7918 Indian rupees per day.

Maximum likelihood estimates of the Cobb Douglas cost functions.

The Table No. 3 (shown below) depicts the maximum likelihood estimates of allocative efficiency, where the value of green fodder, the value of concentrates and veterinary cost shows a positive and statistically significant, which implies it has a direct relationship with the value of milk production. Any 1 per cent increase in the independent variables, will give rise to .27 per cent, .34 per cent and .25per cent increase in the value of milk production. This is the situation of relatively inelastic. The value of dry fodder and labour cost shows a negative sign, which implies that there is an indirect relationship between independent variables and the value of milk production. Any 1 per cent increase in these variables reduces the value of milk production by .46 per cent and .44 per cent and proves statistically insignificant at 0.05. The mean efficiency is only 61.3 per cent with a minimum of

11.9 per cent and a maximum of 91.5 per cent level of allocative efficiency. The variance ratio is .81, which implies 81 per cent of the variations (difference between observed and maximum attainable value of milk production) in the model is under the control of farmers, rest all relates to the random error. So this implies that there exists an allocative inefficiency in the model that is more of under the control of farmers.

Table 3: Maximum likelihood estimates of cob Douglas cost function of the sampled dairy farmers

Variable	Parameters	Co-efficient	Standard Error	t-value
Constant	B0	.1814	.7011	.258
Green Fodder cost	β1	.2756	.4266	.6460**
Dry Fodder Cost	β2	.4643	.24739	.187
Concentrates Cost	β3	.3460	.3769	.918**
Labour cost	β4	-.44899	.7610	-.580
Veterinary cost	β5	.2566	.683	.375**
Variance ratio	.81			

*Source: Computed from primary data, **significant at 5 percent level*

Distribution of Farm Level Allocative Efficiency

Table 4: Distribution of the farm level measures of allocative efficiency.

Allocative Efficiency percentage	Number of farmers	Percentage
Less than 20	5	1.67
20-29	9	3
30-39	22	7.33
40-49	33	11
50-59	57	19
60-69	62	20.67
70-79	85	28.33
80-89	24	8
90-99	2	1
Total	**300**	**100**

Source: Computed from primary data

28.33 per cent of farmers having their allocative efficiency level between 70-79 per cent, followed by 20.67 per cent of farmers having efficiency level of 60-69. Only 1 per cent of the entire samples have an efficiency level of 90-99. That implies that only 1 per cent of the entire sample is working or functioning closer to the cost frontier.

The above table is shown as graph here

Source: Computed from Table No 4

Graph 1: Allocative Efficiency scores of the sampled dairy farmers

Hypothesis Testing

Hypothesis 1

H0= Allocative efficiency is same across the farm sizes

Table 5: ANOVA Results

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	3419.162	2	1709.581	6.693	.001**
Within Groups	75864.855	297	255.437		
Total	79284.016	299			

Source: Primary Data

A statistically significant difference between the groups is proven by one way Anova. The p value is less than 0.05. The allocative efficiency is not same across the farm sizes. The null hypothesis is rejected, stating that the allocative efficiency is different across the sample districts. The larger farmers are more allocatively efficient than small and medium farmers. When the amount production is large, the cost of production will come down.

Conclusion

The study estimates the allocative efficiency of dairy farmers in Kerala state of India using stochastic cost functions. It indicated that the allocative efficiency of milk production is very low. The mean efficiency was estimated to be 61.3 per cent. Dairy farms have the potential to increase their efficiency by 38.7 per cent. It's also revealed that allocative efficiency differs across the farm sizes. Through proper education and training, the cost of production can be reduced; therefore, allocative efficiency can be achieved. The dairy farmers should minimise the use of labour cost and dry fodder.

The allocative efficiency is not the same across the farm sizes. The small farmer can be more efficient than medium and large farmers due to the less cost of production compared with medium and large farmers. There should be a proper education and training should be given concerning the use of inputs for the production.

Abstract

In the article the authors point out the difficulty in developing cases in natural sciences, in particular in chemistry. The proposed case "The Problem of Water in the River" is one of the first developed cases on analytical chemistry in the Uzbek language. Case was tested in analytical chemistry classes. During the work, an increase in students' interest in completing assignments on the case was observed. The importance of the developed case in the acquisition of modern knowledge, skills and abilities of graduates is analyzed. A survey of students shows that students are more inclined to perform the experiments described in the cases than traditional laboratory experiments.

Keywords: Case Study, Analytical Chemistry, Education, Graduate, Knowledge, Skills, Competence.

Introduction

It is well known that employers now impose requirements on higher education institutions on how graduates can be effectively trained and adaptable in the rapidly changing world (Aleksandrov et al., 2015; Zakharova et al., 2019). These include communication skills, teamwork, the use of information and communication technology (ICT), and the ability to work independently on their own (Morova, 2017). In this context, it is important to apply cases in analytical chemistry to graduates of educational fields, including chemistry, chemical technology, oil and gas processing technology, food industry technology, petrochemical industry, ecology, biology. This is due to the fact that graduates of this field must possess the necessary knowledge, skills and competence (KSC) for conducting theoretical and laboratory experiments in order to solve practical problems. The ability to work in a team and with clients is defined as a key factor in hiring.

Therefore, we need to go deeper into the issue of training graduates who will work at a professional level (Erdyneeva et al., 2016; Drovnikov et al., 2016). To do this, we need not only to teach them basic chemical knowledge, relevant practical skills and skills for solving elementary problems. We need to train graduates in analytical and critical thinking skills, apply knowledge and information in the field of chemistry to solve unusual or multiple problems. In addition, a modern graduate must possess KSCs of teamwork, time and information management, independently acquire knowledge and apply ICT.

Method

It is well known that in many disciplines, cases are used to achieve the aforementioned KSCs. For the first time in the 1970s, the medical department of McMaster University began to use case technology in teaching medicine. The method is to group students into small groups and instruct them. Students were given very little information from the patient's medical history, and based on the information provided, it was necessary to determine what they know and what they don't know. Students then worked with literature to find the answer. After exchanging their ideas, they was sent back to work with literature. Next time, students draw conclusions on the case, and the work on the cases was continued (Herreid, 1997).

Since the mid-1990s, the University of Delaware introduced problem solving methods for graduates, and faculty members at Buffalo University began to design and use case studies in rigorous selection.

According to Herreid et al. studies 90% of teachers who use cases in the process of teaching biology and biomedicine, the rest are physics, geology, engineering and chemistry (Herreid et al., 2011). In our opinion, the limited use of cases in chemistry can be explained by the fact that it is difficult to create cases in general chemistry, as well as the difficulty of using cases to explain chemical laws.

As it is known, the intensive use of cases in chemistry began after the 2000s. So far, examples in chemistry and other natural sciences can be found in several Internet resources (National Center; PBL Clearinghouse; CASES Online). Among them – Buffalo University is one of the first institutions in the chemical sector, which first developed and implemented cases in the educational process.

However, it should be noted that chemistry has specific points in the development of cases. Nevertheless, for the development of cases, one can use interdisciplinary relations with such subjects as ecology, manufacturing, pharmaceuticals, medicine and etc. In our opinion the science that covers all this subjects is analytical chemistry or methods of analysis.

We have developed a case (Niyazov, 2017a; Niyazov, 2017b) that has aspects and components of analytical chemistry that are closer to real life, combining ecology, biology, and medical sciences. The case is called "The Problem of Water in the River". It describes the fictitious situation of an environmental disaster in the river with the mass extinction of fish in the winter. For this, each group of students is tasked with "investigating" the same "incident". In the process of solving the case, students were provided with additional information on specific issues (Niyazov, 2017a; Niyazov, 2017b). Corresponding reports and statements of various organizations and authorities were attached to the cases we developed. KSCs related to analytical chemistry and analysis methods were evaluated: sampling procedure, methodology for working with samples and in the area; identification of experimental errors; analysis methods; determination of the cause of fish extinction.

The case was provided to students in parts, 2-4 hours to complete each stage, depending on the degree of difficulty. For independent performance of experiments under the supervision of a laboratory assistant, it took about 3-4 hours. When dividing into groups, students distributed responsibilities among themselves to the leader of the group, who is responsible for collecting additional information necessary to solve the case and prepares the presentation of the case. The remaining members choose features such as speaker, critic, etc. Necessary experiments and analyzes are carried out by all students.

In the first stage of the case, students are provided with a map which shows where the fish was found. In addition, there are interviews of journalists with fishermen and the local population. At the same time, students must report where and how they will take samples and the number of samples based on the

information received (the number of samples is limited) and their assumptions in the form of reports. After writing the reports, students are given a description of the samples taken by environmental experts.

In the second stage, students discuss the results of their experiments. Groups should draw appropriate conclusions from the analysis. In the third stage, students are given another opportunity to obtain additional samples, and they will be presented with the results of a chemical analysis of the requested samples. Based on the information received, they must draw final conclusions.

At the final stage, students will make a brief presentation of all the information and conclusions that should be based on evidence and examples. The presentation should explain the group's chosen strategy, actions, causes of the environmental incident, and the functions of the group members.

Results

Evaluation of the results: a) experimental methods - 30%; answer to the questions of the case - 30%; oral presentation - 30%; question and answer 10%; b) conducting the experiment - 30%; writing a one-page report - 40%; oral presentation - 30%.

Previously, we developed a mini-case "Highlands" on analytical chemistry, which was tested during practical and laboratory studies of second-year students in the areas of "Chemical Technology" and "Professional Education: Chemical Technology". The case was tested in for 4 hours.

This method was considered new to both students and teachers. Students were asked to compare case study method with traditional practical and laboratory exercises and to answer the questions, taking into account the relevance, interest and educational aspects of the case and evaluate them on a scale of 1 to five: agree (5), partially agree (4), neutral (3), partially disagree (2) and disagree (1). A total of 122 students took part in the survey.

The conducted survey shows the following indicators on the questions asked, respectively, 1) Case study helped to better understand the work experience compared to traditional laboratory classes - 4.8; 2) Case has made the experimental work more "fun" than traditional lab classes – 4.5; 3) Case showed that chemical experiments are associated with real life compared to traditional laboratory activities - 4.7; 4) Case helped me learn more - 4.3; 5) I was very impressed with the new method and nontraditional analysis - 4.4.

The survey results show that most students prefer to conduct case experiments than standard and traditional laboratory experiment methods.

Conclusion

The purpose of this study was to facilitate students' understanding of analytical chemistry of various topics and to relate them to practice. In this case, students will have the opportunity to practice what they learn, which will motivate them. The presentation and storytelling of real-life situations encourages students to solve new and unusual problems, in contrast to traditional issues. In the future, the graduate will have the opportunity to easily apply the skills that he acquired during the course of work in case of unusual problems.

Thus, cases in analytical chemistry allows students to work independently, develop analytical methods, make decisions in unusual situations, develop analytical thinking, work with literature, process data and information; identification of errors in the analysis, as well as stimulating research.

Abstract

Now it is something normal to shop online. People can do it from any place, at any time they want. They can check opinions of other customers or competitive e-shops and their products. There is a lot of competition on the e-commerce market. New e-shops appear practically every day. To gain customers and be competitive on the market, a new e-shop must design its services in proper way. One of the tools that can be used in this case is the Kano model. This method helps to classify attributes into groups, e.g. indicate the features that must be considered to convince a customer to buy in a given e-shop or those which can affect his satisfaction. The purpose of the paper was to use the Kano model to classify the e-bookstore's features, in particular the website's features and the sales process through this website. The research part of the paper presents a practical example of using Kano models - case study of the e-bookstore.

Keywords: Kano Model, Customers' Satisfaction, Service Design, E-Commerce.

Introduction

More and more often customers choose to shop without leaving home. In the market of online shops there is a lot of competition, but also customer requirements for the operation in such e-shops are completely different from the traditional one. Therefore, before to open such an e-shop, it is necessary to know both of these elements.

It should be remembered that in order to follow the global trend of satisfying the needs of customers in e-commerce, enterprises must provide high-quality services over the Internet. Knowledge about how to build good relationships and get customer loyalty through the Internet has become an important problem in e-commerce between businesses (Wu, 2010, Klimecka-Tatar, 2018).

The first stage of the pre-production phase of the product is its design. This is an important stage from the point of view of both the enterprise and the customer. Customers' requirements are the ones that should decide on the parameters of products. It should be emphasized that customers' requirements are constantly changing (Pacana and Ulewicz, 2017; Pietraszek, 2013; Kadłubek, 2016) which means that potential future demands should also be predicted and considered. The design phase allows determining the level of product quality which can cause that the customer will buy the product and then will be satisfied with it (Fiorenzo et al., 2017; Kowalik and Klimecka-Tatar, 2018; Violante and Vezzetti, 2017; Knop, 2019).

A specific situation is the opening of an e-shop. Legal provisions relating to online shopping differ from the provisions relating to the traditional one due to the fact that the customer is unable, watching

product only online, to evaluate its quality, and the quality of the sales service. Therefore, the customer of the e-shop has e.g. an extended deadline for return of the product in case if it does not fit or does not meet his requirements. Customers often seek for information, comments on shopping in a specific e-shop. A satisfied customer can share his opinion about shopping, but also can again buy something from the same e-shop. Therefore, for the seller's of the e-shop, quality of the services it provides should be important (Ingaldi and Ulewicz, 2018).

There are different methods and tools, that can be used to understand customers' requirements and asses services quality. Most of them are base on surveys or direct interviews. The Kano model is very specific method because it can be used not only to assess the quality of product, but also to design it. What is more, the Kano model corrects for customer experience bias and computes the non-linear impact of service elements on customer satisfaction. It is to find out the customers' affection towards products and services through questionnaire and then based on the information as references to improve the customers' satisfaction (Kano et al., 1984; Chen, al., 2015).

The purpose of the paper was to use the Kano model to classify the e-bookstore's features, in particular the website's features and the sales process through this website. This study made possible to indicate what attributes should be included so the research e-bookstore will become competitive in the market. The research object is a family enterprise which headquarter is located in the south of Poland, and which is organizing its services and designing a website through which it will sell books and magazines.

The survey presented in the paper is universal tool that allows to design, but also assess the level of quality of the chosen e-shop, and thus customers' satisfaction. Without problem it can be used or modified by other scientists for similar researches and be used in case of other types of e-shops.

Literature Review

Quality of the E-Commerce

Along with social progress and an increase in consumption, people look for personalized products and services, various e-commerce elements for this purpose have been created. According to Michałowska et al. (2015) the existence within the Internet has become a necessity. With the development of the Internet the importance of electronic commerce (e-commerce) has grown. Lots of Internet shops appeared, almost every enterprise has own website. But also there is a change from the side of customers, they often decide to make shopping online.

E-commerce is a way of modern business, which addresses the requirements of business organizations. It can be broadly defined as the process of buying or selling products with use of an electronic medium such as the Internet (E-commerce. Electronic Commerce Approach; Ingaldi and Ulewicz, 2018). E-Commerce includes a number of innovations that make life easier (Kaya and Aydin, 2019). The better data security increases customer's trust in e-commerce transactions (Purnamasari et al., 2019). The most important e-commerce enterprises are: amazon.com, ebay.com, alibaba.com, Netflix.com, dell.com, staples.com, betbuy.com, apple.com, groupon.com, snapdeal.com, flipkart.com, grofers.com, and makemytrip.com.

E-commerce gives customers a lot of freedom and privacy, because they use the Internet to shop for products, agree on different product models, evaluate prices, and compare satisfactory comments of other customers (Sarker, 2016). The trade ban on Sunday had a major impact on increasing online commerce in Poland. Due to the Internet, the customer can shop at any time of the day, every day of the week, from any place with access to the Internet, without a queue. The customer can use the services of companies that are very far away, which means that e-commerce can cross the borders, so the customer has a greater choice and access to a wider range of products.

What's more, the Internet also gives greater trade opportunities to enterprise. An e-shop can refer its services to customers from various countries, including those furthest. The world has no limits when it comes to e-commerce, it can affect the price and shipping cost. The only problem is the language barrier but with different translators available online easy to omit.

E-service quality is a fundamental determinant that affects enterprises' long-term success (Bressolles et al., 2015; Carlson and O'Cass, 2011). As mentioned earlier, thanks to the Internet, customers have easy access to information and opinions of other customers about a given e-shop, as well as to services and products of competitors. That is why the e-service quality is so important. An enterprise that decides to use the online shopping channel must carefully examine the customers' requirements for its operations, take them into account when designing the services it offers, but also must follow the opinions and assessments of the customers who have used its services to constantly improve itself.

Kim (2019) collected information on the characteristics determining the quality level in e-commerce, analyzing the rich literature of the subject. An example of a list of features according to different authors is presented in Table 1. Among the authors, it is possible to find both similarities and differences.

Table 1: Features that determine quality in e-commerce (Kim, 2019)

Authors	Features
Bauer et al. (2006)	Functionality / design, joy, process, reliability, speed of reaction
Collier and Bienstock (2006)	Process dimension (functionality, information accuracy, design, privacy, ease of use); result size (order accuracy, order status, timeliness); dimension of recovery (interactive fairness, procedural honesty, fairness of results)
Ghosh (2018)	Efficiency; system availability; fulfillment; privacy
Francis (2007)	Transaction on the website; supply; customer service; security
Kim et al. (2011)	Convenience; customization; protection and privacy; website look; the value of entertainment
Mummalaneni et al. (2016)	Efficiency; system availability; fulfillment; privacy
Parasuraman et al. (2005	Efficiency; system availability; fulfillment; privacy; responsibility; compensation; contact
Piercy (2014)	Trust; company interface; fulfillment of the service
Prateek (2017)	Protection and privacy; website design; reliability; responsibility; information
Swaid and Wigand (2009)	Quality of information; website usability; reliability; responsibility; certainty; personalization
Wiedmann et al. (2009)	Website design; fulfillment / reliability; privacy / security; customer service
Zhang et al. (2015)	Convenience; accuracy of information; security; functionality

Kano Model

There are many features that can affect the quality of product or service and that result from the customers' requirements. Meeting these requirements is very important element of the quality management (Kotus et al., 2013; Kardas et al., 2017; Pribulova et al., 2011). The enterprise must identify the most important features according to customers and make sure that they are included in the product or service.

One of the tools that can be used to design products and services and assess their quality is the Kano model. It allows for the examination of relationships between the attributes of products or services

and the level of customers' satisfaction. The Kano model was created by a Japanese professor Noriaki Kano in 1980. He proposed the Attractive Quality theory, with its major assumption being the concept of the division of attributes or features of products and services that are perceived and appreciated by the customer (Conti, 2004; Kano et al., 1984; Ingaldi et al., 2018).

There are attributes that the customer considers necessary, as well as not expected. The Kano model proved to be extremely useful, as it allows understanding better the concept of quality. It also helps to find the source of customers' satisfaction (Ulewicz, 2016; Berger, 1993). It should be underlined that the Kano model can be used in case of products and services, but also during design stage and to assess the quality of the produced products and services.

The starting point in the Kano method is skillful management of features that evoke specific emotions in such a way as to meet the expectations and needs of the customers in a way that is adequate to these needs and expectations. Quality is rooted in the emotions of the person who ordered the product or service and expects proper results of work.

The Kano model predicts that each customer should be treated very individually, and satisfying his needs will be assessed subjectively. Everyone has different expectations, different needs, and draws attention to the aame factors. When designing new products or services, it is necessary to understand the essence of quality that is perceived by customers. It turns out that often external features do not have much in common with objective quality (Brajer-Marczak, 2015).

With the Kano model, it is possible to show that not all components of products are similarly important from the customers' point of view. Noriaki Kano categorized attributes into five groups (Lampa, Mazur, 1996; Antony, Preece, 2002; Webber, Wallace, 2007; Ingaldi et al., 2018):

- "Must-be" attributes, which must be contained in the product and service as a standard. Lack of these features can lead to losing the customer. Example of the "must-be" feature in case of the e-commerce and bookstore can be information about the enterprise. Every customer wants to know who the service provider is.

- "One-dimensional" attributes have the greatest importance to customer satisfaction from a product or service. It is critical that meeting this type of attributes is almost proportional with the level of customers' satisfaction, which can translate into the frequency of purchasing the products or using the services. Problems with meeting "one-dimensional" attributes reduce customers' satisfaction. However, this does not progress as fast as in case of the "must-be's". In case of "one dimensional" attributes the assortment diversity can be mentioned. The bigger assortment is, the wilder choice the customers have which influence their satisfaction.

- "Attractive" attributes have to attract the customer to a product or service. Popularity of these attributes is short-term and can be turned into the "must-be's" or disappear. Improperly designed "attractive" attributes can pass unnoticed. Their lack does not have an effect on customers' satisfaction but it may lead to the lack of his or her interest (if the customer is susceptible to continuous making the offer attractive). Here we can mention discounts and promotions. Customers often search for cheaper product.

- "Reverse" attributes occur when the customer prefers absence of the attribute and does not like its presence. More such attributes in the service or product leads to a greater customer dissatisfaction. Many customers do not want to pay before the packs arrive to them. So "payment before delivery" can be treated as "reverse" by many customers.

- "Indifferent" attributes do not impact on customer satisfaction. The color of the website or its style for many customers can be indifferent.

- Contradiction: occurs in the case of the Kano method. It is the attribute which was assessed as functional or non-functional in both forms of questions.

Therefore, the analysis should be conducted to indicate the attributes of a product or service which are important for customers, can cause their satisfaction or dissatisfaction and are neutral. A traditional approach to quality used to assume that customers' satisfaction is directly proportional to product functionality, i.e. the less functional the product, the more satisfied the customer and, the more functional product, the less satisfied the customer. This characteristic is one-dimensional. The "must-be" attributes point to the aspects where the customer is more dissatisfied if the product is less functional but when the customers' satisfaction never increases above neutral, regardless of how the product functions. In case of "attractive" attributes it is indicated that the customer is more satisfied if the product has a particular characteristic but is not dissatisfied if the product lacks an attribute (Keshavarz, 1993; Ingaldi et al., 2018; Shen et al., 2000; Sauerwein et al., 1996; Basfirinci and Mitra, 2015).

The Kano method is used in the form of a special type of the questionnaire. This questionnaire contains positive and negative versions of statements/questions that refer to the attributes of a specific product (Wolniak, Skotnicka, 2008; Velikova et al., 2017). Evaluations of these statements (answers if these questions) are based on the following scale: a) "I like it", b) "That's the way it has to be", c) "I don't mind it", d) "I can put up with it", e) "I don't like it". Analysis of the results is based on the individual types of attributes contained in the questionnaire using the comparison presented in Table 2.

Table 2: Type of attribute in the Kano method (Wolniak, Skotnicka B, 2008; Bakhitar et al., 2015)

		Negative				
Positive		I like it	That's the way it has to be	I don't mind	I can put up with it	I don't like it
	I like it	Q	A	A	A	O
	That's the way it has to be	R	I	I	I	M
	I don't mind	R	I	I	I	M
	I can put up with it	R	I	I	I	M
	I don't like it	R	R	R	R	Q

Notes: A – attractive; O – one-dimensional; M – must-be; I – customer was indifferent to the attribute; R – customer did not like the attribute; Q – there was a contradiction: customers both wanted the attribute to occur and not to occur.

The Kano survey is based on marking the features perceived now and in the future. The customers' task is to determine their attitude to the occurrence, as well as to the absence of a given feature. There is a very big difference between these two variants. In the first, the attribute is present in the service (positive version), in the second - is no included (negative version). The collected information creates a peculiar combination that allows the results to be interpreted.

It is claimed that the Kano model is dynamic, thus not subjected to the continuous evolution while this concerns in particular the "attractive" attributes as they become a standard after some time (Nilsson-Witell and Fundin, 2005). Customers tend to get accustomed to good products and their attributes. Therefore, it is necessary that the enterprise should invest in research and development so that innovative solutions will endear the enterprise to loyal customers.

The customers' assessments, that were given in the Kano questionnaire, are helpful in calculating two important indicators, i.e. customer satisfaction and dissatisfaction indexes (Keshavarz, 1993):

$$satisfaction\ index = \frac{A + O}{A + O + M + I} \quad (1)$$

$$dissatisfaction\ index = -\frac{O + M}{(A + O + M + I)} \quad (2)$$

The minus sign is added to the dissatisfaction index (equation 2) in order to emphasize the negative effect on customer perception if the product quality is not met. The satisfaction index is in the range of (0; 1). If the value is close to 1, customer satisfaction is very high. It is also important that negative values of satisfaction (dissatisfaction index) should be examined. If the value is close to -1, customer dissatisfaction is very high (Ingaldi et al., 2018).

If the positive factor is higher, this means situation when customer satisfaction increases due to the "attractive" and "one-dimensional" attributes. If the negative factor is higher, this means the situation when customer satisfaction decreases (dissatisfaction increases) due to "one-dimensional" and "must-be" attributes. This interpretation is used in the case of product design (Keshavarz, 1993).

Methodology

The research was carried out with use of the previously described Kano questionnaire. Due to this, it will be possible to divide into groups the all characteristics that the e-bookstore should characterize according to the opinion of potential customers. The survey was created on the basis of previous studies presented in many scientific papers. A list of features that were taken into account when developing the action plan of the research facility is presented in Table 3. The set of features has already been selected and used on the occasion of other researches (Ingaldi and Ulewicz, 2018; Ingaldi et al., 2018; Ingaldi and Ulewicz, 2019).

Table 3: Part of the Kano questionnaire for the research e-bookstore - positive version of the features (own study)

No.	**Positive statement**
1	The website of the e-bookstore is well-organized and legible.
2	The information on individual books is current and comprehensive.
3	The Internet data of the e-bookstore is detailed.
4	The offer of the e-bookstore is current.
5	The offer of the e-bookstore is divided into logical categories.
6	The pictures of books have good quality.
7	The e-bookstore regulations is understandable and accessible.
8	The purchase process in the e-bookstore is detailed described.
9	The search engine is easy to use.
10	There is option to filter results.
11	There is option to remember the basket.
12	The ordering options are clear and easy to use.
13	The registration to complete purchases is required.
14	A customer can choose different payment methods.
15	A customer can choose different purchase methods.
16	It is easy to contact the e-bookstore in order to obtain additional information about the products.
17	It is easy to contact the e-bookstore in order to explain any inconsistencies.
18	It is possible to resign from the transaction before its implementation.
19	Delivery of goods is in accordance with the dates indicated on the website.
20	Tracking the shipment is possible.
21	Delivery of goods is at times convenient for the customer.

22	It is possible to refuse the parcel in case of any inaccuracies.
23	The financial transactions is effortless.
24	There is an opportunity to add an opinion about the e- bookstore.
25	The e-bookstore gathers information on the implementation of orders.
26	It is possible to return goods that do not meet the requirements.
27	It is possible to return goods damaged in transport.

The Kano questionnaire was sent to potential customers and made available in various social media. It was decided that min. 200 correctly completed surveys should be analyzed. The research was conducted in January - April 2019. 293 people took part. Respondents were asked to assess features of the research e-bookstore using scale of answers presented in Table 2. They had to do it twice: once when the feature is present (positive version) and once when it was not included (negative version). 257 completed surveys were taken into account for further analysis, the remaining ones were rejected because they were not completed properly (some answers were missing).

On the basis of the obtained responses, the number of answers of particular categories was checked for each features, taking into account the categories presented in Table 1. Then, for each feature, the most frequent category was indicated. Satisfaction and dissatisfaction indexes were also calculated and later located on map of the attribute, where the X axis is the absolute value of the dissatisfaction index, and the Y axis is the satisfaction index. Interpretation of the map is based on Table 4.

Table 4: Interpretation method (Keshavarz, 1993)

Distribution of response	XY Pair	Location on the graph of the point
All attractive	0;1	Top left corner
All one-dimensional	1;1	Top right corner
Evenly split between attractive and one-dimensional	0.5;1	Middle of the top, halfway between attractive and one-dimensional - point A
All must-be	1;0	Bottom right corner
Evenly split between one-dimensional and must-be	1;0.5	Middle of right edge, halfway between one-dimensional and must-be - point B
All indifferent	0;0	Bottom left corner
Evenly split between must-be and indifferent	0.5;0	Middle of bottom edge, halfway between must-be and indifferent - point C
Evenly split between indifferent and attractive	0;0.5	Middle of left edge, halfway between indifferent and attractive - point D
Evenly split among attractive, one-dimensional, must-be and indifferent	0.5;0.5	Exact middle of graph - point E
Evenly split between attractive and must-be	0.5;0.5	Exact middle of graph, halfway between attractive and must-be, without an influence of one-dimensional or indifferent - point E
Evenly split among attractive, one-dimensional and must-be	0.67;0.67	Equally spaced between attractive and must-be, but influenced by one-dimensional - point F

Results and Discussion

In Table 5 the main results obtained with use of the Kano questionnaire are presented. The type of features and satisfaction and dissatisfaction indexes were determined.

