Proportionality is one of the main concepts of distributive justice. It assumes that acknowledgement of differences among participants in division is fair and that allocation of goods is performed in proportion to those differences. In other words, participants in division are treated equally as regards the amounts of their claims, i.e. there is an equal amount of allocated goods for each unit of claims. In case of allocation of indivisible goods, when the accurate proportion is not integer, and thus workable – what happens mostly in practical applications – some integer approximations are applied. However, in some cases one consciously gives up proportionality and unequal, with respect to amounts of claims, treatment of participants in division is acknowledged as just. One of such approaches is known as so-called degressive proportionality which allows unequal treatment of agents with regard to their claims whereas the inequality is directed towards favorable treatment of agents with smaller claims. The source of the problem and resulting terms is the European Parliament and the apportionment of seats among Member States, hence a majority of the first subject matter literature considers it in this context. Since the problem was strictly practical, initially the goal was to find a method of determining the degressively proportional apportionment of seats in the European Parliament. Over time, however, it turned out that the problem is much more complex than expected. As a result, no specific method has been indicated so far and in the meantime the term has been redefined three times.

The purpose of the paper is to present different interpretations of degressive proportionality together with the threats and problems resulting from the lack of its strict formalization. Analysis of each of the interpretation indicates the relationships between them.

Strong Degressive Proportionality

The most "radical" interpretation of degressive proportionality not only assumes unequal treatment of agents, but also increases inequality as claims of agents increase. Therefore, this interpretation is called a strong degressive proportionality. It is defined as follows (Cegiełka, 2011).

Definition 1.

A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i \in \mathbb{N}_+$, is strongly degressively proportional with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1 \leq p_2 \leq \cdots \leq p_n$, if:

(1) $s_1 \leq s_2 \leq \cdots \leq s_n$,
(2) $\pi_1/\sigma_1 \leq \pi_2/\sigma_2 \leq \cdots \leq \pi_k/\sigma_k$,
where for $i=1,2,\ldots,n-1$, $k \leq n-1$,

$$\frac{\pi_i}{\sigma_i} = \begin{cases} \dfrac{p_{i+1}-p_i}{s_{i+1}-s_i} & for \quad s_i \neq s_{i+1} \\ \dfrac{p_{i+j}-p_i}{s_{i+j}-s_i} & for \quad s_i = s_{i+1} = \cdots = s_{i+j-1} \neq s_{i+j} \end{cases}.$$

In terms of division of goods, s_i and p_i denote the amount of allocated goods and the amount of claims, respectively, of the ith participant in division (among n agents). The idea of fairness contained in the above definition simply states that each successive good corresponds to a greater amount of claims. Such approach originates from the first attempt to systemize the apportionment of seats in the European Parliament conducted in 1992 at the meeting of the Council of Europe, where the following algorithm was proposed (Lamassoure, Severin, 2007).

1) Each state receives 6 seats.
2) States with a population of 1 to 25 million receive a mandate for every 500 thousand citizens.
3) States with a population of 25 to 60 million receive a mandate for every million citizens.
4) States with a population exceeding 60 million receive a mandate for every 2 million citizens.

The proposed pattern was never strictly applied (Lamassoure, Severin, 2007), nevertheless it indicated the main idea of strong degressive proportionality – each successive mandate corresponds to a greater number of represented inhabitants (of course, s_i and p_i denote the number of allocated mandates and the population of the ith Member State).

It is worth noticing that the method proposed in 1992 not only tries to give a recipe for the distribution of seats in the European Parliament, but also establishes a lower bound for the number of mandates for the least populated state. According to point 1 of the algorithm each state receives at least 6 seats. Such a limitation is currently called a boundary condition.

Degressive Proportionality

Another interpretation of degressive proportionality no longer increases inequality when dealing with agents as their claims increase. In this approach degressive proportionality is defined as follows (see for example (Cegiełka, 2016), (Cegiełka et al., 2018), (Łyko, Rudek, 2017)).

Definition 2.
A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i \in \mathbb{N}_+$, is degressively proportional with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1 \leq p_2 \leq \cdots \leq p_n$, if:
(1) $s_1 \leq s_2 \leq \cdots \leq s_n$,
(2) $p_1/s_1 \leq p_2/s_2 \leq \cdots \leq p_n/s_n$.

Such interpretation of degressive proportionality originates from legal regulations concerning the division of mandates in the European Parliament imposed in 2007 by the Lisbon Treaty. Article 1 point 15 of this Treaty states that: "*The European Parliament shall be composed of representatives of the Union's citizens. They shall not exceed seven hundred and fifty in number, plus the President. Representation of citizens shall be degressively proportional, with a minimum threshold of six members per Member State. No Member State shall be allocated more than ninety-six seats*" (Treaty of Lisbon, 2007). The article indicates the form of citizens' representation as degressively proportional, but no precise definition of degressive proportionality is given. A more detailed description of degressive proportionality was contained in the Report of the Committee on Constitutional Affairs and the European Parliament Resolution. According to the Report the principle of degressive proportionality was supposed to be understood as follows.

[European Parliament] *"considers that the principle of degressive proportionality means that the ratio between the population and the number of seats of each Member State must vary in relation to their respective populations in such a way that each Member from a more populous Member State represents more citizens than each Member from a less populous Member State and conversely, but also that no less populous Member State has more seats than a more populous Member State"* (Lamassoure, Severin, 2007).

Definition 2 originates in the interpretation contained in the Report. It may be considered as a formalization of the idea of fairness applied in the European Parliament. In practice there are usually more conditions needed to be taken into account. In case of the European Parliament, these are the boundaries for the minimal (m), maximal (M) and total (H) number of seats pointed out in the Lisbon Treaty. Therefore one usually considers degressive proportionality with boundary conditions (Cegiełka, Łyko, Rudek, 2019).

Definition 3.

Let $(m,M,H)\in\mathbb{N}^3$, $m\leq M$, $m+M\leq H$. A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i\in\mathbb{N}_+$, is *degressively proportional with boundary conditions (m,M,H)* with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1\leq p_2\leq\cdots\leq p_n$, if:
(1) it is degressively proportional with respect to sequence p,
(2) $s_1=m$, $s_n=M$, $s_1+s_2+\ldots+s_n=H$.

The boundary conditions introduced by the Lisbon Treaty are: m=6, M=96, H=751. Of course the Treaty bounds the minimal, maximal and total number of seats in the form of inequalities, i.e. $s_1\geq 6$, $s_n\leq 96$, $s_1+s_2+\ldots+s_n\leq 751$, but in practice they have always been treated as equalities and since there are official recommendations to "*fully utilise the minimum and maximum numbers set by the Treaty*" (Gualtieri, Trzaskowski, 2013) we assume equalities in point 2 of the definition 3.

Let us additionally make two comments. First of all, a sequence which is degressively proportional is also strongly degressively proportional (for the details see (Cegiełka, 2011)) and the opposite implication does not hold. That is why the idea of fairness contained in the algorithm from 1992 is called *strong* degressive proportionality.

Secondly, in the subject matter literature, degressive proportionality is now called Rounded Degressive Proportionality (RDP). Such terminology results from the assumption that denominators in point 2 of the second definition are integers. This assumption, undoubtedly correct in relation to the 2007 Report, turned out to be troublesome in practice. Hence, the third idea of fairness was proposed – the *weak* degressive proportionality.

Weak Degressive Proportionality

The most "liberal" interpretation of degressive proportionality relates degressive proportionality to a usual conceptualization of proportionality in the problem of division of indivisible goods. One assumes that inequalities in dealing with agents as regards their claims can be related to some base, not necessarily integer, quantities. In case of proportional divisions such base quantities result from

the accurate proportion, which is then suitably rounded. Weak degressive proportionality behaves in a similar manner.

The origin of the weak degressive proportionality is the modified interpretation of degressive proportionality provided by the MEPs, who stated in 2013 in the Resolution of the European Parliament that degressive proportionality means: "*the ratio between the population and the number of seats of each Member State* ***before rounding to whole numbers*** *shall vary in relation to their respective populations in such a way that each Member of the European Parliament from a more populous Member State represents more citizens than each Member from a less populous Member State and, conversely, that the larger the population of a Member State, the greater its entitlement to a large number of seats*" (Gualtieri, Trzaskowski, 2013). According to the above interpretation the following definition may be proposed (Cegiełka et al., 2018).

Definition 4.

A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i\in\mathbb{N}_+$, is *weakly degressively proportional* with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1\leq p_2\leq\cdots\leq p_n$, if:
(1) $s_1\leq s_2\leq\cdots\leq s_n$,
(2) there exist a rounding rule $[\![\cdot]\!]$ and a function $A:[p_1,p_n]\rightarrow\mathbb{R}_+$ such that $t_i/A(t_i)\leq t_j/A(t_j)$ for $t_i\leq t_j$ and $(s_1,s_2,\ldots,s_n)=([\![(A(p_1)]\!],[\![A(p_2)]\!],\ldots,[\![A(p_n)]\!])$.

Similarly as in the case of degressive proportionality one defines weak degressive proportionality with boundary conditions (Cegiełka et al., 2018).

Definition 5.

Let $(m,M,H)\in\mathbb{N}^3$, $m\leq M$, $m+M\leq H$. A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i\in\mathbb{N}_+$, *is weakly degressively proportional with boundary conditions (m,M,H)* with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1\leq p_2\leq\cdots\leq p_n$, if:
(1) it is weakly degressively proportional with respect to sequence p,
(2) $s_1=m$, $s_n=M$, $s_1+s_2+\ldots+s_n=H$.

As before, let us additionally make some comments. At first glance it is not clear why the phrase "before rounding to whole numbers" was introduced. The authors of the phrase justify their proposal by the fact that the set of degressively proportional allocations may be empty (Grimmett, 2012). Such justification may raise doubts, as for the data from 2012 there are more than 5 million degressively proportional divisions of seats in the European Parliament (Łyko, Rudek, 2013). On the other hand, as mentioned before, the weak approach is naturally justified. In the case of classical integer proportional allocations it is accepted that approximations of strict proportionality, which in general is not integer, are called proportional divisions, even though they are strictly proportional only before rounding to integers (Cegiełka et al., 2018). However, the justification of the phrase does not raise the strongest doubts. It is the unclear understanding of the added phrase which opens the door to considerable abuse. Formally a rounding rule is defined as follows (Pukelsheim, 2014).

Definition 6.

A *jump-point sequence y(0),y(1),y(2),…* is an unbounded sequence that satisfies $y(0)=0\leq y(1)<y(2)<\cdots$. A jump-point sequence defines a rounding rule $[\![\cdot]\!]$ by setting, for all $x\geq 0$ and $n\in\mathbb{N}$

$$[\![x]\!]=\begin{cases}\{0\}\ in\ case\ x=0\\ \{n\}\ in\ case\ x\in(y(n),y(n+1))\\ \{n-1,n\}\ in\ case\ x=y(n)>0.\end{cases}$$

Note that according to definition 6 we are offered freedom of choice when rounding (for example, for $y(0)=0,y(1)=3,y(2)=4,y(3)=7,y(4)=21,y(5)=21$ we have $[\![6]\!]=2$ and $[\![15,9]\!]=3$ (Cegiełka et al., 2018)). Moreover, it can be shown that for any sequence $p=(p_1,p_2,\ldots,p_n)$ such that for $i\neq j$, $p_i\neq p_j$, any positive,

non-decreasing sequence of natural numbers satisfying given boundary conditions is weakly degressively proportional with boundary conditions with respect to sequence p (the details the reader will find in (Cegiełka et al., 2018)). This means that a weakly degressively proportional sequence may be far from the initial idea presuming that more populated states represent greater numbers of inhabitants than less populated states. Probably the authors of the weakened interpretation assumed the rounding rule to be one of the standard rules, i.e. the floor, ceiling or the nearest integer function. Nevertheless, lack of such an assumption makes the new idea of fairness even less clear. That is why in our opinion the formalization ought to indicate the actual rounding rule. Then, e.g. for the rounding rule equal to the floor function (F), one can define an F-weak degressive proportionality (F-WDP) as follows.

Definition 7.

Let $[\![\cdot]\!]$ be the floor function. A sequence $s=(s_1,s_2,\ldots,s_n)$, $s_i \in \mathbb{N}_+$, is *F-weakly degressively proportional* with respect to sequence $p=(p_1,p_2,\ldots,p_n)$, $0<p_1\leq p_2\leq\cdots\leq p_n$, if:
(1) $s_1\leq s_2\leq\cdots\leq s_n$,
(2) there exists a function $A:[p_1,p_n]\rightarrow\mathbb{R}_+$ such that $t_i/A(t_i)\leq t_j/A(t_j)$ for $t_i\leq t_j$ and $(s_1,s_2,\ldots,s_n)=([\![A(p_1)]\!],[\![A(p_2)]\!],\ldots,[\![A(p_n)]\!])$.

Analogously one can define, for example, a C-weak degressive proportionality for a rounding rule equal to the ceiling function or an N-weak degressive proportionality for a rounding rule equal to the nearest integer function. In such conceptualization F-WDP, C-WDP and N-WDP correspond to standard methods of proportional divisions, i.e. to Jefferson's, Adams' and Webster's methods, respectively.

It is also worth noticing that each degressively proportional sequence is weakly degressively proportional (Cegiełka, 2016). That is why the interpretation accepted in 2013 is called weak degressive proportionality.

In the subject matter literature, weak degressive proportionality is now called Unrounded Degressive Proportionality (UDP). Such terminology results from the phrase "before rounding to whole numbers" and together with RDP terminology allows to distinguish degressive proportionality and weak degressive proportionality in a convenient way.

Searching for solutions

Degressive proportionality, an idea of fairness that seemed to be intuitively clear, proved to be much more complicated than expected. So complicated that for over 20 years it has been interpreted in three different ways. And these interpretations, and therefore definitions, do not specify the method of allocation; they only allow to test whether a given solution is (strongly, weakly) degressively proportional. For the European Parliament, however, the main goal is to find a distribution of seats. This is probably why most of the first literature on the subject proposed methods of allocating mandates. And the vast majority of them put forward UDP solutions, usually with the floor, ceiling or the nearest integer function as a rounding rule (see for example (Dniestrzański, 2014), (Dniestrzański, Łyko, 2014), (Grimmett et al., 2012), (Grimmett et al., 2017), (Martinez-Aroza, Ramirez-Gonzalez, 2008), (Pukelsheim, 2010), (Ramirez-Gonzalez, 2007), (Ramirez-Gonzalez et al., 2012), (Słomczyński, Życzkowski, 2012)). With time, however, the problem began to be considered in a general form. A classification of UDP solutions was made in (Słomczyński, Życzkowski, 2012). In (Cegiełka et al., 2018) the authors formalized weak degressive proportionality.

Studies on RDP have been initiated in the paper (Łyko, Rudek, 2013) which contains an algorithm generating all degressively proportional divisions (for given sequence p and boundary conditions (m,M,H)). Since then the research on RDP has been expanded (see for example (Cegiełka, Łyko, Rudek, 2019), (Cegiełka et al., 2019), (Dniestrzański, 2013), (Dniestrzański, Łyko, 2014), (Łyko, Rudek, 2017), (Łyko, Rudek, 2016), (Maciuk, 2011)). One of the interesting approach was proposed in (Cegiełka et al., 2017). The authors of the paper introduced the so-called transfer order (on a set of

all degressively proportional divisions for given p and (m,M,H)) and for the first time, the structure of this set was studied. However, strong degressive proportionality, according to our current knowledge, has not been investigated.

Conclusions

A simple idea of fairness saying "we need to protect the smaller entities" is, in many cases, undoubtedly justified. But, as it often happens, simple ideas can give rise to difficult problems. The problem of degressively proportional division of indivisible goods is one of such cases. Even though its source is such a prosaic task as the distribution of seats in the European Parliament, the attempts to solve it demonstrated that difficulties start as early as at the point of comprehending the idea. Moreover, enormous differences between those insights generated various streams of research into degressive proportionality. Interpretations presented in this paper indicate the origins of those streams.

The Concept of Minimizing Master Data in The Production Planning Process on The Example of ERP Software

Michal JAKUBIAK

Wroclaw University of Business and Economics, Wroclaw, Poland
michal.jakubiak@ue.wroc.pl

Abstract

The purpose of the article is to show the possibilities of reducing master data in the production process and improving their quality on the example of SAP software: S4HANA. The created model was implemented in a large production company and allowed for a significant improvement in the efficiency of managing the master data used in production planning.
The author presents the possibility of a significant reduction in the labor consumption of creating and managing the basic data of semi-finished products, routings and bill of materials. Thanks to the use the object dependency, and production planning based on product characteristics, the number of data has been reduced many times.

Keywords: ERP systems, master data, production planning, CDP

Introduction

Today's dynamic business is becoming increasingly complex with functional units requiring more and more inter departmental data flow for decision making, timely and efficient procurement of parts, management of inventory, accounting, human resources and distribution of goods. In this regard, efficient information systems would improve competitiveness through cost reduction and better logistics (Holland, C., Light, B., 1999). Company management as unified entity is almost impossible without systems which encompass or can encompass all processes that are in progress in a given organization. ERP class systems have been developed since the 80's. The idea behind their creation was that instead of numerous singular IT systems there would be one that could replace them and care for data coherence and processes in a company. Common data, online record of processes, reporting available at any time they all help to make correct managing decisions .The trend, observed in the 80's and 90's, where ERP systems where implemented only in big rich companies, has been complemented by numerous ERP systems implementations in smaller companies (Samaranayake, P., 2008). It proves that those ideas are universal and their goal is to unify the company (Jakubiak, M., 2019), standardize the processes, clarify the data, and to make the information more available for different participants of a business process (Jagoda, K. and Samaranayake, P., 2017).

The implementation of ERP systems apart from changes in the company's organization can have an influence on the way in which the company is seen on the market. According the research by Hayes et al (2001) the capital market increases the value of companies which implemented ERP, because the investors had a positive reaction to the information about the ERP implementation. Similarly, behavioral research done by Huntona et al (2003) confirms this trend. Financial analysts significantly increased the retracement of average profit forecasts, when a company declared to implement ERP systems. Both research showed that the participants of financial market believed that ERP adaptation will increase company's' results , yet the scope in which the results will come true remains unknown.
However, it has to be admitted that apart from many different positive aspects or ERP implementation, there are examples, in the economy, of companies that have a lot of problems after incorrect employment of IT systems. For example, Scott J. (1999) indicates companies like FoxMeyerDrug which as a result of generating wrong orders, problems with shipment and incorrect financial data almost faced bankruptcy and lost their good name on the market. This shows a big importance of

systems which condition company's proper operation on the market and its survival among their tight competitors.

Most respondents indicate that correct system data is necessary and influence a proper operation of ERP systems. Discussion on data quality in IT systems is probably as old as IT (Brodie, ML., 1980) technology itself . Survey concerning data quality in ERP systems show that even the most-cutting edge technological solutions without data and intermediate software do not guarantee a high quality data (Röthlin, M., 2004). The research done by Martin MH. (1998) points out that effort fullness of data preparation needed for ERP systems implementation results in the fact that about 90% of implementations are delayed and go beyond the planned budget.

Mentioned challenges and problems with IT systems implementation ,and in particular with proper and terminable preparation of data for ERP start in a company, bring about a lot of scientific research connected with IT systems implementation in companies (Knolmayer GF., Röthlin M., 2006).

Master Data in Production Planning

Master data is one of the most important elements conditioning the proper functioning of Manufacturing Planning and Execution systems in an enterprise. Master data in production area is defined as the basic characteristics of instances of production process entities such as work centers, products, routings, etc.

Typically, master data is created once, used many times, and does not change frequently hence the companies give special attention to their management (Haug, A., Zachariassen, F., van Liempd, D., 2011). The process of creating and managing master data in ERP and APS systems is very labor intensive and requires a lot of attention from many system users. Along with the desire to better process registration and planning, the need for data creation and quality service is growing rapidly.

Basic data in a production process can be divided into a few main groups: Material master data, bill of materials, routing, work center and production version.

Material master data contains such information like: material type, name and description, its physical characteristics (weight, volume, tenacity), quality characteristics (when quality check should take place, and what should it concern), planning (MRP type, planning cycle, lot size, procurement type, lead time, planning strategy group etc.), additionally all the range of data connected with bookkeeping, supply, all other information significant for company's processes.

Bill of materials is a list of components from which a given product is manufactured, along with the information about their number and elements units used in the production process, the method of elements use in the system (e.g. backflush concept) and variants of their use. In a basic discreet production process, every manufactured material has at least one individual BOM. BOM's are not only used in production process , but in standard cost calculation for finished products by rolling up the cost from raw to semi-finish and then to finished products. A routing is a description showing which operations or list of activities have to be carried out during the production and planning process. Routing also contains information about the order of production operations and their seriality, reorientation times, workstations, information controlling production orders such as type of confirmation, type of scheduling, costs etc.. Just as BOMs in a classic approach to building basic data in discreet production processes, every manufactured product has at least one routing which shows production method.

In ERP systems under the term Work Service there is information about human resources or machine resources that take part in a production process . Working time of given resources is defined there, as well as costs counting method and the way they are ascribed, information about location and people responsible for a given device maintenance, data influencing capacity planning and scheduling process.

Work centers are used in task list operations and work orders. Task lists are for example routings, maintenance task lists, inspection plans and standard networks. Work orders are created for production, quality assurance, plant maintenance and for the Project System as networks.

A production version determines which alternative BOM is used together with which task list/master recipe to produce a material or create a master production schedule. In a production version, you can maintain the combination of BOM and routing. For one material, you can have several production versions for various validity periods and lot-size ranges.

The concept of minimizing master data in the production planning process

The process of minimizing master data in the production was presented on the example of real planning process , implemented in one of the biggest polish enterprises operating in energy industry. During concept works it was observed that there is a need for integrating an ERP system SAP with software for cutting machines. Cooperation with an external system which to a better extent optimizes sheet metal cutting in comparison to standard ERP System, results in dividing the process into two production orders. Both orders are created in SAP, but the first is improved and verified by SigmaNest system (Sheet metal cutting order), second order is fully managed by ERP. The division of process into two production orders requires master data (BOM, Routing, work center and production version) to be created in SAP system for every production stage – cutting (SigmaNest process) and further processing (after cutting process).

The fact, that creating master data used in this production process is very labor-intensive, has forced the author to make an attempt to minimize the data by means of a model based on CDP (characteristic dependent planning) terminology. This functionality allows to run a record as a part of one material index, a lot of SKU, distinguished by their unique characteristics (e.g. one index established in SAP with its features like color, length, etc…can be distinguished as a few variants of the same product. In Planning based on CDP the system books/plans/consumes only the products which have the same values of characteristics. E.G. if red colour is a part of bike's characteristic and this feature is repeated in a bike's component – a frame, then the system will only consume/plan the materials with the same value of characteristics (in this example the colour red). The pattern of CDP functionality in production orders in the examined enterprise is presented below.

Fig. 1: A production process pattern and master data in ERP –SigmaNEST production process
Source: Own elaboration

Index materials created after the second production order are in system S4HANA identified as fully configured material variants (FCMV) having unique characteristics in the class 400 (it means that all features of those material indexes have their values because of that there is no need to create individual material index for every material combination variant). Indexes started as semi-finished products are materials with characteristics, but these characteristics have not got any values. While planning finished products, the system, based on objects dependencies, passes features from superior positions to products which are the components of the second production order (semi-finished products) and in the same time which are a final product on SigmaNEST (the first production order).

Tab. 1: Characteristics for Finished products

Characteristics	Description
CTT00001	Finished Product number
CTT00002	Semi-finished Product number
CTT00004	Initial sequence in routing
CTT00006	Time of initial sequence in routing
CTT00003	Planned amount of sheet metal
CTT00005	Alternative sequence in routing
CTT00007	Time of alter. sequence in routing

Source: Own elaboration

Tab. 2: Characteristics for Semi-finished products

Characteristics	Description
CTT00008	Finished Product number
CTT00002	Semi-finished Product number
CTT00010	Initial sequence in routing
CTT00014	Time of initial sequence in routing
CTT00013	Planned amount of sheet metal
CTT00005	Alternative sequence in routing
CTT00007	Time of alter. sequence in routing

Source: Own elaboration

Fig. 2: An example of object dependency written in ERP dependency editor

Source: Own elaboration

Thanks to this approach while planning a final product A, which in its features has a specific semi-finished product included, out of which it should be made, the system chooses a correct semi-finished product giving it all necessary features from a final product. The semi-finished products become fully featured only when the production order is placed for a final product (going through a planning procedure CDP). This method results in the fact that it is not necessary to make individual material indexes for every semi-finished product variant. The correspondence of features created in the planning process is also ensured by an appropriate pegging, which tells what materials are needed for planning and production.

The process of CDP procedure, created characteristics and object dependencies allow to pick correct technological routes and times. The characteristics like CT0004, CT0006, CT0005, CT0007, CT0010, CT0014 controls the choice of a proper machine in routing and the time planned in the production order.

If $root.CTT0004 specified and $root.CTT0004 = '01'
Then select Laser Kimla machine
Else
If $root.CTT0004 specified and $root.CTT0004 = '02'
Then select Laser FL004
…
End if

Object dependencies saved at the level of BOM and routing (so called super structures) do not require to create individual BOMs and routings for every material index . The system based on features and object dependencies can pick and create new master data (BOM ad routing) which will be used individually in the production order.

Results

As a result of created characteristics and object dependencies model and the use of CDP functionality (Planning based on products characteristics) it was possible to minimize master data needed for cutting and further product processing in the examined company. The charts show real master data reduction in the process.

Tab. 3: The number of master data before the implementation of CDP model

Number of finished products	Number of semi-finished products	Number of BOMs	Number of routings
22.341	22.341	44.682	44.682

Source: Own elaboration

Tab. 4: The number of master data before the implementation of CDP model

Number of finished products	Number of semi-finished products	Number of BOMs	Number of routings
22.341	**105**	**22.342**	**22.342**

Source: Own elaboration

Every reduction in master data is a lower risk of making mistakes while creating it, shortening the time for the whole process (not need to wait for creating additional data) and reducing the time needed for implementing the whole process. This approach is possible to be implemented in other companies, not only while integrating ERP with other systems. Object dependencies (in which we specify the form and the way the information is passed from upper to lower levels) and planning based on characteristics (CDP) allow to minimize master data significantly in the production area.

Marketing Channels for Organic Products: A Cross-National Analysis in The European Union

Mihai STOICA

The Bucharest University of Economic Studies, Bucharest, Romania
mihai.stoica.91@gmail.com

Abstract

This article is a cross-national analysis of the marketing channels concerning the organic market from the European Union. The analysis is carried out on the organic markets in Austria, Denmark, France, Germany, Italy and the United Kingdom, countries that at the end of 2017 were in the first positions regarding the size of the organic food market. The article highlights the competition between general and specialized retailers, as well as how their importance evolves over time and in relation to the size of the total organic market. Thus, it is noted that in most of the analyzed countries the importance of general retailers increases over time if the organic market grows in turn, thus managing to weaken the strength of specialized stores or even to stop their growth. However, against the backdrop of a spectacular growth of the market, in France, the specialized organic stores continue their ascent with approximately the same proportion as the general retailers. The article proposes a link between the evolution of the market size and the importance of marketing channels, this topic being a basis for future research.

Keywords: Marketing Channels, Organic Food, Distribution, European Union.

Introduction

The organic food market in the European Union is constantly growing, amid increasing consumer interest for pure, non-counterfeit and sustainable products. The scandals in the food industry (the bovine spongiform encephalopathy crisis - BSE in the United Kingdom, E. coli infections in Germany, the dioxin scandal, etc.) have partly contributed to the development of the organic food market. However, the improvement of marketing channels has played an important role in promoting the purchase of organic products (Canavari, et al., 2007), the distribution being considered a key factor for the growth of the organic sector (Haas, et al., 2010).

Distribution of Organic Products

The distribution of organic products involves choosing the marketing channels in a way that minimizes the damage done to the environment (Arseculeratne & Yazdanifard, 2014; Eneizan, et al., 2015) and the physical distribution, to ensure the availability of the organic products to the customers interested in the problem of environmental protection. Distribution is a key element in attracting the right customers for organic products. Moreover, Singh and Pandey (2012) consider that customers will not go out of their way to expressly buy green products; where possible, products should be distributed through main outlets so that they won't be available just to a small niche market of green consumers. From the consumer perspective, the essential value offered by the distribution process is convenience. Through their efforts, retailers and service providers will seek to bring together a wide range of goods and services in a way that makes them widely available (for example, by importing organic fruit outside the season) and easily accessible (for example, via 24/7 store operation) (Peattie & Belz, 2010).

Marketing channels for Organic Products

Designing and choosing marketing channels is the first decision to be taken by the company. This involves determining the fundamentals of the distribution strategy, more precisely the decision regarding the basic mode of distribution for the organic products (Vicente Molina & Ruíz Roqueñi, 2003). The increase in the number of organic products consumers has also led to changes in the level of marketing channels and thus, it began to be used other channels than the specific ones to these types of products (Ottman, 2011) (see Table 1).

Table 1: Marketing channels for organic products

Marketing channels	Type of trader
Direct channels	box schemes, community-supported agriculture (CSA), peasant markets, farm shops, door-to-door sales, fairs and fair exhibitions, online marketing
Indirect channels	General retailers: hypermarkets, supermarkets, hard discounter, proximity store, traditional store, etc.
	Specialized retailers: specialized organic stores, specialized health food shops, organic supermarkets
	Emerging channels: Ho.Re.Ca (hotels, restaurants, cafes), public institutions (canteens, schools, hospitals, army)

Source: based on Corsi, et al., 2009; Park, 2009; Atănăsoaie, 2011.

The dimensions of the marketing channel are influenced by a series of specific factors regarding the product and the market, but also by the resources and the capacity of the organization. Many manufacturers have realized that each link in the distribution chain compromises the quality of the products, which triggers a shortening of the distribution channel (Espino & Bolívar, 2002, cited in Vicente Molina and Ruíz Roqueñi, 2003). The use of a direct marketing channel generates lower distribution costs, reduces the impact of the organization's distribution activity on the natural environment and gives the company greater control over the distribution activity (Seyfang, 2006). In addition, companies can be distinguished on the market by creating and managing direct marketing channels, whose quality performance is superior to the competition (Vicente Molina & Ruíz Roqueñi, 2003) and through which they can maintain a stronger connection with the final customer, due to the lack of intermediaries (Atănăsoaie, 2011).

On the other hand, in the case of choosing indirect marketing channels, the organization has the distribution of organic products through general and specialized retailers. The distribution of organic products on a large scale is considered as part of a wider strategy aimed at appealing to those consumers interested in green consumption (Oosterveer, et al., 2007). Even if supermarkets are not in the best position of trust, regular consumers of organic food, whose choices are related to their specific values, are willing to enter into a process of negotiation with themselves and, according to circumstance, they end up renouncing to these values for the convenience of the one-stop-shop (Padel & Foster, 2005). Thus, mass marketing of organic products involves selling within a price range that a significant segment of consumers would be willing to pay, without giving up the traditional basic attributes of the product (functionality, ease of use, reliability, etc.) (Izagirre-Olaizola, et al., 2013). Instead, specialized stores adopt marketing strategies different from those of large retailers. They are based on: (1) a specialized assortment of products that focus on the preferences of their regular loyal customers; (2) local and regional products at lower prices due to direct purchases from producers; (3) higher prices for national or international products, due to lower economies of scale and higher administrative costs; (4) a direct relationship with the consumer; (5) qualified personnel providing advice; (6) additional services for customers (e.g. hot lunches); (7) the ability to arouse customers' interest in ethical and environmental issues and (8) more own brands than the manufacturer's brands (Haas, et al., 2010).

Marketing channels for organic products in the European Union

Estimated at over €34 billion, the EU organic food market accounts for 37% of total worldwide sales. Consistent growth continued in most markets in 2017, some countries (such as France and Denmark) reported exceptional growth. However, it should be noted that there are significant differences in the EU between countries in terms of market size and per capita consumption (Willer & Lernoud, 2019). These differences can also be seen in the distribution of sales of organic products across different marketing channels.

In most European countries, non-specialized retail chains have played and are still playing a crucial role in the development of the organic market. Offering environmentally friendly products for retail channels results, in most cases, in the sale of significant volumes brings profitable economies of scale (Haas, et al., 2010; European Commission, 2010). However, the EU has the largest concentration of organic food retailers in the world. Most are located in Germany, France, and Italy (Willer & Lernoud, 2019).

In countries with a tradition of organic food consumption, on-premise marketing channels, such as catering and food service sector that serve organic food, are beginning to grow in importance. For example, public procurement of organic products (for catering in schools, hospitals, etc.) reached 33% of public consumption in Sweden in 2018 and 20% in Denmark (EU Agricultural Markets Briefs, 2019). There is also a growing number of restaurants, cafes, bars and canteens that uses organic ingredients and/or serve organic products.

In the countries of the EU where the share of organic products does not represent a significant percentage of the total food market (Romania, Bulgaria, Poland, Hungary) there are still significant problems regarding the availability of the products, and the supply of products is generally limited.

Research Methodology

The purpose of this study is to identify the importance of marketing channels for organic products in the EU market. This paper focuses on the analysis of the main marketing channels used in 6 countries in the EU (Austria, Denmark, France, Germany, Italy and the United Kingdom) for the marketing of organic products to consumers. The analysis is based on the total sales of organic products registered on each main marketing channel. In particular, indirect marketing channels are presented, focusing on general and specialized retailers, for which there are data on sales evolution.

The study uses statistical materials published by FIBL and IFOAM, as well as those available in the FIBL database. The time frame of the data is 2015-2017, for which sales were available on marketing channels in the analyzed countries.

Results

The Importance of Marketing Channels for Organic Products

In most of the analyzed countries, sales of organic products are made by more than 50% of general retailers, except France, the country where a significant part of sales is registered through specialized stores (see Figure 1). Also, according to data presented in the EU Agricultural Markets Briefs (2019) in many EU countries, including Austria and Denmark, general retailers dominate the market for the distribution of organic products, accounting for over 75% of sales. The report notes that the distribution structure appears to be related to the share of green products in retail areas: while green products are an integral part of the shopping basket for many Austrians and Danish people, they are widely accessible and easily accessible through the conventional distribution chain.

Fig. 1: Share of organic retail sales of different marketing channels (based on retail sales values) in the case study countries (2017)

Source: based on FiBL-AMI survey 2019, cited in Willer & Lernoud, 2019.

The increase in sales of organic products through general retailers was the result of changes that have occurred at the market level over time. Thus, the decision of retail discounters to offer organic food increased the sales volume and the competition for the specialized organic retail sector, especially in the mature European organic markets (Van Osch, 2008, cited in Haas, et al., 2010). Therefore, organic stores were forced to focus on their core competencies and on adopting niche strategies (Haas, et al., 2010).

However, the channel of organic grocery stores has continued to expand at the European Union level. Besides, the opening of specialized supermarkets offering only organic products has been a trend in many EU countries for several years (Haas, et al., 2010; Willer and Lernoud, 2019), this being the answer to increasing the customers' concerns for healthy food.

Evolution of the importance of marketing channels, in relation to the evolution of the total market

Based on available data on marketing channels (see Figure 2), it appears that most of the organic food in many EU countries is sold by general retailers, as a result of the fact that organic chains are integrated into the mainstream food chains (Sanders, et al., 2016). However, it must be recognized that detailed statistical data on the importance of alternative sales outlets for organic food (i.e. such as farm shops, farmers markets) remains limited.

Fig. 2: Growth of marketing channels for organic products 2015-2017, in the case study countries

Source: based on: Austria: AMA Marketing, Denmark: Organic Denmark, France: Agence Bio, Germany: Arbeitskreis Biomarkt,Italia: AssoBio/Nomisma, United Kingdom: Soil Association, cited in Willer&Lernoud, 2017, 2018, 2019; FiBL, 2020.

France is a country where there is strong growth of the market for organic products. Unlike most European Union countries, specialized retailers play a very important role in the market, registering increasing sales every year. Notable is the presence of Biocoop, which has 400 stores throughout France, and total sales in 2017 amounted to $870 million (Journo, 2018). It is also noted that other marketing channels have a higher share of total sales, compared to the rest of the analyzed countries.

In Austria, the REWE retail chain was a pioneer in the organic market, when it introduced its own 'Ja natürlich' green brand in 1994 (Haas, et al., 2010). The major proportion (over 80% in 2017) of organic products is sold through general retail chains, while over 15% are sold through specialized food stores. While sales volume in general retailers is steadily increasing, sales of organic products through specialist stores are stagnating.

Denmark is the first country that in 1987 implemented a regulatory framework for organic farming (Willer & Lernoud, 2019), being today at the top of the consumption of organic foods worldwide. The market is dominated by general retailers, with over 95% of the sales of organic products being registered within the sales areas owned by them. The rise in sales in general retailers is constantly increasing, the value of sales increased by more than 60% from 2015 to 2017 (from €940 million to €1521 million).

In Germany, the organic market entered into a transition period. Supermarkets have become the engine for development, after the market was built and dominated mainly by specialized stores (Haas, et al., 2010; Willer and Lernoud, 2019). In recent years, general retailers have strongly entered the market, managing to have a market share of about 60% by the end of 2017, while specialized retailers are more and more facing competition. It is estimated that there are more than 2,400 eco-friendly retail stores in Germany (Emily & Rehder, 2017). In 2014, 33% of all organic products were sold in organic stores and this number decreased to 29% in 2017 (Willer & Lernoud, 2019).

In Italy, in 2015, the sales of general retailers were at the same level as those of specialized stores (over 800 million euros), but the evolution in the next two years was radically different. Sales of general retailers nearly doubled, while sales in organic stores remained at the same level. It should be noted that in Italy there are more than 1,200 shops specialized in the marketing of organic products (Organic-market.info, 2018), which means 1 store for 50.500 inhabitants. The largest chain is NaturaSì (2020), which had at the end of 2019 over 270 specialized stores.

The most important sales of organic products in the United Kingdom are registered through general retailers. Discount shops, such as Aldi and Lidl, set the agenda for organic products among supermarkets (Soil Association, 2019). Also, the United Kingdom's organic market continues to be dominated by three major supermarkets - Sainsbury's, Tesco and Waitrose (Soil Association, 2019). The specialized stores represent less than 20% of the sales made on the market, being at the same level between 2015-2017.

Conclusions

A breakdown of the different market channels shows that their relative importance differs from country to country. The similarity lies in the fact that in all the analyzed countries the non-specialized retail chains are in the first place in terms of sales of organic products. However, Italy, France and Germany are the only countries where organic food products are sold in a significant proportion through specialized retailers, with a high number of specialized stores on the market.

This analysis should be extended to all countries of the European Union (in the event of data existence), and especially to countries with a market for organic products at the beginning of the road, in order to identify the structure of marketing channels. It is also important to study the changes in the structure of distribution channels on a market, over several years.

Future research should study the hypothesis that once with the development of the market, the importance of general retailers is increasing, while specialized networks are slowing down, stagnating or even falling off, as we can observe in the conclusion of this analysis.

The Development of The Market for Luxury Goods in China Until 2025

Marcin JALOWIECKI

Poznan School of Banking, Faculty in Chorzow, Poland
mjalowiecki@ewindykacja.pl

Abstract

The macroeconomic perspective on China is that the country will maintain growth momentum by transitioning from an investment - led economy into a consumption - driven and service - driven economy by 2030. This aspect has also affected the luxury goods market, which is growing every year. This trend will be continued until 2025. Various studies in this area are available on the market, but the author of the text, not only based on his many year's experience of cooperation with Chinese consumers and representatives of companies operating in the People's Republic of China, will address the most important key issues that initiated rapid the development of the luxury goods market in China as well as will influence its further growth until 2025. The author of the text will answer questions, including how China's internal policy enables the development of the luxury goods market, how and why a new generation of Chinese consumers are powering the global luxury market, and the double-edged sword they present to the world's leading luxury brands. How will global companies influence sales growth and development of this market in China, taking into account the growing consumer expectations regarding the product, price and brand recognition itself. The author put the question if Chinese consumers are able to be the largest buyer of luxury goods by 2025? The article shows that Chinese consumers are set to contribute more than two - thirds of global growth in luxury spending and how Z generations, will power the Chinese luxury market by 2025.

Keywords: Asia, growth factors, consumer market, emerging markets, economies luxury market.

Introduction

Growing at a pace far surpassing expectations, spending by Chinese consumers on luxury products now exceeds that of any other country. Having leapt past Japan's luxury market, which until recently was the world's largest, China has become the paramount driver of growth in this sector, with purchases by Chinese both at home and abroad accounting for 33% of the global in a research study by D'Arpizio, Levato, Prete, Del Fabbro and Montgolfier (2019). China's current economic slowdown has caused the growth rate in the country's luxury spending to subside recently, and another factor leading some consumers to become warier is heightened concern about corporate gifting to government officials. Despite the recent slowdown of economic growth in major markets including China, the Eurozone, and the US, the luxury goods market looks positive. The US' recent adoption of protectionist policies, the implementation of fiscal policies, tighter monetary policy, and restrictive trade policy have resulted in slower consumer spending, higher consumer prices, and disrupted global supply chains. The outcome of Brexit[1] will undoubtedly have an effect on the Eurozone and beyond. The further deepening of the trade struggle between the US and China will be important for the development of the market in China and USA. Other factors impacting the future of the global luxury market include the digital revolution and the impact of technology, the growing global middle class and the influence of Millennial HENRY`s (High - Earners - Not - Rich - Yet) and Generation Z (Gen Z): the customers of the future on the development of the luxury market. China has 12% share in the global billionaires' assets[2] mentioned Hoffower (2019). In China, billionaires live mainly in Shenzhen and Guangzhou. The

[1] The UK's strategy to leave the European Union.
[2] Number of billionaires: 285 Estimated assets: $ 996 billion.

number of billionaires in this country has fallen due to, among others, the US - China trade war, volatility in emerging markets and the weakening of global growth [3] mentioned Hoffower (2019). China is still on the top of the list of billionaires since years.

The Chinese economy slowed down in 2018 for the first time in 28 years. Despite this, luxury goods sales grew in mainland China, as well as, abroad, and Chinese consumers now lead to the consumption of luxury goods both at home and outside. China ranks second globally for the contribution its travel and tourism makes to the GDP, in 2028 it is forecasted to account for 12.9 percent of GDP mentioned Turner (2019). China has transformed itself socially and economically over the last 40 years, as a result of huge financing support by the government. Since then, more than 700 million Chinese people have come out of poverty thanks to this policy, and another 30 million are to be lifted out of poverty by 2020/2021. This has resulted in a high debt to GDP ratio, a structure, which is clearly unsustainable and in need of policy reform. The protectionist policies of the US are a major threat to the economy, and as a result, China is taking steps to insulate itself from the export market. Made in China 2025 is an initiative to make China self-sufficient and a tech powerhouse in the research study by Jalowiecki (2018).

Indeed, the luxury segment remains robust, amid a continuation of a trend in premiumization that has seen sales of premium cars and premium beer, as well as prestige beauty products, outperform the wider market. Young Chinese consumers view ownership and affiliation with designer brands as a form of social capital; not just something to wear, but a lifestyle choice that marks them as part of a distinct and exclusive community. That community is constantly being refreshed via a glittering stream of online content, keeping pace with which demands consumers are “always on", immersed and engaged in a digital world that is nothing short of a way of life. the majority of these young consumers are fresh to the market, presenting both a tantalizing opportunity and an implicit imperative for brands to stay current, or risk losing out to more digitally savvy rivals. What’s more, while some fashion houses excel at various aspects of online marketing and e-commerce, even the most popular luxury brands have yet to establish a comprehensive presence across the digital ecosystem. Consequently, opportunity abounds as brands seek to engage the attention of consumers in the world’s most lucrative and fastest-growing luxury market.

China delivered more than half the global growth in luxury spending between 2012 - 18 and is expected to deliver 65 % of the world’s additional spending heading into 2025, according to research based on UnionPay transaction data mentioned Nayyar and Ingilizian (2018). In 2018, Chinese consumers at home and abroad spent 770 billion RMB ($115 billion) on luxury items - equivalent to a third of the global spend -with each luxury - consuming household spending an average of 80.000,00 RMB per year. Their outlay is set to almost double to 1.2 trillion RMB by 2025 when 40 % of the world’s spending on luxury goods will be conducted by Chinese consumers (Figures 1). That growth will be primarily driven by an explosion of upper-middle-class households, the population of which will rise at a compound annual growth rate of 28 % from 2018 to 2025, taking the total number of people in China earning between $2.600,00 and $3.900,00 per month per household to 350 million. China’s affluent class (households earning above $3.900,00 per month) will almost triple to 65 million people during the same time period in the research study by Jalowiecki (2018)). The majority of them, about 70 %, in fact, will be doing their luxury spending overseas, a result of an increasing affinity for outbound travel and the price differential resulting from China’s import tax regime and brands’ own pricing policies. However, that ratio may shift in favor of domestic spending as a result of moves to cut luxury import taxes mentioned by Nayyar and Ingilizian (2018). While some luxury brands have posted disappointing results due to weak China demand, the likes of LVMH, the world’s largest luxury group, and Switzerland’s Richemont, owner of Cartier, reported their China sales accelerated in the final quarter of last year in a research study by Hammond, David and Nair (2019). This is in keeping with the notion that luxury in China is a winner-takes-all market, a tendency best reflected in the composition of the country’s fashion market. As explored in State of Fashion 2019 report, the vast majority of fashion-industry profit in China is secured by the top 20 percent of companies, creating a polarized

[3] Number of billionaires: 285 Estimated assets: $ 996 billion.

market dominated by a subset of "super winners." The same can be said for luxury, placing the onus on brands to stay at or near the top of the market or risk sliding into irrelevancy in the research study by Amed, Balchandani, Beltrami, Berg, Hedrich and Rölkens (2018 p.11.). This demands an aggressive yet flexible approach, particularly as we expect macroeconomic headwinds will eventually take a toll on wealthy Chinese consumers, or at least the value of their assets.

Fig. 1: Global personal luxury goods market evolution including Chinese consumers.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Young luxury consumers in China

China's'80s (born in the 1980s) generation, who broadly map to Generation Y, are the driving force of the country's luxury demand. Consisting of 10.2 million luxury consumers, they accounted for more than half the total spending on luxury by Chinese consumers in 2018 (Figure 2). Having grown up in step with China's emergence as a global superpower, they are the primary beneficiaries of the economy's rapid and unbroken growth and spend an average of 41.000,00 RMB per person each year on luxury. Now, at the peak of their career and earnings, and with a passport likely stamped with trips to the world's most glamorous cities, they are spending to show off their success, and to demonstrate individualism in the world's most populous urban landscape. Following in the footsteps of their slightly older peers, China's post-'90s consumers, better known as Generation Z, are delivering the shot in the arm China's luxury market needed to emerge from several years of stagnant growth. Enticed by luxury streetwear and other product lines targeted squarely at their demographic, the post-'90s consumers spend 25.000,00 RMB a year on luxury goods, already as much as their parents - the post-'65s/'70s generation popularly referred to as Generation X. The post-'90s consumers are the vanguard of China's urban middle- class, a dynamic and digitally engrossed cohort that as the "single child generation" are

the recipients of an outsize level of familial support in the research study by Amed, Balchandani, Beltrami, Berg, Hedrich and Rölkens (2018). Two - thirds told us their parents support their luxury spend, with McKinsey Global Institute modeling suggesting that upper-middle - class Chinese families top up their post-'90s children's bank balance by at least 4.000,00 RMB per month, or half their personal income. This financial cushion has a large impact on these young consumers' willingness to spend, and spend big, on luxury.

Fig. 2: The largest luxury spending group in terms of both consumer numbers and total spending.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Young consumers in China are new to the luxury market, and thus have a less nuanced understanding of the heritage upon which the market traditionally trades. Only 13 % of post-'80s/'90s luxury spenders said they grew up in a family familiar with the finer things in life, while half of the post-'90s, and 31 % of post-'80s consumers, only made their first luxury purchase in the last year (Figure 3). Luxury is also a relative novelty for many of the post-'65s/'70s group - just under half bought their first designer item less than three years ago. Nine out of 10 of the youngest generation and more than two - thirds of post-'80s consumers, also only started their engagement with luxury within the last three years. Instead of legacy reputations established over hundreds of years in Europe, these new luxury consumers are influenced more by what is happening right now, leaving ample room for brands with the right strategy to shape their tastes (Global Powers of Luxury Goods 2019). Young consumers want to show off with luxury brands. They are indebted to show their status among the people who are well off. It is also worth noting that young Chinese do not have any inconvenience. An older group of consumers reduces their savings. Younger generations will be the primary engine of growth in the coming years. Generations Y and Z will represent approximately 55% of the 2025 luxury market and will contribute

130% of market growth between now and then, offsetting a decline in spending by older consumers in the research study by Amed, Balchandani, Beltrami, Berg, Hedrich and Rölkens (2018, p. 23.)

Fig. 3: Chinese consumers buying of luxury goods.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Luxury products help young consumers in China feel distinct from the people with whom they live in their cities. They see luxury as a form of social capital that helps mark them apart and achieve personal and social goals. That sentiment intensifies towards the younger end of the spectrum, with well over half the sample, and almost 70 % of post-'90s consumers, showing they buy luxury to "feel different rather than fit in with society." Buying luxury is also a way to convey and enjoy a shared social experience and value system - a lifestyle and community that lives and breathes luxury, online and in the flesh (Figure 4). Young consumers' consumption of media and the luxury lifestyle it portrays is consequently heavily social and trend dependent - a desire to be seen or snapped in the latest styles drives consumption, and with it a need for brands to constantly update their styles or leverage creative marketing to create the illusion of newness. More than 3/4 of young consumers in China are interested in buying iconic styles thus most are easily recognizable, with the trend most prevalent among the post-'65s/'70s consumers. Indeed, the concept of a niche brand has multiple meanings across luxury segments, from one that exhibits unique design to those that are a niche in the sense of being rarely seen on the street, or simply not available in mainland China. In any case, China's luxury market has yet to develop the widespread sophistication necessary to sustain demand for truly niche or boutique brands, as has been the case in the West. The brand remains king when it comes to informing taste across all our surveyed generations, but is relatively less important for younger consumers. For example, the brand was the top reason for the last luxury purchase among 68 % of the post-'90s consumers, compared with 94 % of the post-'65s/'70s consumers (Figure 4).

Fig. 4: Top reason for last luxury purchase by generation.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Brand loyalty tends to be higher among the older generation, some of whom are likely to be VIPs for various brands as a result of several years sharing their insights with peers as key opinion leaders. The overwhelmingly social nature of luxury consumption in China acts as a catalyst for consumers to learn about and share an appreciation for craft; younger consumers, in particular, tend to value design, fabric, and the production process. Young consumers prefer foreign luxury brands, particularly those from France and Italy, closely followed by Great Britain, with Japanese and American labels also more appealing than homegrown luxury alternatives. In fact, post-'65s/'70s consumers have no interest in buying Chinese luxury brands, but there are signs that such negative perceptions about domestic players are beginning to fade: one in ten post-'90s consumers said they would opt for a high-end Chinese brand, and this likely will increase in the near future as Chinese brands gain greater prominence.

Fig. 5: Perceived country of origin vs actual country of origin.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

For the time being, it is European brands that command the greatest recognition, and which are most strongly desired by consumers. Less than half of the consumers were able to correctly name the country of origin for selected American and Canadian brands (Figure 5). Young consumers are loyal not to brands per se, but to iconic brand - product combinations.

Fig. 6: Brand basket and loyalty of consumers.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Everything is media, social is everywhere being relatively new to luxury, Chinese consumers are constantly tapping various forms of content as they strive to improve their awareness of the market. Chinese consumers consult a mix of online and offline sources during the three to five hours per week they spend absorbing information on luxury and fashion, with every single one saying they were exposed to digital influence at some point in their customer journey (Figure 7). At every touchpoint, from e-commerce to in - store, and of course through social media, consumers are seeking to pick up information about the latest luxury products, the celebrities who promote them, and the lifestyles they embody. Only traditional ads fail to command the avid attention of consumers, according to our research (Figure 8).

Fig. 7: Information and channel preference of Chinese luxury consumers.

Fig. 8: How Chinese consumers got information about new luxury brands.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

Despite their affinity for digital discovery, in-person experiences in brand stores are the most impactful when it comes to making a purchase decision for nine out of ten young Chinese consumers (Figure 9). Chinese consumers leverage brands' official channels for information, paid and earned avenues offer a means for brands to differentiate, particularly those trying to expand their reach or alter their image. In keeping with their experience in luxury as social capital, word of mouth is the most commonly accessed source of information on new luxury brands. These channels include cross-border commerce offerings, commonly referred to as Daigou (Bloomberg News 2019). E-commerce, whether third-party or owned, plays a uniquely important role in gathering information. Consumers use e-commerce platforms to source facts about products, as well as reading peer reviews and product experiences. Post-'80s/'90s consumers rely significantly on the kind of online commentary that e-commerce sites provide. Consumer - to - consumer platforms like XiaoHongShu[4] (RED) also allow China's young luxury acolytes to share newly accrued knowledge by posting unboxing experiences, buyer's guides, wearing occasions, and anecdotes.

Fig. 9: How Chinese consumers got information about new luxury brands.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

KOL Kingdom Young Chinese luxury shoppers are heavily influenced by KOLs. Celebrities like Angelababy, Yang Mi, and Tiffany Tang, as well as fashion bloggers like Gogoboi, all play a major role in raising awareness of new products, as they command wider followings than brand-owned channels (Figure 10). They also serve to contextualize luxury products in daily life, making them accessible to the new luxury consumers that constitute the bulk of the China market. Tracking the media journey of Chanel's Gabrielle bag shows how, following the brand campaign launch, celebrity Yang Mi caused a stir by appearing with the bag on the WeChat channel of Mr. Bags[5], another influential Chinese fashion blogger. High-profile local KOLs then took up the reins, serving to deconstruct global high fashion into easily understandable chunks, before a long tail of approximately one million amateur influencers localized the product for consumers all over the country. Successful brands consequently employ a portfolio approach to KOL engagement: working with celebrities and influencers with varying degrees of star power, a trend that has spurred the emergence of online platforms that assist brands with finding suitable KOLs. LV, for example, works closely with a core group of brand ambassadors with global reach such as Chinese - Canadian star Kris Wu[6] but hires others on an ad hoc basis according to the needs of individual events or product launches. The brand also leverages partnerships with KOLs like Mr. Bags, who managed a Beijing pop - up store for a day, and Gogoboi

[5] See: www.mrbags.com 包先生 Mr. Bags.
[6] Kris Wu (吴亦凡).

(Generation T 2019), who ran the brand's Weibo account during the 2017 LV Fashion Week, to help introduce products to the widest possible audience.

Fig. 10: How Chinese consumers got information about new luxury brands.

Based on the research study by Luan, Kim and Zipser (2019), by D'Arpizio, Levato, Prete, Del Fabbro, Montgolfier (2019)

While WeChat remains the foremost platform for branded media, it is also increasingly used to drive interactive consumer engagement, both through official accounts and through mini-programs within the WeChat ecosystem that host interactive digital games and other experiences such as product trials, service reservations, consumer advice, and more. Other platforms like Baidu, Douyin, and Alipay are now establishing their own mini - programs. Moreover, pioneers are pushing into new mediums such as video-sharing app Douyin, also known as TikTok. American fashion brand Michael Kors partnered with KOLs to create a series of catwalk videos in various city streets, before challenging users to follow suit via their Douyin accounts. The campaign generated 200 million views for the more than 30.000,00 user - generated videos submitted. Successfully launching new products thus requires that brands adopt an omnichannel approach that drives a high level of consumer engagement, demanding new creative campaigns on a regular basis. This flow of paid and earned media coupled with multiple opportunities for consumer engagement helps cement a product's iconic positioning in the digital firmament.

Summary

The imperative for global brands is to become the leading form of social capital for China's young luxury consumers and stay there. This demands an "always - on" approach centered around a rapid cycle of new and refreshed product launches that intimately intertwine with ready - to - go viral media, including "sticky" nicknames and innovative campaigns. Newness and exclusivity could also be fostered through launching limited - editions, collaborations with KOLs and influencers, and hosting

an annual calendar of special events, particularly around art and fashion. China's young luxury consumers are more interested in aspiration than heritage, making it imperative for brands to modernize their stories and deliver them through digital channels. Savvy brands should design an integrated marketing strategy that satisfies young Chinese consumers' appetite for consuming media at every available touchpoint, whether they are online or offline, and whether they are traveling or staying in China. Local digital marketing teams should be empowered to make quick decisions and entrusted to experiment with the new media formats and channels favored by young consumers. Since the majority of luxury purchases are made offline, brands should also reimagine the in - store experience. Catering to young consumers' desire for personalization - to feel different and valued - is key, as is doubling down on the concept of the store as its own media channel. Brands would also be wise to invest in highly trained staff capable of maintaining one-to-one relationships with customers in and beyond the store, in effect becoming their personal stylists, backed by customized narratives and personalized product recommendations powered by AI. There is an unparalleled opportunity to tap demand for luxury among the affluent residents of China's lower-tier cities, most of whom remain underserved by brick and mortar stores. Instead of over-expanding store footprint, brands should devise a targeted travel retail strategy that captures these consumers on the move - and follows them home. Having done so, sales staff can maintain a long - term relationship with the consumer through astute use of WeChat and other social platforms. Reaching young Chinese consumers also requires a considered approach to e-commerce, one which cultivates a rich and consistent brand image on owned platforms, while making sharp choices over whether or not to reach for the eye-popping traffic on mainstream e-commerce platforms. Finally, as young consumers blur the line between engagement and purchase, domestic and overseas, and online and offline, the new battleground for luxury brands requires fundamental organizational transformation. This requires not only winning in digital, but also more seamlessly integrating business units across brands, functions, and regions.

As indicated in the study by Chinese consumers, I will be the largest recipient of luxury goods until 2025. Occurrence related to Coronarovirus in 2020 will have an impact on the reduction of purchases of luxury goods in China in year 2020, but the trend in Chinese purchases will continue until 2025. It would be necessary to thoroughly examine how companies producing luxury goods will cope with the lack of purchases by Chinese consumers and how it will maintain their position on the international market.

The Business Sector Proactivity as An Economy Modernization Resource

Nikolay W. GONTAR

Southern Federal University, Rostov-on-Don, Russian Federation

passat01@mail.ru

Abstract

Modern global processes require the implementation of modernization strategies by countries that belong to developing countries and transition economies. In this regard, the relevance of the search and implementation of the modernization strategy on qualitatively new grounds remains. Such a new strategy could be, for example, modernization based on the business sector proactivity. The revitalization of national entrepreneurship and its proactive focus can serve as a method of modernization. The success of such a strategy substantially depends on state policy. The article offers an analysis of the features of proactive strategies, as well as an analysis of the necessary public policy measures in the interest of increasing the business proactivity potential. The directions of adaptation of state regulation for the implementation of such measures are also considered. As an empirical illustration of the use of proactive strategies, the experience of the Rostov factory for agricultural machines («Rostselmash») combine plant is analyzed. This company specializes in the manufacture of engineering products. The work examines the elements of proactivity that the company demonstrates in the markets of Russia and the world. In conclusion, the article proposes measures to improve public policy in the interests of developing business proactivity, including: attracting business to the development of government strategies; the introduction of proactivity in the legislative practice; limitation of tax, tariff and other exemptions from the economy; support for investments focused on innovation and promotion in foreign markets; removal of restrictions on access to advanced technologies.

Keywords: Proactivity, Entrepreneurship, Government Regulation, Modernization.

Introduction

Globalization as a process of constantly changing the balance of forces requires companies and countries to implement strategies to maintain their global position. The tool for such strategies is modernization. Successful modernization strategies should ensure not only the preservation of the existing positions of companies and national economies, but also form their leading dynamics. Among the variety of modernization tools, strategies based on proactivity can be distinguished. The qualities and properties of proactivity are studied in sufficient detail in relation to marketing and management. However, the study of proactivity can be considered in the context of developing strategies for the modernization of national economies. It is important to consider that the modernization of the national economy is based on the transformation of market sector strategies, as well as on the conditions that the state creates. Such a policy should fully take into account the potential for proactivity and provide conditions for the implementation of proactive business strategies. In addition, it is also relevant to introduce, in the interests of modernization, proactive elements in the activities of state bodies themselves.

Brief Literary Review

Theoretical ideas about the key features of business proactivity are a prerequisite for the analysis of modernization strategies at the level of countries and regions. It takes into account that proactivity is characteristic, first of all, for the business sector. At the level of government, it can also occur, but to a much lesser extent. The analysis of proactivity as a mechanism of modernization includes taking into account the conditions of business proactivity formed by national culture and state regulation.

The modern theoretical substantiation of the concept of proactivity is based on the research of such authors as Frankl (1990), Covey (2011), Allport (2002). The development of the concept of proactivity takes into account the importance of proactivity as the personal quality of entrepreneurs, according to Bonnet and Pape (2008), as well as the relevance of a proactive approach to risk management and the analysis of entrepreneurial orientation of a business (see the work of Matthing et al (2004).

The characteristic features of proactive corporate strategies are their proactive nature, the element of predicting the situation and leading actions as an element of such strategies (this distinguishes such strategies from reactive ones that are designed to give an answer to the threats and risks that have already arisen), according to Business Dictionary…,Parker (2010).

Proactivity is seen as an approach that provides flexibility and competitiveness for companies, as well as economies where such companies are well represented, as Accelerating organizations ...says.

Current research on proactivity focuses on a number of key issues. In view of the close connection between the proactivity of companies with personal qualities, proactivity is the subject of research in articles on the characteristics of the entrepreneur's personality, factors of psychological stability, according to Bande et al (2016), Bhaumik et al (2017), Chakraborty et al (2018), Strauss et al (2015). In addition, proactivity is considered as a field of education, and is also analyzed from the point of view of gender.

In business research today, the sphere of environmental policy and related corporate standards of responsibility are important, the implementation of which is associated with the application of proactive policies by companies (see, for example: Marco-Fondevila et al (2018), Carballo-Penela and Castroman-Diz (2015), Ibe et al (2015). Proactivity is also studied as a modern feature of environmental management.

Today, research on proactivity also affects management technologies per se, including entrepreneurship, risk management, and sales management, according to Pereira-Moliner et al (2015), Glaser et al (2016).

It is important that proactivity as a concept and managerial approach is analyzed both in relation to management at the level of government institutions, as well as in relation to regional development, as it is underlined by Robert and Broman (2017), Park and Jo (2018)**.**

The empirical evidence of the effectiveness of proactive strategies on the example of the Rostov factory for agricultural machines («Rostselmash») is supplemented by an analysis of the advantages and risks of the company's interaction with the state during the implementation of the proactive development strategy.

The methodology of studying the impact of business activity on the modernization development of the Russian economy is based on the initial characteristics of the structure of the proactivity phenomenon.

Such an initial study of the structure of the proactivity phenomenon provides for the appropriate correlation of elements of business proactivity and economic modernization.

In the analysis of proactivity factors, special attention is paid to state regulation as a condition for the implementation of business proactivity vectors.

The next stage examines the practice of business (in particular, in the engineering industry, using the example of the Rostov factory for agricultural machines («Rostselmash») from the point of view of

implementing proactive strategies. So, the real policy of the company is compared with the conceptual structure of proactive business strategies.

At the final stage, the work includes an assessment of the risks associated with state support in the implementation of a proactive strategy.

The use of the deductive method of proactivity analysis made it possible to identify practical forms of implementing conceptual approaches, as well as risks and threats that may impede the implementation of appropriate strategies.

Business proactivity: key manifestations and conditions of implementation

As a result of its versatility, a proactive approach can be used by companies of various sizes in various fields - from production management and improving production processes to managing costs and the external environment of a company, as Bezdenezhnykh and Rodionov (2017) says.

In relation to competitors, proactive companies can be characterized as aggressive. However, this property also helps such companies better cope with crisis phenomena in the economy. So, if ordinary companies in times of crisis reduce the marketing activity, R&D, as well as the range of products, proactive companies, according to Tamas and Issues (2015), on the contrary, modernize marketing policies, engage in recruiting, optimize business processes, apply know-how, use crowdsourcing.

Both the scale of entrepreneurship in a particular economy and the realization of its proactive potential depend on national economic and cultural conditions.

In this regard, for example, Sang and Peterson (2000) draws attention to the culture of countries, which leads to differences in the development of entrepreneurship. The reason for the differences is the attitude to the structure of society, hierarchy, job preservation, inequality, individualism and collectivism that is special for each culture.

However, in addition, the presence of macroeconomic incentives for entrepreneurial activity in the economy is of great importance. As an important component of such conditions, for example, UNCTAD calls growth strategies based on domestic demand, as Trade and .. (2013) says. This is possible if the incomes of the population, which are the main source of domestic demand, are maintained and increased. In addition, private investment and public sector spending are driving domestic demand. The growth in the consumption of domestic goods and services is forcing local producers to invest in production capacities. Investment growth contributes to the creation of additional jobs and wage growth, which increases demand, tax fees and public investment.

The state takes the most active role in creating the conditions for entrepreneurship and the formation of its proactive focus. On the whole, two directions of changes in state policy to stimulate business proactivity can be pointed out: reducing its activity in a number of areas while simultaneously increasing its presence in a number of other areas.

In order to encourage proactive business strategies, the state must take into account the role of innovation as a tool for proactivity. Such activities of companies can be implemented in different ways and include: identifying the hidden needs of markets, customer satisfaction, attracting users to model the format of goods and services. In addition, the state must, according to Willis (1985), be competent in protecting rights, especially in the intellectual field.

Ensuring the availability of resources that may be required to implement proactive company strategies includes, for example, a stimulating tax policy, favorable monetary conditions, and a competitive exchange rate mentioned by Trade and .. (2013). In addition, government support for R&D and education, labor mobility, and the import of complex components that are required for the innovative development of companies is important.

On the contrary, government activity should be reduced where it interferes the availability of resources that companies can use to implement proactive modernization. In addition, the use of resources by the state itself should be limited, which reduces the available balance of resources in the markets and increases their value.

So, we can talk about the need to reduce bureaucratic regulation, which generates unproductive time spent on the implementation of regulatory requirements. Here we can mention the need to limit (both in volume and in time) subsidies of companies and regions, since such subsidization is also a factor of unproductive fixing of resources. An important condition for the formation of public policy is its flexibility, as well as the prevention of the risks of turning direct government support into a permanent "rent", mentioned by Trade and .. (2006)

Thus, state regulation not only determines the activities of the market sector and the formation of incentives and resources for the implementation of its proactive strategies, but also forms the modernization development vectors and the status of economies.

The proactive modernization development vectors' formation and implementation (illustrated by the Rostov factory for agricultural machines («Rostselmash»)

The modern practice of managing business processes in market economy demonstrates the companies' proactive behavior possibilities in various business environments. As an example of the proactivity elements spectrum formation, we can consider the the Rostov factory for agricultural machines («Rostselmash», headquarters in Rostov-on-Don in the South of Russia), which is a structural element of the «New Commonwealth» multinational corporation (which also includes «KLEVER», «Buhler Industries Inc.» and others) and occupies a dominant position in the agricultural machinery production in Russia (70%) and a significant share of the world market (17%).

«Rostselmash» includes 13 enterprises located at 10 production sites in 5 countries today. The product line includes more than 150 models and modifications of 24 types of agricultural machinery. In total, by 2019, «Rostselmash» products will be delivered to 50 countries of the world, the company's sales and service network includes more than 500 divisions. «Rostselmash» supplies machinery to 39 countries and is the main supplier of agricultural equipment for agriculture in Russia (mentioned in: About the …).

Due to the agricultural sector's importance in Russia, «Rostselmash» operates in conditions of increased state attention. At the same time, the state regulation conditions are essential for the given plant as well as for other companies.

Speaking about the macroeconomic conditions of the company's development, it should be noted that both the recession in demand in the Russian economy after 2013 and the limited investment are relevant for it. So, according to the Russian Federal State Statistic Service Rosstat, in 2014-2016 the depreciation of investments in Russia exceeded 10%, and it was not offset by the increase in investment in 2017-2018. The FDI surplus in the country's economy in 2014 decreased threefold compared to 2013, after which the average FDI balance during 2015-2018 remained even lower. Incomes of the population in the Russian Federation during 2014-2019 also showed a constant decline.

Resource mobility is also faced with restrictions associated both with the Central Bank's tight monetary policy (a decline in rates was observed only in 2019) and with a significant increase in the tax burden in the economy and investments nationalization. At the same time, the organizing public investment inefficiency has led to the fact that, for example, in 2019, 1 trillion rubles from the funds planned for expenditure was not spent from the state budget, a part of the funds (150 billion rubles) allocated to the National projects in the economy and social sphere, implemented in the country, was not spent.

Thus, there are significant restrictions on both the demand side and the resources availability (in particular, financial resources) that can be used in proactive strategies. The consequence of such restrictions was a decrease in the small and medium-sized business share in the GDP of the Russian Federation in 2017-2018 from 22% to 20,2% (according to Rosstat). This indicates that the opportunities for implementing flexibility and proactivity are retained mainly by the large companies, which is illustrated by the «Rostselmash» example (see Table 1).

Table 1: The proactivity vectors in the Rostov factory for agricultural machines («Rostselmash») policy (compiled from the research materials and the data from the company (see the data in Gontar and Sapozhnikova (2019), About the…)

Proactivity Vectors	**Reflection in the policy of** the Rostov factory for agricultural machines («Rostselmash»)
Creation, search and implementation of innovations, including those involving R&D	Introduction of qualitatively new product lines, production and management technologies Serial production of the ACROS family machines since 2007 In 2014 - a global platform for opening a new agricultural machines galaxy production In 2017 - access to the Agrotronic remote monitoring and control system (developed by «Rostselmash»). Creation of a remotely operated combine harvester, testing an interactive assistance system for the operator in selecting the optimal combine settings «Rostselmash» is the official technical partner of WorldSkillsRussia - the national championship "Young Professionals", the organizer of the agricultural engineering innovative technologies student competition (AEITSC)
Creation, search and expansion of sales markets	In 2005, an innovative rotary threshing and separating device was introduced in Paris (SIMA). In 2018, 2 world records of «Rostselmash»tractor performance were set (RSM 2000 and RSM 1000). TORUM 2nd generation machines, new electronic systems RSM Explorer and RSM OptiMax are presented. Participation in international exhibitions (Kazakhstan), CIAME (China), Moldagroteh (Moldova), AGRO SHOW (Poland), Agro Planta (Romania).
Spatial expansion	Since 2007 - the agricultural machinery manufacturer assets acquisition Buhler Industries Inc (Canada), the tractor production start, the VERSATILE brand presentation. In 2009 - the inclusion of the following sites in «Rostselmash»: for the production of sprayers (Canada), the production of equipment for transshipment, processing and grain storage (USA). In 2011 - the acquisition of equipment production for sowing and tillage (Canada). The full range equipment formation for the entire cycle of agricultural work.
Attention to staffing, including retention in a crisis	Since 2012 «Rostselmash» has been supplying universities with educational materials, equipping classrooms (in 40 leading agricultural educational organizations in Russia), providing agricultural equipment for practical training, paying scholarships and organizing student internships Corporate University - a project within the company («Rostselmash»);
Improving the product line (offering goods and services), including interaction with customers	Since 2004 - the VECTOR family combine harvesters' introduction In 2008 - the release of trailed and mounted equipment for fodder procurement, for processing and storage of grain In 2009 - the start of production of new families of self-propelled agricultural machines In 2016 - the output of fodder harvesters based on the global platform (RSM F 2650). In 2017 - a new tractor building was put into operation; a full cycle of tractor production was launched (model RSM 2375); the release of the new NOVA compact cars. Start of wide adapter production (more than 12 m).

Thus, the in the Rostov factory for agricultural machines («Rostselmash») combine plant is an example of a company with a wide range of proactive policies. At the same time, the strategic importance of the agricultural production sector in Russia determines the company's close interaction with government bodies.

So, the head of the «New Commonwealth» group of companies is the co-chair of the Moscow Economic Forum, heads the Soyuzagromash, the union of agricultural machinery manufacturers in Russia. The «New Commonwealth» Group of Companies concluded strategic cooperation agreements with the regions' Governments and their ministries of agriculture. In 2015, the Rostov Region (Rostselmash-based region) signed a cooperation agreement with the Federal Industrial Development Fund, which offers preferential terms for the co-financing projects' development of new high-tech products, technical re-equipment and the competitive industries creation.

The sales program today includes the state subsidies attraction (by the agency of the state-owned company Rosagroleasing). So, in 2018, «Rostselmash» tractors became cheaper for agriculture, depending on the modification, by 389 - 562 thousand rubles. The company extends a program to reduce the technology cost to the participants in two federal subsidy programs. In general, the cooperation of the plant and Rosagroleasing allowed delivering of more than 5.3 thousand units of «Rostselmash» agricultural machinery under federal leasing (in the amount of 25 billion rubles) to the regions of the Russian Federation. Under the "OPT 2.0 Program", over 50 brands of the company's products are available for purchase. In 2018 the acquisition of equipment by Russian farmers with the help of state subsidies increased by 47%. In 2019 the new leasing portfolio volume was planned at the level of 24-25 billion rubles; Rosagroleasing's plans included the specialized technical modernization programs launch for flax growing, viticulture, vegetable growing and gardening.

At the same time, reliance on subsidies (in the absence of sufficient solvent demand in the economy) is a risk factor. So, the discussion of changing the scheme of subsidizing the purchase of agricultural machinery by the farmers (the abolition of the federal benefits program, according to which the Russian budget allocated funds to the Russian producers of agricultural machinery, which become a discount on agricultural machinery) prompted «Rostselmash» management to declare the possible problems at the enterprise. The discount due to the federal budget reached, according to the program's terms, 15-20%, and 25-30% subsequently. «Rostselmash» and the St. Petersburg Tractor Plant (PTP) accounted for up to 78% of the program's funding, but with the new scheme, a reduction in the companies' market share is possible. The reduction in supplies and profits was considered by «Rostselmash» as a possible reason for the refusal to build a tractor plant in Rostov-on-Don.

Thus, in the absence of sufficient macroeconomic conditions, it is possible to speak about the importance of large producer reliance on direct state assistance to development, which also makes it possible to implement the elements of the proactive company strategy. However, it is also necessary to ascertain the companies' dependence formation on preferential regimes, and the potential decrease in business interest in improving the investment climate quality (trust, interest rates, rights protection, trade freedom, control functions, administrative burden, ensuring the possibility of companies pursuing a flexible policy within the framework of the proactive approach).

Conclusion

Thus, taking into account the characteristic features of proactivity as a resource and a factor of modernization, a productive construction of modernization strategies can be ensured by the market companies proactivity conditions and resources formation. At the same time, the state's function is to remove barriers to the business flexibility implementation (ensuring a sufficient amount of resources and exchange freedom). In this regard, it is possible to speak about the redesign importance, in particular, the modern Russian approach to economic regulation. In particular, the system of government incentive measures for proactive business strategies should include:

• business representatives' participation in the national development strategies development;

• prognostic proactive nature of legislative activity in order to create a system of delimitation and property rights protection in promising economy sectors;

• limitation of tax, tariff and other resources seizures from the companies focused on innovation and promotion in foreign markets;

• removal of trade restrictions denying business access to advanced technologies;

• a radical reduction in the reporting and supervisory burden on the economy (this work was started by the Russian Government in 2019 as a part of the policy to repeal obsolete regulations).

A research vector for realizing the business proactivity potential in this connection should be focused on the formation of a proactive state which activities are aimed at promoting business proactivity. This will provide the modernization problems' solutions, increase the innovative status and competitiveness of the companies and economy as a whole.

Approach to The Narrative About Gender, Otherness and Violence Gender in Higher Education

Elizabeth MORENO-GÓMEZ*[1], Mauricio PRADA-ARÉVALO[2] y Henry W., LEÓN-CALDERÓN[3]

[1, 2, 3] Corporación Universitaria Minuto de Dios, Bogotá, Colombia,
*elizabeth.moreno.g@uniminuto.edu

Abstract

The objective of this research is to investigate the narratives about sexual diversity in fourth and eighth semester students of the Antonio Nariño University Universities - UAN (South Campus), Minuto de Dios University Corporation - UNIMINUTO (South Campus) and Foundation Monserrate University - UNIMONSERRATE (San Antonio- South Campus). This issue appears due to needing to take actions and strategies in universities that avoid, mitigate violence and discrimination against young people belonging to sexual diversity in the higher education. This research project emerged as a need for knowledge about this topic in higher education, the first approach is to consolidate the narratives that have the students of teaching career. In this way, this study expected to found that the universities not facing this issue. Therefore, could require a particular management that allows reflection, critical thinking and analysis in the students to approach diversity from their own experiences as university students and as future teachers. In this sense, three categories of analysis were established: gender, otherness and gender violence which were established from one of the initial phases of the investigation. This research uses a qualitative approach mediated by ethnography and semi-structured interviews, it will achieve an approach to the undergraduate students of the mentioned universities, as well as the understanding how they develop, live and build their experiences. The project seeks to have positive impacts, one of them is to recognize the importance of talking point of view the gender in higher education, based on a pedagogy of care for teacher training, because this will allow to promote educational environments free of discrimination and violence.

Keywords: Gender, Otherness, Violence Gender, Higher Education

Introduction

This research project, which is in the process of collecting and analyzing results, has as a fundamental principle to carry out the recommendations made by UNICEF and the Ministry of National Education of Colombia in 2016 regarding the violence reported before different instances and other cases acquaintances who ended up in the suicide of many young people because of their sexual identity. It uses as a guiding axis the pedagogy of care, like that science of education that allows visibility, recognition, inclusion and adaptation in such a way that education is a scenario of peace and social transformation.

For this reason, more research is required to address this issue, one of them is to know the narratives focusing on the teachers in training of some private universities in the south of Bogotá; in order to evidence and promote inclusion (Narváez Gómez, 2014) based on the gender approach (Viveros & Rodríguez, 2017). Of this way we are looking eradicate discriminatory practices towards children and youth belonging to the LGBTI sectors within the universities considering that they are important context where the people can development of training academic, social, ethical and political. Appreciate the universities as scenarios where there is a traditional and modern cultural dynamics from the perspective of gender will allow to recognize the phenomena that occur there and how from research can mitigate aspects related to gender violence and learning and discussing around this issue during the university.

Metodology

The research uses a qualitative approach mediated especially by ethnography, discussion groups and interviews in order to achieve an approach to university students and understand the context in which they function, live and build academically. The project was developed in four phases, each under a methodological rigor that allows to obtain truthful, reliable and close to reality results. The first phase was a systematic review of the literature on the subject of gender in Latin America. The second was the elaboration and validation of the instrument that was used in semi-structured interviews with the study population. Third phase was the implementation of the instrument and systematization of the results and fourth phase analysis of the results, drawing conclusions in relation to the results obtained and the objectives set. All methods that the researches used were based on the literature and in this sense we approach to the phenomenon.

Results

Phase 1: Systematic review of the literature. A search of articles published in Scielo, Dialnet, Redalyc database was carried out since they are sources of information where most studies have been published in Latin America and Scopus because it represents and includes publication of articles in high-impact journal at the level international.

Phase 2: The design of the questions was carried out with the project researchers, who had as a guidance guide a matrix for the elaboration of questions, in it the conceptual information of each category and its indicators was organized in such a way that it guided the design of the questions The purpose of each of the questions was also established in this work tool, which

It allowed establishing a direction and clarity regarding the intentionality of the question regarding the categories of gender, otherness and gender violence. After that, a validation process was carried out that was divided into three stages mainly: validation by four experts, questionnaire adjustment, validation by expert discussion group, questionnaire adjustment, pilot test, questionnaire adjustment to finally have the guide questionnaire of the questions for the interview.

Phase 3: In this phase of the research project, interviews were conducted in three private universities with offices located in the south of Bogotá, Unimonserrate, Uniminuto and Antonio Nariño University, which, in each one, 10 interviews with undergraduate students of Fourth and eighth semester. The duration of the interviews on average was 35 min and in them it was possible to extract the information through audio recordings which later each were transcription.

Phase 4: In the last phase of the project, which is in execution, and consists mainly of tabulation and analysis of data through the technique of narrative analysis according to the principles of textual analysis discursive in the subjective language present in the answers of the students' interviews, which will allow to extract the relevant information and develop a reflexive and general analysis of the results found in the project.

Conclusion

The documentary review has allowed to establish some theoretical traces that are very well restricted in terms of their diverse senses in the face of the research problem. Gender is a human event that has been understood in analogous ways through time and different cultures.

The epistemological tension of the implications of gender acceptance moves, precisely, between the purely biological, and the conventionally socio-cultural, hence the difficulty of pointing out limits that could be taken into account in addressing the central research problem.

Gender violence is a system of power that is exercised in different ways in the university environment where victims mainly refer to women, homosexual and bisexual population; This means that the university education system must employ pedagogical strategies that integrate and attend to gender diversity.

The University and specifically the educational system recognizes a duality between the gender perspective man - woman on which it builds its policies and fundamentals of professionalization, leading to hegemonic views on the construction of identity.

Effects of Financial Crises on Latin American Economies-Colombia Case and the SMES

Jenny A. SEGURA, Uniminuto, Bogotá, Colombia

jseguraosun@uniminuto.edu.co

Victor J. SARMIENTO, Bogotá, Colombia

vsarmientof@uniminuto.edu.co

Summary

This article analyzes the most representative international financial crises in Colombia since 1990: the Asian crisis of 1997 and the Sub-Prime crisis of 2008 in the United States. Likewise, the impacts and their effects on national production in some Latin American countries are indicated. Finally, it is shown how financial literacy cushions the negative effects on small and medium-sized (SMEs), which are of vital importance in economic for its contribution to GDP and the generation of formal jobs.

Keywords: Financial crisis; financial literacy; GDP; SMEs.

Introduction

Economies have periods of growth, expansion and boom, as well as periods of slowdown and crisis, which occur over time as part of what in economics are called business cycles, which depend on internal and external factors, political, social, natural and demographic (Samuelson, 1967). Among the main causes for which the economies of the countries, both emerging and developed, are affected and present falls in national production as measured by the Gross Domestic Product (GDP), it has to do with what happens to the financial system and its crises, which are expanding rapidly given the degree of globalization and openness not only of an economic and commercial type but also of a cultural and technological type (Larraín and Sachs 2002).

The functioning of financial markets has been of great importance in explaining the falls in real activity, since in the last 200 years approximately 300 financial crises have occurred, the most critical being that of 1930, also known as the " Great Depression "and that of 2008 or" Crisis subprime ", (Machinea, 2009). This author also identifies the instability of the financial system as the main cause of financial crises.

In the development of this article, we present what happened in Asia at the end of the last century in Asian countries such as Malaysia, Korea, Indonesia, Thailand, among others, and that affected several countries, reaching as far as Latin America, including Colombia where they lived. a very strong economic recession (Cepal, 1998). Likewise, the mortgage or subprime crisis that broke out in 2008 in the United States is presented and expanded worldwide (Titelman, Pérez, and Pineda, 2009) and had strong impacts on the Colombian economy (Ocampo 2009).

From the lessons left in the last 22 years, SMES in Colombia and other Latin American countries should be able to make the best decisions in economic and financial matters, for which a certain degree of financial literacy and economic. In accordance with the above, it is desired to show what the effects of said crises were at the macroeconomic level in Colombia and on the economic results of SMES

Methodology

This article is a literature review on what happened in the aforementioned financial crises, which had strong consequences on the dynamics of the Colombian economy and on that of other Latin American countries, in order to identify the factors that make these economies in the presence of these crises and

what are their effects on small and medium-sized companies, which can use financial literacy as a tool to cushion the strong effects of these crises.

According to Guirao, Olmedo and Ferrer (2008), review articles "is a type of scientific article that without being original collects the most relevant information on a specific topic". In that order of ideas, first of all, inquiries are made about crises as part of a country's economic cycle, what is a crisis in the financial system and how it affects the general performance of a country or group of countries, that at a theoretical level, to At an empirical level, the causes, development and consequences of the two crises studied in this document are analyzed taking as a specific case what happened in Colombia.

As an additional analysis tool to the documentary review, it is presented through a table and a graph which were the effects of said crises in other Latin American economies, where it can be seen that the impact was generalized given the high interconnection of the markets and economies globally.

This research shows how even in Colombia and in other Latin American countries there are shortcomings in financial literacy issues, at the level of the general population, but also in people who are in charge of the administration and finances of small and medium-sized companies. Given this limitation of knowledge in this important area, financial literacy is proposed as a tool for SMEs to face financial crises and sustain themselves in the market over time, since many of them are born, but in less than five years are already out of the market.

Results

Stylized facts of the financial crises of 1997 and 2008 and framework

In Latin America, the financial crises of Asia in 1997 and that of the United States in 2008 have been the most important in terms of their negative effect on the economies of Latin America, as shown in Figure and Table 1, after these crisis the annual variation in GDP reflects slowdowns and in some cases falls in this important indicator of economic activity:

Fig. 1: Variation% of real GDP by country, own elaboration with World Bank data

Venezuela, RB	4,0	(0,2)	6,4	0,3	(6,0)	3,7	3,4	(8,9)	(7,8)	18,3	10,3	9,9	8,8	5,3	(3,2)	(1,5)	4,2	5,6

Analyzing the data of the percentage growth of the GDP for the chosen countries, it can be inferred that the United States always had growth, except when the real estate bubble burst in 2008 where the GDP fell 0.1% and 2.5% in 2008 and 2009 respectively, a phenomenon that was not observed in other years of the study period contemplated here. When observing the figures it is also evident that countries such as Argentina, Paraguay, Uruguay and Venezuela, present shorter cycles where the fall in production is more frequent taking into account their particular economic, commercial and political structure, however all of them also coincide in to have a phase of economic recession after the crisis of the Asian countries and the real estate crisis except Uruguay, which by the end of the 2000s came with high economic dynamics and did not suffer significant impacts on its economy.

In the face of the crisis in the Asian countries, Brazil and Mexico presented a slowdown in economic growth, but no drop in GDP, contrary to the great impact of the 2008 mortgage crisis, since their production fell by 0.1% and 5.3% respectively, the great impact in Mexico given its proximity to the country where the crisis was born. In the case of Chile, in both crises its economic growth was affected, since for 1999 its economy decreased by 0.04% and in 2009 by 1.6%. Ecuador, like Colombia, presented a drop in production with the Asian crisis of 4.7% and a slowdown in productive activity after the collapse of the mortgage and financial market in the United States, in 2009 its growth was 0.6%, showing a slowed economy.

In Peru, the impact of the Asian crisis came in 98 and not in 99 since for that year GDP fell by 0.4, this result was also due to internal factors concerning mining and the phenomenon of children (Erdmann, Schulz, Richter and Rodríguez, 2008). For 2009, the year in which the subprime crisis hit most Latin American countries, production growth reached a level of 1.1%, showing signs of a slowdown in the Inca economy.

It can be concluded that the international financial crises of 97 and 2008 had a heterogeneous impact on countries in Latin America, since in some there were drops in production and in others not, however, the negative change in dynamics was evidence in almost all.

1997 Asian crisis and 2008 subprime crisis

The Asian crisis originated from "... The exhaustion of the Asian Miracle and the problems of moral hazard", the first refers to the extraordinary economic growth of these nations decades ago, and the second to the opportunistic behavior of financial entities which acted in a manner that their benefits were increasing while the interests of the users of said financial services were left behind (Clavijo, 2000). Esquivel and Larraín (1999) maintain that this financial-exchange crisis that occurred in Asian countries spread to Latin America, affecting the purchasing power of these countries

Regarding the crisis of 2008, Ferguson (2010), affirms that this crisis was conceived from the end of the 20th century, more specifically from the 1970s, when little by little the legislative power of this country began to deregulate the financial system and the transactions led to out on this. All this led to financial institutions making a series of risky investments that made savers lose their investments. At that time, loans were affordable to the entire public, especially mortgages that financed up to 99% of the nominal value of housing, with which house prices tripled, creating a bubble that, after the crisis, burst and left thousands of homeless americans.

The interconnection of institutions that offer financial services caused this crisis to spread rapidly and widely throughout the world, partly because of the so-called "financial innovation" as cited by Uribe (2011). Belda (2008) points out that the failure to pay these mortgages in the summer of 2007 was what triggered the crisis. This mortgage market underwent changes regarding its regulation in the nineties, with which there was a decrease in the supervision of said loans and gave rise to moral hazard. Something that also favored the increase in subprime loans was financial innovations when mortgage and commercial banks merged, the latter took the opportunity to expand with the benefit of not being subject to rigorous surveillance.

The undervaluation of risk, issued by risk rating agencies, played a role in this crisis, since they gave a rating of AAA to some risky investments. In the end, these rating agencies justified their opinion as an opinion that did not involve a numerical and qualitative methodology of rigor. The crisis erupted and several financial entities went bankrupt, including Lehman Brothers and Merril Lynch, and the Federal Reserve had to intervene by injecting millions of dollars into the financial system, so that its negative impacts would not be as dire as those of the Great Depression of 1929 Ferguson (2010).

Machinea (2009) points out that the instability of the financial system was the main cause of this financial crisis and that three factors influenced its great magnitude: firstly, the large size of the international financial system, which according to this author exceeds the GDP of developed countries, secondly the interconnection and globalization of financial institutions worldwide and lastly the penumbra regarding the information that financial institutions manage in the midst of their operation that knows no limits regarding their earnings and the product portfolio it offers. Chor and Manova (2012), point out that those companies with external sources of financing that were seriously affected at the time of the crisis, since that moment did not have financing.

Palomo and Sanchís (2010) show that even old-age pensions were affected since their profitability decreased and their volume also fell as a consequence of the increase in unemployment and informality and the evasion of the payment of this social contribution, all this product of the drop in

the production of goods and services experienced by economies around the world. Zurdo and Palacio (2010) find that at the corporate level, many firms to avoid bankruptcies are restructured or merged with others, which can lead to the dismissal of employees and thus improve financial ratios. Titelman, Pérez, and Pineda (2009) indicate that the effects of this crisis were generalized, profound and long-lasting, and from one country to another they depended on the degree of openness to international trade and the global financial market, macroeconomic and general conditions, and policies carried out by the economic authority.

Colombia Case

In Colombia, the first crisis began to slow down the growth of the economy and the worst moment was experienced in 1999 when production fell by 4.2%, the lowest in many years. This Asian financial crisis began in 1997 and spread to many countries in the world, including Colombia. Johnson, Boone, Breach and Friedman (2000) found that the Asian crisis of 1997 and 1998 was mainly due to macroeconomic reasons and the way the financial market worked at that time and, citing Krugman, say that it was a consequence of the formation of bubbles in the price of assets. They also maintain that in this crisis there was loss of confidence on the part of national and foreign investors from emerging countries, which aggravated the problem since there was a massive outflow of capital from these nations.

According to Uribe (2011), the conditions for this economic crisis have been in place since the early nineties where there was also a financial opening that caused a decrease in domestic savings, high indebtedness, both private and public. By the time the impacts of this Asian crisis arrived in Colombia, mortgage credit was no longer a State monopoly and instead other entities that also granted this type of credit had entered the market, which were now of the “subprime” type, so that this market was exposed to credit and liquidity risk.

In addition to the -4.2% drop in GDP, there was an increase in unemployment, which was close to 19%. In the face of this crisis, the economic authorities of Colombia requested financing from the Multilateral Bank, the World Bank and the International Monetary Fund, according to Clavijo (2000), which cushioned the negative effects of the crisis, along with the help that it received at that time the country of the so-called "Plan Colombia", which sought to eradicate illicit crops, among other things, but which brought with it serious problems such as the violation of human rights (Chomsky, 2000).

After the recession of 99, the Colombian economy had a recovery and even a high growth of 6.8% for the years of 2006 and 2007, especially marked by high aggregate demand. Already in 2008, given this situation and with great inflationary pressure, the Banco de la República began to raise interest rates, this plus what happened in the United States led the economy to a slowdown in growth, and for that year growth was 3.3 %, the following year 2009 was where the impact of what happened in the United States was felt the most since growth was 1.2%. Although growth for 2009 was not negative, after the 1999 crisis it was the smallest expansion in the economy in the reference period.

Regarding the subprime crisis, Banco de la República (2009) affirms that several factors caused a slowdown in economic activity in our country, but the one that was increased by the decrease in remittances sent from abroad to Colombia, accompanied by a decrease in exports as a result of lower external demand for our products, determining factors in the crisis in the real sector of the economy. For his part, Uribe (2011) maintains that the role of financial institutions is of vital importance and that the lack of transparency affects the well-being of investors and, in general, the macroeconomic stability of a nation.

Importance of Financial literacy in SMEs

Álvarez and Abreu (2008) point out that for a small or medium-sized company, financial strategies are of vital importance when it comes to obtaining good economic results and avoiding unfavorable results; in the same way, it is also essential to cover financially in the face of constant fluctuations in the currency, the instability of interest rates and the constant movements of the stock markets, in order to be able to leverage strong financial movements. This in order to minimize the impact that SMEs may

suffer in emerging countries and especially in the Colombian economy. To say that a company is a micro, small or medium company in Colombia according to Law 590 of 2000, one must consider the number of employees and the total value of their assets.

Table 2: Classification of companies according to their size according to law 590 of 2000

	Employees
Micro	E<10
Small	11<E<50
Medium	51<E<200

According to Banco de la República in September 2009, the international financial crisis of 2008 had an impact on companies and their finances since, given the scarcity of resources in international markets, there was a recomposition of the debt, which generated higher interest payments and due to Thus, a lower profitability that went from 6.9% to 6.7%, liquidity indicators also deteriorated. This report quotes ANDI, and says that some companies endured this situation with financial and administrative education strategies such as optimizing their costs, seeking new marketing strategies, innovations and the development of new products, among others.

Regarding the optimization of costs, Gómez (2011) presents the case of children's clothing in Bucaramanga, which are small companies and concludes that most of these companies did not have a modern system to take their costs into account, but they applied some strategies to minimize them, such as taking advantage of the experience of each worker that is obtained after a certain period of time in which they have worked in that work and taking advantage of technological advances to increase production.

The strategies for cost control and minimization are mainly focused on the good performance of human resources through the experience curve, increases in production levels and the technology applied to processes. Most of these organizations lack cutting-edge tools, although they have specialized machines. One of the strengths is that reflected in the knowledge of human resources expressed in high-quality artisan production, with innovative designs, elements that become added value to compete in the market with differentiated products.

In an empirical study, Restrepo (2005) observes that, despite the modernization and the transition to technology carried out by SMEs, they are not yet within their priorities and sometimes they lack resources in terms of information systems, mining data, commercial creativity.

Whatever the strategy used by companies, any positive or negative result affects their finances and economic results, so financial literacy is very important for the proper management of resources. According to García, Grifoni, López and Mejía (2013), financial literacy is a tool that in times of economic growth can improve finances if the financial markets are used when they have favorable conditions, in the opposite of crisis it is also possible to cushion the effects of the fall in production and the worst conditions in the financial markets.

However, in the Colombian business reality, what is observed is a lack of business financial literacy in SMEs, in the special report on Financial Stability published in May 2019 by Banco de la República, it is evident that the majority of companies in Colombia It is financed through the acquisition of bank credit (in Colombia and abroad), with Financial Leasing and Factoring, through credit with the reinvestment providers of the profits and / or through the own resources that are not derived from the profits. Among the companies that use national bank credit as the first option, many use microcredit as a form of financing, which presents problems of over-indebtedness and the portfolio of the entities that provide this service has deteriorated and in general the perceived economic prospects are not the same. top.

Currently, given the recognition that financial literacy has been given as a requirement for SMEs to have better results, programs have been implemented that seek to train companies in these topics, free of charge, as the initiatives of some entities of the system financial of offering this service, through

booklets and virtual programs. Asobancaria (2017) states that financial literacy is very important for SMEs, since among the reasons for bankruptcy of this type of companies is the low level of financial matters that SMEs have.

Regarding the issue of financial crises and the stability and survival of SMEs, Medina (2015) points out that financial crises are often the result of a lack of solid knowledge regarding the services and products that different financial institutions offer to investors and clients, being financial literacy a tool to improve decision making. Likewise, the author points out that the lack of education in SMEs causes them to have to leverage through their own resources or other non-formal sources, which increases the degree of financial exclusion for these companies. For his part, Soto (2016), points out that financial literacy allows companies to be able to face financial crises and to know the risks they may be exposed to.

Conclusions

The crises studied here had strong effects on the economic dynamics of Colombia and the Latin American countries that were taken as a reference, given the influence that financial markets have on real activity, not only of their countries but of those with which it has commercial and financial relationships. The documentary review shows that, in Colombia after the fall and slowdown in production measured through the percentage change in GDP, after the financial crises of 97 and 2008 respectively, it brought other consequences at the macroeconomic level such as inflation, indebtedness, instability in the financial system, volatility in the exchange rate, among others, which internally accentuated the effects of the crisis.

It was also evident that the crises, apart from affecting the Colombian economy as a whole, negatively impacted the most vulnerable companies, which are the smallest, since they have limited information and of which the people who are in charge of its financial management and administration do not have a sufficient level of financial literacy.

This reflects on how limited financial literacy can lead to the effects of external factors such as international financial crises, affecting smaller companies in the country compared to others with technical tools at their fingertips. Taking into account the importance of financial literacy, governments and private entities have chosen to offer free programs, so that people of all ages and educational levels can learn some of the main concepts contained in this term, however, it is evident that At the national and international level so far they are of little scope and that there is a need to formulate more programs that are focused on SMEs and that are tailored to their needs since most of these are oriented to the issue of personal finances that are the foundation of financial culture.

Manufacturing Output and Labour Productivity: A Comparative Study of Nigeria and South Africa

Adeyemi A. OGUNDIPE and Favour O. OLAREWAJU

Department of Economics and Development Studies,
Covenant University, Ota, Nigeria
ade.ogundipe@covenantuniversity.edu.ng
favourbola1@gmail.com

Abstract

Increased productivity is necessary for improved manufacturing output, better living standards and sustained competitiveness of any country. Hence, to obtain maximum effect, there must be transition and structural change from traditional and modern economic sectors in addition to within-sector productivity. Given various similarities of Nigeria and South Africa, ranging from same British colonisation to similar labour structure, South Africa is known to be more advanced than Nigeria. Hence, this study aims to examine trends and patterns of both Nigerian and South African economies from 1986 to 2018. Thus, evidence was found that regardless of South Africa's much higher labour productivity, the growth of its manufacturing sector, especially in relation to GDP seems to be declining. Meanwhile, Nigeria has low labour productivity and fluctuating manufacturing output, especially since the nation is yet to fully recover from the last recession in 2015.

Keywords: Manufacturing output, labour productivity, Nigeria, South Africa, trends.

Introduction

Productivity growth is a vital requirement for higher living standards and sustaining competitiveness on a global scale. The issue does not just lie in developing more productive avenues of performing business operations but also involves accelerating structural transformation from lower productive undertakings (e.g. skill-extensive services, petty trade and agriculture) to higher productive activities that optimise specialisation, knowledge intensiveness and technological innovations in manufacturing (Tesfahun, 2015; Krause & Kaufmann, 2011; Rosendahl, 2010; Ogundipe et al., 2019). Labour productivity and total factor productivity are related and often interchanged, whereas they mean different things. The former refers to output by worker (that is, gross value added or output per unit of labour input) while the latter is productivity in terms of all aggregate inputs. Higher aggregate labour productivity is typically thought to be a good sign, but this might not necessarily apply for high unemployment economies like South Africa (Nattrass & Seekings, 2014, 2012) and Nigeria. Such increase in overall labour productivity might emanate from more productive workers or employment reallocation from (or replacement of) lower to (with) higher productive employees within firms. On the other hand, it could be because high labour productivity companies are expanding more rapidly than lesser productive ventures or it could be motivated by growing labour productivity industries. As at 2002, labour productivity per worker was $8800 but tripled to $25,600 by 2012. So, given South Africa's characteristics of high unemployment and low-skilled labour, fewer job types that is accessible to the unemployed or poorly skilled workers will actually negatively impact the economy. Whereas, higher labour productivity that is connected to greater productivity of poorly skilled employees is a positive outcome (Rankin, 2016).

Not much is known about how labour productivity of South African manufacturing firms have grown over the years. Generally, real labour productivity has doubled, however, most of this increase stems from within-industry changes, particularly, 'catch-up' by previously lower productive industries. This increment in real labour productivity has co-existed with higher real wages. Interestingly, within-industry changes appear to vary depending on firm sizes. Surprisingly, smaller firms have gained

greater labour productivity in comparison to bigger firms. It does not look like these changes are propelled by variations in capital intensity among various sized industries, rather it seems to be related to differences in real labour costs. Average real wages of smaller companies appear to be increasing faster than larger firms. Comparable surveys reveal that reduction and exit of lower (unskilled labour) productivity. Moreover, such exit is associated with import competition growth and industrial bargaining structure (Rankin, 2016). Undeniably, the manufacturing sector has been crucial to South Africa's progress over time (McCarthy, 1994).

Manufacturing sector's contribution to GDP has varied vastly over time in Nigeria. It increased from 4.8% to 7.4% in 1960 to 1975. However, it reduced to 5.4% by the end of 1980 but increased to 10.7% in 1985. Ever since then, it has been declined to 7.9% (1992); 6.3% (1997) and its lowest of 3.4% in 2001, before scaling up to 4.21% in 2009 (Central Bank of Nigeria -CBN, 2012). By 2012 and 2013, manufacturing share of GDP had risen to 6.67% and 6.83% in 2012 and 2013 (National Bureau of Statistics -NBS, 2014). Unfortunately, the recent economic recession seriously impaired growth of the manufacturing industry, reflected by 8.7% fall of industrial production in Q4 of 2016 over Q4 of 2015.from 2007 till 2016; average production growth was 1.35% with its highest of 20.10% in Q1 of 2011 and least point of 10.10% in Q1 of 2016. Industrial output increased to 0.1% in Q2 of 2016 from -10.1% in Q1, before dropping to -3.6% and -8.7% in Q3 of Q4 of 2016 respectively (Nigeria Industrial Production, 2017; Ogundipe et al., 2018).

Most prior studies have focused on the relationship between manufacturing growth and economic growth (Tsoku, Mosikari, Xaba & Modise, 2017; Meyer & McCamel, 2017; Cantore, Clara, Lavopa & Soare, (2017;) or in terms of trade (Delivani, 1992), structural change (De Vries, Timmer & De Vries, 2015; Nattrass & Seekings, 2012; Maia, 2011); industrial strategies (Rosendahl, 2010; Bethlehem, 1994; Black, 1993; Ismael, 1993);real wages in relation to productivity growth and employment (Asaleye, Olurinola, Oloni & Ogunjobi, 2017); comparative advantage (Sejkora & Sankot, 2017), determinants of capacity utilisation in Nigerian manufacturing (Adeyemi & Olufemi, 2016) and how fluctuations in macroeconomic factors impact manufacturing sector output (Onakoya, 2018; Ogundipe et al., 2019). Data analysis between Nigeria and South Africa shows that on the average, both nations have been increasing in their labour productivity over the years, however, South Africa has been increasing at a much higher rate and is way higher than that of Nigeria. Surprisingly, manufacturing value added as a percentage of GDP for South Africa has been decreasing over time, despite the fact that it was much higher than Nigeria as at 1986, it is now almost at the same level with Nigeria. Whereas, Nigeria's manufacturing output as a share of GDP has been fluctuating over the years but seems to be on a slight decline since 2015. Additionally, manufacturing value added annual growth rate has been fluctuating over the years but has recently been reducing and is trying to pick up. This begs the question, why is South Africa's manufacturing share of GDP reducing despite its increasing labour productivity? Labour productivity is focused upon because it is a vital influencer of economic performance. Also, both countries belong to the group of developing countries whose economic activities are more facilitated by labour inputs. Moreover, both countries were colonised by the British and gained independence in the 1900s.Hence, this paper seeks to examine the trends of manufacturing output and labour productivity over time in Nigeria and South Africa.

Moreover, wages in South African manufacturing is comparatively high but its labour productivity was found to be incapable of supporting such high costs, so either labour productivity rises or costs importance of moving from deindustrialisation to reindustrialisation to aid long term growth and manufacturing employment. Korean assessment by Sundararajan (1987) adopted dynamic framework across debt-equity ratio of firms, growth, investment, cost of capital and interest rates measured in foreign exchange rates have to drastically reduce. Tregenna (2011) recognises the from 1963 to 1981. Contrasting connection was reported in terms of interest rate and manufacturing productivity.

A comparison of Nigeria and South Africa

Trend Analysis: Empirical Evidence from data of Nigeria and South African Manufacturing and Labour Productivity from 1986 to 2018

This section contains explanations of manufacturing output and labour productivity trends from 1986 to 2018 between Nigeria and South Africa. Manufacturing value added as a percentage of GDP, annual

growth rate and constant 2010 US$ are used to provide vast evaluations. The purpose of these analytical trends is to account for the variations in these variables while applying data results to practical happenings in both countries over time.

Figure 1: GDP per person employed of Nigeria and South Africa

Source: WDI (2018)

GDP per person employed for Nigeria begins from about $10,000 in 1986 and was somewhat stagnant till 2002, after which it increased slightly to almost $15,000 in 2004 and gradually continued to rise in subsequent years. Labour productivity reached its peak in 2014 at approximately $25,000. However, it began declining afterwards and is yet to pick up. This illustrates the slow growth of labour productivity over the years in Nigeria. On the other hand, that of South Africa started out at a much higher rate than Nigeria at about $35,000. Although the nation experienced a slight dip in labour productivity between 1992 and 1995, it picked up and has been increasing on the average since then, recently hovering around $43,000. Thus, in general, South African labour productivity is almost three time more than Nigeria's level, despite occasional dips.

Figure 2: Manufacturing Value Added (MVA- % of GDP): Nigeria vs South Africa

Source: WDI (2018)

Nigeria's manufacturing output as a percentage of GDP was slightly above 20% in 1986 (probably due to the initial success of SAP before the long-term adverse effects kicked in). However, it fluctuated severally, especially before 1994which happened to be the year of the highest value added to GDP at almost 21%. Since then till 2010, MVA % of GDP has been decreasing mostly, except for the brief rise in 2014 at almost 10%, which is much lesser than its level in 1986. This is quite worrisome given that several industrial schemes have been implemented in the past, including import substitution strategy in the 1960s; Indigenisation policy in 1972 and 1977; four (4) National Development Plans of 1962-1968; 1970-1974; 1975-1980; and 1980-1985; SAP of 1986, which included export promotion strategy, followed by the foreign private investment led industrialisation Strategy among others.

Almost similarly, South Africa contributed approximately 20% to GDP in 1986 with a brief rise (peak of 21.6%) in 1990. Unfortunately, this was mostly on the decline till 2017. When rationalised with the fact that SA has much higher labour productivity than Nigeria, one would expect the manufacturing sector to contribute more to GDP, particularly as it is arguably the most developed and largest country in Sub-Saharan Africa. However, this is not the case probably due to the lack of dynamism and slow national growth ever since the end of apartheid which has led to de-industrialisation concerns and reduced shares of manufacturing in GDP and employment (Maia, 2011; DTI, 2010; Rodrik, 2008).

Figure 3: MVA (Annual % growth) of Nigeria and South Africa

Source: WDI (2018)

Manufacturing output annual growth for South Africa stood at -0.16% in 1986 before increasing to about 6.5% in 1988. However, there were several periods of sharp decline in 1992, 1996, 1998, 2003, 2009 and 2016. MVA growth has been rather unstable since 2016 in trying to recover from the 2015/2016 economic recession that affected most African nations. Meanwhile, manufacturing growth for Nigeria was negative at almost 10% and has depicted severe instability and fluctuations over the years. This is regardless of the small and medium Industrial equity investment scheme (SMIEIS) by SMI Development Agency of Nigeria (SMIDAN) in 1973 asides other industrial policies. Nonetheless, in recent times, it appears to be recovering slowly from the 2015/2016 recession at approximately 1%.

Figure 4: Graphical Illustration of MVA (constant 2010 US$) of Nigeria vs South Africa
Source: WDI (2018)

Figure 4 portrays manufacturing output in constant 2010 US$ (that is, without accounting for asset depreciation) where Nigeria is seen to start from about 20 trillion dollars, prior to rising slightly to almost 30 trillion in 1988 but falling again to about 24 trillion dollars. Since 1993 when it was valued at 31 trillion USD, it experienced major decline and stagnation from then till 2010, when it began picking up to reach its peak in 2014 at $44 trillion. From that time till now, no serious progress has been observed in the manufacturing sector as it appears rather dormant. Conversely, South Africa on the average was rising and recently has been around $52 trillion.

Conclusion and Recommendations

Analyses the above trend depicts that South Africa is better and more stable than Nigeria, probably because of its much higher labour productivity. Although the South African manufacturing sector has room for improvement, Nigeria still has a long way to go. Hence, this paper suggests that enhancing labour productivity, especially in the manufacturing industries will go a long way to boost and sustain manufacturing output. This is possible either by increasing wages, reducing production costs or introducing technology and policies that favour technological implementation. However, it appears that the latter solution will have the most durable effect into the long run (as is already evident in South Africa). Thus, the Nigerian economy can intensify its steps to increasing the availability and accessibility of infrastructural and technological amenities via public-private partnerships. Additionally, for sustained results, both skilled and unskilled workers must be trained to effectively handle such technology infrastructures (Ola-David, Amoo, Olurinola & Fadayomi, 2013; Oluwatobi, Oluwatobi, Oshokoya, Olurinola, & Alege, 2019).

An Analysis of the Effect of Labour Productivity on Manufacturing Output in Nigeria

Favour O. OLAREWAJU and Adeyemi A. OGUNDIPE

Department of Economics and Development Studies
Covenant University, Ota, Nigeria

favourbola1@gmail.com
ade.ogundipe@covenantuniversity.edu.ng

Abstract

Increased productivity is necessary for improved manufacturing output, better living standards and sustained competitiveness of any country. Transition and structural change from traditional and modern economic sectors are needed for maximum productivity effects in addition to within-sector productivity. Human capital theory is used as theoretical framework in addition to empirical studies. Thus, Johansen co-integration is performed to examine the magnitude of labour productivity's long-run impact on Nigeria's manufacturing output from 1986 to 2018. It was revealed that the non-conformity of other explanatory variables seems to counter the significantly positive effect of labour productivity on Nigerian manufacturing sector. Therefore, evidence was found that Nigeria has low labour productivity and fluctuating manufacturing output, especially since the nation is yet to fully recover from the last recession in 2015.

Keywords*:* Manufacturing output, labour productivity, Nigeria, human capital.

Introduction

Manufacturing sector is seen as an extremely key aspect of any economy due to its capability of fostering effective and diverse forward and backward linkages across various economic sectors (Kayode, 2000). Thus, capacity utilisation of industries is a very crucial aspect since positive relationship exists between capacity utilisation and output growth. Fabayo (1981) asserts that the amount of capacity utilised does not affect how much output can be gotten from more utilisation of existent capacity and he went ahead to specify the needed capacity expansion for a projected output. Moreover, capacity utilisation positively impacts employment through industrial growth and stable prices. Skilled labour and capital resources, which are critical for accelerated economic development are expensive and scarce and is rather tedious to complement with technical dexterity time elements and financial resources (Adeyemi & Olufemi, 2016; Ogundipe et al., 2019). Given Nigeria's poor manufacturing optimisation, Structural Adjustment Programme (SAP) was adopted in 1986 to revamp the sector by diversifying industrial operations. However, this did not have the desired effects on Nigerian manufacturing industries and the economy as there has been frequent fluctuations over the years, including the recent economic recession of 2015. This therefore raises concerns on how Nigeria's manufacturing enterprises can be improved through higher labour productivity in the country.

Manufacturing sector's contribution to GDP has varied vastly over time in Nigeria. It increased from 4.8% to 7.4% in 1960 to 1975. However, it reduced to 5.4% by the end of 1980 but increased to 10.7% in 1985. Ever since then, it has been declined to 7.9% (1992); 6.3% (1997) and its lowest of 3.4% in 2001, before scaling up to 4.21% in 2009 (Central Bank of Nigeria -CBN, 2012). By 2012 and 2013, manufacturing share of GDP had risen to 6.67% and 6.83% in 2012 and 2013 (National Bureau of Statistics -NBS, 2014). Unfortunately, the recent economic recession seriously impaired growth of the manufacturing industry, reflected by 8.7% fall of industrial production in Q4 of 2016 over Q4 of 2015.from 2007 till 2016, average production growth was 1.35% with its highest of 20.10% in Q1 of

2011 and least point of 10.10% in Q1 of 2016. Industrial output increased to 0.1% in Q2 of 2016 from -10.1% in Q1, before dropping to -3.6% and -8.7% in Q3 of Q4 of 2016 respectively (Nigeria Industrial Production, 2017). Nigeria's manufacturing output as a share of GDP has been fluctuating over the years but seems to be on a slight decline since 2015. Additionally, manufacturing value added (MVA) annual growth rate has been fluctuating over the years but has recently been reducing and is trying to pick up. Meanwhile, Nigerian labour productivity is rather low. So, this paper seeks to answer the question: why is manufacturing output not progressing as expected despite several industrial policies that have been implemented over the years? Could this be as a result of low labour productivity of Nigerian workers? Labour productivity is focused upon because it is a vital influencer of economic performance.

Most prior studies have focused on the relationship between manufacturing growth and economic growth (Tsoku, Mosikari, Xaba & Modise, 2017; Meyer & McCamel, 2017; Cantore, Clara, Lavopa & Soare, 2017) or in terms of trade (Delivani, 1992), structural change (De Vries, Timmer & De Vries, 2015;Nattrass & Seekings, 2012; Maia, 2011); industrial strategies (Rosendahl, 2010; Bethlehem, 1994; Black, 1993; Ismael, 1993); real wages in relation to productivity growth and employment (Asaleye, Olurinola, Oloni & Ogunjobi, 2017); comparative advantage (Sejkora & Sankot, 2017), determinants of capacity utilisation in Nigerian manufacturing (Adeyemi & Olufemi, 2016) and how fluctuations in macroeconomic factors impact manufacturing sector output (Onakoya, 2018; Ogundipe et al., 2018).

Nonetheless, this research seeks to investigate the magnitude and direction of labour productivity impact coupled with demand and supply-side factors upon Nigeria's manufacturing output from 1986 till 2018. This investigation is also vital as it relates to achieving Sustainable Development Goal (SDG) 9 of building resilient infrastructure, promoting inclusiveness, sustaining industrialisation and fostering innovation by year 2030 so as to boost industry shares, specifically among least developed countries (LDCs).

Literature Review and Theoretical Framework

Odior (2013) investigated how stochastic features of Nigerian macroeconomic variables impact manufacturing sector within the period of 1975 to 2011. Imoughele & Ismaila (2014) portray insignificant broad money supply and interest rate while exchange and inflation rates alongside external reserves were statistically significant and inversely related to manufacturing both in the present time and a year ago. However, there was unidirectional causality between manufacturing output and external reserves, likewise real exchange rate. Amassoma & Nnwosa (2013), Sanusi (2012) and Njoku & Ihugba (2011) asserted the existence of stagflation (high inflation and unemployment) in Nigeria. This adversely impacts the nations' manufacturing industries as policy makers are constrained in implementing stabilisation or expansionary monetary policies. Unemployment responds more to output changes of manufacturing enterprises (Owyang, Sekhposyan & Vermann, 2013).

Anaman & Osei-Amponsah (2009) adopted error correction mechanisms and cointegration to affirm the determinants of Ghana's manufacturing output from 1974 to 2006. It was indicated that long-term nexus is existent between manufacturing output and export-import ratio, levels of per capita real GDP and political stability, which all impact the manufacturing sector. Similarly, Dauda & Risikat (2008) employed ordinary least square to analyse influencers of manufacturing output in Nigeria between 1972 and 2002. Domestic capital formation, exchange rate deregulation policy and openness index were positively connected to manufacturing sector's growth. Also, manufacturing capacity utilisation significantly and negatively impacted manufacturing growth.

Szirmai (2009) views the manufacturing sector as a major growth propellant due to the following reasons: first, empirical correlation exists between industrialisation depth and per capita income among developing economies. Secondly, manufacturing productivity exceeds that of agriculture. Thirdly, manufacturing has greater dynamism relative to other sectors. Fourthly, developing nations that have higher manufacturing and lesser service shares display quicker progression compared to developed countries. Fifth, unlike agriculture, manufacturing renders specialised avenues for capital accumulation and economies of scale. Additionally, it allows for inherent and segregated technological advancement alongside spill-over and linkage effects. Lastly, higher per capita income reduces agriculture's share in

overall expenditure while increasing expenditure upon manufactured products, as indicated by Engel's law.

For this paper, the human capital theory is modified. Becker (1998) broadly presented human capital resources to include education, health, on-the-job and other forms of training. It should be noted that all these human factors determine labour productivity levels, which is in turn capable of impacting the manufacturing sector. Sturm (1993) posits that human capital theory sees such factors to contribute to an individual' productive and pecuniary gains. Welch (1970) termed this sort of productive educational value as the 'worker (static) effect', which is measured as increased output per unit of change of education holding other inputs constant. Allocative or dynamic impact of education refers to the complementary human capital influence, where training and schooling enhances allocative techniques (Bartel & Lichtenberg, 1987; Schultz, 1975). Hence, better learned persons can leverage on fresh service and production potentials or adapt to newly situated methodologies faster than less trained workers. These efficiency benefits are rapidly converted to superior commodities or reduced prices by productive and educated personnel.

However, in considering the human capital framework, 'screening hypothesis' as postulated by Spene (1973) and Arrow (1973) which asserts the role of education in distinguishing implicitly higher and lower productive workers to sort them into suitable industries, rather than improving individual productivity. Notwithstanding, Willis (1986) and Riley (1979) affirmed that both theories are empirically difficult to differentiate given identical correlations among education, productivity and income. Moreover, human capital impacts manufacturing output and general growth via numerous routes, including technological adoptions (Caselli & Coleman, 2006; Acemoglu, 2003; Topel, 1999; Benhabib & Spiegel, 1994; Barro, 1991 and Romer, 1990).

Thus, skilled-labour facilitated by technology ameliorates productive effectiveness of talented and experienced staff comparative to the unlearned ones (Oluwatobi, Olurinola, Alege & Ogundipe, 2018; Oluwatobi, Oluwatobi, Oshokoya, Olurinola, & Alege, 2019). So, human capital effect posits that adopting high human capital alongside technology will induce quicker growth of such labour-intensive enterprises. Additionally, the 'human accumulation effect' postulated by neoclassicals in relation to international specialisation considers human capital as manufacturing inputs where productive resources should be migrated to school-intensive firms, thereby aiding progression in human-capital intensive sectors (Nunn, 2007; Levchenko, 2007; Romalis, 2004; Ventura, 2005, 1997). Anyanwu (2018) adapted UNECA (2015) to proposed that educational status at primary level affects numeracy/literacy, which provides the minimum manufacturing required skills; secondary stage influences creativity, problem solving and conceptualisations for social flexibility and skilled labour; whereas tertiary phase impacts developmental knowledge for developing research and technological capability.

The European Commission (2009a) noted that diverse factors determine manufacturing performance, including supply-side influences such as research & development (R&D), production inputs (labour and physical capital inclusive of ICT-related techniques),macroeconomic conditions (GDP growth, exchange, employment and interest rates), market structures (industry size, distribution, concentration and turnover, political, regulatory era which affect customer welfare and competition among producers) among other demand-side factors such as investment and consumption expenditure.

Recently, Anyanwu & Ozurumba (2017) found significant U-shaped relationship existed with primary education and transport/machinery equipment whereas inverted U-shaped linkage was seen with chemical MVA. Meanwhile, positive connection was apparent with apparel/textiles MVA. On the other hand, secondary education had U-shaped association with chemicals although it was positively related with machineries and negatively linked with beverages, food, tobacco and other manufacturing industries. Notwithstanding, strong non-monotonic, inverted U-shaped relationship is found among tobacco, beverages and food; clothing and textiles; and other manufacturing enterprises with tertiary education. Nonetheless, tertiary education is positively associated with machineries, clothes/textiles and other manufacturing sectors whereas negative linkage is existent for chemicals and food, beverages and tobacco MVA.

Model Specification

The empirical model for the study is developed in the spirit of Chenery (1960) and European Commission (2009a). The specification adopted the variables from the highlighted extant studies which include: manufacturing value added (constant 2010 US$), used as the dependent variable to measure manufacturing output. The explanatory variables included are financial depth, interest and exchange rates, degree of openness and production inputs (capital stock and labour productivity).

The model is specified as follows:

$$\text{MVA} = \beta_0 + \beta_1\text{LABP} + \beta_2\text{GFCF} + \beta_3\text{FDEPTH} + \beta_4\text{LINTR} + \beta_5\text{OEXR} + \beta_6\text{EON} + \mu \ldots(3)$$

MVA = manufacturing output (captured by manufacturing value added)
LABP = Labour productivity (GDP per person employed (constant 2011 PPP $);
GFCF = Gross Fixed Capital Formation (constant 2010 US$);
FDEPTH = financial depth (Domestic credit to private sector by banks (% of GDP);
LINTR = Lending interest rate (%);
OEXR = Official exchange rate (LCU per US$, period average);
EON = degree of openness [$\frac{Import+Export}{GDP}$](all in constant 2010 US$)];

Description of Variables

Table 1: Variables, their Definitions, Measurements and Sources

Variables	*Definition and Measurement*	*Data Source*
MVA	Manufacturing refers to industries in theInternational Standard Industrial Classification (ISIC), revision 3, divisions 15-37. MVA captures sectoral net output after aggregating outputs minus intermediate inputs. It does not deduct degeneration/extinguishment of natural resources and produced assets. Data is reflected in constant 2010 U.S. dollars.	WDI (2018)
LABP	GDP per person employed is GDP divided by overall national employment. Converting GDP to 2011 constant international dollars through PPP rates is Purchasing power parity (PPP) GDP.	WDI (2018)
GFCF	Average yearly growth of gross fixed capital formation based on constant local currency. Aggregates are based on constant 2010 U.S. dollars.	WDI (2018)
FDEPTH	Domestic credit to private sector by banks refers to financial aid (trade credits, purchasing non-equity securities, loans and other receivables which enable repayment claims (which might incorporate lending to public ventures in some nations).	WDI (2018)
LINTR	Lending rate entails the bank rate, usually determined by financing goals, credit standing of borrowers and vary according to different economies. Thistypically satisfies short- and medium-term funding necessities of private enterprises.	WDI (2018)
OEXR	This is the exchange rate in local currency that is ascertained by national officials or lawfully determined within sanctioned exchange market. It is a monthly mean that is summed up into annual averages.	WDI (2018)
EON	This was calculated by the authors via adding imports with exports, then dividing their sum by economic growth, all in constant 2010 US$.	WDI (2018)

Result Presentation and Discussion

This analysis began by examining the time series property of the variables. Table 4.1 shows that all variables became stationary at first order of integration. The evidence implies that a linear combination of the variables could be attempted using Johansen co-integration analysis.

Table 2: Unit Root Result (Summary)

Variables	T-stat	P-value	Order of integration
MVA	-4.0561	0.004	I(1)
LABP	-4.0574	0.004	I(1)
GFCF	-9.2176	0.000	I(1)
FDEPTH	-4.9089	0.0004	I(1)

The co-integration analysis using the trace and max-eigen statistics help to verify long-run relationship among these variables. For Nigeria, both trace-stat and max-eigen value shows that there is one co-integrating equation. Evidence from Table 4.2 indicates that the existence of long-run relationship among the variables.

Normalized co-integration estimations:

MVA = 23.45174+ 1.245674LABP –0.500447GFCF – 0.005665FDEPTH+ 0.035302LINTR

T-stat [-16.1657] [4.92024] [1.54725] [-11.2730]

– 0.001633OEXR – 0.766536OPENNESS

T-stat [5.06798] [13.9020]

From the normalized equation above, when all regressors are simultaneously equal to zero, MVA will be positive at about $23.45. This study finds that labour productivity is statistically significant and positively impacts manufacturing output by about 125 percent. This positive relationship conforms to theoretical expectation and indicates how relevant labour productivity is to Nigerian manufacturing industries. Hence, an improvement in labour productivity determinants, such as trainings and education will go a long way to boost the efficiency of labour and consequently Nigeria's MVA. A percent increase in capital stock will lead to about 50 percent decrease in MVA. This negative linkage does not align with apriori expectation, thus reflecting the low level of capital stock and infrastructures within

the country. Meanwhile, greater financial depth by a percentage will yield about one percent drop in MVA. This adverse connection indicates that Nigeria's financial depth is really inadequate to bring about positive changes.

Furthermore, a rise in lending interest rate will positively impact manufacturing output by almost 4%. Such positive linkage directly contrasts theory as higher lending rate is expected to discourage lending for profitable investment ventures of manufacturing enterprises. Similarly, one percent increase exchange rate will negatively affect MVA by about 1%. This opposes theory as higher exchange rate leads to currency depreciation (in this case, Naira), which makes exports cheaper and is supposed to boost exportation for a producing nation. However, the reverse is the case for Nigeria due to low production levels and higher imports, which reduces manufacturing output, exports and revenues. A rank increase in the degree of openness will engender about 77% fall in Nigerian manufacturing industries. Despite its statistical significance, this negates apriori expectations, implying that the nation is not leveraging on its open economy and is probably allowing foreign products to overcrowd its market, thereby deterring the effectiveness of manufacturing sector output.

Table 4: Vector Error Correction Estimates

Error Correction:	D(MVA)	D(LABP)	D(GFCF)	D(FDEPTH)	D(LINTR)	D(OEXR)	D(OPENNESS)

Source: Authors' Computation

From the error correction test above, ECM reveals a negative figure of -0.008992for Nigeria, this suggests that convergence of errors, hence, about 1 percent of errors that occur in the short run will be corrected subsequently in the long run. Moreover, R^2 and adjusted R^2 depict that all explanatory variables jointly explain about 23% of variations in manufacturing output.

In order to confirm the reliability of the parameter estimates, some diagnosis tests were conducted which include serial correlation and heteroscedasticity. Serial correlation test was executed to examine presence of serial correlation among variables. The evidence from Table 5 shows the presence of no serial correlation and also void of heteroskedastic.

Table 5: Diagnosis Tests

Conclusion and Policy Recommendations

Given average low manufacturing levels in Nigeria over the years, especially since the last economic recession that affected most African nations, Nigeria's manufacturing value added is yet to fully recover. Coupled with relatively low productivity over time, this research is spurred to ascertain the impact of labour productivity alongside supply (capital stock and labour productivity to represent production inputs) and demand-side factors (exchange and interest rate as macroeconomic influences;

ease of openness for market structure; and financial depth for expenditure levels) on Nigerian MVA within the scope of 1986 to 2018. Human capital theory is adopted to explain the analytical framework. Indicators are chosen from literatures reviewed and selected based on data availability, so as to ensure sufficient data observations for a single country.

All variables are stationary at first difference; hence Johansen co-integration is employed, which portrayed that long-run co-integrating relationship exists among the variables. It should be noted that only financial depth is statistically insignificant in impacting Nigeria's manufacturing output. Therefore, labour productivity is seen to positively impact Nigerian MVA in data findings. However, in reality this influence is not observed probably due to the major role that other variables play. Capital is found to reflect adverse effects (due to deplorable GFCF levels); FDEPTH portrays insignificant and detrimental impact upon Nigeria's manufacturing output; additionally, ease of openness, lending and exchange rates do not conform to theory, thus reflecting deviation from the norm. However, ECM is negatively signed, thus implying that about 1% of errors which occur in the short run would be corrected in the long-run. R2 indicates that all explanatory variables jointly explain about 23%of disparities in MVA. Additionally, diagnostic tests show that the model is free from heteroscedasticity and serial correlation.

Therefore, for policy recommendations, it is necessary to upgrade tertiary education in terms of vocational scholarships and trainings (Ola-David, Amoo, Olurinola & Fadayomi, 2013) as most existing policies within Africa focus on primary and secondary educational levels which engenders skill mismatch. Moreover, such skill acquisition policies must align with national socio-economic agenda. Consequently, strong coordination and interactions is needed among policy makers and stakeholders in public and private sectors as well as deeper university relations. Furthermore, encouraging foreign direct investment (FDI) inflows will help to expand technological innovations and degree/ease of openness economically. These will all help in boosting labour productivity and subsequently domestic production capacities.

Abstract

A country's growth over time is almost entirely dependent on the size and components of its labour force, which in turn determines its labour productivity levels. Given various similarities of Nigeria and South Africa, ranging from same British colonisation to similar labour force structure, South Africa is known to be more advanced than Nigeria. Hence, this study aims to examine trends and patterns of both Nigerian and South African economies from 1986 to 2018. A lot of stylised facts were revealed for the said time period. Thus, evidence was found that South Africa generally performed better than Nigeria in all indicators of labour productivity, human capital and physical capital. These findings indicated apparent reasons for the latter's superior performance in recent times, despite the fact that both economies were around the same level in the 1980s. It was also revealed that both nations are still trying to fully recover from the last recession in 2015. Hence, this research recommends an increase in human and physical capital investment, entrepreneurial activities and training schemes to boost national productivity levels.