Table 5: Kano questionnaire results for the research e-bookstore (own study)

No	Number of answers in the category						Assessment of the attribute	Satisfaction index	Dissatisfaction index
	A	M	O	I	Q	R			
1	27	121	89	18	2	0	M	0.45	-0.82
2	23	76	142	16	0	0	O	0.64	-0.85
3	17	173	45	21	0	1	M	0.24	-0.85
4	51	71	119	13	2	1	O	0.67	-0.75
5	19	21	152	65	0	0	O	0.67	-0.67
6	47	36	101	72	1	0	O	0.58	-0.54
7	19	83	113	41	0	1	O	0.52	-0.77
8	96	16	24	121	0	0	I	0.47	-0.16
9	45	124	65	22	1	0	M	0.43	-0.74
10	22	89	44	102	0	0	I	0.26	-0.52
11	17	113	93	34	0	0	M	0.43	-0.80
12	91	24	136	5	1	0	O	0.89	-0.63
13	6	9	8	34	2	198	R	0.25	-0.30
14	45	111	98	3	0	0	M	0.56	-0.81
15	46	76	121	14	0	0	O	0.65	-0.77
16	23	134	86	13	1	0	M	0.43	-0.86
17	19	165	54	18	1	0	M	0.29	-0.86
18	81	9	119	48	0	0	O	0.78	-0.50
19	49	68	123	7	0	0	O	0.70	-0.77
20	123	44	76	14	0	0	A	0.77	-0.47
21	76	121	46	3	1	0	M	0.50	-0.68
22	82	53	103	9	0	0	O	0.75	-0.63
23	32	145	68	1	1	0	M	0.41	-0.87
24	22	25	86	124	0	0	I	0.42	-0.43
25	19	9	58	164	2	5	I	0.31	-0.27
26	21	156	69	11	0	0	M	0.35	-0.88
27	17	196	36	7	1	0	M	0.21	-0.91

Analyzing the results of the research presented in Table 5, it can be seen that customer responses were very diverse. It should be emphasized that in case of the e-bookstore, potential customers are a very wide group of people, regardless of gender, age or education. Many people buy books, it is often dictated by their profession, education, or just their way of spending free time.

Among the features there should be distinguished 11 "must-be" features, 10 "one-dimensional", 4 "indifferent", 1 "reverse" and 1 "attractive". When preparing the website of the e-bookstore and organizing the functioning of this enterprise, it should be remembered that all features that have been marked as "must-be" have to be considered in the final service. They should be treated as a standard. On the other hand, meeting the requirements defined as "one-dimensional" causes high customers' satisfaction. The greater their fulfillment will be, the more satisfied customers will be.

Potential customers indicated 4 features as neutral ("indifferent") attributes during the research. They were: the purchase process in the e-bookstore is detailed described; there is option to filter results; there is an opportunity to add an opinion about the e- bookstore.; the e-bookstore gathers information on the implementation of orders. It should be remembered that it is not worth investing too much in these features, because their occurrence and fulfillment will not affect too much customers' satisfaction. In this group of features, the presence of the feature: the purchase process in the e-bookstore is detailed described, is surprising. Everyone should know exactly how to shop in a given

e-store. Perhaps this is dictated by the fact that more and more people, more and more often use such way of shopping and do it automatically, without thinking. So they do not need explanation how to do it.

The feature: the registration to complete purchases is required, is reverse feature, that is, potential customers mostly do not want this feature in the case of the research e-bookstore. Customers often make singular orders, they do not want to create accounts, register, because it requires additional time and more customers' data.

As an "attractive" feature of the researched e-bookstore, potential customers have indicated feature: tracking the shipment is possible. This will be an additional advantage for customers, it may cause that a larger group of customers may decide to choose the service of the research e-bookstore. However, it should be remembered that this feature is available in the case of a supplier, not straight in case of the e-bookstore, i.e. it should be taken into account when deciding on a courier enterprise.

When analyzing satisfaction and dissatisfaction indexes, it can be seen that the dissatisfaction index in many cases assumed a value from the range (-0.8, -0.9). In the majority of cases such situation was noted in the case of "must-be" features. The highest value of this index was noted in the case of the feature: the purchase process in the e-bookstore is detailed described, i.e. the "indifferent" attribute.

In case of the satisfaction index, the highest value was noted for the feature: the ordering options are clear and easy to use. The lowest value was noted for the feature: it is possible to return goods damaged in transport, but also in the case of many other characteristics, this value was low.

In Figure 1 the map of attributes according to the Kano questionnaire was presented. This map was created on the basis of satisfaction and dissatisfaction indexes.

Fig. 1: Map of attributes according to the Kano questionnaire for the research e-bookstore (own study)

When analyzing Figure 1, it can be seen that the features are very scattered over the map of attribute. The left upper field of the map is almost empty, only point 20 (the feature tracking the shipment is possible) is in this field, and point 18 (feature it is possible to resign from the transaction before its

implementation) is located on the border of this field. Among all the features, it is impossible to find the one that a clear type of features (a very large predominance of the answer) would indicate a specific type of feature (map corners). This means a large diversity of responses among potential customers. Even if some points clearly moved towards points described in Table 4. Many points are located on the right side of the map (high dissatisfaction index).

Summary

Before opening business, any store, including an e-bookstore, managers should know the customers' opinion and ask them what features should characterize the products and service. This will allow precisely defining customers' requirements, and thus determine the quality of offered services. There are many methods that can be used in such situation. One of them is the Kano model. This method allows indicating which features must included in the service, which will cause customers' satisfaction, and which characteristics customers do not want. This method can also be used at a later stage of the service, to assess its quality level, to improve it, so it can be treated as a universal instrument.

In the case of the researched e-bookstore it was possible to indicate 11 "must-be" features, 10 "one-dimensional", 4 "indifferent", 1 "reverse" and 1 "attractive". Features marked as "must be" have to be included in the service as a standard, one-dimensional and attractive features will result in customers' satisfaction. However, 1 reverse feature, according to customers, should not be taken into account in the case of the research e-bookstore.

The research is not without limitations. The survey was created on the basis of the authors' experience and found references. Some important factors could be omitted due to the subjectivity of authors. Survey itself was quite long so some respondents could feel bored and filled it up without any will or at random. All results, despite their averaging, should be considered as subjective and with a wide range of tolerances (even in the case of the research e-bookstore).

This research contributes to the existing literature on service quality but at the same time it adds value because it offers a simple methodology that can be used in any type of e-shops. It should be emphasized that the survey may be modified for the needs of other type of e-shops as well as for the needs of various type or products. This paper shows that Kano model is quite easy but the same time very useful method that can be used by other scientist but also directly by different type of enterprises in similar research.

Acknowledgment

"The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN".

Abstract

The aim of this paper is to illustrate how statistical tools can benefit healthcare policy makers specialised in the rabies management. Understanding the prevalence of such a disease is crucial for management teams. Seasonality may be a salient feature of data series provided by medical units, that is why the use of an innovative tool for seasonal adjustment is needed. For this paper the data series (number of person examined for rabies, by age and residency) were provided by one single health care unit – *The National Institute of Infectious Diseases "Matei Bals"*. Methodologically, the graphs of both series were analyzed in order to indicate the type of transformation needed: seasonality test and outlier detection. When seasonality detected, the data series were seasonally adjusted using JDemetra+ 2.2.2, a software recommended by Eurostat which incorporates TRAMO-SEATS and X13 procedure specifications. Following Hungarian Central Statistics Office's guidelines (2007), if seasonal variation is not changing along with the trend, then no transformation is needed; however if the seasonal variation is changing along with the trend, a log-transformation is necessary. The results of the analysis show that all the series display clear seasonal patterns and that should be log-transformed prior to seasonal adjustment. The only series that displayed outliers is the number of persons examined for rabies from Bucharest. JDemetra+ offers not only seasonality tests and an automatic procedure for seasonal

adjustment, but also a very useful tool for policy makers, the outlier detection tool, which could be used to evaluate in time different policies.

Keywords: seasonality adjusted data, outlier detection, JDemetra+, log transformation

Introduction

In the last 30 years, due to technological progress, the focus of development has been concentrated on the development of innovative tools for public health (Bos, L. and Blobel, B., 2007; Friede, A. et al. 1995; Baker, E.L. et al. 1995; Khan, A.S. et al. 2010). For this reason, investments in statistics tools for public health have also appeared, these being done by researches organizations or state governments (Lauren, N. Carroll et al. 2014; Driedger, S.M. et al. 2007; Kothari, A. et al. 2008; Robertson, C. and Nelson, T.A., 2010). One of the most widespread research topics has been in the surveillance and management of infectious diseases, mostly on pandemic risk cases (Hills, R.A. et al. 2008; Reis, B. et al. 2007; Chen, H. et al. 2010). One of the most important tools is to view the map or network through which an infection can be transmitted. In the 19th century, John Snow made the first map of London with cholera cases, but nowadays this task is for the computer science, according to Koch, T. and Denike, K. and Chen, H. et al. (2010). One such example is the dashboard created by John Hopkins University (2020). The usefulness of these technologies is also suggested by the significant increase in the last years on all PubMed articles of terms such as "GIS" (Geographic Information System) or "social network analysis" (Lauren, N. Carroll et al. 2014). In general, data are used to identify diseases clusters, how diseases are spread and predict the other outbreaks (AvRuskin, G.A. et al. 2004; Castronovo, D.A et al. 2009; Dominkovics, P. et al. 2011).

With the diversification of data, intelligent management is also needed. It raises the issue of integrating data from several sources, for example about mortality, clinical data (what vaccines a population has, their health status, etc.), geographic, relationships (name of family, name of students in a school, friends etc.), travel plans etc. (Gao, S. et al. 2008; Basta, N.E. et al. 2009; Polgreen, P.M. et al. 2010; O'Carroll, P.W. et al. 1998). Another important aspect is the legality of obtaining and processing this data (Lauren, N. Carroll et al. 2014).

According to World Health Organization (2020) a death caused by infection with rabies virus, transmitted in 99% of the cases by dog bite, occurs every 9 minutes, going up to more than 59,000 deaths annually, an estimation subjected to underreporting and uncertainty, and with 40% of the victims being children bellow age 15, predominantly in rural areas. The same organization claims that rabies is 100% preventable, if at least 70% of the dogs in a region are vaccinated against the virus, the transmission cycle is broken. Hampson et al. (2015) provided valuable insights, that due to national markets inefficiencies in promoting canine vaccination and post-exposure prophylaxis, by providing an estimation on the worldwide economic burden of contracting and treatment of rabies, incurring a direct loss of productivity, and death by rabies infection to 8.6 billion dollars, at 95% confidence interval: 2.9-21.5 billion dollars. This argument contradicts the 100% rabies preventability claimed by WHO. The same authors point out that the most affected regions are those subjected to extreme poverty, like those in rural India, which account for nearly 35% of the global death toll. A 2017-2018 study (Sreenivasan et al. 2019) across 23 Asian and African poorest countries which account for more than 90% of deaths by rabies infection, identified the main factors affecting access to post-exposure prophylaxis, from which we enumerate: limited availability at lower administrative levels, patients are required to pay, although the medical procedures are theoretically free, the lack of funds for a state-level prevention strategy for rabies infections and the lack of effective monitoring tools of potentially infected patients. To enhance national initiatives, WHO with the Food and Agriculture Organization and the World Organization for Animal Health made a commitment in 2015 to globally eradicate dog-mediated human rabies (2015). This initiative, along with all other public policies targeted at rabies prevention, make use of statistical tools ranging from simple descriptive statistics, like those used by WHO (2020), to raise awareness in among general public and for setting the public policy agenda, to more sophisticated instruments, such as decision trees (Anothaisintawee et al. 2018) or simulation models, providing a more robust decision support in selecting the optimal intervention route (Rattanavipapong, 2018). Based on these arguments, in this paper we propose a novel statistical approach in the statistical treatment of data pertaining to this subject-matter.

Broadly, the aim of this paper is to illustrate how statistical tools can benefit healthcare policy makers specialised in the rabies management. Managing such a disease means ensuring enough personnel, equipment, spaces dedicated to treatment as well as current supplies. In this respect, it is crucial for management teams of medical facilities to understand the patterns of the prevalence of such a disease. A critical component in understanding patterns in a data series with a frequency less than a year is exploring seasonality (Mirica et. al. 2019). Seasonally adjusted data are used in order to calculate growth rates between consecutive sub-periods of a year, therefore choosing the suitable techniques and tools for this process is extremely important (Mirica et al. 2016). In this respect, the specific objective of this paper is to analyse whether or not the number of persons examined for rabies present a seasonal component and, if seasonality is indeed present, to demonstrate the use of an innovative, easy to use tool for seasonal adjustment.

Methodology

For the purpose of this paper data on the number of persons examined for rabies at the National Institute of Infectious Diseases "Matei Bals" – Centre against rabies will be used. One should note that Toma and Mirica (2018) pointed out that the lower the aggregation level, the more statistically relevant is. In this respect, we consider that analysing seasonal patterns in the number of persons examined for rabies should be performed for data at health care unit. The data can be found at https://www.mateibals.ro/index.php/component/content/category/13-antirabic-statistici?layout=blog (accessed February 3, 2020) and resent the total number of persons examined for rabies, as well as by age (children and adults) and residency (Bucharest or not) from January 2015 to May 2019.

In order to seasonally adjust these series, the methodology proposed by Andrei et. al. (2019) will be used: the graph of each series will be analysed in order to have some insights with regard to the appropriate type of transformation; seasonality tests and outlier detection techniques will be performed for each series; in case seasonality is present, each series will be seasonally adjusted using TRAMO-SEATS and X13 procedure. In order to apply this methodology as efficiently as possible, JDemetra+ 2.2.2, software officially recommended by Eurostat will be used as it incorporates several seasonality tests, an outlier detection tool, a calendar tool as well as predefined specifications for both X13 and TRAMO_SEATS (Grudkowska, 2015). Moreover, JDemetra+ provides an automatic procedure for choosing the ARIMA model as well as other specifications of the seasonal adjustment model (Grudkowska, 2015). The appropriate transformation for the time series will be decided based on the guidelines of the Hungarian Central Statistical Office (2007) as follows: if seasonal variation is not changing along with the trend, then no transformation will be applied; however if the seasonal variation is changing along with the trend, a log-transformation with be performed. If the automatic procedure will select an different transformation compared to the decision taken based on the graphical inspection, the respective time series will be seasonally adjusted manually. With regard to seasonality tests, both for the initial series as well as for residuals, all tests available in JDemetra+ will be considered. However, when conflicting results occur, the autocorrelation at seasonal lags will be used (Mirica et al. 2016). Considering the time series length, each series will be tested as it is, as well as for the last 3 years (as suggested by UNECE (2012) to be the minimum length). In order to choose from TRAMO-SEATS and X-13 as well as from different series spans, the AIC will be used (as suggested by Andrei et al. 2019). Moreover, we will use a similar template for reporting the results as Andrei et el. (2019).

Results

Figure 1 displays the evolution of the total number of persons examined for rabies as well by age and area of residency. As one can observe, all the series display clear seasonal patterns. Also, one can observe that all series present a relatively constant trend with small changes in the magnitudes of the seasonal variations. Therefore, all series should be log-transformed prior seasonal adjustment.

Figure 1: Total number of persons examined for rabies, by age and area of residency at the National Institute of Infectious Diseases "Matei Bals" – Centre against rabies, source: designed by the authors based on data available at: https://www.mateibals.ro/index.php/component/content/category/13-antirabic-statistici?layout=blog (accessed February 3, 2020)

Table 1 presents the results of the seasonality tests applied to the selected time series. As one can observe, all the tests showed significant results at 5% threshold. Therefore, there is clear evidence that seasonality is present within all the time series.

Table 1: Results of the seasonality tests (values), source: designed by the authors

	Total number of persons examined for rabies	**Number of adults examined for rabies**	**Number of children examined for rabies**	**Number of persons examined for rabies from Bucharest**	**Number of persons examined for rabies from the rest of the country**
Auto-correlations at seasonal lags	26.9616*	30.5531*	24.4507*	9.8962*	22.6700*
Friedman (non parametric)	34.0385*	32.3648*	30.2741*	23.1923*	31.0560*
Kruskall-Wallis (non parametric)	37.4222*	38.1203*	35.7401*	27.5289*	35.4409*
Periodogram	7.1820*	8.7425*	6.3620*	3.4066*	6.8584*
Seasonal dummies	39.8493*	34.3587*	39.7627*	16.7055*	15.3209*

**P-Value lower than 5%*

Next, all the series were analysed using the outlier detection tool in JDemetra+. The only series that displayed outliers is number of persons examined for rabies from Bucharest. Thus, the tool detected a

transitory change outlier in September 2017 (381 persons), a level shift outlier in November 2017 (222 persons) and another level shift outlier in April 2018). This outlier in September 2017 could be explained that in the long run, the series returned to its usual level, even if in the short, starting October 2017 and culminating in November 2017, a sharp decrease can be observed. The return of the series to its original level prior August 2017 happens following the second level shift outlier.

Table 2 presents the results of the automatic procedure implemented in JDemetra+ 2.2.2 for TRAMO-SEATS and X13 used in order to seasonally adjust the five series. As one can observe, for the total number of persons examined for rabies, the number of adults examined for rabies, the number of children examined for rabies and the number of persons examined for rabies from Bucharest the lowest AIC was obtained using X13 on a three years length. In the case of the number of persons examined for rabies from the rest of the country. The lowest AIC was obtained using TRAMO-SEATS on a three years length. Moreover, one can observe a negative Easter Effect in the case of the first three series. This means that the total number of persons, adults and children may decrease before Easter.

Table 2: Results of the seasonal adjustment process of the entire series

	Length	**Procedure**	**Series Transformation**	**Calendar effect**	**Outliers**	**Residual seasonality**	**Quality**	**AIC**
Total number of persons examined for rabies	Entire series	X13	Log-transformed	Julian Easter (15) = -0.2891*	none	Not present	good	446.5
		TRAMO SEATS	Log-transformed	none	none	Not present	good	446.2
	3 years	X13	Log-transformed	Julian Easter (15) = -0.304*	none	Not present	good	253.7
		TRAMO SEATS	Log-transformed	none	none	Not present	good	262.9
Number of adults examined for rabies	Entire series	X13	Log-transformed	Julian Easter (15) = -0.174*	none	Not present	good	394.0
		TRAMO SEATS	Log-transformed	none	none	Not present	good	404.2

Conclusions

This study was based on researching the effect, that it might have on the seasonal component of people examined for rabies, of using an easy to use and innovative tool for seasonal adjustments. This research contributes to the existing literature illustrate how statistical tools can benefit healthcare policy makers specialised in the rabies management in two ways: firstly, to our knowledge, the National Institute of Infectious Diseases "Matei Bals" – Centre against rabies is the only entity that publicly discloses monthly data on examinations on rabies in Romania, permitting an analysis at the lowest aggregation level possible, that of healthcare unit; secondly, the paper proposes the use of JDemetra+ an open source software, easy to use for non-statisticians. The seasonally adjusted data can be used by decision makers to compare consecutive months within a year so that they can better allocate resources.

In order to seasonally adjust data regarding the rabies examinations, one should be careful when choosing the series span, the series transformation as well as the procedure. With regard to the series span, best results were obtained with 3 years series. The automatic procedure implemented in JDemetra+ chooses whether or not the series should be log-transformed. However, the user should endorse the choice based on graphical examination. Finally, the X13 procedure proved to be the best option when choosing the procedure.

Besides seasonality tests and an automatic procedure for seasonal adjustment JDemetra+ offers a very useful tool for policy makers, the outlier detection tool. This tool can be used to identify abnormal values within the time series (whether very low or very high) and hence evaluate in time different policies.

Abstract

This paper analyzes the effect of family ownership on company's tax avoidance practices in Indonesia. This study also analyse whether there is change in tax avoidance practice after the tax amnesty program implemented on 2015-2016. We used three measurements to capture tax avoidance practices, (a) effective tax rate, (b) cash effective tax rate, and (c) book-tax difference. Our sample for this study is forty-nine non-state owned non-financial private Indonesian firms who participated in the tax amnesty program 2015-2016. This study covered data for 2013 to 2017 period divided into before tax amnesty and post-tax amnesty program. We found that family ownership has a positive impact on tax avoidance practice. In other word, family-own companies avoid tax payment more aggressively compared to non-family own companies. However, despite regulator expected the tax amnesty program to reduce company's tax avoidance practice, we found different results. Company's tax avoidance behaviour does not change even when tax authorities have implemented a tax amnesty program.

Introduction

Tax plays an essential role in the running of the government and the development of almost every country in the world, including Indonesia. The Indonesian government recorded that the portion of tax revenue in the national budget increases each year. Unfortunately, the degree of tax compliance in Indonesia is no better than that of other regional countries. One of the tools that represents the degree of tax compliance in a country is the tax ratio. Until 2016, Indonesia's tax ratio was only 10.33%. This was much lower than that in Singapore (14.29%), Malaysia (13.76%), Thailand (15.69%), and even Cambodia (15.26%) (Direktorat Jenderal Pajak, 2016).

One of the reasons behind low tax compliance is the large amount of tax companies must pay. Through taxes, the government takes a significant share of a firm's revenue. This substantial tax becomes a considerable cost that must firms and shareholders must endure, directly and indirectly. This burden encourages firms to engage in corporate tax avoidance activities (Chen, Chen, Cheng, & Shevlin, 2010). The preferences regarding involvement in tax avoidance activities may be different for each firm since tax avoidance activities are considered risky (Armstrong, Blouin, Jagolinzer, & Larcker, 2015). Companies must consider the tradeoff between the marginal benefits and marginal cost of managing taxes. Such examples of the marginal benefits include smaller tax payments, and the marginal cost consists of the potential penalty enforced by the tax authority, time/effort and transaction cost of implementing tax avoidance, and agency costs accompanying these activities (Chen et al., 2010).

Several studies have investigated the determinants of corporate tax avoidance practices. Size, leverage, profitability, and corporate governance can drive companies to avoid taxes. Furthermore, family ownership is also believed to be a determinant that encourages companies in practicing tax avoidance, since companies owned by a family are recognized as a new set of economic organizations (Gaaya,

Lakhal, & Lakhal, 2017). Two opposing results from numerous studies may explain the effect of family ownership on tax avoidance activities. Using a sample of 1,003 companies from the S&P 1500 index, Chen et al. (2010) found that the tax aggressiveness of family firms are less than that of non-family firms. This means there is a negative relationship between family ownership and corporate tax avoidance. Family owners are considered to be more aware of the potential conviction imposed by the tax authority and the damage to the family's reputation (Chen et al., 2010). In contrast, Gaaya et al. (2017) concluded that family ownership has a positive relationship with corporate tax avoidance in Tunisian companies. This conclusion is in alignment with Annuar, Salihu, & Obid (2014), who found that family ownership is a potential determinant that encourages a company to implement corporate tax avoidance in Malaysia. This result suggests that the protection of minority shareholders in less developed countries is weak. This inadequate protection will lead family owners to expropriate minority shareholders by extracting high rent from tax-saving positions (Gaaya et al., 2017).

The purpose of this study is to enrich literature about tax avoidance practiced by family firms, especially in Indonesia. We try to examine the influence of family ownership on tax avoidance activities and to depict the impact of the Indonesian tax amnesty program on corporate tax avoidance. We use a sample of 49 listed companies in the Indonesian Stock Exchange from 2015 to 2016. These companies participated in the tax amnesty program offered by the Indonesian government. To examine the firms' tax avoidance aggressiveness, we used three measurements: effective tax rate, cash effective tax rate, and book-tax difference. The lower effective tax rate and higher book-tax difference shows that one firm's aggressiveness in practicing tax avoidance is more than that of other firms (Chen et al., 2010).

This paper's outline is as follows: Section 2 develops the literature review and hypothesis on the relationship between family ownership and corporate tax avoidance; Section 3 presents the study's research sample, data, and methodology; Section 4 discusses the results of the study; and Section 5 consists of conclusion and recommendation.

Literature Review

Corporate tax avoidance

Many companies apply earning management for tax savings since tax is defined as an obligatory contribution to the government without any direct reciprocity to the taxpayers (Zeng, 2014). Ideal taxation treats all taxpayers equally. Furthermore, tax must also be efficient and easy for all taxpayers. Companies treat tax liabilities as costs that must be highly considered since tax takes a significant portion of a company's profit. More than one-third of a company's is profit distributed to the government through tax payments (Chen et al., 2010). Therefore, many managers try to reduce the company's tax liabilities. One activity that can minimize tax payments and increase income after tax is corporate tax avoidance (Gaaya et al., 2017).

The definition of tax avoidance is the distribution of resources or values from government to company owners (Desai & Dharmapala, 2005). Moreover, tax avoidance can also be defined as a set of company activities in arranging and rationalizing the tax burden through evaluating all potential benefits and costs of avoiding taxes (Dyreng, Hanlon, & Maydew, 2008). These company activities in managing revenue to avoid taxes could be categorized as legal or illegal practices, or lie in between (Steijvers & Niskanen, 2014).

When companies practice tax avoidance, there is a tradeoff between the benefits and the costs. The most obvious benefit of being tax aggressive is the higher profit generated from more significant tax savings. Shareholders and the managers obtain these benefits if they are compensated for their efforts in managing tax payments. Another potential benefit of corporate tax avoidance is rent extraction (Chen et al., 2010). Along with the profits generated by tax avoidance, however, there are some potential costs that companies will have to bear. One of the most obvious burdens of practicing corporate tax avoidance is the likely punishment imposed by the tax authorities. When the practice of tax aggressiveness is detected, the tax authority will audit the compliance of companies' tax liabilities and

impose significant fines as a penalty (Chen et al., 2010). Another cost of being tax aggressive is the potential price discount forced by other shareholders if they perceive that decision-makers use tax avoidance to increase rent extraction (Desai & Dharmapala, 2005).

Among these costs, Sánchez-Marín, Portillo-Navarro, & Clavel (2016) say that there are three risk factors that companies must consider in practicing tax avoidance: economic, reputational, and transactional factors. Concerning economic and reputational factors, companies tend to be more conservative in avoiding taxes since there is the potential for damage to a company reputation even though the tax burden that must be carried by companies will increase. Regarding the transactional factor, companies will calculate their tax complexity before deciding to apply tax avoidance practices. The decision will depend on the company's experiences and capabilities in managing taxes (Sánchez-Marín et al., 2016).

Family ownership and corporate tax avoidance

More than half of the companies in East Asia are owned and controlled by family members. The family ownership of these companies' assets are very significant. Claessens, Djankov, & Lang (2000) find that the ten most prominent families in Indonesia, the Philippines, and Thailand control half of the total assets of all companies in those countries. Family firms are not only prevalent in East Asia, but also in the most developed countries where 75%of companies are family firms. Moreover, these companies have a substantial proportion of global wealth production (Nicholson, 2008).

Anderson & Reeb (2003) defines a company as a family firm if the founders or their family members occupy crucial positions in the company such as executives, directors, and primary block holders. Furthermore, companies may be categorized as a family firm if those companies have unique properties such as genetic identity, intergenerational transmission, and wildcard inheritance (Nicholson, 2008).

Besides that, family firms also have several unique characteristics in terms of an agency relationship compared to non-family firms. Companies with high family ownership have a relatively well-aligned relationship between owners and managers. This minimizes the occurrence of agency conflict and agency cost that must a firm carries (Jensen & Meckling, 1976). However, Schulze, Lubatkin, Dino, & Buchholtz (2001) say that agency conflicts in family firms are precisely more challenging to solve than in non-family firms due to the existence of altruism. Indeed, family firms have lower agency conflict between owners and managers, but greater potential for agency conflict between majority shareholders and minority shareholders (Chen et al., 2010).

Along with these unique traits, high involvement of family in company management may their corporate decisions, including the corporate tax policy (Gaaya et al., 2017). Traditionally, family firms tend to be more conservative in avoiding taxes. There is high concentration of ownership and low diversification of investment. Hence, reputation becomes essential for family firms (Sánchez-Marín et al., 2016). Nevertheless, there are two conflicting results regarding the influence of family ownership on corporate tax avoidance.

Chen et al. (2010) found that companies owned by families are less aggressive in practicing tax avoidance than non-family firms. Family firms are more aware of the potential penalty imposed by tax authorities and the damage to their reputation. Thus, the incentives from tax avoidance activities are less than the potential risk that a company will. This result is supported by Steijvers & Niskanen (2014) and Sánchez-Marín et al. (2016), who find that the high involvement of family members in ownership and management has a negative relation on corporate tax avoidance.