Keywords: Human capital (HC), Physical capital, Unemployment, Labour productivity, Nigeria, South Africa.

Introduction

Nigeria possesses the highest populace of over 190 million people among African countries and is globally the seventh most populated nation with a life expectancy of 49 years (World population review, 2019). However, the country's large labour force has not contributed substantially to her productivity and living standards as more than half of the population still wallow in poverty, unemployment and underemployment. In United Nations Human Development Report (2005; Ogundipe et al., 2019), Nigeria was grouped as a developing nation with regard to uniformity in educational access. In terms of student enrolment, primary school net enrolment rate is 63:59.8 percent; Adult literacy rate is 63:75 percent and 46:57 percent; Youth literacy rate is 77:85 percent and 67:75 percent; Educational attainment is 55:45 percent; while labour force participation is 70.3:64.5 percent for males and females respectively. In terms of infrastructural facilities regarding Nigeria's populace, at least 20 per cent of these nationals usually distrust government as very little have been achieved over 55 years post-independence in providing physical amenities (Ali, 2019).

On the other hand, the South African economy with Gross Domestic Product (GDP) of US$159 886 million in 2003, was by far lesser than Netherlands' US$511,556 million and Korea's US$605,331 million (World Bank, 2005). Conversely, unlike other African states, predominantly Sub-Saharan Africa (SSA), South Africa is comparatively more industrialized and bigger as 6.6 per cent of her populace yields 75.7 per cent of its manufactured exports and 45.5 per cent of sub-continent's GDP. Insufficient skilled personnel, as needed for labour-intensive growth is barely given adequate attention. Under apartheid, restrictions on upward mobility and absence of proper schooling and training for

massively numbered black persons, is apparently a key restraint in the growth of unskilled and higher-skilled labour-intensive firms (McCarthy, 2005).

Over time, there has been numerous contentions over which country is the largest African economy. South Africa was at the peak for a while till 2014 when Nigeria outpaced the former. Ever since then, it has been continuous turbulence between the two giants (Daoui, 2017). Daoui (2017) further noted that a fundamental disparity between Nigeria and South Africa is their economy's attributes. The latter is broadly diversified while Nigeria is mainly a mono-product economy. Initially, South Africa grew around two main pillars: conducive agricultural terrain and abundant mineral reserves. Notwithstanding, her economy expanded to develop tertiary sectors of trade, communications and tourism.Undoubtedly, Africa has made substantial progress over the past two decades, however, she is still backwards in terms of output, productivity, adoption of modern inputs, technology, accessibility to insurance or credit markets which is mostly incomplete or failing (FAO, 2015; Dillon & Barrett, 2014).

The capability of a nation to enhance quality of her labour force is referred to as human capital development (HCD). Human capital comprises education (knowledge), training (skill) and health. It is expected that higher training engenders higher skill of any country's labour force (Ogunleye, Owolabi, Sanyaolu& Lawal, 2017; Adejumo, Olomola & Adejumo, 2013; Ogundipe et al., 2018). Lack of technical know-how (poorly developed infrastructure) as well as insufficient skills to boost technological production and utilization is a key development barrier (Oketch, 2006). Grossman (1972) and Bloom, Canning &Sevilla (2004) have proven that education and health are components of human capital as they directly influence people's wellbeing and increases individual capabilities. Schultz (1993) sees it as an instrument for propelling national comparative edge. Importantly, although human capital is sustainable, it is untransferable e.g. land as a fixed capital (Mba, Mba, Ogbuabor&Ikpegbu, 2013).

Physical capital refers to man-made goods that facilitates production process (Majaski, 2019). Prominent economists such as Adam Smith, Robert Solow, and Harrod Domar all recognized that physical inputs play a vital role in assisting production process. Examples of physical capital include; bridges, machineries, buildings, cash, computers, and so on (Segal, 2019 and Majaski, 2019). It is therefore considered as one of the three major factors of production. After the World War II, Asian nations like South Korea, China and Japan have been able to develop their physical capital and this has proven effective in eliminating poverty and making them some of the world's most powerful economies.

To some degree, human capital's role in Nigeria's growth has been given attention (Ajetomobi & Ayanwale, 2005, Olomola, 2007; Dauda, 2010) but its contribution in different sectoral output is yet to be properly tackled. Some studies have observed education's impact on output growth; other extremes assessed effect of human capital on technological changes by implementing new technologies (Ashish & Badge, 2008); as well as real wages in relation to productivity growth and employment (Asaleye, Olurinola, Oloni & Ogunjobi, 2017). Many have evaluated human capital influences on economic growth (Bloom et al, 2004; Adejumo et al., 2013) analyses human capital in relation to industrial growth while others have considered this topical area from the angle of human capital investment (Lawanson, 2009; Isola & Alani, 2012) as well as government capital and recurrent expenditures on health, education, gross fixed capital formation (GFCF) and labour force (Oluwatobi & Ogunrinola, 2011).

In this paper, we argue that the divergence in gross domestic product (GDP) progression of countries specifically Nigeria and South Africa, whose level of labour productivity varies, can be attributed to contrasting volumes of human and physical capital. Although levels of productivity in these two countries has been similar over the years, their economies have different human and physical asset indicators. We focus on labour productivity because it is a vital influencer of economic performance. Also, both countries belong to the group of developing countries whose economic activities are more facilitated by labour inputs. Thus, this research aims to fill this gap by performing a comprehensive analysis of the by examining combined effects of human and physical capital on labour productivity. This will be done using comparative analysis of two selected countries: Nigeria and South Africa.

Stylized Facts

In aspects of labour productivity, measures like higher investment in infrastructures, schooling access, educational attainment and skill acquisition by National Directorate of Employment (NDE) have been embarked upon to enhance labour quality but have been grossly inadequate to realize full potentials of productivity. For instance, as labour force expanded by about 12% from 2010 to 2014, unemployed persons (those with less than 20 work hours per week) rose by over 40% while fully-employed increased by just 7% (NBS, 2015). Reverse applies for South Africa recognized for her transformed structural production and investment in capital-intensive industries (McCarthy, 2005; Ogundipe et al., 2019).

Generally, developing countries are known for their low levels of low income, literacy, living standards, healthcare systems and gender inequality levels (Todaro & Smith, 2011). These low human capital developmental levels obstruct individual productivity, resulting in socio-economic issues such as unemployment and poverty. Nigeria as an LDC launched her Universal Basic Education (UBE) in 1967 at Sokoto by Obasanjo. That same year, she initiated Universal Primary Education (UPE) which also failed due to corruption and inadequate funds amongst other factors (Ogunleye, Owolabi, Sanyaolu& Lawal, 2017).Since the emergence of a new democratic epoch in 1994, development of education in South Africa has received intense attention in form of government measures such as National Education Policy Act of 1996 which defines the rules that governs educational facilitators; South African Schools Act which provides right to quality education; Annual National Assessment programme which was introduced to monitor learning outcomes, amongst others (SAYB, 2016).

Welcome (2011) and Aregbeshola (2019) stated that Nigerian government have introduced various health schemes which includes a 10-year development plan (1946–1956) with numerous health schools and institutions established, primary health care plan (August, 1987); Midwives Service Scheme (MSS); National Immunization Coverage Scheme (NICS); Nigerian Pay for Performance Scheme (P4P); and National Health Insurance Scheme (NHIS) which had minute influence on health sector, due to persistent personnel and infrastructural deficit, as well as poor public health administration. Whereas, In the last 20 years, despite several challenges, state of health in South Africa has improved as seen in reduced maternal mortality rate, higher life expectancy and public health spending via conscious effort to improve data quality, accessibility and medicinal availability via Central Chronic Medicines Dispensing and Distribution Programme (Measure Evaluation, 2019; Agyepong, Sewankambo, Binagwaho, Coll-Seck, Corrah, Ezeh, Fekadu, Kilonzo, Lamptey, Masiye, Mayosi, Mboup, Muyembe, Pate, Sidibe, Simons, Tlou, Gheorghe, Legido-Quigley, McManus, Ng, O'Leary, Enoch, Kassebaum& Piot, 2017).

Infrastructure Tax Relief (ITR) was introduced in April 2012, Road Infrastructure Development and Refurbishment Investment Tax Credit Scheme in January 2019, Nigeria's National Integrated Infrastructure Master Plan (NIIMP) validated in 2015, likewise Economic Recovery and Growth Plan (ERGP) with aims of providing strategic framework for transformation of Nigeria's weak physical facility base comprising uncontaminated water, hygienic sanitisation, tarred roads and electricity which are deficient due to low income levels and swiftly expanding populace (Bello-Schünemann& Porter, 2017). For 2016/17, World Economic Forum Global Competitiveness Index ranked Nigerian infrastructure among lowest of 132 from 138 countries, this has been said to be one major barricade to doing business nationally. In South Africa, the new growth path was established in November 2010 to drive Infrastructure and Job creation, after which National Infrastructure Plan was introduced in 2012 to create more jobs and promote economic growth. Government also invested 827 Rand to revamp existent facilities. President Infrastructure Coordinating Committee (PICC) was introduced to organise, merge and fast-track implementation. Despite this, a report published by South Africa Reserve Bank in 2017 stated that there has been prolonged decadence infixed capital stock and GFCF, which has affected her economic productivity level.

Low productivity can be attributed to non-augmentation of factor inputs including physical capital, infrastructures, human capital, innovation/technology which affects labour force quality. Average growth rate of 6.53 percent between 2005 and 2010; 6.68 percent from 2011 to 2014. But between 2015 and 2016, it reduced to 2.8 percent and a negative 1.56 percent respectively. This did not provide

relief in terms of unemployment which was about 2.9 percent in 2005; increasing to 5.8 percent in 2008; 11.8 percent in 2009; 21 percent in 2011; 23.9 percent in 2012 and 29 percent in 2015. Nonetheless, this reduced in 2016 to 14.2 percent. Ajakaiye, Jerome, Nabena&Alaba (2015) ascertained that Nigeria's employment elasticity is as low as 0.11.

Nigeria's educational system is plagued with the inverted pyramid. According to National Universities Commission (NUC), there are about 43 Federal, 48 State and 79 Private Universities (Funmilola, 2019), constituting 170 universities in total; over 100 polytechnics, 82 colleges of education comprising 14 private, 46 state and 22 federal colleges, over 50,000 primary schools. Primary school enrolment was about 25.6 million in 2016 (Ajikobi, 2018).

A comparison of Nigeria and South Africa

Trend Analysis: Empirical Evidence from data of Nigeria and South African Capital and Labour Productivity from 1986 to 2018

This section contains explanations of labour productivity (captured by GDP per person employed) as well ashuman capital(gross primary school enrolment, total life expectancy at birth) and physical capital (gross fixed capital formation) trends from 1986 to 2018 between Nigeria and South Africa. The purpose of these analytical trends is to account for the variations in these variables while applying data results to practical happenings in both countries over time.

Figure 1: Labour Productivity of Nigeria and South Africa

Source: WDI (2018)

GDP per person employed for Nigeria begins from about $10,000 in 1986 and was somewhat stagnant till 2002, after which it increased slightly to almost $15,000 in 2004 and gradually continued to rise in subsequent years. Labour productivity reached its peak in 2014 at approximately $25,000. However, it began declining afterwards and is yet to pick up. This illustrates the slow growth of labour productivity over the years in Nigeria. On the other hand, that of South Africa started out at a much higher rate than Nigeria at about $35,000. Although the nation experienced a slight dip in labour productivity between 1992 and 1995, it picked up and has been increasing on the average since then, recently hovering around $43,000. Thus, in general, South African labour productivity is almost three time more than Nigeria's level, despite occasional dips.

Hence, graphical illustrations showing labour productivity of Nigeria and South Africa clearly depicts that although both countries have relatively experienced increasing labour productivity over the years, South Africa's speed of growth is nearly twice as much as Nigeria and is comparatively more

stable.Also, Nigeria's labour productivity was rather low and declining for nearly half of the total period and has been rising at a comparatively slow rate, and declining in recent years. Conversely, South Africa has been increasing at a much faster rate. This explicitly establishes the gap.

Figure 2: School enrolment, primary (% gross): Nigeria vs South Africa

Source: WDI (2018)

The ratio of primary school enrolment (PSE) to the overall population of Nigerians within this age group started out higher than that of South Africa in the 1980s from almost 100%. However, by 1998, it had decreased to almost 80%. From then till 1994, PSE fluctuated a bit but improved slightly before dropping to its lowest point of 78% in 1996. It hovered around this point till 1998, and afterwards was on an upward trend till 2006 with an average of 98.47. Meanwhile, PSE for South Africa skyrocketed and fluctuated at over 100% from 1988 till 1997. Unfortunately, enrolment levels for South Africa began declining till recently in 2015, when it showed indications of picking up its pace. Sadly, PSE suddenly declined again to about 83.76% in 2008 and remained around that level till 2010. Since 2010, it has been fluctuating but generally been at a low level of approximately 90%. One interesting observation is that despite the fluctuations in both countries, enrolment levels among South Africans is generally higher than that of Nigeria.

Figure 3: Life expectancy at birth, total (years): Nigeria vs South Africa

Source: WDI (2018)

Total life expectancy at birth for Nigeria was at 46 years and has gradually been rising till 2015 when it peaked at almost 53 years before dropping and being stagnant at about 50 years. Conversely, that of South Africa began at about 60 years before rising and declining from the late 1990s up till 2006. Since then, it has been increasing till 2015 when it reached its highest point prior to reducing and hovering around 54.6 years. Overall, life expectancy for South Africans remains higher than Nigerians.

Figure 4: Gross fixed capital formation (constant 2010 US$): Nigeria vs South Africa

Source: WDI (2018)

GFCF started at almost $16 billion and fluctuated till 2005 with an average of $15.6 billionfrom 1986 to 1995. Similarly, from 1996 till 2005, it averaged $17.65 billion. After then, it began an upward trend to $39.6 billion in 2008, $61 billion in 2010 and $70 billion in 2015 despite occasional fluctuations. However, it decreased to $48.5 in 2016 but has been increasing gradually till now. Contrarily, South Africa was initially at 28.3 billion in 1986 and fluctuated till 1999 when it was almost $37 billion, thereby averaging about $31.85 billion within this timeframe. Notwithstanding this periodic

fluctuation, it rose continually till 2008 when it reached its peak of almost $81 billion. Sadly, it dropped again to about $72.3 and has been rising gradually since then.

Reasons for Likely variations in productivity levels between both African countries

Chalfin, Danieli, Hillis, Jelveh, Luca, Ludwig & Mullainathan (2016) recognized rising interests in advancing productivity and production variability in reality illustrates that marginal labour productivity substantially depends on the kind of new hired workers which is based on predictions rather than estimating causal effect. Hence, they show that via machine learning tools, productivities of workers are predictable.

As observed by Ikechi & Anayochukwu (2014), Nigerian government spends rather excessively on recurrent expenditure, rather than channelling such resources to building human capital via health and education (Oladeji, 2015; Olalekan, 2014; and Eigbiremolen & Anaduaka, 2014). Moreover, Ajose & Oyedokun (2018) note that another possible reason for productivity disparity is Nigeria's deplorable GFCF condition, which is nowhere near that of South Africa.

Moreover, poorly skilled personnel and affordability given Nigerians living standards is yet another cause since South Africans are consciously and intentionally making efforts to improve their expertise and professionalism (Ogunleye, Owolabi, Sanyaolu & Lawal, 2017). Thus, such differences must be bridged, possibly through vocational and entrepreneurship training for both skilled and unskilled workers if there is to be substantial improvement in Nigerian productivity(Ola-David, Amoo, Olurinola & Fadayomi, 2013).

Conclusion

This research compared the state of labour productivity, human and physical capital in two African countries (Nigeria and South Africa). From this, we can see that a peculiar problem in South Africa is its high unemployment levels, which is also evident in Nigeria. This is most likely due to low wages, which can be said to account for low skills and efficiency of her labour force (Rodrik, 2008). Moreover, Burger & Teal (2015) found strong schooling effects that are linked to individual earnings.Also, empirical evidence shows that South African physical capital remains the most essential resource accounting for her corporate achievements and efforts (Firer & Mitchell-Williams, 2003).

Policy Recommendation

In view of the observations from stylised facts and trend analysis, this study proposes that the Nigerian government should raise overall educational expenditures of requisite educational amenities for comprehensive education delivery. This should be in addition to ascertaining adequate budgetary allotment for sufficient health care provisions accessible to Nigerians. Also, all educational levels should prioritise qualitative curricula and government should improve health care and schooling via accessibility to many individuals to facilitate national progressions via HCD. Lastly, South African government can keep encouraging innovative ideas which would increase entrepreneurial establishments and provide opportunities for job creation of unskilled and skilled labour.

Abstract

Strategic management is set up with the main goal, vision, vital targets, and activity arrangements of the firm and the operational plans geared for attaining these goals. Strategic management is important for the employees and ensures to follow a career path and the strategy of the employee changes with the competitors, suppliers, regulators and customers. Once the strategic opportunities have been recognized and potential dangers considered, a list of particular steps that will be taken to actualize the arrangement ought to be shaped. The strategy is devised as a plan which is a set to detailed steps that needs to be implemented in phases to guide the organization in achieving its objectives. The strategic directions give a set of indicators that gives operational processes that are applied to various departments in the organization. The business model and operational plan ensure that the organization creates and distributes the products and services with high operational value and high quality. The aim of this paper is to investigate the strategic management practices especially on the abilities of the public sector to increase the organization performance through engaging in strategic management activities. In addition, this paper contributes to strategic management practices by exploring novel sets of managerial methods to improve public organization innovativeness in the United Arab Emirates (UAE).

Keywords: Strategic management, Organisational, Performance, UAE

Introduction

Fundamentally, the first stage of the strategic management process is commonly known as strategy implementation. In this stage, business strategy is actually implemented. It involves activities such as establishing annual objectives, devising policies for each business function, and allocating resources for the achievement of organizational objectives (David, 2007). The next stage of the strategic management process is strategy evaluation. This stage is aimed at changing or taking corrective actions in strategy and measuring and evaluating the performance. To achieve these purposes, it involves updating key internal and external evaluation matrices continuously, formed in the strategic planning stage, and identification of other internal and external factors emerged. In addition, it involves comparing actual performance with planned. If key internal and external factors change during the continuous assessment of environments or new factors are identified, and/ or during comparison of standard performance with actual performance, actual performance is found less than the standard performance. Then, this calls for corrective actions to be taken in this stage of the strategic management process (David, 2007).

As discussed above, strategic management has been one of the most influential and visible novel approaches to the art and science of management (Mintzberg, 1987; Marlin et al., 2007). Recent research has established that strategic management influences organization performance by providing

organizations with an effective framework to implement their innovation strategies (Ciabuschi and Martin, 2012; Moustaghfir and Schiuma, 2013). Thus, it seems that strategic management is an effective means for increasing the innovation performance of an organization. A great deal of research has focused on issues such as the relationship of generic strategic processes like strategic acquisition, sharing, and creation (Chen et al., 2010; Lee et al., 2013) or strategic-based assets like human, structural, and relational capital (Wang and Chen, 2013; Castro et al., 2013) on innovation performance. Even though some previous studies have examined the association between strategic management practices and an organization's performance, they have either considered only one or a few strategic management practices (Chen and Huang, 2009; Donate and Canales, 2012; Soto-Acosta et al., 2014) or organization's performance outcome indicators aside from those related to innovation (Gold et al., 2001; Lee and Choi, 2003; Atapattu and Jayakody, 2014). Unfortunately, this issue has not been explored or investigated in United Arab Emirates (UAE) yet. So, there is a need for conducting this study.

Literature Review

The word strategy originates from the Greek "stratus" which means the army and "again" assuming to lead or the art of the final (Macmillan & Tampoe, 2000; Quinn, 1988a). Up to now, several principles of military strategy apply to business things. Grant (2000) stated and emphasized that the business strategy and military strategy, allocate a variety of common principles, ideas and characteristics, where the strategy and techniques are the basic issues. However, the understanding and construct of strategy evolved over time to a company (both internal and external) and relevant to the business world. Different researchers have outlined the concept of strategy in many ways that capture its diverse components, functions and dimensions. Chandler (1962) as one of the earliest strategy theorists has outlined and defined a strategy as "the determination of long-run goals associate degree objectives of an enterprise and also the adoption of courses of action and also the allocation of resources necessary for effecting these goals". Chandler's views were later amplified by Andrews (1971) mentioned as the "strategy as a pattern of major objectives for achieving those goals in such some way on outline the type of business the corporate is in or is to be in". Different strategy theorists (e.g. Thompson, 1994; Johnson & Scholes, 2003) focused on the strategy because a company mostly utilized it or it has been thought as the main key for an organization. Besides, Johnson and Scholes (2003) stated that strategy is the direction and scope of a company over the long-run. Thompson (1994) defined strategy as a transparent direction for the organization and a way of obtaining there.

According to Mintzberg, Lampel, Quinn and Goshal (2003), the strategy is difficult to be determined within the period of one year and this includes goals and objectives. The author further elaborated that, strategic often refers to the purpose and development as formulated by some scientists and they refer to it as Advanced Strategy. Porter (1998) said that strategy is a very meaningful thing, with the main purpose is to create a competitive benefit of the organization. According to Quinn (1980), "the descriptive school of thought sees strategy formation as an emergent process where everyone in the organization goes through a process of learning is a strategist". The lesson learnt is incorporated into a plan of action as the whole. It is the belief of this school of thought that strategies must emerge in small gradual steps as the organization adapts and learns what works and what does not. Its contribution to theory is based on the fact that more people learn not just the leader of the firm, hence reducing the complexity and unpredictability in strategy formation. Strategy formulation and implementation are intertwined as they emerge.

It is also difficult to analyze and evaluate the strategy. Management strategy is not always the success of the project. It can also fail, as there are many factors that affect the outcome of the strategic process. Mintzberg et al. (2003) stated that for management strategy to be effective, it must meet specific factors to reduce the negative consequences. Quinn (1980) emphasized that the strategy must have clear objectives and also be flexible and coordinated which indicated the need for management strategy and committed leadership. The author further stated that strategy in business is needed for security (and logistics resources) and also to keep the initiatives during the performance of the tasks of responding to the challenges.

Different views and definitions of "strategy" exist (Porter, 1996). He also pointed to the many ways in which the definition of strategy, citing the common theme underlying all definitions, is a group of deliberate and conscious guidelines that determine the decisions in the future. According to Mintzberg (1978), a strategic pattern is a continuous series of decisions over the long term, holding some kind of consistency. Mintzberg & Water (1985) have developed strategies and implemented them according to the plan set (deliberate) and on the other hand, simply strategies without any form of planning. In Japan, the Japanese contractor's public companies were successful in many markets in different parts of the world due to the attention given to the business strategy (Hasegawa, 1988). U.S. banks show the highest return on equity for banks that have both strategic commitment to the planning and delivery of regular strategic management training. Companies with good performance such as The Body Shop, Sony and Merck have effectively exploited the visionary strategies. Although, the strategic management and, until recently, the activity highlights inside many public companies, today it is more widely used by many large organizations that are allocated substantial resources to the task. Price and Newson (2003) found that methods of strategic management, in general, can improve efficiency in various organizations.

Strategies in natural systems seem to emerge spontaneously from the interaction between the environment and organisms over time. Whether an individual or a population will be more o less successful to cope with environmental changes is determined by their capability to respond to such changes, or in other words, by their capability of adaptation. Therefore, there is an implicit link between strategy and the need to adapt successfully to new conditions in the surrounding environment. In this way, strategy likewise suggests advancement. Regardless of whether an individual or populace will be more or less effective to adjust, survive, and extend its descendants into what's to come in, all things considered, dictated by the historical backdrop of adjustment of their ancestors and the correct. In strategy, time and history matter.

For individuals and their organizations, it is very little unique since strategy additionally respects the mission for survival. Regardless of whether we are pretty much effective in life relies upon how we figure out how to react to the adjustments in the earth we are drenched into. That capacity will be resolved to some extent by the attributes of our identity and by the dynamic harmony amongst circumstances and boundary in our encompassing condition. In this unique situation, the strategy appears to speak to objective decision-production instead of to intuition, in spite of the fact that we typically are slanted to make concurrent utilization of both methodologies. Andreeva and Kianto (2012) defined strategic management practices as the set of management activities conducted in an organization with the aim of improving the effectiveness and efficiency of organizational strategic resources. Strategic management practices refer to the aspects of the organization that can be manipulated and controlled by management activities (Andreeva and Kianto, 2012; Foss and Michailova, 2009). Accordingly, this current research conceptualizes them as the set of management activities that enable the organization to deliver value from its strategic-based assets (Malmi, 2010; Malmi & Brown, 2008). Protecting the strategically significant knowledge of the organization from competitor imitation is a key issue for ensuring the appropriateness of intangibles-based profits (Teece, 1998). Organizations that utilize both informal and informal mechanisms of strategic knowledge protection (Olander, 2011) are likely to be more successful in terms of both competitiveness and innovation performance.

Strategic management can be defined as the strategic planning, implementation, and updating activities related to the strategic-based assets in the organization (Kianto et al., 2014). It taps into identifying the key strategic practices within the organization and building a knowledge-based strategy, as well as activities for monitoring and measuring strategic assets in the organization, and their developmental needs in relation to the business environment (Dalkir, 2005; Kianto, 2008; McKeen et al., 2005). Strategic management activities can increase organizational performance through the following mechanisms: first, they enable the organization to focus on the most value-creating activities of the organization, which is important as researchers have suggested that the intangible assets are the focal sources of competitive advantage (Barney, 1991; Conner and Prahalad, 1996; Grant, 1996; Walsh et al., 2002). Second, strategic management also enables the organization to craft strategies based on the strategic-based advantages they have over their competitors.

The ideas of strategic management issues developed over long ago with an expanded accentuation on a proactive, integrative, and esteem are driven way to deal with strategic management. The field of strategic management sees strategic assets as resources for business and management. Strategic management issues characterize how the organization carries on and tries to adapt to its business condition. Since strategic management depends on strategic management standards it generally fuses the ideas of procedure, which demonstrates that strategic management is really a sound way to deal with the management of individuals (Sims, 2007). Various researchers and professionals have concentrated the strategic management and its appropriate execution in various nations bringing about in achievement and disappointment of strategic management practice. Then again, there is another side of this marvel. Since the pioneering work of Kaplan and Norton (1992) on the balanced scorecard and their later work on strategy maps, academic and practitioner interest in, what has become known as, strategic performance measurement systems and the roles they play in organizational strategy has grown. The potential role of strategic management issues in organizational strategy has been espoused and debated in the literature. In principle, strategic management issues are said to be an important mechanism for translating strategy into objectives and measures which can be clearly communicated (Bisbe and Malagueno, 2012), facilitating the implementation of strategy, tightly aligning management actions with strategic goals, and enhancing organizational performance (Bisbe and Malagueno, 2012; Micheli and Manzoni, 2010). Academic researchers have examined whether and how these potential benefits can be realized in practice, mostly in private-sector organizations. Yet, strategic management issues are also arguably relevant and applicable to public organizations, albeit typically with some modifications that take into account fundamental contextual differences between the public and private sectors.

Earlier research on strategic management issues has concentrated basically on looking at the degree to which these frameworks are received and the variables related to their fruitful implementation (Micheli and Manzoni, 2010). Wheelan and Hunger (2000) define Strategy implementation as "the process by which strategies and policies are put into action through the development of programs, budgets and procedures in an organization. The development of strategic management involves the design or adjustment of the organization through which the varying financial, economic, human and operational changes. There are constant changes to existing roles of people, their reporting channels, their performance evaluation and control mechanisms in the company. Therefore, the environmental analysis and strategic direction have not been addressed as commonly by boards as they are for financial matters. They also establish that government authorities tend to focus additionally on the strategy than for-profit boards, which they characteristic to the government member's consideration to organizational values and mission statement. Prior studies implicitly assume that, after a system has been implemented, it functions in intended ways to generate organizational impact. Consequently, they fail to examine the links between strategic management issues and practical activities of strategizing, with the implicit assumption that performance improvement can be explained by strategic management implementation. As Bisbe and Malagueno (2012) contended, little consideration has yet been paid in experimental reviews to alternate parts that strategic management issues can play past negligible methodology execution out in the public organizations.

Given these major contracts for further research on performance measurement in the general population division, specifically investigate identified with the unforeseen part of different organizational variables (Boyne et al., 2006), this review focuses on the utilization of performance data in strategic basic leadership out in the public organizations (Luft & Shields, 2003; Olson et al., 2005; Lukka, 2010). Considerable recent research on performance information use exists in public management literature, in particular, research related to the determinants of performance information use in decision making, the characteristics of strategic management issues that are capable of producing useful information for this purpose have not been specifically studied. Because strategic management is based on strategic management principles it always incorporates the concepts of strategy; which proves that strategic management is actually a coherent approach to the management of people (Sims, 2007). Furthermore, strategic management practices enable the organization to make strategic decisions of allocation, utilization, expansion and sharing of the company's strategic base that follow the overall strategic aims of the organization. Therefore, by evaluating these all, few variables can be identified for the current study that suits the business setting on the United Arab Emirates (UAE) in terms of the public sector.

Strategic Management in the United Arab Emirates (UAE) Public Sector

Besides this oil industry, agricultural products also play a vital role in the United Arab Emirates (UAE) economy. According to Antipolis (2002), horticulture produces flavouring sustenance for a nearby market, as well as supplies crude material to the nation producing industry. Albeit an extensive variety of mineral assets found in diverse locales of United Arab Emirates (UAE), including iron metal, salt, phosphate, clay and building materials, not every one of them is currently of business significance. Therefore, the new interim government has taken an important step in public development especially for light industries (food, textile, leather, furniture, chemical, basic metal, cement and building materials) which may become more important contributors in the new United Arab Emirates (UAE) economy. Making these modern foundations has been for the most part focused on metal and concoction commercial enterprises. The legislature arrangements accentuated to assign the enormous plants outside the significant urban areas of Abu Dhabi and Dubai and the little public facilities to be appropriated to all towns on the coast or inner part of the nation. So as to create a recently modern culture all through the nation, the state wanted to make a little scale mechanical focus in pretty much all urban areas to utilize between 30 to 50 specialists and to focus basically on ladies workers to build their interests in the job workforce.

United Arab Emirates (UAE) is a developing nation spotted on the shore of the Mediterranean Sea. It is essentially a petroleum delivering nation with a bond industry, needed to build up the nation's foundation (Alghadafi & Latif, 2010). Nonetheless, it is perceived that the concrete business is not able to meet the developing requests of the United Arab Emirates (UAE) and worldwide markets. Hokoma (2010) pointed out that, for proper implementation of such strategic moves for the United Arab Emirates (UAE) public sector needs to confirm the proper practices and help from the senior managers towards usage. The official administration body ought to take genuine activities through applying an agreeable method towards a large portion of the ranges that are considered as being urgent in any compelling usage of the new vital practices. Absence of a point by point arrangement towards attaining to the full usage is impossible. Imparting the vision of satisfying the usage process with all the related representatives and guaranteeing the obliged assets for compelling execution of these practices get to be required. This implies a huge measure of assets will need to be distributed for training and preparing. The vision of enhancing the United Arab Emirates (UAE) modern area can be completely acknowledged just if all the related proficient bodies assume the full liability and cooperate to accomplish this objective.

Organizational Commitment

Mowday, Porter and Steers (1982) described hierarchical duty by (an) "an in number faith in and acknowledgement of the association's objectives and qualities; (b) a readiness to apply extensive exertion for sake of the association; and (c) a powerful urge to keep up participation in the association" (Mowday et al., 1982, p. 27). Tragically, duty has truly been found to apply minimal direct impact on real work execution, albeit reduced turnover aim and steady participation are themselves basically critical star hierarchical demeanour and activities (Mathieu & Zajac, 1990). Authoritative predecessors of responsibility have additionally been the centre of extensive consideration, with different features of the hierarchical society seen as equipped for improving or taking away from the representative's bond with the association. Some exploration on responsibility has centred upon the impact of other remarkable work encounters, for example, the initiative style to which a representative is uncovered (Morris & Sherman, 1981). Positive relationships exist in the middle of responsibility and both pioneer launching structure and pioneer thought. This relationship is obvious in mechanical settings also, with strong practices from the top administration, for example, input, affirmation and collective critical thinking related with more elevated amounts of hierarchical duty (Billingsley & Cross, 1992; Rosenholtz, 1989).

Hall (1968) said that experts ought to be allowed to practice self-sufficient judgment and choice-making in their work, demeanour which by definition would be incongruent with various levelled, bureaucratic authoritative structure. Hall (1968) additionally found that top administration, for the most

part, saw their associations as profoundly bureaucratic, while his exploration likewise uncovered that workers were a standout amongst the most "firmly professionalized" word related gatherings. It is absolutely this mix of characteristics that could possibly bring about contention in the middle of expert and hierarchical premiums, making the way of duty among representatives an essential subject for experimental examination.

Organizational Performance

Each organization has a technique and an inner activity, motivation for executing it, however cognizant or decently considered or flawed they may be (Barney & Hesterly, 2006). Now and again vital arrangements are straightforwardly expressed by the administration and in some cases; they stay verifiable in administration choices and the association's examples of operation (Abell & Oxbrow, 2002). Besides, now and then blueprints are picked after comprehensive investigation and in some cases, vital choices develop indiscriminately from chance events and recorded mishaps occasioned by the encounters and identities of past pioneers, the position of the organization in the business and the monetary circumstances encompassing its advancement (Stewart, 1998). Peng (2007) recognized that maybe, in the most successive case, a venture's menu of vital activities and methodologies is the result of numerous inner investigations and surveys, years of business criticism with respect to what worked and what did not, earlier key moves and choices, evaluations about what the future will bring and a strong measurement of experience and judgment, at the end of the day all the learning increased in time by an association.

As indicated by Hambrick et al. (1982), the points of interest of top-notch vital speculation and a profound duty to the key administration methodology incorporate the direction it gives to the whole administration progression in making clear simply what it is the organization is attempting to do and to accomplish. Henceforth, the commitment it makes to perceiving and reacting to market changes, new open doors and debilitating improvements (Johnson, 1989). The reason it accommodates administration in assessing contending solicitations for venture capital and new staff, the coordination it includes the whole technique related choice-making done by directors over the association and the proactive rather than receptive carriage that it provides for the association (Mathew & Patrick, 2007). As effectively expressed, high-performing organizations utilize their insight and worldwide mastery to deliberately attempt to affect their target markets with a compelling procedure; they attempt to start and lead, not simply respond and guard (Abell & Oxbrow, 2002). In that view, the genuine reason and estimation of the method is to concoct an activity arrange for that will effectively draw in purchasers, deliver a supportable game-changer, support the company's business sector stature, however, included aggressive weight opponents, and push execution to predominant levels (Stewart, 1998). Therefore, the success of the organization deeply relies on the proper strategic formulation, implementation and evaluation.

Conclusion

The strategic direction gives a set of indicators that gives operational processes that are applied to various departments in the organization. The business model and operational plan ensures that the organization creates and distributes the products and services with high operational value and high quality. The strategy is made at the top and executed at the bottom. The strong decision making process with the top management while implementation and execution role with the middle management of the organization, the strategy fails in an organization where the ineffective plans and unproductive work allocation in strategy execution is seen

Abstract

In cutting edge organizational levels, people do formalize strategies as a capacity to direct and center their endeavors. In a business organization (a firm), such endeavors will concentrate on making an incentive for benefit and directing the organization towards future. In this specific situation, the earth is a market with restricted assets and along these lines in which rivalry exists. This condition may be pretty much steady; however it is in consistent change. Firms will battle to adjust to abstain from being chosen off. Strategy in here turns into a systemic and levelheaded act, a procedure that can be overseen so as to effectively achieve the objectives of the firm. strategy permits an organization to position itself effectively inside its surroundings to succeed in its most potential, whereas perpetually observance those surroundings for changes which will have an effect on it thus on create changes in its strategic set up consequently. The purpose of this paper is to discuss the general context based on the literature review on the key success of factors on the strategy implementation.

Keywords: Strategic management, Organisational, Performance

Introduction

Today, organizations operate in a very competitive global environment along with the focus on employing potential employees. However, sometimes the performance does not really achieve to the expected level due to lack of strategic management. Despite of the importance of policy formulation for business entities, research that studies the impact of policy formulation, implementation and control of strategic management on government sector are limited (Thill et al., 2014). In fact, proper strategy development has evolved from a basic step of any organization, followed by the proper management initiative to become an important technique to support organization, organizational learning, and innovation. Though policy formulation has always been identified as an important tool in the strategic management context, one observable fact is that the usage of these styles among public organizations is very limited; often they are not used to their full potential (Otley, 2003; Ulrich et al., 2013). On the other hand, the organization and public associated with the organization want to see evidence of the efficiency and effectiveness, with particular concern on quality services, service delivery and cost reduction. The public sectors in the United Arab Emirates (UAE), experienced poor reward systems, absence of strategic plan implementation, lacked effective information communication system and so on. According to many researchers and experts, the key research gap in the field of the public organizations is a better understanding of the relationship between strategic management and firm performance (Heisig, 2014; Perez-Arrau et al., 2014). Therefore, a topical issue worthy of further study is the demonstration of how engaging in strategic management practices enhances organization performance in terms of direct financial benefits or indirectly through, such as increased innovation performance.

Strategic management studies across sectors long to response to the market demand and changes in customer demand and also to the continuous changes in technology (Price & Newson, 2003). The adoption of a clear strategy in the area of management organizations at the present time is one of the main factors that influence the organizations performance (Salancik & Pfeffer, 1977). Earlier literature showed that the existence a good strategy in management is one of the significant factors that enable organizations to stay within global competitions. According to Stahl and Grigsby (1992), strategy is a road map or guide by which an organization moves from a current state of affairs to a future desired state. Johnson, Scholes and Whittington (2007) further explained that, it is not an example of daily selection; however this is a tool for future plans and related strategy for an organization. Therefore, strategy permits an organization to position itself effectively inside its surroundings to succeed in its most potential, whereas perpetually observance those surroundings for changes which will have an effect on it thus on create changes in its strategic set up consequently (David, 1988). In short, strategy defines wherever we tend to do, wherever we tend to go and the way we tend to plan to get success.

Phelan and Lewin (2000) further stated that strategic management is a plan of action designed to reach and achieve a specific objective. The strategic plan seeks to always win the position of competitive advantage over its competitors in terms of better exploitation of the existing potential and employment optimization. There is always an element of uncertainty about the future, more strategy on a range of options (strategic options) from a fixed plan (Chandler, 1962). Nag, Hambrick and Chen (2007) pointed out that strategic management is the process of analyzing the major initiatives taken by general managers on behalf of their owners, which focuses on resources and performance in outdoor environments. The authors further came out with that the strategic management determine the organization's mission, vision and objectives, through the development of policies and plans, often in terms of projects and programs, and allocate the necessary resources to implement, policies, plans, projects and programs. And often uses the balanced scorecard to evaluate the overall performance of the business and its progress towards targets.

Associated Factors on the success of Strategic Management

Stoney (2001) stated that management strategy has become more sophisticated and has been considered as a strong potential for organizations in recent decades. Stahl (2002) emphasized on the importance of strategic management process and the necessity to provide individuals concerned to ensure the success of the company. This study also indicated that the senior management of any modern organization has a great responsibility to ensure the success and overcome the high competition from global markets. Meanwhile, Hunger and Wheelen (2003) showed that the organization has to be more effective and people at every level within the organization should follow the strategic way of doing daily jobs and duties, and the process should not be limited to senior management. They also showed that the process of strategic management include environment assessments for critical information, recommend changes to enhance strategic programs and to work with others as a team.

The structure of the business is evolving dynamically not only in the relationship between subsidiaries but likewise, in a shift towards increased market presence. New markets recognize economic benefits, technological advancement and increased opportunities that globalization can bring to them, which encourages attractive global investors and business initiatives. Several specific factors motivated companies to search for business development and growth through global operations, such as markets, monetary value, competitive factors and international business environment. Consumer demand has developed and continues to influence successful economies which in turn sustain our day to day life activities. Goods from all over the universe are almost instantly available at doorsteps with affordable costs. Hence, there is a need to understand the factors associated with the critical importance for the successful implementation of strategic management in the United Arab Emirates (UAE) public sector. For better understanding, these will be discussed in the following section.

Strategy Formulation

Fundamentally, strategy formulation is defined as a process of making a decision on what to do (Carpenter & Sanders, 2009). Consequently, it is necessary for organizations to decide on "what to do" by carrying out a beneficial strategic technique for long term accomplishment (Jiang & Alis, 2009). However, the decision of strategy may constrain a specific market, manufactured goods or service. Likewise, the use of strategy is affected by the decision maker's anticipation. Strategic concern takes into cognizance challenges encountered in the current state of affairs. Thus, organizations should make a decision on "what to do" considering the study of internal possessions, potentialities and external situations (Analoui & Karami, 2003).

This strategy formulation can be identified as an input factor; because this is the foremost step is to identify the mission and vision of the organization. Rieple and Haberberg (2008) said that creating a mission and vision statement is an essential element of strategic management, which should be established before setting up an organization. Vision and mission are the basis for an organization to ascertain what is required in order to accomplish, and it must evidently state in the organization through a way of attaining long-term objectives (Jiang & Alis, 2009). Organizations generally possess a passionate entrepreneurial expectation shared among employees within the organization. They shall be accountable for an increase in the production if they utilize a recognized strategic method in organizational activities (Tikkanen, Nokelainen, Suur-Inkeroinen & Lamberg, 2009). Developing mission and values in any organizations is important. O'Gorman and Doran (1999) concluded from a study, the importance of the mission statement in the interest of the continued existence of a product or services. Hence, the importance of vision and mission actually decides the aim and objectives of the business, and it takes part in an active position in the management for an organization's progress.

Pearce et al. (2005, p. 38) describe the organisation's target as "the basic reason that distinguishes a firm from other forms of its nature and identifies the extent of its functions in product and market conditions". Pearce et al (2005:37) recognise 'mission statement to be comprehensive of the prospects of all shareholders in the organization's assessment over the long run.' Consequently, these necessitate the formulation of a mission declaration; management needs to be highly susceptible arguments shareholders, within and outside the organization. Vision supersedes utterances, it requires practical action. The vision of an organisation needs to be sustained. Once more, "that is not so much through formal plans and programmes as by unofficial activities, the rolling up of sleeves and getting in there with everybody as well" (David, 2009, p. 53). Pearce et al (2005, p. 34) argue that the mission of an organisation is the distinctive reason that places it differs from other similar companies and identifies the capacity of its functions.

Furthermore, the objectives are a universal declaration of aim or purpose (Johnson, Scholes & Whittington, 2007). Top management in any organisations usually tries to find opportunities based on particular resources. David (2009, p. 176) emphasised, "obviously assured and communicated objectives are very important for accomplishment due to the following rationales; first of all, objectives assist stakeholders to recognize their responsibility in the organisation's future and also, they also give a basis for dependable decision making by administrators whose ideals and thoughts differ". He also declared that, "objectives put forward organisational main concerns and inspire effort and achievement. They remain as standards by which individuals, factions, sections, divisions, and the whole organisation can be assessed. The objectives offer the foundation for scheming jobs and sorting out activities to be executed within an organisation. Objectives should be quantitative, computable, reasonable, understandable, demanding, hierarchical, available, and congruent with organisational divisions". Thompson et al. (2003, p. 325), stated that "the reason of setting objectives is to alter professional declarations of strategic vision and mission into precise performance results and outcomes the organisation desires to accomplish". Furthermore, the authors also noted that, when a company-wide aims are explained into precise goal for a specific organisational department and lower- cadre managers responsible for attaining them, a result-orientated environment emerges all through the enterprise. Recognising and assessing external opportunities and risks permits the organisations to come up with an understandable mission, to plan strategies in order to accomplish a long-standing objective and to make guidelines to attain yearly objectives. Pearce et al. (2005, p. 221) concluded that, "In real decision

situation, the strategic option would be complex by a diversity of interactive opportunities, possible company objectives, promising impressive strategic opportunities, and assessment criteria".

Defining strategic choices is an additional way to develop a strategy. A doubtful market situation and rivalry influence business owners of deciding the proper strategy. By applying strategies, they can recognize the weaknesses and strengths of the company which assist the owners of the business to formulate other strategies at the same time predicting potential choices for competing with their competitors. Hence, a strategic option is also required to decide the subsequent steps, "go or no go", by following business opportunities (Analoui & Karami, 2003). Mintzberg (1988) proposed that a strategic decision was governed by the productive exploration of new opportunities. Johnson and Scholes (2003) view strategy formulation as a type of strategic lens, design lens, experience lens and idea's lens. The designed lens is comparable to Mintzberg's preparation mode that observes strategic growth as an intentional placement of the organisation by a logical, critical, planned and instructional process. They also examine strategic growth as a reasonable process whereby economic forces and limitations of the organisation are examined cautiously through critical and evaluative methods in order to set up a clear strategic direction. Quinn (1988 (b)) emphasised the need why management progress can best be explained as reasonably incremental. Those strategic conclusions do not provide the opportunity to combine into a single substantial decision matrix and all reasons will be taken care of comparatively and concurrently in order to achieve a holistic outcome. Hitt, Ireland and Hoskisson (1997) argued that managers decide openly and experimentally from a wide perception in order to achieve precise commitments, making the second tangible as late as probable in order to slim the bands of doubt and to take advantage from the best accessible information.

Another methodology to strategy formulation has created progress in a bid to consider the influence of cultural characteristics in strategy formulation (Webb, 1989). The cultural analysis believes that strategies can be seen as a result of experiences, values and beliefs that are taken for granted statements and practice of the organisations. Those taken for granted statements and practices are likely to be dropped down after some period of time in a group. Thompson (1994), formulated a relationship connecting culture and strategy creation and the courage and extent of strategic transform, either through the resultant from incremental change it will reveal all essential values and culture in the organisation. Johnson (1989) suggested strategy as a predictable result of not only the cultural process but also as a political process in the organisations. He also asserts that "organisational action view" of strategy formulation argues that strategy can best be viewed as a result of the political, cognitive and cultural fabric of the organisation. The political viewpoint is of the opinion that strategy progresses as the effect of processes of arbitration involving prominent internal and external concerned shareholders (Huy, 2001).

Mintzberg (1987) succeeded in postulating a different aspect to strategy formulation by arguing that strategies can structure as well as being planned. Also, he indicated that a recognized strategy may materialize in reaction to a developing condition, or it may be deliberate during the formulation process thereafter by execution. However, when intended objectives do not generate the required actions, organisations aim becomes an unrealized strategy (Wheelen & Hunger, 1991). Moreover, the achievements of the organisation are dependent on a long-term business strategy which recognises its goals, offers a structure for accomplishing set targets and a system for measuring their success (Mintzberg, 1987). Hence, the process of strategy formulation is dependent on an all-inclusive assessment of future requirements, which transform into a cautiously planned and strategy of implementation.

Strategy Implementation

Another input factor, strategy implementation, can be defined as a management process of executing necessary activities to achieve what has been planned (Carpenter & Sanders, 2009). Woods and Joyce (2003) argued that the strategic execution plan is considered as a process which may require alterations relating to the general traditions, arrangement and/or management system of the whole organisation.

David (2009, p. 260) states that strategic management is a continuous process. This signifies that the strategic management process does not come to a conclusion once an organisation has decided on a strategy. Importantly, strategies need to be executed successfully. David (2009, p. 37) accepts that "strategies executed, serve executed serve no valuable reason." Moreover, he suggested that strategy implementation involves an organisation to institute yearly objectives, formulate plans, inspire employees, and assign assets so that formulated strategies will be implemented. Strategy implementation consists of developing a strategy encouraging culture, expanding a successful organisational structure, readdressing market endeavours, planning resources, developing and making use of information workers'ms, connecting workers reward to organisational effective performance. Thompson (1994) reveals the possibility to analyse implementation as an action that is in line with strategy formulation; where arrangements and plans are altered to take into consideration changes in strategy. Though, implementation, as an alternative of formulation, may be considered thoroughly and simultaneously as the recommended strategy is considered through before the concluding decisions are finally decided.

Strategic implementation can also be described as the "action plan" of strategic management. Quality strategy formulation cannot be separated from business entrepreneurship. Wickham (2004, p. 293) generally defined strategy as, "the actions an organisation takes to pursue its business objectives". He also suggested that strategy positively influences performance and useful strategy results for better output. The strategy is described as an assertion that concentrates on the company's aspiration and implementation. The strategy generates a feeling of agreement or reliability of action, all through an organisation. Thompson and Strickland (2003: 1989) suggested use that "good strategy implementation involves a tough fit connecting the method things are completed internally and what it will take for a strategy to do well". A sequence of requirements must be generated which will involve strategy and the organisation's proficiencies, capabilities, policies and structure, budgetary allocation, internal support system, compensation structure and corporate culture (Grant, 2000; Thompson, 1994; Webb, 1989).

The setback that confronts most organisations is the change from strategy formulation to strategy implementation. David (2009, p. 38) stressed in the statement that, "the changeover from strategy formulation to implementation necessitates a shift in responsibility for separations to separation and functional managers" Ehlers and Lazenby (2007, p. 212) defines strategy implementation as, "the development that translates strategic plans into a sequence of action tasks, and guarantees these missions are executed in the strategic plan objectives of strategic plan are accomplished. In other words, strategy implementation is the communication, interpretation, adoption and enactment of strategic plans". It is evident that the strategic implementation interprets idea or strategic into an achievement. The leadership must make certain the incorporation strategy to circumvent uncertainty. An incorporated process to strategy, culture and formation translates to continued improvement. Pearce et al (2005, p. 288) noted that immediately corporate and business strategies have been decided, and long-standing objectives are set, strategic management process progresses into a crucial new segment transforming a strategic idea into organizational achievement. The slayings of two well-worn expressions, they progress from "planning their work" to "working their plan" as they alter their centre of attention from strategy formulation to strategy implementation." In the perspective of the public sector, the responsibility of top management as strategic decision-makers has a superior impact for executing the strategy and they have power in decision making that influences the entire organisational structure (Jiang & Alis, 2009). Managerial expertise is crucial for management to implement strategy accurately and properly. Certainly, successful strategies are dependent on effective implementation (Carpenter & Sanders, 2009).

Strategy Evaluation

Besides a few input factors that can be treated as an independent variable, the final process of strategic management is control and assessment, in which the company performance is evaluated to its prospect (Miller & Friesen, 1984). For the time being, managers receive information from their assistants to take timely and corrective actions to resolve the challenges (Analoui & Karami, 2003). The strategy assessment and control are the final phases in the strategic management model. Consequently, the

comparison results with required performance, managers have to make amendments in the formulated strategy and/or implementation (Karami, 2007). Anderson and Sohal (1999) noted that strategic evaluation and control are significantly significant and should not be disregarded by the organisation. It aspires at investigating the possibility and practicality of strategies that suit in the firms' economic progress or not. However, strategy evaluation consists of three fundamental activities (Aaker, 2001; Andrews, 1971; Carpenter & Sanders, 2009; Chandler, 1962; Hitt et al., 1997; Karami, 2005; Macmillan & Tampoe, 2000):

- Revaluating the possible external and internal reasons attributed to the source of the present strategies,
- Evaluating the performance output, and
- Adopting acceptable actions

The entire progression of strategic management is illustrated on a model chart designed by David (2009, p. 46) and it is incorporated three-phase decision-making structure, as demonstrated in Figure 2.5. The model chart is imitated to develop the structure for this study. Hence, this report will focus on strategy formulation and strategy implementation, particularly with their incorporation. The reason for adopting this option is that strategies cannot be executed successful possesses a crucial problem to strategic leadership and the entire organization. Majority of organizations expends extra assets in the formulation stage and occasionally become unsuccessful in implementing the strategies, thus consequence is unproductive and uneconomical expenses of limited assets.

Formulation of Strategy in an Organization

A policy is a broad guideline for decision making that links the formulation of a strategy with its implementation. Companies use policies to make sure that employees throughout the firm make decisions and take actions that support the corporation's mission, objectives, and strategies. Floyd and Wooldridge (1994) define senior management and the senior director as: "the coordinator between daily activities of the departments and the strategic activities of the hierarchy and organizational structure." They stress the senior director's role as "a link, departmental objectives and operational workers more than the 'hierarchical' definitions." Gilbert (1994) stated that quality management standards provide a common yardstick against which purchasers can check an organization's quality management system, resulting in a quality assured organization. The quality systems in an organization create an environment that supports innovation, creativity, and risk-taking in meeting customer demands, using participative problem solving that incorporates managers, employees, and customers. The adherence to quality management systems ensures that mutual co-operation of everyone in an organization and associated business processes to produce products and services which meet and, exceed the needs and expectations of customers. The strategic management in an organization cannot be successfully used as an aggressive weapon unless quality can be precisely characterized, measured, assessed, and observed over the long haul. Through such investigation, a healing centre can choose how to consume it constrained assets toward those quality change ventures which will affect client impression of administration quality the most.

Conclusion

The development of strategic management involves the design or adjustment of the organization through which the varying financial, economic, human and operational changes. There are constant changes to existing roles of people, their reporting channels, their performance evaluation and control mechanisms in the company. Strategic management are important for the employees and ensure to follow a career path and the strategy of the employee changes with the competitors, suppliers, regulators and customers. Once the strategic opportunities have been recognized and potential dangers considered, a list of particular steps that will be taken to actualize the arrangement ought to be shaped. Quantifiable results are portrayed as described to every target and must be dictated by the statement of purpose. Obligations regarding actualizing the objectives and targets ought to be built. The key

arrangement sorted out through objectives and goals offers an arrangement of quantifiable results which can be assessed.

Abstract

For an organization to attract and retain experienced and qualified employees, smart quality of work life is important. Work-life efficiency is a vital topic with much significance in the life of the employee. Work-life efficiency (EQWL) suggests a good work-life balance that also guarantees organizational effectiveness and job satisfaction for employees. This paper attempted to review literature in the context of UAE on the relationship between work-life experience of the employees and organizational culture. EQWL 's study is very valuable since it can distinguish between high and low performers among organizations. There is, however, a significant gap in studies to investigate the quality of such work-life at UAE. The work-life quality studies conducted in UAE are less and less limited, so it is important to conduct more and more comprehensive research in this area. Especially when the enhancement of work-life quality and its relationship with job satisfaction is advocated is very significant.

Keywords: Quality of work-life, Job satisfaction, UAE, Public sector

Introduction

The United Arab Emirates (UAE) is keen to accept an open market economy that supports free trade, free movement of capital and resources, facilitates investment, and encourages work-life quality to play a greater role in the growth cycle in various economic activities. The country explicitly seeks to take advantage of advanced-state experience in achieving economic growth and development. In line with this strategy and as part of its efforts to broaden and diversify the economic base, the government has taken significant measures to restructure the economy to enhance the private sector's position in the economic and social spheres (Schilirò, 2013). Through widening the reach and duration of the privatization process, which plays a crucial role in the liberalization process and the development of the economy, it has allowed the private sector to take over many of the tasks that the government has carried out itself (Hvidt 2013). This is considered one of the key ways of equal wealth distribution, the widening of the ownership base, the implementation of new management structures and modern strategies for public institutions, and the development of more effective financial policies that minimize spending and help improve the quality of different services (Toledo, 2013). This move will also result in developing and diversifying goods and services at competitively affordable rates. Hence, the national economy's competitiveness will be improved at global and international level. This will also lead to a reduction in bureaucracy, national savings and help eliminate corruption and nepotism, as the private sector, focused on cost and operational economization, will apply appropriate economic standards in the job cycle (Toledo, 2013).

Literature Review

Quality of work life is a broad term covering physical and psychological health, economic circumstances, personal opinion, and environmental engagement (Khorsandi et al., 2010). In existing administration, the perception of the quality of work-life has been transformed to a social issue, while in the past decades only the personal life was emphasized (Mirkamali & Narenji Sani, 2008; Swapna, 2015; Ahmat et. al., 2013). The definition of work-life quality is subjective imagination, and organizational staff's understanding of the physical and psychological desirability of the work environment and their job circumstances (Yavari, Amir Tash, & Tondnevis, 2009). The quality of work-life has been described as the reaction of workers to work; in particular its important outcome in terms of job preferences satisfaction and psychological wellbeing (Mejbel & Almsafir, 2013), in line with this concept, quality of work-life emphasizes personal results, work experiences and ways of improving added order in order to fulfill non-public preferences (Ahmad, 2013). Walton provided a theoretical model to explain the quality of work-life, which consisted of sufficient and fair pay, a secure and healthy environment, constitutionalism in organization, preparing the potential for continued growth and stability, social connection of work-life , social integration, human capacity creation and also the complete house of life (Walton, 1973). A lot of research has been done on the quality of work-life since thirty years ago, and findings suggested that there is a clear positive relationship between EQoWL and employee satisfaction (Adhikari & Gautam, 2010; Fatihe et al, 2015; Ramawickrama & Pushpa Kumari, 2017).

Job satisfaction has been described as information, awareness and positive attitudes and reactions of career personalities that are influenced by factors such as the work environment, the organizational structure, the relationship between the work environment and socio-cultural factors (Mirkamali & Narenji Sani, 2008; Armstrong 2006). Over the last five years , the population of the United Arab Emirates (UAE) has risen to approximately 9.5 million, and the local population constitutes approximately 1.4 million (15 percent) of the country's total population (Snoj, 2015). Having benefited from the government's comprehensive higher education opportunities, Emirates women, with an overall literacy rate of 91 per cent, account for a large portion of the country's graduates and are projected to be actively engaged in the country's economic growth (Jabeen, Friesen & Ghoudi, 2018). Different survey-based evidence has identified Emiratis's strong preference for public sector employment (Al Waqfi & Forstenlechner, 2012).

In UAE, the EQWL is becoming an important human resource management subject and has become a top priority for staff across the world. Some public and private organizations in the UAE are attempting to recruit and maintain their valued workers by introducing and maintaining a successful EQWL system strategy and policies (Jabeen, Friesen & Ghoudi, 2018). It is not enough for organizations to have good visionary leaders; rather, organizations need to build a distinguished work atmosphere to achieve their strategic goals (Zare Janani, 2015), and Quality of Work-Life (QWL) has recently become an significant issue (Narehan et al, 2014; Zare Janani, 2015). In practice, several researchers have agreed on the value of QWL for organizations seeking to boost their employees' levels of job satisfaction and engagement (Normala, 2010; Mirkamali & Thani, 2011).

In addition, Narehan et al. argued that the company should continue with improvement of QWL in order to increase the quality of the product or service to the company. The study stressed the link between work environment and QWL. In reality, some researchers considered QWL as "an indicator for paying attention to the needs of humans and putting them in the content of jobs" (Mirkamali & Thani, 2011). This means that if they want to succeed and thrive in the current competitive environment, management will give high priority to the needs of the most important component of their company, namely, human resources. Job quality is a vital term, having much significance in the life of an employee (Islam, 2012). Work-life quality indicates a good work-life balance which also guarantees organizational efficiency and job satisfaction for employees (Islam, 2012). This research study attempted to find out the relationship between work-life quality of employees and job satisfaction, and also to find factors that influence the quality of work-life of employees in the Abu Dhabi Emirate Scientific Centers & Presidential Camels Market.

Quality of work life in the UAE

Quality in a company is described as a benefit, as a premium, as conformity determination, and as meeting the needs of the consumer. Smart working quality is critical for an organization to attract and retain qualified and experienced employees (Johanim et al., 2018). Employees are any organization 's prime assets and their success or failure depends on their skills and results. In order to survive in the competitive market attributable to liberalization, privatization and globalization and to lower employee rates, the standard of work-life initiatives is vital, motivated employees and happy customers are the backbones of any productive organization (Fauzaia et al. 2018).

Growing demographics in developing countries, and the need to have an attractive business climate, need enhanced infrastructure. There is a growing demand in developing countries for higher quality in the delivery of services, whether healthcare, electricity and telecommunications or transportation, and whether they are delivered to the public or to businesses. And government-wide focus is put on remaining in the management of public finances. The disparity between the burden on the general public purse and also the resources out there to serve them leads governments to appear at whereby infrastructure is built, services are given, and business in collaboration with the personal sector is progressive.

EQWL's study is very interesting since it can differentiate between high and low performers among organizations. There is, however, a significant gap in studies to investigate the quality of such work-life at UAE. This study aims to investigate the relationship between work-life productivity of the employees and work-life satisfaction in the public organization of the UAE. There are good numbers of local and non-local people working in public organizations in UAE, and they contribute to their organizations a certain level of valuable time. We do offer their utmost to gain a responsibility and helpfulness for organization, though.

However, the standard of work-life is such a phenomenon that requires some balance in both professional and personal life (Pio & Tampi, 2018). The goal of this study is to identify factors which directly affect the quality of work life. Getting a good level of work-life experience is very necessary if the employee of every company wishes to give the company its high activity effort. Quality of work life is an attitude or group of leaders that maintains that workers are dependable, accountable and able to make a positive contribution to the company (Gupta & Bag, 2019). However, work-life efficiency is strongly affected by job satisfaction and external environment, as well as personal like.

The work-life quality studies conducted in UAE are less and less limited, so it is important to conduct more and more comprehensive research in this area. Especially when the enhancement of work-life quality and its relationship with job satisfaction is advocated is very significant. There was no research in a UAE public agency on the quality of work-life and job satisfaction of the employees. Furthermore; according to the importance of these two variables for advancing organizational goals and creating greater performance, as well as certain situations in the Scientific Centers & Presidential Camels sector in Abu Dhabi Emirate such as a shortage of amenities, this study aimed at determining the relationship between work-life quality and job satisfaction in the Scientific Centers &

Organizational Culture

Organizational culture consists of the culture of organization through different referents such as managers, superiors, and peers. Knoll and Gill (2011) clarify that organizational culture in peer culture and organizational culture in subordinate is not necessarily related, but the organizational culture in superior is strongly linked to insubordinate organizational culture, and peer organizational culture. The importance of the cultural relationship of organization culture or organization in preserving organizational culture has insisted on engaging in exercises to construct organizational culture (Knoll and Gill, 2011). Positivity in a leader results in followers showing higher leadership organizational culture and a greater appreciation of the efficacy of leaders (Bhandarker and Rai, 2015). It also describes how proactive leadership contributes to a favorable organizational climate. As a consequence,

the positive atmosphere generated within the company produces positive interpersonal relationships. Organizational culture can be regarded as one of the most common and controversial ideas in the study and practice of management. Therefore, there is no widely accepted definition for the word culture of the organisation. First appeared in the 1970s and 1980s, the idea of organizational culture (Hofstede, 1981; Schwartz & Davis, 1981), after which other scholars developed different theories and meanings for this idea.

Schein 's organizational culture model began in the 1980's. In organizational cultures, Schein (2004) identifies three distinct levels: artefacts and procedures, spouse beliefs, assumptions. The three rates allude to how much the eyewitness perceives the complex social marvels. Artefacts incorporate any components which are clear, manifest or verbally identifiable within an organization. Technology, furniture, traditional clothes, workplace jokes, all embody artefacts of organization. Artefacts are the distinct components of a society, and it is not a portion of the way of life that individuals view them. Spouse principles are the embodied beliefs and behavioral standards of the company. It's the way individuals talk to the company about themselves as well as others. This is expressed frequently in official rationalities and open character proclamations. Frequently it may be a prediction of what the individuals want to turn into for the future. Cases of this would be polished employee capacity, or a mantra of "family first."

Inconvenience may arise if the values adhered to by leaders do not obey the deeper implied assumptions of the way of life. For few purposes, this work integrates Schein's concept of organizational culture. The shared basic assumptions in this model are the deeply built, understated behaviors that are typically oblivious; nevertheless, they constitute the substance of culture. Such perceptions are generally embedded so much in the complexities of the workplace that they are hard to detect from inside. This model is therefore one of the appropriate models for the business organizations in the Abu Dhabi government organization to assess the current situation of transformational leadership behaviour, organizational culture, and job efficiency. Jerónimo García et al (2018) proposed that there is a positive relationship between the corporate culture and both consumer satisfaction and corporate efficiency.

The Relationship between EQWL and Organizational Culture

In Islamic Azad University of Tabriz (IAUT), Valizadeh and Ghahremani (2012) analyze the relationship between organizational culture and employee quality of work-life. The findings showed that there is a strong and significant connection between the organizational culture and the quality of the work life of the employees. Each aspect of work-life quality has a direct and significant relationship. -- University controlled community is kind of an intellectual one. Rahmawati and Setiawati (2017), in their study of the impact of work-life quality (QWL) and organizational culture (OC) towards employee efficiency (EP) and job satisfaction (JS), found that QWL and OC had an important and positive effect on EP and JS. JS also had strong and constructive impact towards EP. QWL's indirect impact toward EP through JS was greater than direct effect, and OC's indirect influence toward EP through JS was greater than direct effect. Young and Ruggiero (2011) studied the causes and predictors of organizational performance, with a emphasis on organizational culture and work quality. The findings indicate a strong connection between organizational culture, work-life efficiency, and organizational effectiveness. Vignesh Shankar (2014) defines the consistency of employees ' work-life and productivity, and their effect on the culture of the company. The findings indicate that the quality of work-life and organizational culture are significantly related.