In contrast, different results were generated from several studies. Bauweraerts & Julien (2013) find that family involvement in a company's business has a positive relation on corporate tax avoidance. Furthermore, Gaaya et al. (2017) found that Tunisian family firms avoid tax obligation more aggressively than non-family firms to minimize their tax liability, since inadequate protection of investors' rights encourages family firms to use tax avoidance activities to escalate their benefits at the expense of minority shareholders. Annuar et al. (2014) found that family ownership is one of the

potential determinants that encourage companies to implement corporate tax avoidance in Malaysia. Meanwhile, Sari & Martani (2010) found that Indonesian family firms tend to be more aggressive in avoiding taxes than non-family firms. Thus, our first hypothesis is as follows:

H1: there is a positive relationship between family ownership and corporate tax avoidance.

Tax amnesty and corporate tax avoidance

Andreoni (1991) defines tax amnesty as a program that is held by the government that forgives penalties owed by taxpayers if they repay their malicious taxes voluntarily. Tax amnesty was designed as a one-time opportunity for taxpayers to be free from any tax penalties through participation in this program (Alm & Beck, 1993). Furthermore, tax amnesty must be coupled with tax reform to discourage former amnesty participants from backsliding (Parle, Hirlinger, & Parle, 1986). Many countries offer tax amnesty programs for three reasons. First, they are designed to generate additional tax revenue in the short term to cover budget shortfalls. Second, they can increase future collection of tax revenue. Third, they can improve the tax compliance rate overall (Tilman, 2006).

There are two different perspectives on the importance tax amnesty programs. Proponents of such programs assert tax amnesty could increase compliance in the long run if the program is followed by better law enforcement efforts and better services to taxpayers. Moreover, the amnesty program could generate tax compliance if the government can get those who did not file tax returns to do so with the tax authorities (Alm & Beck, 1993).

However, different opinions come from the opponents. They argue that compliance after tax amnesty is far more likely to decline. Obedient taxpayers will consider tax amnesty as an unfair program. The program gives advantages only to those individuals who cheated. Furthermore, the tax cheaters may expect another amnesty program to be offered in the future. Thus, the tax amnesty program may make taxpayers aware of the widespread presence of noncompliance (Alm & Beck, 1993).

One of the few countries that have executed a tax amnesty program is Indonesia. Utilizing Law Number 11 Year 2016 about tax amnesty, the Indonesian government ran a tax amnesty program for all taxpayers who did not disclose their assets correctly from 1985 to 2015. The participants of this program were forgiven for their tax evasion at all times until 2015 if they repay some ransom for all of their undisclosed assets to the government. One of the purposes of the Indonesian government enacting this program is to increase taxpayers' awareness and compliance. As stated in the introduction above, the level of tax compliance in Indonesia based on the tax ratio measurement is still worse than other countries in this region, such as Singapore, Malaysia, Thailand, and even Cambodia (Direktorat Jenderal Pajak, 2016). Thus, our second hypothesis is as follows:

H2: there is a negative relationship between a tax amnesty program and corporate tax avoidance.

Methods

Sample Selection and Data Collection

The sample of this study includes listed companies on the Indonesian Stock Exchange (IDX) that participated in the tax amnesty program held by the Indonesian government. Financial companies and state-owned companies are excluded from the sample of this study. The period of this study is from 2013 to 2017. Tax data and firm characteristics are generated from financial statements and annual reports of listed companies that were available either on firm websites or on the Indonesian Stock Exchange website. This study excludes firms with negative tax expense and negative taxable income. Firms whose financial statements are not stated in Indonesian Rupiah also excluded from the sample.

Corporate Tax Avoidance Measures

Gaaya et al. (2017) stated that corporate tax avoidance activities are so various and comprehensive, it is impossible to measure corporate tax avoidance only with a single measurement. Thus, three kinds of corporate tax avoidance a used in this study.

The first measurement of corporate tax avoidance is Effective Tax Rate (ETR), which refers to total tax expense scaled by pre-tax income. Dyreng, Hanlon, & Maydew (2008) says that ETR could represent many forms of tax avoidance practices through tax shelters and loopholes in tax regulations. Moreover, ETR is also able to depict tax planning activities through permanent book-tax differences, such as investing in a tax paradise country or investing on free-taxed assets (Chen et al., 2010).

$$ETR_{i,t} = \text{total tax expense}_{i,t} \,/\, \text{pre-tax income}_{i,t} \tag{1}$$

The second measurement of corporate tax avoidance is cash effective tax rate (CETR). CETR refers to

$$CETR_{i,t} = \text{cash tax paid}_{i,t} \,/\, \text{pre-tax income}_{i,t} \tag{2}$$

cash taxes paid scaled by pre-tax income. Chen et al. (2010) said that CETR could reflect a company's tax planning activities through permanent and temporary book-tax differences. CETR is also able to exclude the impact of earning management. ETR and CETR are inverse functions of tax avoidance. Lower values of ETR and CETR represent greater aggressiveness in corporate tax avoidance (Chen et al., 2010).

The last measurement of corporate tax avoidance is book-tax difference (BTD). BTD refers to pre-tax book income minus estimated taxable income scaled by total assets. We calculate the estimated taxable income based on the current tax expense divided by the statutory tax rate. Companies that have higher BTD tend to be more aggressive in practicing corporate tax avoidance (Gaaya et al., 2017).

$$TD_{i,t} = (\text{pre-tax book income}_{i,t} - \text{taxable income}_{i,t}) \,/\, \text{total assets}_{i,t} \tag{3}$$

Models

To examine the relationship between family ownership and corporate tax avoidance, as stated in the first hypothesis of this study, we estimate the following regression:

$$TaxAvo_{i,t} = \alpha_{0t} + \alpha_1 FAMILY_{it} + \alpha_2 SIZE_{it} + \alpha_3 ROA_{it} + \alpha_4 LEV_{it} + \varepsilon_{it} \tag{4}$$

Where $TaxAvo_{i,t}$ is the corporate tax avoidance measure, either ETR, CETR, or BTD. $FAMILY_{it}$ refers to family ownership that is measured as 1 (one) if family ownership is more than 50%, and 0 (zero) if otherwise. Meanwhile, to examine the relation between tax avoidance and corporate tax avoidance, as stated in the second hypothesis, we estimate the following regression:

$$TaxAvo_{i,t} = \alpha_{0t} + \alpha_1 TaxAmn_{it} + \alpha_2 SIZE_{it} + \alpha_3 ROA_{it} + \alpha_4 LEV_{it} + \varepsilon_{it} \tag{5}$$

$TaxAmn_{it}$ refers to the research period, which measured as 1 (one) for the post-tax amnesty period (2016 to 2017), and 0 (zero) if otherwise (2013 to 2015). We also include a set of control variables in our regression models referring to firm characteristics that may affect tax avoidance behavior. $SIZE_{it}$ is firm size measured by the natural logarithm of total assets. More prominent companies tend to be more tax aggressive since larger companies have more economic and social power than smaller companies (Lin, Tong, & Tucker, 2014). ROA_{it} is the ratio of return on assets for a firm which is measured as net profit scaled by total assets. Companies with higher profitability tend to be more encouraged to apply corporate tax avoidance (Lanis & Richardson, 2012). LEV_{it} is measured by the overall long term debt

scaled by total assets. Companies with higher leverage tend to be more tax aggressive because the interest payments generated by the firm's debt are tax-deductible (Richardson, Taylor, & Lanis, 2015).

Result and Discussion

Descriptive Statistics

Table 1 below summarizes the descriptive statistics of all variables used in this study. To measure corporate tax avoidance, this study uses three measurements. They are ETR (effective tax rate), CETR (cash effective tax rate), and BTD (book-tax difference). The mean values of ETR and CETR are 21.62% and 26.14%. These two mean values show that firms included in the observation have an average effective tax rate which is not different from the statutory tax rate. The statutory tax rate for corporations based on tax regulation in Indonesia is 25%. Meanwhile, the mean value of BTD is 1.87%. This means that pre-tax book income on average is still greater than taxable income based on tax regulation.

Table 1: Descriptive statistics of all variables

Variable	Mean	Maximum	Minimum	Std. Dev.	Observations
BTD	0.0187	0.2239	-0.0834	0.0409	245
CETR	0.2614	0.8645	0.0010	0.1406	245
ETR	0.2162	0.8513	0.0001	0.1103	245
LEV	0.1537	0.6224	0.0062	0.1239	245
ROA	0.0896	0.4578	0.0012	0.0763	245
SIZE	12.3630	13.7541	9.7117	0.6484	245

Moreover, table 1 shows that the aggressiveness of corporate tax avoidance varies in each company. The minimum value of ETR (0.01%) and CETR (0.1%) depict that the companies' tax payments are much lower than the statutory tax rate, 25%. Moreover, the minimum value of BTD (-8.34%) shows that pre-tax book income base is much smaller than taxable income based on tax regulation. Meanwhile, the maximum value of ETR (85.13%) and CETR (86.45%), which are much greater than the statutory tax rate, could be caused by the company's industry which has particular tax characteristics different from other common sectors.

This study also compares the mean value of ETR, CETR, and BTD between family firms and non-family firms, as stated in Table 2 below. Table 2 shows that the mean value of CETR is significantly different between family firms and non-family firms. The CETR mean amount of family firms (15.64%) is lower than non-family firms (26.83%). This means that family firms tend to be more aggressive in implementing corporate tax avoidance than non-family firms.

Table 2: Mean value of family firms and non-family firms

	ETR	CETR	BTD
Family firms	0,2003	0,1564	0,0225
Non-family firms	0,2172	0,2683	0,0184
sig. (2 Tailed)	0,568	0,003	0,710

Meanwhile, this study also compares the mean value of ETR, CETR, and BTD between the pre-tax amnesty period and the period after the tax amnesty program is performed, as stated in Table 3 below. From Table 3, we find that there is no significant difference of mean value (ETR, CETR, and BTD) after the tax amnesty program is performed compared to the pre-tax amnesty period. This indicates that both family firms and non-family firms do not change their behavior in avoiding taxes even if they participated in the amnesty program.

Table 3: Mean value comparison (pre-amnesty and post-amnesty).

		ETR	CETR	BTD
Family firms	Pre-amnesty	0,2026	0,1501	0,0127
	Post-amnesty	0,1969	0,1657	0,0372
	sig. (2 Tailed)	0,894	0,790	0,274
Non-family firms	Pre-amnesty	0,2144	0,2643	0,0181
	Post-amnesty	0,2214	0,1552	0,0189
	sig. (2 Tailed)	0,642	0,599	0,890

This finding is interesting since one of the government's purposes in offering a tax amnesty program is to improve compliance of overall taxpayers in addition to increasing the collection of tax revenue.

Regression Analysis

Table 4 below presents the regression results that examine the relationship between family ownership and corporate tax avoidance. Table 4 shows that the FAMILY variable has a negative coefficient of CETR with a significance below 1%. The results of this test reflect that family ownership has a positive influence on the tax avoidance rate of a company because the aggressiveness of the company against tax evasion is inversely proportional to the value of CETR. Meanwhile, the relationship of the FAMILY variable to BTD and ETR has no significant correlation.

Table 4: Regression result (family ownership and corporate tax avoidance)

VARIABLE	ETR		CETR		BTD

C	0.3955	0.0463	0.3690	0.2566	-0.0676	0.3458
Adjusted R-squared	0.0366		0.0807		0.2701	
Prob (F-statistic)	0.0114		0.0004		0.0000	

These results support the first hypothesis of this study that family ownership has a positive influence on corporate tax avoidance. These findings are in line with Bauweraerts & Julien (2013), Annuar et al. (2014), and Gaaya et al. (2017), who find a positive relationship between family ownership and corporate tax avoidance. The high aggressiveness of family firms in avoiding taxes is driven by the lack of protection against minority shareholders so that minority shareholders will see the profits derived from tax avoidance (Gaaya et al., 2017). Moreover, the transfer of control in family firms to the next generation will also encourage increased aggressiveness in tax avoidance efforts. The successor generation of a family firm is considered to have experience and knowledge in managing more complicated tax issues so that they will be better able to practice tax evasion (Bjuggren & Sund, 2005).

However, the results of this study contrast with Chen et al. (2010), Steijvers & Niskanen (2014), and Sánchez-Marín et al. (2016), who find a negative relationship between family ownership and corporate

tax avoidance. Chen et al. (2010) say that family firms are less aggressive in avoiding taxes because they are very concerned about sanctions imposed by the tax authorities as well as damage to the company's reputation as a result. Furthermore, Gedajlovic & Carney (2010) argue that family firms have a broader business horizon and are more concerned about the company's good name. This situation indicates that financial gain is not the only goal held by a family company.

Table 5 below presents the regression results that examine the relationship between tax amnesty and corporate tax avoidance. The regression test results show that the TaxAmn variable has no significant effect on corporate tax avoidance, whether it is measured by ETR, CETR, or BTD. The finding indicates that a company's tax avoidance behavior is not affected by the implementation of a tax amnesty program. This result does not support our second hypothesis that tax amnesty has a negative influence on corporate tax avoidance.

Table 5: Regression results (tax amnesty and corporate tax avoidance)

VARIABLE	ETR		CETR		BTD	
	Coef	Prob.	Coef	Prob.	Coef	Prob.
TaxAmn	-0.0054	0.7309	-0.0116	0.4757	0.0105	0.1435
LEV	-0.0544	0.1665	0.0246	0.8593	-0.0227	0.3331
ROA	-0.8106***	0.0000	-1.4931***	0.0000	0.6397***	0.0000
SIZE	0.0314	0.1133	0.0627	0.1700	-0.0174	0.2289
C	-0.0892	0.7025	-0.3798	0.5041	0.1765	0.3194
Adjusted R-squared	0.4738		0.3039		0.6934	
Prob (F-statistic)	0.0000		0.0000		0.0000	

This finding is in line with the research of Alm & Beck (1993), who find that a tax amnesty program does not have an impact on increasing tax revenue or compliance in the long term. A tax amnesty program is precisely considered to reduce compliance in the long run. Taxpayers who have adhered to laws and regulations will judge tax amnesty as unfair because it only benefits those who have been disobedient in carrying out their tax obligations. Meanwhile, those who engaged in tax evasion will assume that there will be another similar tax amnesty program in the future. Therefore, there is a fear that non-compliance would increase with the implementation of the tax amnesty program (Alm & Beck, 1993).

Meanwhile, to improve long-term compliance, the tax amnesty program is followed by improved law enforcement and service to taxpayers (Alm & Beck, 1993). Furthermore, tax amnesty must be coupled with tax reform to discourage backsliding on by former amnesty participants (Parle et al., 1986).

Conclusion

This study examines the tax aggressiveness to avoid tax payment of family firms relative to their non-family counterparts. We used three measurements to capture tax aggressiveness. They are effective tax rate, cash effective tax rate, and book-tax difference. The observation was conducted from 2013 through 2017 of all non-financial public companies which were not state-owned. These companies also participated in the tax amnesty program. The results of this study prove that family firms have a significant positive effect on corporate tax avoidance, using cash effective tax rate as a proxy of corporate tax avoidance. From this finding, it can be interpreted that the higher the family ownership in a company, the more it will be encouraged to increase corporate tax avoidance activities. Also, there is a tendency for firms to be more aggressive in tax avoidance, as presented by the significant difference in the mean value of the family firm's cash effective rate compared to the mean value of the same variable in non-family firms. However, this study does not provide empirical evidence regarding the effect of tax amnesty on tax avoidance activities and found no significant difference in the mean value of each tax avoidance measurement between the pro-amnesty period and the post-amnesty period, both in family firms and non-family firms. This finding indicates that a company's tax avoidance behavior does not change even when tax authorities have implemented a tax amnesty program. Finally, some

limitations need to be considered for following research. First, future research may classify companies included in the study based on their industry sectors since the tax characteristics for each industry may be different. Second, future research may consider extending the period of study, especially the period of post-tax amnesty program, to capture the effect of the tax amnesty program on tax aggressiveness in the long run.

Entrepreneurial Competencies and the Factors Determining the Success of an Entrepreneurs in the Market

Anna KOMARNICKA

UTP University of Science and Technology, Bydgoszcz, Poland
E-mail: anna.komarnicka@utp.edu.pl

Abstract

Purpose: The aim of the paper is to identify the key range of entrepreneurial competencies. The article seeks to answer the question: What factors have a significant impact on the success of entrepreneurs in the market? Is it necessary to have adequate predispositions? Which abilities does an entrepreneur need to possess to run a successful business? What is more, are these innate features? Or quite the contrary, features and entrepreneurial abilities, shaped and strengthened through various educational programmes? **Design/Methodology/Approach:** The data collection process consisted of two steps. First of all, desk research and the review of the Internet sources were applied. Secondly, there were conducted national qualitative research: 10 in-depth expert interviews. The recipients of the study are: scientists, business psychologists, certified business coaches, experts with several years of experience in advising small and medium-sized enterprises and business environment institutions in the field of business incubation and innovation. The qualitative study took part recognized experts from various universities and institutions in Poland: University of Warsaw, Poznan University of Economics and Business, SGH Warsaw School of Economics, Polish Business and Innovation Centers Association, University Technology Transfer Center at University of Warsaw. **Findings:** The results indicate, that in the opinion of the experts studied, the entrepreneur's success in the market is determined by a synergic combination of: (1) innate entrepreneurial aptitude, (2) sociological conditions, and (3) educational programmes (including training and courses). The lack of any component, in their views, limits the individual potential of an entrepreneur. **Originality/Value:** The paper provides the knowledge in the range of the key entrepreneurial competencies that enable to set up, survival and development of a business ventures. The paper might be valuable to scholars who wish to understand the key range of entrepreneurial competencies.

Keywords : Entrepreneurial Competence, Entrepreneurial Orientation, Entrepreneurs, Entrepreneurial Skills.

Introduction

Entrepreneurial competence is an important factor that determines the success or failure of the organizations. In general, competencies have been defined as "(…) combined and integrated components of knowledge, skills, and attitudes." (Kyndt & Baert, 2015, p. 14). Entrepreneurial behaviour is a key factor of employment creation, wealth creation, and expansion. The companies must behave entrepreneurially in order to have a competitive advantage over competitors. Therefore entrepreneurial behaviours are a critical success factor to sustain competitive advantage on the market. (Nwachukwu, Chládková, & Žufan, 2017, p. 3–5).

The aim of this paper is to identify the entrepreneurial competency and establish which competencies are the key. The study allows to identify the key factors having a significant impact on the success of entrepreneurs in the market. The paper is structured as follows: section two presents a literature review about the role and importance of the entrepreneurial competencies. Section three describes and explains the methodology of own research. Section four presents the results of the data analysis; and provides an interpretation of the findings.

The Range of Entrepreneurial Competencies

The factors determining the entrepreneur's success in the market include personality features, knowledge, motivations, cognitive mechanisms and self-efficacy. (Figure 1.)

Fig. 1: Entrepreneurial competencies
Source: own work based on (Glinka & Gudkova, 2011, p. 123) and (Urbaniec, 2016, p. 81–82).

These are the characteristics of an entrepreneur, referred to as entrepreneurial competences, which enable the establishment, survival and development of a business enterprise. These elements of competence are subject to varying degrees of change. The easiest ones are subject to modifications of knowledge resources, while the most difficult ones are personal features, which usually have an inborn character. The interaction between the individual elements of an entrepreneur's competence and the actions undertaken by the entrepreneur takes place. The effectiveness of the undertaken entrepreneurial activities depends on the competences, while competences are changed under the influence of feedback concerning the results of undertaken actions. Therefore, the entrepreneur is constantly in an active interaction with the environment, which is a source of market opportunities and necessary resources for him.(Glinka & Gudkova, 2011, p. 122–123).

The results of many years of research carried out in the field of entrepreneurial personality features have so far not led to the creation of a consolidated concept, explaining the conditions for making decisions on setting up one's own company and achieving success on the market by entrepreneurs.

One of the reasons for this may be the specific nature of the entrepreneurial process, which is characterized by high risk and uncertainty. However, in the literature there are several personality features characterizing entrepreneurial persons. These are: motivation of achievements, placing a sense of control and risk-taking. (Glinka & Gudkova, 2011, p. 124) (Pokrajčić, 2004, p. 26–40). (Figure 2.)

Fig. 2: Characteristics of personalities identifying entrepreneurs

Source: own work based on (Glinka & Gudkova, 2011, p. 124–127) and (Pokrajčić, 2004, p. 26–40).

The motivation of achievements is a feature that shows the entrepreneur's desire for permanent improvement in order to improve the quality of his own activities. McClelland's research has shown that highly motivated individuals have set themselves ambitious goals and pursue them (McClelland, 1961, p. 261, 360–361). Davidsson, on the other hand, has shown that the company's founders are more likely to be motivated than those who inherited the company. His research has also shown that entrepreneurs with higher potential for motivating their achievements have more often led their companies to advanced stages of development. (Davidsson, 1991, p. 405–429).

Locus of control is "(....) an individual characteristic reflecting the degree of control over own destiny". (Davidsson, 1991, pp. 394). Rotter identifies the external and internal location of the control. Persons with an external control location are looking for reasons for their successes and market failures in external factors. However, entrepreneurs usually have an internal sense of control. They take responsibility for their own actions and are convinced that they can control the progress of the market.

The next feature connected with entrepreneurship is risk-taking ability. (Khedhaouria, Gurău, & Torrès, 2015, p. 485). Many of authors indicate that - taking risks seems to be an inherent and very important part of the life and success of an entrepreneur. (Kyndt & Baert, 2015, p. 14). Risk propensity refers to willingness to commit to sources of opportunity when there is possibility of failure. However, there is a lack of incontestable empirical proofs that people running their own business distinguish acceptance of a higher level of risk. Some studies have found that "(…) persons who create a new enterprise and fight to make it successful may perceive and react to risk in a different way." (Sánchez, 2013, p. 451). Entrepreneurs view business risks as controlled rather than random risks. However, taking risks can bind to setbacks and it is important that entrepreneurs possess the competencies that allow them to deal with these risks and possible consequences. "Hence a first competency that has been identified is perseverance." (Kyndt & Baert, 2015, p. 14). However, successful entrepreneurs also seek to reduce risks when planning for the future.

Other distinguishing features of entrepreneurs are also mentioned in the literature. Among them: the need for independence, creativity, determination in action, openness to new experiences, perseverance in pursuing the goal. However, it should be remembered that having the aforementioned individual personality features does not affect the decision of entrepreneurs to start a business or guarantee their success in business (Man, Lau, & Snape, 2008, p. 257–275).

Entrepreneurship motivation is defined as the state of human readiness to take actions leading to starting business. Carter et al., based on the analysis of the survey results, identified six basic categories of motivation for starting up a business. (Carter, Gartner, Shaver, & Gatewood, 2003, p. 17–19). (Table 1.).

Table 1: Categories, motivation factors for establishing a new business

No.	Categories	Motivation factors
1.	Innovation	A willingness to do something new, the necessity of personal development, the needs to learn.
2.	Independence	Control over the use of one's own time, independence in decision-making, flexibility
3.	Recognition	A need for achievements and acceptance (achievement of social position)
4.	Roles	Personal patterns, social relations, contacts of entrepreneurs with: family, other entrepreneurs, customers
5.	Financial success	A willingness to obtain financial benefits, maximize the company's growth rate
6.	Self-realization	A desire to check out and realize your vision for the future

Source: own work based on (Carter et al., 2003, p. 20).

The research on the cognitive mechanisms of entrepreneurs was conducted in the late 1990s. One of the first researchers who made an attempt to relate the achievements of cognitive psychology to the entrepreneurial process was Baron. He has distinguished the basic properties of human cognitive systems, which may determine the existence of differences between entrepreneurs and other people. These include: limited human capabilities in processing new information and a tendency to limit cognitive effort. (Baron, 1998, p. 275–278).

Cognitive mechanisms, as emphasized by Baron and Shane are shaped under the influence of individual life experiences of each person. It is a typical "research tool" that enables people to see concrete market opportunities in the environment. (Baron & Shane, 2007).

Another component of entrepreneurial competence is self-efficacy. On the basis of entrepreneurship, they are defined as the belief of the entrepreneur in the possibility to perform a specific task in business conditions with the use of accessible or available resources and entrepreneurial competences. (Glinka & Gudkova, 2011, p. 134). The sense of own effectiveness is not only related to the entrepreneur's decision to set up a company, but also to subsequent actions undertaken by him/her. Bandura stresses that the higher this feeling, the more active a potential entrepreneur can be involved in exploiting market opportunities with high development potential. He also points out that individuals with a high level of self-efficacy have higher ambitions and are willing to pursue more ambitious strategic objectives. (Bandura, 2006). Factors shaping the entrepreneur's own effectiveness are divided into two groups:

- internal factors based on own entrepreneurial experience, as exemplified by the following: first attempts of entrepreneurs to execute market transactions, take actions by them and observe their effects,
- external factors, in connection with the mechanism of influence of social relations (personal contacts) through the influence of: experiences and opinions of other entrepreneurial persons.

Knowledge is the last component of entrepreneurial competences, enabling entrepreneurs to make rational decisions and effective management. It is a key resource, creating a competitive advantage and undertaking undertakings aimed at knowledge management. (Kochmańska, 2008, p. 36). Compared with other elements: personality traits, motives for action, self-efficacy knowledge has a dynamic character. J. Cope has identified the main areas of knowledge that an entrepreneur should have. These include self-knowledge, business knowledge, knowledge of the environment and networks, knowledge of managing small enterprises, knowledge of the nature of relations and their management capabilities. (Hrehová & Ilecko, 2016, p. 227–232). The basic sources of knowledge necessary for entrepreneurs to start and conduct business activity are their own experiences and social relations. Entrepreneurs learn from their mistakes, and through actions and observation of their effects they gain experience, which is then transformed into knowledge. Learning by contact, on the other hand, creates a social dimension to learning. (Nastase, Dobrea, & Valimareanu, 2016, p. 5–7).

However, it should be remembered that the intensities of using both knowledge sources vary depending on the degree of maturity of the entrepreneur and the stage of development of his company. (Glinka & Gudkova, 2011, p. 139–140).

Ideas and opportunities	Resources	Into action
• spotting opportunities, • creative, • vision, • valuing ideas, • ethical and sustainable thinking.	• self-awareness and self-efficacy, • motivation and perseverance, • mobilising resources, • financial and economic literacy, • mobilising others.	• taking the initiative, • planning and management, • coping with ambiguity, uncertainty and risk, • working with others, • learning through experience.

Fig. 3: The Framework of entrepreneurs competency
Source: own work based on (Nwachukwu et al., 2017, p. 6) and (Krečar & Lukić, 2016, p. 528–538).

Bacigalupo et al. (2016) indicate three competency areas and fifteen competencies which are the most critical success factors for entrepreneurs. To three main competence areas there belong: 'Ideas and opportunities', 'Resources', and 'Into action'. Each area includes five competencies, which together represent the core of entrepreneurship and develop the fifteen competencies. (Nwachukwu et al., 2017, p. 6–7). For an entrepreneur it is important to think ahead, to be creative and have a vision for the mid- term or even long-term goals. In addition, successful entrepreneurs become successful when they have the ability and wish to keep on learning to deal with new challenges. "(…) an orientation towards learning refers to the fact that successful entrepreneurs search for new knowledge and skills in order to develop themselves." (Kyndt & Baert, 2015, p. 14). Besides identifying and evaluating opportunities and risks, an entrepreneur should also be able to make important and clear decisions. Making decision and independence is an essential asset for entrepreneurs in order to move ahead and refers to the ability to decide what to do.

According to Driessen there are ten basic competencies that must be owned by an entrepreneur. For those competencies belong: need of achievement, need of autonomy, need of power, social orientation, self-efficacy, endurance; dan risk taking propensity. The skill components, such as: market awareness, creativity, and flexibility. (Ismail, Zain, & Zulihar, 2015, p. 179) and (Bagheri & Pihie, 2014, p. 4–6). Entrepreneurial self-efficacy is defined as "(...) a person's belief in his/her ability to successfully launch an entrepreneurial venture." (Khedhaouria et al., 2015, p. 487). In turn, entrepreneurial creativity is defined as "(...) the generation and implementation of novel, appropriate ideas to establish a new venture." (Khedhaouria et al., 2015, p. 488).

According to Paiva Júnior, Leão and Mello there are six entrepreneurial competencies: opportunity competencies, relationship competencies, conceptual competencies, administrative competencies, strategic competencies and commitment competency. (Minello, Scherer, & da Costa Alves, 2014, p. 5).

Other competencies mentioned in the literature that are considered important and influential for achieving entrepreneurship effectiveness, are the following: troubleshooting, negotiation skills, leadership, self-control, innovation, dynamism, self- confidence, ability to create and develop social networks, teamwork, responsibility, engagement and compromise. (Robles & Zárraga-Rodríguez, 2015, p. 829). Dornelas expands these competencies adding future view, coherent decision, opportunity exploration, determination, dedication, optimism and passion, good relationships, organization, planning, acceptation of calculated risks and value creation to society. (Minello et al., 2014, p. 3).

Methodology of Own Research

Expert research was conducted in four voivodships, mainly in central Poland, as seven out of ten interviews were conducted with experts from the mazowieckie and łódzkie voivodships. In the northern and north-western regions, three interviews were carried out. (Figure 4.)

Fig. 4: Area of expert research realization

Source: own work.

Expert interviews were conducted in the form of individual in-depth interviews (60.00%) and telephone in-depth interviews (40.00%). The duration of one IDI interview lasted on average 80 minutes, while TDI - about 50 minutes. The universities and institutions represented in the expert study included: University of Warsaw, Poznan University of Economics and Business, SGH Warsaw School of Economics, Polish Business and Innovation Centers Association, University Technology Transfer Center at University of Warsaw. (Table 2.)

Table 2: List of nationwide expert research

No.	Gender	Represented University / Education Institution / Position	Location	Research technique	Duration of the interview	Total work experience (in years)
1.	M	University Technology Transfer Center at University of Warsaw	Warsaw	Individual in-depth Interview (IDI)	1h	over 20
2.	F	University of Warsaw	Warsaw	Individual in-depth Interview (IDI)	45 min.	17
3.	M	Personal coach, Lecturer	Grudziądz	Individual in-depth Interview (IDI)	1h 15 min	over 20
4.	M	Poznań University of Economics and Business	Poznan	Telephone in- depth Interview (TDI)	50 min	10
5.	F	Business psychologist, Managerial Trainer, Coach, International Coaching Community (ICC)	Warsaw	Individual in-depth Interview (IDI)	1h 30 min	13
6.	M	SGH Warsaw School of Economics	Warsaw	Telephone in- depth Interview (TDI)	1h	10
7.	M	Lodz University of Technology	Łódź	Telephone in- depth Interview (TDI)	1h	13
8.	F	Polish Business and Innovation Centers Association	Warsaw	Individual in-depth Interview (IDI)	1h 30 min	over 20
9.	M	Poznań University of Economics and Business	Poznan	Individual in-depth Interview (IDI)	2h	11
10.	M	Certified business coach	Warsaw	Telephone in- depth Interview (TDI)	45 min	over 20

Source: own work.

Two methods of data collection were used in empirical research: direct and indirect survey measurements. In order to conduct nationwide expert studies two research techniques were used: individual in-depth interview and telephone in-depth interview. (Maison, 2010, p. 61-62). Table. 3 presents data collection methods, research techniques, and applied research tools in implementation of nationwide empirical research. The interview questionnaire consisted of six open-ended questions.

Table 3: Type of data collection methods, research techniques and research tools

Expert research			
Type of data collection methods	**Research techniques**	**Research tool**	**Number of interviews**
Direct survey measurements	Individual in-depth Interview (IDI)	The interview questionnaire	6
Indirect survey measurements	Telephone in- depth Interview (TDI)	The interview questionnaire	4

Source: own work based on (Kaczmarczyk, 2006, p. 124) and (Kaczmarczyk, 2014, p. 57-59).

The first phase of the analysis of qualitative data was to prepare the transcription of the whole collected material. As a tool supporting the process of qualitative data analysis was applied MAXQDA program, from CAQDAS family - Computer-Assisted Qualitative Data Analysis Software. (Silverman & Konecki, 2012, p. 179-184, 234–235). MAXQDA is a software package that supports qualitative data analysis. (MacMillan, 2005, p. 1-2), (Niedbalski, 2013, p. 197). The last step of the research procedure was the interpreting of the interviews content and the processing of results.

Research Results

At the individual and telephone in-depth interviews, a group of experts, representing the scientific and business community, were asked about the profile of an entrepreneurial person, if in their opinion there is a set of necessary characteristics/qualities desirable when it concerns to start and run a business. Respondents concordantly claimed that if one wants to set up and run a business it is necessary to have the appropriate predispositions. To be an entrepreneurial person, according to the recipients, one must certainly to have the following characteristics: (1) internal obstinacy ("(…) if we cannot feel this enthusiasm at all and that is not a passion, later on it is difficult to find themselves and upon first failure, the willingness to run a company somewhere disappears."), (2) determination in actions - that is a characteristic that is downright essential to running a business and, (3) perseverance to pursue a goal. ("(…) the winners are those who are persistent, determined and able to go through with the worst stages of business. This is the key to achieve a success."), "(…) endurance of failure is important, mainly in the first stage and the ability to analyze their acts in categories: what is my plan, what I do to produce effects, what can I improve. When the results are different than the planned, the entrepreneurs treat it as information that there is need to be change, and they do not perceive it as a failure."). Besides the mentioned traits, the participants also point out the (4) courage, (5) willingness to learn and to act, (6) orderliness, and (7) the ability to work hard. Moreover, an entrepreneur has to be (8) consistent, (9) not be afraid of responsibility, (10) be highly motivated to action The relevant features of the entrepreneurial person that have been emphasized in the survey are the (11) communicativeness, (12) ability to pursue opportunity and tools that are offered to entrepreneurs. A further essential set of entrepreneurial qualities required for the success of a business are: (13) open-mindedness to new ideas, (14) decision-making ability, (15) risk-taking ability, (16) stress tolerance, (17) optimism, (18) flexibility, and (19) aptitude of adapting to different situations. In addition, an entrepreneurial person is (20) ambitious, (21) creative, (22) amenable to cooperate with other individuals - partners, contractors, employees, subcontractors, as well as (23) strongly future-oriented manner, (24) who has a vision and tries to realize it consistently, taking advantage of the opportunities. According to half of the respondents upon running a company, it is necessary to correct their actions repeatedly, in their opinion "(…) those who believe in being infallible - forfeit". In the opinion of the studied scientists, business psychologists, certified business coaches, experts with several years of experience in advising small and medium-sized enterprises and business environment institutions in the field of business incubation and innovation, to the personal characteristics (predisposition) for run own business should be primarily include: high self-esteem, imagination, capacity to convince, high conviction in the control of their own destiny, and need for achievement. Obviously, these are only examples of the most important features, but in the opinion of experts, listed characteristics are a wider universal significance for entrepreneurial people. The respondents pointed out that in the event of run their own company it is also very important to consider entrepreneurship through the prism of so-called managerial behaviors, which include: strategic orientation, oriented at opportunities, ability to utilize specialists knowledge, direct contact with the environment, or similar.

The conducted research allowed also to assess the factors that in the interviewees opinion are the most important in business and determining the entrepreneur's success in the market. Most of the responders pointed to several factors. The most important of them is to find an innovative product/service that that has not already been on the market, or to find such an offer or idea that will meets the customers and contractors expectations. The promotion and suitable highlighting of the product/service is the second factor, in the opinion of the respondents, has a significant impact of entrepreneurial success in the market. Among the characteristics of an entrepreneur, which in their

views are the most important in business, they listed: (1) determination, (2) self-belief, (3) perseverance and (4) creativity. The respondents admitted that in order to succeed, especially as an entrepreneur, and to realize their ambitions and to reach his/her goal, a set of key factors is needed, such as: personal characteristics, systematic and consistent work, knowledge, ability to use opportunities in the environment and motivation. Talent and idea are also a component of this success.

Nevertheless, the respondents emphasize that the most successful in the business activity are people with appropriate inborn characteristics, positively shaped by the local environment and enhanced by relevant educational programmes. In their opinion, entrepreneurial success is therefore determined by a synergic combination of: (1) innate entrepreneurial aptitude, (2) sociological conditions, and (3) educational programmes (including training and courses). The lack of any component limits the entrepreneurial an individual potential, because even a person with high predispositions without knowledge and skills (acquired in the course of educational programmes) will not be able to completely develop "entrepreneurial wings".

Additionally, during in-depth interviews, the participants were asked if imitating of other well-known entrepreneurs and their achievements is well perceived in business, and whether it is worth to be inspired by someone's entrepreneurship or, better that beginner entrepreneurs to find own original path. The respondents indicated that obviously one can be inspired the experiences of people who have already been successful in business, observe, analyze, gain knowledge from other entrepreneurs, but most of all in order to find their individual path. As they stressed, the path of other entrepreneurs should not be copied and never imitated because such actions often lead to failure of everyone’s who doing that.

Conclusions

Summing up, the study showed that to run their own business requires certain predispositions, which could be defined as "entrepreneurial aptitude". The literature proposes many combinations of universal features, aptitudes, skills and/or competences that are desired in the running a business. Those sets are highly valued and it is worth to base theoretical studies as well as empirical research on them. However, it should also be noted that the characteristics useful for running their own business change over time and actually, it changes with the growth of the company. For example, insofar as the first period of a company's existence, the initiative and the ability to work hard becomes paramount, it with the growth number of employees the role of leadership and managerial skills (including planning and control) increases.

Annex

Interview Questionnaire - Module Related To Define The Profile Of An Entrepreneur And The Determinants Of Entrepreneurial Success In The Market

1. Let's start with a question about the profile of an entrepreneurial person. In your opinion, is there a set of necessary characteristics/qualities, desirable when you want to start and run a business? Is it necessary to have appropriate predispositions?
2. What do you think can be learned by run their own businesses?
3. In your opinion, what is the most important in business? What factors have a significant impact of entrepreneurial success in the market?
4. How to succeed, especially as an entrepreneur? What should be done to fulfill ambitions and achieve your goal? Is it enough to be highly motivated? Great talent? Or maybe you need to have luck or the opposite - to choose to work above your strength?
5. In your opinion, what are the key factors that determine entrepreneurial success? Are these primarily inborn/natural characteristics? Or, quite the opposite are they entrepreneurial traits and predispositions, formed and enhanced by various educational programmes?
6. Beginning entrepreneurs frequently concentrate on imitating well-known entrepreneurs and their achievements. In your opinion it would be useful to imitate others? Is imitating the behavior of other entrepreneurs well perceived in business? Whether to be inspired by someone's entrepreneurship or, beginner entrepreneurs should find their own original path?

Abstract

A new provocation regarding the knowledge of the financial environment a good financial health and the abilities to manage money are essential in a economic systems in continuing changing. Today the ability and financial skills allow people to allocate their financial resources throughout their lives in a life of uncertainty and imperfection. The lack of healthy financial education leads to inequalities between customers and consumers. Without a general understanding of financial concepts, we cannot make wise choices in financial terms we are not open to saving and we do not know how this behavior can help us in the future. We do not know how to make investments, we do not understand how and when we can access a loan, we do not understand the financial terms present in a contract of a financial entity. The Klontz Money Behavior Inventory present in this study examined the internal consistency and convergent validity of the KMBI, through comparison with similar measures, among a sample of 472 academic staff from AKU Turkey and Cluj Napoca University Romania, 232 academic staff. The multi-scale measure the presence of eight distinct money disorders and establish relationship between mental health and financial behaviors, results which can be used to obtain a professionals and financial planners for different culture and behavior. The results indicate that culture has no influence in financial health behavior and give an image about the new profile of consumer in a global market. These findings highlight a need for literature and assessments to identify and describe disordered money behaviors with specific tradition and culture and adapt the economical strategies.

Keywords: Affective Money Behavior, Comparison Study, Statistical Analysis, Financial education

Introduction

Today, more than ever, any person needs basic financial knowledge to understand how society works and how to make the best decisions for its future. Knowledge of the financial environment and the abilities to manage money are essential to tackle the complex economic systems of the present. Why it is important to have a financial health education? Because education improves management costs, balance and reduces the probability of declaring bankruptcy or survives during the financial crisis.

Shawn et.al (2012) examining mechanisms of financial education they observed that financial education increases people's financial participation and behavior and decision making through: attitudes, borrowing behavior, discount rates, risk-aversion, and influence also co-workers and families environment. Yamauchi and Templer (1982) established that money is not only an instrument of commerce; it also has a multidimensional psychological meaning which also can be treated as a symbol of status, prestige, power and value. The attitudes towards use of money may be influenced by demographic factors such as age, gender, income, education, cultural background, etc.

Lochner and Moretti (2004) measure the effect on financial market taking in consideration the age, education and gender but not correlated with the ability, parental characteristics or other factors.

Shawn et al. (2012) in their research, introduce a new concept as smart money as effect of education on financial behavior has a smaller impact on financial market participation but statistically and economically has significant effect.

An academic interest in the psychological beliefs and behaviors related to financial outcomes dates back to the early 1970's of Furnham (1996), Klontz, B. and Klontz, T. (2009) were designed a model to assess for the presence of disordered money behaviors, taking in consideration the systemic changing on life quality as a feedback Klontz et al.(2012) adapted and developed a new model to identify the behavior money inventory KMBI.

The Klontz Money Behavior Inventory (2012) and Taylor et al (2016) used the KMBI scale to be a standalone, multi-scale measure than can screen for the presence of eight distinct money disorders. Given the well-established relationship between mental health and financial behaviors, results from the KMBI can be used to inform both mental health care professionals and financial planners. Klontz, B. et al. (2011) identify eight behavioral patterns that have been noted in the literature relating to money disorders behaviors: compulsive buying, pathological gambling, compulsive hoarding, workaholism, financial dependence, financial enabling, financial denial and financial enmeshment. The patterns were measured by Klontz et al.(2009, 2012) using the KMBI model and they associate money behaviour with poor financial health (Taylor et al, 2016).

Benson and Silver (2015) sustain in their article regarding the connection between hoarding and money attitude that individuals who resonate with the money status belief pretend to have more money than they actually do and use credit cards as a means to purchase status-enhancing goods from designer or luxury-related brands.

Yeong Nain Chi and Gaurango Banerjee (2013), study the money attitude but bicultural, where a growing number of individuals are taking responsibility for their own financial security, they are faced with increasingly more complex financial instruments, and there are still many who are ill-prepared for making sound savings decisions.

Brief review of the literature

Roberts and Sepulveda (2013) investigate the consumer culture and money attitude between Mexican and US peoples. Their conclusion was that the common language of the consumer culture is money. Money attitude influence all areas of persons life. In the mean time it is important to take in consideration the negative part of consumer culture regarding the financial health which is compulsive buying which becomes a primary response to negative evens and feelings. Gallen (2002) suggested that money disorders are problematic financial behaviors that people engage in to attempt to avoid emotional pain. Taking in consideration that money attitude dimension are power-prestige, retention –time, consumer competency and anxiety (Roberts and Sepulveda 2013).

Benson-Townsend and Silver (2013) mention compulsive hoarding as a function of money attitude. Money attitude dimension are power-prestige, retention–time, consumer competency and anxiety. Klontz, B. et al (2016).When family financial structures become so intertwined that the traditional roles of parents and their children become blurred. On the other position Klontz et al (2011) consider family as a very important and the perfect environment for children to learn about money having a good example parent's behavior example. Jorgensen and Savla (2014) establish a direct relationship between parent and children attitude and behavior upon money and also parental financial socialization of their children. Kemitz et al. (2016) establish an area of concern in parent – child relationships are the impact of boundaries and roles. Parents whose boundaries with their children are rigid and inflexible do not prepare their children to effectively deal with stress in their lives. Similarly, parents whose boundaries are too flexible may impede their children's ability to develop appropriate coping skills.

On the other hand Danes and Dunrud (1993) conclude the importance from earlier age of children to be taught by their parents about finance. In the same time Danes and Dunrud (1993) and Toraman et al (2016) consider credit cards a source for advertising and appropriate financial behavior in family which create a dynamic environment for financial enmeshment. Segrin et al. (2013) suggest another new concept of helicopter parents and their narcissism and their selfish motivation and divorce couple and the negative environment for the young and future adult in financial health. According to Wąsowicz- Kirylo (2008) the attention paid to money shown by the parents, as well as their ways of coping with financial matters, play a significant role in how their children find their way in the world of finance.

According to Kowalczyk and Chudzian (2015) the results of the research, individuals who in their youthful age benefited from banking products, are the more consistent with the characteristics of a rationalist's person. This situation can be explained by the fact that people who used to use banking products (e-banking, card, e-commerce, transfer of money) treat them as a tool a fast and safe instrument and rapid solution for their financial health. Also children who had their own money better deal in financial problems in their adulthood and managing the financial situation better. Hoarders save items for reasons related to sentimental attachment, usefulness, and aesthetic qualities, and possessions become an extension of the self as Belk (1998) for the first time in his studies have shown that hoarding develops as a result of conditional emotional responses to various thoughts and beliefs concept used also by Klontz et al (2011), Grisham and Barlow (2005), Trachtman (1999) and Lowrance (2011) considered that money has been argued to be one of the most neglected topics in psychological research and practice. Kershaw (2008) identified hoarding as a problem financial behavior and the desire for money is related to the desire for the things it can buy, but like Lea and Webley (2006) mention the two are logically distinct.

Taking into account the literature of the field and the results obtained from national or cross-cultural studies, the authors have established a map of the consumer's behavior and the financial education required and the factors or barriers identified as having a positive or negative influence on the behavior financial.

In 2014, Canale and Klontz (2014) transfer the notion of hoarding disorder from psychological disorder, to the money as management disorder from financial health point of view. In conclusion in the new society peoples must to spend the money in order to live life and those that save money to the point of ignoring leisure, medical care, personal hygiene, or creating dangerous situations from clutter, need to develop a healthy relationship with money and to find ways to use money successfully with the help of financial education help.

Consumers save and borrow to have enough money left for retirement, to make stable and expensive purchases and to protect themselves against unforeseen expenses Bucciol and Veronesi (2014). It is therefore useful to research whether parental financial teaching can lead to specific consumer saving and borrowing behavior.

Many previous studies of Bucks and Pence (2006) and Simkiv (2013) have discussed the role that financial education plays in relation to financial behavior and whether financial education is relevant to increasing financial knowledge.

Research results show that people from Ukrain who work in state institutions are more meticulous about planning their budget, projecting all income and expenses, they try to pay all the bills on time to avoid financial punishment and generally are more prudent and careful about spending money. In the United States of America, the 2018 United States Study (2018) shows that economic education has grown insignificant and that there has been no growth in personal finance.

Last but not least, there is a need for financial education, which is an important pillar of economic sustainable thinking like in Fig 1.

Money management skills in an ever-changing economy of adapting to a modern market have become an essential and important element and most states have not yet prioritized the development of a personal financial culture since the school's banks. Financial inclusion and financial health are the solutions that can solve the problems of individual life if the current causes and challenges of the economy are understood and the existing gaps in the traditional financial system are being remedied like Dan Schulman the CEO of PayPal (2016) sustain that issue even the study was realized in a country very well know as an economical power.

Hogarth (2006) in his paper provides also a picture of financial education in the USA because it refers to the development of the community and the economy. He answer to the major W's ''why it is necessary to analyze? why financial education is important? and what is "financial education?" In the actual global market of the 21st century financial education differ from previous epochs.

From individual financial education perception differ from a person to another, Hilgert et al (2003) have demonstrated that the higher consumer-based level financial knowledge shows that the consumer has undertaken several positive financial management behaviors and has used several financial products and services. In change they (Hilgert et al.2003) establish and have underlined that financial knowledge can be statistically linked to credit-related financial practices as well as cash flow management, savings and investment.

Hanushek and Woessmann (2008) also analyzed and demonstrated a very close link between the cognitive abilities of a country's population and the country's economic growth rate. Hanushek (2008) carried out an analysis of all teachers, so improving the quality and efficiency of teachers is directly related to strengthening students' financial literacy. Hanushek et al (2008) present the impact of good training increases as the student advances to a higher level, but the teachers rely on average performance in students and set their instructions accordingly.

Swinton et.al (2007) in their study in Georgia as ex-communist country with different behavior and mentality, discover and have shown that high school students are required to pursue a course of economics before graduation.

This attitude it is necessary especially now when the global economy it is in a dynamic changing and we have to prepare the new citizens of tomorrow. In addition, they require students to undergo a state level state-level test at the end of the high-school economics course.

This test is calculated for 15% of the final grade during the high school. For these reasons, Georgia is uniquely suited to analyzing whether personal training for high school economics teachers improves pupils' learning.

In conclusion the situation from Georgia, like in Romania and other countries from East Block communist countries, we can make a difference by building deeper links between the public, private and social sectors to develop new curricula and educational models that encourage and encourage knowledge and financial understanding from a young age.

Most empirical and theoretical literature suggest that there is a relationship between social indicators and economic growth, therefore human capital has been subjected to research by Mohun et al (2010) as it is and will remain a great unknown. In their study in Mauritius, they tried to identify the determinants of economic development.

They viewed education as an investment in human capital because the benefits belong to an educated individual during a lifetime. To test this hypothesis, human capital has been considered as an important role in economic growth, mainly as an engine for improving production and society through sound financial education.

The money behavior of people and question of money attitudes was explored and described by Kowalczyk and Chudzian (2015), in their article about money attitudes and economic socialization in Poland.In their research implications arising from the awareness of the existence and operation of specific factors affecting attitudes towards material values.

Not at last Ünal and Düger (2015) in Turkey also applied an empirical analysis on the relation between academics financial well-being and financial behavior. In addition, it was found that people with higher education comes a better ability to refrain from spending money.

Taking in consideration that factor in their research Kowalczyk and Chudzian (2015), Roberts and Sepulveda (1999), Tang (2007), Tang and Gilbert (1995), Tang and Chiu (2003) found that people with higher incomes are likely to evaluate the money as a good thing, a proof of the successes.

Yoko Mochizuki and Audrey Bryan (2015) bring an important contribution through the concept of climate change in education in the context of sustainable development education and especially for financial education.

In the final document entitled "The Future We Want", participants from all countries have renewed their commitment to "ensure the promotion of an economically, socially and environmentally sustainable future for our planet and for present and future generations" from United Nation UN, 2012, p. 1, (2012). Financial education is a life cycle that sometimes requires adaptation and harmonization with the new conditions imposed by time and space. The paper presents the importance and role of financial education in modern society when the dynamics of turbulent factors often lead to economic and financial changes. The paper presents the advantages and the current importance of financial education for the young generation and for individuals as well as for economic units and last but not least for the whole society as we share the same economic space. The article follows the position of financial education in two countries with different traditions and cultures, as well as the need to inform the public about the financial education needed at European level in a dynamic and global society.

The conclusion is that it is necessary to prepare a national financial education so Starček and Trunk (2015) have noticed that economic changes, demographic problems, the dynamic evolution of technology and the other in Europe lead to a delegation of responsibility in the field of financial activities and security of individuals. The purpose of this study is to examine and determine the effective factors on affective money behaviors of academic staff via statistical techniques and compare the results of Turkish and Romanian academic staff simultaneously.

The article may provide a boost to help realize that currently often ignored issue of the existence of shaped money attitudes is often a source of social as well as economic problems from market and give a complete image of financial health.

Materials and Methods

Purpose of the Study

The paper and research done until now in literature confirms that the profession of professor is more popular as income increases and therefore attracts more motivated and skilled people. For that reason the study want to identify the academic staff behavior upon the money behavior and identify the level of financial education between two countries with different culture and perception. The participants of this study is composed of 472 academic staff working at Afyon Kocatepe University and Technical University of Cluj Napoca between the dates 15 March -15 April 2019. To measure the effective factors which influences the financial behavior of academic staff, a Likert scale type questionnaire, ranging from 1 to 5, from strongly disagree to strongly agree is applied on a face-to-face individual questionnares for each academic staff from university. The questionnare is Klontz's (2012) money behavior inventory has commonly formed this questionnaire (KMBI). The questionnaire was composed of 60 questions. Seven of them were related with demographic characteristics (age, living place, gender, education level, marital status) and 53 of them were related with their the financial behavior, because of some unfilled and wrong filled questionnaires, the statistical analyses are applied over 472 questionnaires.

Sample and Measurement Tool

Explanatory Factor Analysis (EFA) is applied first to data set to determine the dimensions of the scale. Then, by independent samples *t* test the hypothesis whether the obtained dimensions' means differ according to country is tested. Finally, regression analysis applied to determine the effective of other variables (which are obtained from the results of EFA) on the Affective money Behaviors of academic staff. SPSS software is used to perform these statistical analyses.

Reliability and Validity of Scales

As a result of Explanatory Factor Analysis (EFA) 23 items have subtracted from the scale because of getting loadings in a wrong factor and forming a separate factor combining with wrong items theoretically. Finally, analyses are applied over 30 items for six factors named as:

1. Affective Behavior (AB1-AB11);
2. Pathological Gambling (PG1-PG5);
3. Compulsive Buying (CB1-CB4);
4. Financial Enabling (FE1-FE4);
5. Financial Enmeshment Family (FEF1-FEF3);
6. Compulsive Hoarding (CH1-CH3).

These six factors also explained the 58.266% of total variance. The factor loadings, Eigen values and Cronbach's Alpha values of each factor are given in Table 1. The total Cronbach's Alpha value of the scale which consists of 30 items is calculated as 0.884 which is statistically one of the indicators that the reliability of the scale is well enough.

Results

This paper attempts to bring to the existing literature new evidence on the relationship between education and economic growth, but also to investigate, if the formal models so far are valid from the point of view of culture, a cross cultural model of the traditions and the mentality of the money people behavior and attitude.

The study also highlights the statement that education plays a central role in economic growth regardless of country and level of economic development. The role of education in universities through their staff can provide the theoretical economic conditions needed in the formation of the next generation of consumers, tomorrow's entrepreneurs.

The patterns developed in each country through the growth effects of education as presented in today's literature are presented in the study carried out in Turkey and Romania universities with different culture and traditions and also people mentality.

The authors consider that financial education is very important and teachers are, in turn, models that shape tomorrow's generations that's why the target was selected from academic universities staff.

The results are presented and organized so as to bring a contribution through:

1- Short analysis and the effects of the prospects of the economic growth theory for each country and separately following the application of the KMBI questionnaire;
2- Provides the interconnection between education, financial education and economic growth for sustainable education;
3- Develops and present a possible cross cultural model from financial education point of view;
4- Describes behavioral analyzes in relation with individual and family affairs money and activities for educated peoples;
5- Explains the relationship between education and economic growth;
5-Also highlights the negative money transformations behavior and attitude in financial behavior and gives information about them.

As we can see from Table 2 the results are establish for academic staff from both countries and their behavior the maximum value of 7.894 was obtain for affective behavior (AB) sentimental behavior it is similar for both countries the responsibilities of educated people in front of themselves and their families, the maximum score was obtain by the item AB1 *''I often return items because I feel bad about buying them''*.

Table 2: Results of Explanatory Factor Analysis for academic staff behavior

Factors		Loadings	Eigen values	% of Variance	α
AB	**Affective Behavior**		7,894	12,621	0.835
AB1	I often return items because I feel bad about buying them.	.634			
AB2	I have made promises to myself or others to work less but have had trouble keeping them.	.610			
AB3	I feel anxious or panicky if I am unable to shop.	.580			
AB4	I have hid my gambling from people close to me.	.578			
AB5	I hide my spending from my partner/family.	.567			
AB6	I hide my need to hold on to items from others.	.543			
AB7	I often find myself feeling resentment or anger after giving money to others.	.529			
AB8	I feel guilt and/or shame after making purchases.	.514			
AB9	I feel irresponsible if I get rid of an item.	.501			

AB10	Shopping interferes with my work or relationships.	.478			
AB11	I have tried to reduce my spending but have had trouble doing so.	.433			
PG	**Pathological Gambling**		3.276	12.075	0.859
PG1	I have to gamble with more and more money to keep it exciting.	.829			
PG2	I have committed an illegal act to get money for gambling.	.791			
PG3	I have borrowed money for gambling or have gambled on credit.	.761			
PG4	I gamble to relieve stress or make myself feel better.	.752			
PG5	I have trouble controlling my gambling.	.679			
CB	**Compulsive Buying**		2.246	11.164	0.831
CB1	I feel irresistible urges to shop.	.817			
CB2	I shop to forget about my problems and make myself feel better.	.792			
CB3	I buy more things than I need or can afford.	.756			
CB4	I obsess about shopping.	.732			
FE	**Financial Enabling**		1.764	8.819	0.682
FE1	I sacrifice my financial wellbeing for the sake of others.	.727			
FE2	I give money to others even though I can't afford it.	.704			
FE3	I have trouble saying "no" to requests for money from family or friends.	.642			
FE4	I lend money without making clear arrangements for repayment.	.627			
FEF	**Financial Enmeshment Family**		1.223	7.155	0.764
FEF1	I ask my children (under 18) to pass on financial messages to other adults.	.810			
FEF2	I talk to my children (under 18) about my financial stress.	.739			
FEF3	I feel better after I talk to my children (under 18) about my financial stress.	.730			
CH	**Compulsive Hoarding**		1.078	6.432	0.629
CH1	I have trouble throwing things away, even if they aren't worth much.	.750			
CH2	Throwing something away makes me feel like I am losing a part of myself.	.708			
CH3	My living space is cluttered with things I don't use.	.425			

As Klontz establish in his scale of measure of behavior on money we identify also another factor pathological gambling (PG) which obtain a value of 3. 276 and situate the behavior on second place for entire target which present the hidden part of people and also the feeling of power for a moment. The maximum score was obtain by the item PG1 *''I have to gamble with more and more money to keep it exciting'' s*o extra activities of spending time and be relax in each country it is important, it is

necessary to view the positive part of situation on one site gambling help to develop the creativity and ability and also to assume the risk in different situations in individual or family life style.