Conclusion

The study was important not only to the Abu Dhabi public organizations directors but also other managers in other industries. The government ministries and policymakers may also gain knowledge of the effect of privatization on public organizational performance of Abu Dhabi Emirate. The government agencies may make use of this study, as it provides complementary knowledge on privatization and organizational performance and uses the knowledge to develop policies that enhance positive participation of such organizations. The study aimed to bridge the gap in knowledge of EQWL

on organizational change and performance of Abu Dhabi public organizations. Such knowledge may be used by researchers and scholars to add to their understanding of WQWL in the Abu Dhabi Emirate. The thesis was to provide the foundations and material for further work related to it. This also presented valuable new comparative insights to tackle problems raised by the relationship between the EQWL and work satisfaction.

Abstract

This paper aims to review the body of literature on the relationship between employee quality of work-life and employee job satisfaction, in general, contextualized it with an interest in the process affects employees' quality of life. The available literature varies significantly in approach and emphasis as authors tend to specialize in individual business or macro-economic topics. There is little structured research and much of what is written tends to explain the reluctance of regional government including comprehensive programme. In essence, there has been little academic literature written on the relationship between EQWL and employee job satisfaction both in the private and public sectors.

Keywords: Quality of work-life, Job satisfaction, Employee

Introduction

Job satisfaction is called a good feeling about one's work. Newsstrom (2007), job satisfaction as a set of feelings and emotions with which employees view their work. One of the main factors driving growth efficiency expansion is assumed to be in the health care facilities and job contentment of the female paramedic professionals (Hanan, 2009). Intellectual depiction of the import of values by an employee that vary about job satisfaction or dissatisfaction. For example, some employees in their jobs may exert a sense of accomplishment, as other employees do not. Oldham's and Hackman (1980) were found to be identical, comparing blue and white-collar staff, and categorizing them by the extreme insistence that the ultimate stimulating tasks were not as competitive as job security and blue-collar workers' bonuses. By comparison to blue-collar workers, the determinations also suggested that inspiring and diverse initiatives were of advanced importance to white-collar workers (Hackman & Oldham 1980).

Literature Review

Research findings from Okele and Mtyuda (2017) suggested that a shortage of funding, too many cou rse crowds and indiscipline among pupils were serious sources of dissatisfaction among the teachers. Management effects are other causes of work dissatisfaction among teachers. All of these factors gen erate disengagement among teachers and filled their work with negativity. In second career teachers, Troesh and Bauer (2017) investigated work satisfaction and stress as compared to first career teachers and the role of self-efficacy in this context.

Results showed second career teachers are extremely pleased with their profession relative to first car eer teachers.

Tharikh et al. (2016) analyzed the data, and the findings showed that there is a statistically significant and positive relationship between employee satisfaction, organizational engagement and organizatio nal nationality. Spencer and Byrne (2016) suggested high job satisfaction for senior managers compar ed to junior level managers. Darrat et al. (2016) indicated that organizational job embedding is optimi stically related to organizational deviance, interpersonal deviance and direct client deviance among sa lespersons with lower workplace satisfaction. However, among salespeople with higher job satisfacti on, work embedding is negatively related to organizational deviance and not significantly associated with either relational or client directed deviance.

Robertson and Kee (2016) have studied workplace satisfaction in a computer-mediated context, particularly with social media use. Results showed that employee satisfaction at wo rk is linked optimistically by the amount of moment they spend on Facebook connecting with a collea gue. It also found that part- time employees reported having spent the increasing amount of time with their colleagues on Facebook, and that agreement employees reported the greater degree of job satisfaction at the workplace. Results of Monga et al. (2015) revealed that pay, social association, contact, senior citizens' attitudes, workplace environment and teamwork are more relevant than the factors of training and progress, honor and reward, nature of work, job security, morality and clarity of role in determining bank workers' workplace satisfaction. Saner & Eyupoglu (2015) investigated whether there is work satisfaction amongst bank workers. The study revealed bank workers were moderately filled with their job satisfaction.

The current organization claims the job contentment of female paramedics is the product of rational organization and has a direct link to leadership and work commitment through good management and encouragement to health care organizations (Giallonardo et al. 2010) (Wong & Laschinger 2013). Finally, contentment with the job for female paramedical workers is more closely linked to exact problems such as work-related environment (Hamama et al. 2014) (Kinzl et al. 2004) or ethics (Goldman and Tabak 2010).

Meanwhile, Platis et al. (2015) studied the level of work contentment with female paramedical professionals being happy with self-occupation. Results have revealed that proper management plays an important role in creating superior workplace environments. A current female paramedical professionals management has to face a lot of demanding situations such as fast changes in the area of medical and paramedical services, the difficulty of female paramedical professionals' profession and of course the mental effects incurred by the nursing work. Additionally, the willingness of female paramedical professional managers to speak to the employees and respect their views despite the high importance of the workforce of the female paramedical professional.

The association in the workplace is also measured strongly amid output and contentment. Personal feelings, thoughts and even attitudes of women paramedic's professionals play a critical role in their success, in particular for medical and paramedical services. This research investigation highlights several issues such as intensions, knowledge, individual culture which needs further investigation. Bardan and Youssef-Morgan (2015) found that Psychological Energy, anticipation, endurance and positivity are optimistically related to the work contentment of workers, individually and when developed into a whole in the high order.

Effect on Labour Market

Thompson (2016) highlighted the UAE labour market of the UAE may be characterized as being two-tiered and constitutes one hand expatriates and their subsets of various nationalities and occupational groups on the one hand and the Emirati population segment of the labour market on the other. State-owned assets in the UAE were not established primarily to provide strategic public goods and services to the minority Emirati population but equally as important they fulfil an additional goal of being used as a part of a broader citizen empowerment policy directive. Having said that, it would be remiss to

conclude that privatization would on the expatriate segment of the population more than how it would affect the well-being of Emiratis who essentially the government would not be unwilling to downsize.

Employees Quality of Work Life

Leaders in the new time have been confronting stem difficulties in this bleeding edge of innovative progression and the procedure of globalization. Free market rivalry, open-showcase economy, exchange progression, cross-fringe megamergers and acquisitions, deregulation, satellite media transmission, innovative headways, and developing worldwide financial reliance have brought nations closer than any time in recent memory. Further, online business, Internet transformation, territorial power coordination, regular monetary forms and multifaceted decent variety in the workforce have consistently been changing the conventional business practices and influential positions far and wide. Worldwide challenge and a changing business condition have incited a hierarchical change because of the expanded weights to improve proficiency and execution. As the piece of workforce keeps on changing, organizations concentrating on nature of work-life (QWL) of representatives are depend on to pick up influence in enlisting and holding profitable individuals. QWL is a complete program assigned to improve workers' fulfilment. It is a state of awareness about individuals, work and association and makes a feeling of satisfaction in the brains of the representatives and contributes toward more prominent occupation fulfilment, improving efficiency, adaptability and in general adequacy of an association.

Concept of Employees Quality of Work Life

Job Life Quality carries various consequences depending on different understandings and practices. In 1979, the American Society of Training and Development formed a committee on the QWL, and the committee described QWL as "a work association method that empowers its individuals in all dimensions to take an interest effectively in molding the environment, techniques and outcomes of the association. This esteem-based approach is aimed at achieving the twin goals of improved association viability and improved quality of life at work for members." Nadler and Lawler (1983) have shown that the definition of QWL has undergone a shift of change over time. QWL, which was known as a 'component' in the 1969-1972 period, has become a 'methodology' in the midst of this era.

QWL, as a variable, means a person's response to work or the individual outcomes of the work involves. It concentrated on such individual results as employment fulfilment or emotional well-being, with an accentuation on the effect of the work on the person. As a methodology, QWL concentrated on the individual as opposed to authoritative results, yet the accentuation appeared to be on the joint work the executives' co-usable undertakings, especially those went for improving results for both the individual and the association. QWL is viewed as a lot of strategies, methodologies or advancements for upgrading the workplace and making it progressively beneficial and all the more fulfilling. Here, the QWL is progressively synonymous with so many ideas as self-sufficient work gatherings, work advancement, on the structure of new plants as incorporated social and specialized frameworks. QWL as development is by all accounts a greater amount of an ideological explanation about the idea of work and the specialist's association with the association. At this stage, the terms, 'Participative Management' and 'Mechanical Democracy' ended up perfect frameworks of the QWL development. As an umbrella idea, QWL is viewed as a worldwide idea and all authoritative improvement or hierarchical viability endeavours would, in general, be named as an integral part of QWL.

Factors Influencing EQWL

Work is an integral part of everyday life since it depends on our livelihood or profession or business. We spend about twelve hours a day on average in the workplace which is nearly one. Third part of our life; that influences the overall quality of our life. It is therefore expected that there will be work satisfaction, peace of mind, fulfilment of completing a mission, without any fault, and fruitful, positive and purposeful spending time. While it is a small step towards our lifetime target, it gives us the satisfaction of completing the day's work and the eagerness to look forward to the next day at the end

of the day. If the feeling is good, we love the work-life, we blame the factors responsible for it if it's wrong. The factors affecting and determining the degree of work-life quality are attitude; environment; opportunities; nature of work; people; stress level; job prospects; challenges; growth and development; and including risk and reward.

Attitude: The individual entrusted with a particular job requires sufficient knowledge , skills and abilities, appropriate experience, enthusiasm, level of energy, willingness to learn new things, dynamism, sense of belonging to the organization, participation in the work , interpersonal relationships, adaptability to changes in the situation, openness to creative ideas, competitiveness, zeal, ability These are positive attitudinal factors that decide work acceptance and consistency with improved results, which have a reasonable effect on the QWL

Environment: The job may include interacting with customers with a varying degree of tolerance, interests, behavioral habits, level of understanding; or it may involve working with dangerous machines such as drilling pipes, cranes, lathe machines, welding and soldering machines, or even with animals where full safety measures need to be taken. It's a reality that job requires a lot of focus, alertness, mental awareness, eye coordination, hand and body, often a high degree of flexibility, tactfulness, empathy, and emotional sensitivity and power. If positive, the atmosphere prepares a man to work efficiently both mentally and physically and the opposite is true when negative.

Opportunities: Some jobs offer learning, study, experimentation, self-development and skills improvement opportunities, creativity rooms, public attention, exploration, celebrity status and loads of fame. Others are monotonous, repetitive, slow, predictable, without space for change and dull in any way. Of example, the former are fascinating and also very satisfying in generating value for improved results while enjoying it while the latter demotivates contributing to low QWL.

Relationship between EQWL and Job Satisfaction

Gupta and Bag (2019) analyzed the relationship between job satisfaction and the efficiency of bank employees' work-life factors; their findings indicate the existence of variation in job satisfaction as explained by work-life efficiency constructs. A negative correlation with job satisfaction has been demonstrated by the unconductive work environment. The research envisages bringing valuable knowledge to the organizations' top management level to increase the overall work satisfaction of workers (Gupta & Bag, 2019).

Guzi and Pedraza (2015) examine the role of working conditions and job characteristics in relation to three indices of subjective well-being (SWB): life satisfaction, work satisfaction and work-life balance satisfaction. The findings shed light on the significance of such workplace features not just in assessing work satisfaction but also in other subjective areas of well-being. The findings support the spillover perspective hypothesis, according to which satisfaction in one field influences other domains (Guzi and Pedraza, 2015; Ahmad et. al., 2013).

Pio and Tampi (2018) are researching the impact of spiritual leadership on ethical behavior, work-life efficiency (WLQ), job satisfaction, organizational engagement and performance of the employees. The findings showed substantial direct spiritual leadership effects on work-life quality, spiritual leadership on job satisfaction, work-life quality on job satisfaction, work-life quality on organizational citizenship activity, work-life satisfaction on organizational citizenship behaviour (Pio & Tampi, 2018). Arif and Ilyas (2013) are discussing different aspects of work-life quality (WQL) as it affects the lives and attitudes of private university teachers in Lahore, Pakistan. It was found that perceived job importance, job climate; work-life balance and satisfaction with relationships in life were the major factors that influenced work attitudes and perceptions of overall work-life quality among employees.

Lee and Chan (2015) study the quality of work-life and job satisfaction among frontline hotel employees, their analysis examines perceived quality of work-life (QWL) needs attributes among front-line employees in the lodging industry, assesses asymmetric relationships between QWL attributes and job satisfaction (JS) and prioritizes QWL attributes for successful management of JS (Leee and JS) The

result indicated that each QWL attribute had major asymmetric or linear impacts on JS or work dissatisfaction (JDS) as well as others. Jabeen, Friesen, and Ghoudi (2018) investigate the quality of work-life (QoWL) and its effect on job satisfaction and turnover (job-leaving) intention of Emirates women working in various public sector organizations in the UAE. The results indicated that QoWL was found to have a significant relationship with all variables in the model, and as hypothesized, it was found to have a positive effect on job satisfaction and a negative impact on turnover intention.

Conclusion

This paper explored a multiplicity of areas that interrelated with privatization. The literature on the nature, methods, and the political economy of privatization were explored. In, the chapter delved briefly into how privatization would impact on the lives of employees in general and to a lesser extent in the United Arab Emirates.

Abstract

The idea of perceived organizational support (POS) has gotten extensive enthusiasm among authoritative conduct analysts. They have recognized the precursors and outcomes of POS and its mediating and moderating roles between numerous factors. Perceived organizational support characterized as individuals' worldwide convictions about the degree to which the association thinks about their prosperity and qualities their commitments. Employees may utilize apparent perceived organizational support to pass judgment on the potential increase of material and emblematic advantages that would result from exercises supported by the association.

Keywords: Perceived organizational support, Organization efficiency, job performance

Introduction

There is a strong evidence in the literature that supports the significance of the job performance of workers , which in turn influences professional conduct (Won Kim et al., 2017; Kim & Koo, 2017). Employee performance in government sectors is well thought-out and significant in its relationship to organizational productivity and outcomes; thus, it is expressed as a key factor in enhancing organizational performance (Bridget Rice et al., 2017; Johanim Johori et al., 2019). While the value of employee performance is well understood (Tanya & Nicholas, 2013; Won Kim et al., 2017), less is known about how organizations enhance job performance of their workers through organizational processes (Sununta & Patarakhuan, 2016).

The ability to measure job performance has been considered over the last few years as an important prerequisite for development within organizations, both public and private sector, one of the significant methods utilized to improve competences of organization has been through their implementation of employee job performance and measure their capability (Soumendu & Kapil, 2017). In Human Resource Management, the development and arrangement of current employee job performance is seen as a key factor. A public sector employee success in UAE has many advantages for an organization by having a standardized strategy that allows for a consistent emphasis on programmers, strategic strategies, priorities and results. Additionally, the work output of employees tells workers how they contribute to the organization's success. Employee performance assessment provides organizations – and the different management levels within the company – with details about how well the company performs, whether it has achieved its targets and how consumers are pleased, thus helping the organization enhance what it does (Osman Karatepe, 2012; Mon & Tae, 2015).

Most of all, organizational support; for employee development, such as high equity rates and good working conditions are very critical. When the company's employees are respected and paid, they will be more relaxed and satisfied, and clearly show their loyalty to their organization and perform highly for their employment (Sununta & Patarakhuan, 2016). Despite the fact that organizational respect can be found across a variety of organizational dimensions, the current research focuses mainly on perceived organizational support (POS) for employee effectiveness. This relationship can be logically explained by understanding that POS and its interactions are growth variables that appear for an organizational commitment while employee output is a variable outcome. It is also assumed that the efficiency of organizational processes is likely to influence the performance of employees (Imran et al . , 2018). Taking into account previous research findings indicating important relationships between POS and employee job efficiency, the following study takes a different view as it questions the evaluation of POS' contribution directly to employee work performance.

Literature Review

The effectiveness of an organization, in the end, relies on the quality and productivity of its human resources. Patton concluded that human resource policies should help executives, department heads or supervisors better understand what the human resource team should bring to the successful table. "(2007, p.24) HRM 's role is to turn the company's strategic goals into human resource policies, and to establish human resource activities and strategies that create competitive advantage (Convertino, 2). Organizations have tried to improve their workers' job performance in order to meet high levels of productivity, quality and effectiveness (Awais et al, 2018). Job performance therefore needs to be clearly described and completely understood by the workers who are supposed to perform well at work. Job performance can usually be split into two parts job performance and contextual performance from a more analytical viewpoint (Stacy Ann et al , 2018). Task success refers to the particular roles that are recommended for each work title (Stacy Ann et al, 2018). It includes the activities that help sustain the technological center of an organization or the method of turning inputs into outputs of an organization. In other words, work success includes all actions that are specifically related to primary job functions and, in short, is the abilities of tasks that are officially recognised as part of the job of the employee (Stacy Ann et al, 2018).

The Relationship between POS and Employee's Performance

To contextualize the concept of perceived organizational support and performance of the organisation. Byrne & Hochwarter, (2008) outlines that perceived organizational support is considered a resource that can influence performance positively by reducing stressors and encouraging engagement. Although organizational efficiency is an omnipresent term, management books are defined by Griffins (2006) as the capacity of an organization to acquire and use its limited resources and valuables in the pursuit of its operational goals as quickly as possible. The connection between perceived organizational support and organizational performance was developed based on a recent empirical focused, guided study by Zhang and Tekleab. Some of the research findings revealed: The study reveals that work pressure, work power, and perceived organizational support have a direct effect on in-role performance from the implementation of two theories and the data collected from some 594 employees employed by three companies are based in China. Significantly, two-way and three-way interaction effects show how in-role efficiency is at its best while job control and POS are both high , compared to when one or both is low (Zhang and Tekleab, 2018).

Mohamed and Ali (2015) discussed some of the results from the study conducted among academic and non-academic workers at a Malaysian University in their publication entitled "The Impact of Perceived Organizational Support on Employee Job Efficiency." The inference drawn from the study review is that there was a positive strong relationship between these two variables, since the independent variable POS had a positive effect on the output of dependent variable work. It followed that workers with good views of their employers and perceive their employers as generally caring for their well-being would, that type of attitude would positively affect their job performance. Referring to another earlier piece of study, Isaks' (2002) review of this led to the conclusion that when there is a high degree of

understanding, they would reciprocate to good job results from organizational justice. There are growing empirical studies that have shown a positive relationship between perceived organizational support (POS) and performance of the employees. Conversely, there are other research that have also shown that only a moderate association between support and success has been seen, according to Byrne & Hochwarter, (2008), indicating moderators influence this association. Some of the research 's unexpected findings show that some of the 241 workers surveyed those showing high cynicism personally construe support rates negative. Specifically, performance was best for cynics when perceived support was only at moderate levels.

Conversely, performance was lowest for cynics when perceived support was either high or weak. It detracts from other empirical studies found by researchers including Tansky & Cohen (2001) and opined that they considered organizational support to create organizational engagement among employees. Likewise, Krishnan and Mary (2012) noted that research on perceived organizational support began with the observation that if managers are concerned with the loyalty of their employees to the organization, employees are based on the loyalty of the organization towards them. I claim that perceived organizational support (POS) will enhance the felt responsibility of workers to help their organization / s achieve its goals, their affective contribution to the company and their anticipation that increased performance would be rewarded. From surveying 325 full-time employees at an industrial organization in Iran, Arshadi (2011) also found that POS was positively related to organizational engagement and in-role efficiency, and negatively related to turnover intent. Byrne & Hochwarter, (2008) and Arshaid (2011) note that POS' behavioral findings will include improvements in in-role and extra-role output and decreases in behaviors of tension and withdrawal, such as absenteeism and turnover. Nonetheless, according to Patel and Ankit (2016), irrespective of the clear research findings regarding the positive association between perceived organizational support and organizational efficiency, the relationship between various types of organizational support and pro-active behavior has not yet been investigated.

Enhancing Employee Performance in the UAE Public Sector

The genesis of such a method of performance management derives from a multitude of issues. As for Salem and Jarrar (2009), who observed and noted that the UAE public sector suffered from a reluctance to exchange information and a generally low level of confidence among competing individuals and groups, a condition which is again blamed on the prevailing social and cultural context in Arabia. The viewpoint of Analoui and Al- Madhoun (2016) on a fundamental problem facing managers in the UAE's state bureaucracy and government-related entities (GREs) from a cross-cultural perspective is that Arab managers operate organizations as family units and sometimes take on a paternalistic role within them. They (the managers of Emirates) value loyalty over efficiency.

Al Ghuflio (2012) observed how other emirates implemented the achievement of the Government of Dubai 's system of excellence, triggered similar programs aimed at enhancing employee efficiency in the country. For instance, the Abu Dhabi Award for Excellence in Government Performance came into force in 2007, and the Ajman Excellence Program was introduced in 2008 in the northern emirate of Ajman. Ryan (2018, July 30) points out that, given the good-intentioned nature of the UAE 's attempts to boost employee efficiency through a variety of initiatives, it has not been easy to introduce public sector reform initiatives. This has thus prompted Dubai's Vice President and Ruler to express their frustration with the results of a study showing how low job satisfaction was shown by workers in five departments of government (Ryan 2018, July 30; Al Hammadi, et. al., 2019). Sheik Mohammed said that 'while some satisfaction was as high as 93%, just 60% of workers at five offices said they were happy at their workplace "(Ryan 2018, July 30).

Organizational Commitment

Organizational engagement is not a new Human Resource (HR) Organizational Behavior (OB) concept, and has been at the forefront of individual and organizational success research for many decades. Since this time, much has changed in the way companies treat themselves, including the

emergence of modern ways of workplace relationships and modern contractual contracts (Swailes, 2003, Al wahaibi, 2016). The Organizational Engagement (OC) model was conceptualized in a number of ways. It says "the majority of organizational engagement-related work can be interpreted in terms of attitudinal and behavioral conceptualizations" (Eslami and Gharakhani, 2012, p. 86). Recent theoretical debate was built around Mowday, R.T., Steers, R.M., & Porter, L.W. Morris & Sherman (1981), Morris & Sherman (1981), and Myer and Allen (1997) respectively.

Organizational involvement as observed by Mathieu and Zajac, 1990 cited in Eslami and Gharakhani (2012) has been extensively studied in terms of its elements, antecedents, causes, and implications. Organizational loyalty is considered, according to Roweden (2000), a fundamental element for workers and the organization; it enriches feelings of belonging, career development, job protection, and more intrinsic recompenses. In terms of a thorough reading of publications and literature review on the idea of organizational commitment, Miroshnik (2013, p. 208) defines it as "one of the essential corporate objectives to make." Early definitions of organizational commitment by Mowday, Porter, and Steers (1982) as quoted by Jex, and Britt (2014, p. 269) clarified how "commitment reflects both the feeling"

Factors Affecting Organizational Commitment

Personal characteristics

Age and tenure in previous research organizations found that age and tenure could affect organizational commitment in the three-component engagement; which continuance component has the greatest impact (Suryani, 2018:30). Nifadkar and Dongre (2014) found that age, gender, marital status, and tenure are closely linked to the organizational commitment of girls' college in India; while education level is negatively linked to organizational commitment. Alotaibi (2001) study of public service staff in Kuwait revealed that gender and organizational engagement are closely associated. Opayemi (2004), re-articulated by Eslami and Gharakhani(2012), suggested that there was a substantial relationship between gender and employee organizational involvement in public sector organizations; and that women were more engaged with their organizations than men.

Organizational Climate

From a definitional point of view, James et al. (2008) propose that an organizational climate is the amount of psychological environments which are individuals' acuities regarding their work environment. Mullins (2010) states that an organization's environment is not an easy concept to describe, and is therefore dependent on employee views. And, environment is believed to have a significant effect on the disposition of employees toward their sense of belonging and interpersonal relationships.

Bahrami et al . (2016) indicate that one of the organizational variables that greatly influence employee engagement is organizational environment. Top management therefore has a obligation to consider the organizational environment and its effects to improve organizational engagement among its employees. Managers at various levels should build an atmosphere that is the supportive and acceptable climate for staff members with the view to enhance their willingness to continue with their organization / s and attain the organizational objectives, this is usually considered to be equal normative engagement.

Conclusion

This study covered some of the UAE's public organizations to examine the impact of strategic human resource management on employee attitude and job performance in public organizations across Abu Dhabi. The Abu Dhabi Emirates public organizations are the main players in the Abu Dhabi Emirates government. The justification for this is that they are the engine which is supposed to drive government business and the incompetence of government policies and programs can be traced directly to the actions or inactions of employees working in these Emirates public organizations

Abstract

Perceived organizational support, which is an indication of the employee involvement of the company, creates a responsibility within the employee to care for the organizations and to reciprocate with dedication and loyalty. Here, it would have an effect on job satisfaction and has been widely studied in the literature as many analysts, managers as well as researchers agree that their patterns will affect and influence work efficiency, employee morale and retention of employees. Expatriate employees mostly from South Asia and UAE nationals dominate the labor market of the UAE labor market. It was estimated that nearly 95 percent of private sector companies absorbed the expatriate labor supply in 2012 and that just 5 percent of the Emirates work in the private sector. In this paper the effect of perceived organizational support and work satisfaction in the UAE will be addressed.

Keywords: Perceived organizational support, Organization efficiency, job performance, UAE

Introduction

The United Arab Emirates (UAE) has been one of the fastest-growing and strongest economies within the Gulf Cooperation Council for Arab States (GCC) and worldwide within a very short time span. The UAE is ranked second in GDP within GCC, third in the Middle East and thirty in the world in 2011 (Askary, Kukunuru and Pech, 2014, p. I. The UAE is a contented location with many expectations. Its inhabitants, who account for less than one-fifth of the 8.2 m residents in the country, are among the most pampered worlds. The population typically enjoys cradle-to-grave welfare; lavished by the oil-rich regime, and the value of what has long been the most open and welcoming way of life in the Gulf "(www.economist.com:2011). Thompson (2016) illustrated how the rapid socioeconomic development of the UAE has drawn an enormous influx of transnational companies and diasporic communities into the county; consisting of expatriate labor from Europe, Africa, Asia, the Americas, Australia, New Zealand, Turkey, the Caribbean and the other Arab States. Within a century, Dubai's once dimly populated Sheikdom has become a melting pot of nearly two hundred nationalities and many more ethnic subgroups. Such a multiplicity of nationalities and races / ethnicities makes the UAE "one of the most ethnically diverse nation-states or city-states worldwide" (Global Compact International Yearbook 2009, p. 61).

Literature Review

Perceived Organizational Support

In the theory of organizational support, it suggests, perceived organizational support, which is an indication of the employee engagement of the company, creates a duty within the employee to care for the company and to reciprocate with dedication and loyalty. Activity by organizations showing care and consideration for employees can enhance commitment by organizations (Krishnan and Mary

2012:60). Similarly, Riggle, Edmondson, and Hansen (2009) have argued how meta-analytical findings show that perceived organizational support has had a solid, positive relationship not only on job satisfaction but also on organizational engagement. Similarly, Vandenburge et al. (2007) found that perceived organizational support and various organizational engagement bases were linked and generated different outcomes among certain employees in the fast-food field. Significant research by Rahman and Karan (2012) entitled Perceived Organizational Support and Organizational Commitment: Bangladesh the study findings confirm the pre-estimated study hypotheses. It found that perceived organizational support was strongly and positively associated with organizational commitment along with its three dimensions, but the relationship between POS and continuing commitment is found to be poorer in contrast with the relationships of POS with affective continuance and normative.

Perceived organizational support (POS) and its antecedents

According to Ali and Mohamed (2015:1-2),' in 1986 Eisenberger et al. introduced the idea of perceived organizational support (POS). It has to do with how workers view their organisations. Any behavior and human resource management practices taken by the organization that affect the expectations of employees about the commitment of the organization to them. According to Eisenberger (1986) quoted in Ali and Mohamed (2015, p.1-2), "the idea of POS relates to workers forming global assumptions regarding the degree to which the company respects their efforts and cares about their well-being." Management theorists and organizational scholars such as Jackson et al, (2004) used conceptually interpreted organizational support to define their efforts. A systematic analysis of POS literature uses social exchange theory definition of organizational commitment to explain how the commitment of an employee to an organization is primarily defined by the engagement of the organization toward its employee. Hutchison, Eisenberger, Huntington, & Sowa, (1986) quoted in Miao (2010) stresses how perceived organizational support (POS) denotes the degree to which an organization respects the efforts of its workers and cares for their well-being.

Antecedents of POS

Rhoades and Eisenberger (2002) argued that perceived organizational support is affected by three basic precedents: incentives and working conditions, support from superior justice and procedural justice. Nevertheless, Zhang, Farh, and WangGuangHua Management College, Peking University, Beijing, P.R. China perceived organizational support in China in their research entitled Organizational antecedents of employees: a grounded investigation has observed and expressed how "perceived organizational support (POS) has gained much research attention since it was implemented into organizational behaviour" The research found that perceived organizational support is a major driver of employee engagement, efficiency, and organizational commitment (Zhang, Farh, and Wang 2011, p.1). A gap was found in the literature and Ahmed (2015) noted that it has been a long seven years since any work was conducted on the results and nearly 12 years since any analysis was conducted on the POS antecedents.

Zhang et al., (2011, p.1) Research findings have showed that 'in contrast with similar findings in Western literature, established organizational antecedents of POS in China, the main precedents of POS in China included certain common factors (e.g. administrative justice and supervisory support) as well as cultural-specific factors (e.g. caring for poor workers and caring for the family of employees).

(i) Equity (e.g., procedural justice in performance evaluation, forum for voicing grievances, etc.)
(ii) Support to supervisors (e.g., work-family community, perceived support to supervisors, etc.)
(iii) Benefits and conditions of employment (e.g., job stress, incentives for development, etc.)

Glorigi, Shoss and Di Fabio (2017) explains that specific combinations of antecedents (such as work pressure, job conditions and social support) are is be expected on the basis of the multiple dimensions and distinguished categories ascribed to the studying of perceived organizational support. Ishfaq and

Muhummad (2015) and Kutessis et al. (2015) combine meta-analysis of over 800 studies come to the conclusion that the antecedents of perceived organizational support fall into the following groupings:

- Justice
- Growth potential
- Superior support
- Support from other co-workers
- Human Resources practices and the conditions of the working environs
- The quality of organization-employee relations
- How employees treat each other.

Based on the earlier literature survey, it can be clarified that the main factor-antecedents of POS are under the headings below. Glorigi, Shoss and Di Fabio sum up appropriately in noting that the variety of stressors and strains will need further investigations in order demarcate clearly the combinations of interconnected processes that may arise in the perceived organizational support construct.

Job Satisfaction

The literature has established the antecedents of various organizational commitments. Variables have been established, such as work satisfaction and job satisfaction is one of the important variables (Khan and Zafar, 2014). Samaratunge's scholarly research, (2003); Kanter, (2004); McNulty and Ferlie, (2004); George and Jones, (2008); Mohamadkhani and Nasiri, (2012) and Kahtani, (2012) have made the connection between job satisfaction leads to worker engagement. Employment satisfaction acts as an intervention variable in the relationship between the relationship between the co-workers and organizational engagement (Lin and Lin, 2011).

Gangai & Agrawal (2014) study the correlation between the three constituents of employee commitment along with job satisfaction, the results revealed that there is no significant nexus between these variables, and noted that the construct of job satisfaction, has no bearing on organizational commitment in such case. However, it might be argued that organizational commitment exists among employees at different levels. The findings of this study is similar to a piece of a research by Lok and Crawford (2001) who established that there is a mind-set that prevails and which echoes the notion that employees remain with an organization simply because they need the work and not because they are necessarily satisfied. In addition, Intan, Munir, Hashim, Mat Ali, Baharom Ab Rahman and Ramlee Abdul Rahman (2014) in their cross-sectional survey that looked at the; relationship between Job Satisfaction and Organizational Commitment at Health Tourism Hospital in Malaysia found that diverse facets of job satisfaction have substantial positive relationships with the three dimensions of organizational commitment.

Markovits, Davis, Fay and Dick (2010) investigated the connection between public sector employees and private sector employees among 617 Greek employees in both industries. The findings showed that workers because workers in the public and private sectors face different working conditions and employment relationships are different in their attitudes towards their jobs and organisations, and in their relationships. According to Markovits, Davis, Fay and Dick (2010), the findings further indicate that extrinsic and intrinsic satisfaction is more closely associated with affective and normative involvement for government workers than with those in the private sector.

Job Satisfaction in the UAE

The definition of job satisfaction was widely studied in the literature since, according to Eslami and Gharakhani (2012:86), many experts, managers and researchers believe that their patterns will affect and influence work efficiency, employee morale and retention of employees. In Brazilian and international literature the concept of job satisfaction is considered complex and difficult to define, partly because it is understood as a subjective condition that can differ from person to individual, from situation to situation, for the same individual over the years, and is potentially subject to the impact of the internal and external powers of the immediate work. The term job satisfaction refers to the

disposition and positive feelings about various aspects of their employment, arising from an appraisal of their characteristics, such as the type of work they do, their co-workers, bosses or superiors and their pay (Robbins & Judge, 2013). Job satisfaction "is itself a multi-layered construction and several hypotheses have been suggested to explain job satisfaction definition. Perhaps the most popular are the theories of Maslow (1954) and Herzberg (1966) who, through meeting human needs, introduced the idea of motivation "(Delobelle et al 2011:372).

As it relates to the study of work satisfaction in the United Arab Emirates, there has been increased studies that spread through both the private and public sector. Employees in the UAE are changing jobs more often than the rest of the world. What's behind all of this? Khalife (May 1-2016). This assertion is further supported by Khalife, whose extrapolation from the "Hays GCC 2016 Salary & Jobs Report shows that in 2015, 31 percent of workers working in the UAE switch employers, with 57 percent preparing to do so in 2016 - a far higher rate than the global one (Khalife, 2016). Shallal (2011) ground-breaking research on employment satisfaction among women in the United Arab Emirates and findings across the private and public sectors revealed a strong association between job satisfaction and demographic components such as age, marital status and gender. The findings also show the correlation between work satisfaction and highly educated and high earning power female Emirati women. Study in Askary, Kukunuru and Pech (2014) in which they investigated employee dedication to work as shown by UAE national men and women across three sectors: public, semi-public and private (specifically in the Abu Dhabi and Dubai Emirates). Research results showed a high degree of job satisfaction in the private sector. In comparison, in the public and semi-public sectors, the main disappointment was that respondents thought that there was generally a lack of appreciation for successful work and that they did not have opportunities to participate in dialogue about the success of the company for which they worked.

In another relatively recent survey conducted by Ababneh (2016), in which data from 249 faculty members working at 26 different universities in the UAE on the effects of expectations met, trust, job satisfaction, organizational commitment, and the availability of job opportunities on faculty intent to stay with their current employers. Research results showed that a large percentage of academic workers perceive their employers as not meeting their expectations about a say in strategic decision-making process (58%), study support (53%), involvement in major institutional decisions (53%), and compensation (47%). Results from path analysis show that expectations achieved have direct positive effects on the confidence, organizational commitment and job satisfaction of employees "(Ababneh (2016, p. ii) Drawing on a research study from Bayt.com and YouGov Siraj that examined employee satisfaction, engagement and loyalty in the Middle East. Significant findings indicate that employee satisfaction in the UAE is comparatively poor in the field, with only 27% of employees being extremely satisfied and 34% of respondents being pleased with their jobs (Bayt.com, May 1 2008). Using the case study of Al-Ain Municipality, Al Jenaibi (2010, p.75) research finding that "the main causes of job dissatisfaction are the volume of work, the disorganized work flow and the heavy responsibility suffered by the employees; the work and working conditions themselves represent major dimensions affecting the level of job satisfaction." The obstacles workers face in attaining promotions often minimize work satisfaction (ibid.: 75). This explains to some degree Biygautane & Al-Yahya's statement (2010, p. 2) that '66 percent of government agencies previously surveyed decided to sacrifice core competences when their staff members move to other organisations or departments or move to the private sector.' Ryan (2018, July 30), further explains HR professionals concerned about the pervasiveness of employee discontent.

Research is conducted in UAE, showing a high level of job satisfaction in the private sector (Askary et al, 2014; Al Hammadi et al., 2019). On the other hand, the greatest dissatisfaction was in the public and semi-public sectors where respondents felt that there was generally a lack of recognition for good work and that they did not have opportunities to engage in discussion about the progress of the organization for which they worked and weak support for the process of performance evaluation (Askary et al, 2014). In addition, UAE research showed that workers in the banking sector in UAE are not inspired to boost their performance in the present situation (Indranil Bose, 2018).

In the fields of HRM labor relations and organizational psychology, the effect of perceived organizational support on employee attitude and work satisfaction and performance is a crucial subject (Othman, 2009; Tzafrir, 2006; Lopez, Peon & Ordas, 2005; McGunnigle & Jameson, 2000; Huselid, 1995; Jones & Wright, 1992; Boudreau, 1991). A that workforce calls for the introduction of inclusive work practices that can improve the talents, abilities and expertise of existing and future employees in a company. Such activities also encourage high performance standards and can be extended to all facets of HRM, such as recruitment and selection of staff, training and development, and evaluation and reward for success (Edgar & Geare, 2005; Guest, 2002; Huselid, 1995).

Therefore, good human resource management strategies improve the morale of workers, enhance their engagement and happiness, shrink staff and improve the retention of professional staff, while allowing non-performers to leave the company (Rad & Moraes, 2009; Petrescu & Simmons, 2008; Mosadeghrad et al., 2007; Huselid, 1995; US Department of Labor, 1993; Jones & Wright, 1993; Nonetheless, HRM has not received due attention in Jordan, especially as it concerns institutional engagement, job satisfaction and performance (Menafn, 2008; Ameinfo, 2006; Weir & Abu-Doleh, 1997). Reports and anecdotal evidence from the Ministry of Trade and Trade indicate that HRM departments appear to lack initiative and neglect their duties and activities during a range of Jordanian organisations (Ameinfo, 2006).

As a result, they face major problems closing the human capital event, together with high turnover rates and a lack of delicate workers. Such issues have been exacerbated by the low disbursement on research, coaching and development (Menafn, 2008). Consequently, to advance our understanding of the effect of HRM on the creation and maintenance of employee attitudes and job performance, more empirical evidence and theoretical development are needed. This would also improve our knowledge of the working-value-to-HRM relationship (Falkenburg & Schyns, 2007; Chang & Hung, 2005; Heraty & Morley, 1998; Huselid, 1995).

Conclusion

This paper has presented a review of relevant literature on the evolution of private sector organizations in the UAE, and how theories of management can be applied to some of the challenges they face. Issues include employee satisfaction, organizational engagement and the interaction between perceived organizational support and organizational efficiency.

Abstract

This paper investigates the implementation of strategic management issues in public organizations in the United Arab Emirates (UAE). This is the very first chapter that is organized in a few sections. At the beginning of this study briefly presents the background, importance, followed by identifying the current situation of the implementation of strategic management issues in public organizations in the United Arab Emirates (UAE). The management practitioners, especially those who are engaged with implementation in strategic management, need to be involved in applying the strategies to manage the people management techniques to address the dynamic global market trends with the war for talent and competencies. The knowledge economy is booming up and has become trendy for organizational success factors leading to the competitive success of the organizations. The successful management professionals leverage the existing talent and competencies for future jobs by developing them to take up higher responsibilities with the right competencies for organizational success

Keywords: Strategic management, public organization, UAE

Introduction

Wooldridge *et al.,* (2008, p. 1191) pointed out that middle management is required to observe the organizational process associated with related to building and developing capabilities. Furthermore, Bartlett and Ghoshal (1993, p. 44) confirm the horizontal integrators help to ensure the distribution of knowledge-based resources throughout the organization where managers decide which goals need to achieve and determine in order to accomplish the goals of the organization. Concerning that the middle management should plan to determine the team goals and develop comprehensive strategies to enabling change in culture, development and sustainability of quality teams and solving problems (Harrington and Williams, 2004, p. 302). However, in practice the management overlook and have less attention to middle management during the business process which leads to loopholes or delays in efforts towards organizational development. When the organization act as a social unit, it means that it has several employees who have been given a specific role to carry out a task. They have to cooperate and work with each other in order to complete a task. The event that they need to carry out the duties without close supervision. Therefore, it is important to get involved the middle management in the strategic decision-making process (Floyd and Wooldridge, 1994, p. 49). An organization requires middle management to work in a team in order to achieve the desired goals. If there is no solidarity among employees, the organization is not able to carry out its activities effectively properly. The commitment of middle managers is crucial to implementing good management systems. Here, the middle managers need to monitor the strategic goals that they are pursuing the actual performance (Harrington and Williams, 2004, p. 304). This paper seeks to explore how the implementation of strategic management issues take place in public organizations in the United Arab Emirates (UAE).

Literature Review

The notion of strategic management issues started during the 1980s and 1990s with an emphasis on a proactive, integrative, and value-driven approach (Butler, Ferris, Napier & Schuler, 2008). Here, the focus includes the assets and human resources rather than reactive, prescriptive, or administrative in nature (Budhwar, Buyens and De Vos, 2014). Strategic management issues according to Sim (2007) can be defined as the concepts of strategy which demonstrate that strategic management is a coherent approach to the management of people (Sims, 2007). Meanwhile, strategic planning is a long-term planning process where organizations will determine the mission of the objective to achieve a defined mission. Strategic management exists as a result of the planning that being carried out and it has two main components. The first component is the ' strategic issue management ' itself, which is an extension of strategic planning. The second component is to complement an executive of the nature that is always vigilant and willing to be prepared in any situation inside the organization. Due to today's business challenges and changes in demand, organizations need to formulate and assess various alternatives through the best strategy formulation to achieve the vision, mission and objectives.

On the other hand, there is another side to this phenomenon. Since the pioneering work by Kaplan and Norton (1992) the implementation of the Balanced Scorecard is an initiative that can not only measure organization performance as a whole and balanced it with financial and non-financial elements but also align the management towards the implementation of the same strategy. The same thing also applied in the concept of strategic management issues where an organizational strategy has been espoused and debated in the literature. Here, strategic management issues is an important mechanism for translating strategy into objectives and can be communicated (Bisbe and Malagueno, 2012), facilitating, tightly aligning management actions with strategic goals, and enhancing organizational performance (Bisbe and Malagueno, 2012; Micheli and Manzoni, 2010). The researchers have seen the potential benefits in practice strategic management issues, mostly in private-sector. In the meantime, less research of the related issues being discussed in the public organization which than can be a further explorer in the context of academic research.

The previous study indicates that strategic management issues especially factors related to the success of the implementation need to be further confirmed (Micheli and Manzoni, 2010). They found that, after the primary focussed have been examining, the intention should trigger a good impact on the organization. However, up to now there is no confirmation on examining the relationship between strategic management issues and practical activities in the organization strategy, with the implied assumption that performance improvements can be explained by the implementation of strategic management. Bisbe and Malagueno (2012) expressed that attention should be given to empirical studies with a focus on other roles related to strategic management issues before it can play beyond the implementation of strategies in public organizations.

The public sector in the UAE

The public sector including the typical business firm usually considers tree types of strategies such as corporate, business and functional. Corporate strategy defines the overall direction of the company in term of its attitude to the growth management of its various business and product lines (Wheelen & Hunger, 2013; Gautam, 2015) Business strategy occurs at the business unit or product level and it emphasizes improvement of the competitive position of a corporation’s product or service in the specific industry or market segment served by that business unit (Wheelen & Hunger, 2013, p.23). The organizations are mindful of strategizing their strategic intent with the core-competencies available or to create competencies to face the challenges in the dynamic marketplace. To overcome those challenges, the main reasons need to be revealed to the public organization, which is lacking in terms of the UAE perspective. Definitely, this appears as a real-world problem for them.

On the other hand, according to the Sullivan, (2004, p.86) “The ultimate strategic measure is the profit. It is the ratio between profit and total employee costs. Firms that generate more dollars of profit for every dollar spent on employee costs are the most productive”. It was further described stating “This

Measure more strategic because it includes the ultimate bottom line total profit compared to the total employment cost. Managers and human resource department that are effective at managing their human resource will have the highest ratio, the continual improvement of the ratio gives great credence to the argument that workforce productivity is improving. For some organizations, employee costs are actually quite high (relative to other firms) because they decide to offer higher incentives or hire more qualified people. However, costs are only a side of the picture. If the strategy of investing more in your people in order to get more output works, the additional profit generated by hiring these more expensive or more qualified individuals will far exceed their additional costs.

Besides, the impact of policy formulation and management controls include a wide variety of tools/mechanisms designed to ensure that decisions are executed properly; resources are utilized appropriately and used for effective decision making (Armstrong, 2006; Caliskan, 2010). It has been traditionally considered to be the formal feedback and control systems that monitor organizational outcomes and used to correct deviations from standard performance (Zelewski, 2007; Oladipo and Abdulkadir, 2011). However, in recent times, policy formulation and management control systems have been recognized as important tools supporting organization, organizational learning, and innovation in terms of strategic management (Bisbe and Otley, 2004; Chenhall, 2003; Kumar, 2011; Simons, 1990; Chang and Huang, 2005). This is because the essential idea of policy formulation entails ensuring that an organization achieves its goals (Otley 2003), it is mostly applicable to the government sector in the United Arab Emirates (UAE).

Strategic Management Issues in the UAE

In general, there are many difficulties and challenges for strategic management issues that need to be addressed. But the difficulties and challenges showed a roadmap where a strategy should strive to find the solutions. This paper is tentatively recommending that future strategic management issues should be focused on the following aspects.

Good Theoretical Evaluative Criteria

Theoretically evaluative criteria are the basic strategies by which scholars may be directed to work on it. Here, a good theoretically evaluative system is important for theoretical research (Sutton and Staw, 1995; Corley and Gioia, 2011) in order to reduce uncertainty, just as in mathematics, a formula with clear variables can give a conclusion based on the variable values. Moreover, a good theory should not just be proven by practice, it must also be supported by indirect evidence, such as being verified systematically. This means that if its corollaries are not true, the theory will be rejected.

In the meantime, theoretical research should focus on creating on the clarification and understanding, and should also pay attention to the prediction of the business environment (Bacharach, 1989; Corley and Gioia, 2011). There are two main types of explanation: causality and influential relationship. If an influential relationship cannot be used to predict, then the relationship itself must be questioned. Without explanation and understanding, there is no scientific prediction. A good theory must give a better understanding, under more accurate interpretation and forecasts.

If the theory can only clarify the phenomena, which is no better than competing theory, common sense or simple probability prediction, theoretical research will become an entertainment vehicle. In other words, ff the theory cannot be validated, it is also absurd. Based on the complexity of strategic management issues, researchers can not expect strategic management research in UAE to prepare forecasts in the way that the astronomic theory forecast eclipses, but strategic management research should provide theories that are precise enough to guide practitioners in their strategic management in public organizations. Scientific law refers to the cause and effect between certain phenomena and should always be in force under certain circumstances. Core theory is legal; If no law, the result of the study cannot be called theoretical (Mumba et Al., 2009). The law that explains must be able to predict, and the theoretical research mission should expose the law to know scientific law should be a mission

on strategic management issues in the public organization in the UAE even though it is not widely recognized.

Theoretical Critique and Reflection

Strategic management issues require critical realism to make healthy progress to his undivided epistemology and stressed that reality is free from human concept (Thomsen, 1986; Scott, 1978; Järvensivu and Törnroos, 2010; Miller and Tsang, 2011). The critical realists believe that there are unnoticed events that cause them to be observed; Therefore, the social world can be understood only if people understand the structure that generates an unnoticed event (Thomsen, 1986; Scott, 1978; Järvensivu and Törnroos, 2010). While verifying the possibility of knowing the truth, the critical members admitted that the limitations of a human being debilitating claims to the knowledge or objectives of the Know (Miller and Tsang, 2011). Methodologically, critical research emphasizes the dialogic and dialectic methods. Lincoln and Guba (2000) showed that as a way to go beyond the permission taken to be given (Gephart, 2004). From a critical perspective of realism, strategic management issues can be wrong and need criticism to visualize and prevent potential mistakes (Thomsen, 1986; Scott, 1978). Criticism of weight combination factors, both for and against any statement. Its value lies in making us understand the theory more comprehensive and identify their advantages and disadvantages from the third point of view. In fact, without criticism, theoretical research can not be monitored and alarmed freely and errors and errors in theory research will not be able to be tracked efficiently.

Organizations generally possess a passionate entrepreneurial expectation shared among employees within the organization. They shall be accountable for an increase in production if they utilize a recognized strategic method in organizational activities. Developing missions and values in any organization is important. Defining strategic choices is an additional way to develop a strategy. A doubtful market situation and rivalry influence business owners in deciding the proper strategy. By applying strategies, they can recognize the weaknesses and strengths of the company which assist the owners of the business to formulate other strategies at the same time predicting potential choices for competing with their competitors. Besides, strategy implementation can be defined as a management process of executing necessary activities to achieve what has been planned. This signifies that the strategic management process does not conclude once an organization has decided on a strategy. The setback that confronts most organizations is the change from strategy formulation to strategy implementation. From the perspective of the public sector, the responsibility of top management as strategic decision-makers has a superior impact on executing the strategy and they have power in decision making that influences the entire organizational structure, whereas the successful strategies are dependent on effective implementation.

Conclusion

Fundamentally, strategies in natural systems seem to emerge spontaneously from the interaction between the environment and organisms over time. Whether an individual or a population will be more or less successful to cope with environmental changes is determined by their capability to respond to such changes, or in other words, by their capability of adaptation. Therefore, there is an implicit link between strategy and the need to adapt successfully to new conditions in the surrounding environment.

Abstract

The main objective of the current research is to examine the strategic management issues and the implementation in public sector organizations in UAE. The study involved respondents from several organizations. The profile of the respondents is suggestive of valid responses as well as providing better insights on the strategic management issues. It is found that there is a significant positive impact of the Strategic Management Direction on Implementation of Strategic Management issues. The study results have shown that a one-unit increase in Strategic management direction will increase the expected value of the implementation of strategic management by 0.207. It is found that there is a significant positive impact of Strategic Management planning on the implementation of Strategic Management issues.

Keywords: Strategic management, public organization, UAE

Introduction

Regardless of the importance of policy formulation for business entities, research studies on the impact of policy formulation, implementation and control of strategic management on the public organization are limited (Thill et al., 2014; Ahmad et al, 2009). Implementing the proper strategic management should be evolved from a basic step of any organization, followed by the proper management initiative to become an important technique to support organization, organizational learning, and innovation.

Literature Review

Though policy formulation has always been identified as an important tool in the strategic management context, one observable fact is that the usage of these styles among organizations is very limited; often they are not used to their full potential (Otley, 2003; Ulrich et al., 2013). Furthermore, the control system via strategic management used in organizations is most often restricted to the use of traditional (Abdulkhaleq, 2006). This is also a common phenomenon in the UAE context, as well observed through a research study on management and strategic management practices in quoted in organizations in UAE. However, though policy formulations are important, ineffective and inappropriate strategic management control can encourage dysfunctional activities, which will have a negative influence on organizational performance. Therefore, it is useful to identify which strategic management issues contribute to the growth and improve organizational performance as well as achieve its service objectives. Based on these facts and limiting the scope of the study, the problem statement for this study can be presented as what impact the policy implementation in executing proper strategic management in the public sector in United Arab Emirates (UAE)

On the other hands, many researchers have identified the research gap (Wu, 2013; Heisig, 2014; Perez-Arrau et al., 2014; Thill et al., 2014) in the public organizations where the lack of understanding exists

in implementing of strategic management issues in public organizations (Heisig, 2014; Perez-Arrau et al., 2014). The dearth of research in public organizations in the United Arab Emirates (UAE) is even more rampant. Therefore, potential and useful research is needed to bridge this gap in existing knowledge. As a result, this research will determine the implementation of strategic management issues in public organizations in the United Arab Emirates (UAE).

Methodology

The data from the quantitative questionnaire are summarized in Excel (version 2010) and then analyzed by SPSS 22 (updated 2014). SPSS is the Statistical Package for Social Science. In addition, SPSS software can integrate a series of computer programs providing different ways to produce a wide range of reports, models and graphics together with documentation. In specific, as Dale (2003), Cronbach's alpha can be applied to test reliability, an analysis factor to eliminate non-correlative variables, and multiple regression is efficient in examining given hypotheses, etc.

Results and Discussion

A total of 418 respondents participated in the research. The respondents are classified into four age groups. Of these groups, 22.7 percent of the respondents are of less than 30 years of age. 38.5 percent of the respondents are between 31 to 40 years old. 41 to 50 years of age group is represented by 22.2 percent of respondents. 16.5 percent of the respondents belong to the above 50 years, age group. The age group-wise distribution of respondents shows nearly 20 percent representations of all age groups. However, respondents between 31 and 40 years are of a significantly higher proportion (38.5 %). Among the total respondents more than half (54.1 percent) are working at the middle level. Nearly 25 percent of the respondents are working at the junior level. While 16 percent are working at the senior level, only 5 percent of the respondents are at the supporting staff level.

Testing Hypothesis H1 - There is a significant positive impact of Strategic Management Direction on Implementation of Strategic Management issues.

For the path analysis, at first the impact of Strategic Management Direction on Implementation of Strategic Management issues is examined. The path analysis results indicate that, there is a significant positive impact of Strategic Management Direction on Implementation of Strategic Management issues. The path estimates (β =0.207, t=3.163, p<.001) are indicating that a one-unit increase in SMD will increase the expected value of ISM by 0.207. The hypothesis H1 is accepted.

Testing Hypothesis H2 - There is a significant positive impact of Strategic Management Planning on the Implementation of Strategic Management issues.

For the second path analysis, the impact of Strategic Management planning on the Implementation of Strategic Management issues is examined. The path analysis results indicate that, there is a significant positive impact of Strategic Management planning on the Implementation of Strategic Management issues. The path estimates (β =0.407, t=12.253, p<.001) are indicating that a one-unit increase in SMP will increase the expected value of ISM by 0.407. The hypothesis H2 is accepted.

Testing Hypothesis H3 - There is a significant positive impact of Strategic Management Evaluation on the Implementation of Strategic Management issues.

For the third path analysis, the impact of Strategic Management Evaluation on the Implementation of Strategic Management issues is examined. The path analysis results indicate that there is a significant positive impact of Strategic Management Evaluation on the Implementation of Strategic Management issues. The path estimates (β =0.349, t=5.200, p<.001) are indicating that a one-unit increase in SME will increase the expected value of ISM by 0.349. The hypothesis H3 is accepted.

Testing Hypothesis H4 - There is a significant positive impact of Strategic Management Monitoring on the Implementation of Strategic Management issues.

For the fourth path analysis, the impact of Strategic Management Monitoring on the Implementation of Strategic Management issues is examined. The path analysis results indicate that there is a significant positive impact of Strategic Management Monitoring on the Implementation of Strategic Management issues. The path estimates (β =0.222, t=5.009, p<.001) are indicating that a one-unit increase in SMM will increase the expected value of ISM by 0.222. The hypothesis H4 is accepted.

Testing Hypothesis H5 - Internal and External Environment moderates the relationship between the Strategic management Direction and the Implementation of Strategic Management issues.

Moderation analysis was examined to assess whether IEE moderated the relationship between SMD and ISM. The effect of SMD on ISM was examined in the first step of the regression analysis. In the second step of regression analysis, the IEE variable was added and the non-interaction between SMD and ISM was verified. In the last step the interaction between SMD and IEE was added to the non-interactional regression model in the previous step. These regressions are tested at 5% level of significance. SMD was significantly predicted ISM, β =0.725, t=13.022, p<.001. Hence the first condition was satisfied. The non-interaction effect between SMD on ISM was significantly predicted, β =.201, t = 6.447, p<.001. The second condition was also satisfied. The interaction effect of SMD and IEE significantly predicted ISM, β =0.262, t = 6.497, p<.001. So, the last condition is also verified. Thus, it is indicated that the interaction model explains significantly more variance than the non-interaction model based on an alpha of 0.05. In order to visualize the moderation analysis, IEE was dichotomized into high and Low categories using a median split. The High category indicates all observations of IEE above the median, and the Low category specifies all observations of IEE below the median. From the interaction graph, it is clearly visible that, there is a strong positive interaction effect of IEE between SMD and ISM. As the SMD increases from low to high and due to the corresponding interaction of IEE from low to high, ISM is also showing an increase. The hypothesis H5 is accepted.

Figure 1: Moderating effect

Table 1: Moderation Analysis with ISM Predicted by SMD Moderated by IEE

			Estimate	S.E.	C.R.	P	Label
ISM	<---	SMD	.725	.056	13.022	<.001	Significant
ISM	<---	IEE (Non-Interactional)	.201	.031	6.447	<.001	Significant
ISM	<---	SMD & IEE (Interactional)	.262	.040	6.497	<.001	Significant

Figure 2: Interaction effect

Moderation effect of IEE between SMP and ISM

Testing Hypothesis H_6 - Internal and External Environment moderates the relationship between Strategic management planning and the Implementation of Strategic Management issues

Moderation analysis was examined to assess whether IEE moderated the relationship between SMP and ISM. The effect of SMP on ISM was examined in the first step of the regression analysis. In the second step of regression analysis, the IEE variable was added and the non-interaction between SMP and ISM was verified. In the last step the interaction between SMP and IEE was added to the non-interactional regression model in the previous step. These regressions are tested at 5% level of significance. SMP was significantly predicted ISM, β =0.965, t=16.801, p<.001. Hence the first condition was satisfied. The non-interaction effect between SMP on ISM was significantly predicted, β =.680, t=2.787, p=.005. The second condition was also satisfied. The interaction effect of SMP and IEE significantly predicted ISM, β =0.757, t = 15.174, p<.001. So, the last condition is also verified. Thus, it is indicated that the interaction model explains significantly more variance than the non-interaction model based on an alpha of 0.05. In order to visualize the moderation analysis, IEE was dichotomized into high and Low categories using a median split. The High category indicates all observations of IEE above the median, and the Low category specifies all observations of IEE below the median. The figure shows the regression lines for ISM predicted by SMP for the High and Low categories of IEE. From the interaction graph, it is clearly visible that, there is a strong positive interaction effect of IEE between SMP and ISM. As the SMP increases from low to high and due to

the corresponding interaction of IEE from low to high, ISM is also showing an increase. The hypothesis H6 is accepted.

Figure 3: Moderating Analysis

Table 2: Moderation Analysis with ISM Predicted by SMP Moderated by IEE

			Estimate	S.E.	C.R.	P	Label
ISM	<---	SMP	.965	.057	16.807	<.001	Significant
ISM	<---	IEE (Non interactional)	.680	.244	2.787	.005	Significant
ISM	<---	SMP_IEE (Interactional)	.757	.050	15.174	<.001	Significant

Figure 4: Interaction effect

Moderation effect of IEE between SME and ISM

Testing Hypothesis H_7 - Internal and External Environment moderates the relationship between the Strategic management evaluation and the Implementation of Strategic Management issues.

Moderation analysis was examined to assess whether IEE moderated the relationship between SME and ISM. The effect of SME on ISM was examined in the first step of the regression analysis. In the second step of regression analysis, the IEE variable was added and the non-interaction between SME and ISM was verified. In the last step the interaction between SME and IEE was added to the non-interactional regression model in the previous step. These regressions are tested at a 5 % level of significance. SME was significantly predicted ISM, β =0.389, t=11,851 p<.001.

Hence the first condition was satisfied. The non-interaction effect between SME on ISM was significantly predicted, β =.150, t=3.401, p=<.001. The second condition was also satisfied. The interaction effect of SME and IEE significantly predicted ISM, β =0.504, t = 12.991, p<.001. So, the last condition is also verified. Thus, it is indicated that the interaction model explains significantly more variance than the non-interaction model based on an alpha of 0.05. In order to visualize the moderation analysis, IEE was dichotomized into high and Low categories using a median split. The High category indicates all observations of IEE above the median, and the Low category specifies all observations of IEE below the median. The hypothesis H7 is accepted.

Figure 5: Moderating Analysis

Table 3: Moderation Analysis with ISM Predicted by SME Moderated by IEE

			Estimate	S.E.	C.R.	P	Label
ISM	<---	SME	.389	.033	11.851	p<.001	Significant
ISM	<---	IEE (Non-interactional)	.150	.036	3.401	p<.001	Significant
ISM	<---	SME &IEE (Interactional)	.504	.039	12.991	p<.001	Significant

Figure 6: Interaction effect

Moderation effect of IEE between SMM and ISM

Testing Hypothesis H_8 - Internal and External Environment moderates the relationship between Strategic management monitoring and the Implementation of Strategic Management issues.

Moderation analysis was examined to assess whether IEE moderated the relationship between SMM and ISM. The effect of SMM on ISM was examined in the first step of the regression analysis. In the second step of regression analysis, the IEE variable was added and the non-interaction between SMM and ISM was verified. In the last step the interaction between SMM and IEE was added to the non-interactional regression model in the previous step.

These regressions are tested at 5% level of significance. SMM was significantly predicted ISM, β =.409, t=12.333 p<.001. Hence the first condition was satisfied. The non-interaction effect between SMM on ISM was significantly predicted, β =.433, t=3.401, p=<.001. The second condition was also satisfied. The interaction effect of SMM and IEE significantly predicted ISM, β =0.711, t = 13.438, p<.001. So, the last condition is also verified. Thus, it is indicated that the interaction model explains significantly more variance than the non-interaction model based on an alpha of 0.05. In order to visualize the moderation analysis, IEE was dichotomized into High and Low categories using a median split. The High category indicates all observations of IEE above the median, and the Low category specifies all observations of IEE below the median. Figure shows the regression lines for ISM predicted by SMM for the High and Low categories of IEE. From the interaction graph, it is clearly visible that, there is a strong positive interaction effect of IEE between SMM and ISM. As the SMM increases from low to high and due to the corresponding interaction of IEE from low to high, ISM is also showing an increase. The hypothesis H8 is accepted.

Figure 7: Mediating effect

Table 4: Moderation Analysis Table with ISM Predicted by SMM Moderated by IEE

			Estimate	S.E.	C.R.	P	Label
ISM	<---	SMM	.409	.033	12.333	<.001	Significant
ISM	<---	IEE	.433	.033	12.982	<.001	Significant
ISM	<---	SMM_IEE	.711	.053	13.438	<.001	Significant

Figure 8: Interaction effect

Conclusion

The present study is carried out mainly to examine the implementation of strategic management issues in public organizations in the United Arab Emirates (UAE). Through the study, it is attempted to understand the factors of strategic management issues and the relationship between strategic management issues and organization performance. The study also focused to assess any moderating effect of internal and external environments between strategic management issues and organization performance in the public sector in the UAE. Through the study, the necessary implications are drafted for strategic management issues. To fulfill the study objectives, an exploratory approach was used initially for clear problem formulation and developing the hypotheses. The study covered various government offices and public sector organizations that are accessible in the UAE for collecting the required data.

Abstract

In this article the process of formation of "Head and Shoulders" graphic pattern as well as further quotes movement after the pattern formation is considered. The purpose of the work is to verify the suitability and efficiency of using the Head and Shoulders pattern in order to make medium-term and short-term investment decisions and to forecast the profitability of trading positions. The paper presents the results of formation analysis of the Head and Shoulders pattern both on the market with an upward trend and on the market with a downward trend. The main emphasis was made on price objectives in the formation, as well as the identification of specific features of the pattern that increase the probability of investment decisions. The results of the study provide the data on the most probable average values of such indicators as: the period of pattern formation, the period of achievement of the absolute and relative H&S target, the average value of price movement after the pattern confirmation etc. Furthermore, our findings can be interesting and useful for technical analysts and portfolio managers in the process of stocks price patterns charting and analysis.

Introduction

In recent years, more and more people are getting interested in forecasting the dynamics of asset prices in the medium term. This is caused by the growth of the stock market, which is expressed in the growth of world stock indexes and rising stock prices. Since in such an investment period fundamental analysis gives low rate of return [Twardowski S., Parshikov S., 2012], professional speculators rather use technical analysis methods, particularly visual analysis. Many patterns were described before the 20th century, and statistical testing of these patterns were conducted more than 10 years ago. During this time plenty of new ways to make profit on price fluctuations have appeared. To make forecasting process easier investors created different trading robots and algorithmic trading system using financial and its knowledge. The emergence of high-frequency trading had an impact on trading platforms, and

these two facts could have influenced the formation of price patterns [Volodin S., Kopyrina O. 2015]. In this paper, a study of the Head & Shoulders pattern (H&S) was conducted, based on data for the period of 1994-2019 YY. The results of the research gained additional recommendations for investment and speculative decisions.

Literature Review

The analysis of the Head and Shoulders pattern has been carried out in various scientific works specialized on statistical evaluation of the pattern's suitability [Savin N., Paul A. and Zvingelis, J., 2007; Chang and Osler, 2001; Dawson and Steeley, 2003], as well as studies in evaluating the profitability of using this pattern in various markets [Chang and Osler, 2001; Park and Irwin, 2007]. An important feature of these studies is the estimation base.

Chang and Osler evaluated the pattern on charts of 6 different currency pairs [Chang and Osler, 2001], Dawson and James analyzed shares listed on the London Stock Exchange [Dawson, Edward&Steeley J., 2003], and Andrew Lo conducted the research based on American companies' stocks [Lo A., Mamaysky H. and Wang J., 2000]. These studies were mostly conducted to simulate mathematical patterns of identification of the Head and shoulders pattern [Weller, Paul A. and Friesen, Geoffrey C. and Dunham, Lee M., 2007], while such formations may be incorrectly identified during a chaotic market analysis by analytical systems. The point is that many patterns are set without taking into account other parameters that a professional trader should keep in mind, moreover there are always some specific factors and market parameters which can hardly be effectively integrated in analytical systems and are difficult to consider in one complex analytical approach [Nyangarika A., Mikhaylov A. and Richter U. 2019a; Nyangarika A., Mikhaylov A. and Richter U. 2019b; An J., Dorofeev M. 2019; An J, Dorofeev M. and Zhu S., 2020; Nyangarika A., Mikhaylov A. and Tang B-J 2018; Dorofeyev M., Kosov M., Ponkratov V., Masterov A., Karaev A. and Vasyunina M. 2018; Nyangarika A., Mikhaylov A. and Tang B-J 2018; An J., Mikhaylov A. and Sokolinskaya N. 2019a; An J., Mikhaylov A. and Sokolinskaya N. 2019; Mikhaylov A. 2018a; Mikhaylov A. 2018b; An J., Mikhaylov A. and Moiseev N. 2019; Mikhaylov A., Sokolinskaya N. and Lopatin E., 2019; An J., Mikhaylov A. and Sokolinskaya N., 2019; Mikhaylov A., 2019; Meynkhard A. 2020; Denisova V., Mikhaylov A. and Lopatin E., 2019].

The treatises on technical analysis [Schwager J., 2018; Edwards R., Magee J., Bassetti W., 2007; Pring M. 2002] reveal the idea of when such patterns can be formed and for what reasons they are formed. Thomas Bulkowski in his research also revealed behavioral reasons for pattern formation [Bulkovsky. T. 2003], John Murphy argued that H&S top patterns should appear only after strong growth and at the top of medium-term upward motion [Murphy J., 1986]. Mathematical trading systems cannot take into account such factors and the identification process generate high quantity of false patterns. To reduce the influence of this factor, identification process has to take into account special filters. That is why we decided to analyze the pattern using technics of visual analysis, according to the supplemented principles, which were outlined by Schwager, Murphy, Pring and the others. Indirect factors, which could have influenced the formation of the pattern also were taken into account.

Concept Headings

Head and shoulders (H&S) - the price pattern represented by 3 ascending peaks, the second of which is higher than the others. The second peak is called "head" and the first and the third tops are called "shoulders" and the line joining their bottoms is called Neckline.When the price closes below the Neckline, H&S pattern supposed to be completed and the probability of changing the upward trend to a downward one becomes extremely high. The process of violating the Neckline on the downside is called breakout. Retracement move – price movement after the breakout, usually back to the neckline. After the retracement move, price continues downward trend.

If price closes above the right shoulder level during a day or a week, the pattern is false and most likely the price movement will go in an upward trend. The pattern height is used to determine the absolute target value of price movement. To measure the relative target, the percentage change from the pattern's head to the neck level is estimated and the change is postponed until the neck breaks down. Relative targets trigger more often and faster than absolute targets in this pattern. For an inverted H&S pattern, all rules work the same way, only in reverse.

It was decided to take shares of the American S&P 500 index as a sample set. This index was taken as the most representative one, which is explained by the high liquidity of shares in this basket.

We identified H&S patterns that have occurred since 1994 to 2019. For identifying the patterns, we used logarithmic scales with weekly timeframe. The data provided only closing, opening, maximums and minimums for each week. A weekly timeframe has been chosen, because this time period performs smoothing price changes and represents behavior of market players on medium-term time period.

To determine the main indicators, we measured the following points: start date of formation; pattern breakdown date; head level; breakdown level; 3% level; absolute target; relative target; dates when absolute and relative targets were reached.

In addition to these measurements, we analyzed basic pattern characteristics, such as: type of pattern (top, bottom) type of pattern (top, horizontal, top-down), whether the pattern H&S triggered or not. 3% breakdown level and horizontal level were used as parameters increasing the probability of pattern triggering.

A pattern is confirmed when at least one of the delayed targets, relative or absolute, H&S been reached. Only when prices close at the level which is above the right shoulder amount the pattern can be considered as failed one. This requirement of H&S has been introduced with the purpose to reduce false triggers of pattern cancellation.

On the basis of the data received average statistics and it’s median level for the following group of indicators were formed: pattern formation period; pattern width; number of touches of horizontal level; absolute target achievement period; relative target achievement period; average annual return on relative target; average annual return on absolute target. For comparison of profitableness of each possible transaction, we calculated annual profitableness for absolute and relative targets. The returns have been calculated for working patterns.

To confirm the suitability of the pattern, we used the relative performance criterion, which reflects the ratio of working patterns to non-working ones. If the number of triggered patterns is less than the number of failed patterns, then the relative performance of the pattern is less than 1 and this pattern is not applicable for use in investment and speculative activities.

Discussion

After analyzing the available data on S&P 500 stock quotes, we identified 156 formations that corresponded to the top Head and Shoulders and Head and Shoulders bottom technical analysis patterns. The study found 109 top H&S and 47 H&S bottom patterns. The number of false formations for each pattern was 39 and 5 patterns, respectively. This indicates a lower probability of causing false H&S bottom patterns than for the top H&S patterns, which can significantly increase the profitability of a trading strategy based on the identification of these formations.

Patterns considered at a higher time interval show greater returns than patterns found in other studies [Chang K. and Osler C., 2001; Scott I. & Cheol-Ho P., 2007; Lucke, B., 2003]. Indirect factors increase

the accuracy of forecasting and allows you to get a greater return on investment. Currently, the use of the Head and Shoulders pattern is a reliable tool for forecasting price movements in the medium trading period. Using the data obtained during the study of the pattern formation period, the investor can predict the moment of the pattern breakdown in order to open positions in advance.

Results

To achieve the expected results of the research, first of all, its main parameters were determined. Then, on the basis of in-depth analysis, the average and median values of the indicators were obtained. In the course of the research, 156 patterns were identified, including 109 patterns of the top Head and Shoulders and 48 patterns of the Head and Shoulders bottom. The number of patterns that worked was 112. Totally 44 false patterns, of which 39 are top H&S and 5 H&S bottom patterns.

Table 1: Pattern formation period

Distribution of the formation period, units				
	H&S top	Percentage of the sample	H&S bottom	Percentage of the sample
From 180 to 365 days	37	33.94%	32	68.09%
From 365 to 730 days	49	44.95%	10	21.28%
More than 730 days	23	21.10%	5	10.64%

Our own calculations based on the Research. ICE data base

Mostly all top H&S patterns were formed within 1 to 2 years (about 45% of all patterns), while patterns with the formation period longer than 2 years were twice as rare (21% of all patterns). In the group H&S bottom pattern the objectives with the formation period of less than one year prevailed (68% of observations), while the patterns with the formation period of more than 2 years were extremely rare (10.6% of the subgroup patterns). At the same time, the study results showed that the average period of formation of top H&S is 563 days or 1.54 years. At the same time, 50% of all patterns of top H&S were formed in less than 462 days (1.26 years). As for the H&S bottom pattern, the average formation period of the pattern was 453 days (1.24 years), and 50% of all patterns were formed in less than 315 days (0.86 years). The key calculations are presented in table 1.

Table 2: Analysis of reaching pricing targets and annual return on transactions

Characteristics	H&S top	H&S bottom
Average period for reaching the absolute targets, days	177.12	404.55
Median period for reaching the absolute targets, days	154	304.5
Average period for reaching the relative targets, days	146.91	413.16
Median period for reaching the relative targets, days	91	308

Our own calculations based on the Research. ICE data base

The results of the study showed that the top H&S patterns do not always achieve their absolute targets. Absolute targets for the top H&S pattern are achieved on average within 177 days (0.48 years), and for the H&S bottom pattern within 404 days (1.1 years). At the same time, the relative target for the top H&S pattern is achieved in an average of 147 days (0.4 years), and for the H&S bottom pattern, this target is reached in a period of 413 days (1.13 years). The key calculations are presented in table 2.

From a practical point of view, it is necessary to consider the profitability of opening a trade, based on the recognition of the pattern, to determine the moments for opening and closing trade position. Annual returns on trade position are calculated with assumption that the opening of the trading position occurs at the time of pattern confirmation, and closing at the time of reaching the target, the annual returns on transactions were calculated.

Using the top H&S pattern to open a short position, market participants on average could get 270.9% annual return on invested capital for an absolute target and 273.8% for a relative target. This result will be significantly lower in real trading, because our research did not take into account the cost of servicing a short sale, which requires additional collateral and interest payments. Opening a position on the H&S bottom pattern brought an average of 42.45% per annum for the absolute target and 39.26% for the relative one. Average price movement after the breakout (is lower than the top Head and Shoulders pattern because it takes more time to reached targets. H&S bottom pattern proved to be a tool for long-term investment, since most often prices did not return to the points of this pattern after the breakdown of targets.

This study confirmed the applicability of the patterns, since the ratio of working patterns to (false patterns is greater than 1 (the relative effectiveness of 2.54). In particular, the H&S bottom pattern proved to be more reliable than the H&S top (relative performance of 8.4 versus 1.79 for the top H&S). The key calculations are presented in table 3.

Table 3: Analysis of annual return on patterns

Characteristics	H&S top	H&S bottom
Average annual return on an absolute target	270.98%	42.45%
Median annual return on an absolute target	144.92%	35.80%
Average annual return on the relative target	273.86%	39.26%
Median annual return on the relative target	167.28%	35.86%

Our own calculations based on the Research. ICE data base

The study allowed us to deduce the key features of the formation and recommendations for using the pattern, which can be used in the course of making investment decisions on the stock market.

1. To open or close a position, there is a need to wait until the pattern is confirmed. This approach helps to reduce the probability of loss, especially when the trade relates to the opening of short positions.
2. Depending on the aggressiveness of the market participant's investment policy, we recommend setting the price levels of position cancellation at a level above 3% of the breakout point for less aggressive investors and at the right shoulder level for more aggressive investors. The level of the right shoulder as an indicator of cancellation makes it possible to increase the expectation of a correct forecast, as it provides a margin for the quote rate.
3. Patterns usually reach relative targets, since they are closer to the moment of opening a position.
4. Given the low profitability of using the H&S bottom pattern compared to the top H&S pattern, the use of this pattern can be targeted at making long-term investment decisions.
5. Using the data obtained during the study of the pattern formation period, the investor can predict the most convenient moment of the pattern breakdown in order to open positions in advance. This approach can be used for high-risk speculation.

Abstract

This work discuss the concept of use of an eye tracker in the role of a sensor of human gaze in a social robot. The prior motivation is to establish a solid base for development of joint attention competency in a robot. The concept is presented against the background of related solutions. The discussion is conducted from two perspectives: Human-Robot Interactions (HRI) and User Experience (UX).

Keywords: eye-tracker, shared attention, UX study, social robot.

Introduction

In recent years we have seen a significant development of robotic technology aimed at cooperation and assistance to humans. Brief study of the contents of (Siciliano and Khatib 2016) emphasizes an enormous progress in intelligent vehicles, medical, rehabilitation, surgery, health care assistive and social robots. The new robots aren't just doing the job of a human being. They cooperate directly with him/her, accompany him/her, extend his/her independence.

Social robots stand out from other robots with their ability to communicate naturally with humans and with good adaptation to the human social environment (Fong et al. 2003), (Breazeal et al. 2016). The role of multimodal communication in social robots is comprehensively discussed in (Breazeal et al. 2008) and (Breazeal et al. 2016). The authors of the aforementioned works identify a number of factors that are essential in this context, in particular they stress the importance of shared attention. If a robot is capable to identify the current attentional focus of a human then progress in the conversation is more efficient while errors and misunderstandings are immediately identified and corrected. The ability of the robot to share attention with a human facilitates communication in cooperation. In particular, it helps to establish a common ground with others (Breazeal et al. 2008).

The role of joint attention and gaze detection in social robotics is studied in a numerous other works such as: (Huang 2010). Much of them is related to autism, see e.g. (Scassellati et al. 2012), (Xu et al. 2016). The above works can be complemented by activities of the recently completed or ongoing international projects: DE-ENIGMA, DREAM, SARACEN, BabyRobot. Identification of the human attention focus often is based on the human gaze detection and analysis, (Zaraki et al. 2014), Classic RGB cameras are commonly

applied sensors for the gaze detection (Droeschel et al. 2011). Some works reports application of more sophisticated sensors such as eye-tracker, (Courgeon et al. 2014) The use of an eye-tracker for gaze detection seems to be a good idea although the original purpose of these devices is completely different. In recent years, there has been a clear development of them with a simultaneous drop in price. A brief overview and analysis of eye-trackers is done e.g. in (Hume 2016). The one of most common used robotic research platform in HRI research is NAO. It has been used in various HRI studies, (Arent et. al. 2017), in particular in research on autism therapy. In these studies NAO plays a role of a mediator who stimulates a child to engage him/herself in gradually more complex interactions with the robot (Scassellati et al. 2012). Usually such studies are partially based on the WoZ method due to limitations of the sensory system of NAO. The build-in sensors are insufficient for understanding paralinguistic regulatory cues by NAO in the course of communication with a human. However NAO has proven to be very flexible in terms of expansion capabilities.

We believe that under certain circumstances an eye-tracker integrated with a robot might be a valuable source of information for the robot concerning the human attention focus. It could deliver a feedback allowing the robot to adapt its goals and activities to the current perception of a human. In consequence the quality of interactions between a human and a robot could be improved and in turn the user experience (UX) could be gained. This issue is the subject of considerations of this article.

UX can be defined as users' judgment of a product arising from their experience of interaction and qualities of the product, which engender the effective use of the product and user's pleasure (Sutclie 2009). UX evaluation methods for robotic systems with shared attention capability is not obvious. Here we employ and refer to the ideas included in the following works: (Holmqvist et al. 2011), (Lazar 2017), (Chynał et al. 2016), (Chynał & Sobecki, 2016).

Gaze Tracking and Attention Sharing in Human-Robot Interactions

Attention sharing is considered to be the one of crucial elements that are necessary for proper, smooth and meaningful multi-modal communication of a human and a robot (Fong et al. 2003), (Breazeal et al. 2008), which is the distinctive feature of a social robot among other robots. Precursors of a multimodal communication are already present in the first humanoid robots WABOT and WABOT-2. It is a central issue for Embodied Conversational Agents (e.g. Greta). Nowadays, all of the shelf robots designed for Human-Robot Interactions (e.g. NAO, Pepper) as well as new robots developed within the frame of scientific projects (BabyRobot, DREAM, DE-ENIGMA) possess advanced communication capabilities in the context of natural conversation. Despite the high workload, this is still an active research area including sensing, data processing and acting.

A natural conversation involves exchange of verbal and non-verbal information between two or more parties (Fong et al. 2003). This issue is discussed in more detail in (Breazeal et al. 2008). In particular, the non-verbal information, provided by para-linguistic cues, supplement the linguistic information. The para-linguistic cues are expressed by facial expressions, gestures, prosody, etc.. Because the sound has strong property of attracting attention the auditory cues can be used for interruption. But they are not suitable for continuous use. Contrary, visual para-linguistic cues are silent and therefore they can be used continuously. Breazeal et al. 2008 classify the roles of para-linguistic cues into three categories: regulators, state displays, illustrators. The regulators are used in particular to smooth and synchronize the exchange of speaking turns. The state display cues are used to display the conversational or cognitive state. For example, the listener can feedback information to the speaker confirming keeping up the conversation or confusion and loss of the conversation thread. A special display cue is a gaze direction. It can be a silent cue to provide the attentional focus, either to the speaker or to the listener. This is very useful when the speaker is trying to point out a particular object as the attention sharing point. The illustrator cues are used to persuade the

listener to perform joint attention. They involve gaze, head pose, pointing gestures and conversational speech.

Multimodal communication between a human and a social robot requires that they conduct a dialogue as peers who know each other (Fong et al. 2003). In consequence a social robot should be able to read and understand all the linguistic and paralinguistic cues that are used by a human and simultaneously the robot should be able to use the same cues for conveying information to the human.

Due to the current state of the technology, capabilities of robots with respect to reading and displaying various linguistic/para-linguistic cues are diverse. Focus attention recognition on the basis of gaze direction detection by a robot seems to be one of most challenging. This and related problems have attracted a considerable attention in the literature.

In (Xu et al. 2016) the authors focus on gazing at each other face in a course of a human-robot interaction. They try to answer the question *at what moments and in what ways the robot should look at human user's face as a response to the human's gaze behavior*. To this end they developed an experimental system based on NAO robot and ASL head mounted eye-tracker (Applied Science Laboratories, LLC). The idea of the real-time control system was to detect the human-attention based on real-time eye tracking (Holmqvist et al. 2011), and then to generate gaze-contingent responsive behaviors. One of the findings was that the participants demonstrated more coordinated and synchronized multimodal behaviors between speech and gaze when more eye contact was successfully established and maintained. A related research with use of eye-tracking and virtual humans is reported in (Courgeon et al. 2014). The work (Zaraki et al. 2014) presents a context-dependent social gaze control system designed and implemented as a part of a social robot. The gaze-control system employs MS Kinect skeleton tracking together with speech and facial expression recognition. To evaluate the system performance, the authors used a DIKABLIS eye tracking system for measuring and analysis of the participants gaze. The results of the evaluation have shown that the systems replicated human gaze behaviour 89% of the time.

Gaze tracking and shared attention are of particular interest in autism research, (Scassellati et al. 2012), including robot-based interventions for autism spectrum disorders. The work is carried out in many dimensions. For example, in (Cao et al. 2019) the authors compare gaze of children with ASD against gaze of typically developed children towards a robot NAO and a human. For this purpose they use Tobii X3-120 eye-tracker system. One of the results was that both groups of children showed more interests in the robot's face, but the robot induced a lower proportion of fixation time on the target. The work (Esteban et al. 2017) concerned to a supervised autonomous system for robot-enhanced therapy for children with ASD. The core elements of the sensing part of the proposed system are: gaze estimation, human action recognition, facial expression recognition, object tracking and audio processing. It's not difficult to see some similarities here with (Zaraki et al. 2014). The hardware base for the sensory system are three RGB cameras and two MS Kinect sensors. This system was integrated with one of two robotic platforms: NAO (commercially available) or Probo (experimental).

The considerations to date allow to conclude that gaze tracking is meaningful for social robotics. This applies for development of new socially interactive robotic systems capable of highly believable human-robot interactions. Whats more, gaze tracking is essential for further research on attention sharing and related problems in multimodal human-robot interactions.

Selected Technological Aspects Concerning Gaze Tracking in Human-Robot Interactive Systems

With reference to the previous section we are interested in an interactive system consisting of a human and a robot that is supposed to evolve within a predefined scenario where gaze tracking or attention sharing matters. As an example, we can consider an interactive play of the child and the NAO robot, e.g. a child's imitation of a dance performed by NAO (Arent et. al. 2019). Notice, that if the robot is able to monitor the attention focus of a child during the play then it can adapt its behavior to the current subject of interest of a child. In particular, it will be able to wait with the play until the child returns to this play. From the UX perspective the usability of the system with a robot aware of the human focus of attention should be higher in compare to the case of a system with a robot that is unaware of the human focus of attention.

NAO is perhaps the most popular robot used in experimental studies on human-robot interactions, especially when they are addressed to children. It is also used as a therapeutic aid. This is an autonomous, programmable humanoid robot developed by Aldebaran Robotics. Its sensory abilities deserve special attention. The set of hardware sensors include two cameras, one facing forward and the other at a downward angle. Besides, there are four microphones mounted on top of the head. The virtual sensors based on these hardware allow for human posture recognition, face recognition, human tracking by specific body parts, detection of sound direction, simple speech recognition. The hardware parameters are insufficient for gaze tracking, emotions recognition or human actions prediction. Nevertheless, the software architecture allows for integration of external sensors with NAO as well as performing selected computational tasks on external hardware units. The flexibility of NAO in this aspect is widely exploited, e.g. in (Esteban et al. 2017), (Xu et al. 2016). The SDK associated to NAO is very extensive and well documented. It can be used directly in C++ or Python code or indirectly e.g. by means of a NAO robot stack in ROS. The latter is particularly important because ROS has become a standard in robotics. Many sensors used in robotics (MS Kinect, Intel RealSense, RGB cameras) have dedicated nodes in ROS that facilitates integration of these devices with NAO. This applies to selected eye-trackers (e.g. Tobii Pro Glasses 2, Pupil Labs) although they cannot be considered as regular robotic sensors. Thus, NAO is open for specification and implementation of an advanced communication system with numerous external sensors, including selected eye-trackers.

An eye-tracker guarantees the best gaze tracking among currently available sensors. Therefore it is justified to develop experimental testbeds for HRI study by integrating an eye-tracker with an interactive robot (e.g. NAO). However, eye-trackers have also significant drawbacks. They are very expensive, sensitive for damage and allow for limited mobility only. A survey and comparative analysis of various eye trackers can be found e.g. in (Hume 2016). Eye-trackers can be considered as a sensors where the hardware is split into sensory and computational unit. The computational unit can be a regular computer (PC, laptop, mobile phone, etc) while the form of the sensory unit differs depending whether the eye-tracker is stationary or mobile. In the last case the sensory unit has the form of a spectacle frame to which three cameras are attached. One of them (a scene camera) is a forward-facing camera that captures the scene. The next two cameras (eye cameras) focus on the one or both eyes. They record reflections of an infrared non collimated light directed from the source mounted on the frame towards the pupil. The recordings are processed in the computational unit to derive various forms eye movements, in particular saccades and fixations (Holmqvist et al. 2011). Eye-in-head angles are derived in the World Coordinate Frame which is being established during calibration. The human head movements are registered and taken into account in eye-in-head coordinates derivation thanks to inertial unit mounted in the frame. It is also possible to obtain coordinates from other predefined coordinate systems.

Integration of an eye-tracker with a NAO robot faces the designer and programmer with specific problems that are discussed in (Labarussiat 2017). It is a case study but some conclusions give useful intuitions that are not limited for the considered case. The author have used an eye tracking system manufactured by the company SensoMotoric Instruments (SMI): SMI Eye-Tracking Glasses (ETG).

The hardware base consists of SMI ETG Source (a sensory unit) and a SmartRecorder (a mobile phone) or a laptop (a computational unit). The associated software consists of two applications: iViewETG and BeGaze. iViewETG is designed for conducting and management of an experiment (calibration, data processing and storage). BeGaze is intended for analysis of the data acquired in the course of an experiment. The last software is not essential in the considered context. iViewNG SDK is a software that is essential. It includes a RemoteViewer Tutorial that allows among other development of a program for continuous monitoring whether the gaze is within the predefined Area Of Interest (AOI) or not. Note that if the AOI is associated to NAO we can have at dispose current information whether the person involved in the interaction with NAO focuses on this robot or not. Noteworthy is that it is the ETG SMI computational unit that returns the boolean type information (the gaze within AOI/outside of AOI) that is needed to be broadcasted to NAO. This is a low size information that can be easily send via computer network without overloading it. The interprocess communication using sockets is practically the only solution here because the SMI software is written under Windows 7 OS and MS Visual Studio 2008 compiler. NAO runs under Linux Gentoo and NAOqi - a dedicated robot operating system. Technically such a communication can be solved in many ways. One of them is to develop a ROS node that will communicate with the modified RemoteViewer application running at the ETG SMI computational unit. At the same time this ROS node could publish the received information to a ROS topic that is available for the ROS interface to NAO. Labarussiat (2017) in this case study shows that two technically complex devices: SMI Eye-Tracking Glasses and a NAO robot, developed independently, for different purposes, at different times, based on different technology can be integrated in one system that is potentially useful for studies concerning attention sharing in human-robot interactions. The idea such system is illustrated in Figure 1. To the best knowledge of the authors similar integration of NAO with newer mobile eye-trackers is possible and potentially easier. For example, all the software developed for the Pupil Labs is Open Source and available for Linux.

UX Analysis of a Robotic System Possessing Human Gaze Tracking Capability

In the previous two sections the authors discussed the need and feasibility of developing of robot based systems possessing capability of human gaze tracking. It has been shown that there is considerable amount of research related to such systems reported in the literature devoted to HRI. The considered systems are also interesting for UX research but to the best knowledge of the authors much less studies

in this area has been carried out. Therefore in this section the authors survey and discuss open problems, potential methods and available tools that might be useful of such studies.

Adjustment of the selected social robot applications with application of visual focus of attention

The authors are planning to implement a scenario of human-robot interactions, in which robot's decisions on actions will depend on selected human behavior linked with intentions and/or attention concentration. The scenario will be stationary or will have a restricted realization area, and will be based on the NAO robot (or a similar robot). This scenario will involve a population of children in a preschool age as partners of interactions with the robot. The scenario will refer to known scenarios from a literature such as playing a board game or educational – revalidation games like recognition of body parts or dance in common. The research goal of this task is to determine whether and to what extent it is possible, given the available contemporary technology ground, to elaborate:

- effective monitoring of attention concentration of the user (a child) playing the educational – revalidation game with the robot,
- improvement of concentration duration of the user playing an interactive game task, that is characterized by a short-term attention span,
- incorporation of behaviors into the social robot platform that attract a user attention for a longer periods of time (and in consequence improving usability of a robot as an teacher assistant).

The research goal is to determine whether and to what extent it is possible on the ground of available technology to elaborate:

- effective monitoring of user's attention concentration on selected elements of the environment,
- usability enhancement of a guide robot by incorporating into the robotic platform such behaviors as re-attracting attention of a guided person, adaptation of own position to the current location of human and recognition of his/her interest.

Comparative UX studies of HRI systems concerning the application of visual focus of attention

The general principles for conducting human-robot interaction studies focused on objective observation of user behavior will be developed. These principles will be defined based on the UX methods currently used in the HCI domain, and then will be adapted for our HRI system requirements accordingly. For example, in the analysis of the usability of mobile systems, the research uses observation of behavior of a single user with application of a special stand with an eye tracker or a specialized glasses system (Holmqvist et al. 2011) that enable eye tracking analysis during user's free movements during the use of the verified application. In this case the ready-made procedures and rules for usability evaluation can be used for our HRI system.

The new procedures and principles dedicated to the study of HRI systems are planned to be developed. To measure users' behavior eye tracking devices and other devices will be used that allow to register ongoing psychophysical activity of users, including recognition of their sensations with devices such as: EEG recorder (Falkowska et al. 2016) and (Chynał et al. 2016), thermal imaging camera (Chynał & Sobecki, 2016), heart rate monitor or devices for measuring galvanic skin reaction, as well as FaceReader's software developed by Noldus. The proposed methods and principles will be verified in the experimental manner. The experimental verification procedure will be using comparisons of UX measurements of users'

interactions with the robotic system that have implemented mechanisms of shared attention and the robotic system with no such mechanism. The experiments will consider two scenarios. The first considering teaching of children and the second museum guide for adults. Additionally, as part of the proposed procedure deliberated will be detection introduced disturbances in the researched implementations of human-robot interaction. Depending on the interaction scenarios, intentionally introduced disturbances will include violation of the optimal distance of the robot from the user, frequency and length an "eye contact", sharing of the attention point, etc.

Conclusions

The main contribution of the paper is a proposition and preliminary verification of application of eye tracking to human-robot joint attention control. The paper also discusses motivation, technological aspects and UX perspective to robotic systems, which applies gaze tracking techniques to enable sharing attention. Sharing attention between a human and a social robot is nowadays active but still maturing research field. At the moment there are no off the shelf robots that are ready to support such research without any expansion. Authors have shown that gaze tracking expansion of the robotic system is feasible although it requires to overcome a number of specific technological problems. Finally, it has been shown that it is justified to study robot based systems possessing capability of human gaze tracking from the UX perspective. In particular, it is possible to indicate specific methods and tools that can be used here, however they also should be adjusted to the HRI requirements and sharing attention particularities.

Abstract

The main purposes of the paper are: the identification of internal and external factors prompting Japanese investors to locate their capital outside of Japan and an assessment of the investment attractiveness of selected European countries, taking into account the relationship existing between the size of the inflow of the Japanese investments to individual countries and factors that may affect this investment attractiveness of the locations. To study the relation between these two areas, econometric models were applied. The results of the adopted research procedure confirmed that even in the case of Japanese investors who usually locate their capital in the most development European countries; there are visible differences between the assessment of the attractiveness potential of these countries and the real value of Japanese investments. Because of that, according to authors, the more advance research procedure to predict the further Japanese investments in Europe should be applied.

Keywords: Japanese Investments, Attractiveness Of Location, Econometric Models, Annuity

Introduction

Increased mobility of foreign direct investment (FDI) has been observed on global markets for many years. It is the effect i.e. of progressive financial globalization and related to it an increased activity of international corporations. These changes hamper the interpretation of data on international financial flows and also affect the quality of forecasts regarding changes in both the value and directions of FDI flow. It is important because these investments are defined in the literature (Sohinger, 2005; Balcerzak and Zurek, 2011; Pietrzak and Lapinska, 2015) as one of the most important forms of capital flow between countries and a stimulus enabling faster economic development. According to Xu and Wang (2007), foreign direct investment is an important factor stimulating the economic growth of host countries due to the export growth, the number of jobs and economic recovery on a local scale. The negative consequences of these investments are also known, which may cause in the host countries: job losses in local plants, depletion of natural resources and degradation of the natural environment. The advantage of benefits over the possible negative effects of foreign direct investment can certainly be seen in the case of Japanese investments, which, apart from considerable technological advancement, are also characterized by a large ability to attract subcontractors and even competitors to the location of capital allocation from that country (Witkowski and Baraniecka eds., 2018). The Japanese culture of business management also includes striving to create close relationships with the environment of the organization, e. g. by acquiring knowledge from clients or cooperators, which is treated as one of the most important elements of the growth strategy of these organizations (Ahmadjian and Lincoln, 2000; Nonaka and Takeuchi, 2000). These companies most often create close relationships with the environment. According to the Japanese management system, the main goal of business operations is to provide customers with the value they expect while using the resources at their disposal as little as possible. The basis of this system is also continuous improvement introduced at all even the lowest levels of the organization. This improvement covers both the cost and functional sphere of the

organization's activities and applies to products and implemented processes, including production lines, warehouses and places of contact with a client and their main effect is to organize and standardize in principle all activities undertaken in organizations (Cheba, 2018). All these elements make Japanese investments perceived as attractive from the point of view of the host countries. It is worth noting, however, that in this case their influx is influenced by both specific internal conditions including i.e.: different culture, social and economic norms and historical past, as well as external conditions perceived from the perspective of the attractiveness of a given investment location from the point of view of Japanese investors. In the literature, a lot of space has so far been devoted to the analysis of internal conditions for the development of Japan as one of the most important investors on global markets. The directions of Japanese investment flow are also known; in Europe these are usually highly developed countries with a stable socio-economic situation (Witkowski, 1998; Ahearne et al., 2002; Cieslik and Ryan, 2005; Somlev and Hoshino, 2005; Fletcher and vin Staden, 2013; Anderson et al. 2014). On the other hand, issues related to the identification of factors attracting Japanese investment to individual European countries are raised less frequently. Such analyzes are usually carried out at a fairly high level of generality; it is checked, e. g. whether geographical proximity has an impact on attracting Japanese investors to particular geographical regions of the world (Asian countries and regions of Europe), (Zhou et al., 2005; Cassidy et al., 2006), opinions are also commonly quoted confirming the high attractiveness of United Kingdom as a location for Japanese investments. However, according to the authors of this study, there is a need for a more comprehensive approach to this issue and attempts to identify factors affecting the perception of attractive location by Japanese investors.

Therefore, the main purposes of the paper can be considered in two ways. The first one concerns the identification of internal and external factors prompting Japanese investors to locate investments outside of Japan. The second one concerns the assessment of the investment attractiveness of selected European countries, taking into account the relationship between the size of the inflow of this type of investment to individual countries in Europe and factors that may affect the investment attractiveness of the locations most often chosen by Japanese investors.

The paper is divided into 5 sections. The first presents the aim of the research and important elements that make up the background for further discussion. Next, there is a review of the literature on the essence and complexity of identification the internal and external factors influencing on expansion of Japanese FDI in the world. The third section is dedicated to the research method. The fourth section contains the research results, and the fifth is devoted to conclusions.

An Identification of Internal and External Factors Influencing on Expansion of Japanese FDI in the World

In economic practice one can frequently come across questions about the reasons for such and not another volume of Japanese investments in different parts of the world (Cieslik and Ryan, 2005; Buckleya et al., 2013). The answer to the question should be sought in the analysis of different determinants existing both in Japan (internal factors), as well as in the target country of an investment (external factors) (Witkowski et al., 2017). In the case of internal factors to the most significant determinants influencing the economic relations of Japan with other countries of the world one should include (Ahearne et al., 2002; data of Statistics Bureau of Japan):

a) the problem of deflation – in November 2019 Japan's consumer price inflation rose to 0.5 percent year-on-year; inflation rate in Japan averaged 2.95 percent from 1958 until 2019, reaching an all-time high of 24.90 percent in February of 1974 and a record low of -2.50 percent in October of 2009.
b) low unemployment rate, standing in Japan around 2.2% (as of November 2019) is one of the lowest in the world.
c) gradual withdrawal of investment funds from Japanese market which might indicate that the market is becoming less attractive for investors,
d) gradual increase of employment in services and fall in production, which in the case of Japanese economy which significantly relies on export is a negative phenomenon (it is more difficult to export services),

e) increase in investments on the part of large Japanese companies in foreign markets causing a decline in orders for small and middle companies in the country, which have been contractors for big companies.

Although Japan's economy is recognized as the third economy in the world in terms of global value of GDP (after the US and China, according to International Monetary Fund in 2019) for over 20 years it has been in a state of economic stagnation. The main reasons for this stagnation are problems associated with an aging population, low rate of fertility of women or mistakes in macroeconomic policy (Bayoumi, 1999; Fletcher and vin Staden, 2013). The decade of the 90s are called the Lost Decade in Japanese economy and the following 10 years, which also have not brought any improvement as the Second Lost Decade (Goodfriend, 2001). There are many reasons for economic stagnation, which has lasted in Japan for over 20 years, from wrong macroeconomic decisions up to demographic environment (Takatoshi and Mishkin, 2006). The experience of recent financial crisis and the following recession changed the perspective of perceiving Japan solely through the prism of errors in macroeconomic policy (such as wrong decisions of Japanese Central Bank and the lack of sufficient coordination of fiscal and monetary policy). Specific environment: geographic, political, cultural, economic and social has made Japan one of the biggest investors in the world for many years. These events coincided with demographical changes connected with aging of the society and as a consequence of a long-term fall of the growth rate *per capita* as a result of for example shortening the time of work, worsening the quality of work or as mentioned hereinbefore, lowering the tax revenue. The economic model dominating in Japan based on mainly export supported by the government and the banks fitting better less developed countries worsened the unfavorable situation. The model did not allow obtaining the same effects in the case of developed countries such as Japan, mainly due to limited possibilities of increasing export along with the increase in economy (Cooper, 2014). A collection of external factors which can also have impact on location decisions considered from investors perspective may include many determinants, such as (Dunning, 2006; Saviotti and Pyka, 2008; Coy and Cormican, 2014):

a) resource sufficiency indicators,
b) general economic development indicators (e.g. market size and growth, GDP *per capita* or GDP growth),
c) structural changes indicators and indicators of changes in efficiency of use and development of production factors, also informing on the freedom of movement of such factors in a given country e.g.: openness, which are positively related to inward FDI, distance and infrastructure (physical and cultural), this is a determinants which encourages FDI, its goal are to attract FDI, corporate tax rates, this is an indicator which have a negative influence on inward FDI, labor market flexibility, the indicator which is seen as a key determinant for attracting FDI,
d) engagement in international trade, pointed out also as the gauge of international competitive position of a given country.

In the case of Japanese investors, this list should also include factors describing the competitive potential of the target investment locations. Although the necessity to seek new markets with lower production costs is shown among the main reasons for taking up foreign business activity by Japan after 2000, Japanese investors as places for their investments in Europe choose primarily high developed countries with stable socio-economic situation. The main reason is the search for locations that will provide Japanese investors with access to highly qualified employees, and access to consumers interested in high-quality, technologically advanced products. (Somlev and Hoshino, 2005; Yoshimatsu and Ziltener, 2010; Witkowski and Cheba, 2016). According to Driffield et al. (2013) the main motivation of Japanese FDI is also to maintain access to the European market through sales networks and by adding production facilities for some manufacturing industries and a range of services subsidiaries, especially in the banking, finance and insurance industries. Currently, the countries with the biggest amount of Japanese investments in Europe are: United Kingdom (163 498 million USD in 2018) and the Netherlands (132 756 million USD) (JETRO data). However, in the last decade Japanese firms are in the process of reconfiguring their U.K. presence. In the last years the number of Japanese firms in the U.K. has declined considerably. In the remaining countries of Europe the volume and the number of Japanese investments is much smaller. In the Eastern Europe it is possible to discuss Japanese investments in the case of Poland and the Czech Republic, in the Southern Europe in the case

of Italy and Spain, and in the Northern Europe, apart from United Kingdom only in the case of Denmark, Ireland and Sweden. Table 1 contains the information about total outward FDI invested by Japanese investors in selected EU countries (International Investment position) in 2008-2018.

Table 1: Japanese total outward FDI by country (investment position) in 2008-2018 in million USD

Research Method

Scope of the study

In the work of Guzik (2008) it was proposed that investment attractiveness should be considered not only from the point of view of the potential of a given location, but also as an effect of the relationship between this potential and measurable effects in the form of the size of investment. Factors describing the location potential may be perceived differently by investors. In the case of higher technological commitment of planned investments, investors will rather look for places where they will be provided with an access to highly qualified employees, university graduates with a specific profile. On the other hand, the expectations of investors seeking middle and lower-level employees for whom a higher unemployment rate will be an attractive factor will be different. However, the literature is dominated by the view that the higher potential of a given location is synonymous with higher investment attractiveness. According to the authors of this study, this approach to studying the factors determining investment attractiveness does not fully exhaust the research problem posed in the work and investment attractiveness, as a complex phenomenon it should be considered from the perspective of the relationship between the potential and the achieved effects.

Research Material

The adopted research assumption required the preparation of two data sets. First of them included the results of competitiveness of national economies published annually by the World Economic Forum (WEF) in the reports: “The Global Competitiveness Index" (GCI). In the paper the results of this study were applied to describe the potential of selected economies to compete on the world markets. In the second one, the information published by Japan External Trade Organization (JETRO) on the annual value of Japanese foreign direct investment in 2008-2018 in European countries was collected. In the paper this data represents the achieved effects of investments attractiveness. The analyzes were conducted in 3-year cycles, it was assumed that the average value of Japanese FDI in European countries for example in 2008-2010 could be related to the level of competitiveness of the host country of those investments.

Econometric modelling of Japanese FDI

The econometric models (regression models) were used to study the investment attractiveness of European countries considered from the perspective of Japanese investors. These models allow to

compare the potential of given country and the obtained results in term of investment attractiveness. The size of Japanese FDI per 100,000 inhabitants can be described as a function of the development of 12 pillars describing the competitiveness of these countries:

a) basic requirements subindex: F1 – institution, F2 – infrastructure, F3 – macroeconomic environment,
b) efficiency enhancers subindex: F4 – health and primary education, F5 – higher education and training, F6 – goods market efficiency, F7 – labor market efficiency, F8 – financial market development, F9 – technological readiness, F10 – market size,
c) innovation and sophistication factors subindex: F11 – business sophistication, F12 – innovation.

The research to date (Cheba, 2018), shows that the so-called basic requirements are the least decisive for the investment attractiveness of a given location for Japanese investors. As already mentioned, in Europe these investments are located in highly developed countries with a stable socio-economic situation. In connection with the above, the first three indicators of basic nature were excluded from further analyzes. Econometric models were estimated taking into account indicators describing the higher level of development of countries (subindices: 2-3). Japanese FDI changes over time have been analyzed considering each country separately. For these purpose the following normative models were estimated:

a) linear model (L): $Y_{ti}=w_1F_{4ti} + w_2F_{5ti} + \ldots + w_8F_{12ti}$,
b) exponential model (W): $Y_{ti}= exp\ (w_1F_{4ti} + w_2F_{5ti} + \ldots + w_8F_{12ti})$,
c) power model (P): $Y_{ti}= F_{4ti}^{w1} * F_{5ti}^{w2} * \ldots * F_{12ti}^{w8}$,

where: $F_{4ti}, \ldots, F_{12ti}$ – the values obtained in each pillar of competitiveness according to the WEF methodology in *t*-year for *i*-th country and $w_1, \ldots, w_8$ – regression coefficient.
The rests of this model estimated for each country are differences between the actual values of Japanese FDI in the selected EU countries and the model values calculated on the basis of estimated models. Positive residuals indicate that, for example, the current investment value is higher than the normative value and the surveyed EU country is more attractive to Japanese investors than it can be estimated according to model and vice versa. To estimate these differences between the values calculated based on models and actual values of Japanese FDI in the reporting economy, the RAI meter can be calculated in the following way (Guzik, 2008):

$$RAI_{ocountry} = \frac{e_{country}}{\bar{Y}}, \quad (1)$$

where: $\bar{Y}$ – mean value of Japanese FDI per 100,000 inhabitants, $e_{country}$ - the residuals of the normative model, the difference between the empirical value and the value from the model.

Study Results

Table 2 presents the research results obtained on the basis of estimated reference models presenting the relationship between the size of Japanese foreign direct investment and measures describing the competitiveness (in the paper it is treated as a synonym of investment attractiveness) of the selected European countries. The criterion for choosing the models was the level of matching to real data measured by the coefficient of determination R^2. Only the explanatory variables that are significant are included in the presented model. Models were estimated using step-wise regression.

Table 2: Reference models for selected EU countries

Country	Estimated model	R^2	S_e	V_{Se} [%]
Netherlands	$\hat{y}_t = -844.82 + 346.47x_{5t} + 229.76x_{7t} + 144.02x_{9t} - 460.097x_{11t}$ $(-0.56)\quad(11.16)\quad(2.98)\quad(1.56)\quad(-1.67)$	0.9858	15.70	2.72
United Kingdom	$\hat{y}_t = -2700.45 + 692.45x_{11t} - 188.54x_{12t}$ $(-6.27)\quad(4.81)\quad(-2.03)$	0.8857	23.93	19.89
France	$\hat{y}_t = -132.80 + 15.76x_{7t} + 12.73x_{8t} + 5.78x_{12t}$ $(-2.60)\quad(3.01)\quad(3.36)\quad(1.30)$	0.7454	1.52	6.25
Belgium	$\hat{y}_t = -1149.21 + 88.43x_{5t} + 40.39x_{7t} - 26.76x_{8t} + 140.18x$ $(-4.43)\quad(4.07)\quad(10.77)\quad(-2.24)\quad(2.96)$	0.9931	3.18	2.05
Germany	$\hat{y}_t = -103.65 + 17.96x_{7t} + 8.05x_{9t}$ $(-9.02)\quad(4.21)\quad(3.69)$	0.9668	0.99	4.26
Luxembourg	$\hat{y}_t = -2479.13 + 1498.86x_{5t} + 1796.55x_{6t} - 2152.47x_{8t} - 2693.39x_{9t} + 2561.62x_{10t} + 1531.13x_{12t}$ $(-0.64)\quad(5.48)\quad(7.90)\quad(-6.70)\quad(-6.42)\quad(-6.70)\quad(4.03)$	0.9937	34.27	1.93

Italy	$\hat{y}_t = -0.0065 + 0.007x_{5t} - 0.005x_{8t}$ $(-0.44)\quad(3.21)\quad(-3.68)$	0.9677	0.0001	7.21

Source: own calculation

For all the analyzed countries it was possible to estimate models characterized by a high degree of matching with empirical data. The R^2 determination coefficient for 6 out of 9 analyzed countries was above 0.96. It should be noted that in all cases, linear models were characterized by the highest matching to the actual volume of FDI investment inflow to a given country. In the case of countries such as the Netherlands, the United Kingdom, France, Belgium and Luxembourg, the estimated models include variables that are used to describe the last subindex (innovation and sophistication factors subindex).

It should be noted, however, that in the case of the Netherlands, an increase in the value of F11 – business sophistication, assuming unchanged values of other factors included in the model can cause an average decrease in the FDI value. The same situation applies to another factor describing this subindex: F12 – innovation, in the case of the United Kingdom (while the F11 factor has been positive for this country). The opposite situation was observed in models describing the development of Japanese investments in France and Belgium. Japanese investments in these countries are much smaller and it may mean that the improvement in innovation and business sophistication will have a positive impact on the growth of Japanese investments in these countries. It is also worth taking a closer look at the model estimated for Spain. In this case, the increase in the value of factors: F5 - higher education and training, F8 - financial market development, F9 - technological readiness should cause a decrease in the value of Japanese investments in this country. In this case, a profound analysis of specifics of Japanese investment in this country should be carried out.

In the situation of less technologically advanced production, negative values of coefficients standing next to variables describing the potential of a country in terms of e.g. education and access to less qualified employees is natural. Similar results were also obtained in previous papers published in the literature (Guzik, 2008). Investment attractiveness does not always have to be positively correlated with the level of socio-economic development and the increase in the value of measures in the area of labor resources will not always be treated as attractive from the point of view of foreign investors, as it may also mean an

increase in labor costs (e.g. related to higher salary expectations). The results obtained on the basis of estimated models can be interpreted in a similar way; an increase in the area of higher education (F5) may also mean a decrease in investment attractiveness caused by an increase in expectations regarding remuneration, and it may also mean a decrease in the resources of employees performing work requiring vocational education.

It should be also pointed out that the models were estimated based on the normalized values of synthetic measures, which are usually quite strongly correlated with each other. The study showed that due to the strong correlation of variables used for the construction of synthetic measures in the GCI ranking, only some of them can be used in further analyzes (Cheba and Szopik-Depczynska, 2017). This problem is particularly important for econometric modeling. Hence the step regression, which allows eliminating variables that are too strongly correlated with each other, has been proposed.

In the following, Table 3 presents the values of the investment attractiveness ratio relative to the average value of Japanese foreign direct investment. Positive RAI values apply to countries in which Japanese FDI is greater than the values estimated on the basis of the reference model. These countries obtain so-called attractiveness annuity, while in the case of negative values it is called disability annuity.

Table 3: The RAI value for selected EU countries

Country	RAI (%)								
	2008-2010	2009-2011	2010-2012	2011-2013	2012-2014	2013-2015	2014-2016	2015-2017	2016-2018
Nether-lands	-0.09	-0.26	-2.61	1.08	-0.83	4.29	-0.58	-1.42	0.42

Source: JETRO data

Positive RAI values (attractiveness annuity) for the last 3 years has been obtained in the case of the Netherlands, the United Kingdom, Belgium, Luxembourg and Sweden. The highest positive value has been obtained in the case of the United Kingdom. The RAI indicator at this level means that the value of Japanese investments in this country is definitely higher than it could result from the estimated model. The attractiveness rate constituted 24.46% of the average Japanese direct foreign investment in this country. These results also confirm the observations of other authors, according to which in the case of this country the overall investment attractiveness perceived by Japanese investors is also influenced by factors other than those, included in the WEF rankings. Most often it is indicated that this is conditioned by tradition and historical factors. Japan has been investing its capital in United Kingdom for many years. This situation has not been changed by the decision to leave the European Union. However, the largest negative difference (-4.90%) between real Japanese FDI and investments resulting from the reference model relative to the average size of Japanese FDI in the last three analyzed years concerned Italy. In this country, the actual volume of Japanese FDI was smaller than the amount of investment that should occur in it, taking into account the level of competitive ability of the country's economy estimated by WEF.

Conclusions

In order to estimate the investment attractiveness of selected European countries from the perspective of Japanese investors the method proposed by Guzik (2008) and Cheba (2018) was used. When considering the investment attractiveness from the perspective of foreign investments one should also take into account certain characteristic regularities regarding these investments. Japanese investors often choose the countries designated as the most competitive with a stable socio-economic situation (e.g. in Europe it is United Kingdom and the Netherlands and the United States in the world) as well as culturally-close or dynamically developing countries (e.g. China). This theoretically means that you can look at the investment attractiveness of a given country also from the perspective of its competitive ability.

In this work, the results of the competitiveness ranking published annually by WEF were used, which were compared with information on Japanese FDI in the analyzed European countries. Although the competitiveness of the economy is one of the factors considered by Japanese investors in making investment decisions, the comparison of competitiveness results with the actual inflow of Japanese FDI to a given country completely changes the results of the WEF ranking.

This procedure allows the estimation of the so-called attractiveness or disability annuity, i.e. the difference, respectively: "in plus" or "in minus" between real Japanese FDI and investments resulting from the estimated reference model relative to the average size of Japanese FDI in the analyzed European countries. Therefore, it is a kind of two-stage procedure for testing investment attractiveness carried out from the perspective of foreign investors, considered in the work in relation to Japanese investments in the examined European countries.

Análisis Crítico Del Discurso En El Derecho Del Consumidor Desde La Constitución, La Jurisprudencia De Indecopi Y Del Tribunal Constitucional Del Perú

Critical Analysis on The Speech of Consumer's Rights From The Constitution, Indecopi Jurisprudence and Constitutional Court In Peru

Hugo GONZÁLEZ

Universidad Autónoma del Perú, Lima, Perú

hugo_augencio@hotmail.com

Resumen

El presente artículo tiene como finalidad estudiar la relación entre el consumidor, el proveedor y el Estado. A pesar de que existen los mecanismos legales para proteger los derechos del consumidor, no obstante, este se ve afectado en dos aspectos: el tiempo que dura el proceso para resolver su caso y el pago reducido de costas y costos por el procedimiento. Por tanto, existe una asimetría de poder entre el proveedor y el consumidor como se aprecia en la jurisprudencia analizada del Indecopi y del Tribunal Constitucional peruano.

Palabras clave: Análisis crítico, derecho del consumidor, jurisprudencia, asimetría.

Summary

The present article has the aim to study the relationships among the consumers, suppliers and the state. Despite there are lawful mechanisms to protect the consumer's rights; nevertheless, they are affected in two aspects: time that takes the process to solve the case, and the reduced payment for the costs due to procedure. Therefore, there is a power symmetry between supplier and consumer just like you can appreciate in the jurisprudence analyzed from Indecopi and Peruvian Constitutional Court.

Keywords: Critical Analysis, Consumer's Rights, Jurisprudence, Symmetry.

Introducción

Se han analizado los criterios constitucionales que protegen los derechos del consumidor, desde los derechos fundamentales, el cual implica que debe recibir información veraz y oportuna sobre los productos o servicios que adquiere y por tanto debe existir una relación de simetría entre proveedor y consumidor; en la parte legal sí se mantiene ello, pero no en los casos reales, porque el proceso para resolver algún reclamo demora y además porque las costas o costos a favor del consumidor no cubren lo invertido por este.

En este sentido se requiere un análisis de la normativa, la jurisprudencia y la realidad que se refleja a través de cómo han resuelto las autoridades de Indecopi y del Tribunal Constitucional, en muchos casos a favor del consumidor, pero con algunas afectaciones sobre la compensación económica o el pago de costos o costas del procedimiento que verdaderamente no cubren los gastos realizados por el usuario o consumidor.

El presente estudio se enmarca dentro de la teoría crítica del discurso, en la que se demuestra una asimetría entre el consumidor y el proveedor, entre el Estado y el consumidor. El mayor poder se

concentra en el Estado quien decide a través de las resoluciones que emite. El poder también está en el proveedor quien no realiza el pago justo de las costas o costos; más bien el consumidor se ve afectado por la inversión económica y por el tiempo de espera.

El presente estudio es solo un estado inicial y una aproximación al problema del poder de quienes administran justicia, de los proveedores en afectación al consumidor, que se puede verificar en los mismos casos que se han resuelto; en tal sentido se debe ampliar el estudio a mayores casos y separarlos por áreas o especialidades.

Antecedentes Y Fundamentación

Diversos estudios enfatizan sobre la afectación de los derechos del consumidor, específicamente después del contrato que se da ciertos incumplimientos que se derivan de la buena fe (Isler, 2019); otras afectaciones están relacionadas con la falta de claridad de la información que contiene la publicidad (Fernández, 2019); también sobre la responsabilidad por el incumplimiento del contrato sobre el peso de la prueba y por la imputación de los daños que puede recaer en el acreedor o el consumidor (Erbetta, 2018); otros sobre el consumidor inmobiliario (caso colombiano) que tiene un marco legal para proteger sus derechos en el caso de que se vean vulnerados los derechos del consumidor que a veces es la parte más débil (Villalba, 2017; Momberg, 2015).

De los antecedentes también se puede identificar que el poder lo tiene el proveedor o acreedor; sin embargo, otras posturas establecen que el Estado ha creado ciertas normas que impidan esta asimetría y operen en equilibrio (Alvear, 2016); es pertinente precisar que quienes tienen mayor poder económico, también tienen mayor control (Van Dijk, 2016) como es el caso de los acreedores o empresarios.

El derecho a los consumidores y usuarios protege sus intereses, en base a la recepción de una información veraz sobre los bienes y servicios que se van a adquirir (Landa, 2017). La veracidad y la idoneidad son la columna vertebral del derecho del consumidor (Villalba, 2017).

El contenido fundamental del derecho al consumidor comprende: acceso libre al mercado de bienes y servicios, recibir información idónea, recibir trato igualitario para acceder a los servicios públicos de calidad, derecho a formar asociaciones que defiendan sus derechos, derecho a recibir diversas ofertas, derecho a la protección de su salud, derecho a reclamar sobre los productos o servicios deficientes, acceso a los solucionar sus controversias de manera oportuna, derecho a la protección judicial en caso se vean afectados sus intereses (Landa, 2017).

Por otro lado, el Tribunal Constitucional (Exp. nro. 3315-2004-AA) ha establecido los siguientes principios: proconsumidor donde prevalece el rol protector del Estado frente a desventajas o asimetrías; proscripción del abuso del derecho que protege contra toda práctica contractual adversa y afecte el interés del consumidor o usuario; isonomía real que implica un tratamiento igual ante la ley; *restitutio in íntegrum,* el cual implica que el Estado promueva o asegure el resarcimiento por daños o perjuicios en favor del consumidor; transparencia para asegurar el acceso a la información de los productos o servicios; veracidad que comprende el conocimiento veraz sobre la calidad o propiedad de los productos o servicios; *indubio proconsumidor*, el cual implica que las autoridades interpreten las normas en favor del usuario o consumidor; y proasociativo, el cual permite que los consumidores o usuarios puedan fundar sus asociaciones para defender sus intereses.

Por tanto, el derecho al consumidor y usuario debe asegurar la protección contra riesgos que afecten su salud, proteger sus intereses económicos y sociales, recibir indemnización por daños y perjuicios, recibir información correcta (Casanovas, 2016), a fin de evitar el abuso del poder de las mismas autoridades que tienen el control legal o de los empresarios o proveedores que tienen mayor poder económico.

El aspecto normativo se desarrolla dentro de un contexto social, donde existe poder de ciertos grupos que conocen y utilizan las normas, y son capaces de controlar los actos y las mentes porque tienen acceso a la información, estatus (Van Dijk, 2016). En este contexto los ciudadanos en conflicto se ven afectados por tensiones, y sus expectativas o intereses no se ven satisfechas (Vargas, 2013).

Método

El tipo de estudio es cualitativo, basado en la interpretación documental de contenido desde el análisis crítico del discurso. No tiene propósitos de generalizar por tratarse de un estudio cualitativo, sino solo evidenciar la afectación del consumidor. Se ha tomado en cuenta la norma constitucional peruana, cierta jurisprudencia, de los últimos años, de Indecopi y del Tribunal Constitucional, donde se evidencia efectivamente la afectación del consumidor quien tiene menos poder frente a los empresarios o proveedores y del Estado.

La búsqueda de la jurisprudencia se realizó a través de la página web de Indecopi y del Tribunal Constitucional con los términos clave: consumidor, cotos, costas.

Análisis De Resultados Y Discusión

La Constitución Política del Perú, en su artículo 65 referente al consumidor, establece:

El Estado defiende el interés de los consumidores y usuarios. Para tal efecto garantiza el derecho a la información sobre los bienes y servicios que se encuentran a su disposición en el mercado. Asimismo, vela, en particular, por la salud y la seguridad de la población (art. 65).

Del artículo citado, se establece dos aspectos fundamentales: primero: garantizar el derecho a la información sobre los bienes y servicios que se ofertan en el mercado, centrados en la veracidad e idoneidad. Segundo: velar por la salud y la seguridad de la población, el cual comprende que los productos o servicios que reciba el consumidor no deben afectar a su salud o bienestar. El problema está en el incumplimiento de esta por algunos operadores de justicia quienes tienen el poder de aplicar la ley.

De Indecopi se han seleccionado algunas resoluciones del Tribunal, donde se puede evidenciar que el pago de costos o costas que se le ordena al empresario o proveedor a favor del consumidor es muy bajo, teniendo en cuenta que ha realizado un gasto en el proceso administrativo que ha seguido ante Indecopi. Por ejemplo, tenemos el caso de la Resolución 0039-2019/SPC-INDECOPI (2019, p. 6), en la que resuelven a favor del consumidor sobre un problema con una financiera a la cual le sancionan con un pago de:

costas y costos del procedimiento […] que a la fecha ascienden a S/ 36,00; sin perjuicio de ello y, de considerarlo pertinente, una vez que se ponga fin a la instancia administrativa, el denunciante podrá solicitar el reembolso de los montos adicionales en que hubiese incurrido para la tramitación del presente procedimiento para lo cual deberá presentar una solicitud de liquidación de costas y costos.

De este caso se colige que el consumidor se ve afectado por el tiempo de duración del proceso y por el gasto económico realizado, y que los costos o costas establecidos por Indecopi son irrisorios (S/ 36,00), teniendo en cuenta que el proceso se inició en mayo del 2014 y finalizó en enero de 2019. Este proceso lento y agónico vulnera los principios de celeridad, razonabilidad y eficacia. También se verifica que las faltas del empresario o proveedor están en la carencia de idoneidad (art. 18 del Código del Consumidor), es decir que este no ha cumplido con hacer llegar una información veraz sobre el servicio o producto que ha proporcionado al consumidor.

De esta manera se configura el control del poder legal del Estado, que en apariencia resuelve a favor del consumidor, pero no se consolida plenamente por el monto irrisorio que establece en el pago de las costas y costos del procedimiento y otros gastos que implican este proceso.

Del Tribunal Constitucional se han seleccionado, las resoluciones que han sido publicados en su página web, a través de las palabras clave: consumidor, costas, costos. Se obtuvo 22 resoluciones. Se han seleccionado algunas donde se evidencia la afectación de los derechos del consumidor o usuario. Algunos procesos tienen más de cinco años de antigüedad, lo cual implica que el consumidor se ve afectado por todo el proceso que ha durado para resolverse.

En el Exp. nro. 03310-2015-P1-1D/TC, el Tribunal Constitucional (2019) declara fundado y ordena pago de costos procesales. Se trata de un caso donde se deniega la información de los usuarios sobre información de su padre fallecido. Se genera una asimetría ya que la entidad o AFP sí tiene la información completa y termina negándole a los usuarios, generando no solo la pérdida de tiempo, sino también la inversión que se genera en dicho proceso, aparte de los costos procesales a que alude el TC.

En otro caso, sobre la resolución del Tribunal Constitucional (2019), en el Exp. nro. 05077-2014-PA/TC, se evidencia que la agraviada se ha visto afectada porque no ha cumplido con todo el procedimiento; sin embargo, los magistrados que han declarado improcedente, en sus argumentos, alegan que efectivamente ha existido una afectación a su derecho fundamental sobre dignidad, calidad de vida; no obstante han resuelto declarar nulo todo lo actuado, lo cual implica un mayor alargamiento del proceso y la afectación de la consumidora sobre el acceso a un servicio básico. Solo un magistrado ha actuado de manera pertinente basándose en la Corte Interamericana quien establece que el Estado está obligado a hacer valer sus derechos y defender sus intereses del justiciable de manera efectiva, que en este caso es urgente por tratarse de un servicio básico: acceso a la energía eléctrica; y para que no sea más agonizante la petición de la consumidora o usuaria, se le debe escuchar previamente a las partes y que luego se admita a trámite la demanda, criterio pertinente el cual impide que la usuaria siga sin perjudicar su calidad de vida.

Con ello se demuestra, que quienes asumen la judicatura del Estado, amparados en el formalismo legal, no atienden una necesidad real que requiere ser tratado o resuelto con urgencia, además por tratarse de un derecho fundamental. Con esto se confirma que el poder no solo está en el proveedor, sino que se ve reforzado muchas veces por la actuación de la judicatura.

También se establece el poder de la mayoría de los magistrados, quienes con su decisión terminan afectando un derecho fundamental que requiere ser tratado con celeridad. El hecho de declarar nulo todo lo actuado, implica empezar el proceso de cero, generando pérdidas económicas y afectación a la salud por una prolongada espera, teniendo en cuenta que el proceso se inició en agosto del 2013 y terminó resolviéndose en el Tribunal en junio de 2019.

Otros acciones o inacciones que afectan a los consumidores se dan por la falta de la aplicación de la ley que protege al consumidor, por ejemplo, en el art. 51 establece que el Indecopi, previo acuerdo de su Directorio, puede impulsar acciones judiciales en favor del consumidor o usuario; no obstante, esto no se ve reflejado en las resoluciones de este organismo, más bien a fines del 2019 emitió una directiva (002-2019/DIR-COD-IDECOPI) donde Indecopi debe ejercer atribuciones para realizar acciones judiciales.

Otra limitación legal que existe es que Indecopi no está facultado para realizar acciones que permitan el resarcimiento de daños y perjuicios. Aunque sí es relevante, la inclusión de la resolución de conflictos vía el arbitraje de consumo que sí permite solucionar en forma rápida y sencilla las controversias entre los proveedores y consumidores. En este caso la resolución de conflictos se debe realizar de manera voluntaria a petición o mutuo acuerdo de las partes en someter sus diferencias al arbitraje (Alejos, 2019).

A partir del análisis legal y de la jurisprudencia, de Indecopi y del Tribunal Constitucional, se colige que se vulneran los derechos del consumidor por una falta de claridad en la información que se le brinda a este (Fernández, 2019, art. 18 de Código del Consumidor); por la controversia entre la Ley Constitucional y la actuación de los magistrados, en el caso del Tribunal que resolvió declarar nulo el caso del usuario que peticionó acceso a la energía eléctrica que es un derecho fundamental y como tal

requiere resolución con celeridad, con lo cual se demuestra que controlan el poder a través del conocimiento y la aplicación de la norma (Van Dijk, 2016). Con los hechos concretos analizados se evidencia la vulneración económica de los consumidores y usuarios (Landa, 2017).

A pesar de que, en algunos casos, los órganos han resuelto a favor del consumidor; no obstante, se ve afectado por el paso del tiempo y el reconocimiento económico reducido que recibe de los procedimientos obtenidos a su favor.

Conclusiones

Existe asimetría entre el proveedor y el consumidor, el cual afecta su derecho fundamental a recibir un servicio o producto idóneo, también su economía porque los procesos son largos o agónicos respecto a su resolución; asimismo, los costos o costas que paga el proveedor a favor del consumidor por el procedimiento realizado son irrisorios.

Abstract

The scientific novelty of study is to implement a spatial approach to assessing the state of economic security of certain regions of Russia. The content of the economic security of the regions is determined by four systemic projections of the socio-economic system study: industrial, economic, social and innovative. It is of great interest to study for searching spatial patterns the local statistical characteristics of the geo-variation of regional indicators, which allows to assess the spatial trends in the components of economic security. The successful solution of these problems is facilitated by the use of integrated indicator assessment tools using a system of indicators. The state of economic security of the studied regions of Russia is characterized as very variable at the average level of the region with several spatially expressed points of a satisfactory level of economic territories security.