For the other factors as we can see from Table 2 the values are lower for example compulsive behavior (CB) obtain a value of 2.246 but the item with significant importance it is CB1 '' I feel irresistible urges to shop'' which reflect exactly the actual society when shopping became a routine in people life style.

The financial enabling (FE) has a value of 1.764, and the important item it is ''I sacrifice my financial wellbeing for the sake of others''. The role of financial education it is important for the financial health of family situation. Even we are in a consumerism society the family still represent the base of society so the culture cannot influence yet the family relation between members and involving also the children it is important because they can get the significant information's and parents behavior from an early child age and they can be model future situation.

For financial enmeshment (FEF) from Table 2 using the data base a value of 1.223 was obtain and the most significant score was for item FEF 1 '' I ask my children (under 18) to pass on financial messages to other adults'' from here we can observed that traditional relations between family members remains in each countries.

The low value as minimum value for compulsive hoarding (CH) of 1.078 item CH1 ''I have trouble throwing things away, even if they aren't worth much'' for both country it is important because they are feeling attaché of the objects, situations and moments from their daily life and give them memories of childhood and youth.

Correlation between Turkey and Romania academic staff behavior and financial education

To test whether Affective Behavior (AB), Pathological Gambling (PG), Compulsive Buying (CB), Financial Enabling (FE), Financial Enmeshment Family (FEF), and Compulsive Hoarding (CH), score means differ according to country variable, the study hypothesis are as below in Fig. 2.

Fig.2: Research model hypothesis

Source: By authors

The hypotheses are:

H_{0a}: There is no difference between Turkish and Romanian academic staff's Affective Behavior means;

H_{0b}: There is no difference between Turkish and Romanian academic staff's Compulsive Buying means;

H_{0c}: There is no difference between Turkish and Romanian academic staff's Compulsive Hoarding means;

H_{0d}: There is no difference between Turkish and Romanian academic staff's Financial Enabling means;

H_{0e}: There is no difference between Turkish and Romanian academic staff's Financial Enmeshment means;

H_{0f}: There is no difference between Turkish and Romanian academic staff's Pathological Gambling means.

After determining the dimensions of the related scale, for each dimension, mean and the standard deviations, we calculated for both countries Turkey and Romania like in Table 3 the values for each country and establish which factor has big influence in academic staff money behavior.

Table3: Means and Standard deviations of the sub factor related with each country

Country	Statistics	AB	CB	CH	FE	FEF	PG
Turkey (n=300)	Mean	2,069	2,232	2,316	3,063	2,502	1,401
	S.Dev.	0,595	0,919	0,865	0,921	0,834	0,673
Romania (n=172)	Mean	1,740	2,350	2,058	1,616	1,424	1,188
	S.Dev.	0,461	0,717	0,547	0,740	0,638	0,428

Turkey has bigger values for financial enabling a value of 3.036, and for FEF financial enmeshment a value of 2.502 in comparison with Romania which obtain bigger values only for compulsive behavior CB= 2.350 and compulsive hoarding CH=2.058. In conclusion Turkey has a different perception in money behavior in comparison with Romanians academic staff. But in both countries pathological gambling (PG) obtains low score that's mean that people don't like to assume risk especially financial or losing money just for fun.

The results of independent samples *t* tests are given in Table 4 and indicates that there is a statistically significant ($p<0.05$) difference between the means of Affective Behavior (AB), Pathological Gambling (PG), Compulsive Buying (CB), Financial Enabling (FE), Financial Enmeshment Family (FEF), and Compulsive Hoarding (CH) scores of academicians.

Table 4: Results of independent samples *t* tests for Turkey and Romania

Variable	*t* value	Degrees of Freedom	*p*
AB	-6.250	470	0.000
CB	1.446	470	0.149
CH	-3.532	470	0.000
FE	-18.648	470	0.000
FEF	-14.649	470	0.037
PG	-3.735	470	0.000

Consumption has led to the emergence of the new fashionable term for today's consumerism. The compulsive hoarding problems arise as Jefferys and Moore (2008) sustain when negative attitudes arise in the relationship of consumption - the economy or in the relationship of acquiring and throwing the goods without suffering.

This process is well managed most of the time, but for those who hide compulsively, this process has a negative effect does not resist the need to acquire goods, which are sometimes valuable and unable to discard even in the excess point that leads to crowded living spaces.

For both countries a low value -18.648 was obtain for Financial Enabling (FE) followed by the value of -14.649 for (FEF) Financial Enmeshment Family. A positive value the biggest score 1.466 was obtain for compulsive buying (CB). To be able to identify the influence of each factor for academic staff from each country, and to be capable to determine the effects of CH, FE, FEF, PG on Affective behavior (AB), regression analysis applied to related data set and the results are given in Table 5 and Table 6.

Table 5 indicates that the regression models for Turkey and Romania are statistically significant.

Table 5: ANOVA Results of the Regression Analysis

Country	Source	Sum of Square	df	Mean Square	F	*p*
Turkey	Regression	42.759	5	8.552	39.732	.000
	Residual	63.28	294	0.215		
	Total	106.039	299			
Romania	Regression	22.8061	5	4.561	55.486	.000
	Residual	13.646	166	0.082		
	Total	36.452	171			

Table 6 also indicates that while for Turkish academicians, the effect of financial enabling (FE) is not statistically significant, for Romanian academician's compulsive hoarding (CH) and financial enabling (FE) is not statistically significant on their Affective Behaviors.

Table 6: Coefficients of the Regression model for both countries

Country		Constant	CB	CH	FE	FEF	PG
Turkey	β	0.755	0.169	0.266	-0.025	0.091	0.121
	t value	5.714	5.108	7.715	-0.835	2.786	2.762
	p	0.000	0.000	0.000	0.404	0.006	0.006
Romania	β	0.190	0.224	0.096	0.009	0.127	0.532
	t value	1.804	5.665	1.975	0.220	3.170	7.982
	p	0.073	0.000	0.050	0.826	0.002	0.000

As we can see from Table 6 academic staff from Turkey obtains a maximum value for t value of 7.715 for compulsive hoarding (CH) and an insignificant value of -0.835 for financial enabling. For Romania the results are different the maximum values of 7.982 it is for pathological gambling (PG) and the minimum score of 0,220 was obtain for financial enabling (FE). We have to mention that for pathological gambling (PG) we take in consideration also the virtual games and play station games which is very familiar especially now and when the parents spend more time with their kids and play on computer games very attractive and a way to spend free time in and with family. The low score for financial enabling (FE) present the same problem faced by both countries even they have different culture and perception, that's mean that the people interact yet with others needs and desire and the

feeling of doing well for others or making sacrifices for family and assurance a financial health still remain a mentality and also a duty for both culture.

Regression model for Turkey and Romania

Related with Table 5 the regression model for Turkey (1) and Romania (2) is as below:

$$\acute{Y}_{Turkey} = 0.755+0,169CB + 0.266\ CH - 0.025FE + 0.091FEF + 0.121PG \quad (1)$$
$$\acute{Y}_{Romania} = 0.190 + 0,224CB + 0.096\ CH + 0.009FE + 0.127FEF + 0.532\ PG \quad (2)$$

The differences for each country are for compulsive buying point of view (CB), for Romania it is 0.224 bigger than the Turkey values which is 0.169 maybe because Romanians are spending more time for shopping as a way to spend the weekend with family and enjoy together movies on cinema mall's giving them the feeling of spending time together and adapting step by step with the new brand for consumerism society.

Also Romanians academic staff obtain bigger values score for financial enmeshment (FEF) of 0.127 in comparison with Turkeys academic staff with a value of 0.091 which present again some differences of culture and behavior but here we must to take in consideration also the mother status in some Romanians family where the responsibilities are equal and share with entire family.

Turkey academic staff obtains good score of 0.266 for compulsive buying (CB) which present an oriental behavior specific for traditional family, to be dependent of family things and memories, a sentimental and sensitive behavior of Turkey culture in comparison with Romanians who obtain a value of 0.009 because the modern society model and transform the traditional concept of old Romanians family.

Discussion

According to t test results Turkey and Romania differs by Affective Behavior (AB), Pathological Gambling (PG), Compulsive Buying (CB), Financial Enabling (FE), Financial Enmeshment Family (FEF), and Compulsive Hoarding (CH) when we examine the means of these behaviors, Turkish academicians AB, CH, FE, FEF are greater than Romanians which means that they more return items because they feel bad about buying them, they have much trouble throwing things away, even if they aren't worth much. They sacrifice their financial wellbeing for the sake of others, and they ask their children (under 18) to pass on financial messages to other adults then Romanians.

On the other hand even if there is no statistically difference for the Turkish and Romanian academicians' compulsive buying (CB) means, Romanian academicians much feel irresistible urges to shop than Turkish. Another cultural difference it is between Romanians pathological gambling perception (PG) means are greater than Turkish ones, which mean that, they have to gamble with more and more money to keep it exciting and a way to spend free time. Regression analysis indicate that on Affective Money Behaviors while CB, CH, FEF and PG are statistically effective on Turkish academicians, on Romanians' CB, FEF and PG found statistically significant. The regression coefficients also indicate that while CH is the most effective factor on Turkish academicians' Affective Money Behaviors, PG is the most effective factor on Romanian academicians' Affective Money Behaviors. It's known that legally it's forbidden to gamble in Turkey, however in recent years by the developing internet technology, it's a known fact that Turkish people play gambling via internet. On the other hand, they play sportive gambling with an increasing numbers. However, it's free to play gambling in Romania.

Psychologically Romanians like much exciting activities and they consider winning extra money for their family. Even if they think like that, they consider remaining in this virtual world (gambling, sport bets, video games, card games) following the rule that always the casa wins, but they lose much and much. Because of the earlier regime restrictions in Romania, the new type of the society create a new type of consumer changing their behavior and became much compulsive for buying items.

Because of Turkish people are more emotional, they make much connections with the old (memorize) things and they feel trouble to put them away. On the other hand again Turkish are used to thing the other people much then themselves, they are able to sacrifice their financial wellbeing for the sake of others, and they consider the opinions of their children, related with their culture.

Conclusion

By the purpose of determining and comparing, the effective factors on affective money behaviors of academic staff at Turkey and Romania, the study present that Romania is adapted to the new global situations regarding the effect of the past and current. In Turkey, related with the traditional, family and effect of earlier money behaviors, there are significant differences between Romania and Turkey are presented in this study.

As a final conclusion the changing of money attitude can be examined with the help of certain available instruments or a new instrument can be developed to measure attitude towards money social, cultural and economic settings that are different from the one for which the tools have been developed already.

The study shows that there are still cultural influences in the way of thinking due to the peculiarities and traditions specific to each country. These furtive influences also manifest in relation to financial education. As society is in constant change, initiation in financial education since high school could help develop the abilities of the young generation to inform it about how to invest and equalize money. These abilities will also contribute to shaping the future citizen the consumer of a society subject to constant change. Financial education in Romania has become a need, recognizing that economic and financial education helps young people to better manage their personal finances. Young people who have received information and have notions of an economic nature are more confident in themselves, are able to make better financial decisions and act responsibly as informed citizens. Financial education is based on basic economic concepts and a way of thinking economically and is conceived as a genuine program of financial knowledge. Basic knowledge education is needed to manage daily finances; the rest of the specialized areas, such as investment or retirement planning, should be left by professionals. Certain research studies have shown that there is a relationship between financial knowledge and financial behavior, but causality is not clear. Financial education plays an important role in guiding individuals to achieve their financial goals and to contribute to the economic well-being of society as a whole (Jefferys and Moore ,2008).

The content of educational programs should focus on actions that effectively use the available social resources and setting goals and planning to reach life goals. Assessing the effectiveness of financial education for low-income consumers should not only increase knowledge acquisition but also financial confidence and improvements in financial behaviors and results. Information provided only by traditional financial education is likely to be insufficient to improve the economic well-being of consumers, especially those with low incomes, in the absence of financial integration. Low-income consumers are more likely to need additional support for actions such as financial products that support specific behavior, counseling, coaching or mutual support, access to language services, child care, transport, etc.

It is therefore necessary to recognize the significant barriers faced by the population in terms of financial soundness or anticipated financial behaviors so that public systems, legal processes and public policies can help by creating additional barriers to certain financial behaviors.

On the basis of literature, Suciu and Lacatus (2013) the study work has also identified the most important principles of financial education that are illustrated by long-term active learning;

- orientation towards individual financial education;
- getting information on early economic education provided by both (schools) and non-formal and informal training programs such as those offered by NGOs;
- identification and recognition of risks and financial problems.

This type of financial education can be done through different forms of financial education in formal, non-formal, and developing to critical thinking, and comparative cultural analyzes being chaired beneficial. In Romania, financial education is, in most cases, part of the school curriculum, and other social partners are interested, so banks are also interested in contributes to financial education and a society with stable financial health. Universities and staff could help schools carry out financial activities, and curricula can also help develop their own financial education through various programs.

At regional level, local and regional institutions as well as universities as important pillars in financial education through the long-term perspective could make a difference for sustainable development and develop a strategy of development in which investment in lifelong learning, business and financial education have a crucial role to play.

Abstract

Researchers have studied the role of capital markets in the economic development of a country for more than 100 years. They have unanimously agreed that capital markets have a positive influence on the economies. When analyzing capital markets, we refer to a framework where capital or resources are exchanged and reallocated, from those who have an excess to those who are in demand of it. We analyze a database of 50 stock markets from 47 countries around the world during the 2008-2017 in order to find out the role of capital markets in the economic recovery post-crisis.

Keywords: Stock Markets, Capital Market Development, Post-Crisis

Introduction

The correlation between the development of the capital market and economic growth of a country has been intensively studied by researchers and professionals in the financial-banking area during the last 100 years. Among the first to analyze this topic, more than 100 years ago, was Joseph Schumpeter in 1911. He supported the importance and positive impact of financial institutions and their development on economic growth (Schumpeter, 1911). Levine and Zervos (1996) further argue that the development of the capital market is positively associated with long-term economic growth, based on an analysis of 41 countries from 1986 to 1993. In the same vein, Beck et al. (2000) highlights the impact that a developed financial system has on the evolution of the Gross Domestic Product (GDP) per capita and on the productivity growth, noting that country specific elements are of great importance. Looking closer to a vast database for almost 10 years is intended to highlight determinants and role of capital markets in the economic growth.

Dimension and Size Indicators

In this analysis we will use the Gross Domestic Product (GDP) as an indicator of the size of the economy and of the population income. A higher GDP means higher incomes, more business opportunities, better education, so the expected impact is a positive one. For the capital markets indicators, we will analyze the market capitalization of all listed companies, the indicator most often used by analysts to estimate the capital market size. The main disadvantage relates to the moments when the value of this indicator is distorted by excessive stock price increases of some companies, without them being the result of market operations and that finally, have no impact on market development. Another dimension of the market is given by the number of listed companies, which is not influenced by price fluctuations. The number of companies indicates a market's ability to attract and maintain listed companies. The traded value is used by analysts to describe the ability to sell and buy shares, often used to measure market liquidity. The Initial Public Offering (IPO) or a primary share sale by a company for listing purposes, is the fundamental

instrument by which stock exchanges mediate the financing of the economy and directs the available investor funds to profitable investment projects.

Data and Methodology

Database

The data collected in this study characterizes the 50 most important stock exchanges, from 47 countries, in the period 2008-2017, using the databases of the World Federation of Exchanges, Federation of European Securities Exchanges (FESE). Regarding the Japanese stock exchanges, until 2012 two stock exchanges operated, one in Tokyo and one in Osaka, for this study the data of the two being aggregated. In analyzing the size of capital markets, the first indicator is market capitalization.

The economies of the 47 countries have generally increased in the analyzed period. The largest increases were recorded in: China (the leader also in terms of market capitalization increase), India and Sri Lanka. In the top 10, GDP growth exceeds 60% in 10 years, while market capitalization growth exceeds 115%. Generally, the GDP growth was doubled by more accentuated market capitalization increases, with one exception. Jordan is the only country in top 10 that had economic growth and at the same time recorded a decrease of market capitalization, as it had a small stock market and registered a decrease of almost one third of the number of companies listed in the analyzed period.

Among the largest economies in the world - the US - registered a GDP increase of 32% and an average increase of 243% of the market capitalization of the two stock exchanges operating in the country - NYSE and NASDAQ. China - the second largest economy in the world, by GDP, in 2017, registered the largest GDP growth, of 166% and had the largest increase in stock market capitalization, of 591% on average, for the two-local operating exchanges, Shanghai Stock Exchange and Shenzhen Stock Exchange. The following economies of the world - Japan, Germany and the United Kingdom registered decreases in GDP (in $, at current prices), but doubled their capital markets' sizes. Of the 47 economies analyzed, 13 recorded GDP decreases and only 6 recorded decreases in market capitalization.

The economies with the biggest GDP decreases were Greece (-43%), Cyprus (-22%) and Spain (-20%), doubled also by decreases in stock market capitalization. The Greek stock market experienced accelerated growth rates during the 1980s and 1990s, but the country's economic and debt crisis caused a sharp slowdown of market development, massive capital outflows, as well as a market status downgrade from developed to emerging, since 2013. Italy's economy contracted by 19% in 2008-2017, with an increase of the Italian Stock Exchange market cap of 35%. A similar situation is found in Norway, with a 14% drop in GDP and a 97% increase in stock market capitalization.

Stock exchanges around the world have not only recovered from the economic crisis of 2008-2009, but experienced strong development during the analysed period. Analysing the indicators chronologically, although in the first years the market capitalization registered decreases, many exchanges in the 10-year period, experienced an average increase of the capitalization of 151%, to USD 79,820 billion, while the average GDP growth was 32%, to USD 67,093.7 billion.

For example, at the end of 2017, on the 50 stock exchanges that were analysed there were almost 46 thousand listed companies and over 12,600 Initial Public Offers (IPOs) took place in the analysed period. On average, the total number of listed companies rose by 15% in the period 2008-2017, the differences from the number of IPOs being given by delistings. Most of the stock exchanges (37) have less than 1,000 listed companies. The stock exchanges with most companies listed at the end of 2017 were: BSE India Limited with 5,616, followed by Japan Exchange Group Inc. with 3,604, TMX Group and BME Spanish Exchanges with more than 3,000 companies. Regarding the analysed IPO value, in the 10 years it

was of USD 1,823 billion or 2% of the total market capitalization. Almost 80% of this value was concentrated among the top 10 stock exchanges.

Methodology

In order to analyze the influence relations between GDP and Market Cap we will use the vector autoregression (VAR) model. The VAR model is one of the most popular and flexible models used in time series analysis. Being a natural extension of univariate autoregressive models, it is largely used in dynamics analysis and forecasting. The model was developed by Sims (1980) and popularized in the financial area by Hamilton (1994) and Tsay (2001).

The mathematical form of a model with p lags is:

$$Y_t = c + \beta_1 Y_{t-1} + \beta_2 Y_{t-2} + \cdots + \beta_p Y_{t-p} + \epsilon_p$$

Where $Y_t = (y_{1t}, y_{2t}, \ldots, y_{nt})'$ is a $(nx1)$ vector of time variables, β_i is a (nxn) matrix of dimension coefficients, and ϵ_t is a white noise vector.

The data series will be made stationary at the first difference. Stationarity will be tested using the ADF test.

Intermediate Results

From the impulse response function graph, we can deduce that a 1% shock applied to the Market Cap will cause an almost 2% GDP growth, after almost 2 years, and that the shock will be amortized by the economy after about 6 years. On the contrary, the GDP does not statistically significantly influence the market capitalization, the growth shock determining both the increase and the decrease of the market value.

Preliminary Conclusion

The economic recovery was driven by capital markets during the post-crisis timeframe, mainly after 2009. In general capital markets had large increases in 10 years in the leading countries, in many cases doubled by significant GDP growth. The lag of the impact may explain the difference in recovery path. Other determinants than market capitalization to be analyses in conjunction with GDP – the number of listed companies, IPO number and value, and traded value.

Abstract

The article analyzes the trends in the export of higher education services from Russia to Latin America. Based on the data obtained during the statistical analysis, a sociological research technique was designed and a pilot study was conducted. Based on the results of the pilot study, conclusions and recommendations were formulated regarding the prospects for the development of the export of educational services to Peru, and the methodology was tested. In particular, it was concluded that Latin American students are interested in getting education in Russia, and the main problem for the promotion of educational services is the lack of awareness of the possibilities of Russian universities and the lack of necessary institutional support in terms of inter-university agreements. A further task is to validate the methodology on a larger sample and on different types of universities in the leading countries of Latin America. The analysis presented in the article may be useful to management when choosing tools to accelerate university changes in terms of the development of the export of educational services.

Keywords: Higher Education, Latin America, Republic of Peru, Export of Russian Federation's Educational Services.

Introduction

The practice of attracting foreign students to study in Russian institutions was developed in pre-revolutionary Russia in the second half of the 19th century. In the Soviet period, the export of educational services was traditionally considered not so much from an economic perspective, but from the perspective of political interaction with the USSR-friendly countries of Asia, Africa, Latin America and Eastern Europe. Moreover, by 1990, the country occupied the 3rd place in the world after the United States and France in the total number of foreign students. For modern Russia, the educational services export is again gaining relevance in the context of global trends in the education internationalization, as well as in the formation of a national vector for the non-resource of the economy. The modern world market places a demand on the most competitive national higher education systems, which, in turn, gives states an impetus to improve the quality of education, search for effective educational technologies and ways to attract foreign students. It should be noted that the expansion of the educational services export has a certain impact on the economies development of the host countries in the form of social, demographic, economic and political effects (Falchenko, O.D., Savelyeva, I.N. and Maydanik, V.I. (2017)). For example, in the United States, where the

number of foreign students exceeds 1 million, the income from the educational services export is more than $ 30 billion. In Russia, the number of foreign students reaches 230 thousand, 60% study on a contract basis bring about $ 1 billion to the national budget.

In this regard, it seems relevant to assess the prospects for the development of the export of educational services of the Russian Federation to Latin American countries based on an analysis of the position of the Russian Federation as an exporter in the world market of educational services in order to determine the directions of export of higher education services to Latin American countries that contribute to the formation of positive effects of internationalization of education.

Literature Review

The market of educational services has been considered as an object of research by international organizations since 1919. Thus, the International Institute of Education analyzes and evaluates the mobility indicators of foreign students, as well as educational services provided by both state organizations and private and non-commercial representatives of the educational sector. In the mid-1970s the first official classification of international education standards appeared, developed by the United Nations Educational, Scientific and Cultural Organization (UNESCO). Today, UNESCO continues to carry out active work in the field of popularization of education, analysis of problems arising in this field, upholding the idea of the central role of education in the development of human potential, society and the economy.

The internationalization of education continues to be a subject of considerable interest from foreign and Russian researchers. Among researchers in the problems of the market of educational services, strategies and trends of internationalization in the modern educational space, we can distinguish authors such as Altbach (2006), Abbott (2009), Neumann and Terosky (2007), de Wit and Hunter (2015), Kulen, R. (2016), Hudzik, J. (2015), Borjas (1994), Ivakhnyuk (2016), Aleshkovsky and Iontsev (2008), Ledeneva and Tyuryukanova (2002; 2005), Massey (1999), Mukomel, V.I. (2005), Duleep, Reget and Sanders (1999), Falchenko, Savelyeva and Maydanik (2017), and others. The influence of internationalization on the innovative development of universities is devoted to the scientific paper by Bednyy, A. B. and Grudzinskiy, A.O. (2014), Savelyeva, I., Falchenko, O., Kovalev, V. and Pliusnina, O. (2018), and others. The problem of export of educational services is studied by Larsen, Martin and Morris, R. (2002), Chadee and Naidoo (2009) , Amirov (2018), Arzhanova and Vorov (2016), Sheregi, Dmitriev and Arefyev (2002), Risin (2009), Torkunov (2017), and others.

Speaking about the internationalization of education, we join the position of Knight (2011), defining internationalization as the process of purposefully giving higher education an international, intercultural or global dimension with the aim of improving the quality of education and science for all students and university staff, as well as making a significant contribution to society. De Wit and Hunter (2015) emphasize that the internationalization of higher education is not an end in itself, but a mechanism for improving the quality of education, which is based not only on economic factors. According to Risin (2009), when analyzing the foreign practice of developing the export of educational services, a number of factors are identified to have a positive impact on the national educational system, which increases the priority of higher education for the state and allows the formation of an appropriate effective state policy, which ultimately contributes to the country's international image improvement. In this context, the processes of internationalization of education have an impact not only on the quality of education, but also on the competitiveness of a country in world markets of goods and services.

Problem statement and Research Methods

Based on the existing theoretical and methodological approaches to the development of the higher education export, as well as being guided by the current problems of the development of the educational services export in Russian universities, the authors formulated the goal of this article: to assess the position of the Russian Federation as an exporter in the world market of educational services and determine directions of higher education services export contributing to the formation of internationalization of education positive effects. As an goal of study, the educational services export of Russia to the countries of Latin America (in particular, to Peru) was selected.

The hypothesis of the study is that the Russian Federation is considered as a promising exporter of educational services to Latin America (on the example of a sociological survey of universities in Peru).

In accordance with the goal of this study, the authors identified the main stages and identified the main methods of this study.

The first stage of this study involves determining the position of Russia in the educational services export by the example of key Latin American countries and substantiating the attractiveness of Russian universities for foreign students based on methods of analysis and synthesis of statistical information relating to this area of research. As the information base of the first stage of the study, statistical and analytical materials of the UNESCO Institute for Statistics and the Ministry of Science and Higher Education of the Russian Federation were used.

The second stage is devoted to a sociological study of the opinion of students from Peru on the question of the choice of education in the Russian higher educational institutions. As the main method of the second stage of this research, the sociological method was used - the survey. The authors developed an electronic questionnaire, including 41 questions. It should be noted that the research methodology was not a product of the subjective opinion of researchers, but was the result of a synthesis of existing and approved methods. Based on the analysis of modern questionnaire practices, the authors formed a construct of a sociological survey for this study, which includes three blocks: 1) a block of general questions regarding the analysis of a survey audience; 2) a value-motivational block dedicated to the selection by Peruvian students of Russian universities as a platform for higher education; 3) the resulting block devoted to the analysis of future career paths of students after receiving education in Russia. The respondents were students (Public Institute of Higher Technological Education “Simon Bolivar” was chosen as the information base for this stage of the study due to inter-university cooperation agreements).

Results

The first stage of the study is to determine the place of Russia in the export of educational services by the example of key countries in Latin America and justify the attractiveness of Russian universities for foreign students.

According to UNESCO, the Russian Federation, in comparison with the key countries of Latin America, occupies a leading position in the admission of foreign students, showing a positive migration balance, indicating that the number of accepted foreign students is 4 times higher than the number of Russian students graduating abroad (Table 1). For comparison, the migration balance of key Latin American countries is negative, i.e. they are net importers of educational services in the global market.

Table 2 presents the dynamics of the total number of foreign citizens studying at the universities of the RSFSR / RF in the academic years 1950 / 1951–2016 / 2017 in full-time and part-time study programs. We note that the dynamics of attracting foreign citizens in general for the period under review is positive; the proportion of foreign students in the total number of students in Russian higher education institutions is relatively small, but tends to increase. So, in 2000/2001 this share was 1.53%, and in 2016/2017 - 7.11%.