Keywords: Economic Security, Spatial Heterogeneity, Regions Of Russia, Integral Indicator, Statistical Estimation

JEL Classification Codes: E7

Introduction

Regions of Russia as spatial socio-economic systems demonstrate the supporting framework of resettlement, the dynamics of the translation of innovative impulses, the distribution of infrastructure potential and the differentiation in the industrial complex across Russia. In the current circumstances of the external and internal territorial problems existence, it seems necessary to assess the economic security of the Russian regions in order to ensure and improve the mechanisms for developing and making decisions aimed to achieving the priorities for long-term planning and for its provision (Kuzmina Yu. D., Oshchepkov V.M., 2018). Studies of domestic economists in the field of economic security of the regions are not systematic, a universal set of indicators has not been approved, and a single algorithm for assessing the economic security of territories has not been formed.

Today, the economic security of a territorial entity (republic, federal district) is understood as a combination of conditions and factors characterizing the current state of the economy, stability, sustainability and progressive development, the degree of its independence in the processes of integration with the country's economy (Tatarkin A.I.., Kuklin A.A., 2012).

As shown by numerous studies, the most appropriate approach for conducting a safety diagnosis is an indicative analysis. An indicative analysis of the economic security of territories is carried out on the basis of a set of economic security indicators that can signal a threatening decline in its level, quantify the integral indicator of economic security and form a set of program-targeted measures to stabilize the situation.

Materials and Methods

The methodology of the study is based on a comprehensive study of security economic indicators in the Russian regions, and is based on conducting structural-dynamic analysis, building a complex of economic and mathematical models, analyzing economic, industrial, social and innovative processes, using complex integrated indices reflecting the level of economic security in the regional cutaway.

An economic and statistical study of the economic security of regions involves the calculation and analysis of certain indicators that determine the degree of protection against internal and external threats due to a sufficient amount of resources. In this regard, the performance indicators of the economic security of the regions include indicators grouped according to the following four projections (table 1). These indicators are selected by the list of indicators approved in the “Strategy for the Economic Security of the Russian Federation until 2030” (Decree of the President of the Russian Federation, 2017).

Table 1: Economic and statistical research projections of economic security in regions

Economic projection	Industrial projection	Social projection	Innovative projection
Gross Regional Product Volume Index (GDP)	Production index by type of economic activity "Mining" by subdivisions of the Russian Federation	The unemployment rate of the population aged 15-72 years by subdivisions of Russian Federation	Technological innovation costs of organizations by type of innovation activity in subdivisions of Russian Federation
Gross regional product per capita	Industrial Production Index by subdivisions of the Russian Federation	The number of fatal victims’ accidents at work	Developed advanced production technologies in subdivisions of Russian Federation
Government debt of Russian Federation subdivisions and municipal debt	Producer price indices on the type of economic activity "Production of industrial goods" by Russian Federation subdivisions as a whole in accordance with OKVED2	The level of participation in the labor force of the population by Russian Federation subdivisions	The share of high-tech and knowledge-intensive industries in the gross regional product in Russian Federation subdivisions
Energy intensity of gross regional product	Share of investment in fixed assets in gross regional product	The population with cash incomes below the subsistence level as a whole in Russia and in Russian	Information on the use of intellectual property in Russian Federation subdivisions

		Federation subdivisions	
Retail turnover	The share of investments in machinery, equipment, vehicles in the total investment in fixed assets aimed at reconstruction and modernization, by Russian Federation subdivisions	The share of employees in organizations with accrued wages below the subsistence level of the working-age population as a whole in Russia and by Russian Federation subdivisions	The share of domestic spending on research and development in GRP

Descriptive component, and factor methods were used to study economic security in this study. Descriptive methods include: a method of analyzing dynamics and structure, a graphical method. Component methods include the method of determining integral indices, and factor methods include methods for constructing multiple regression models. To achieve the greatest effect, it is necessary to combine various methods (Zuev, V.M., Manakhov, S.V., Gagiev, N.N., Demenko, O.G., 2018).

The information and empirical base of the study includes legislative and regulatory documents of federal significance, data from the Federal State Statistics Service and information portals of state programs. The results of the work are also based on data obtained in the process of independently conducted author's research and conclusions made (Federal State Statistics Service, 2020).

Results

Spatio-Temporal Analysis of Economic Security of Certain Russian Regions by The Methods of Structural-Dynamic Analysis and Forecasting

The gross regional product (GRP) is used to characterize the results of economic activity on a regional scale. In the analysis of GRP, an important place is occupied by the identification of the tendency for a change in the gross regional product per capita. This indicator, to the greatest extent, reflects the dynamics of economic activity unfolding in the region (Figure 1).

Fig 1: Dynamics and forecast of gross regional product per capita in the Volga Federal District, USD

Compared to 2007, gross regional product (GRP) per capita increased by $ 2,291.3 (40%) compared to 2007, and by $ 572.9 (7.7% compared to 2017) and in 2018 amounted to $ 8,026. Between 2007 and 2018, GRP per capita increased annually by an average of $ 208.3 (3.1%). According to the forecast, a decrease in per capita GRP in the Volga Federal District is expected in 2019 and 2020, however, by 2021, the studied indicator will increase and amount to $ 8058.3.

The index of physical volume of the gross regional product of the Volga Federal District decreased from 109.1% in 2007 to 99.7% in 2018. In 2018, compared with 2017, the index of physical volume of VLR decreased by 1.7 pp This indicator does not have a clearly expressed downward or upward trend, it changes in different ways. There has been a decrease in the index from 2007 to 2009, an increase from 2009 to 2011, the index begins to decline in 2011 until 2015, and from 2015 to 2017 the indicator grows again. In the period from 2007 to 2018, the index of physical volume of gross regional product of the Volga Federal District decreased annually by an average of 0.86 percentage points.

Energy intensity of GDP (Energy consumption per GDP unit) is a specific indicator of energy consumption in relation to GDP, usually measured in tfe (tons of fuel equivalent) per unit of GDP value in national or foreign currency (Figure 2). Based on Figure 2, we can conclude that in all Volga Federal District regions for the period from 2012 to 2018, there was a positive trend towards a decrease in the studied indicator. Based on the forecast, it can be concluded that in the next two periods the volume of retail turnover will grow, but in 2021 another decrease in this indicator is expected. In 2021, retail trade turnover in the Volga Federal District will amount to $ 107.9 billion, which is $ 2.9 billion less than in 2018. During the period under review, the studied indicator grew most slowly in the Samara Region, the fastest - in the Udmurt Republic. In the Samara Region, from 2007 to 2018, retail trade turnover increased annually by 6.9% (by 30.6 billion rubles) on average. In the period from 2007 to 2018, in Udmurtia, retail trade turnover increased by an average of 12.2% (15.2 billion rubles) (Figure 2).

Fig. 2: Dynamics and forecast of retail turnover in the Volga Federal District, billion US dollars

In the period from 2007 to 2018, there was a positive upward trend in municipal debt in the Volga Federal District. In 2018, compared with 2007, the municipal debt of the Volga Federal District grew by $ 1.5 billion (2.8 times) and amounted to $ 2.3 billion. Annually, the studied indicator increased by an average of 132 million US dollars (by 9.8%). When visualizing the levels of the series, it was revealed that there is no clear trend in the indicator's dynamics, therefore, it was decided to perform exponential smoothing, on the basis of which the forecast of the municipal debt of the Volga Federal District in 2019 - 2021 was carried out. Based on the forecast, we can conclude that in subsequent periods an increase in municipal debt is expected. According to the forecast, in 2021, compared with 2018, the volume of municipal debt will increase by $ 396 million and amount to $ 2.6 billion.

The largest growth in the reporting period was recorded in the Republic of Tatarstan: the amount of debt from 2007 to 2018 increased by 21.8 billion rubles. The smallest growth was recorded in the Republic of Mari El: from 2007 to 2018, the amount of debt increased by 0.3 billion rubles.

Let us analyze the dynamics of economic security indicators of the Volga Federal District regions by the social group of indicators.

Consider the population of the federal district with cash incomes below the subsistence level (Shakirova L.R., 2018). In most regions, from 2011 to 2018, there was a positive trend towards a decrease in the studied indicator. Growth was noted only in such regions as the Perm Territory and the Kirov Region. In the Nizhny Novgorod Region, the population with cash incomes below the subsistence level in 2011 amounted to 12.5% of the total region population, decreasing by 3.0 percentage points by 2018. (24.0%), and amounted to 9.5% according to Rosstat. In the Perm territory, the value of the studied indicator from 2011 to 2018 increased from 14.4% to 14.9% (by 3.5%), in the Kirov region it increased from 15.0% to 15.5%, by 3,3%.

Let us proceed to the analysis of the employees share of organizations with accrued wages below the subsistence level of the able-bodied population in the Volga Federal District regions. It should be noted that in the federal district as a whole, in 2005 the value of the studied indicator amounted to 28.6%, decreasing by 4.0% to the index of 86.1% in 2018. This change indicates a positive upward trend in the employees` wages of organizations in Volga Federal District for the study period. Obviously, from 2005 to 2018, the studied indicator was reduced in all regions of the district. So, in 2005, in the Republic of Bashkortostan, the employees share of organizations with accrued wages below the subsistence level of the able-bodied population was 25.5%, decreasing by 1.2% in 2018 (by 95.3%) (Fig. 3).

Fig. 3: Forecasted values of the employees share in organizations with accrued wages below the cost of living of the able-bodied population in the Volga Federal District by 2020, %

Next, we analyze the level of unemployment at the age of 15 - 72 years in the Volga Federal District and its individual regions. In the Volga Federal District as a whole, from 2007 to 2018, the studied indicator decreased by 27.9% to 4.4% in 2018.

In 2018, compared with 2007, in all regions of the okrug, the studied indicator was reduced, except for the Republic of Mordovia. There was an increase in the unemployment rate of the population aged 15-72 by 20.0% to 4.2% in 2018. The maximum decrease in the studied indicator for the period from 2007 to 2018 occurred in the Republic of Mari El and the Chuvash Republic - 44.4% from 9% to 5.0%. Provided that the main development trend is maintained, we can conclude that in the studied federal

district the unemployment rate of the population aged 15-72 is expected to decrease to 3.6% in 2020. That is, compared with 2018, the indicator will drop by 17.7% (Fig. 4).

Fig. 4: The forecast value of the unemployment rate of the population aged 15-72 in the Volga Federal District by 2020, %

During the study period, in the majority of the studied regions, there was a decrease in the level of participation in the workforce of the population aged 15-72 years, but it cannot be called significant. Thus, in the Mari El Republic, the studied indicator fell by 6.3%, amounting to 64.5% in 2018, and in the Perm Territory, the level of participation in the workforce of the population aged 15-72 years decreased to 64.7% (by 3.3%). In the Penza region in 2018 compared with 2007, there was an increase in the studied indicator by 8.2%, and in the Republic of Tatarstan – by 6.7%.

In comparison with 2018 the studied indicator is expected to grow to 69.1% - by 2.0% in the Volga Federal District by 2020, considering maintenance of the general development trend (Fig. 5).

Fig. 5: The forecast value of the level of participation in the workforce of the population aged 15-72 in the Volga Federal District by 2020, %

Finally, we analyze an indicator - the number of victims in fatal accidents at work. In 2007, in the Volga Federal District, the value of the studied indicator amounted to 739 people, decreasing to 211 people by 2018 (fig. 13). A positive trend towards a decrease in the studied indicator was noted in all regions of the district for the period from 2007 to 2018.

The predicted value of the studied indicator for the federal district as a whole for 2020 is amounted to 85 people, which indicates the expected reduction in the number of victims of industrial accidents in the Volga Federal District by 59.5% compared with the same indicator for 2018 (Fig. 6).

Fig. 6: The forecast value of the number of victims in industrial accidents in the Volga Federal District by 2020, people

To assess the innovative potential of Russian Federation at the regional level, the Association of Innovative Regions and the Ministry of Economic Development of Russian Federation compiled a rating of innovative Russia regions (Rating of innovative Russia regions, 2018). In accordance with the value of the integral index of innovation development, which includes 29 indicators, the subjects of Russian Federation are divided into the following groups: strong, medium-strong, medium, medium-weak and weak innovators (Sadovnikova T.S., 2018). The place of the Volga Federal District regions in this rating in 2018 is shown below (table 2).

Table 2: Rating of the Volga Federal District subjects in the ranking of innovative regions of Russian Federation in 2018

Rank	Region	Index	Group	Rank change to 2017 level
2	Republic of Tatarstan	0.67	strong	1
8	Nizhny Novgorod Region	0.55	strong	3
9	Ulyanovsk region	0.54	medium strong	-1
10	Samara Region	0.54	medium strong	-1
12	Republic of Bashkortostan	0.52	medium strong	0
13	The Republic of Mordovia	0.52	medium strong	0
18	Perm region	0.49	medium strong	0
19	Chuvash Republic	0.49	medium strong	1
29	Udmurt republic	0.43	medium strong	0
31	Penza region	0.43	medium	-6
34	Kirov region	0.42	medium	12
39	Saratov region	0.40	medium	4
41	Mari El Republic	0.40	medium	-3
61	Orenburg region	0.33	medium-weak	1

Thus, the Republic of Tatarstan and the Nizhny Novgorod region are included in the group of leaders in terms of innovative development among other subjects of Russian Federation. Ulyanovsk and Samara regions, as well as the Republic of Bashkortostan, Mordovia, Chuvashia, Udmurtia and Perm Territory are medium-strong innovators. Penza, Kirov, Saratov regions and the Republic of Mari El are characterized by an average level of innovative development. The level of innovation in the Orenburg region is below the average in Russian Federation, and thus, the region entered the group of medium-weak innovators.

Modeling the Economic Security of the Volga Federal District territories

To summarize the spatio-temporal analysis of economic security indicators, we implement a cluster analysis of the regions with the aim of identifying individual groups of entities depending on their socio-economic, innovative and industrial development.

After applying hierarchical methods of clustering, using different methods - the near and far neighbors, the Ward method, the average connection - approximately the same results were obtained. As a result, the subjects were divided into 4 groups. (table 3).

Table 3: Grouping of the Volga Federal District regions by the level of economic security in the social sector in 2018

Regions of the Volga Federal District	Total ranks	Grouping
Saratov region	18	1 group
Mari El Republic	20	
Perm region	26	
Chuvash Republic	28	
Ulyanovsk region	34.5	2 group
Kirov region	35	
Republic of Bashkortostan	36	
The Republic of Mordovia	37	
Orenburg region	41.5	3 group
Penza region	45	
Samara Region	46,5	
Nizhny Novgorod Region	50.5	4 group
Republic of Tatarstan	53	
Udmurt republic	54	

Note that the first group includes regions with the lowest level of economic security in 2018 (total ranks less than 30 units), the second group includes entities for which the average level of the indicator under study was typical. Among them there are Ulyanovsk and Kirov regions, Republic of Bashkortostan and Mordovia. Three regions of the Volga Federal District – Orenburg, Penza and Samara Regions – were characterized by the level of economic security above the average in the social block of indicators. The highest level of the studied indicator in 2018 (group 4) was noted in Nizhny Novgorod region, Republic of Tatarstan, and Udmurt region, for which the total ranks exceeded the value of 50 units.

In the framework of this study, it was decided to build an integrated index of economic security, based on the assignment of weighting factors to individual indicators of economic security, depending on the degree of their significance. In order to solve this problem, it is proposed to use the method of principal components. The advantage of this approach lies in its objectivity in the selection of weighting factors for factors, in the possibility of identifying latent variables that characterize economic security, and also in reducing the dimension of the attribute space.

The construction of the classical regression model in this case is complicated by the presence of high multicollinearity between the characters, which subsequently can cause distortion of the simulation results.

At the first stage of this statistical study, the main components were built on the indicators of economic security of Volga Federal District after their preliminary standardization. The indicators of economic security of Volga Federal District were taken for construction, where: $x1$ – GRP per capita; $x2$ – GRP physical volume index; $x3$ – retail turnover; $x4$ – industrial production index by type of economic activity, "Mining operations"; $x5$ – industrial production index; $x6$ – producer price indices by type of economic activity "Industrial goods production"; $x7$ – share of investments in fixed assets in GRP; $x8$ – the share of internal research and development costs in GRP; $x9$ – costs of technological innovation of organizations; $x10$ – unemployment rate of the population aged 15-72 years; $x11$ – level of participation in the workforce of the population aged 15-72 years; $x12$ – the proportion of the population with cash incomes below the subsistence level. A brief description of the obtained first eight components is given in table 4.

Table 4: Description of the main components of the economic security indicators in Volga Federal District

Indicator	PC1	PC2	PC3	PC4	PC5	PC6	PC7	PC8
Standard deviation	2.10	1.42	1.35	1.07	0.96	0.84	0.66	0.49
Proportion of variance	36.9%	16.9%	15.1%	9.5%	7.6%	5.9%	3.6%	2.0%
Accumulated fraction of variance	36.9%	53.8%	68.9%	78.4%	86.1%	92.0%	95.6%	97.7%

For the purpose of a detailed study of the constructed main components and their meaningful description, we consider the factor load matrix. The first main component with the highest weights included GRP per capita (x1), retail turnover (x3) and the share of the population with cash incomes below the subsistence level (x12) with a negative coefficient. The first main component characterizes the cash income of the population. The second main component includes the industrial production index by type of economic activity, "Mining operations" (x4), and the industrial production index (x5). Thus, the second main component describes the production activities of the region. The indicators of the index of physical volume of GRP (x2) and the producer price index of industrial products by type of economic activity "Industrial production" form the third main component that characterizes the change in GRP. The fourth main component is most affected by the level of participation in the workforce of the population aged 15-72 years, therefore, the component describes the economic activity of the population in regions (table 5).

Table 5: The factor loads matrix of the main components

Source variables	Main components			
	PC1 income	PC2 industry	PC3 GRP	PC4 economic activity
$x1$	0.387	-0.059	-0.120	-0.308
$x2$	0.008	0.158	0.601	-0.280
$x3$	0.387	-0.172	-0.158	-0.360
$x4$	0.067	0.493	-0.117	-0.220
$x5$	0.103	0.542	-0.206	0.327
$x6$	-0.233	-0.134	0.430	-0.018
$x7$	0.246	0.406	0.365	-0.179

$x8$	0.196	-0.240	0.307	0.239
$x9$	0.418	-0.274	0.125	-0.116
$x10$	-0.311	-0.232	-0.294	-0.392
$x11$	0.259	-0.188	0.045	0.532
$x12$	-0.441	-0.014	0.164	-0.053

To improve the interpretation, it was decided to rotate the main components by the varimax method, maximizes the spread of the squared loads for each factor, which leads to an increase in large and a decrease in small values of factor loads. After rotation, the substantive characterization of the first and second main components remained unchanged; the third main component with the largest weights still includes the index of physical volume of GRP (x2) and the share of investments in fixed assets in GRP (x7); the fourth main component with the highest weight includes the level of participation in the workforce of the population aged 15-72 years (x11) and with a negative weight the unemployment rate (x10) – table 6.

Table 6: Factor load matrix after rotation

Source variables	Components			
	RC1	RC2	RC3	RC4
$x1$	0.882	0.101	0.075	0.109
$x2$	-0.104	-0.127	0.877	0.008
$x3$	0.952	-0.039	-0.007	0.084
$x4$	0.127	0.650	0.230	-0.319
$x5$	-0.065	0.907	-0.052	0.112
$x6$	-0.507	-0.479	0.354	-0.015
$x7$	0.271	0.437	0.770	0.149
$x8$	0.180	-0.272	0.190	0.616
$x9$	0.814	-0.211	0.176	0.480
$x10$	-0.173	-0.425	-0.395	-0.708
$x11$	0.221	0.013	-0.176	0.785
$x12$	-0.790	-0.331	0.064	-0.419

According to the Kaiser criteria, the first four main components should be selected. Moreover, this number of principal components satisfies the rule of thumb, according to which the extracted principal components must describe at least 70-80% of the variance of the original features. In accordance with the "scree" method in the graph below, you can also notice that the bend of the line occurs when the number of clusters is 4.

Thus, at this stage of the statistical study, four main components were constructed as linear combinations of the initial features. Moreover, the first main component characterizes the cash incomes of the population and the financing of innovations; the second component is the level of industrial development; the fourth main component is the economic activity of the population, the third main component is investment in fixed assets and GRP. It is on the basis of these components that an integrated economic security index will be built, which is calculated by the formula:

$$I\text{economic security} = (I\text{inc.} + I\text{industry} + I_{GRP} + I\text{ec.act.})/\ 4$$

where each of the intermediate indices represents the corresponding main components, recalculated in the range [0; 1]. Calculations of the integrated index of economic security of the region are presented in table 7 and fig. 7.

Table 7: Calculation of the integrated index of economic security in the Volga Federal District regions

Regions of the Volga Federal District	*I*inc	*I*industry	*I* ec.act.	I_{GRP}	*I* economic security
Republic of Tatarstan	1.000	0.818	0.584	0.959	0.840
Nizhny Novgorod Region	0.736	0.231	1.000	0.643	0.652
The Republic of Mordovia	0.020	0.993	0.529	1.000	0.636
Orenburg region	0.477	1.000	0.381	0.636	0.623
Ulyanovsk region	0.153	0.836	0.540	0.861	0.598
Samara Region	0.576	0.597	0.546	0.515	0.558
Penza region	0.127	0.881	0.477	0.686	0.543
Republic of Bashkortostan	0.827	0.844	0.130	0.278	0.520
Saratov region	0.327	0.653	0.085	0.932	0.499
Perm region	0.740	0.421	0.000	0.748	0.477
Kirov region	0.167	0.886	0.380	0.464	0.474
Udmurt republic	0.331	0.986	0.548	0.000	0.466
Chuvash Republic	0.000	0.334	0.542	0.504	0.345
Mari El Republic	0.081	0.000	0.218	0.534	0.208

Fig. 7: Integrated economic security index by region of the Volga Federal District

Thus, at this stage of the statistical study, the integral economic security index of the Volga Federal District regions was calculated, which takes into account the cash income of the population and financing of innovations, industrial development, economic activity, investment in fixed assets and GRP dynamics. In general, the results on the integrated economic security index are similar to the results of cluster analysis – Republic of Tatarstan is the absolute leader with an indicator of 0.84; the five leaders also included Nizhny Novgorod region (0.652), Republic of Mordovia (0.636), Orenburg region (0.623) and Ulyanovsk region (0.598). The regions with the lowest level of economic security are Republic of Mari El (0.208), Republic of Chuvashia (0.345), and Udmurt Region (0.466). It should be noted that an adequate interpretation of the integral index can be obtained only by comparing the regions of Volga Federal District.

Conclusion

The results of the economic and statistical study of the economic security in the regions are necessary as a basis for the development and adoption of decisions aimed at increasing its level in various territories and long-term planning for its provision and withstanding economic threats.

Based on the results of a spatio-temporal study of the economic security in Volga Federal District territories, an integrated index of economic security was formed, based on the level of industrial development, innovative, investment potentials, economic activity of the population and its level of well-being. Monitoring and regulating the level of economic security territories favors the formation of a healthy economic environment in the country that can minimize the conditions and causes of challenges and threats in the economic sphere, and ensure the effective development of regional economies through the application of scientific methods.

Abstract

The article on the statistical data of the regions of the Ural Federal District of the Russian Federation analyzed the indicators of economic security. The most appropriate approach for conducting and predicting safety diagnostics was the cumulative T-criterion method, as shown by the research. According to this approach, an economic security is diagnosed by groups of indicators, which allow to signal the threatening danger, to assess the level of security threats.

Keywords: statistics, economic safety, diagnostics, forecasting.

JEL Classification: M21; O1

Introduction

The economic security of the Territory was reflected in the efficient use of natural, labour, material and financial resources, as well as the acceleration of economic growth, the improvement of the quality of products, services and competitive production.

The problems of ensuring economic security at the corporate and state levels are reflected in the research Artemova (2010), Beketov (2009) and Burtsev (2003). Research by Fishakov (2012), Gorokhova (2019), Kapkannikov (2018), Arbuzov (2017) and Kuznetsova (2017) is devoted to determining the most significant indicators of territories economic security. Research by Kovalev (2017), Pisarenko (2018), Potrubach (2018) and Vlasenko (2010) confirms the relevance of identifying factors that pose threats to the economic security of the territories of the Russian Federation, including the Ural Federal district (UFD).

Therefore, the problem of economic security of the Russian region is extremely acute, because the developed region of Russia forms the security of the state. The Ural Federal District was a developing and stable region of the Russian Federation, which was able to predict negative impacts and counter internal and external threats.

Methodology

A trend in the original series of dynamics is a prerequisite for time-series-based forecasting. The identification of changes trends in the main factors of economic security of the Ural Federal District was fulfilled by the cumulative T-criterion. During the implementation of this method there was a hypothesis (H0) that there is no trend in the initial series of dynamics of indicators characterizing the economic security of the federal district of the Russian Federation.

In order to carry out a statistical analysis of the economic security indicators of the Ural Federal District, the «Strategy for Economic Security of the Russian Federation until 2030», approved by Presidential Decree # 208 of 13 May 2017, was studied. According to this document, a list of 20 indicators divided into 4 groups – economic (Gross Regional Product Volume Index (GRP)) was selected from 40 indicators of the state of economic security of the territories; Gross regional product per capita; State debt of subjects of the Russian Federation and municipal debt; Energy intensity of gross regional product; Turnover of retail trade), social (Unemployment rate of the population aged 15-72 in the constituent entities of the Russian Federation; Number of victims of fatal occupational accidents; The level of participation in the labor force of the population by the constituent entities of the Russian Federation; The number of the population with monetary incomes is lower than the subsistence minimum in Russia as a whole and in the constituent entities of the Russian Federation; The share of employees of organizations with accrued wages is lower than the subsistence minimum of the working-age population as a whole in Russia and in the constituent entities of the Russian Federation), innovative (Costs of technological innovations of organizations by type of innovation.

Results

The authors studied the «Strategy for Economic Security of the Russian Federation until 2030», approved by Presidential Decree # 208 of 13 May 2017 to carry out a statistical analysis of the economic security indicators of the Ural Federal District. According to this document, we chose a list of 20 indicators divided into 4 groups. The choice of indicators for building models is determined by the availability of official statistics. Among them economic (gross regional product volume index; gross regional product per capita; state debt of Russian regions and municipal debt; energy intensity of gross regional product; turnover of retail trade), social (unemployment rate of the population; number of victims of fatal occupational accidents; the level of participation in the labor force of the population by the constituent entities of the Russian Federation; the population with monetary incomes is lower than the subsistence minimum in Russia and in Russian regions; the share of employees of organizations with accrued wages is lower than the subsistence minimum of the working-age population in Russia and Russian regions), innovative (costs of technological innovations of organizations by type of innovation activity in Russian regions; the developed advanced production technologies for the Russian regions; share of products of high-tech and knowledge-intensive industries in the gross regional product of the subject of the Russian Federation; the information about the use of intellectual property objects by Russian regions; share of domestic expenditures for research and development in GRP) and industrial (production index by type of "Mining" economic activity by Russian regions; an index of industrial production by Russian regions; the producer price indices on the type of "Production of industrial goods" economic activity for Russian regions in accordance with the OKVED2; the share of fixed investment in gross regional product; the share of investments in machines, equipment, vehicles in the total volume of investments in fixed assets aimed at reconstruction and modernization, according to Russian regions). These indicators will be used to predict an economic security parameter in the Ural Federal District of the Russian Federation.

Based on the results obtained in the implementation of the cumulative T-criterion, it can be concluded that at the specified level of significance $\alpha = 0.05$ the hypothesis on absence of trend in the initial time series is accepted: by the group of economic indicators of economic safety ($Tc = 5.49$, $Tc = 2.62$, $Tc = 3.11$, $Tc = 3.59$). At the same time, the indicator "State debt of the subjects of the Russian Federation" was not considered, as it shows data only for 2019, and therefore, it is impossible to calculate dynamics and forecast (Table 1).

Table 1: The Results of the implementation of the Cumulative T-Criterion for the Group of Economic Indicators of Economic Security in the Ural Federal District for 2007-2018

In order to give a forward-looking assessment of economic security indicators in the Ural Federal District of the Russian Federation, forecast values for 2019-2021 were obtained for dynamic series with the presence of a trend by the method of analytical equalization according to the line function.

As a result of the calculations made, it was revealed that since 2007 by 2021 the largest growth of GRP per capita in absolute terms is expected in the Tyumen region by 1504290.4 rubles (2.8 times), and in relative terms - in the Kurgan region (3.4 times) and will amount to 2335595.7 rubles and 293314.0 rubles, respectively. By 2021 compared to 2007 there will be the largest increase in retail turnover in the Sverdlovsk region by 1003952 rubles (3.5 times).

According to the forecast data, the largest reduction in the energy consumption of GRP in absolute terms will be observed in Chelyabinsk region by 326.2 p.p. (0.3 times), and in relative terms - in Yamalo-Nenets Autonomous District (90.8%) (Table 5).

Table 5: Forecast values of economic indicators of economic security in the Ural Federal District of the Russian Federation for 2019-2021

Indicator	Trend equation	Expected value		
Ural Federal District

In order to determine the prospective values by 2021 in the series of dynamics that do not have a trend, the probabilistic method of assessment, namely the method of forecast of a bad trend, was used. So, with the probability of 10.70%, 22.54%, 7.37%, 18.22%, 9.85%, 22.54% and 10.70% can be claimed that the index of physical volume of a gross regional product by 2021 in comparison with 2007 will increase in the Ural Federal District of the Russian Federation and regions entering it, respectively (Table 6).

Table 6: Probability of favourable index trend
Physical volume of GRP by 2021, % to total

Subject	Probability of favorable trend,%
Ural Federal District	10,70
Kurgan region	22,54
Sverdlovsk region	7,37
Tyumen region	18,22
Khanty-Mansi Autonomous District - Ugra	9,85
Yamalo-Nenets Autonomous District	22,54
Chelyabinsk region	10,70

As a result of the calculations made on social indicators of economic security, it was revealed that from 2007 to 2021 the largest reduction in unemployment rate of population aged 15-72 is expected in Khanty-Mansi Autonomous District - Ugra by 6.12 p.p. (by 80.49%).

By 2021, compared to 2011, there will be the largest increase in the number of people with monetary incomes below the subsistence minimum in Chelyabinsk by 4.92 p.p. (per 45.51%).
According to the forecast values, the largest reduction in the number of victims of fatal accidents at work in absolute terms is observed in the Sverdlovsk region by 69 p.p. (0.2 times), and in relative terms – in the Kurgan region (88.31%).

The share of employees of organizations with accrued wages below the subsistence minimum of the working-age population by 2021 according to the prospective values will be reduced in absolute terms by 14.61 p.p. (0.2 times) in Chelyabinsk region, and in relative terms – in Yamalo-Nenets Autonomous District (109.25%) (Table 7).

Forward-looking values were also obtained for non-trending series. On their basis the following conclusions were drawn: with the probability of 19.68%, 19.68%, 15.01%, 19.68%, 19.68%, 22.54% and 42.68% the level of participation in labor of the population at age of 15-72 years by 2021 will increase in the Ural Federal District of the Russian Federation and regions entering it, respectively.

The unemployment rate of the population aged 15-72 in the Ural Federal District in central, Sverdlovsk and Chelyabinsk regions with a probability of 15.01%, 19.68% and 19.68%, co-responsibly, will increase.

With a probability of 18.22%, 27.89% and 18.22%, the population with monetary incomes below the subsistence minimum will increase in the Sverdlovsk region, Khanty-Mansi Autonomous District-Ugra and Yamalo-Nenets Autonomous District.

The number of victims of accidents at work with a fatal home will increase with a probability of 8.35% in the Tyumen region.

With a probability of 11.90% in the Kurgan region and Khanty-Mansi Autonomous District-Ugra, the share of employees of organizations with accrued wages below the value of the industrial minimum will increase (Table 8).

Table 8: Probability of favorable trend of social indicators of economic security by 2021, % of the total

Subject	Probability of favorable condition,%				
	Labour force participation rate	Unemployment rate	The number of persons with de-gentle children below the level of	Number of victims of fatal occupational accidents	Proportion of employees of organizations with accrued wages below the subsistence minimum

Khanty-Mansi Autonomous District - Ugra	19,68	-	27,89	-	11,90
Yamalo-Nenets Autonomous District	22,54	-	18,22	-	-
Chelyabinsk region	42,68	19,68	-	-	-

According to the forecast values of innovative indicators of economic safety, since 2010 by 2021 the largest increase in the share of domestic expenditures on research and development in GRP in absolute terms is expected in the Sverdlovsk region by 0.50 p.p. (1.42 times), and in relative terms - in the Yamalo-Nenets Autonomous District (14.63 times).

By 2021, compared to 2010, there will be the largest increase in the share of products of high-tech and knowledge-intensive industries in the gross regional product in the Kurgan region by 2.22 p.p. (by 9.02%).

According to the perspective values of the developed advanced production technologies, you announced that the largest increase will be observed in Chelyabinsk region by 157.6 p.p. (11.51 times). Information on the use of intellectual property objects by inventions by 2021 will increase most in absolute terms in Chelyabinsk region by 233 p.p., and in relative terms - in the Tyumen region (by

168.79%). In the Sverdlovsk region, data on the use of intellectual objects on useful models will increase by 124 p.p. (47.85%) by 2021 compared to 2010.

The largest increase in information on the use of intellectual property objects by computer programs by this period in absolute terms will be marked in the Sverdlovsk region by 151 p.p. (2.85 times), and in relative terms - in the Chelyabinsk region (8.76 times) and will amount to 233 and 140 p.p., respectively (Table 9).

For the series of dynamics without trend got promising values. With a probability of 7.78%, 10.70% and 22.54%, the share of domestic spending on research and development in GRP will increase by 2021 in Khanty-Mansi Autonomous District-Ugra, Kurgan and Chela-bin regions, respectively.

The share of products of the high-tech and knowledge-intensive industries in a gross regional product with the probability of 22.54%, 15.53%, 15.53%, 7.37% and 10.70% in the Ural Federal District in general, the Sverdlovsk, Tyumen regions, the Khanty-Mansi district Yugra, the Yamalo-Nenets Autonomous Area, respectively, will increase.

With a probability of 13.72%, information on the use of intellectual actual objects by inventions in the Sverdlovsk region will increase. With the probability of 10.70%, 10.70%, 22.54% and 10.70% in the Ural Federal District in general, Kurgan, Tyumen and Chelyabinsk regions of data on use of objects of intellectual property on useful models will increase.

By 2021, information on the use of intellectual property objects on industrial samples will increase with a probability of 13.72%, 22.54% and 13.72% in the Ural Federal District as a whole, Sverdlovsk and Chelyabinsk regions, respectively.

Information on the use of intellectual property objects by databases with a probability of 13.72% will increase in the Ural Federal District as a whole and the Tyumen region that enters it.

By 2021, with a probability of 16.73%, information on the use of intellectual property objects under computer programs will increase in the Tyumen region (Table 10).

Table 10: Probability of favorable trend of innovative indicators of economic safety by 2021, in% to the total

Subject	Probability of a favorable trend, %						
	Share of domestic research and development costs in gross regional product	Share of products of the hi-tech and knowledge-intensive industries in a gross regional product	About Using Intellectual Property by Invention	About Using Intellectual Property by Useful Models	About Using Intellectual Property by Industrial Pattern	About Using Intellectual Property by Database	About Using Intellectual Property by Computer Programs
Ural Federal District	-	22,54	-	10,70	13,72	13,72	-

Chelyabinsk region	22,54	-	-	10,70	13,72	-	-

For dynamic series with a trend in industrial indicators of economic safety, forecast values for 2019-2021 were also obtained. Thus, the share of investments in machines, equipment, vehicles in the total volume of investments in fixed assets aimed at reconstruction and modernization will decrease in the largest volume in Khanty-Mansi Autonomous District-Ugra by 13 p.p. (by 69.67%).

The index of industrial production by 2021 according to the forecast values in the Yamalo-Nenets Autonomous District will increase by 26.83 p.p. (1.28 times).

The share of investments in fixed assets to GRP will be most reduced in Kurgan region by 27.4 p.p. (86.9%) (Table 11).

Table 11: Forecast values of industrial indicators of economic safety in the Ural Federal District of the Russian Federation for 2019-2021

Indicator	Trend equation	Expected value		
Ural Federal District				
x1	y_t=-1,50x+41,85	2019	2020	2021

Khanty-Mansi Autonomous District - Ugra	19,68	-	27,89	- 11,90
Yamalo-Nenets Autonomous District	22,54	-	18,22	- -
Chelyabinsk region	42,68	19,68	-	- -

Conclusion

Recent political and economic developments in the world show that the task of ensuring economic security is now still relevant at both the federal and regional levels. In the current situation, it is necessary to organize effective monitoring of the economic security of the Territories, including a comprehensive assessment of the state of the economic security system in order to identify external and internal threats. Monitoring is traditionally assessed with the help of indicators reflecting the strengths and weaknesses of the development of regional economics in various spheres (real economy, financial sphere, food supply, etc.). Indicators of economic security should have the following distinctive characteristics: to quantify threats to economic security; Have high sensitivity and variability; Interact with each other to a sufficiently strong extent. In addition, threshold values should be defined for all indicators – limit values, the disregard of which impedes the poor development of the economy and social sphere and leads to the formation of destructive trends in the production and standard of living of the population. The approach of indicators to their thresholds signals the emergence of economic threats without danger, and the excess signals the crisis socio-economic situation.

Abstract

What became the trigger for getting interested in the issue of ghosting in organizations were signals from practitioners about the intensification of this phenomenon. It became noticeable because, for many years, in the area of hiring of employees, we were dealing with the employers' dictate. The purpose research was to deepen the identification of the ghosting phenomenon. The authors used on line their own research questionnaire; they didn't reach secondary date in this area. It focus was on causes, characteristics, conditions of its intensification in Poland as well as steps that could limit its negative effects for companies. The research was carried out in two stages; the first was carried out at the turn of 2018/2019 and took into account the perspective of organizations represented by their owners, managers and HR services. The second stage, carried out at the turn of 2019/2020, concerned the perception of *ghosting* by candidates participating in these practices, who wanted to be recruited, future employees. The research has confirmed the spread of *ghosting* and related problems in companies regarding recruitment of employees and maintaining the level of employment. The results of the survey, justifying the need for further research in the context of its consolidation, allowed to initially address the issue of limiting the negative effects of *ghosting* on companies.

Keywords: Labor Market, Phenomenon of *Ghosting*, Recruitment .

Introduction

For decades, on the labor market (not only in Poland), employers have played a dominant position taking advantage of the relatively well-established prevalence of the labor demand over supply. They the ones who mainly selected employees to meet the needs in terms of work potential necessary to achieve their organization's goals, both in terms of operational dimension, i.e. related to the ongoing performance of tasks, as well as in the strategic dimension, setting the assumptions of the personnel strategy as a component of the organization's development strategy. As part of implementing the recruitment function, it was the employers who would work out the appropriate procedures for recruiting employees by preparing an offer (advertisement) containing the desired employee profile, inviting to interviews during which the details of the job offer were presented and the candidates were verified and finally finalizing employment contracts (addressed to selected candidates). Today, such a scheme of recruiting employees turns out to be ineffective. It is becoming increasingly difficult for companies to meet the challenge of finding and retaining appropriately engaged, loyal and responsible employees who would be ready to stay with the given company for longer.

This is the result of changes in the labor market, which today is becoming more and more often (in specific segments and in specific time intervals) the employees' market. This causes a reversal of roles. Employees become the party making the choice, not the employer as before. After the economic transformation in the 1990s, the Polish labor market remained a market in which there was

a surplus of labor resources for many years, and this situation was reflected in the persistently high level of unemployment. In 2004, at the time of Poland's accession to the European Union, the unemployment rate was over 20% (while in recent years this indicator has been at the level of 2010-12% and in 2019-5%) (GUS, 2019).

Since then, intensive emigration of Poles, mainly to Western Europe, has started. The process of emigrating in search of work was somewhat slowed down in 2008-2010, which was during the economic crisis and then resumed (with less intensity) in 2011 resulting in a flow of 1.5 million emigrants from Poland to the EU.

Changes on the Polish labor market took place also as a result of economic growth (its pace did not slow down significantly even during the economic crisis). Foreign investment proved to be a particularly favorable factor, as it utilized the existing surpluses of labor resources. In the meantime, certain demographic changes have also occurred, including depopulation and aging. All this gradually led to the disclosure of deficiencies in the labor market, initially qualitative (the lack of suitably qualified employees) but with time also quantitative shortages (i.e. people willing to take up employment irrespective of matching in terms of knowledge, skills and experience). The situation on the Polish labor market has also deteriorated through the impact of social policy solutions (e.g. the 500+ program, which corroded the interest in taking up paid employment) or through legal regulations allowing a wide spectrum of forms of temporary work, which, regardless of many positive effects, led to the reduction of young people's (representatives of generations Y and Z) interest in settling in professionally by working with any company for longer.

The cumulative impact of these and other conditions ultimately resulted in the inversion on the labor market, i.e. the loss of the dominant position of the employers who previously abused their position, among others, in relation to job applicants, which was manifested by such phenomena as CV documents, cover letter, etc., "falling into a black hole" i.e. employers not confirming their acceptance, not notifying of the results of the next stages of recruitment or the final selection, or generally not maintaining any contact during the recruitment process (which was proof that the employer lost interest in employing the given candidate).

The labor market in a situation where we are dealing with a predominance of job offers over the actual interest in taking up that job/employment becomes the employees' market. Employees are then those who try to use their bargaining position, try to point out that, in these conditions, they are the ones who make the choice. They often go further, play a kind of game, ultimately "disappointing" the recruiter because they decide to participate in the recruitment process not necessarily respecting the applicable rules/arrangements, e.g. by interrupting this process without showing up for the next stages, or by resigning (giving up work) in a relatively short period of time after finalizing the recruitment process and in this way "turning into a ghost." *Ghosting* is therefore a phenomenon that refers to the practices used by future candidates and potential employees consisting in withdrawing from the intention to obtain a job (employment), i.e. resigning from participation during the recruitment process and not proceeding to its subsequent/final stages, or after having the employment promised/provided, not taking up the job or quitting within a relatively short period of time from the date of employment (premature departure) - without notice, any notification or explanatory information (What is Employee Ghosting ..., 2019).

The Essence of Ghosting and Its Spread

The term *ghosting* derives from psychology and is generally used to describe the phenomenon of the breakdown of relationships in interpersonal relations as a consequence of the lack of communication of one of the parties or its unilateral omission, interruption without warning, notification or explanation (Freedman, Powell, Le, Williams, 2019). As M. Dreger (2017) notes, this happens because a person who withdraws from fulfilling their intentions for fear of confrontation, focuses solely on their needs, does not take the opinion of the other person/party into consideration.

JM. Rosenberg (2018) points out that such ease of cutting off contacts is manifested more by young people, which would indicate that this phenomenon may have a generational context. Wanting to avoid potential conflicts, having less experience in conducting difficult conversations, and at the same time, being assertive (caring for their comfort), not deprived of other alternatives young people simply "break" communication. This behavior is interpreted negatively by older/previous generations as an unacceptable lack of stability and responsibility.

G. Bauer (2005) indicates that the phenomenon of ghosting can also be understood as breaking the terms of the (formal) contract between parties, which may stand for not only the employer and potential employee, but also companies providing each other with specific services.

Both dimensions of the phenomenon of ghosting, i.e. manifesting itself in the termination of contacts as well as the withdrawal from the contract immediately after it came into effect, manifests itself mostly in implementing the recruitment function of the organization (business, public and social). Behaviors consisting of "turning into a ghost" penetrate into organizations and become increasingly difficult to accept, although it is hard to say that the essence of this phenomenon is something completely new.

The ghosting phenomenon occurs in various industries and professions. Previously, it mainly concerned less paid jobs in construction, production and transport. Currently, it also covers administrative employees in many industries (Davidson, 2018). It is estimated that the phenomenon of ghosting in Poland, i.e. situations in which candidates reject an offer after previous accepting it, affects 5-20% of recruitment processes (depending on the industry and type of position) (Stolarski, 2018) and is gaining momentum (Miller, 2018).

Currently, this phenomenon is also spreading to specialists and managers, where the labor market is quite hermetic and the number of employers is limited (Błaszczak, 2017). The intensification of this phenomenon in recruitment activities is caused by factors suggesting that the practices in this field are not adapted to the needs, or even that certain errors are being committed (according to HBRP, errors in recruitment and selection account for 80% of unsuccessful recruitment endeavors) (King, 2018).
Studies mainly indicate the lack of a partner-like relationship between the potential employer and the candidate. 50% of respondents have to wait too long for the employer's decision or for being accepted to the next stage, 34% of candidates do not receive information about the planned recruitment process, 28% of respondents, in the end, receive an offer below their previously presented financial expectations, and 21% of respondents do not receive information on important elements of the job offer (Activity of specialists and managers on the labor market, 2018).

In addition, the growing awareness of the strong position of candidates on the labor market means that the pool of passive candidates increases. Passivity is currently the dominant attitude on the labor market. Nearly 70% of specialists and managers are not actively looking for a job (Activity of specialists and managers on the labor market, 2018). Employees take their carrier seriously and carefully plan its stages, becoming more and more demanding. According to the Antal report (Activity of specialists and managers on the labor market, 2018), the motivation to change jobs is influenced not only by salary, but also more attractive career development opportunities (45%), bad organization management (43%), bad atmosphere at work (33%) or unclear prospect of promotion or lack of it in the company (30%). Therefore, employers need to examine the needs of employees and their expectations more consciously and propose various development opportunities to limit the scope of ghosting.

It is worth noting that ghosting is not only the domain of the Polish labor market. In the United States, in 2018 (MacLellan, 2018) an increase of this phenomenon from 10% to 20% was observed. The problem of "disappearing candidates/employees" was noted by the Federal Reserve Bank of Chicago, which tracks employment trends, confirming that the number of "ghosts" is still growing. Economists report that employees are starting to behave like millennials on Tinder (an application that helps meeting new people) - leaving work without any explanation (Paguette, 2018).

In turn, in France, the industry which is experiencing a lot of ghosting is the IT industry, in which the first half of 2019 saw the phenomenon exceed the result for the entire 2018 (Wolski, 2019).

The emergence of the new trend, as it turns out, causes the launch of professional services in this area. e.g. in Japan, where resignations from long-term employment are quite rare - there are organizations that specialize in "resolving" resignation from employment on behalf of employees (Fogarty, 2019). They exist to meet the needs of Japanese employees who are paralyzed by the fear of confronting with their employer and the traumatic experience related to informing the employer about resignation from the job or employment offer (Ciesielska, 2019).

The dissemination of *ghosting* and its negative effects, when it comes to meeting the needs of recruiting and retaining employees in a company, i.e. shaping the work potential that determines the efficient, effective and effective functioning of the given company, has sparked interest in this phenomenon and the desire to check how it is perceived by the managerial staff, HR services and others who are responsible for the efficiency and competitiveness of their companies, as well as by those who, realizing the practices in the framework of *ghosting*, in a sense, see the chance to "get back at the employers" (also business owners) for the decades of the practice of "dealing cards".

Stage I - *ghosting* from a company perspective (2018/2019)

In the first stage of the survey, the focus was on the perception of *ghosting* from the perspective of an organization that experiences this phenomenon. The recipients of the questions/respondents comprised of owners, managers/board members, HR employees and others who come into contact with this type of practices. The purpose of this research was to identify the premises, scale and conditions associated with the occurrence of *ghosting*, its effects as well as possible actions limiting such practices from the company's point of view. Selected results of these studies are presented below. It has to be noted, however that, due to the unrepresentative character of the sample - the results of these studies do not give grounds to make generalized conclusions.

According to the criterion of the number of employees, among the 84 surveyed entities (n = 84), small enterprises accounted for 29%, medium-sized enterprises - 38% and large enterprises - 33%. As for the coverage (with n = 84), companies with local coverage constituted 25% of the sample, with national coverage - 21%, with international coverage - 16% and with global coverage - 38%. The majority of the respondents were associated with the production industry - 30%, IT constituted 22% of the respondents, personal consultancy constituted 14%, and logistics and automotive representatives both constituted 11%. Other industries, including SSC, call center, construction, real estate, and advertising constituted 3% each.

Approximately 15% of those surveyed were business owners and managers. Employees directly related to the personnel (personnel/recruitment specialists, HR managers / directors) constituted 48%. The remaining respondents were managers of various levels and functional areas - 37%.

Of the surveyed entities, 23% confirmed that they had encountered ghosting once during the last year (before the moment of the study), 50% of entities qualified for the range covering 2-5 of such experiences over the past year and 27% confirmed that in the year preceding the survey ghosting cases exceeded 5 (see Chart 1). As for the latter, they most often took place in large companies from the logistics and manufacturing industry.

Figure 1: Occurrence of the *ghosting* phenomenon

Source: Table based on author's research.

Identifying *ghosting* symptoms for n = 84 (see Chart 2), it was noted that the most common phenomena experienced in the employee selection/employment process are:

- the fact that the candidate did not appear at the recruitment meeting, despite confirming the date (37%); this mainly concerned production and specialist positions in large enterprises from the manufacturing industry,
- candidates becoming a "ghost" after being presenting the offer (25%); this mainly concerned specialist positions in large IT companies,
- the moment when a candidate does not take up work on the first day of employment (21%); this mainly concerned production and specialist positions in large enterprises from the manufacturing industry.

Figure 2: Manifestations of *ghosting*

Source: Table based on author's research.

Considering the type of position affected by the *ghosting* phenomenon, it can be seen that it concerned more employees applying for production and specialist positions (45% and 30%) and less for administrative (15%) and management (10%) positions.

In an attempt to identify the causes of the ghosting phenomenon, the conditions potentially related to it were divided into three groups, i.e. those related to the organization's environment, organization

itself and candidates. The following tables 1-2 show the first two groups of causes of this phenomenon. When commenting on the above results, it is worth paying attention to the determinant impact of macro conditions, the current relationship between supply and demand for work guarantees freedom of choice for employees. In addition, it is supported by the entire spectrum of system solutions regarding flexible forms of employment and occupation. Retaliation-motivated reasons (2%) should also be noted.

As for the causes of ghosting at the organizational level, they are primarily related to the process of recruiting employees ("recruitment sins"). The issue of setting employment conditions (they are either not sufficiently defined or they do not coincide with those given in the offer, or they are not negotiable, they are too rigid, etc.) has the biggest influence. Communication factors (providing information, respecting set deadlines) also have a relatively large share here. It is worth noting that the image of the employer is an important factor as well, which may confirm the sense of the employers' efforts in this regard.

Table 1: Reasons for resigning from the job application process. Causes rooted in the environment

No.	Reasons for resignation	% share
1	Situation on the labor market - employee market; many possibilities of finding a competitive offer, free choice of employers by job candidates	74%
2	The existence of many alternatives to employment based on an employment contract (forms of temporary work)	14%
3	The lack of any obligations towards a given employer, as well as legal and financial sanctions, no sense of reprehensibility of such behavior, no motivation to take up employment due to the use of social benefits	10%
4	Miscellaneous, including the opportunity to get back at the employer, who made a choice according to his criteria, for the dominant position in the past.	2%

Source: Table based on author's research

Table 2: Reasons for resigning from the job application process depended on the organization/employer

No.	Reasons for resignation	% share
1	Unspecified employment conditions; discrepancy between the terms in the offer and in reality	25%
2	No possibility to negotiate employment/working conditions	19%
3	Uncompetitive job offer (not adapted to current conditions on the labor market)	15%
4	Too long (dragging) and non-transparent recruitment process	11%
5	Unattractive image of the employer (*employer branding*)	10%
6	Being kept unanswered too long about the recruitment result from the recruiter	9%
7	No feedback after each completed stage of the recruitment process	5%
8	Conducting extensive recruitment campaigns (excess of candidates), convincing candidates that the disappearance of one/several of them will not harm the effectiveness of the recruitment process in the company)	1%
9	Organizing recruitment for non-existent positions to expand the database of candidates, an attempt to attract valuable employees to other positions	1%

10	Unilateral use of new technologies in the recruitment process (machine learning) limiting direct contact with the company and people working in it.	1%
11	Conducting passive recruitment (regarding persons already employed and potentially not interested in changing jobs)	1%
12	Miscellaneous: including no feedback, fear of getting an employment contract, inappropriate treatment of candidates, e.g. showing no respect, no time for explanation.	3%

Source: Table based on author's research

The majority of respondents who represented companies stated that the phenomenon of *ghosting* will soon intensify, indicating that we are dealing with:

- a tendency to limit/reduce communication (paradoxically, with growing technological possibilities in this respect),
- ever smaller identification - employees' relationships with the company they are employed at become more and more anonymous (the employee's own development is the priority),
- the ethos of work and responsibility of the generation entering the labor market is lowering,
- thanks to technology, access to job offers becomes easier, but relationships become more anonymous, etc.

Therefore, taking into account the possible effects of the increase/persistence of this phenomenon, respondents/companies intend to act in two ways. On the one hand, improve the efficiency of recruitment processes through, among others, helping candidates for employees to "get closer" to the people with whom they will work in the future (already at the recruitment stage), devote more time for adaptation in the new work environment, etc. On the other hand, curb this type of practices by introducing sanctions for unjustified withdrawal from the recruitment process or premature abandonment of employment.

As part of the general assessment of this phenomenon by employers, it should be emphasized that 66% of the respondents said that the experience with *ghosting*, de facto, saved the company from problems related to uninvolved and not too responsible employees, thus preventing deterioration of productivity and loss of competitiveness.

Stage II - *ghosting* from the candidate/employee perspective (2019/2020)

The survey questionnaire at this stage of the research contained a metric to characterize the respondents as well as questions identifying the *ghosting* phenomenon from the candidate's perspective - its causes and conditions, characteristics and intentions of people using this type of practice and the effects on future human resource management.

Deliberate selection of the research sample was used, inviting people from all over Poland who have resigned at least once during the recruitment process and did not proceed to its subsequent/final stages, or after being promised/provided employment did not take up work or abandoned it in a relatively short period (premature departure) without notice, any notification or explanatory information.

174 respondents took part in the study (n = 174). Such a sample obviously does not meet the criterion of representativeness, thus the results of the study do not give grounds to make generalized conclusions. Nevertheless, the acquired data may contribute to shaping the perception of this phenomenon on the part of people employing such practices.

The scope of this study does not allow for full presentation of the test results however, below are selected results and synthetic findings obtained on their basis.

- In the studied sample, ¾ of the respondents were those who participated in *ghosting* once. On the other hand, less than a quarter were those who repeatedly engaged in activities falling within its scope. Respondents for whom *ghosting* is a permanent practice when applying for

a job constituted 3%. It should be noted that seniority was not a differentiating criterion; the phenomenon of *ghosting* concerned both, those entering the labor market and those with at least 10 years of professional experience. People born between 1980-1999 (generation Y) participated in it to the greatest extent;

- Most often, it concerned administrative service positions at a similar level, i.e. approx. 20% of executive positions, specialists and managerial positions. Candidates with secondary education were almost twice as likely to use it. On the other hand, the level of use of this type of practices by employees with vocational education was relatively low. The above results have not yet confirmed the stereotypes that *ghosting* primarily concerns executive positions and employees with vocational education;
- It is noteworthy when analyzing Chart 3 that, 43% of respondents withdrew after being presented a job offer by a potential employer, and nearly 20% of the respondents quit their job a few days after becoming employed, which would indicate a relatively expensive type of *ghosting* for the employer (after finalizing the recruitment process). It cannot be ruled out that candidates/employees postpone the decision to resign/withdraw until they have full knowledge of the employment conditions;
- The reasons for resigning from the job application process (without explaining/notifying the potential employer) from the point of view of the candidate/employee are presented in Table 3.

Therefore, when it comes to the reasons that candidates/would-be employees claim to motivate them, their subjective (negative) feelings resulting from contacts with the future employer are the most important ones. They also admit that their decisions are too hasty, result from a relatively high risk appetite, willingness to "get acquainted" with the rules and the recruitment process. Finally, there is typical resistance/fear of change (especially if it concerns passive recruitment).

In summary, *ghosting* is able to manifest itself under the influence of a wide spectrum of more or less interdependent factors. Some of them can be shaped through appropriately targeted actions; the organization itself has relatively the greatest scope to act to limit this phenomenon in the context of recruiting employees;

- Referring to the need for specific actions by organizations to build countermeasures to *ghosting* in the study, an attempt was made to check whether, in current practice, companies have tried to launch possible sanctions against candidates/employees falling under the scope of *ghosting*. It turned out that only in two cases sanctions were written in the terms and conditions of recruitment. Nearly 80% of respondents using *ghosting* did not take into account any sanctions from the employer (they behaved with impunity).

Figure 3: The moment of withdrawal from the recruitment process or resignation from the offer or undertaken job

Source: Table based on author's research

Table 3: Prerequisites for resignation from the process of applying for a job depending on the candidate/employee

No.	Reasons for resignation	% share
1	Unfavorable experience after direct contact with the company/people/recruiter	31%
2	Hasty decision to participate in the recruitment	24%
3	Willing to "test oneself" (gain experience) during the recruitment process without intending to change ones current job	11%
4	Fear of making a change	10%
5	Random events	9%
6	Tendency to take risks related to the opportunity for additional benefits (not available in the current position / workplace)	7%
7	Miscellaneous (choosing a better job offer; stress and lack of self-confidence; suspicion that recruiters are dishonest during the interview)	8%

Source: Table based on author's research

- Ultimately, in 23 cases, the respondents experienced a sanction consisting in the inability to take part in other recruitment processes conducted by the same employer. Although this way of influencing the scale of *ghosting* is rather limited and should be treated as an element complementing the full spectrum of activities, it can deter the irresponsible behavior of those who report their participation in recruitment procedures;
- In the survey, the respondents referred to the nature of *ghosting* in the near future. According to 45% of the respondents, this phenomenon will intensify and spread (as a manifestation of the employees' market associated mainly with a shortage of relevant employees on the labor market). In the opinion of 30% of those surveyed, the phenomenon

will stabilize at a certain level as a "permanent element" of the game on the labor market. According to 20% of the people, it will be associated with the phenomenon of "a pendulum" in the labor market (emergence and disappearance over time). Only about 5% of the respondents indicated that it would decrease (there will be a return to the dominant position of the employer).

- In the light of this research, it appears that the " future" of *ghosting* is determined (this is additionally demonstrated by the respondents' declarations of their intention to use this type of practice in the future, although they have been slightly offset by declarations of non-use of this type of practice). Companies/organizations must take this into account and take specific measures to limit the undesirable effects of this phenomenon;
- according to directed activities related to limiting *ghosting* in the future (i.e. acquiring and retaining an employee in the company), respondents believe, it will be necessary to undertake actions focused on the development of artificial intelligence in order to reduce the demand for people to perform specific tasks (indicated by 45% of respondents). Companies will also be forced to re-evaluate motivators for work (remuneration will lose its power, other benefits will gain in attractiveness, e.g. implementation of non-routine/creative tasks, flexibility of working time) - this is expected by 34% of the respondents). There will be a need for a clear orientation of human resource management towards employee well-being and energy management of people in the organization (this is suggested by 21% of respondents).

Summary - Research Findings and Implications

The first stage of the research (the organization's perspective) has confirmed that ghosting is a real phenomenon increasing its presence in Polish companies, regardless of the size, scope of activity or industry. Most often, it manifests itself in the interruption of the recruitment process (not showing up for recruitment meetings), but quitting the job after being presented the offer or after the first days of employment also have a significant share here.

The decisive condition for the emergence of ghosting is the situation on the labor market, i.e. the free choice of employers by the job seekers and, in addition, a significant extension of various forms of temporary work and flexible forms of employment, which allow people to postpone the decision to start a permanent job until they find a fully satisfactory offer.

The recruitment process that does not meet the expectations of future employees (candidates) also constituted a very important factor triggering ghosting; expectations regarding the manner and frequency of communication, or even "getting to know" (appropriate adaptation) the company by future employees are increasing here. It is also important for them to be able to consistently implement *lifelong learning strategy* in the chosen place of employment.

As for the ghosting phenomenon from the candidate's perspective, the selection of the sample did not allow determining how common such practices are in the entire population of applicants.

However, the research shows that among those using this type of practice, the representatives of generation Y are relatively the largest group. Still, ghosting concerns people of different ages, with different seniority, those looking for a job as a contractors and those who are in the sectors of service, specialists or managers.

Respondents (candidates) see the causes of ghosting mainly on the side of employers, emphasizing the lack of positive attitude towards candidates and the lack of efficiency in the organization of recruitment processes. On the other hand, as reasons connected to themselves they attribute making too hasty decisions about participating in recruitment processes (often on the basis of passive recruitment), typical fear of changing the current status, propensity to take risks, all the more so because such practices still remain "unpunished" - few cases of sanctions e.g. prohibition of participation in subsequent recruitments of the same employer.

Due to the fact that the majority of employees anticipate that this phenomenon will spread/expand or remain stable at some level, it will be a permanent element on the labor market and due to the fact that almost half of the respondents declared their intention to use this type of practice in the future, it would be appropriate to correct the activities of companies/organizations to avoid negative effects (including the costs of unsuccessful recruitment).

It seems that improving recruitment processes may prove to be an insufficient course of action. It seems that it is necessary to create changes in the area of human resource management, including reevaluation of motivators for work (increasing the importance of those that enable development), launching activities promoting employee "well-being" and inclusion of people energy management in the organization in the subject of management in the operational and strategic dimension.

Acknowledgment

Problems of Tax Competition in The Contemporary Financial System Against the Background of The European Union

Mariusz TOMCZYK

War Studies University, Warsaw, Poland
E-mail address: m.tomczyk@akademia.mil.pl

Abstract

In recent years, due to the globalization of the world economy, progressive international economic integration, rapid technological progress and increasing competition, an increase in interest in the problems of taxation of income generated in national economies can be observed. The free movement of goods, services, people and - which is particularly important from the point of view of this article - capital is the basis for the functioning of the European Union. Entrepreneurs have the opportunity to choose the place of business, as well as the method of tax settlement that will be optimal for them - will cause the lowest tax burden. Tax competition is a phenomenon directly related to globalization processes. The liberalization of capital flows and a decrease in transaction costs have caused investors to look for attractive deposits not only in the country but also abroad. In order to increase investments in their countries, governments are trying to make them as attractive as possible from the perspective of entrepreneurs, which they can do, among others, by reducing taxes. Theoretically, a reduction in tax rates does not have to cause a decrease in budget revenues, as the tax base will increase as a result of the inflow of investors. However, if all countries decide to reduce taxes, the relative attractiveness of countries to investors will remain unchanged, while their budget revenues will decrease. The decrease in tax revenues caused by the lowering of rates with an unchanged base means that the state may spend less funds on the implementation of its tasks in the field of providing public goods. This model only presents the general concept of tax competition. In practice, its mechanism is much more complex and ambiguous. Such a process of reducing tax rates resulting in an excessive reduction of budget revenues is often called race to the bottom.

Keywords: Tax Competition, Transfer Pricing, Shifting Benefits

Introduction

In recent years, due to the globalization of the world economy, progressive international economic integration, rapid technological progress and increasing competition, an increase in interest in the problems of taxation of income generated in national economies can be observed. The free movement of goods, services, people and - which is particularly important from the point of view of this article - capital is the basis for the functioning of the European Union. Entrepreneurs have the opportunity to choose the place of business, as well as the method of tax settlement that will be optimal for them - will cause the lowest tax burden. Tax competition is a phenomenon directly related to globalization processes. The liberalization of capital flows and a decrease in transaction costs have caused investors to look for attractive deposits not only in the country but also abroad. In order to increase investments in their countries, governments are trying to make them as attractive as possible from the perspective of entrepreneurs, which they can do, among others, by reducing taxes. Theoretically, a reduction in tax rates does not have to cause a decrease in budget revenues, as the tax base will increase as a result of the inflow of investors. However, if all countries decide to reduce taxes, the relative attractiveness of countries to investors will remain unchanged, while their budget revenues will decrease. The decrease in tax revenues caused by the lowering of rates with an unchanged base means that the state may spend less funds on the implementation of its tasks in the field of providing public goods. This model only presents the general concept of tax competition. In practice, its mechanism is much more complex and

ambiguous. Such a process of reducing tax rates resulting in an excessive reduction of budget revenues is often called race to the bottom.