Table 2: Dynamics of foreign students' number enrolled in full-time and part-time study programs in RSFSR / Russian Federation higher education institutions in 1950/1951–2016/2017 academic years and its change in the structure of all Russian higher educational institutions population

Academic Years	The number of foreign citizens studying at universities of the RSFSR / RF, thousand people	The total number of students in universities of the RSFSR / RF, thousand people	The share of foreign citizens in all students of Russian universities,%
1950/1951	5.2	796.7	0.65

Ministry of Science and Higher Education of the Russian Federation, Center for Social Forecast and Marketing, Moscow. [Retrieved January 13, 2020], http://socioprognoz-ru.1gb.ru/files/File/2018/Arefiev_Sbornik_8_001_536_2018_ispr8_15_11_18.pdf

Despite the fact that the Russian Federation is only just beginning to be actively involved in the internationalization of higher education, it is possible to assess the opportunities this process provides to donor countries of educational services. After the collapse of the Soviet state, the Russian Federation, as the successor of the USSR, did not pay enough attention to this problem for a long time, which led to a deterioration in Russia's position in the educational services market. They started talking about this problem relatively recently, only in the early 2000s. To date, Russia has developed a priority project "Development of the export potential of the Russian education system", approved by the Presidential Council for Strategic Development and Priority Projects. The key objective of the project is to increase the attractiveness and competitiveness of Russian education in the international market for educational services and, thus, increase non-resource exports. The main indicators of this project are presented in table 3.

Table 3: Key indicators of the priority project "Development of the export potential of Russian education" for the period 2017-2025

Base value	2017	2018	2019	2020	2021	2022	2023	2024	2025
1. The number of foreign citizens studying full-time in Russian educational institutions of secondary vocational and higher education, thousand people (main indicator)									
200.0 thousand	220.0	240.0	260.0	310.0	400.0	450.0	520.0	600.0	710.0
State scholarships 15.0	15.0	15.0	15.0	15.0	15.0	15.0	15.0	15.0	15.0

Table 4 shows the official statistics of Russia on the cost of education for foreign citizens. For example, in 2019/2020 getting an education at a prestigious Russian university costs an average of 250 thousand rubles. For example, a master's study for a foreign student will cost 240-260 thousand rubles (or 3690-4000 thousand dollars), while the minimum cost of training is 127 thousand rubles, and the maximum is 450 thousand rubles. Compared to the 2017/2018 academic year, prices for tuition of foreign students increased by 1/3 in ruble terms.

Table 4: The cost of education for foreign citizens in Russian higher education institutions

Indicator	2016/2017		2019/2020	
	Cost, thousand rubles per year	Cost, dollars per year	Cost, thousand rubles per year	Cost, dollars per year
Full-time undergraduate studies for foreign students

According to official Russian statistics, the majority of foreign consumers of various Russian educational services are citizens of the CIS countries (Fig.1). The share of Latin American countries remains at the level of 1.1%, which is also explained by the remoteness and isolation of this continent from the Russian Federation.

Fig. 1: The proportion of foreign citizens from various countries who studied at various types of Russian educational institutions in the 2016/2017 academic year,%

Ministry of Science and Higher Education of the Russian Federation, Center for Social Forecast and Marketing, Moscow. [Retrieved January 13, 2020], http://socioprognoz-ru.1gb.ru/files/File/2018/Arefiev_Sbornik_8_001_536_2018_ispr8_15_11_18.pdf]

Thus, we can conclude that Russia is a net exporter of educational services. However, the proportion of individual regions of the world is not large enough. This also applies to Latin America. In this regard, it is of interest to study factors that influence students in Latin America to choose higher education in the Russian Federation.

The second stage of the study is a sociological survey of students from Peru regarding the choice of education in higher educational institutions of the Russian Federation.

1) Target audience. 324 respondents took part in the survey, including 46% men and 54% women. According to the age parameter, the survey is dominated by people aged 17-27 years (80% of respondents), including 17-20 years (39%), 21-23 years (24%) and 24-27 years (17%). The other age categories of respondents occupy an insignificant share of 20% of the total target audience, including 28-31 years old (10% of respondents), 32-35 years old (4%) and over 35 years old (6%). The level of education is dominated by undergraduate students who are currently studying in Peru (95%), and the remaining 5% are those who are currently completing their studies at a Peruvian university (2%), having an academic degree (2%), having completed higher education in undergraduate and / or graduate studies (1%). Most of the respondents have (are getting) education in enterprise management programs (40.2%), accounting (20.8%) and industrial electronics (15.8%).

2) Value-motivational component of the Russian universities students' choice process and the features of education in Russia from the point of view of foreign students. 86% respondents clearly expressed a desire to get higher education in Russia. Among the motivational factors that influence the decision to study in Russia are the student's own decision (65%) and the influence of parents on this decision (21%). It can be noted that respondents rated the degree of interest in studying in Russia as very high (29%) and high (31%). Analyzing the attitude to the quality of education in Russian universities, more than half of the respondents (51%) say that studying at Russian universities is more difficult than in Peru. Among the difficulties of studying in Russia are mentioned such as speaking the Russian language (68%) and studying special disciplines (27%) (Figure 2).

Fig. 2: Difficulties of studying in Russia, pers. and %

Source: compiled by the authors based on sociological survey of Peruvian students

Among the factors for choosing Russian universities, Peruvian students noted the existence of cooperation agreements with Russian universities (47%) and the quality of Russian education programs (12%) (Figure 3).

Fig. 3: Factors in favor of choosing a study in Russia, pers. and %

Source: compiled by the authors based on sociological survey of Peruvian students

3) Future career paths of students after receiving education in Russia. The survey showed that Russian education is very much appreciated in Peru: 88% of respondents see the value in getting an education in Russia with their future employment (Figure 4).

Fig. 4: Opinions on the value of education / internship in Russia for employment opportunities in Peru, pers. and %

Source: compiled by the authors based on sociological survey of Peruvian students

Among the most attractive employment areas after graduating in Russia the leaders are: industry (37%), public service (33%) and services (20%). According to respondents, getting an education in Russia will help to find jobs in large companies (41%) or open their own business in Peru (35%). After receiving education in Russia, the majority of respondents plan to find a job in Peru (56%) in order to put the acquired knowledge into practice, or in Russia (35%), taking advantage of the knowledge of Russian and Spanish.

In the course of the study, it turned out that Peruvian students are not sufficiently informed about educational opportunities in Russia: 66% of respondents do not have information about training programs. Among the problems (barriers) associated with their stay in Russia, respondents noted a language barrier (43%) and climate (17%), but migration legislation, in their opinion, was not a significant obstacle (5%) (Figure 5).

Fig. 5: Factors (barriers) associated with the stay of Russia, pers. and %

Source: compiled by the authors based on sociological survey of Peruvian students

Thus, we note that Peruvian students are interested in receiving education in Russia, highly appreciate the quality of Russian education and the possibility of applying the acquired knowledge in future employment. However, a constraining factor is the lack of awareness of students about study programs in Russia.

Conclusion

1) In the course of the study, a hypothesis was discovered that, being a net exporter in the global educational services market, the Russian Federation remains a promising exporter of educational services to developing countries in Latin America. Despite the fact that the share of Latin American countries in the export of educational services is currently small, historical experience, the potential for political and socio-economic cooperation between the countries of the Russian Federation and Latin America allow us to conclude that there is a great prospect for such interaction.

2) A pilot case study based on an analysis of the factors by which Peruvian students choose Russian universities for higher education allows us to conclude that there is a high potential for exporting Russian higher education to the Latin American market.

3) The main reasons for choosing Peruvian students of Russian universities (including regional ones) are the quality of Russian education, which is highly valued in Latin America, as well as the prospects for further employment of graduates.

4) From the point of view of Peruvian respondents, the language barriers, climatic conditions and intercultural characteristics, which, nevertheless, do not reduce the motivational component and interest in receiving education in Russia, are the constraining factors for obtaining education in Russia.

5) The main obstacles to the development of the export of educational services to Latin American countries, according to the data obtained during the pilot study, are insufficient awareness of educational opportunities in Russia and the lack of cooperation agreements between Peruvian and Russian universities.

Abstract

The paper presents the results of an empirical study aimed at identifying students' choice of profession and satisfaction with the quality of training at the university. The study revealed the motivation of students to enter economic specialties, their assessment of the quality of theoretical, practical and socio-psychological training, views on job prospects, students' opinions on the importance for employers of various aspects of the quality for training and personal characteristics of graduates. It was found that most students do not appreciate the level of their practical training and take into account the prospects for further employment in their specialty upon admission.

Keywords: Choice of Profession, Academic Satisfaction, Economics Students, Requirements of Employers, Employment Prospects.

Introduction

The goal of any university is to meet the needs of society and the state in qualified specialists with higher education (Aleksandrov et al., 2015; Yepaneshnikov et al., 2017). In accordance with this goal, activities to meet the needs of students in education and development can be considered a key element of the educational activities of the university (Morova et al., 2017). Given the current trends and requirements for universities in the framework of ensuring the effectiveness of the functioning of the higher education system (Leonteva, 2010), these activities to meet the needs of students in education and development should be considered as a system of interrelated processes: from career guidance activities of the university among applicants to promoting the employment of graduates. Among them, undoubtedly, the most important element is the satisfaction of students with the quality of the educational activity of the university, which contributes to the growth of confidence of future graduates in successful employment (Golushko, 2016; Nikolaev, 2019).

In order to assess their activities and identify deficiencies in the functioning of universities (Kurbanov et al, 2017), periodically, or on a regular basis conduct research on student satisfaction with the educational activities of the university (Obraztsov, Polovnev, 2017). The results of such studies allow the university to timely identify shortcomings in its activities and make effective management decisions to develop and improve its activities (Leonteva et al., 2019; Zakharova et al., 2019).

The purpose of the study was to analyze the reasons for profession choice in economics students and their academic satisfaction in the quality of education and expectations in the field of their future employment.

Method

During the study, methods of scientific analysis were used (generalization and systematization, analysis and synthesis), as well as the collection, processing and interpretation of empirical data using a specially designed 18-point questionnaire.

The study included several stages:

1. Development of the questionnaire. The questionnaire contains several blocks of questions reflecting the motivation for higher education, an assessment of various aspects of the quality of training, employment prospects, and an assessment of the expected needs of employers.

2. Definition of a representative sample. In order to test the questionnaire, three academic groups consisting of 63 undergraduate students of the Faculty of Economics of Ulianov Chuvash State University were involved. They were aged from 18 to 23, 18 males (28%) and 45 females (72%).

3. Determining the procedure for filling out and collecting questionnaires. For the convenience of students, questionnaires were developed in the Google Forms service, which made it possible to quickly fill out questionnaires and get partially processed results.

4. Processing the information collected. The data obtained in the course of the questionnaire in tabular form made it possible to identify the structure of the respondents' answers, including those grouped according to various criteria.

Questioning, as a form of collecting information, was chosen in connection with a large number of respondents, convenience for respondents, the need to obtain generalized information about the problem being studied, and to ensure anonymity for respondents.

Results

Identification of the reasons why respondents decided to get higher education at the Faculty of Economics shows that the most popular motive is the desire to get a prestigious profession. The second most popular reason was the ease of learning. A more detailed study of the reasons for entering the Faculty of Economics shows that 40% of respondents' answers relate to reasons related to successful employment opportunities: a prestigious profession, the prospect of receiving a high salary, the possibility of employment abroad and the ease of employment. 30% of the answers are related to the reasons for the ease and comfort of learning: easy to learn and convenient location of the institution. When asked about whether higher education is a prerequisite for a decent and prosperous life, only 14% of respondents expressed full agreement with this statement. 57% of respondents believe that the presence of higher education can significantly affect the achievement of social success, and 24% of the respondents expressed doubts about this dependence.

It is known that university graduates are not always employed in their specialty. The reasons for this may be a lot. According to the survey the most compelling reasons for refusing to work in a specialty are the lack of acceptable demand (35% of answers), the low level of salaries of specialists (23%), and the not interesting content of work (17%). Five people indicated that they did not want to work in their specialty. Among the motives for higher education, the most significant for the economics students was the acquisition of professional knowledge and skills - 28% of the responses. Second in importance were the opportunity to get a well-paid job and the prestige of higher education in society,

which scored 20% of the responses. Fifteen students indicated that the decision to receive higher education was influenced by their parents and relatives.

When deciding whether to enter university, 59% of respondents took into account the prospects for further employment, and 25% of respondents focused only on the need for higher education. Six people regretted entering the Faculty of Economics. It is worth noting that those who regretted choosing the Faculty of Economics as the reasons for admission indicated a low competition for admission, advice from parents / friends and ease of training. Among the 37 people who, upon entering the university, hoped to find a job in the specialty, 24 people (65%) indicated the prestige of the profession as the main reason for receiving an economic education.

To identify the quality of training perceived by students, we compared the students opinions on the importance for employers of various components of the quality of students' training with the level of student satisfaction with the quality of training. Such components of the quality of student training as theoretical training, which assumes the possession of basic and special knowledge, practical skills consisting in the ability to put theoretical knowledge into practice, as well as socio-psychological training, which implies the ability to build communication with colleagues and work in a team, were examined. Based on the comparison, we determined the level of students 'satisfaction with the quality of training, which was calculated as the ratio of students' assessment of the quality of training and their opinion about the needs of employers. The assessment was carried out on a 5-point scale, where 1 point corresponded to a low rating, 5 - a high one.

Students rated their socio-psychological preparation above all - the average rating was 3.54. The level of theoretical training was estimated at 3.41, and practical - only 2.94. An assessment of students' satisfaction with the quality of training shows that students rated only the quality of their theoretical training higher than its estimated importance for employers. According to students, their quality of socio-psychological training was lower than the expected value for employers - the satisfaction level was 80%. With regard to practical training, the students who took part in the study believe that the quality of their training was significantly lower than what employers expect from them - the satisfaction level is only 64%.

A more detailed study of students' opinions on the characteristics of graduates who were most interested in employers showed that students consider working ability, responsibility and organization as the most important characteristics for employers. Least of all, according to students, employers are interested in the desire for continuous development, the presence of leadership qualities and the willingness to work regardless of wages. In turn, students, when choosing a place of employment, were also guided by a number of requirements that they impose on employers. The most significant factors that can influence the choice of a job were pleasant management, material well-being and good working conditions. The data obtained indicate that students are more interested in the issues of fulfilling their professional duties in favorable working conditions than the need for self-realization.

Conclusion

Based on the results of the study, the following conclusions can be drawn. Students receiving higher education at the Faculty of Economics are dictated by the desire to receive a prestigious profession that can provide a decent life. When entering an educational institution, most students take into account the prospects for further employment and after graduation expect to find a job in their specialty. Economics students evaluate the level of their theoretical training at a good level compared to their ideas about the needs of employers. The level of satisfaction of economics students with socio-psychological and practical training is insufficient in comparison with their ideas about the needs of employers. The results should be the basis for adjusting educational programs to strengthen the practical orientation of training future economists and deepen the university’s interaction with employers.

Acknowledgment

The research was carried out with the financial support of the RFBR and the Chuvash Republic in the framework of the scientific project No. 19-410-210010.

Impact of Unbundling Distribution System Operators on the Financial Potential of Polish Energy Capital Groups

Abstract

Energy capital groups in Poland will need significant additional capital influx to develop further. At present, the majority shareholding is held by the State which does not agree to the reduction of its shares. This means that it is not possible to raise funds through emission of shares. Enterprises of this kind will have to obtain debt financing, which requires maintaining an EBIDTA index at the appropriate level. Currently, transmission system operators make a significant contribution in capital groups. In 2019, the Energy Regulatory Office obliged operators to comply with European Union regulations regarding the clear separation of their activities from the capital group actions.
This article performs a synthetic analysis of the impact of the above decisions on the value of energy groups and thus their ability to obtain debt financing.

Keywords: Energy Policy, Power Engineering, Financial Potential.

Introduction

In Poland, the energy sector is dominated by four capital groups (PGE, TAURON, ENEA and ENERGA), which have in their structures the segment of generation, distribution, trading in electricity and, with the exception of ENERGA, coal mines. In this process chain, transmission system operators (TSOs) are important players from the point of view of the possibility of generating cash and debt within the energy capital group. This is possible due to stable revenues they receive. TSOs are natural monopolies, therefore their revenues are regulated. The Energy Regulatory Office (ERO), when approving the prices of their services, takes into account the level of investment and operating costs. TSOs operate within capital groups, which can be used to "shift" the costs of other entities within the group. Cross-subsidization would lead to potentially uncontrolled price increase, which violates the operating principles of a regulated market.

Therefore, regulations are being introduced at EU and national level to ensure TSOs unbundling. In 2019, ERO obliged TSO to develop and submit programs for approval that would ensure effective separation of operators' activities from those of the remaining entities within the capital group (URE, 2019).

The purpose of the article is a synthetic analysis of the impact of the above decisions on the value of energy groups (Panfil, Szablewski, 2011 and Chomać 2004), and thus their ability to obtain debt financing.

Main directions of changes in the functioning of TSOs outlined by the Energy Regulatory Office

In February 2019, the Energy Regulatory Office implemented guidelines for TSOs that oblige these entities to take actions to obtain full independence from other enterprises within the capital group. These documents define the conditions that must be met by operators to perform their functions without hindrance. The developed guidelines result from EU regulations that refer to TSOs. The most important of them are:

- "Directive 2009/72 / EC of the European Parliament and of the Council of 13 July 2009 concerning common rules for the internal market in electricity and repealing Directive 2003/54/EC" (Journal L 211 dated 14.08.2009).
- "Directive 2009/73/EC of the European Parliament and of the Council of 13 July 2009 concerning common rules for the internal market in natural gas and repealing Directive 2003/55/EC" (Journal L 211 dated 14.08.2009).
- "Act of 10 April 1997 - Energy Law" (Journal dated 2018, item 755 amend.).
- "Note of the Directorate-General for Energy and Transport on Directives 2003/54 / EC and 2003/55 / EC concerning the internal market in electricity and natural gas - Business separation system" (16.01.2004).
- "Interpretative note on Directive 2009/72/EC concerning common rules for the internal market in electricity and Directive 2009/73/EC concerning common rules for the internal market in natural gas - Retail market" (22.01.2010).
- "Guidelines for Good Practice on Functional and Informational Unbundling for Distribution System Operators. Ref: C06-CUB-12-04b" (15.07.2008).
- "Status Review of DSO Unbundling with Reference to Guidelines of Good Practice on Functional and Informational Unbundling for Distribution System Operators. Ref: E09-URB-20-05" (09.09.2009).
- "Status Review on the Transposition of Unbundling Requirements for DSOs and Closed Distribution System Operators. Ref: C12-UR-47-03" (16.04.2013).
- "The Future Role of DSOs - A CEER Conclusion Paper Ref: C15-DSO-16-03" (13.07.2015).
- "Status Review on the Implementation of Distribution System Operators' Unbundling Provisions of the 3rd Energy Package. Ref: C15-LTF-43-03" (1.04.2016).

At the beginning, the regulator notes that the operator's independence requires that both the brand and its logo are different from other entities within the capital group. Currently, the largest TSOs operating within energy groups have their 'personal details' starting from the name, through email addresses and ending with the web domain – shared within the group domain. Often, they rent premises to other, unrelated, companies.

The TSO management must be able to make independent decisions. All activities related to the current situation, capital expenditure, structure of assets and liabilities, or documents related to management (e.g. various types of policies, procedures, regulations) must result from an objective situation and be an independent decision of the TSO. Therefore, no body from within the capital group may, directly or indirectly, issue orders or even opinions to the company in question. This applies to both the management board and individual employees. The role of another body from the capital group may only consist in supervising the implementation of the approved financial plan or other equivalent document. On the other hand, TSO employees cannot participate "in the management structures of a vertically integrated enterprise or an energy enterprise dealing with transmission, production, generation or trade of electricity or be responsible, directly or indirectly for ongoing operations in this field" (URE, 2019). It also means that the operator's personnel willing to change job/ career moving to other enterprises belonging to the energy group cannot use sensitive information and other important data obtained at the TSO – in the new workplace.

An independent employee remuneration and motivation systems, which must be based solely on the decisions of the operator's board and the employee achievements is also a valid question. Therefore, the assessment of individual work effects cannot be made conditional on capital group standing.

In the guidelines, the ERO reminds that TSOs are to independently decide on the outsourcing of areas within their activities. They may not be obliged to access a shared service center in a vertically integrated enterprise. Possible separation of some functions carried out independently from the structure and their transfer to other entities should be performed with utmost transparency to select the service provider. The minimum condition for TSOs to outsource services is to prove the market and non-discriminatory nature of centralization decisions and the transparency of the process of concluding contracts for the provision of services and purchases. In the energetic capital groups operating in Poland, the standard procedure is to separate some functions and transfer them for implementation to the chosen enterprise. The company acting as a shared services center (SSC) usually deals with financial and accounting services, IT and human resources. Changing the approach will make it necessary to verify the operation of SSCs and reorient the entire system. For example, the operator will not be able to use IT solutions that do not provide unbundling. Therefore, it is not possible to create integrated systems located on a shared server with an internal flow of information or to share IT solutions with a selected marketing company. ERO also considers it unacceptable that the systems supporting the TSO's operational activity (e.g. in the area of asset or network management), investment management, development, connection of customers, material management, distribution services and customer service, physically existed in another enterprise within the capital group or were managed by services other than those directly subordinate to the operator.

The guidelines presented above indicate the desired direction of changes in the functioning of operators. They fundamentally change cooperation within vertically integrated energy companies. Generally, operators are to become entities operating next to capital groups. At the same time, the President of the Energy Regulatory Office expects that TSOs will implement these principles by the end of 2019.

Changes in the functioning of TSOs and the value of energy capital groups

The energy sector is currently facing challenges. First of all, it must restore decapitalized asset-generating wealth, which would allow to maintain electricity production at the current level (owing to the age, by 2030 all units of joint power over 16 GW must be shut down) in the future and adapt power plants to the EU's stringent environmental regulations (demanding, among others, a significant reduction in harmful gas emissions for which it bears responsibility). Moreover, it requires, for example investments in renewable energy (Jankiewicz, 2017a). In addition, the increase in their production potential will contribute to the even and balanced development of the Country, due to the mostly local nature of this type of units (Jankiewicz, Grądzik, 2016).

Secondly, modernization of energy networks is necessary due to their decapitalisation and maladaptation to scattered power engineering(Jankiewicz, 2016). The development of the country also requires an increase in network density (in Poland there are 41 km of network per 1000 km2, while e.g. in Switzerland it is 161 km, Greece - about 120 km, Germany - 100 km, France - 90 km, Netherlands - 80 km (Kleiber, Steinhoff, Żmijewski, 2015; Maciejewski 2011, Stankowska 2009). In addition, there is need to gradually increase the number of underground-laid lines, which will reduce their failure rate. All this adds up to the large investment outlays that energy groups will have to incur. However, not having high enough profitability to finance such ventures independently, they require significant debt capital. Financial entities will only be willing to borrow money if enterprises in question have a good rating. Until now, TSOs were an important asset that positively influenced the assessment of energy groups on the financial market (among others due to the stable EBITDA value and the ability to generate cash). The regulated activity carried out by this type of enterprise allows for stable revenues, because the Energy Regulatory Office sets distribution fees at a level covering running costs and return on capital employed in the activity (Jankiewicz, Ziółkowska, Golej, 2016). The regulator's

guidelines change this situation. Their implementation may cause separation of TSOs from energy capital groups, which means that the latter will not be able to use the operator's financial leverage. As a result, the price of vertically integrated energy businesses will be reduced and they may have their EBITDA not sufficient to obtain the necessary debt financing and thus will be forced to reduce the pace of change.

In addition, without TSOs, the investment risk will expand, as the remaining enterprises are characterized by greater variability in operation. The value of their assets may fluctuate significantly depending on the market situation, and thus the likelihood of the capital group defaulting.

The solutions proposed in the guidelines will also increase legal risk. At the end of 2018, the Government "froze" electricity prices. This situation caused confusion on the market because the legal changes occurred unexpectedly and no implementation rules were in force to realize them. The document issued by the Energy Regulatory Office in 2019 seems to be another law interpretation – again, unexpected by the market. In addition, it is not precise in terms of provisions. The result is that it is not clear what is consistent with and what violates the unbundling principle. The volatility of regulations and their low transparency mean that the entities do not know how to proceed and, as a result, make wrong decisions (Jankiewicz, 2017b). This strengthens the legal system based on discretion, i.e. the one we are dealing with in Poland (see also the statement by the Polish Committee for Electric Power on the expected trends in the update of Po-land's Energy Policy, PKEE 2013). This has a negative impact on the valuation of energy groups.

Another factor negatively affecting the valuation of the energy sector is the risk related to the costs of compliance with the guidelines and the height of possible fines for their violation, which is difficult to predict, if the Energy Regulatory Office considers that the industry has not complied with them.

Difficulties for capital groups also result from the lack of comprehensive solutions proposed by the Energy Regulatory Office that does not seem to perceive interdependence in the functioning of vertically integrated enterprises. In order to protect customers against excessive cost increases, which ERO, as a monopolist, may impose on TSOs, an index of acceptable changes in prices and rates of charges in subsequent years has been introduced in Poland. It is based on changes in the basic economic parameters (i.e. inflation and an increase in the level of selected prices and rates). However, the restrictiveness of this indicator was limited, so it did not force TSOs to minimize costs. In this respect, the ERO did not accomplish its control role well. Despite the powers it enjoyed, ERO could not force operators to significantly improve efficiency (including cost-effectiveness). The parent company from the capital group may be able to perform better its control functions. It can enforce a much greater increase in TSO's operations optimization than the regulatory body in question. Depriving the owner of full control over the operator may result in a loosening of the cost policy. This will reduce the profitability of such entities and result in increased costs that society will have to bear. This is another risk factor that will cause a decrease in the value of energy capital groups and increase the cost of obtaining debt capital.

Summary

The synthetic analysis of the proposal presented by the Energy Regulatory Office in relation to the independence of DSOs carried out above shows that the proposed solutions do not serve the development of the energy sector in Poland. The operator's lack of cooperation with other vertically integrated companies will negatively affect energy capital groups. It will reduce their effectiveness and increase the risk of conducted operations. This will reduce the value of Polish vertically integrated energy groups and reduce their debt potential. In addition, the guidelines change the concept of DSO functioning, which means they must focus on developing new operating strategies instead of development, which would also negatively affect their value.

Types of Organizational Culture in the context of Project Management Methodologies

Katarzyna PIWOWAR-SULEJ

Wroclaw University of Economics and Business, Wroclaw, Poland
e-mail: katarzyna.piwowar-sulej@ue.wroc.pl

Abstract

The aim of the study is to present the relationships between organizational culture and project management methodologies. In the first section of the paper, on the basis of literature studies, the characteristics of so-called "project management culture" and hypothetical linkage between types of organizational culture and types of project management methodologies are presented. This was the basis for preparing research questions. The second section, i.e. the empirical part of the paper, presents original research using the case study method and aiming to verify the relationships. The paper contributes to knowledge about cultural aspects of project management and delivers future directions for researchers.

Keywords: Project Management, Organizational Culture, project Management Culture, Project Team Culture, Typology by Cameron and Quinn.

Introduction

The interest of researchers and practitioners in intangible management factors increased in the 1980s. Other types of non-economic reasons which affect the success or failure of an enterprise were investigated. Among these factors, organizational culture was of particular interest. It has been studied from a variety of perspectives ranging from disciplines such as anthropology, sociology, organizational behavior and management sciences.

Organizational culture represents the collection of dominant values, norms, beliefs, attitudes and assumptions in a company. These elements may not have been articulated but shape the ways in which people in organizations behave and things get done. "Values" refer to what is believed to be important about how people and organizations behave. "Norms" are the unwritten rules of behavior (Armstrong and Tylor, 2014, p. 120). The culture connecting people in an organization remains very closely linked to the organization's performance. Modern human resource management (HRM) – which is one of many subdisciplines of management sciences – promotes the use of human resource policies to reinforce an appropriate (or change an inappropriate) organizational culture and underlines that human resources are valuable as a source of competitive advantage. These resources they may be tapped most effectively by mutually consistent policies that promote commitment and which, as a consequence, foster a willingness in employees to act flexibly in the interests of the "adaptive organization's" pursuit of excellence (Legge, 1989, p. 25).

Simultaneously, radical changes in the functioning of an organization have occurred in the last several decades. The increasingly uncertain environment, competition activities and short life cycle of many products and the growing expectations of customers and employees have forced companies to introduce

changes. Repetitive, routine operations are gradually losing importance in favor of unique and complex activities – i.e. projects.

A project can be defined as an "endeavor in which human, material and financial resources are organized in an innovative way to carry out an extraordinary scope of work, in line with the defined specification, within cost and time constraints, to achieve a positive change determined by quantitative and qualitative goals" (Turner, 1993, p. 8). Project management, in turn, is the application of knowledge, skills, tools and techniques, in relation to project activities, in order to meet or exceed the needs and expectations of stakeholders associated with the project (Ward, 2000, p. 168).