In order to make any assessment of the phenomenon of tax competition, it should be explained first what tax competition is. This phenomenon, connected directly with globalization processes, in particular with the increase of international capital mobility, liberalization of its flow and decrease of transaction costs causes that investors (both companies and natural persons) look for attractive deposits not only in the country but also abroad . It is common nowadays to pay your tax liabilities where they are lowest. As a result, we are dealing with tax competition defined as inefficient setting of tax rates by independent governments. The choice of a given (tax) policy influences the allocation of the mobile base (especially capital) among the regions (Member Countries) represented by their governments. As a part of tax competition, it is easy to assess differences between countries in nominal tax rates. However, it is difficult to determine the strength of the impact of effective rates differences, which are the main sign of "tax competition" on the phenomena that are considered to be its effects. For example, it cannot be clearly determined what percentage of the total decline in revenues from Corporate Income Tax in a given country is caused by a change in the effective rate of this tax in another country. In addition, the strength of the effect of the phenomenon of tax competition on a given country depends on its specificity, for example the degree of economy opening, as well as on the characteristics of the "tax competitor". After all, even if taxes are radically reduced in a country, but the risk of doing business remains very high, the likelihood of attracting taxpayers from abroad is small.

The OECD is the most important forum for cooperation in tax matters between developed countries. The organization's report on tax competition published in 1998 indicates that harmful tax competition, which is one of the effects of globalization, can lead to trade and investment distortions. By accepting this report, OECD countries have committed themselves to act jointly and individually to eliminate harmful tax practices (applied by those countries).

The purpose of this article is to present an outline of the issues of tax competition of European Union Member States and to describe the mechanisms of shifting income as part of tax optimization used by multinational enterprises (MNEs).

Tax competition in EU Member States - analysis of CIT tax rates

The Corporate Income Tax rate is a very important determinant of economic growth and competitiveness of the economy. The table below presents information on applicable CIT tax rates in European Union countries.

Table 1: Corporate Income Tax rates in EU countries

Country	Last		Previous
Hungary	9,00%	Dec/19	9,00%
Bulgaria	10,00%	Dec/19	10,00%
Ireland	12,50%	Dec/19	12,50%
Cyprus	12,50%	Dec/18	12,50%
Lithuania	15,00%	Dec/18	15,00%
Romania	16,00%	Dec/19	16,00%
Croatia	18,00%	Dec/19	18,00%
United Kingdom	19,00%	Dec/19	19,00%

Slovenia	19,00%	Dec/19	19,00%
Poland	19,00%	Dec/19	19,00%
Czech Republic	19,00%	Dec/19	19,00%
Latvia	20,00%	Dec/18	15,00%
Finland	20,00%	Dec/18	20,00%
Estonia	20,00%	Dec/18	20,00%
Slovakia	21,00%	Dec/18	21,00%
Portugal	21,00%	Dec/19	21,00%
European Union	21,30%	Dec/18	21,90%
Sweden	21,40%	Dec/19	22,00%
Denmark	22,00%	Dec/19	22,00%
Euro area	23,30%	Dec/18	24,10%
Italy	24,00%	Dec/19	24,00%
Spain	25,00%	Dec/19	25,00%
Netherlands	25,00%	Dec/19	25,00%
Austria	25,00%	Dec/18	25,00%
Luxembourg	27,08%	Dec/18	27,08%
Greece	28,00%	Dec/19	29,00%
Belgium	29,00%	Dec/19	29,00%
Germany	30,00%	Dec/19	30,00%
France	31,00%	Dec/19	33,00%
Malta	35,00%	Dec/18	35,00%

The main conclusion from the presented information (Table 1) regarding international tax competition is the fact that differences in tax rates between countries mean that resources can move to areas with low (lower) tax burdens, thanks to which they attract human and physical capital, which is an additional development stimulus for these countries. Moreover, this attraction of capital seems extremely important for countries that do not have enough domestic capital, and therefore have to rely entirely on foreign capital. In such conditions, countries are forced to compete with each other for easily displaceable capital through artificially low tax rates. As a result, globalization has a visible impact on tax structure and government spending. With the increase of international integration, governments in individual countries are losing part of their monopolistic power in the field of fiscal policy. They are increasingly in a situation of being strategically linked to their foreign counterparts. The effect of rivalry between them becomes a game of competing for tax revenues. The consequence of such tax competition may be the difficulty for the state to achieve its goals, including the financing of public expenditures.

The significance and scale of the problem within the European Union is evidenced by the data from Table 2. The content of this table shows, that before the enlargement of the European Union by New Members (2004 and 2007), most of them were subject to tax reforms leading in particular to increasing

the attractiveness of these countries in terms of taxation of corporate income. For the new countries, changes were seen as an indispensable element in preventing capital outflows to more stable Western European economies. On the other hand, for the countries of the "old" Union it was perceived as ordinary tax dumping, which is a form of unfair competition.

Table 2: Summary of CIT rates in the years preceding EU membership until accession to the European Union and the total change in CIT rates in this period for New Members of the European Union

Country	Corporate tax rates (%)				Total CIT rate change (%)
	1995	2000	2004	2007	
Bulgaria	40	32,5	19,5	10	-30
Czech Republic	41	31	28		-13
Estonia	26	26	26		-
Cyprus	25	29	15		-10
Latvia	29	24	15		-14
Lithuania	29	24	15		-14
Hungary	18	18	16		-2
Malta	35	35	35		-
Poland	40	30	19		-21
Romania	38	25	25	16	-22
Slovenia	25	25	25		-
Slovakia	40	40	19		-21

The information presented in Table 2 indicates that almost all countries have reduced their CIT rates before accession to the European Union. The exceptions are Estonia, Malta and Slovenia, which did not change their rates before accession to the European Union. A desirable situation for both the old and new Member States is to develop the Union as a whole in a way that it becomes more financially attractive. It should be noted that the diverse fiscal policy of EU countries is also an element attracting capital from outside the European Union. Although various tax rates are perceived as a sign of harmful competition (among EU Members) but at the level of EU as one economy, it contributes to the prosperity of the entire Union. This variety of tax rates incentives investors (from inside and outside EU) to chose to pay their liabilities in one of the Member States – not outside EU. Therefore, imposing an increase in tax rates on newly admitted states could be detrimental to the entire group. Although it would calm non-competitive countries. In such a situation, the EU would have to do without capital paid in taxes by enterpreneurs, who decided to transfer their income somewhere else, and the development of the poorest regions of the Union, perhaps even more than currently, would have to be supported by the funds of the general budget of the Union. This lack of (potential) source of capitał would effect on higher transfer of Member States to EU budget. From the point of view of benefits for the European Union, in the context of attracting foreign investment it would be necessary to harmonize the tax system not by raising taxes for New Members, but rather by reducing them in some countries of EU. Despite the differentiation of CIT rates in the European Union Member States, the average rate of corporate taxation in the European Union is falling. Figures below show effects of tax competetiveness in European Union.

Fig. 1: Revenue loss due to profit shifting as % of CIT revenue (2016)

Data for 2016 (Fig 1) show that the countries most affected by losses resulting from the artificial transfer of profits by corporations are Germany (EUR 18 billion), Great Britain (EUR 14 billion) and France (EUR 11 billion). The result is a serious loss of public revenue, which must be complemented by other sources of funding.

Tax havens existing within the EU apply specific legal regulations encouraging international corporations to artificially transfer their profits to their jurisdictions. One of the most frequently used tools are special purpose vehicles, often founded in the Netherlands or Luxembourg, which are becoming a vehicle for transferring capital. In this way, small businesses employing several people become entities through which billions flow. Companies bend tax law so as to be able to explain themselves to the tax office in the country of operation, while artificially transferring profits.

Fig. 2: CIT revenue collected due to artificially attracted profits (2016)

Some EU Member States benefit from artificial profit transfer. The tax gap resulting from the "CIT transfer" reaches EUR 60 billion a year in the EU. Less than EUR 12 billion of this amount is transferred to non-European countries. The lion's share - EUR 48.5 billion per year - is transferred to other Member States. The largest beneficiaries of tax optimization are: the Netherlands, Ireland, Belgium, Luxembourg, Malta and Cyprus (Fig 2).

Shifting Benefits in Economy – Transfer Pricing

Price of merchandise and service is regulated by free market and it is an result of friction between demand and supply. However, there are situations, where price is not determined by its natural factors. When independent enterprises make transaction, the terms of that transaction are determined by financial and trade strengths – especially sale prices are shaped by market. The situation is different when related enterprises make a deal. In this case one enterprise (e. g. seller) can influence on the other side (e. g. buyer). These relations may have an impact on terms of trade and for the price (and for the final amount of paid tax). Finally, transaction between related enterprises may cause aberrations in stating the revenue because one of the companies will not state revenue (cost) as high as it should if it would be an independent enterprise (transaction). In the end, it will induce lower tax paid for the government.

One of the instruments for lowering tax commitments is transfer pricing. Transfer pricing is perceived as a price set between two related companies. The main feature of transfer pricing is they are always established between related companies. Moreover the price is not affected by the market forces.

Organisation for Economic Co-operation and Development (OECD) defines transfer pricing as a price, adopted for book-keeping purposes, which is used to value transactions between affiliated enterprises integrated under the same management at artificially high or low levels in order to effect an unspecified income payment or capital transfer between those enterprises.

Eurostat defines transfer pricing as terms and conditions surrounding transactions within a multi-national company. It concerns the prices charged between associated enterprises established in different countries for their inter-company transactions, i.e. transfer of goods and services.

The definition of transfer pricing by International Monetary Fund says, that transfer pricing is a price used in a transaction between associated enterprises. When independent enterprises transact with another, market forces determine the pricing of those transactions. This may not always be the case in transactions between associated enterprises. Transfer pricing is a legitimate and necessary feature of the commercial activities of multinational enterprises. However, where the transfer prices between the associated enterprises do not accord with internationally applicable norms, they can distor the allocation of profit among the countries in which a multinational enterprise operates.

Another definition of transfer pricing comes from United Nations. Transfer pricing" is the general term for the pricing of cross-border, intra-firm transactions between related parties. Therefore, transfer pricing refers to the setting of prices for transactions between associated enterprises involving the transfer of property or services. These transactions are also referred to as "controlled" transactions, as distinct from "uncontrolled" transactions between companies that are not associated and can be assumed to operate independently ("on an arm's length basis") in setting terms for such transactions.

International enterprises with huge financial resources striving to maximize their profits use the transfer pricing instrument for tax optimization. They are carried out by large international companies but also by middle and small companies. Their aim is to transfer revenues between branches or companies forming part of a multinational enterprise in various countries, so that the largest part of them appears in countries (or areas, e. g. economic zones) in which there are lower taxes or with which a double taxation agreement has been concluded which provides for lower taxation. The figure below shows the mechanism of use of MNEs.

Fig. 3: Themechanism of use transfer pricing by multinational enterprises

For the purposes of this example, let us assume that companies A and B are companies operating in the same tax area (the income tax rate is the same - 20%). Company A is a typical post-production company, while company B deals in selling products to final product consumers. In the example, the production costs in company A are 5,000. If company A sell their products to company B directly - for 8,000, company A is required to pay income tax of 600 [(8,000-5,000) * 20%]. Let us now consider a transaction which, in effect, gives rise to the same result (Company B will buy the goods produced by company A for 8,000). Company A creates related enterprise C in country (or district, tax paradaise etc.) where tax liabilities are lower than in tax jurisdiction where A and B companies are located (in this example tax liabilities for company C is 0%). If company A first sells the goods at production costs to its subsidiary C, it will avoid taxation of income (production costs will be equal to sales revenue). Company C will sell the goods to company B with a 3,000 margin without paying any taxes. The price between related enterprises in multinational enterprise MNE is the transfer price. Thanks to transfer pricing and making a subsidiary C multinational enterprise (A and C) saved 600. The above example shows how MNEs can be used to avoid taxing their revenues. It should be noted that such transactions are one of many instruments that can be used in tax optimization. Table 3 presents other ways of shifting income.

Table 3 : Ways of shifting income from countries with higher taxes to more attractive countries in terms of income taxation

Action	Effect
Overproduction of the foreign company's production costs - a branch of a corporation	Reduction of taxation of income in the company making the purchase
Lowering the value of finished products transferred to the company - a branch of the corporation	Reduction of taxation of profits in a company producing goods
Increase in the value of intangible services that are difficult to be priced (eg know-how, licenses) purchased from foreign subsidiaries.	The value of intangible services is subjective, so the transfer of these services between branches of the same company can easily lead to the transfer of profits
Inflated interest rates and loan guarantees for payments on loans taken from foreign subsidiaries	Interest rates related to loan payments can be tax-deductible, so if they are calculated above the market interest rates, it allows the transfer of profits between different tax areas
Allocation of general business costs of the entire corporation incurred in the head office (such as: management costs, financial services, consultancy in the scope of production, marketing, distribution) and fees in foreign branches	The management of the corporation makes decisions on the distribution of central costs and the selection of profits to be charged to the costs of central services between the members of the corporation. As the cost allocation may be subjective, which in connection with the lack of cooperation between the tax services of different countries gives the possibility of making such an allocation to transfer profits to less taxed areas
Central financial management	As part of the central fund management activities, various branches of the corporation make cash transfers later shown as loans from which interest is not taxable, which gives the opportunity to transfer profits to less taxed areas

As we can see in the table above, generating additional income in an entity whose tax burden is lower leads to a reduction in the total tax burden borne by a group of related entities (MNEs). The institution of income shifting may refer to a situation when one entity belonging to multinational enterprise MNE uses in the country exemptions or tax allowances and this entity transfers profits of other entities in the form of understated prices of goods, products or services. Affiliated entities may obtain benefits also in the case when one unit belonged to MNE incurs high capital expenditures whose aim is to achieve economic benefits by the entire group and this unit is co-financed by other entities from the group by way of inflated prices for goods purchased from it. Another situation is when a subsidiary of strategic importance for the entire capital group incurs losses, the subsidiaries may sell goods for it below the cost of their acquisition or production. Thanks to such transfer pricing, such an entity may take advantage of an additional cash inflow resulting from a higher margin when selling these goods. Transfer pricing may be used by related entities as a fictitious level of costs incurred in the provision of financial, licensing and administrative services, as well as an instrument for distributing profits generated to special economic zones or tax havens.

Conclusion

Taxes are very important tool in competition between countries for foreign investors. Recent studies show that about 40 percent. profits of international corporations are passed through companies registered in tax havens, which allows them to pay very low taxes there. A comparison of corporate income tax rates in European Union countries has shown that the tax rate is undoubtedly an instrument of competition between Member States for investors. The possibility of allocating profit in the so-called tax havens is an example of using an aggressive corporate tax strategy. As a result of tax competition,

there are concerns about a "race to the bottom" with tax rates successively reduced to zero. Some scientists share the fear that low state revenues from taxes may not be sufficient to ensure financing at the appropriate level of public goods and services. However, this allegation cannot be confirmed by observation - an analysis of tax receipts in Europe does not show such trends .

In the opinion of the author of this article, the generally accepted assumption that countries with relatively low tax rates attract "unfairly" a high proportion of global capital, thereby depriving other countries (those in which the capital was generated) of the investments they need is too far-reaching. The author of the article shares the view that places (tax jurisdictions) with low taxation act as a means of relief, enabling capital to flow around the world to the most favorable investment prospects. Capital flows through them rather than remains there for purpose of financing physical capital investments. The realities of the world of business investments (for example, the need to equip with developed infrastructure or proximity to sales markets) mean that most of this investment capital will be directed back to developed countries. So it is not true that tax oases, which are an extreme case of tax competition, capture world capital - they only allow it to flow more efficiently.

However, the fact is, that money not paid in the form of tax is not public money and it is difficult to expect private investors to spend their money for social purposes.

The article outlines the issues of tax competition (at the field od Corporate Income Tax) against the background of European Union countries. The issue of tax optimization is an important area for any economy. From the point of view of an ordinary EU citizen, there is no escape from paying taxes. That is why people find it difficult to understand (and accept) how large corporations can avoid paying taxes without breaking the law. The author of the article hopes, that this paper (being one of many papers), dealing about tax competitiveness among European Union Member States will encourage other researchers to take into account this important problematic.

The Problem of Financial Bubble Determination in The Market in The Context of Modern Monetary Policy

Alexander S. AKHMETOV

Financial University under the Government of the Russian Federation, Moscow, Russia,
alexander.akhmetoff@gmail.com

Abstract

an early identification of financial bubble in the market is extremely crucial as it allows investors to reduce their potential losses and authorities to prepare for a possible recession in the economy. The last large bubble "burst" occurred in 2007 (the US mortgage crisis), but today the economic system is still not immune to such damage. Most central banks, primarily in the USA, Europe and Japan, execute an ultra-loose monetary policy and will support financial markets in case of collapse. In this regard, some traditional methods for determination of a price bubble does not work accurately, therefore there is a necessity to select the most representative ones and search for better indicators. This paper is presented a classification of various indicators of financial bubble determination with their advantages and disadvantages and the most representative indicators are selected.

Keywords: ultra-loose monetary policy, recession, financial market, financial "bubble"

JEL Classification: E32, E44, E52, G01, G1

Introduction

To begin with, it is necessary to determine what is mean by such a category as "financial bubble" in modern economic science. Despite the existence of various points of view in the scientific literature about what is considered a "financial bubble", the following definition most clearly and fully reflects its essential characteristics. A "financial bubble" is a rapid and steady increase of the asset price (more than 10%; it depends on the type of financial market) during a certain period of time, typically from 1 to 3 years, not associated with a similar growth of its fundamental value, and mostly caused by the irrationality of market participants and investors and (or) the features of the economic policy executed by government and the central bank (ultra-loose monetary policy, debt growth, etc.), after which undoubtedly an opposite movement is accrued - a significant and rapid asset price drop.

Literature Review

C. Kent and P. Lowe (1997) determine that when price bubbles "burst", primarily relate to assets that are used as a collateral for loans, the inflation will below the central bank's target and output will below potential that negatively affects the financial system stability. Therefore, in order to mitigate the consequences of bubble "burst", the central bank should use a more tightening monetary policy (an increase in interest rates), even if the inflation target may not be achieved. In addition, according to the authors, it is necessary to strengthen financial supervision and regulation. In his turn, J. Gali (2014) approves that monetary policy, including tightening one, cannot affect rational financial bubbles. Moreover, any growth in the real rate by the central bank will have a tendency to expand the bubble's size and lead to its large fluctuations.

Having analyzed the bubble on oil market in 2006-2008, D. Sornette, R. Woodard and W.X. Zhou (2009) conclude that geopolitical tensions increase the uncertainty factor, which is good base for speculations and bubble forming, the distinguishing feature of which is the divergence its market price from the fundamental and fair value. regulation and supervision.

We found a number of relevant works related to oil prices analysis: Mikhaylov A. (2018a), Mikhaylov A. (2018b). The predictive models based on the relations between oil futures prices and economic indicators are described and discussed in the following papers: Nyangarika A., Mikhaylov A. and Richter U., (2019a), Nyangarika A., Mikhaylov A. and Richter U., (2019b), Nyangarika A., Mikhaylov A. and Tang B-J, (2018). Further development of their analytical approach was done in [An J., Mikhaylov A. and Sokolinskaya N., (2019a); An J., Mikhaylov A. and Sokolinskaya N., (2019b); An J., Mikhaylov A. and Moiseev N., (2019); An J., Mikhaylov A. and Sokolinskaya N., (2019); Mikhaylov A, (2019); An J, Dorofeev M. and Zhu S., (2020); Mikhaylov A., Sokolinskaya N. and Lopatin E., (2019); Meynkhard A., (2019); Meynkhard A., (2020)]

Some interesting aspects of short-term forex market price forecasting for classical and crypto markets are analyzed in research studies of: Dorofeyev M., Kosov M., Ponkratov V., Masterov A., Karaev A. and Vasyunina M. (2018); An J., Dorofeev M., (2019); Denisova V., Mikhaylov A. and Lopatin E., (2019)

To identify financial bubbles and its time period in developed markets an econometric model can be used and the statement that current market price of asset represents discounted future dividends (B. Arshanapalli, W. Nelson and M. Pollak, 2019). If price bubble phenomena are observed immediately in some countries, then it will "burst" soon because of a lack of time for fundamental indicators to adjust to financial market indicators. S. Wang and L.Chen (2019) conclude that determining factors of financial bubble formation in the stock market are a large trading volume, high asset volatility, as well as increase in money supply and credit.

To sum up, there are different opinions about the correlation between monetary policy and financial bubble in the market in the scientific community, as well as various models have been developed for their identification.

Concept Headings

As a result of analysis of various sources by price bubble identification in the financial market, the author proposed the following classification of methodologies for its determining.

The first group is **macroeconomic indicators**, which includes:

a) *LEI- Leading Economic Index from Conference Board*. It represents the index of leading economic indicators, which is calculated based on ten indicators (average weekly initial claims for unemployment insurance, manufacturers' new orders, nondefense capital goods excluding aircraft orders and others)
b) *labor market indicators*, which are a set of macroeconomic indicators to evaluate the labor market condition. The most widespread are the unemployment rate, average weekly hours of production and nonsupervisory employees in the manufacturing sector and initial jobless claims.

The next group of indicators is called **"financial multiples"** and includes:

a) *R. Shiller 's P/E ratio* (CAPE) that is based on the traditional Price-to-Earnings multiple and calculated as the ratio of the company's market capitalization to the average real profit for 10 years
b) *Q-Tobin ratio* is an indicator according to which the total market capitalization of all companies in the financial market should be approximately equal to the cost of their replacement (book value);
c) *market capitalization to GDP ratio* (MCap/GDP) correlates the total market capitalization of all companies in the stock market with the country's GDP, so ratio compares how much the situation in the financial market relates to the real situation in the economy. It also known as the W. Buffett's ratio.
d) *the total debt to GDP ratio* (Debt/GDP) compares the country's total debt with its GDP and allows to determine the country's debt burden and find out whether economic growth is primarily caused by debt increase.

e) *gold to copper ratio* shows the price divergence between gold and copper and allows to assess the market participants feelings regarding the future prospects of the global economy as during the

recession the gold being a protective asset, its price rises, and the price of copper falls due to a reduction in industrial growth.

The third group is **indicators of interest rates and yield spreads,** including the following ones:

a) *sovereign bond yield curve inversion* which means a change in the slope of the curve, when in one of the sections it takes a horizontal or negative angle of inclination. In this case, market participants expect an early interest rate cutting

b) *the central bank key rate and the spread of stock market returns*. These indicators reflect the additional income for investor for taking on additional risks and consider the current conditions of monetary policy

The fourth group is **corporate indicators** which includes:

a) *dynamics of the number of delinquencies and defaults rate on all commercial bank loans.* The growth rate of the number of delinquencies and defaults on loans is a clear sign of excessive credit expansion and deterioration in the financial condition of borrowers

b) *buyback volume* (share repurchase by companies) allows researchers to take into account the amount of money used by companies that buy their own shares from the market, their growth rate, as well as the ratio between capital costs and dividend payments (Andreou, Cooper, Lopez, Louca, 2018). When the company does not find economically interesting and effective investment projects in the near future, capital investments are reduced, and more money goes to buyback. It pushes stock prices up and they move more away from their intrinsic fundamental value – the financial bubble forms

c) *dynamics of companies' after-tax profit.* In accordance with the fundamental analysis, with the growth of this indicator, the stock price of the company should also show similar dynamics. The divergence between the price indicator (the P/E numerator) and the after-tax profit (the P/E denominator) indicates overbought in the market and the occurrence of a bubble - in case of an outstripping price increase over profit, or about underestimation - when the price growth rate is lower than the after-tax profit growth rate.

The next group of indicators is **technical indicator,** which is represented by *VIX or volatility index (fear indicator).* It is based on the S&P 500 index and estimates expected volatility by aggregating weighted SPX put and call option prices over a wide range of strike prices.

The last, the sixth group is called **"other and exotic indicators"** and includes:

a) *the resignations of leading companies' top management* show on the one hand concern about the further development of economy and company, and on the other, getting a job advance or more favorable working conditions

b) *the dynamics of the number of pregnancies* characterizes the growth rate of the number of conceptions and indirectly shows the economic situation, since the couple will not have a baby if they are not sure that in the future they will be able to maintain him (her) and the family as a whole
However, not all these indicators are appropriate and relevant to apply today, in view of the following features of the economic policy of the leading world economies:

- ultra-loose monetary policy: ultra-low interest rates and the active use of quantitative easing, as a result, lead to an increase of the central bank's balance and money supply growth in economics and stock markets
- an increase in the debt burden both on the part of the government and the corporate sector. These measures are aimed at stimulating economic growth, business activity and achieving inflation targets (Europe and Japan).

Discussion

All of considered indicators evaluate the current situation and market data from different angles with their indisputable advantages, strong economic basis, explaining their wide distribution among financial market participants in making various investment decisions as well as with serious disadvantages that do not allow at any moment in time with 100% of likelihood to rely on the indicator's values. Main advantages and disadvantages of the groups of indicators for financial bubble determination in the market are as follows (see Table 1).

Table 1: advantages and disadvantages of the groups of indicators for financial bubble determination in the market

Group of methods	Characteristic
Macroeconomic indicators	Estimate the economic situation as a whole by analyzing the labor market and the level of debt. The inability to accurately characterize the market situation due to the lack of clear border, critical values
Financial multiples	Allow by calculating a relative indicator to compare two phenomena in the market or economy. The excess of the obtained value beyond the normative borders indicates the occurrence of an imbalance. In connection with the use of historical mean value as a reference for an indicator, the practical value of using indicators under changing conditions in the economy decreases
Indicators of interest rates and yield spreads	The most fully consider and reflect the emotions, feelings and expectations of market participants and investors, take into account the features of the current central bank monetary policy and a situation in the economy. It has positive experience in identifying past crises (inversion of the US government bond curve)
Corporate indicators	Compare the main business indicators with financial market data and take into consideration the financial condition of companies. However, there is an inappropriate comparison of indicators among themselves, which relate and reflect the result of different time periods (for example, P/E: profit is the result of the company's activities in the past, and its future assessment is included in the price), and there is also the possibility of the company intentionally distortions of the information presented in the reports.
Technical indicator	Interprets the expectations and emotions of most market participants regarding the future dynamics of financial markets and economic situation. There is not enough historical data to confirm or refute the findings.
Other and exotic indicators	They help to evaluate the current situation in the economy by analyzing indirect processes and factors. There is no solid economic basis that would explain the observed market phenomena from the standpoint of economic theory. There is a difficulty in collecting primary data and the inability to generally use the results obtained due to the peculiarities of the socio-economic development of other countries

Results

To summarize, the analysis of existing financial bubble identification methods in the context of modern monetary policy has allowed to formulate the following conclusions and recommendations:

1. The most practical and relevant methods for identifying financial bubbles in the markets are indicators of interest rates and yield spreads (a trend to hike/ cut the central bank's interest rate, the inversion of the government bonds yield curve and spreads of stock market returns), the dynamics of the number of defaults and delinquencies in loans, as well as the volume of buybacks of stock repurchases by companies, allowing to estimate the expectations of the company for the future development of the economy and the presence of attractive investments projects in the industry.

2. The least practical are VIX indicator, the dynamics of top management resignations (include in a group of other, exotic indicators) and a number of financial multiples (Q-Tobin ratio, R. Shiller's P/E, MCap/GDP) and representative of the group of corporate indicators - an indicator of the dynamics of companies after-tax profit

3. Now there is no integral indicator in the public domain that could very likely identify the financial bubble in the market in the current economic and political conditions.

Conclusion

To sum up, the identification of financial bubble in the market, which is a complex economic phenomenon and defines as a sharp and unjustified increase in asset price of terms of its fundamental value, is complicated and ambiguous process. There are many different indicators and methods that allow to identify a financial bubble before it "bursts", but it is necessary to take into account the current monetary policy, the level of rates, which significantly affect the behavior of investors and the dynamics of indices.

Abstract

Professional communication is a complex, multifaceted process, caused by many factors and its structure is complex. This fact confirms the impossibility of complete and accurate reproduction of the selected type of communication in the classroom. The study attempted to maximize the use of basic components of foreign-language professional communication. Our aim was not to imitate real-life processes, but to approximate learning situations to the natural conditions of communication. The basis for the formation of foreign language professional communicative competence of future non-language specialists is based on the types of work, the form of organization of which implies a reflexive attitude to one's own activities, which focuses not on the form of statements, but on its pragmatic focus. Such competence is both a tool and the essence of the activity. In this study, the concept of "learning to communicate" is filled with its own content, since it is about the formation of foreign-language professional communicative competence of future non-language professionals. Speaking about the requirements for the preparation of a modern specialist, it should be noted that modern programs are increasingly focused on practical training, while the emphasis is shifted from the purpose of teaching to the purpose of learning. Using a problem-based approach to teaching a foreign language for specific purposes not only makes the learning process more effective, it also structures teaching methods in accordance with modern requirements for the specialist training process and contributes to enhancing students' intellectual, verbal, intellectual and creative independence.

Keywords: Interaction, Communication, Professional Communication, Communicative Competence, Non-Language Expert, Problem Approach, Psycholinguistic Analysis.

Introduction

The concept of communication in the contemporary science is considered with close reference to the concept of activity, and such phenomenon as communication was the focus of numerous studies (Vigotskiy, 1982; Zemskaya,2006; Zimnyaya, 1991; Leontyev, 2001 et al.), development of the linguistic activity, studies on functional linguistics (Vinogradov, 1981; Kosenko, 2011; Shcherba, 1974 et al. and culture of speech (Vinokur, 1984; Golovin, 1988; Ozhegov, 1974 et al.). Research into the peculiarities of professional and pedagogical communication (Gumenyuk, 2005), analysis of different aspects of text study (Galperin, 2007; Yeshchenko, 2009; Kochan, 2008 et al.), attention to the issues of speech tiquette (Stakhiv, 2008) provided the possibility to improve teaching methods, allowed to create methodical systems that are able to solve the tasks of building communicative competence.

The terms “interaction” and “communication” being sometimes used as synonymic are interpreted in different ways by various researches.

Thus, the study “Fundamentals of communication theory” (Vasilik, 2006) deals with three approaches to the above-mentioned concepts.

The first approach lies in the identification of these terms (Vygotskiy,1982; Leontyev, 1969)

Supporters of the second approach separate these concepts (Kagan, 1988; Sokolov, 2002).

The third approach is based on the conception of information exchange and its supporters (Lisina, 1997) think that communication doesn’t cover all informational processes in society.

Language communication was singled out as an independent object of the research in the 60-70s of the XX century when structuralism as a dominant approach in language study and teaching methods exhausted its possibilities.

The works of J. Searle and J. Austin and the creation of the speech acts theory allowed to change drastically the way the utterance was considered. Traditionally it was interpreted from the point of the relation of content and expression and became to be regarded from the point of extra-linguistic activity.

In other words, the main issue in studying the act of communication were the questions: “What is one person doing when another one is speaking? What language means does a person try to use in order to achieve pragmatic goals?”

Philosophical encyclopedia gives the definition of interaction as “a process of coordination and interrelation of general subjects, in which the exchange of activity, information, and experience, skills and abilities as well as the results of activity take place; one of the necessary and general conditions of formation and development of society and personality” (…).

Famous psycholinguist A. Leontyev defines interaction as the process of establishing and maintaining purposeful, direct or indirect contact among people related psychologically.

Performing this contact allows either to change collective activity due to the coordination or incoordination of individual activities by certain parameters or perform purposeful influence on the formation and transformation of an individual in the process of collective or individual, but socially mediated activity.

Interaction can have a personal motive, can be directed by a specific communicative need, and in this case interaction serves as an independent activity and represents “the same kind of activity as productive and cognitive and in psychological respect, it has the same principal organization, i.e. it is motivated and has a specific goal” (Leontyev, 1974: 33–47).

Suggested by A. Leontiev the model of speech production includes the following stages: motivation, intention, implementation; comparison of implementation with the intention (Leontyev, 1969: 19–22.).

Correspondingly, the main characteristics of interaction as a type of speech activity are motive, goal, structure, means, subject, product and result.

Motivation forming the basis of language activity is closely related to needs.

From the point of language activity, the needs can be classified in the following way: needs aimed at the object and the goal of interaction; needs aimed at the interests of another person or society as a whole; needs aimed at the interests of the communicator himself (Leontyev, 1974: 111).

Need is objectified in a motive. Motives of interaction can also be divided into three groups.

The first group includes the motives of interaction, whose aim is to establish business relations among people to perform a necessary mutual activity.

These are the motives of business communication.

The motives of the second group imply interaction with another person or a group of people to influence an individual and a group of people.

The motive of the third group is a person's need in interaction, which is manifested in the desire to be understood.

It is the form of interaction that aimed at making closer another person to oneself in the same way as at making oneself closer to others (Graboy, 2002: 65–84).

It was the most important for this research to highlight the goals of interaction, as the curriculum of a foreign language for specific purposes was developed in the way so that students participate in communication with clearly defined goals.

Research Methods

Methodological background of the research consists of the most significant principles about social essence of a person, his or her active nature; unity of theory and practice; unity of empirical and theoretical in scientific research.

Systemic, person-centered, communicative-activity, competency-based, problem-based approaches make up methodological guidelines of the research.

To perform the research a set of theoretical and empirical methods were applied.

In our study the following theoretical methods were applied, such as analysis and synthesis; generalization and interpretation of the literature in psycholinguistics, pedagogy and teaching methods; modeling of the educational process in training foreign language for specific purposes.

To empirical methods used in our research belong social and pedagogical analysis of programs, textbooks, study guides, means and forms of education.

Main Body

Communication can be implemented with the help of different means of expression that allows to divide it into language communication, body language, communication with the help of actions, codes, and symbols.

This study is focused on the types and possibilities of language (speech) communication. In our opinion, to the most adequate types of communication that correspond with the programs in foreign language for specific purposes belong the following: business, emotional, individual and group business communication in the form of the dialogue, argumentative, socially-oriented, group subject-centered and person-centered, pedagogical communication, informative and professional communication (Leontyev, 1996; Skalkin, 1973; Yakobson, 1969).

Traditionally, in methodical literature scientists distinguish three levels in the training foreign language communication: learning a language as a language system; language learning, communication learning (Shcherba, 1974: 219).

In contemporary methodical literature published over recent years it has been stressed that it is necessary to approach communication learning from the point of pragmatics, and the goal "to teach interaction" has become generally recognized (Kuzmenkov, 2013: 169).

"Interaction" as one of the basic concepts of the methods of teaching a foreign language is recognized as a necessary prerequisite of mastering language as means of communication (Shchukin, 1984).

Moreover, interaction in the theory and practice of teaching foreign language is considered as both the aim and means of the educational process.

In our research we draw attention to another aspect, to the interaction as the means for the formation of foreign language professional communicative competence of future non-language specialists.

Specific set of the criteria and requirements to the level of foreign language professional communicative competence, outlined within inter-disciplinary approach, determined the tasks to solve in the organization of classroom studies.

In teaching foreign language communication there are objective limits to the scope of methodical goals and ambitions.

Insufficient language proficiency of students, determined and limited character of the plane of content and the plane of expression, the role of a teacher as a manager, that has to intervene with the process of communication, which can reduce the process of communication to the basic and primitive dialogic communication with the control of lexical and grammar correctness.

Efficiency of communication in the process of teaching foreign language for specific purposes is aimed at the formation of foreign language professional communicative competence, at revealing intellectual and creative qualities and potential of future specialists while discussing professionally relevant information from the point of their future job, using important forms of work organization.

Future specialists should realize the importance and necessity to acquire such forms for their further professional activity.

While selecting dominant types of communication, used at classroom studies, the main criterion is their orientation on the area of activity, thus the preference is given to business and professional communication, teamwork.

In the first place, it implies the selection of relevant areas of communication important for certain conditions of teaching spheres of communication, a number of similar communicative situations, that are characterized by uniform language stimul us of an individual, by relations among communicators and uniform communicative environment; spheres in which the processes of language communication take place in the context of skills and abilities of a certain activity, and its implementation (suggestibility and convictions), in motives and needs, affirmations, values, beliefs (Leontyev, 1974: 35–40).

Spheres of business and professional communication, in which the process of teaching communication is organized, were determined by the course program in a foreign language for specific purposes.

Professional oral communication has its own specific features, it is more strictly regulated, canonized, and what is more important, communicators in their interaction are not free to choose the means: standpoints, that are taken by the participants of spoken interaction, defined by a fixed procedure and clearly defined action framework and modes of expression.

It is important to note that professional communication means to follow strictly defined roles, that imply different communicative intentions of participants.

It is necessary to add, that at the current stage, "competitiveness" is excluded in professional language, which increases the importance of intellectual work at the text.

The speech of an expert in the process of training professional communication, though being beforehand well-thought, is not previously written. Oral speech, unlike written speech, is characterized by a particular addressee, and possibility to influence through the feedback channels; expressiveness and emotional intensity of a message, irreversibility of the message in time; possibility of complex use of different sign systems: linguistic, paralinguistic, psycholinguistic, kinetic" (Komarkov, 1975:19–23).

Professional communication has one more feature, which is polylogue by content and monologue by form. O. Berkalova notes, that "concept of audience can be divided into several types of "interlocutors".

The statement of each participant implies an answer or a question of the other participants of the process.

In contemporary professional communication, we face the dialogue in its broad sense, understanding everything spoken, as well as the dialogue in a narrow sense (Berkalova, 1989: 6).

In our research, we regard the dialogue as a polylogue in a broad sense.

As researchers note, polylogue has its own peculiarities.

Thus, for non-professional communication is inherent the fact that in the process of language communication there is the exchange of information, thoughts, statements, questions, and answers.

In this case, all participants are in an equal situation.

Statements can be exposed to analysis and criticism from another part.

The most illustrative example of such dialogue can be scientific dispute, practical seminar, roundtable discussions, etc.

Any subtype of professional communication is characterized by the fact that addressee of the information, the person for the sake of whom the communication is performed, do not become its participants, but the third interested person.

Thus, the areas of professional communication is regulated by verbal and non-verbal behavior of communicators in the process of communication.

Formation of professional communication implies singling out the training of teaching oral speech according to a strictly defined structure as a separate task.

This circumstance determined the choice of activities dominating at classroom studies in foreign language for specific purposes. The activity that develops and improves the following skills and abilities, such as to analyze, to compare, contrast, prove one's point, confute an argument, work in a team, keep to one's standpoint, becomes dominant.

The types of work that suggest reflexive attitude to own activity, that put emphasis not on the form of speech, but its pragmatic focus (What am I doing while someone is talking?) make up the basis for the formation of foreign language professional communicative competence of future non-language specialists.

This allows to shift professional communication skills and abilities into other areas of activity of future specialists.

Besides, classroom studies, aimed at formation of foreign language professional communicative competence, also leads to the formation of psychological qualities of a personality, his or her awareness and self-awareness (Lomov, 1981).

Formation of foreign language professional communicative competence of non-language future specialists is exercised according to its own rules.

It differs from specific features of natural communication that "develops as a succession of cycles with each cycle being a connected act of communication participants.

In the natural communication, the succession of cycles isn't defined by any previously formed program or determined plan.

It is quite flexible and is directed by the course of mutual activity. The important part of professional communication is the coordination of actions, performed by the participants of the communication in time (Lomov, 1979: 43).

It is also necessary to take into account that there is a great difference between the processes of mastering native and foreign languages, which is noted by many researchers.

For example, "they are separated by the element of awareness and deliberateness inherent to the training of a foreign language and on the contrary, total absence of such elements while acquiring a native language.

"In the process of acquiring a foreign language, more complicated properties of language develop earlier, related to awareness and intentions and only at the later stage more elementary properties develop, that are related to spontaneous, fluent use of speech" (Vygotskiy, 1956: 119).

"A new intellectual base doesn't develop in the consciousness of an individual, that learns a foreign language in the process of speech-mental action, a similar mental content is formed with the means of another language system" (Ignatova, 1997: 13).

Classroom studies aimed at the formation of a foreign professional communicative competence of future non-language specialists should be constructed according to the level of intensification of difficulty.
At the first stage problem-solving tasks should be chosen as the main type of activity, at the second stage – case study, that implies improvement of the following technique as analysis, comparison, argumentation, etc.; at the third stage it is worth using business role-playing game "Professional debates".

We think that the choice of the mentioned activities is adequate to the goals and tasks for formation of foreign language professional communicative competence of future non-language specialists.

Professional business segment of communication, that was singled out as a basic educational unit, defines the choice of certain language and communicative means.

Traditionally, language means include a set of lexical and grammatical units that reflect a certain functional style, language etiquette unites; to communication means belong a number of language actions, communicative tasks and situations, that are implemented within professional area of communication.

The choice of language means can turn out to be quite difficult for the course of foreign language for specific purposes.

Specific character of communication topics for discussion lies in the fact that situations are taken from a real-life and their description cannot be reduced to a closed list of lexical minimum.

In other words, standard language is distinguished by universality in the functional sphere; "scientific papers, publicists papers, scientific and technical tractates are created on the basis of this language, it is the basis of fiction literature, business letter writing" (Kozhin, Krylova and Odintsov, 1982: 23).

It is impossible to ignore the fact that general literary language isn't attached to any professional aspect of the activity of a future specialist.

The most frequent lexicon in a conversational language is a general literary lexicon. The same refers to the non-terminological scientific lexicon and other language means.

Besides, a peculiarity of the language in a professional sphere lies in the fact that it combines prepared and spontaneous forms, clichés that have to be practiced at the lesson.

Oral foreign language professional communication is characterized by a literary nature, caused by its preparedness.

This factor limits the number of functional styles, syntax and grammar structures to be practiced and included in the program.

Violation of the functional style and use of collocations shouldn't be encouraged, but in the case when the general background is followed in the necessary functional style, it is not necessary to lower the mark for the language competence.

During the organization of classroom studies, aimed at the formation of foreign language professional communicative competence of non-language specialists the control of language, communicative and professional competences was conducted separately.

It allows to make the work at every single topic more sensible for a future specialist and allows to implement principles of differentiation and individualization of education and control in practice.

Thus, it is worth evaluating students with different initial language proficiency according to different requirements: "prepared", "average" and "non-prepared".

That is, a student with lower language proficiency can get an excellent mark in case this will show that he made some progress compared to his own initial level of knowledge.

It is often mentioned in methodical and psychological literature that there should be a factor of trust in the organization of classes in language interaction.

Trustful interaction is characterized, on the one hand, by the novelty, importance and informative value of foreign language material, on the other hand, by the trust to a partner or a teacher.

We should not forget about this general methodological principle, which is conformed during classroom studies when the behavior and active participation of a future specialist can directly depend on the choice of a partner in language communication.

Specific character of professional communication of a specialist isn't consistent with the principle "suits – doesn't suit".

Therefore, during the training it is advisable to avoid allowing students to choose the partners according to the interests.

As a rule, a teacher should define the structure of the groups and roles that the participants should follow throughout an organized communication at the lessons.

Methodologists note that to achieve the results in learning, it is important to take into account not only abilities of students, their general knowledge, level of training, but, first of all, to know personal qualities of a future specialist as a personality, to know "the status of his or her personality in a team" (Baranov, Ladyzhenskaya and Lvov, 1990).

In our research, we take into account such methodological principals, but we strive to improve the ability of students to establish new communication relations, teach them to find the contact and to organize the work in a new environment, which is achieved due to a constant change of a group structure, and restriction of position choice.

Such quite strict behavior of a teacher shouldn't exclude respectful and trustful attitude to students, desire to create a favorable climate during the lessons, to provide the cooperation of the partners, on whom the result of training communication depends.

Defining the goals of the classroom and out-of-class studies as well as the choice of communicative tasks is determined depending by the working stage at a certain topic in such a way so that to provide logically justifiable organization of training of foreign language professional communicative competence of future non-language specialists.

In such a way, organization of substantive and language actions at classroom studies becomes the basis for training management of mental activity of a future specialist, as "substantive and language actions that generate thinking and direct it are subjected to management" (Itelson, 1970: 56).

It is possible to achieve this goal by means of correct task setting adequate to the forms of control as well as including analytical and synthetic part in the external plan.

Specific character of a foreign language communicative competence of future non-language specialists can be reflected in the curriculum when problem-solving and competence approaches to the course of foreign language for professional purposes are used.

Conclusions

Modern requirements for education and the qualities of a contemporary specialist imply the change of teaching methods at higher educational establishments.
The issue of methods is especially relevant in training future specialists when the focus is shifted from the traditional methodical question "how to teach" to the question "what to teach" a future expert.

Thus, speaking about language training within a cross-disciplinary approach, the attention should be focused on the fact that the acquisition of professional communication skills becomes the goal of teaching, that is mastering the ability to purposefully carry out communication, following clear formalized (canonized) rules that provide achievement of goals.

As it was stressed many times in our research, foreign language professional communicative competence of future non-language specialists is a tool and simultaneously the essence of activity as the ways of executing communicative intentions in professional communication are limited.

It is important to mention that while developing the curricula on foreign languages for professional purposes it is worth focusing attention on two basic foreign language communicative competences: reading and speaking.

An insufficient amount of academic hours for training a foreign language makes a teaching methodology expert follow the principle of "urgency and sufficiency".

It is necessary to highlight the following criteria as the content of singled out competences: definition of reading goals, choice of search orientation, determination of conceptual information blocks; revealing the sources of available information according to its origin, importance and content, etc.; fixation of retrieved information.

Communicative competence "speaking" correlates with techniques that are used in interpersonal communication and includes: establishing the contact on the basis of the evaluation of the own position, position of a conversation partner and meaning of the conversation; fixation of the position of the conversation addressee, encouragement to information transfer, its distribution, establishing the relation between the subject and the goals of a conversation, its adequacy and truthfulness; formulation and substantiation of the own position; questions, additions, elements of discussion, influence on the argumentation of the addressee, making additions or objections; making general conclusion.

Depending on the goals of a certain curriculum on the training foreign language for professional purposes the content of the levels can be diverse.

In this study, the concept of "teaching communication" is filled with its own content, since this is about the formation of foreign-language professional communicative competence of future non-language professionals.

According to the applied methods and technique, the process of formation of a foreign-language professional communicative competence of future non-language professionals is based on language competence that determines the choice of lexical and grammar material within a certain topic; taking into account psycholinguistic peculiarities of acquiring a foreign language, stage-by-stage formation of language and communication skills, and the choice of adequate means for managing this process.

Speaking about the requirements for the training of a contemporary professional it shouldn't be left without attention that the current curricula aimed at practical training. In this case, the focus is shifted from the goal of teaching to the goal of learning.

The differences in training and learning lie in the fact that the training is aimed at the transmission of knowledge on how to solve a problem, while learning has the goal to develop the skills and desire to solve a problem.

Specific character of the course in a foreign language for professional purposes requires the combination of the elements of training as well as learning.

Transfer of knowledge and skills underpinning a foreign-language professional communicative competence of future non-language professionals implies, in the first place, the application of up-to-date methods of teaching languages.

Such general methodological principle allows to use the working experience of future professionals on the material of a native language, rely on those professional communicative skills that can be

developed and improved by organizing special courses within cross-disciplinary approach, for example, “Business logic and rhetoric”, “Professional debates”, “Business role-playing games” etc., based on the problem-solving approach to the training of future non-language professionals.

Professional communication is a complex, multifaceted process with a complex structure caused by many factors.

This fact makes us admit the impossibility of a complete and precise reproduction of an outlined type of communication at classroom studies in a target language.

Taking into account the fact that training foreign language for professional purposes is aimed at the formation of a foreign-language professional communicative competence of future non-language professionals, which implies the development of communicative skills specific for particular specialities, it is reasonable to pay more attention to a specially organized polylogue communication at classroom studies.

The main criterion in choosing dominant types of communication for classroom studies should be their relevance to the area of activity, that is preference is given to business and professional communication. In our study, the peculiarity of this type of communication lies in the fact that the influence on a conversation partner is achieved due to a special organization of a text, and the behavior of communicators is strictly regulated by their positions.

The most effective types of work in the formation of a foreign-language professional communicative competence of future non-language specialists are those that allow to develop and improve the skills and abilities to analyze, compare, substantiate one’s point of view, to confute an argument, to work in a team, to stick to the position.

Using a problem-based approach to teaching a foreign language for specific purposes not only makes the learning process more effective, but it also structures teaching methods in accordance with modern requirements for the specialist training process and contributes to enhancing students’ intellectual, verbal, intellectual and creative independence.

Specific nature of language as an academic subject requires a corresponding adaptation of general-didactic method, limits it usage and reduces its forms.

The necessity to combine both methodic tasks: improvement of language competence, formation and improvement of a foreign-language communicative competence of future non-language professionals determines the algorithm of working at a topic session that implies gradual increase of difficulty of problem-solving tasks and complication of communicative tasks of professional orientation.

Abstract

The fourth industrial revolution leads to radical changes in production systems. Enterprises are looking for innovation to survive and effectively competition. The number of employees in the service-providing sector and creative industries will be increasing. In this way, creating new research space, especially in the area of the effect of working conditions on workers' psychical health and their creativity. We are already observing more and more research devoted to the individual-level psychological processes implicated in creativity highlights organizational work environment influences on those processes. The aim of this study is to identify the nature of the relationship between working conditions and the way and scope of implementation of 5S practices. This leads to identification of the objectives set for the implementation of 5S in the perspective of working conditions and an analysis of their potential and actual impact on the creativity of employees. The authors conducted bibliographic search, in-depth interviews with company managers and employees, analyzed the implementation of the 5S. Consequently, the practices used in manufacturing companies during implementation of 5S principles were identified. In the analyzed implementations the context of working conditions were not taken into account. The potential effects of the implementations on mental comfort and the creativity of employees also not included. The survey was conducted in several companies from the Lower Silesia region of Poland. In the cognitive layer the research allows for a better understanding of the phenomena accompanying the implementation of 5S practices and their effect on working conditions.

Keywords: creativity, lean management, 5S, working conditions.

Introduction

The research results presented in the article are part of a wider project on the impact of implementing the 5S practice on working conditions, employee health and their creativity. The results of the research in the part concerning the identification of goals set for the implementation of 5S in the perspective of working conditions and the analysis of their potential and actual impact on the health of employees were described in detail in the article by Cierniak-Emerych&Golej (2019). This article presents the rest of the research. This section focuses on answering the potential and actual impact of working conditions on the creativity of employees shaped during the implementation of 5S practices. The aim of this study is to identify the nature of the relationship between creativity and the way and scope of implementation of 5S practices. The analysis the problems arising at the interface between lean manufacturing and working conditions shaping creativity is the main subject of the researches. It can be said that the authors examine the sequence, implementation 5S-working conditions-creativity. Frequent practice is the transfer of LM principles and the adaptation of LM tools such as 5S to non-production areas Becker

(2001) Gapp,Fisher&Kobayashi (2008). There is even a new concept of LEAN OFFICE and a lot of literature promoting this approach, e.g. Schipper (2019).

A question can be asked if such an approach is justified in the case of: creative industries, R & D departments and other organizational units whose aim is to create innovative solutions such as: algorithms, business models, products, sales models and others. Proponents of "ordering everything" states that orderly reality organizes thinking, but the issue related to activate the mind to look for new, unconventional solutions is used in practice in a very small degree. Rather, the organization do orientate towards increasing productivity and improving "what is" Zimon (2012). This concept can be a hidden internal blockade of novelty. Another problem is if the organization wants to be creative, is it going to be a “mess” and what is the acceptable level of clutter and at what positions?

It is also necessary to ask the question: whether excessive organization of the work environment, especially in departments related to creative activity (using creative potential) is not the greatest waste. This waste is not noticeable because it is potential, blurred, and deferred benefits, therefore it is in the nature of lost benefits. The waste LM focuses on is concrete, visible and immediate. It can be said that LM consumes reserves of simple efficiency, long-term effectiveness seems to be the result of creative solutions coming from outside or inside the company. What better stimulates order or mess to create new creative solutions. This question is particularly important at the time of the triumphal march of LM philosophy and its tools by industrial organizations.

Theoretical background

5S practice as a tool for the LM concept

Acting according to the ‘lean’ concept means the most efficient use of available materials and company resources to achieve the best possible results. This mainly means a series of activities aimed at eliminating waste in the broad sense of the term, not only that occurring during the manufacturing process, but also from the entire area around it, including the network of logistic connections.

In the book by Kornicki and Kubik (2008) we read that, in Japan, three types of waste have been enumerated:

-muda (futility) - when production exceeds demand,
-mura (unevenness) - sometimes production exceeds demand, sometimes it does not,
-muri (unreasonableness) - when demand exceeds production.
This method identifies seven basic types of waste: overproduction, excess inventory, improper transport, defects, unnecessary processing, unnecessary downtime, excessive traffic. The literature indicates the entire range of LM tools from basic KANBAN, KAIZEN, TPM, through SMED, JiT, 5S. It is worth mentioning the 5S system is considered to be particularly related with shaping and even improving working conditions. Gapp et al. (2008) proves the 5S system (practice) is considered to be a tool used to support solving problems related to work organization. In the book by Karaszewski (2009) we read he reference to 5S requires consideration of:

- seiri, as sorting and elimination of what's unnecessary,
- seiton, as an expression of systematization, setting in order and segregation,
- seiso, as sweeping and cleaning category,
- seiketsu, which favours standardization and thus order,
- shitsuke, relating to self-discipline.

As a consequence of using 5S practices, safe working conditions result directly from the essence of the discussed system. This system somehow enforces the respect of legal regulations in the field of occupational safety and health, but also determines internal guidelines concerning desirable behaviours and activities at workstations, important from the point of view of providing employees with safe and healthy working conditions. Szatkowski (2014) states, that ‘*Good organization in and around your own workplace*’ is the term used to define the 5S system. To sum up, the 5S concept focuses on

instilling in employees' behaviors aimed at introducing, maintaining and perfecting order. The key concept in this method is ORDER. However, if one looks critically at the objectives and tasks of LM which are commonly discussed in literature, it can be observed without much insight that the dominant objective of LM is to improve only the efficiency of production, and ultimately its effectiveness. Timing and layouts are often defined in the light of performance radicalization, forcing an increase in work intensity and inappropriate, painful and tedious postures or increasing the risk of injuries and accidents caused by physical fatigue or fatigue related to the lack of concentration caused by mental fatigue.

Working Conditions

The analysis of the literature on the subject leads to the conclusion that in practice we are dealing with a very enigmatic approach to the definition of working conditions, which probably inspires some authors to consider the conditions we are interested in mainly or exclusively in terms of their components. Consequently, the conditions discussed are most often considered to be divided into two main groups, i.e. physical and non-physical components, within which individual items are additionally distinguished. The physical components include physical, material, chemical and biological elements such as e.g. workstation and room equipment, lighting, microclimate, noise, etc. The non-physical components mean e.g. working time, interpersonal relations, and social and living activities Cierniak-Emerych (2005).

According to many authors e.g. Krot&Lewicka (2015), the quality of the working environment consists of many elements, including: the level of trust in the organization, fairness in the organization, feeling of support from the organization and support from superiors. However, as usually, the reality is much more complex as it turns out that research demonstrated the psychosomatic character of human health.

The broadly understood work environment that maintains employees in a good psycho-physical condition also means the possibility of realizing their talents and abilities (including those resulting from temperament Strelau (1998). and level of activation). In the perspective of employees 'creativity, we are looking for such elements of working conditions that can facilitate the release of employees' creative potential. The work environment of the creative activity can differ significantly from the working conditions on the production line. In the perspective of employees' temperament, an environment that stimulates innovation can have different characteristics for different people. Searching for a uniform standard seems erroneous and paradoxical and unexpected solutions are possible. This sphere requires further and complex research.

The other side of the coin– Creativity

It is widely recognized that enterprise innovation, which should be defined as the ability to implement new solutions into the organization, is the strategic competence of a modern enterprise. Modern concepts of creativity define it as the ability to create or discover new ideas, solutions and possibilities. Amabile said (1996) *All innovation begins with creative ideas. We define innovation as the successful implementation of creative ideas within an organization. In this view, creativity by individuals and teams is a starting point for innovation; the first is a necessary but not sufficient condition for the second.* Innovation involve the generation of novel ideas. According Amabile (1988), Van de Ven (1986), Kanter (1983) Drazin, Glynn, & Kazajian, (1999) and meny another authors, creativity is usually associated with the generation of new ideas as an end to itself, innovation emphasizes the applicability of new ideas to address particular problems. The creativity of individuals and teams drives organic innovation in organizations. There is nothing to implement without creative ideas. Studies by Gonga, Huang & Farth (2009) show that employee creativity relates to overall work efficiency. This has special and obvious implications for the innovative performance of the organization. The ability to encourage employees to innovate, having the right mechanisms for managing innovation and the resources necessary to develop innovation builds a broadly understood work environment affecting individual and group creativity. At the same time determines the company's ability to use individual creativity. Supplying to the innovation development process with new ideas requires: influencing employee creativity, identifying and using social, psychological, process and other mechanisms to

identify and develop new ideas; using methods of motivation and choosing people whose competences, knowledge and skills are related to the tasks performed. 5S practices directly affect working conditions. The question that can be asked in the light of creativity is whether 5S stimulates or not creativity.

Holistic and cross-sectional studies, proposals for innovation management models, the relationship between individual creativity and innovation of the organization, conducted by Amabile (1988), Amabile & Pratt (2016), Woodman (1993), Geynor (2002), Cooper (2017), Golej (2013).

Winner of The Nobel Prize in Chemistry 2009 (2010), Thomas A. Steitz commenting on his achievements said, looking back over the development and progress of my career in science, *I am reminded how vitally important good mentorship is in the early stages of one's career development and constant face-to-face conversations, debate and discussions with colleagues at all stages of research.* This statement clearly indicates that being creative depends on the conditions and interaction with the social environment. The more social contacts at the level of discussion and ideas, the more inspiration and ideas. In practice, this means the need to create a space for exchange of views and discussions. The discussion often takes the form of which has little in common with order but is filled with passion.

As in the light of previous considerations one has individual creativity, does order and order really improve creativity? Or maybe a little mess can be a creative leaven of creativity. The following are considerations for clutter and creativity. Riposte Albert Einstein which he cited, Fedirko (2009) : "If a cluttered desk is a sign of a cluttered mind, is it a sign of what is empty?" has become the favorite motto of the mess. According to American scientists, the disorder on the desk is to stimulate the mind for hard work. Experiment of researchers Vohs, Redden & Rahinel (2013) showed that people working in disordered rooms invented more uses of the ping-pong ball. Another experience of the same researchers proved that disorder encourages people to leave the beaten path and try new things. The experiment consisted of choosing a fruit smoothie. The respondents in a neat environment preferred classic drinks, while the participants introduced into the disordered rooms decided on new combinations. Researchers Vohs, Redden & Rahinel(2013) concludes that: orderly environments promote convention and healthy choice, which can improve life, helping people abide by standards and increase well-being; disordered environments stimulate creativity, which is of great importance for culture, art and business (eg creative industries).

Fondness for order is conducive to conservatism, and creativity does not like him very much. New ideas are often the result of associating distant elements, finding common features of very different objects, so chaos can provoke you to look for similarities where you would not expect them to be found. A combination of seemingly mismatched elements can be a simple solution to a complex problem. Abrahamson & Freedman (2007) argue that "Organizing and over-organizing entail high costs that we do not notice, while ignoring the fact that people or disordered organizations are often more effective, creative and flexible."

Important from the perspective of the considerations are the studies of Whittaker & Hirschberg (2001), who examined the effects of paper-processing strategies on archive structure. They discovered different paper-processing strategies (filing and piling), filers amassed more information, and accessed it less frequently than pilers. Given the effort involved in organizing data, the filers are also loath to discard filed information, even when its value is uncertain. Filers maintain clean desktops, and do not allow papers to pile up. They systematize their archives (using alphabetical, conceptual or temporal methods for organization). In contrast, pilers have messy desktops cluttered with paper piles, making few attempts to organize stored information.
While filers seem to find it easier to access information, they do so at the cost of acquiring large archives which they then have to organize and manage. The access data suggest that in moderation, piling has the benefits of providing somewhat ready access to materials as well as reminding about tasks currently in process.

One of the basic conditions for being creative is the ability to go beyond patterns and beaten paths. In this context, many methodological suggestions have been made on how to be creative. We include the

basic ones. The concept of horizontal thinking, lateral thinking or creative intelligence. Creativity is often assessed as a function of one's ability to engage in divergent thinking. Divergent thinking can be described as thinking "outside the box;" it allows an individual to arrive at unique, multiple solutions to a given problem.

Research Methodology

Four research questions were asked in the study. The first question was: Were the widely understood working conditions taken into account when implementing solutions of lean manufacturing in companies in Lower Silesia which implemented at least LM elements? The second question was: Were the effects on the physical and mental health of workers before and after the implementation of lean methods studied? A detailed discussion of the research results regarding the answer to the first two questions was presented by Cierniak-Emerych and Golej in a previous article (2019). Another issue taken up in the study referred to the awareness of the impact of working conditions shaped by 5S practices on employee creativity. This study also examined the flexibility of using 5S practices depending on the job title and type of work performed.

This led to two research questions. Was the impact of working conditions on the creativity of employees taken into account when using 5S? Does the shaping of working conditions using the 5S method take into account the goals and specificity of work in different positions? The next part was based on the empirical material related to lean management (LM) implementations collected in three manufacturing companies in Lower Silesia which implemented LM in the form of 5S practices in 2017-2018. Given the qualitative nature of the problems discussed, the case study method was chosen to present them, with a greater focus on their in-depth understanding. Wójcik (2013) claims this was aimed to find what can be only suggested by qualitative results.

Data sources concerned the analysis of documents concerning the implementation of the 5S system in enterprises of three manufacturing enterprises. These implementations were made in 2017-2018. Participant observation and free-form interviews with managers and employees involved in the implementation of the system were also used. More specifically, an in-depth interview (IDI) was used, which is the direct method of the primary survey, with the respondent being an active object of the measurement, and the interviewees being in direct contact with the interviewers (conversation). In detail the interview was conducted in accordance with the principles proposed by Kaczmarczyk (1999). The analysis was conducted using a descriptive method. In the enterprises surveyed, the 5S method was the basic tool to reduce waste. This method was used first. Other LM methods have not yet been implemented.

Results. Analysis of 5S implementations

Performance improvement was indicated as the main goal of 5S implementations. In each of the analyzed implementations, an attempt was made to organize everything perfectly. Starting from the production hall, through the technological process, to the offices of the accounting department, technologists, in laboratories and R&D departments. In first a selection was made, all employees working in the Production, Laboratory and Office Departments marked items with red and green labels. In the next step – seiton, done the right layout to things available at the workplace, shadow tables were prepared, storage places and internal transport routes were designated. Desk photos were taken as a standard and norm.

Standardization, consisted in the development of documents which would enable all procedures to be regulated. Self-discipline: will be implemented include continuous improvement of cleaning methods, caring for the order in the workplace, following the principles of the 5S method. In the research conducted in each enterprise, the instillation of self-discipline in maintaining law and order in each of the areas of the enterprise's activity was recognized as a success. Control methods were defined: regulations, shadow boards, desk order, and other standardizing documents. The non-physical working conditions in the 5S method were shaped by stringent regulations and high expectations in terms of order.

In interviews, terms such as orderliness, order and reduction of waste were repeated. There were no such statements in the interviews as innovation and creativity.

Some employees provided book responses that were literally consistent with the leading training message.

An attempt to stimulate employee creativity was encouraged by their active participation in the 5S implementation project. Which was reflected in the expectations in terms of: identifying things to remove, proposing the organization of the workplace and / or accepting the new layout of the position, cleaning and joyful compliance with many rules (type of court etiquette).

Next, employees (in accordance with the KAIZEN concept) are expected to: propose continuous improvement of "what is" and make them feel responsible for the costs incurred. One could say that the main keynote of the entire implementation of the 5S principles is the constant search for waste.
Before and after implementation, the quantity and quality of ideas submitted were not measured in the surveyed enterprises. Entries describing labor productivity in the non-productive sphere are also not recorded. Lack of this information makes it impossible to objectively assess the impact of 5S implementation on employee creativity.

Some employees indicated that they were very much waiting for systemic settlement of matters related to order. The employees explained that they could not look at the mess in their colleagues' jobs. And they do not want to spoil the relationship with their colleagues by paying attention to the mess. Other people have signaled that the sterile order will de-personalize their workplace and will feel like guests or intruders in the company who create a mess.

The study found that with the implementation of the 5S principles, the employees felt fear:

• that they will not be able to cope with the new requirements;
• that they will not adapt to the new order, that they will have to look for something for a longer time, with the current state considered good;
• that the cleaning process will take additional time and they will not perform their basic assignments;
• that the cleaning will have to be carried out after the working time agreed with the employer (without appropriate overtime).