Projects can be managed in accordance with guidelines presented in project management methodologies. These methodologies are referred to as guides to the types of documentation and entitlements necessary to complete the particular project stages. The subject literature offers two general approaches towards running projects: traditional (managerial) and modern (agile, adaptive, dynamic, light). The traditional approach has its roots in 1950s, while the modern one is from the 1990s. The main difference between those two methodologies lies in the fact that – in case of the first one - it is not important to perform initial planning since the actions are adapted on an ongoing basis. The differences between these two approaches to project management should be also expressed in organizational culture because one of the main causes of project failure presented in the subject literature is that the organizational culture in which projects have to be delivered is not suitable for projects (Gray and Larson, 2003).

The aim of the study is to present the relationships between organizational culture and project management methodologies. In the first section of the paper, on the basis of literature studies, the characteristics of so-called “project management culture” and hypothetical linkage between types of organizational culture and types of project management methodologies are presented. This was the basis for preparing research questions. The second section, i.e. the empirical part of the paper, presents original research using the case study method and aiming to verify the relationship. The research project is financed by the Ministry of Science and Higher Education in Poland under the program "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Literature Background

Project Management Culture as A Construct in The Subject Literature

Returning to the issue of organizational culture, it should be stated that organizational “project management culture” has been described in the subject literature discussing project management (e.g. Henrie and Sousa-Poza, 2005; Shore, 2008; Stare, 2011). It consists of strictly defined features supporting both the introduction of changes in an organization and teamwork.

A project can also be defined as an organization, which can be said to be the pattern of interrelationships, authority and responsibility that is established between the contributors (i.e., client, supervisor and contractor) to achieve the client’s objectives (Walker, 2015). Therefore, in the subject literature one can also find such terms as “organizational culture of a project” or “project team culture”, which is associated with the way people in a specific project think and apply their values. It impacts their behavior and how they perform their responsibilities during the project life cycle. The team culture affects the team’s productivity, work attitudes and overall commitment to the project (Billows, 2016).

There is a mutual relationship between project team culture and organizational culture of a company (see Figure 1). In the organizational culture there is specified how valuable projects and working in projects are.

In turn, norms and rules of working in project teams resulted from project management methodology and jargon can be transferred into the organizational culture of a whole company.

Figure 1: Relationship between project management methodology, project team culture and organizational culture of a company (Piwowar-Sulej, 2012)

For example, Graham and Englund (1997) identified eight factors that directly influence project success. These include strategic emphasis of projects, upper management support, project planning support, customer/end-user input, project team development, project execution support, communication and information systems and organizational systems support. In such an environment teamwork and cross-functional operation are the norm, conflict is recognized and dealt with and excellence is the driver (Billows, 2016). The research conducted by Doolen, Hacker and Van Aken (2003) shows that the organizational culture promoting communication and cooperation between teams influences team members' satisfaction and the effectiveness of team management. It can be related to project management, which depends on teamwork. Taking into consideration the different characteristics of organizational culture, one can create a list of features (norms or values) of project management culture. Speaking about values it should be noted that the most important elements are: mutual trust, respect, open communication, helpfulness, fairness and ethical behavior. These values are treated as predictors of a project success (Young, 2000, pp. 40-41; Morrison, Brown and Smit, 2008, p. 32; Du Plessis and Hoole, 2006, pp. 36-43). In terms of cultural artefacts it should be mentioned that in "project management culture" English language prevails regardless of the official language which is used in a company.

The literature studies show that the relationship between the characteristics of organizational culture and types of organizational culture with the standards entered into project management methodology, which are adopted in an organization, has not been fully studied so far. Piwowar-Sulej (2012) made some attempts to combine the characteristics of project management methodologies with the types of culture distinguished by Cameron and Quinn (The Competing Values Framework – CVF; Cameron and Quinn, 2011). The concept hasn't been empirically proven so far.

A hypothetical linkage between characteristics of project management methodologies and types of organizational culture

As mentioned above there are two main types of project management methodologies, i.e. the traditional one (which includes a set of developed techniques used for planning, estimating, and controlling activities, e.g. PMBoK - Project Management Body of Knowledge or Prince2) and the modern/agile one (which is

more flexible, e.g. Scrum). There are some differences between these approaches in how tasks are performed and project teams are managed (see Table 1).

Table 1: Cultural artefacts – differences between traditional and modern project management methodologies (own study based on Piwowar-Sulej 2012, Špundak , 2014)

Traditional approach	Agile approach
The way of acting	The way of acting
▪ General task: carrying out project management processes in a given order ▪ Accomplishing tasks: the use of defined tools in above-mentioned processes ▪ Waterfall approach ▪ End-users are not involved in further project stages	▪ General task: simplifying processes and procedures, sequential actions ▪ Accomplishing tasks: more flexible ▪ Iterative approach End-users are involved in further project stages
Role of project manager	Role of project manager
▪ formal manager, coordinator	▪ moderator, coach, mentor
The value of knowledge	The value of knowledge
▪ formal knowledge (codified, explicit) ▪ completed documentation is required	▪ tacit knowledge as a source of innovation
Specific language	Specific language
• basic project management terms, e.g. milestones, Triple Constraint, WBS (Work Breakdown Structure)	▪ E.g. time box, sprint, back log

The traditional approach involves the mechanistic division of work, with an underlying assumption of manageability and predictability (Saynisch, 2010). It is highly structured and is referred to as “waterfall” as the work of one phase continues downstream into the next stage. The initial phases of the project are intended to set the stage for all project work, including establishing the project’s scope and the requirements that are necessary to deliver that scope (Thomas and Fernandez, 2008). The traditional approach takes the perspective that a rigorous, hierarchical control best manages complexity.

Agile is a term, which stems from Agile Manifesto and the phrase was coined in the context of projects in February 2001 in Snowbird (Utah, USA) during a meeting of 17 major players of new software development methodologies. The term Agile has at least two definitions. According to the first definition Agile is a way of thinking (mindset) about complex tasks management (from projects to entire organizations). Main characteristic traits of this philosophy are:

- close cooperation among the parties;
- iterative and incremental way of delivering results,
- openness towards changes and flexible adaptation changing circumstances.

The second definition of Agile is an umbrella term for all agile project management methodologies (e.g. Scrum, Extreme Programming, Dynamic Systems Development Method), which are based on principles outlined in the Agile Manifesto (Agilemanifesto.org, 2019).

The reason for declaring Agile Manifesto was an increasing number of failed software development projects which were based on waterfall approach. Inefficiency of the waterfall approach was and is connected with one of the basic assumptions of this model, i.e. focus on delivering IT project in the form which was specified in the first stage. Moreover, a project is carrying out in organized, distinct and in most cases lengthy stages which makes it difficult to verify results in the course of the project. Such way of working doesn't contribute to a culture of cooperation and ongoing communication and it has the negative impact of the end result of a project.

For example, Scrum methodology emphasizes working in sprints of 30 days and also focuses heavily on daily meetings. The strict role of the project manager does not exist. One interesting aspect is the way project teams are defined. There is no formal hierarchy in the teams; job titles are not given either. The team should be self-organized and self0-managed. Team members choose by themselves the project tasks according to collective agreements, their skills and other factors (e.g. time). People who work in one team cannot be involved in other projects.

Jovanović and Berić (2018) found that general characteristics of traditional methodologies (e.g., PMI, IPMA) make them more adequate to be implemented in larger and more complex projects such as: investment, military, manufacturing or overhaul. On the other hand, general characteristics of agile methodologies lead to a conclusion that these methodologies are more suitable to use for IT projects as well as for some smaller and less complex projects, such as devising various studies, project reports, etc. However, Pace (2019) indicated that project management methodology has a weak correlation with reported project success, and this correlation is moderated neither by industry nor by project manager experience. His results did not align with previously conducted studies.

The relationship of organizational culture features with the project management methodology is an interesting research problem. The above-mentioned features of "project management culture" such as, e.g., trust are so general that they will stimulate projects regardless of project management methodology used. Trying to assess a correlation between a culture and a methodology it is worth taking into account cultural differences which are highlighted in organizational culture typologies.

One can form the detailed hypothesis that the features of Agile project management are similar to so-called "clan culture" while the features of traditional project management are similar to "hierarchy culture" (Cameron and Quinn, 2011). Clan culture (CC) is connected with a friendly, almost family-like atmosphere. A manager is treated as a mentor. The glue of an organization is loyalty and tradition. The key to success is usually taking care of the needs of clients and employees. The values are teamwork, participation and consensus. Hierarchy culture (CCH) means a working environment which is structured and formalized. Employees use defined procedures in carrying out their everyday tasks. The values are effective coordination and order. The primary goal is to maintain effective functioning and stability, and the results are achieved through performing tasks efficiently. Success is defined by good planning and low costs. It seems that these culture types (CC and CCH) should remain the dominant types in the cultures of organizations managing projects in different ways (i.e. using traditional and Agile approach).

This leads to formulating the following research questions:

RQ1: What type of culture dominates in an organization which adopts a traditional approach to project management?

RQ2: What type of culture dominates in an organization which adopts a modern approach to project management?

At this point, it is worth noting the fact that in 2017, along with the new edition of PBOK, Agile became an essential element of traditional project management. PMI, in cooperation with Agile Alliance, developed the Agile Practice Guide to encourage a hybrid approach to project management (combining traditional and Agile approaches). Moreover, Andersen (2006) states that an organization should apply methodologies assigned to specific types of projects – i.e. different in the case of IT projects and different in the case of business projects (e.g. organization of employee training). Hence, the next question arises:

RQ3: What type of organizational culture occurs in the situation of hybrid or mixed project management methodologies?

Research Methodology and Results

As little is known about the relationship between cultural types and project management methodologies, a qualitative approach based on the case study method was chosen as an appropriate way of studying this phenomenon. The use of case studies to trigger new empirical and theoretical insights is a popular approach in the literature (see Mintzberg, 1979; Yin, 1981; Eisenhardt, 1991; Cepeda and Martin, 2005; Eisenhardt and Graebner, 2007; Siggelkow, 2007).

The empirical investigation is based on semi-structured interviews and conducted with project managers working in organizations which use different project management methodologies. Of a total of 6 semi-structured interviews (2 respondents from each organization), all were in-depth and in-person. They lasted about 2 hours. This is considered acceptable for the purpose of the present work (see, for example, Mintzberg, 1979; Guest et al., 2006; Eisenhardt and Graebner, 2007; Siggelkow, 2007). The term "organizational culture" was defined and the typology of cultures by Cameron and Quinn became the focus of the interviews. The interview questionnaire included The Organizational Culture Assessment Instrument based on the CVF. A description of the cases is presented below.

Case A

The company operates in the construction industry. The main business is residential housing, which includes single-family, multi-family and high-rise housing. The projects in residential construction are predominantly designed by architects and engineers, whereas their construction is carried out by the specialized construction companies which employ subcontractors to perform the construction, technical, electrical and other works (Hendrickson and Au, 2003). The number of people engaged in projects carried out by the company is more than 50. The timeframe for construction projects is about 2 years on average, and the scope of cooperation with external partners is huge.

Construction projects require large financial, material and personnel expenditures; therefore, almost every construction project is of a highly complex nature. Projects are delivered with the use of traditional methodologies. At the beginning, a detailed scope of the project is developed. Each project stage is divided into tasks with an assigned project team coordinator.

Construction projects consist of three general and four or five detailed phases. In the first case there are three phases: pre-investment, investment and liquidation. The second case includes a preparation phase, design phase and obtaining the necessary administrative permits and decisions, project implementation phase, as well as an investment settlement and commissioning phase. The third approach covers zero phase (the analysis of needs), feasibility study, designing, implementation and potential decommissioning (along with demolition and the subsequent recycling or environmentally friendly decommissioning of the building materials and reclamation of building plots).

Construction projects are burdened with high risk. Project success depends on external environmental conditions (e.g. weather). In construction project management, attention should also be paid to such factors as market behavior (e.g. the suppliers of equipment or construction materials), the condition of the national economy, the economic situation in the region and the availability of employees, which is usually problematic. All the above-mentioned factors result in the fact that the initial assumptions of a construction project frequently do not work in the course of its implementation, thus generating high financial costs as well as a delay in the implementation of the project. Finally, a construction project is standardized at every stage by the respective legal provisions and specific formal and administrative requirements. This standardization aims at implementing the project in accordance with construction law and, above all, delivering safety for its users. Special institutions are appointed to supervise the projects implemented in this industry.

The hierarchy culture dominates in the organization under analysis. This type of culture can be also identified as a type which fits the industry. The values are: effective coordination and organization. The primary goal is to maintain effective functioning and stability, and the results are achieved through performing tasks efficiently. Success is defined by good planning and low costs.

Case B

The company is relatively young; it operates in the IT industry and employs about 50 people. The Agile approach is used in software development projects. The company offers, e.g., accounting software, comprehensive systems for running online stores and auction services, and runs industry portals. Approximately 15 people are involved in projects carried out in the company. The timeframe for IT projects is about 6 months on average. The company do not cooperate with external partners in order to deliver project results.

The company represents a “Wholeness Teal Organization” (Laloux, 2014). It forms self-organizing project teams. The values typical for “Teal” are as follows: synthesis, collective individualism, collective consciousness and changes. The company employees jointly formulated such organizational values as openness, respect, trust, equality, cooperation, innovation. In addition, they defined behavioral patterns which correspond to these values. The organizational structure is based on a network of commitments and correlations.

Employees make collective decisions. A job candidate is always invited to meet the team he/she will be working with in the future. It is the team that decides if the candidate has the right skills and can be hired. More experienced members of the organization take on more significant roles which require greater responsibility, leaving simpler tasks to less experienced individuals. The remuneration rules and the related path of development were defined in the company by the employees themselves. In addition, many employees work on a teleworking basis. The money which in traditional organizations is used to maintain the headquarters (rental costs, office equipment, and electricity costs) in this case is spent on teambuilding.

The internal organizational culture is referred to as a process and quality culture. Bearing in mind the typology by Cameron and Quinn, it should be noted that clan culture is the dominant one in the organization. Some elements of adhocracy culture can also be noticed.

Case C

The organization represents a large bank. About 20 people are engaged in projects carried out in the company. The timeframe for projects is about 6 months on average. The scope of cooperation with external partners depends on the goal of a given project (e.g. the marketing department usually cooperates with

external suppliers, while IT projects are carried out with the use of internal human resources). Initially, the Waterfall approach was used in project management. In recent years it has changed – primarily in the methods of IT project development. The Agile approach has been implemented. However, numerous barriers have been noticed in the successful development of projects. Despite many years of working together, the employees had significant problems in carrying out their new roles, or even problems with transferring their current roles to the new model. Another barrier was the unavailability or insufficient availability of the internal clients, as well as communication problems. The dominant position of traditional methodologies in the organization is associated with certain employee habits. The implementation of novelty in the form of Agile moved them out of their comfort zone.

In addition, the organization had to meet the challenges in terms of ensuring the Agile model's compliance with the legal requirements applicable to bank operations. For example, the legal provisions (of the Polish Financial Supervision Authority) emphasize a strong and active role of the bank's management board in the decision-making process and in the organization of day-to-day operations. The Agile model assumes a limited role of the managing body. The management board is supposed to set the strategic goals, but without interfering or supervising e.g. the manner of their implementation. This raises the risk of considering the role and activity of the Management Board in the Agile model as both insufficient and failing to meet the supervision expectations. An obligatory element of implementing an effective bank management system by the bank's management board is ensuring the organizational structure adapted to the size and profile of the risk incurred and allowing the effective performance of tasks. An unbalanced and unstable structure may be considered as failing to comply with this requirement and hampering internal audits.

Currently, some of the projects implemented in the organization are based on the traditional project management methodologies, some are based on the Agile methodologies and others – in a hybrid manner. This approach results in organizational chaos. However, the hierarchical type still dominates in the bank culture. The cultural type identified as a second in this organization is the "market culture".

Discussion

As results from the above-presented cases, the traditional project management methodology is accompanied by hierarchical culture, while Agile approach is accompanied by clan culture. In the organization with hybrid and mixed project management methodologies, hierarchy is the dominat type of culture.

Construction projects integrate a large number of materials, raw materials and semi-finished goods which are processed using many different technologies, and serviced by many specialists and employees using various tools, machines and devices (Levy, 2002). As indicated earlier, such projects are burdened with high risk. In addition, their result affects not only the overall customer satisfaction but, above all, the safety of their users. The hierarchy culture supports the implementation of complex projects. Employees use the defined procedures in the course of performing their tasks – often resulting from the construction law regulations.

The analyzed IT company operates in a dynamic and creative sector. At the same time, a dynamic and creative approach is expected internally, i.e. from the employees. These characteristics are consistent with "adhocracy culture". However, the values of team work and participation in the decision-making process result in the dominating, in this case, "clan culture". Experiments and innovations allow development, but the entire team celebrates the success in the form of project completion. The presented features and types of cultures are consistent with the assumptions of the Agile manifesto, according to which:

- people and interaction should be favored over processes and tools,

- working software over extensive documentation,
- cooperation with a client over formal arrangements,
- responding to changes over following the plan.

Case A shows the relationship between the traditional project management approach and hierarchy culture while Case B shows the relationship between the Agile approach and clan culture (with added adhocracy culture). These cases allow the researcher to formulate a hypothesis: Hierarchy culture exists in organizations which use traditional project management methodologies. However, regarding the last company (Case C), despite a mixed approach to project management, there is no mixed culture consisting of hierarchy culture and clan culture. The hierarchy culture prevails in this organization. This company operates in the financial industry, which, similarly, to the construction industry, is characterized by numerous detailed legal provisions that have to be complied with (e.g. the Act on Banks or Loan Products). The hierarchy facilitates control, including the one carried out by the external supervisory institutions. At the same time, the organization focuses on financial results. Gaining a larger market share is considered success, which corresponds to "market culture". As indicated in the description of Case C, such culture has become an obstacle in the implementation of Agile project management methodologies and still remains the dominant one in the organization. Case C results in the following hypothesis: Industry is a mediating variable between project management methodology and the type of organizational culture.

Conclusions, limitations and directions for Further Research

This study investigates a subject that is rooted in two or three different disciplines: human resources management/organizational behavior and project management. This research contributes to knowledge by showing linkage between the type of organizational culture and the type of project management methodology.

At this point it is worth highlighting the limitations of the research process, which simultaneously provide indications for further research. The aim of the qualitative research approach is to "simplify, reconnect and redirect theory and practice" and accordingly provide new impulses (Lee, 1999, p. 166).

Firstly, only three case studies were presented. Two respondents participated in each study. Therefore, it is worth conducting in-depth research – also based on case studies, but covering a larger number of respondents (and addressing the question about culture to those who do not work in projects).

Secondly, the analyzed organizations function in various industries and each industry has unique features which affect the organizational culture. Therefore, a quantitative research, focused on a specific industry (e.g. construction), can be taken up. The author formulated two hypotheses which can be verified in further studies. Taking into account the identified impact of the industry on the type of culture in the last company under study, it is worth carrying out further research with the use of the industry as a mediating variable.

Thirdly, the research results identify the culture type which dominate in the course of conducting the research. Culture is subject to continuous changes. Perhaps in a year other culture types will dominate in the analyzed organizations. In addition, it is emphasized in the subject literature that the dominance of one culture type may prove to be a factor which negatively affect the business. Leaders should be able to balance inconsistent and competing demands, suggesting that high performance requires concurrent mastery of seemingly contradictory or paradoxical abilities (Yu and Wu, 2009). In contrast, cultures which are considered "imbalanced" tend to highlight values linked with rational goals (market) and internal process (hierarchy) cultures at the expense of values that characterize other cultures, thereby resulting in comparatively poor organizational performance (Denison and Spreitzer, 1991). Therefore, it is worth conducting long-term research covering many years of a given organization's operations.

Analysis and Evaluation of Education Costs in Romania - Methods and Techniques

PhD. Anca Leontina (PAPP) MARINESCU

West University of Timisoara, Romania
leoankm@gmail.com

Abstract

The cost of education may be the smallest monetary value belonging to the system inputs needed to reach a certain level of outputs. In order to understand the concept of cost of education, the notion of suitability of education must be understood in advance. There are two fundamental questions related to the educational adequacy concept: what is the amount of money that allows a school to provide its students with an adequate education and how the resources available in schools can be distributed so that all students receive an adequate education regardless of the circumstances in which the education process takes place.

Keywords: Cost, Education, Cost Analysis, Cost Evaluation, Quality Standards

JEL Classification: I_2, I_{25}

Introduction

The Romanian educational system is financed from public funds which determines the acceptance of more responsibilities. It is impetuous to keep track of data that will allow performance evaluation from a managerial point of view as well as from the point of view of system outputs in society.

The outputs of the system are difficult to quantify financially because most of the time the evaluation is done from the perspective of the knowledge acquired by the student evaluated through national exams and not necessarily from the point of view of its integration in production on the labor market.

The present paper presents the theoretical part and the functioning of the system.

The cost of education and the specific costs of education

At a very general level, the cost of education represents the minimum amount of expenditures needed to provide the student society with a certain level of theoretical and practical training, considered appropriate (Andrews, M., Duncombe, W., Yinger, J. (2002) Revisiting economies of size in American education: are we any closer to a consensus? Economics of Education Review, no. 21, pp. 245-262).

The cost of education may be the smallest monetary value belonging to the system inputs needed to reach a certain level of outputs. In order to understand the concept of cost of education, the notion of suitability of education must be understood in advance.

The adequacy of education can be seen as an absolute measure of how sufficient funding levels can be offered to enable students to learn at a higher quality level (Picus, LO (2000) Adequate Funding, in About School Spending: American School Board Journal , p. 34). Taking into account the above, one can observe the difference between the suitability and the equity characteristics, which are concentrated on the relative levels of distribution of funds. The existence of an adequate funding system should allow the identification of the resources necessary for schools to ensure equal

opportunities for students in achieving the quality standards existing at national level. Suitability should not be confused with equality, as students with special needs, for example, may need additional funds to reach the set quality level.

The adequacy of education has several definitions. From the point of view of system inputs, suitability refers to the number of teachers required to perform a certain task or to the skills that can be performed using specific resources (Myers, J., Silverstein, J. (2002) calculation of the cost of a suitable education in Montana in 2001-2002 using the Professional Judgment Approach, available at http://www.mtsba.org/study/Final%20Report.pdf, accessed 20.01.2020). Another definition regards adequacy as achieving a certain level of student performance in standardized national assessments (Haveman, M. (2004) Determining the Cost of an Adequate Education in Minnesota: Implications for the Minessota Education Finance System, available at http: / /www.mntax.org/cpfr/education.pdf,).

From the perspective of suitability, a model that identifies a certain required level of the amounts with which the education is funded offers only a starting point or a lower limit on the value of these funds.

Research (Norman, J. (2002) Funding our Future - An Adequacy Model for Wisconsin School Finance, Institute for Wisconsin Future, p. 26) has identified a number of steps that need to be taken to determine the need for funding from the perspective of adequacy, namely:

- Setting quality standards
- Determining the resources needed for schools to meet the previously established standards
- The monetary quantification of resources for determining the need for budgeted expenses
- Establishing the ratio between the level of expenditures and the available funds: in case the level of necessary expenditures is much higher than the available funds, it is necessary either to revise the standards or to adjust the level of expenditures in time to support the appropriate level of rewards.

There are two fundamental questions related to the conceptual adequacy of education: what is the amount of money that allows a school to provide its students with an adequate education and how the resources available in schools can be distributed so that all students receive an adequate education regardless of the circumstances in which the education process takes place.

Two categories of costs can be identified: costs related to the provision of educational services in order to meet the educational needs of the population (both general and specific) and costs related to increasing the performance level of students at a certain level, which vary according to the specific needs. students, and depending on the context in which the educational process takes place (Baker, J., Green, D. (2010) Politics, Empirical evidence and policy design, in Handbook of Education Politics and Policy. ed. Bruce S. Cooper, James G. Cibulka, Lance D. Fusarelli, pp. 311-337). It can be considered that the two categories of costs represent: costs related to the provision of educational services in order to meet the educational needs of the population (both general and specific), these may be related to the system inputs and the costs related to the increase of the performance level of the students at a certain level, which varies according to the specific needs of the students and depending on the context in which the educational process takes place may be related to the outputs of the system.

The factors that influence the structure of the specific costs of education are represented by the needs of the students, the size of the school or the territorial administrative units but also the geographical characteristics of the area in which the educational unit is located.

Difficulties in learning and low results in assessments may be associated with not meeting the needs of students. The needs of students can be differentiated into two categories: basic needs in terms of the educational process and special needs for minorities, students with disabilities or those from poor families.

Costs must identify needs as closely as possible and relate them to the resources needed to meet them.

An example of such special needs of students is that of students from poor families, who do not have access to the same learning experiences or resources that allow them to make the most of what is offered in the school. Under these conditions, the school together with local administrations must provide additional resources to compensate for these differences. A solution would be to employ more qualified staff, smaller school groups, extra-curricular programs financially supported by the Ministry of National Education or by local administrations. There may also be additional costs related to student mobility that may affect the total costs.

Students with disabilities are another example of students with special needs. Differences from a mental, physical or emotional point of view must be eliminated or diminished. Additional funds are needed to reduce or eliminate these differences. The size of the school units is also an important factor in the evaluation of costs. As long as an education unit operates below the optimum level in terms of number of students and the funds allocated to it are reduced. These aspects can be identified in rural areas where the number of students is low.

The geographical characteristics of the area in which the schools are located can cause differences in costs both in the costs associated with the teaching staff and in the costs associated with the expenses with the goods and services needed for the good educational instruction for each beneficiary of the education.

Concerns can be identified about determining cost estimation models since the 1970s when trying to estimate costs using a cost regression model of educational system outputs based on estimating the specific costs of reaching a specific level of student performance in reading and mathematics *(Garms , WI, Smith, MC (1970) Educational need and its application to state school finance, The Journal of Human Resources, vol. 5, no.3, summer, pp. 304-317)*. At the same time, equal opportunities in education is defined as the permission granted to all schools to provide at least a minimum educational standard with reasonable financial effort (*Garms, WI, Smith, MC (1970), op.cit. ,, page 304)*.

Methods of General Cost Analysis

Cost analysis has become an important tool in both performance evaluation and decision making in the education system in the context where the staff in the education system must have an increasing degree of performance with less funds, and at the same time need to provide as much tangible evidence as possible of the effectiveness of educational programs.

We can identify two rational reasons for using cost analysis. On the one hand, the existing budgetary constraints on the other, the educational policy makers and the leaders of the school units that face limited resources.

There are several approaches to cost analysis that answer different types of questions. A cost feasibility analysis can provide useful results when it is necessary to know the cost of a certain educational program or the possibility of implementing it in the context of a budget constraint.

To determine the usefulness or effectiveness of some programs, it is useful to use a cost-benefit analysis, or cost effectiveness or cost utility.

The multitude of terms associated with cost analysis (cost effectiveness analysis, cost benefit analysis, cost utility analysis, etc.) are used as synonyms in specialized literature even though each term represents a different method of analyzing economic information. Even if in practice the differences between the methods of cost analysis can be considered small, the assumptions from which each method starts are different (qualitative or quantitative) and the results are different.

The main steps required to perform a cost analysis within an educational program are presented in figure 1.1.

Figure 1.1 - Cost analysis steps
Sursa: Jennifer L. White, Craig A. Albers, James C. DiPerna, Stephen N. Elliott, Thomas R. Kratochwill, and Andrew T. Roach, Cost Analysis in Educational Decision Making: Approaches, procedures and Case Examples, p.3

Cost Effectiveness Analysis

In order to elaborate decisions, the cost effectiveness analysis is based on a systematic approach to the costs and consequences of their production. As HMLevin exemplifies, there are several ways of approaching how the goals of increasing student performance in math and reading can be achieved, for example, such as adopting a new curriculum, additional teacher training, computer-assisted instruction, diminishing the number of students in classes, etc. The cost-effective solution is to identify the costs and effects that their production has on increasing student performance for each chosen alternative, and ultimately choosing which alternative has the greatest impact on increasing student results in standardized tests *(Levin , HM (1995) Cost-effectivness Anaysis, International Encyclopedia of Economics of Education, 2nd ed. Oxford: Pergamon, pp. 381-386).*

Both cost-effectiveness and cost-benefit analysis are methods of evaluating the resources used in some alternatives, and quantifying costs. However, unlike the cost and benefit analysis method, only alternatives whose outputs can be quantified monetarily are considered in the cost effectiveness analysis.

The purpose of practicing cost effectiveness analysis is to determine the minimum cost at which an educational program can achieve its objectives and the hypothesis from which the method development started is that each alternative is associated with both different costs and different outcomes. Moreover, cost minimization results in a more efficient use of society resources, which allows the development of other aspects of education.

Prior to carrying out the cost analysis, it is necessary to know the problem for which it is necessary to elaborate a decision, the alternatives considered as well as their potential effects. After the problem is formulated, it is necessary to evaluate the effectiveness of the considered alternatives, in this sense being needed concrete dimensions and measures of the effectiveness. (Table 2.1) Then, formulating alternative programs is the next step that opens the way for evaluating the effectiveness of these alternatives. As a methodology, standard methods of evaluation, or previous results of similar evaluations, can be used. What is important to keep in mind is that efficiency assessment is not synonymous with cost evaluation *(T.D., Campbell, D.T. (1979) Quasi-Experimentation. Houghton Mifflin, Boston, Massachusetts).*

By definition, the cost of an alternative represents the value of the resources that the company gives up for the alternative to become possible. Thus, the total cost is the representation of social value, and this total cost is subsequently broken down and distributed over the entities that make up the educational system.

Table 2.1.: Measures of effectiveness

The objectives of the program	Measures of effectiveness
Program completion by students	The number of students completing the program
Reducing the number of students who drop out of the program	The potential number of dropouts that do not occur
Employing graduates	The number of graduates employed
Student learning	The results of standardized tests
Student Satisfaction	Program evaluation is for students
Physical performance	Assessment of the physical condition of the students
Continuation of university studies	Number of students enrolled in the university cycle

Source: Levin, H.M. (1995) Cost-effectivness Anaysis, International Encyclopedia of Economics of Education, 2 ed. Oxford:Pergamon, p. 383

Cost estimation can be done by analyzing the component elements of the considered alternatives, which involves identifying these components, determining their cost and total cost and analyzing these costs by following a certain decision-oriented evaluation framework. Most alternatives include as workforce components, equipment, materials, deployment areas, etc. The level of detail of these components must be adequate to guarantee the inclusion of all necessary resources and their value. As sources of data for this stage are used interviews, observations or different existing reports.

The effectiveness analysis that follows the previous step must take into account the suitability of the unit of cost expression and the cost payers. Generally, the effectiveness in education is evaluated in relation to the sizes associated with the students (the number of students who…) which naturally leads to the determination of a cost per student, obtained by dividing the total cost by the number of students. Another way to evaluate the effectiveness of education is the effectiveness rates that are based on the average effects of the analyzed programs and on the cost per student, or the use of the marginal cost. The most widely used measure of cost effectiveness is the efficiency rate obtained by reporting cost effectiveness.

The final stage of the effectiveness analysis is that of comparing the alternatives in terms of cost intensity, separated into fixed costs and variable costs, intensity which differs significantly depending on the number of students enrolled in the programs.

The content of the education program is one of the most frequently analyzed areas in terms of effectiveness, followed by the additional training of teachers.

Cost-Benefit Analysis

Cost-benefit analysis has been defined as a practical way of assessing the desirability of projects, where a long-term and broad vision is needed which involves listing and evaluating all relevant costs and benefits *(Perst, AR, Turvey, R. (1965) Cost-benefit analysis: A survey, The Economic Journal, 75, pp. 683-735)*. The method dates from the early 20th century, and has been extended over time to all areas of public sector investment and beyond. In the area of education, the method was applied to investments in education where it became known as the rate of return analysis *(Cohn, E., Geske, T. (1990) The economics of education, Pergamon Press)*

The cost-benefit analysis must adhere to a number of principles, namely:

- The existence of a common unit of measure
- The assessment of costs and benefits must present consumer or producer assessments that reflect their current behavior
- The measurement of benefits is made through market options
- The gross benefit of increasing consumption is below the demand curve
- Certain measures of benefits require the evaluation of some component elements of human life
- Avoid double-suming of costs or benefits
- Establishing some decision criteria for projects

If in terms of costs these can be relatively easily identified, the same cannot be said about benefits. Determining the benefits of education starts from a philosophical approach to the purpose of education and the ways in which it can be achieved. Since Greek antiquity, education has been considered as centered on the moral fulfillment of individuals and the welfare of the society in which they live. Recent studies have shown that education contributes both to better performance of individuals in the labor market but also to improving their health, promoting an active civic attitude and reducing violence. It has been shown that educated people tend to live longer, the data revealing a strong association between life expectancy and education level. Educated people tend to be more involved in civic activities just as they tend to be happier.

The main output of the educational system is the information and skills transmitted to students, which they will use throughout their life. School is the place where students learn what adults already know, and is the place where knowledge transfer takes place. The content of the learning is determined by the specialized research, the practical needs and the experience of the teachers. Learning and skills development takes place by gathering and evaluating new information that is transmitted to students, which leads to an increase in their intellectual capacity resulting in an improvement in the intelligence level of the population *(Husen, T., Tuijnman, A. (1991) The Contribution of Formal Schooling to the Increase in Intellectual Capital, Educational Researcher, 20 (7), pp. 17-25)*. Through the school, the differences between the different categories of students considered disadvantaged and those who do not fall in this category are reduced.

One child's education contributes to the well-being of others by ensuring a stable and democratic society *(Husen, T., Tuijnman, A. (1991) The Contribution of Formal Schooling to the Increase in Intellectual Capital, Educational Researcher, 2007, pp. 17-25)* . This is why governments invest considerable amounts in education because of the responsibility that the school has for the individual development of students but also for economic and social well-being *(Feinstein, L., et al. (2006) What has the Effects of Education on Health ?, in Measuring the Effects of Education on Health and Civic Engagement: Proceedings of the Copenhagen Symposium, R. Desjardins and T. Schuller, Eds, OECD, Paris, France, pp. 171-353).*

An educational system with a high level of quality and efficiency offers significant benefits to individuals who are aggregated within communities and which in turn generate major social and economic benefits. The dropout rate affects the unemployment and implicitly the consumption of social assistance funds, the crime rate is low among the educated people, as well as the mortality rate.

The synthesis of the main characteristics and particularities of the methods of cost analysis are presented in table 2.2.

Table 2.2: Particularities of the methods of cost analysis

Analysis method	Main features
Basic cost analysis	- answers questions about the financial viability of a program in terms of overall costs -It is used to describe economic data - describes distributions to both real and adjusted costs that are necessary for the implementation of a particular program - is the most limited form of cost analysis - does not take into account the benefits of the program - it is useful in the planning phase of a project but does not allow comparisons between programs
Cost feasibility analysis	- answers questions about the financial viability of a program - is useful in the elaboration of the decisions regarding the described economic data - is used to determine the extent to which a program can be successfully implemented under the conditions of budgetary constraints - allows the evaluation in non-monetary terms (decrease of the instructional time, increase of the number of students of a class, etc.)
Cost effectiveness analysis	- answers the questions related to the effectiveness of a particular program compared to other programs - allows comparisons between programs especially when the comparison is made according to a single criterion such as progress in the results of national assessments on a particular subject
Cost-benefit analysis	- is used to compare programs that may have different purposes or structure - Cost is defined in monetary terms
Cost utility analysis	- allows comparisons between educational programs with different measures of outputs, using conceptual utility - the cost is not necessarily defined in monetary terms - the definition and operationalization of the notion of utility is made in relation to the beneficiaries of the information provided - is a subjective method of evaluation

Methodology specific to the analysis of costs in education

The analysis of the costs generated by the educational system implies the completion of a series of stages that we present in the following:

a – Defining the specific parameters of the evaluation

When evaluating an educational program, evaluators should consider the level at which the program is feasible and ensure that the assessment is conducted in a prudent and realistic manner. For this purpose it is necessary to define the parameters of the evaluation taking into account the available resources, the information needs as well as the nature and number of outputs related to the program. Depending on these parameters it can be determined which method of cost analysis is appropriate. Determining the appropriate method must go through the following steps *(Levin, H.M., McEwan, P.J.*

(2001) Cost-effectiveness analysis: Methods and applications, Thousand Oaks, Ca, Sage Publications):

- Formulate specific questions for evaluation
- Determining the suitability of an economic evaluation
- Selection of alternative evaluation programs
- Identification of the beneficiaries of the evaluation results and their informational needs
- Selecting the most appropriate cost analysis method

b. Formulation of research-specific questions

In order to determine the cost analysis form, it is necessary to clearly formulate the questions to which the research undertaken must provide an answer. In this way, it is possible to effectively plan the collection of the data needed for the study, and depending on the nature of these questions, the most appropriate form of cost analysis can be determined which can answer these questions.

Table 2.3 presents some specific questions for the evaluation of the educational programs as well as the methods of analyzing the most appropriate costs.

Table 2.3: Choosing cost analysis methods in relation to research questions

Evaluation / research questions	Forms of cost analysis
What is the cost of the program and what is the cost distribution	Fundamental cost analysis
Can the program be implemented under budgetary constraints?	Cost feasibility analysis
Which program offers the highest efficiency at the lowest costs?	Cost effectiveness analysis
Which program offers the most benefits at the lowest costs?	Cost-benefit analysis
What is the program with the highest utility and lowest costs?	Cost utility analysis

Source: own systematization

c. Determining the adequacy of the economic evaluation of the educational programs

The adequacy of the economic evaluation of the educational programs must be interpreted in terms of feasibility and usefulness. Even if any educational program can be subjected to a cost analysis, it is not always appropriate to evaluate the economic edicacity of program outputs. Evaluation may not find its usefulness when its likely outcomes are no greater than the costs of performing that evaluation *(Scriven, M. (1974). Evaluation perspectives and procedures. In JW Popham (Ed.), Evaluation in education: Current applications Berkeley, CA: McCutchan).*

d. Selection of alternative programs used in the evaluation

After formulating questions and choosing the most appropriate method of cost analysis, it is necessary to identify a benchmark for comparing the results of the evaluation. Thus, it is necessary to identify a large number of programs from which a reasonable subset will be chosen for analysis *(Hopfenberg, W.S., Levin, H.M., Chase, C., Christensen, S.G., Moore, M., Soler, P.L., et al. (1993). The accelerated schools resource guide. San Francisco: Jossey-Bass).*

e. Determining the limits of the evaluation

The limits or boundaries of the evaluation can be identified considering the nature of the program or the nature of the policies related to it, determined by the initiator of the program (the ministry of

education, the school inspectorate, the municipality, etc.). The main limits can be imposed by time, context and the group of beneficiaries of the evaluation.

f. Identification of the beneficiaries of the evaluation results

Identifying the beneficiaries of the evaluation is one of the most important steps in defining the purpose of performing a cost analysis. Depending on the number of these beneficiaries and their decision-making power, the depth of the resource evaluation is established, which may vary depending on different parameters.

g. The actual cost analysis

After defining the parameters of the evaluation, the analysis of the costs represents the process of collecting and organizing the information about the resources necessary for the implementation of an educational program or an educational policy *(Barnett, WS, & Escobar, CM (1990). Economic costs and benefits of early intervention. In SJ Meisels & JP Shonkoff (Eds.), Handbook of early childhood intervention, New York: Cambridge University Press, pp. 560-582). Cost is defined as the value of all the resources to be used by a program and which can be allocated to it (Levin, H.M., McEwan, P.J. (2001) op.cit).*

Regardless of the form of cost analysis used, it involves more than just cost accounting or budget analysis. Performing a simple budget analysis is not appropriate for the cost analysis because within the budgets all the information regarding the total costs involved by a program, such as donations, volunteering services, etc. is not specified. Also, the budgets are made up of a period of one year, which may be shorter than the period of the development of an educational program and most often reflects the way of the distribution of expenses, at the expense of highlighting the way of spending the available funds.

Conclusion

The reporting of the expenses in education is carried out by categories of expenses.

A traditional approach to the way in which education expenses are reported is by category of expenses: expenses with staff in education, expenses with auxiliary staff, material expenses, etc. This type of approach can be considered effective when it comes to a simple entity, and it has been used until the role of education has been extended from providing simple instruction to providing social services. Thus, there was born the need to report expenses by functional categories: instruction, educational support, administration, other operations, etc. Another cause that led to the need to differentiate the expenditure by certain categories in order to understand them was the recognition of certain categories of population with special needs, such as students with deficiencies, students from economically or socially disadvantaged families, minorities. and so on Thus, the users of financial information specific to the pre-university education system (directors of educational units, persons involved in the elaboration of educational policies, taxpayers, parents) have focused their attention on understanding how the amounts allocated to education are spent on general educational activities, special education, vocational education, education of children with special abilities or primary education. The interest of these users of information is also related to the benefits generated by spending the amounts allocated to education, reflected in the students' performances or social benefits.

Reporting the data related to the specific expenses of the pre-university education system on objects was thus useful until the complexity of the educational and social policies increased. At present, the reporting of expenses by categories of objects (salaries and related contributions, suppliers, materials) is important only in the context of the functions served (educational, administrative, support activities). In order to evaluate the performance or productivity of the pre-university education system, however, it is necessary to establish how the allocated resources are organized to ensure the provision of specific services.

The determination of a model for the allocation of resources on educational areas must start from useful and consistent data. One of their main dimensions has to be the comparability of the data, a unitary reporting system that is based on common standards and definitions consistent in time and space. Also, in order to ensure the usefulness of the information, the data related to the resource allocation templates must contain useful information to the social and educational policy makers whose task is to determine new ways to improve the performance and productivity of the education system. All these arguments justify the need to classify, organize and measure resources in a way that helps to understand the impact they have on the outputs related to the education system.

The Identification of Changes in Employment Shares in The Sections of Knowledge-Intensive Services – Dynamic Classification of The European Union Regions

Małgorzata MARKOWSKA

Wroclaw University of Economics and Business, Wroclaw, Poland
malgorzata.markowska@ue.wroc.pl

Abstract

Service sector is an important component of the global economy – a complex and dynamically evolving entity. In the globalizing economy, including the European Union countries and regions, the service sector importance in creating GDP or value added is growing. The employment number is increasing, however, this increase presents a different dynamics in the individual sections identified in this sector. The pace and direction of these changes result from many factors including economic, social, cultural and historical ones. A special role, due to the growing importance of knowledge in the economy, is played by the sections in which knowledge is intensely used.
The purpose of the research carried out within this study was to identify and assess the changes in employment shares in the sections of knowledge-intensive services. The research procedure was based on the dynamic classification method. The studied objects were the European Union regions at NUTS 2 level. Due to the current availability of complete data, the analysis period covers the years 2008-2018.

Keywords: dynamic classifications, European Union, employment, knowledge-intensive services, NUTS 2

Introduction

The European Union is a complex socio-political structure which, at the regional level, consists of almost 300 NUTS 2 units, presenting extensive diversity in terms of population, area, location, history and culture as well as the level and pace of changes in economic structures. The regional economy consists of economic entities and the network of correlations and mutual connections between them. The entities constituting the regional economy, i.e. enterprises, organizations, institutions and other units conduct business activities or are involved in developing economic relations and, at the same time, operate at higher than local levels, i.e.: countries, continents, regions of the world or at the global level. The dynamics of the regional economy and the system of structural correlations are of significant importance. The occurring changes result in permanent evolution. The pace and direction of changes is influenced by the initial status – historical conditions allowing the development of the components within economic structures.

In 2018, almost 230 million people were employed in the European Union. The increase in total employment (from 222.8 million in 2008) was accompanied by the employment decrease in most sectors – excluding services. In 2008 the service sector employed 149.4 million people (67.0% of the total number), and 164.1 million (71.4%) in 2018. The years 2008-2018 were also characterized by higher employment shares in individual service sections identified based on the intensity of knowledge used: in knowledge-intensive high-technology services from 2.6 to 3.0%, in knowledge-intensive market services (except financial intermediation and high-technology services) from 5.6 to 6.5%, and in other knowledge-intensive services from 25.7 to 27.8% (Eurostat, 2020). The diversification of employment shares in service sections is significant – and changes over the years – in the European Union countries, this also applies to the EU regions at NUTS 2 level. It seems interesting to focus on identifying the groups of regions similar in terms of the level of employment shares and the scale of percentage changes using the dynamic approach.

The purpose of the research was to identify and assess the changes in employment shares, in the sections of knowledge-intensive services, in the European Union regions at NUTS 2 level using the dynamic classification method. Such a aim makes possible to answer the question whether we can identify groups of regions similar from the point of view of starting level and changes in employment shares in high knowledge intensive services, in the analysed period.

Brief Research Survey

The importance of service sector in the economy is undeniable. In addition to higher number and percentage of employment in services, also an increase in this sector efficiency and GDP share in the global economy can be observed (Buckley and Majumdar, 2018; Attiah, 2019). The service sector and the individual sections identified within this sector represent the dynamically developing elements of the economy. Therefore, they constitute an important segment of interest for the researchers. Textbooks and their subsequent volumes are published, such as the Handbook of Service Science (Maglio et al., 2019). The book edited by P. Wood (2004a) assesses the national context, structure and trends, restructuring processes and impact on the development of knowledge-intensive services (KIS) based on the example of historical data for such countries as e.g.: France (Farcy, Moulaert and Gallouj, 2004), Germany (Strambach, 2004), Italy (Cavola and Martinelli, 2004), United Kingdom (Wood, 2004b), Spain (Rubalcaba-Bormejo and Cuadrado-Roura, 2004). The addressed problems also include: the diversity of processes and policies (Wood, 2004c), spatial divisions of knowledge-intensive business services (KIBS) and regional development (Bryson and Rusten, 2005), the organizational and territorial changes of services (Hermelin and Rusten, 2007), the service industry research imperative (Beyers, 2012). Additionally, the typologies of services are an important element of the conducted research (Glückler and Hammer, 2011, 2013). In the perspective of the EU regions, the research covers, e.g.: the determinants of market extension in KIBS (Bettiol at al., 2015), localization of business services (stand out large urban areas) (Camacho-Ballesta, Melikhova, Hernández-Peinado, 2014), specialization in KIBS across Europe and permanent co-localization (Gallego and Maroto, 2015), regional significance of knowledge-intensive business services (Wood, 2006), geographical distribution and regional specialization (Delgado-Márquez and García-Velasco, 2013). From the short literature review – limited by the size of the paper – of the research approaches, we can see the multi-aspect treatment of employment structure changes, and the sector of high-intensive knowledge services as the important subject of these research.

Method: Dynamic Classification

The research conducted within the framework of the study – spatio-temporal cluster analysis – was carried out using the following scheme (Markowska, 2012):

1/ determining the set of diagnostic variables, the analysed objects and time range based on the subject literature,;
2/ collecting data and (possibly) supplementing the missing data;
3/ preliminary analysis of the set of variables;
4/ ensuring comparability of the variables, if necessary (the data presented as shares do not require normalization);
5/ global standardization using the arithmetic mean and standard deviation determined for each variable from all analysed periods;
6/ using Ward's method (Ward, 1963) to determine the number of clusters;
7/ applying k-means method (Steinhaus, 1957; MacQueen, 1967) in the classification of objects;
8/ assessing the composition and changes within the groups,
9/ estimating the group centre based on dynamic data – to determine the objects typical for individual clusters.

The objects stand for the operational taxonomic units (OTUs) in the proposed [YT,Z] system. It means that each object, in each unit of time is approached separately, and their configuration is subject to assessment in the space defined by the selected characteristics.

Variables, Countries, Regions and Research Period

The following variables were used in the assessment of changes in employment structure in the sections of knowledge-intensive services (htec_emp_reg2) (Eurostat, 2020):

S_1 – employment in knowledge-intensive high-technology services (percentage of total employment),
S_2 – employment in knowledge-intensive market services (except financial intermediation and high-technology services) (percentage of total employment),
S_3 – employment in other knowledge-intensive services (percentage of total employment).

The initial assessment, constituting the background of the conducted analyses, used the data referring to 28 countries of the European Union, and the detailed study covered 272 out of 281 EU regions at NUTS level 2 (96.8%) – excluding two Spanish (Ciudad Autónoma de Ceuta, Ciudad Autónoma de Melilla) and Portuguese (Região Autónoma dos Açores, Região Autónoma da Madeira) and also five French (Guadeloupe, Martinique, Guyane, La Réunion, Mayotte) regions due to no available data (Regions, 2018). The summary of basic characteristics covering the analysed countries and for regions is presented in Table 1.

Table 1: Basic statistics of variables – EU countries and regions

Source: author's calculations based on Eurostat data

The overview of data referring to the employment shares in the assessed sections shows as follows:

– the highest share of employment in knowledge-intensive high-technology services in 2008 referred to Sweden and Finland, and in subsequent years to Ireland;
– the lowest share of employment in section S_1 was recorded in Romania in 2008-2014 and in 2018, whereas in 2015-2017 and in 2018 in Greece;
– the highest share of employment in knowledge-intensive market services was observed in Sweden in 2009-2018 and in Luxembourg only in 2008;
– the lowest share of employment in sections S_2 and S_3 occurred in Romania
– the highest share of employment in other knowledge-intensive services in 2008 and in 2015-2018 took place in Sweden and in 2009-2014 in Denmark;
– standard deviation is almost always present for the variables identifying the use of knowledge – at country level;
– declining diversification at the country level – assessed using the coefficient of variation and the correlation of outliers.

In terms of the changes in the diversity of employment shares in knowledge-intensive sections, the standard deviation (as opposed to the correlation of outliers) increased in the first two sections, and dropped in the third one, while the coefficient of variation (determining the diversification) decreased in each of the analysed sections. Regarding the outliers, the highest employment shares, in the case of the analysed sections, refer to:

– S_1 – British regions: in the years 2008-2010 and 2013-2014 Berkshire, Buckinghamshire and Oxfordshire, in 2011 and in the years 2015-2017 Inner London – West, in 2012 Outer London - West and North West, and in 2018 the region of Bratislavský kraj,
– S_2 – in the years 2008-2014 and 2016-2018 in Inner London – West, and in 2015 in Stockholm

– S_3 – Prov. Namur (2008-2012, 2014, 2016-2017) in the years 2013 and 2018 of Övre Norrland region, and in 2015 in Limousin.

In turn, the lowest employment shares were recorded for (the years are presented in brackets):

– employment in knowledge-intensive high-technology services (percentage of total employment), in the Greek region of Thessalia (2008-2009 and 2015), French Franche-Comté (2011-2013), Romanian Nord-Est (2010), Hungarian Észak-Magyarország (2014 and 2016), and in the last two years of the assessment in the Greek Anatoliki Makedonia, Thraki,
– employment in knowledge-intensive market services (except financial intermediation and high-technology services) (percentage of total employment), w Romanian regions: in 2008 in Nord-Vest, and in the years 2009-2018 the region of Nord-Est,
– employment in other knowledge-intensive services in the following Romanian regions: Sud – Muntenia (2008), Sud-Vest Oltenia (2009-2011), Nord-Est (2012 and 2015-2018), Vest (2013-2014).

Results of Spatio-Temporal Cluster Analysis

In order to carry out the above described "research path", the variables were standardized and the taxonomic units were analysed. Ward's method was used to determine the number of groups – the full dendrogram is shown in Fig. 1a, and its "lower part" – which allowed better assessment and visualization of the groups' number selection, in Fig. 1b.

Fig. 1a: Ward's full dendrogram for EU regions

Fig. 1b: Ward's lower part of dendrogram for EU regions

Source: author's compilation based on Eurostat data

The preliminary assessment shows that the most accurate number of subgroups is 6 – although the reduction in the critical agglomeration distance would already result in eight groups, of which two (the ones on the right side of the dendrogram would be small).

The final division of regions was performed using the k-means method, and the number of groups (the classification covers taxonomic units, hence such large numbers) is shown in Table 2.

Next part of the study – Table 3 – presents acronyms and names of the regions included in the given group for at least 10 years (i.e. over 90% of the studied period) and average distances from the centre of the group, calculated based on the years in which the region was in the group. The regions including the capital or being the capital are marked in bold and the regions from Central and Eastern European countries are shown in grey boxes.

Table 2: Characteristics of clusters of EU regions

Group	Number of taxonomic units	Percentage of all	Number of regions 10 or more times in a group (core)	Percentage of core regions in a group
1	526	17.58	26	4.94
2	386	12.90	25	6.48
3	682	22.79	36	5.28
4	668	22.33	37	5.54
5	561	18.75	36	6.42
6	169	5.65	12	7.10

Source: author's compilation.

Groups 3 and 4 are the most numerous – regarding OTUs they include, followed by groups 5 and 1. However, in terms of the share of taxonomic units present relatively the longest in the group in relation to the number of OTUs in the group, the groups 6, 5 and 2 were indicated.

In the first five clusters there are between 25-37 core regions, and in the sixth group there are only twelve of them.

Discussion

All three variables selected for the analysis present a very good discriminatory capacity. While comparing average groups, in the analysis of variance all *p* values equal 0.0000. Mean values of W for groups is presented in Table 4.

Table 4: Mean values in clusters

Group	Mean values		
	S_1	S_2	S_3
1	2.39	6.16	23.63
2	4.40	8.67	31.26
3	1.64	4.36	28.72
4	2.40	5.76	34.60
5	1.33	3.58	20.06
6	7.10	11.51	29.11

Source: author's compilation.

Certain outliers are present in the last three groups of regions. The fifth group is particularly unfavourable in this case – all shares in the analysed sections are the lowest. The fourth group is distinguished by the highest share of employment in other knowledge-intensive services, whereas the sixth group by the highest share of employment in knowledge-intensive high-technology services and in employment in knowledge-intensive market services. Among the first three groups of regions, the

second group stands out – the highest share of employment in the assessed sections. The third group is characterized by the smallest share of employment S_1 and S_2 (out of the three groups). Figure 2 can be helpful for interpretation purposes.

The list presenting core regions assigned to groups divided into countries is shown in Table 5. And so:

1/ in the first group, out of 26 core regions there are ten Italian, three German and two Spanish and Austrian regions,
2/ out of 25 regions included for ten or more years in group two, it covers six British regions, five German, four Dutch, three Belgian and two Swedish ones,
3/ the core of the third group consists of 20 German, five French, four Hungarian and three Spanish regions,
4/ in the fourth group (the highest average level of variable S_3) out of 37 regions included in it for at least 10 years there were 17 British, five Belgian and French, four Swedish and three Danish regions,
5/ among 36 core regions in the fifth group (the lowest average levels of each variable) there were as many as 30 regions from Central and Eastern European countries (11 Polish, seven Romanian, four Bulgarian and Czech, two Hungarian and one from Slovakia and Slovenia). Additionally, four Greek and Spanish and Portuguese regions also belong to the core regions in this group.

Source: author's compilation.

In the least numerous sixth group (169 OTUs) every twentieth EU region at NUTS 2 level was listed, including 12 regions present in this group for at least 10 years, out of which ten are the capital regions (including some of the capitals – London: UKI3, UKI4 and UKI7) or including the capital. Central and Eastern European countries were represented by Polish, Czech and Hungarian regions. In this group the average level of S_1 and S_2 variable was the highest and the third highest regarding the value of S_3 variable.

Conclusions

Based on the conducted research, the following conclusions can be formulated. It was possible to conduct the research for the majority of the EU NUTS 2 level regions (272 out of 281) – the availability of complete or possible to supplement missing statistical data. Correlations of outliers decrease for employment shares in knowledge-intensive high-technology services and in knowledge-intensive market services in the EU countries and regions. In the EU countries and regions, the coefficient of variation (determining diversification) decreased in each of the analysed sections, and variables selected for grouping are highly discriminatory. In the identified six groups of regions, the core regions amounted to 172 out of 272 (63.3% of the assessed regions), i.e. the ones which remained in the same group for at least 10 years. In many cases half or almost half of the regions in a given country are included in the same group: Italian in the first; German in the third; Swedish, Belgian, British and Danish in the fourth; Polish, Bulgarian and Czech in the fifth, which may confirm either well-established or changing in a similar way employment structures in knowledge-intensive sections.
Regarding the regions from post-socialist countries, the impact of many years outside the sphere of market economy is still visible (historical determinants).

The proposed research procedure, applying global standardization (i.e. using the arithmetic mean and standard deviation defined jointly for each variable from all analysed periods) allowed identifying the groups of EU regions at NUTS 2 level characterized by: 1/ similar initial level of employment share in the analysed service sections presenting different knowledge intensity; 2/ similar changes of share in the discussed sections in the assessed period.

Results of this research, including the identified groups of regions with similar employment structures in the analysed sections – especially with low shares – are important tips for decision makers in the field of regional policy. They can be used also as a tool for evaluation of EU cohesion policy – cluster

membership and regions' movement between clusters. The further research should concentrate on finding the relations between employment shares in KIBS and foreign investments, measuring economic potential in identified groups of regions, and comparing employment structural transformations in selected groups. The results could be compared with findings from some recent papers (Koutský, et al. 2014; Hlaváček, 2015; Hlaváček, et al. 2019).

Acknowledgements

The study carried out within the framework of the project no. 2015/17/B/HS4/01021, entitled Smart growth vs. sectoral transformations in the European regional space – measurement methods, financed by the National Science Centre.