Conclusions

The first problem examined is the question. Was the impact of working conditions on the creativity of employees taken into account when using 5S? It was identified based on the interviews that most of the activities were aimed at improving efficiency by reducing waste of time. One of the biggest conclusions is that when introducing 5S, enterprises did not aim to support the creativity of employees. With regards to the question whether working conditions were taken into consideration during implementation of 5Ss the working conditions were not indicated as the aim of this implementation. The implementations did not validate the results of the implementation in terms of the effect of the changes on employee creativity, their well-being at work or the level of stress they experienced.

Another issue concerned the answer to the question. Does the shaping of working conditions using the 5S method take into account the goals and specificity of work in different positions? 5S practices applied in all departments did not take into account the specificity of positions and the nature of creative work. In enterprises, striving for standardization, the aspect of adjusting working conditions to various positions in the light of the demand for creativity was omitted. Another effect of standardization and systematization is that the workplace was depersonalized in favor of its standardization. Many researchers indicate that tightening the requirements for order may be associated with loosening employees' ties with the organization. The logical consequence of recognition that, order, standardization, systemization are perfect is uniformity. Such a view can, and should, be disputable. One of the reasons for progress is the tension resulting from diversity. Diversity also means a different

level of arrangement considered by a particular person as an order. Obviously, as a form of place where group activities are performed, company cannot accept excessive disorder.

Further interviews showed that the feeling of anxiety did not disappear but it was replaced by a habit that weakened its effect. They showed that the 5S method, was implemented in a way that raised a lot of concerns among employees. Other results of the 5S implementation observed during the interviews were:

• feeling pressure on perfect order and avoiding clutter at all costs,
• guilt in the absence of order,
• high employee specialization and no immediate substitution, but the possibility of quickly training a new employee,
• high specialization and inability to transfer knowledge from other areas - routines,
• higher assessment by the management staff of employees perfectly ordered than those who solve problems.

It can be said that the implementations have attempted to program employees to maintain perfect order. The 5S control system leads to the consolidation of the belief that only order is the proper state, and a dose of clutter instead of inspiration leads to internal stress, guilt. It also leads to a feeling of anxiety that a person will be judged not on what they did, but on whether they have order on their desk. People who find it hard to maintain order are assessed as those who do not have order in their thinking. Therefore, in line with the need for recognition, they degrade their self-esteem and focus on maintaining order, often wasting their creative potential.
In the area of production, a restrictive 5S approach seems justified, but where the organization needs some creativity and flashes of genius it is not justified.

The assessment of the 5S system implementation is largely determined by the temperament of person making the assessment. There is significant temperament mismatch resulting from different temperaments and personalities of people subjected to 5S pressure. For some, perfect order is not perfect enough for others, knowing what is where is enough. Previous considerations lead to the conclusion that these excessive requirements, especially for creative people, can lead to psychological problems. According to the version of the temperament division introduced by Hippocrates-Galen described by many researchers, among others Strelau (1985). Phlegmatic and melancholy temperaments try to organize everything in the smallest details, devoting a lot of time to this task. Cholerics are goal oriented. Sanguine people are interested in how others perceive them, and the concept of order is incomprehensible to them.

An important conclusion can be derived from the inverted U-theory that indicates that no extremes give the highest efficiency. It would seem that the reverse U theory, which clearly explains that no extremes of the explanatory variable give an optimal long-term effect to the explained variable, is unnoticed Czakon (2012) and Uzzi (1997). In this context, maintaining a workplace in excessive clutter is inappropriate, as is an ascetic and sterile desk.

Returning to the concept of creative thinking, it should be firmly stated that none of the implementations supported lateral thinking, divergent, creative intelligence or horizontal thinking.

We should apply such methods of shaping working conditions that will stimulate the implementation of specific goals. The results of the study encourage development of such solutions in the 5S system that, on the one hand, will ensure stimulating individual creativity, and on the other hand, will provide a level of workplace order. Responsible and safe in production processes and unconventional in creative activities. The 5S method seems too restrictive for creative activities. Such a solution may be offered by the adaptation of 5S principles to individual employees and to their temperament. It can be said that this would mean the development of the 5S+P concept.

Abstract

Industry 4.0 with its rapid development challenges academic circles to obtain scientific evidence for empirically observed phenomena. Primarily, it relates to traditional business models (BM) conversion processes. The article reveals an attempt to sort out the BM definition problem, mark out the pillars of BM and its typologies as well as BM requirements, caused by Industry 4.0 development. To this end, we analysed recently introduced BM definitions and found out that mainly they are based on either process or descriptive approach. We prove that both approaches are significant for business-model description.The review of literature devoted to business model elements revealed the divergent view of scientists on this issue. We suggest three key elements that are universal pillars for all existing business models: value creation, value capture and value offer. The following issue states the problem of business models typologies. Currently, there are just a few articles dealing with BM types in digital economy. Studied them, we identified four general types of BM: digital communities, service providers, ITCs-based production and digital brokerage. In the end, we claim three key requirements to Business Model in Industry 4.0. To our point of view, the successful business model ought to be flexible, knowledge-based and smart.

Keywords: Business-Model, Industry 4.0, BM Types, BM Definitions, Business-Model Concept.

Introduction

Business model concept is quite new and it has become topical with the development of Industry 4.0 ideas. Academic science still work on revealing the essence of business models, its varieties and its practical use for business since the IT has become widespread. Globalization and digitization are bringing new challenges for scientific circles to stand out the business model evolution specifics in scientific-technical revolution context. Despite the worldwide scientific community express fundamental and growing interest to this issue, common approaches to defining this scientific category are still not elaborated. Moreover, there are no conventional scientific paradigms corresponding to the Industry 4.0 current issues.

We suggest our own view on solving these scientific issues in the article. First, we reviewed the existing approaches to defining business model as a separate scientific category. After that, we represent the classification of these approaches and set forth our own understanding of the business models. Then, we examined the main elements of business models, which are evolved in scientific literature. Finally, the literature review allowed us to identify four most common business model types in digital economy. In conclusion we suggest the requirements that any business model should meet in the context of Industry 4.0.

Relevance. Modern approaches to business model definition

Definitional question is the initial point for any scientific research, and is particularly important for elaborating scientific theories. In fact, there is plenty of literature dealing with "business model" definition. We selected several articles to examine prevailing approaches.

During the business model conceptualization, the issue of distinguishing it from business strategy and business processes and making it a separate category was disputable. So, some authors initially separated business models from strategies. Specifically, Yip G. [2004] noted that "a strategy concerns a firm's positioning in relation to external conditions such as market competition, whereas a business model structures a firm's value-creating capabilities and value-capturing transactions'. Other authors either defined strategy as an element of business model *(Lee Y., Shin J., Park Y. 2012; Chesbrough H., Rosenbloom R. S. 2002)* or used these concepts interchangeably *(Kallio et al., 2006)*. Mutaz Al-Debei justified BM independence stating that just business model narrows the gap between business strategy and business processes in digital economy by "translating business strategy into business process" *(Mutaz Al-Debei et al., 2008)*.

BM-related literature review allows us to conclude, that mainly authors espouse the BM independency concept. There is number of definitions which are quite similar and could be generally formulated as "business model reveals understanding of how a company performs activities (transactions) to provide value to customers or/and stakeholders". The common part for all definitions is that they focus on the main feature of business model, namely creating value. The main differences are closely connected with the awareness of the beneficiary of created value – for customers *(Osterwalder A., Pigneur Y., 2010; Chesbrough H., Rosenbloom R.S. 2002; Taran Y., Boer H., Lindgren P. 2015, Müller J. M., Buliga O., Voigt K. 2018; Demil B., Lecocq X., Ricart J. E. Zott C. 2015; Yip G. 2004)* or shareholders *(Mustafa and Werthner, 2011)*, or for both parties *(Bouwman H., Nikou S., Reuver M. 2019; DaSilva C. M., Trkman P. 2014)*. Besides, it is worth noting that business model should be considered as a process since it is primarily defined as creating value.

In their works Ng I.C.L., Ding D.X., Yip N. [2013], Massa L., Tucci C., Afuah A. [2017] and Bouncken R.B., Fredrich V. *(Bouncken and Fredrich, 2016)* consider business model more widely, defining it as the way of "how organizations interact with their suppliers, partners, and customers".

Clausse T. [2017] in his article, dealing with the issue of measuring business model innovation, examines business model through the BM ability to design and represent business: "configurations, which integrate particular business dimensions". A number of researchers share this approach in their definitions, describing BM as "money earning logic" *(Osterwalder, 2004)*, "abstract representation of an organization" *(Al-Debei, 2008)*, "specific combination of resources" *(DaSilva, 2014)*, "the value logic" *(Fielt 2013; Hartkamp D., Zalewska-kurek K., Loohuis R., Haaker T. 2017)*. All the named authors consider business model as descriptive, structuring category that indicates it as static.

Figure 1 reveals modern definitions roughly divided by us into two approaches. For now, the most common approach is the process one that associates with defining BM as a process of creating a value for companies' clients.

The process approach attempts to reflect the dynamic nature of business model, meanwhile descriptive is aimed at showing it static. Indeed, business model has both properties. Business model, on the one hand, develops in time, evolves, and, on the other hand, can be described by an algorithm of actions as any other process. It manifests this scientific category in dynamism. Besides, business model in every specific moment of time could be described by combined elements or configurations, reflecting 'the value logic of a business'. Due to this, BM could be considered static category. Sociology and economics have many similarities with it. So, human model in socio-economic sciences proceeds from the concept that human is active, performs a defined set of actions that is a set of processes could describe it. Human is described with decision-making algorithms or through economic behaviour, social roles or other behavioural patterns. Meanwhile, human has a set of personality traits, knowledge, abilities and skills, that justifies using static descriptive models. These models are widely employed in human capital theory and goodwill valuation.

Fig. 1: Viewpoints of authors within BM field researching
(Source: compiled by the authors)

Accordingly, we suggest that business model is a scientific category that can be described by both static and dynamic ways. Besides, the BM's dynamic and static nature is inextricably linked. Its interaction in time forms the basis of business model evolution for single business as well as for the economy itself. So, any business model can be described as a business configuration that combines a set of elements. Evidently, business process implementation within the configuration (in other words, value creation process) is precisely dynamic property of BM. Business configuration and value creation process mutually influences each other. Supplier, client and competitor relationships generate the need in business logic transformation. Thus, business model constituent elements issue is topical from the perspective of descriptive as well as of process approach.

Business Model Elements: Contemporary Approach

Table 1 lists approaches to defining constituent elements of business models, proposed by a range of authors in recent studies. It is clear from the table that the wide gap between authors' views exists. Nevertheless, all approaches have a common element – the customer value element that incorporates

marketing elements (customer segments, value propositions, customer relationships, mission). The second group of elements, proposed by researchers, relate to income generating business processes (financing, the cost structure and profit potential, revenue streams, key resources, the value chain/network, key activities, key partnerships). And finally, the rest of mentioned elements are elements, connected with strategic management (competitive strategy, capability, globalization, organizational architecture).

Table 1: selected Scholarly Definitions of BM

№	Author(s)	Elements / components of BM	Year of research
1.	Osterwalder A., Pigneur Y.	customer segments, value propositions, channels, customer relationships, revenue streams, key resources, key activities, key partnerships and cost structure	2010
2.	Lee Y., Shin J., Park Y.	mission, offering, strategy, capability, business process, value network, financing and globalization	2012
3.	Gassmann O., Frankenberger K., Csik M.	client (Who is the target customer?), offered value (What does the company offer to its clients?), processes, activities, resources and capabilities of the company (How does the company create and provide value?), income-generating model (What is the firm's benefit?)	2013
4.	Fielt E.	the customer, value proposition, organizational architecture and economics dimensions	2013
5.	Girotra K., Netessine S.	4W approach: «What» strategy (What to sell, What to achieve, What significant issues should the BM help to solve?), «When» strategy (When should the decision be made within BM?), «Who» strategy (Who makes key decisions within BM?), «Why» strategy (Why do the key BM members make these decisions?)	2014
6.	Klimanov D.E., Tretyak O.A.	Value chain structure / inter-firm networks («frame», network); BM members interaction mechanism; BM members interaction outcome	2014
7.	Chesbrough H., Rosenbloom R. S.	BM includes the value proposition, the identification of the market segment, the value chain and value network, an estimation of the cost structure and profit potential and as last a formulated competitive strategy	2002
8.	Müller J. M., Buliga O., Voigt K.	value creation, value capture, and value offer	2018

(Source: compiled by the authors)

From our point of view, the main criteria for referring to BM elements are BM inherent properties, since it logically flows from its functional purpose – value creation. Hence, in case when there is no customer value, it is not possible to create company value and, consequently, stakeholder value.
According to Baden-Fuller and Mangematin [2013] BM's main purpose is "to capture the essence of the cause-effect relationships between customers, the organization and money". Accordingly, we suggest that the most common BM constituent elements are value creation, value capture, and value offer. However, specific content of these elements is still fuzzy, despite its importance.

What business models are corresponding with Industry 4.0?

To answer this question we reviewed recent scientific researches in e-commerce and made a list of business models that are applied in this field. Susan C. Lambert [2015] underscores the importance of justified business model type identification. The author points out that "it is widely recognized that classification is a necessary step in understanding a research area". Sharing her point of view, we find it reasonable to make typologies in the form of traditional (common sense) classifications of business model types that mentions in literature. We found only five studies that reveal e-commerce related business models in Industry 4.0 (Table 2). As indicated in table below, the listed types are lexically different. In fact, every author suggests different ways of doing e-business. In addition, the substantive content analysis of proposed typologies demonstrates significant similarities of them.

Table 2: business model types proposed in e-commerce-related researching

№	Author(s)	BM types in Industry 4.0
1.	Timmers, P. [1998]	E-shops, e-procurement, e-malls, e-auctions, virtual communities, collaboration platforms, third-party marketplaces, value chain integrators, value-chain service providers, information brokerage and trust other third-party services
2.	Rappa M., [2000]	Brokerage, advertising, infomediary, merchant, manufacturer/direct, affiliate, community, subscription, utility
3.	Weill P. Vitale M.R. [2001]	Describe eight so-called atomic business models. Content Provider, Direct to Customer, Full-Service Provider, Intermediary, Shared Infrastructure, Value net Integrator, Virtual Community, Whole-of Enterprise/Government
4.	Osterwalder, A., Pine, I. [2013]	Separation of business models (Zara, Compass Health). "Long tail" (Pulscen.ru, Price.ru and Avito.ru, Drom.ru, Zipcar). Multi-sided platforms (Surveymonkey.ru, 2do2go, Coursera, Afisha.ru). Free as a business model (2GIS, Alawar, Blizzard Entertainment). Open business models (PayPal, Qiwi)
5.	Laudon K., Traver C. [2003]	seven types of business models: portal, e-tailor, content provider, transaction broker, market creator, service provider, community provider.

(Source: compiled by the authors)

According to substantive content proposed BM types can be consolidated into more general types:

- virtual communities, all business model types, that encourage creating communities of different kind – social, professional, business-communities (according to the table 2: virtual communities, collaboration platforms, community, value net integrator, virtual community, community provider);
- service providers: from information to digital environment specific services (e-procurement, value-chain service providers, advertising, subscription, utility, content provider, full-service provider, shared infrastructure, whole-of enterprise/government, content provider, market creator, service provider, portal, e-tailor, information brokerage);
- production using internet technologies (manufacturer/direct, affiliate) – ITCs-based production;
- digital brokerage including different ways to facilitate transactions between counterparties via the Internet, such as infomediary, brokerage, intermediary, transaction broker, value chain integrators, e-auctions, e-shops, merchant, e-malls, transaction broker.

This typology is quite relative because information technologies can be connected with brokering activities as well as production can combine with own e-store.
We were unable to include in the above typology business model types by Osterwalder A., Pine I. They co-created by crowd of 470 practitioners from 45 countries a study "Building of business models" and identified the following types:

- separation of business models - three fundamentally types of businesses (customer relationship businesses, product innovation business and infrastructure business) should be “unbundled” into separate entities;
- "long tail" - offering a large number of niche products, each of which sells relatively infrequently;
- multi-sided platforms - bring together two or more distinct but interdependent groups of customers;
- free as a business model - at least one substantial customer segment is able to continuously benefit from a free-of-charge offer;
- open business models – can be used by companies to create and capture value by systematically collaborating with outside partners.

As described above, all models except for the first one – can be considered as a set of marketing strategies for doing e-business rather than business model in the sense we consider it in this article.

According to Statista [2019] Industry 4.0 in its development in the near future will lead to the emergence of service-based revenue models, mass customization, smart manufacturing, back shoring and modular workstations. Thus, authors of mentioned research outline that service-based revenue models are rapidly gaining ground due to their high return rates. It should be noted that this business model type fits our suggested typology as a form of service providers.

We consider that the need to establish “flexible production process through the use of modularized systems that can be reconfigured in quick time” *(Statista, 2019)* would affect business model development. Particularly, Industry 4.0 will make firms transform their business model in a way that would meet the three key requirements. These are:

- BM should be Flexible – business should be able to reconfigure its value creating processes to meet customers’ requirements as soon as possible;
- BM should be Knowledge-based, using frameworks for handling big data in order to maintain the high level of its flexibility;
- BM should be Smart – business model, being ‘the logic of businesses, should harmonize business processes of different level with business strategy. As we consider, in the near future this task will be accomplished by artificial intelligence that will allow establishing self-adaptive business models.

Conclusion

To conclude, the study demonstrates that there are grounds to consider business models as both dynamic and static phenomena. We also suggest considering business model as value creation process, primarily, for customers, that includes three insight pillars – value creation, value capture, and value offer. These three constitutive elements, from our point of view, are common for business models as such and reflect the static basis of the concept. The analysis of business model types in digital economy proposed in scientific literature helped us to identify four general BM types: digital communities, service providers, ITCs-based production and digital brokerage. Besides, the second BM type is able to make a higher profit. Nevertheless, any business operating in digital economy will challenge to meet the Industry 4.0 requirements. That means, that in the near future we will witness business model evolution under the influence of digital technologies.

Academic scientists will have to develop evidence-based mechanism for accomplishing complicated tasks such as creating fundamentally new business model or transforming traditional ones. In that regard, we suggest that further researches can concern: comparative analysis of business model types using different parameters (transaction costs, value creation to the firm, rate of changes, etc.) and also investigating factors that form business model features for specific sectors of economy.

Using the DEA Method Based on the Example of Analysing Polish Hospitals from the Mesoeconomic Perspective

Dariusz PORĘBSKI

Wroclaw University of Economics and Business, Wroclaw, Poland
dariusz.porebski@ue.wroc.pl

Abstract

Use the word "Abstract" as the title for the abstract section. The abstract should be no more than 250 words. It should capture research motivation, research Design/methodology, and main findings and implications. The abstract should provide an excellent summary of the paper. In Poland, the issue of the situation of health service, hospitals in particular, is always relevant. Despite the fact that debates and conferences on this topic occupy a leading position on TV, the topic remains unsolved. Health service efficiency and its measurement are important subjects as they provide information on the efficiency of the activities taken in each unit, region, borough, borough union, county, sector, i.e. in the mesoeconomic environment. The article presents and verifies research results of several authors who were the first in Poland to measure the efficiency of hospitals from the mesoeconomic perspective using the DEA method, with the outlay-oriented CCR model applied. The aim of the article is also to draw attention to the issues related to using and interpreting DEA results. One of the first mesoeconomic studies, i.e. studies of three authors based on the Centre for Healthcare Information Systems (CSIOZ) data, was analysed. One has to bear in mind the fact that these were built around different criteria and covered the problematic period preceding the implementation of the 2011 act on medical entities and the 2017 act on hospital networks.

Keywords: Efficiency, DEA, Mesoeconomic Perspective

Introduction

The efficiency of health service as well as its measurement are important subjects as they provide information on the efficiency of the activities taken in each unit, region, borough, borough union, county, sector, i.e. in the mesoeconomic environment. Contrary to business entities, medical entities do not compete for clients/patients. These entities have an excess of patients. The situation is completely opposite when it comes to financial resources necessary for completing service. According to experts and hospital directors, these are always insufficient.

In Poland, it is possible to distinguish some periods for the health service that condition legal acts:

- Act of 30 August 1991 on healthcare facilities – used to be the longest valid one; despite its imperfections, it guaranteed wide access to services and the independence of public hospitals called SPZOZ; its problem was growing debt and expenses.
- Act of 15 April 2011 on medical activity – its effect was contrary to the improvement intended. With the commercialization and privatization of hospitals, the state of health service deteriorated, throwing it into chaos due to no minimum norms defined for the number of beds and hospitals (medical entities acc. to that act), initiating uncontrolled limitation of public hospitals, payment for services, i.e. limiting access for patients; growing debt and expenses were not curbed everywhere, in some cases improvement was possible through debt write-off.

- Act of 23 March 2017 was a consequence of suspending the commercialization by the Polish government in 2016. The Parliament passed a bill that created the System of Basic Hospital Protection of Healthcare Services (Polish: *System Podstawowego Szpitalnego Zabezpieczenia Świadczeń Opieki Zdrowotnej*), the so-called hospital network. The hospitals (often the county ones) whose situation was more difficult were incorporated into a network together with larger entities.

The author managed to come across several papers on the efficiency of hospitals from the period of 2009-2012, i.e. one summarising the period of the first bill. It was a period that required changes and forced hospitals to analyse the efficiency of resources. It was concluded that SPZOZ was a deficient and ineffective legal form. It was also important to take into account the issue of rivalry among entities and voivodeships for resources for conducting their activities, which exacerbated due to commercialization. Efficient entities were supposed to keep their high contracts, whereas the less efficient ones faced to risk of being closed down. The patient, however, could not be left without healthcare. At that time, many analyses, including scientifically-based ones, were carried out that indicated how to solve the problems or presented the situation of hospital competitiveness from the mesoeconomic perspective. In this article, the author presents some solutions that were pioneering at that time and that used the Data Envelopment Analysis (DEA) method, as well as compares them and indicates difficulties in implementation.

The DEA Algorithm and The Selection of The Method

The DEA method is widely used to study economic efficiency both in business enterprises and the public or non-profit sector. One should also bear in mind the fact that it has been used to assess organizational efficiency. Undoubtedly, efficiency is one of the categories that influences the essence of an organization as a managing entity, conditions its functioning and determines its growth (Fura B. 2017: 103).

An interesting definition of the areas of DEA application comes from the following authors: John S. Liu, Louis Y.Y.Lu Wen-Min L, Bruce J.Y.Lin. Table 1 presents the results of their research. It shows the total number of academic articles and its sum indicates the main areas of the application of the DEA method.

Table 1: The most frequent areas of the DEA method applications

Real world applications	Total no. of papers	Percentage (%)	No. of papers 2005–2009	Fraction of total papers (%)
Banking	323	10.31	147	45.5
Health care	271	8.65	107	39.5
Agriculture & farm	258	8.23	140	54.3
Transportation	249	7.95	131	52.6

The results of research presented in Table 1 show that the DEA method is used in health service extraordinarily often around the world and it comes second after banking as far as publications in 2005-2009 are concerned. In Poland, such papers are still scarce especially when it comes to the topic of healthcare.

As far as the essence of the method is concerned, it refers to the function of production which tends to be extremely difficult to define in practice. In such cases, non-parametric solutions based on linear programming are frequently used. DEA stands for Data Envelopment Analysis, and Polish literature uses its direct translation (*analiza graniczna danych*) or less direct terms (*metoda obwiedni danych, metoda otoczki danych*) (Marzec, Pisulewski, Prędki 2015: 7–8).

In the DEA model, the efficiency of the j-th object (j=1,...n) transforming x_{ij} outlay (i=1,…,m) into y_{rj} results (r=1,…,s) is defined by the formula:

$$\theta_j = \frac{\sum_{r=1}^{s} u_r y_{rj}}{\sum_{i=1}^{m} v_i x_{ij}}$$

where:

θ_j – efficiency of the j-th object

v_i – outlay weights (i=1,…,m)

u_r – effect weights (r=1,…,s)

s – number of effects

m – number of outlays.

DEA makes it possible to define the so-called relative efficiency or, in other words, the efficiency of the object as compared to other objects. This method differentiates two main models: CCR and BCC. Both abbreviations are derived from the surnames of the forerunners who proposed the algorithm. The models can be outlay-oriented (they indicate how to reduce outlays while keeping a steady level of effects) or result-oriented (they provide information about the possibility of maximizing effects while keeping a steady level of outlays) (Domagała 2007: 24). In the first model, its creators W. Cooper, A. Charnes and E. Rhodes proposed linear programming whose solution consisted in maximizing the efficiency (i.e. a weighted sum of effects by a weighted sum of outlays) in the form of a CCR model (Charnes et al. 1978: 429–444). As the time passed, further models based on the CCR model were designed, incl. the BCC model (whose name is derived from its authors' surnames: Banker, Charnes and Cooper) (Banker, R.D 1989: 125-129) that allows to define the scale efficiency (Perek 2014: 223). What is characteristic for DEA is the name of the units that are taken into account in a study – they are called Decision-Making Units (DMU). The limited number of input and output indicators is a result of the fact that DEA operates more powerfully when the number of DMUs exceeds the number of the combined total of inputs and outputs by at least two times (Drake & Howcroft 1994).

Due to the mesoeconomic analysis and small number of objects in this study (16 provinces), all authors of the three mesoeconomic analyses (Guzik, Hass-Symotiuk, Biernacki) include only five variables. It is in line with the condition of the DEA model that the number of inputs (m) and outputs (s) in DEA models should be lower than the number (n) of analysed Decision-Making Units divided by 3. As a result, DEA is limited to some extent. Its basic limitation is its redundancy, i.e. overstating the number of objects indicated as efficient (Guzik B 2009: 75). This situation is especially visible in the initial models of the method. Another substantial limitation is also the sensitivity and instability of the results in the situation of using untypical data or their strong correlation. One can also indicate the limiting character of the price relativity, linked to defining efficiency by comparison to other entities. This limitation, however, applies to all multidimensional methods. Due to this feature, these methods are often referred to as benchmark methods.

To avoid redundancy, B. Guzik proposed to modify the DEA method. The model he designed is recommended to evaluate the efficiency of the entities that are not profit-oriented. This is the research area that experiences redundancy most frequently when using the classic model of the method.

Selected Studies Carried Out with The DEA Method in The Mesoeconomic Perspective

Due to their identical number of variables, i.e. 5, source of CIOZ data, similar time of research conducted and of course the mesoeconomic perspective, the analyses published by three authors: B. Guzik (2009), M. Hass-Symotiuk (2010/11) and M. Biernacki (2012) were selected.

The first author, Professor B. Guzik, selected the variables that characterize the results as (Guzik B 2009: 80):

- The percentage of people who positively evaluate their state of health (healthy), and
- The number of people treated at general hospitals (patients).

  On the other hand, the variables that characterize the outlays are:
- The net value of fixed assets in the sector of healthcare per 10,000 people (in thousand PLN) (property)
- The number of doctors per 10,000 inhabitants (people) (doctors), and
- The number of nurses per 10,000 inhabitants (people) (nurses).

Professor's research on the efficiency of healthcare conducted using the DEA method indicated that 9 out 16 voivodeships in Poland were efficient. The same research conducted using a modified method, called NPE (method of defining the efficiency of non-profit institutions) by its author, indicated that only two voivodeships could be deemed efficient in the sense of using the outlays for health service. Even though B. Guzik's proposal is interesting, research results are surprising and, according to the author, can spark some controversy.

Table 2: Comparison of results with the DEA and NPE methods for the health service by voivodeships

Voivodeship	DEA CCR result	CCR rank	NPE rank
dolnośląskie	0.84	15	14
kujawsko-pomorskie	0.98	10	7
lubelskie	0.88	12	11
lubuskie	0.86	14	8
łódzkie	1	1	16
małopolskie	0.66	16	12
mazowieckie	1	1	6
opolskie	1	1	4
podkarpackie	1	1	13
podlaskie	0.87	13	10
pomorskie	0.90	11	5
śląskie	1	1	3
świętokrzyskie	1	1	15
warmińsko-mazurskie	1	1	1
wielkopolskie	1	1	2
zachodniopomorskie	1	1	9

Source: Guzik B (2009, s. 86)

Professor Guzik explains it by the fact that both rankings are very clearly different, especially when it comes to leaders, which is linked to the redundancy of efficient objects that occurs in the CCR method. Still, it is surprising to see that the zachodniopomorskie voivodeship falls from the first position as far down as to the ninth, not to mention the podkarpackie voivodeship.

A similar analysis was carried out by the team of Professor M. Hass-Symotiuk, who conducted a comparative analysis of the measures and indicators of hospital achievements. In the 2010 publication, it was called hospital analysis (Hass-Symotiuk 2010: 271), though it should be called the analysis of the efficiency of healthcare of the sixteen voivodeships, as in the paper by B. Guzik. Due to its mesoeconomic perspective, Professor Hass-Symotiuk's research was presented once again in a publication by a new team (Kocisova, Hass-Symotiuk, Kludacz-Alessandri 2018: 132). Output variables were represented by:

- The average number of patients per bed per year
- Share of accredited hospitals as a proportion of the number of all hospitals, and
- Net profit per physician.

Input variables included:

- Average length of hospitalisation (in days), and
- Average costs of day hospital treatment in each Polish province.

The research conducted by the above-mentioned author made it possible to indicate five efficient voivodeships whose efficiency was 100%, i.e. that were first in the ranking. The list included the dolnośląskie, lubuskie and lubelskie voivodeships that were 15th and 14th (dolnośląskie), 14th and 8th (lubuskie), 12th and 11th (lubelskie) in B. Guzik's study; only the warmińsko-mazurskie and świętokrzyskie voivodeships were listed on the same positions; the wielkopolskie voivodeship had a similar position. All the remaining voivodeships were located more or less on the same positions, but for two other exceptions. The małopolskie voivodeship was classified by Prof. Guzik as last, whereas Prof. Hass-Symotiuk listed it in the upper range of the voivodeships analysed (90.8% on the efficiency scale). The kujawsko-pomorskie voivodeship was deemed as the worst and inefficient in Prof. Hass-Symotiuk's research, whereas it was 10th in Prof. Guzik's analysis. M. Biernacki's analyses also present completely different results, as shown in Table 3.

Of course, they depend on the variables selected, i.e. criteria for evaluating efficiency adopted. Using the same data sources (CSIOZ), M. Biernacki carried out a similar analysis, using the DEA method with reference to voivodeships in three different combinations. The value of the treatment outcome was expressed in each analysis by (Biernacki 2013):

- Infant mortality rate, and
- Life expectancy.

As mentioned above, the value of resources was defined in three combinations, which were (Biernacki 2014: 111):

- The number of doctors and nurses per 10,000 people and the number of hospital beds
- The number of CAT scanners and MRIs, and
- The number of doctors and nurses per 10,000 people and the number of CAT scanners and MRIs.

Table 3: Comparison of results with the DEA method according to M. Biernacki's criteria for health service by voivodeships.

Voivodeship	DEA (1)	Rank	DEA (2)	Rank	DEA (3)	Rank
dolnośląskie	0.77	11	0.64	9	0.83	11
kujawsko-pomorskie	0.94	8	0.47	13	0.83	12
lubelskie	0.64	13	0.81	7	0.81	13
lubuskie	1	1	0.55	11	1	1
łódzkie	1	1	1	1	1	1
małopolskie	1	1	1	1	1	1
mazowieckie	0.6	16	0.3	16	0.64	16

zachodniopomorskie	0.8	10	0.733	8	0.89	10

Source: M. Biernacki (2013: 259).

Table 4 shows the results of analyses by B. Guzik, M. Biernacki and the team led by M. Hass-Symotiuk. The subject literature does not include any contraindications for aggregating different research results based on different evaluation criteria. It is a considerable simplification, but it gives some kind of multidimensionality, and DEA results (which are in the 0-1 scale) facilitate it. For example, each aspect of a hospital can be evaluated separately and it can gain different results, e.g. in patient service, staff management, finance management, environment protection. The aspects may have a different value at a different moment in time, yet putting them all together provides us with a full picture of the whole entity. One can thus assume that a voivodeship with the highest final score is the most efficient from the point of view of the criteria adopted or that it reached full efficiency in a given evaluation criteria most often. Thus the podkarpackie, łódzkie, wielkopolskie and opolskie voivodeships are characterized with a high total score. On the other hand, the śląskie, świętokrzyskie and mazowieckie voivodeships have the lowest scores.

Table 4 also shows an average for the rankings presented by the authors. This average, however, does not correspond with the results of aggregated efficiency, especially in case of the lubuskie voivodeship whose average is understated by the unfavourable rank in B. Guzik's study.

It is not a perfect solution, but it makes it possible to show how the results may differ depending on criteria and time. Benchmarking can be achieved in this way, and if unified criteria and a 3-year period were applied, the Malmquist index could be used to monitor the increase or decrease in efficiency according to a given criterion.

The aggregated efficiency is shown in Picture 1.

Table 4: Comparison of results with the DEA method according to M. Biernacki, B. Guzik and M. Hass-Symotiuk's criteria for health service by voivodeships.

Results/Rank / Voivodeship	DEA acc. to M. Biernacki (1)		DEA acc. to M. Biernacki (2)		DEA acc. to M. Biernacki (3)		DEA acc. to B. Guzik		DEA acc. to M. Hass-Symotiuk		DEA Σ	Rank $\bar{x}$

Source: own compilation based on: Biernacki M (2013), Guzik B(2009), and Hass-Symotiuk (2010)

Fig. 1: Results of the DEA analysis in the mesoeconomic environment for the Polish health service.

Source: Own compilation based on the data in Table 4.

In all the three examples, the analyses were carried out from the mesoeconomic perspective, because aggregated data from the region, i.e. voivodeship, were used. What is more, they were carried out on a very small number of factors, i.e. 5 (Hass-Symotiuk 2010: 21).

Many directors who manage hospitals are skeptical about this approach of aggregating data to voivodeships and analysing that, because they would like to receive a detailed analysis of their own hospital as compared to other hospitals in the country, i.e. on the macro scale. In fact, in Poland it is very difficult to come across individual data on each hospital, because they can only be made available with the participation and upon the consent of the director of a given hospital. When one uses voivodeship data, one does not know what the share of a given hospital is in generating the achievements of the entire voivodeship; it is even unclear which hospitals were aggregated. CSIOZ does not make such information available and refers those interested to hospital directors. The CSIOZ statistics do not take into account the hospitals managed by the Ministry of Internal Affairs and Ministry of National Defence. Even though these hospitals are not in majority in Poland, some of them employ over 2,000 people and have over 500 beds, whereas the size of their assets is often 50 million PLN or more (when they are included in a mesoeconomic analysis, they can change the position of a region).

There are still many inaccuracies and crucial topics that should be analysed in depth as far as the issue of hospital efficiency is concerned. The author did not find many Polish publications on the subject. Some publications are outdated and deal with the system of healthcare from a period earlier than 1990s. Even though most papers touch upon the topic of DEA, they do not present the data sets that are owned by individual hospitals. It is probably the result of a lack of willingness and difficulty in obtaining the documentation, especially that including non-financial data of qualitative nature which are not obligatory (but are frequently key for evaluation).

Among older analyses, there is an interesting article dedicated to the DEA method applied with reference to hospitals that was presented by Prof. J. Rój in 2003. The original data for analysis were gathered by conducting a survey study and a questionnaire interview. The author contacted 49 general short-term care hospitals of the 2nd referential level in Poland (whose main objective is to carry out treatment functions of a wide medical scope), belonging to voivodeship self-governments, that used to function as voivodeship hospitals before changes were introduced. Out of the 49 hospitals, 35 decided to share the results; however, there were only 27 hospitals whose scope of data could be deemed fully credible (after verification). Thus, analyses were carried out for 27 hospitals. The period covered by the study was 1996-2001, i.e. three years before and after introducing the system of insurance and budget financing of healthcare in Poland, i.e. healthcare reform (J. Rój: 155). Although the healthcare system changed diametrically after restructuring and appointing the institution of the National Health Fund (Polish: *Narodowy Fundusz Zdrowia*), it is impressive to see as many as 27 hospitals on the list, due to the fact that it is very difficult to establish contact and obtain specific data to analyse a hospital. J. Rój measured the hospital service efficiency only, and in her paper it is assumed that the effect of a hospital operation is a medical service measured with the number of patients being treated, whereas outlays were defined as the number of beds (that are a capital substitute, or to state it in a slightly simplifying way, a hospital's entire technological fittings), the number of doctors and the number of nurses. According to the above-mentioned author, such an approach in selecting outlays and services is commonly used around the world when measuring service (technical) efficiency of hospitals (J. Rój: 155).

Due to the access to data, it is easiest to carry out DEA efficiency analyses on the mesoeconomic level. In practice, it seems important to underline gathering and analyzing macro data. In Poland, attempts have already been made at collecting data, for example in the project by M. Węgrzyn called

Portrety szpitali - mapy możliwości (Korenik, Węgrzyn: 5). This type of data would be perfect for DEA method analysis that researchers in Slovakia are already trying to apply (Hajduova, Herbrik, Beslerová S. 2015: 147)

Going back to the voivodeship analysis based on the Ministry of Health bulletins that do not include Ministry of National Defence hospitals, one has to state that the analysis which can be obtained is rather inaccurate. For example, by excluding the Military Hospital (a very big hospital with 26 wards and serving about 60,000 patients) from the analysis for the dolnośląskie voivodeship, a considerable oversight is caused in analysing the efficiency of healthcare units.

Conclusion

The aim of the article was to present and compare research results of several authors who were the first in Poland to measure the efficiency of hospitals from the mesoeconomic perspective using the DEA method. Problems in using and interpreting the results of the data envelopment analysis were also mentioned. The issue of the flaws of the DEA method was also touched upon; in this respect, one should remember not so much about its redundancy, but about the feature of the DEA method that is frequently forgotten about and that is linked to the difficulties in interpreting the results. Effective units (medical entities or regions) are often those that use small outlays (e.g. staff) to achieve high results (in the form of e.g. the number patients accepted), which means that these units may be heavily overburdened. The author would also like to state that the comparative example in the article is not perfect; it is barely an illustration of simple possibilities that the DEA method allows and of how different the results collected can be when using it.

Results of research into using the DEA method in health service from the mesoeconomic perspective by B. Guzik, M. Hass-Symotiuk and M. Biernacki were presented. Although the authors used the same data sources, they did not apply identical criteria. The results of their analysis of voivodeships are considerably different. It is a consequence of not only years (though similar) but also variables that create different criteria although they come from one source. Even in M. Biernacki's research, there may be different results when the same output variables are used but the combination of the input variables makes the difference. This means that the DEA method is criteria-sensitive. It is enough to remove one significantly differentiating parameter and the result of the analysis can be completely different. This is what actually happened in the research analysed. The zero-one nature of the DEA result makes it possible, however, to aggregate the achievements of voivodeships and show the efficiency stemming from all the achievements of the three studies, which was done by the author of this paper. The author is aware that it is not a perfect solution, but it is feasible and makes it possible to achieve a benchmarking effect of the healthcare efficiency in voivodeships.

This type of research should be carried out according to strictly defined, identical criteria, where the period of data covering three years seems to be optimum for the turbulent environment of health service in Poland. With identical criteria adopted, it is possible to replace simple aggregation with a slightly more complex Malmquist index that works well when comparing DEA results in time, and allows to estimate the improvement or deterioration of a unit's efficiency in time.

One should also remember that the essence of mesoeconomic research passes over significant units that influence the results of a region. This type of research should be conducted again and defined more precisely.

Yet for practice, it would be most important to carry out an analysis on a macroeconomic scale. It is, however, difficult and requires unit data. When submitted to the DEA algorithm, they can provide crucial solutions, benchmarking and results referring to the actual efficiency of individual medical entities.

There are still no clearly defined criteria in Polish research that would be realistic as far as data collecting is concerned and tightly linked to the aim of the research. And yet, the latest publications already include research where, for example, P. Łagowski evaluates the efficiency of providing medical services by hospitals taking into account their organizational and legal form, as well as studies the efficiency of financing selected hospital wards in the dolnośląskie voivodeship in 2012-2014. In this case, the scope of analyses was more precise, and in the other it was limited as far down as to wards. Research similar to that presented in the article was conducted by, for example, J. Kujawska, who analysed hospitals from the mesoeconomic perspective (Kujawska 2013).

Unfortunately, even though the number of articles on the application of the DEA method for the Polish health service is on the increase, it is not as impressive as in Western countries where DEA is widely used. Despite this, however, it is very positive that there are studies like those of J. Kujawska or P. Łagowski, because the DEA method itself is still being developed in Poland, even though in different fields. There are more and more new computer programs for DEA, and researchers gain expertise at interpreting results. Further studies and interesting solutions can thus be expected in the field discussed.

Abstract

The correct structure of equity capital in total assets is crucial. In fact, the suitable level of equity in total assets may lead to competitive advantage. On the other hand, the incorrect one may lead up to many problems, among other things, the loss of corporate ability to pay off its debts. Purpose of the article was to identify the impact of a high share of equity in the total assets on the turnover ratios of manufacturing companies. The paper focused on manufacturing sector in the pe-riod of sixteen years (2000-2015). In the examined interval of time over 15 thou-sand companies from the sector in question were flirted drawn from the EMIS. The gathered data enabled calculation of the following financial ratios for the itemized companies total asset turnover (TAT), fixed asset turnover (FAT), days' sales in inventories (IT), average collection period (RT), current liabilities turno-ver (CLT). Next selection of firms was carried out to pick these with a high share of equity in its total assets. The proportion was regarded to be high if it reaches fifty one percent. Businesses with quantities below this threshold have been re-jected from the sample. Later defines intervals (classes) for the equity ratio. De-pending on the value of equity, the remaining enterprise were assigned to their corresponding class. In order to analyze the impact of the size of equity on the level of turnover ANOVA test has been applied. The comparative analysis of the size of equity ratio with the turnover indexes did not confirm that there was a sig-nificant impact on the value of turnover ratios of manufacturing companies with some exceptions.

Keywords: Equity Capital, Turnover Ratios, Manufacturing Sector, ANOVA Test.

Introduction

The level of capital structure in a company concerns many different individuals and groups interested in the success or failure of a given business, the most relevant are managers, investors, lenders and creditors. Managers have a dual interest in the anal-ysis of financial performance. They estimate the efficiency and profitability of a business and assess how effectively the resources of it are being used. In turn, there are also the owners to whom managers are responsible and accountable. The key interest of the shareholders is the return on investment, but also the disposition of earnings that belong to them and the effect of business results achieved as well as future expectations about results. The main concentration of managers as well as investors is toward the business as a going concern. Creditors are focus on funding the needs of a successful business that will operate as expected. Simultaneously, they must deal with the possible negative consequences of insolvency and liquidation (Helferd, E., 2001).

The paper concerns the manager's point of view and most of all the productivity of the used of assets. In measuring the productivity, one tries to find out how hard the assets of the business are employed in generating useful activity, i.e. generating reve-nues. Knowing that the only reason an enterprise ought to own an asset is because the asset boosts incomes growth and consequently profits for the enterprise. Assets that do not directly or indirectly boosts incomes growth have no business being owned by the

company (Priester Ch. and Wang J. 2010). Moreover, the involvement of capital in circulation also affects the efficiency of asset utilization, especially when it comes to inventory manage-ment, debt collection and repayment of liabilities. Inventory management depends on sales, so sales should be estimated before target inventories can be established. The validity of inventory policy is due to the fact that errors in setting inventory levels lead to lost sales or excessive carrying costs (Brigham, E. F., and Houston, J. F. 2012). When it comes to debt collection or receivables management, the aim of collection policy is to cut down the average period of time that receivables remain unpaid as well as lower the percentage of bad debts. If credit sales are a large part of total sales, then receivables management turns to a very crucial part of the running of business. The higher the portion of credit sales, the more serious collectability of receivables is (Priester Ch. and Wang J. 2010). Besides the collection of receiva-bles period, the repayment of liabilities period is also crucial. Especially, when a com-pany is not able to pay back its debts and is trying to arrange a workout with its lend-ers. If the negotiation between the company and creditors fails, the enterprise may become insolvent and file for bankruptcy (Brealey, R. A., Myers, S. C., Allen, F., and Mohanty, P. 2012).

The above-mentioned indicators are used to assess the financial condition of en-terprises, because they have predictive and discriminatory ability in a research study by Tomczak (2014a) (2014b), et.al, (2016), Tomczak S. and Górski A. (2011) or Wilimowska (2016) also Kopiński A., Porębski D., (2015), and Zięba, (2016). Therefore, they occur in prediction bankruptcy models of course by well-known Altman, E (1968) but also Appenzeller (Hadasik), D. and Szarzec K. (2004), Legault, J.C.A. and Score A. (1987). Due 'Warning system for small business failures' by Mączyńska, E. and 'Zawadzki M. (2006), Tomczak S. (2014) for 'The early warning system,' and once again Zięba, M, Tomczak, S. and Tomczak, J. (2016).

The impact of the size of equity on corporate profitability was examined in the re-search conducted by Tomczak, S. K. (2017). Results of his research study concluded that the statistical impact of a high percentage of equity in the total assets on the profitability of manufacturing enterprises was insignificant. He also added that corporate profita-bility did not decline along with the increase equity in the total assets and the busi-nesses with a high percentage of equity in the total assets (almost one) were not char-acterized by lower profitability.

The article struggles with verification of the impact of size of equity in total assets on the turnover of an enterprise. It will allow to give an answer to question: are the companies with a huge share of equity in the total assets characterized by higher efficiency? Statistical significance of the impact of equity on productivity ratios was tested by using ANOVA test. This test is a commonly applied method for analysing dissimilarities between means of two or more groups (in this particular case differ-ences between five defined intervals of values of the indicator). This test one can assess whether the existing difference in means of examined groups is statically rele-vant.

Research Methodology

The paper focuses on production sector. The time period is set to sixteen years (2000-2015). The period is determined by data availability. In the analysed class of time over 15 thousand companies from the sector in question were flirted drawn from the EMIS (86 thousand financial reports were analyzed). The collected data enabled calculation of the following financial ratios for the itemized companies: the sales-to-assets (or asset turnover) (TAT), fixed asset turnover (FAT), days' sales in inventories (IT), average collection period (RT), payables period (CLT). Then selection of com-panies was performed to choose these with a high share of equity in its total assets. The proportion was regarded to be high if it reaches fifty one percent (according to the median of 16 years of a ratio of an enterprise). Businesses with quantities below this threshold have been rejected from the sample.

The next step determines intervals (classes) for the equity ratio. The following were chosen: 0,51-0,60; 0,61-0,70; 0,71-0,80; 0,81-0,90; 0,91-1,00. Depending on the value of equity, the remaining companies were designated to their corresponding interval. For instance a particular enterprise with the value of its equity ratio at the level of sixty five percent is going to be assigned to the interval 0,61-0,70. In addition, other computed indicators of this company will be allotted to the interval representing the size of equity. For example the business is described by the median values of indexes in the research period: ER=58%; TAT= 1,5; FAT=2,30%; IT=30; RT=60; CLT=90. The values of these indicators will point to the class 0,51-0,60 the quality of equity. Each company will be choose to its corresponding interval of the size of equi-ty. Thanks to this one can investigate how the increase in equity will influence the levels of turnover ratios. According to the size of the equity ratio different firms have been assigned to different classes. There are 1131 companies in the first class 0,51-0,60. The second 0,61-0,70 contains 1976 and in the third 0,7-0,8 there are 1847 companies. The penultimate 0,81-0,9 and the last comprise 1452 and 598 firms ac-cordingly.

The aim of setting intervals (classes) of the equity ratio is to identify its impact on corporate turnover. Making use of these classes is to answer the questions: does cor-porate turnover shrink with the increase equity in the total assets? Are the firms with a high percentage of equity in the total assets (nearing one) characterized by lowest turnover ratios?

This paper is written with the following hypothesis in mind:

- H10: A high share of equity in the total assets has statistically significant impact on the turnover of manufacturing companies.
- H1A: A high share of equity in the total assets has no statistically significant im-pact on the turnover of manufacturing companies.

The ANOVA test has applied in order to analyse the impact of the size of equity on the level of turnover (the hypothesis will be tested against the significance of 0.05). This test one can assess whether the existing difference in averages of examined groups is statically significant. The ANOVA test was applied by the use of the Statisti-ca suite.

Results

The reference indicator for turnover ratios to be analyzed with is the size of equity ratio. This index states to what degree company assets is covered by equity capital. Equity capital is needed for setting up a business. The values of this ratio circulate from zero to one, but also can be less than zero. If the value of this indicator are neg-ative the company is in danger of bankruptcy. There is, however, some regularity, the higher value of this ratio the better financial standing of a company is. Thanks to a high value of index of equity capital in financing the assets companies feel more independent of lenders of external sources of financing (Walczak M., 2007)

In order to verify importance of impact of the size of equity capital on turnover the following intervals of this ratio has been defined: 0,51-0,60; 0,61-0,70; 0,71-0,80; 0,81-0,90; 0,91-1,00. In the research sample there have been companies with the share of at least 51 percent equity in the total assets such businesses have been cho-sen. Each firm is assigned to its corresponding class of the size of equity. The ana-lysed turnover ratios are going to be compared with equity. The results are going to be presented on figures 1 through 5.

The first examined turnover ratio associated with the indicator of the size of equity is the sales-to-assets (or asset turnover) ratio (figure 1). Using this indicator, you can examine the value of sales assigned to the asset used one zloty. The increase in the value of this indicator is considered as a positive trend. The higher value of the index, the higher the productivity of engaged assets of the company is. According to the literature value of this ratio should oscillate between 0.5 and 1.5 (Kowalak, R. 2008), but the values depend on the sector (Tomczak S. K., 2014).

Fig. 1: Yearly values of the indicator of the total asset turnover within the division into classes.

During the analyzed period, the median value of the asset turnover ratio fluctuates in the range of 1,03-1,64. In the first 8 years, the value of the total asset turnover for the companies with a high share of equity in the total assets coincides with the median of the values of the indicator for the whole research sample. However, in the end of the period the values of this indicator are lower for the companies whose shares of equity in the total assets are up to 90% and up to 100%. The second analysed turnover ratio with the connection to the size of equity is the fixed asset turnover (figure 2). It is similar to the already mentioned ratio of the total asset turnover. There is only one difference in the formula. Here the value of sales is to be divided by fixed assets.

Fig. 2: Yearly values of the indicator of the fixed asset turnover within the division into classes.

By analyzing the second indictor, it can be pointed out that the median of the fixed asset turnover ratio is almost three times higher than the total asset turnover ratio and it takes values within the interval

2,67-4,20 in the period in question. It should also be noted that the value of the median for the whole sample is higher than the value for companies with equity in the assets assigned to the each interval. In addition, it has been observed that the companies that increase the share of equity in total assets have lower efficiency of asset utilization.

The third studied ratio with reference to the indictor of the size of equity is the in-ventory turnover (figure 3). This index indicates the number of days during the period the company renews its inventory. Too high a level of indicator (low inventory turns per year) is judged negatively because it shows the involvement of larger stocks, by freezing more cash. In that case the company does not manage inventory properly (Dudycz, T. 2005). It is noteworthy that innovation performance has a big impact on the inventory turnover (Lee, H-H, Zhou, J. and Hsu, P-H., 2015)

Fig. 3: Yearly values of the inventory turnover with the division into classes.

The values of the inventory turnover ratio are strictly related to the nature of the business. In this industry, maintenance of a stock at the right level is crucial. Based on the analysis of the figure 3, it is found that median value of the indicator for whole sample oscillates between 33-41 days. It can be said that the values of the indicator for the whole sample coincides with the ones for the companies possessing equity in the total assets in the interval 0,5-0,60; 0,61-0,70 and 0,71-0,80. However, the median values are varied for these companies whose shares of equity in the total assets are up to 90 % and up to 100%. Because over the period considered the medi-an value for these companies are either higher or lower than the median value for the whole research sample.

The fourth calculated ratio with reference to the indictor of the size of equity is the receivables turnover ratio (figure 4). The receivables turnover ratio means the average number of days which payment is due from customers (Richard, A. B., Stewart, C. M., & Alan, J. M. (2016). A high level of this index demonstrates sloppy revenue collection policy, which is troublesome for the compa-ny as it means greater involvement of capital in the circulation and higher credit risk. High levels may signal the presence of hard recoverable receivables, uncollectible in the future (Mohr, A. 2006).

Fig. 4: Yearly values of the receivables turnover with the division into classes.

The median value of the receivables turnover ratio for whole sample during the peri-od oscillates in the range of 52-60 days. In addition, also here the median of the val-ues of the ratio for the whole sample do not coincides with the businesses whose shares of equity capital in the total assets are very near one.

The last ratio that is analyzed in connection with the size of equity is the current li-abilities turnover (figure 5). This indicator is the average number of days during which the obligations towards suppliers is repaid. The value represented by the indicator shows the average number of days that have elapsed from the date of purchase of goods, materials or services to the date of payment. Both the receivables turnover and the current liabilities turnover shall be considered together, especially when the date of outflow liabilities is shorter than the period of inflow of accounts receivable.

Fig. 5: Yearly values of the current liabilities turnover with the division into classes.

Having analysed the current liabilities turnover ratio, one can conclude that the value of this ratio for the companies with a high share of equity in the total assets is lower than the median of the values of the ratios for the whole research sample that resides in the interval 67-80 days. The companies whose shares of equity in the total assets are very near one generate the lowest values of this indicator. The companies repay its liabilities approximately four times faster than companies in the sector.

It is worth noting that for sector median there is a significant difference between the debt collection and repayment of liabilities. This situation for companies in the sector is very beneficial because at first

businesses in the sector recover its accounts receivables, and then after approximately 18 days pay their own debts. As a result, sector companies have spare cash, which can invest, for example on a bank deposit until repayment of obligations. However, the companies with a high share of equity in total assets do not have the positive trend in collecting receivables and paying their debts. The ones outflow its liabilities on average of 21 days and inflow receivables on average of 50 days. It can be considered as negative phenomenon, as companies have to find the money 29 days before the collection of accounts receivable.

Based on the study it can be concluded that companies with a higher share of eq-uity in total assets are characterized by a lower efficiency in employing assets. De-spite this it cannot determine any level of statistical relevance of the individual clas-ses of the median. Thus the level of relevance of differences between the intervals is going to be verified by means of the ANOVA test (table 1). Before the ANOVA test was used, the values of the indicator were cleared from outliers in order to reach a normal distribution.

Table 1: Results of the ANOVA test for the investigated intervals of values of median for the itemized financial indicators (2000-2015)

Year	Class\ Ratio	TAT	FAT	IT	RT	CLT
2000	1	no	no	no	no	5
	2	no	no	no	no	5
	3	no	no	no	no	no
	4	no	no	no	no	no
	5	no	no	no	no	1,2
…	…	…	…	…	…	…
2010	1	5	5	5	no	yes
	2	4,5	5	5	5	yes
	3	5	5	5	no	yes
	4	2,5	no	no	no	yes
	5	yes	1,2,3	1,2,3	2	yes
…	…	…	…	…	…	…
2015	1	no	no	no	no	3,4,5
	2	no	no	no	no	3,4,5
	3	no	no	no	no	1,2,5
	4	no	no	no	no	1,2
	5	no	no	no	no	1,2,3
legend 1 =0,51-0,60; 2 = 0,61-0,70; 3 = 0,71-0,80; 4 = 0,81-0,90; 5 = 0,91-1,00; no = difference between the compartments are statistically insignificant; yes = difference between the compartments are statistically significant						

By analyzing table 1, it can be stated that the differences between intervals in most cases in the period were statistically irrelevant apart from the current liabilities turnover ratio. From 2006 through 2015 the dissimilarities are statistically relevant for this ratio. The results for current liabilities turnover ratio only confirm that the higher share of equity in the assets the lower corporate turnover will be.

Conclusions

Fifteen thousand manufacturing companies were analyzed in this paper in the pe-riod of sixteen years (2000-2015). The businesses that possessed a high percentage of equity in the total assets were selected among all businesses being examined for fur-ther consideration. The relevance of the impact of equity

ratio on turnover ratios was verified by calculating several financial indicators: total asset turnover (TAT), fixed asset turnover (FAT), days' sales in inventories (IT), average collection period (RT), current liabilities turnover (CLT) and by employing ANOVA test.

Statistical analysis of the data pointed out that values of the median of the tested turnover ratios for the manufacturing firms with high share equity in the total assets were slightly different than the median of values for the whole research sample that equals to fifteen thousand companies. The greatest impact of the size of the equity in the assets on turnover can be observed by analysing the values of current liabilities turnover ratio. The ANOVA test also confirmed that the difference between intervals were relevant for examining dissimilarities between the averages in the selected groups for current liabilities turnover ratio. However, it can be conclude that the sta-tistical influence of a high share of equity in the total assets on the turnover of manu-facturing companies was irrelevant. Therefore, the null hypothesis should be rejected.

It is worth adding that the estimation of median of ratios for the whole research sample can be considered as the standard value for the selected indexes of the man-ufacturing sector. The standard values of indexes for the selected sector oscillate in the range:

- 1,03 – 1,64 for the total asset turnover ratio,
- 2,67 – 4,20 for the fixed asset turnover ratio,
- 33 – 41 days for the days' sales in inventories ratio,
- 52 – 60 days for the average collection period ratio,
- 67 – 80 days for payables period ratio.

Future research will cover a broadened research area of companies – the analyses will go beyond manufacturing companies.

Examining the Drivers of Human Development in European Union

Maria-Daniela TUDORACHE

Bucharest University of Economic Studies, Bucharest, Romania,
E-mail: mariadanielatudorache@gmail.com

Abstract

This paper provides an analysis of the human development drivers in the European Union. The variables used cover the 2010-2017 period, during which the Member States have faced different economic and social challenges generated by the global economic crisis. In the analysis, I used Panel Estimated Generalized Least Squares, weighted with the Period SUR option. The paper confirms a direct relationship between three independent variables (life expectancy, corruption perception index and gross fixed capital formation) and the dependent variable - the human development index. In this context, the study demonstrated that a decrease in the dimension of corruption leads to an increase in the human development, since the growth of corruption perception index is associated with a fall in the corruption dimension. On the other hand, an inverse relationship was identified between the other two exogenous variables (the share of people leaving education and training early, respectively employment in agriculture) and the human development index.

Keywords: Human Development, Corruption, Employment, Education

JEL Classification: O15, D73, I25, J21

Introduction

Economics is a science that generally focuses on maximizing results, and for this reason, sometimes, it fails to address the social challenges that nations are facing with. In some cases, economic policies are targeting utopic results such as economic growth objectives without having in mind any social costs, and do not attach much importance to the fundaments of a healthy economic growth, namely human development.

Especially, human development is related to the quality of health and education systems and standard of living, factors that are also taken into consideration by United Nations Development Programme (UNDP) in computing the Human Development Index, the most used proxy for human development in scientific economic literature. However, the main economic researchers followed the UNDP methodology in their attempts to assess the impact o human development drivers, but in my view there are also other variables that may drive the human development, as is the case of corruption. In this context, I defined the drivers of human development by using corruption, early leavers rate (as a substituent for education), life expectancy (as UNDP methodology indicates - as a substituent for health), and a combination of employment in agriculture and gross fixed capital formation (which may be relevant for standard of living).

The motivation for choosing this topic consists in the lack of studies focusing on the main drivers of human development at a granular level, as I indicated above, but also in the fact that human development is the first thing that economists should have in mind in designing sustainable economic growth policies.

Bearing in mind all the arguments I have mentioned, the main objective of the paper is to determine the impact of human development drivers, which can be ensured by reaching the following specific objectives:

- ✓ estimating the impact of corruption on human development;

- ✓ computing the impact of early leavers rate on human development;
- ✓ estimating the impact of life expectancy on human development;
- ✓ computing the impact of employment in agriculture on human development;
- ✓ estimating the impact of gross fixed capital formation on human development;
- ✓ validating the maximum verisimilitude of the estimators.

Literature Review

The scientific economic literature in the field of human development is vast, and many studies used different approaches to assess the impact of human development drivers. First of all, Dinu (2006) stated that success of modernisation depends on the focus of the economic transformation on the human dimenssion, which can be driven by actions in the field of education, civic participation of the population and political will to promote the values of democracy and legality.

Shah (2016) showed that some determinants of the human development index, including literacy rate and life expectancy at birth, had a positive impact on human development, given that countries with a higher level of the mentioned exogenous variables registered also a higher value of the human development index.

On the other hand, Sangali (2016) demonstrated that life expectancy at birth had a positive impact on the human development index, with the mention that positive evolutions of the the life expectancy shall be promoted by the government through high quality health programs. The author's recommendation is that high quality health programs should be expanded to cover a higher number of the individuals, especially to improve the access of the poor population to high quality medical services. Another author, Crafts (1997) examined the interaction between the index of human development and growth of the gross domestic product per capita for 16 developed countries since 1870, concluding that the conventional measures which had supported economic growth have led to a improvement of the life expectancy. Also, Khodabakhi (2011) examined life expectancy and education in India over the period 2005-2010, finding that low rates of life expectancy at birth led to a decline in the human development index. From another point of view, Farid (2010), stated that since the begining of the Enlightenment, education has been considered the way by which human capital is formed, this being a therapy for the soul - necessary for human development.

Regarding the impact of investments on development, several authors (Jalava and Pohjola, 2002; Daveri, 2002 and Stiroh, 2000) found a positive impact between these two variables in developed countries. Moreover, Bankole et al. (2011) showed that countries investing in technology, information and communication sectors also registered an increase in the human development index, given that this have the ability to improve the standard of living and educational outcomes. Mughal and Manzoor (1999) proved that high quality education leads to social development, given that the educational system will advance high-skilled people to hold responsible positions in public and corporate administrations.

Anderson (2010) analysed the effects of increased trade and investment in the US and Mexico, demonstrating that investment had a major impact on the human development index. Moreover, Arcelus et al. (2005) examined the effects of foreign direct investment on human development in the case of middle - and low-income countries, finding a positive impact for both country groups.

Sharma and Gani (2004) assessed the effects of investment on human development for two groups of countries and found that states with a higher level of human development attract more foreign direct investment, which also positively influences the human development for both country groups. Another opinion is that of Gokmenoglu et al. (2018), which states that foreign direct investments are very important for the host country, contributing to the human development and to the increase of the income of high-skilled graduates. This proves that attracting FDIs should be a priority in the policy-making process.

Mauro (1999) and Robinson (1999) stated that corruption generated high costs for political, economic and social dimensions, respectively lowered the level of investment (Rose-Ackermann, 1996). The direct relationship between corruption and human development was also analysed by Qizilbash (2001) and Akcay (2006) which found a negative impact of corruption on the dependent variable. This hypothesis was also supported by Bscherair and Tahtane (2017), but they argued their conclusion stating that corruption impede human development through the channel of political instability. Other authors (Nielsen and Haugaard, 2000) stated that this inverse relationship also affect the democracy state of play.

Jianu et al. (2019) concluded that linkage between income inequality (a relevant indicator for the social dimension) and its determinants depends on the institutional quality, this kind of inequality being more persistent in countries with extractive institutions that are also associated with states facing high levels of corruption.

Absalyamova et al. (2016) have shown that stability of human capital development is largely determined by the high level of corruption in Russia, the lower values of corruption being associated with increasing human development, reducing income inequalities and increasing economic growth rates.

Methodology

In this section, I have described the techniques used to estimate the impact of the human development drivers, using a quantitative method to provide a rigorous construct for this analysis.

The method used aims to bring an added value in this field by examining the determinants of the human development index (HDI) over the analysed time period. In order to analyse this phenomenon, I started from establishing and verifying the following hypotheses:

- ✓ Human development index is positively influenced by life expectancy;
- ✓ The increase in the number of people leaving early the education and training systems negatively influences the human development index;
- ✓ The growth of corruption perception index (which reflects a fall in corruption level) leads to an increase in the human development index;
- ✓ The increase of people employed in agriculture favors the fall of human development.
- ✓ Human development index is positively influenced by gross fixed capital formation.

In the paper I used the panel technique, given that this approach is considered effective because it improves the robustness of the estimation and increases the degrees of freedom. On the other hand, it may trigger other challenges, such as the correlation between cross-sections and heteroscedasticity.

For testing the stationarity, I have used the Summary window, respectively the automatic lag selection option using Schwarz Criterion, which provides an overview of the following tests: Levin, Lin & Chu t*; Breitung t-stat; Im, Pesaran & Shin W-stat; Augumented Dickey-Fuller - Fisher Chi-Square; Phillips-Perron - Fisher Chi-Square. The technique used indicated that the variables included in the model are stationary at the initial level and at the first difference, which motivates the use of an Autoregressive Distributed Lag (ARDL) model. However, I have tried to isolate the impact of the autoregressive term, taking into account the specific lags of the independent variables in accordance with the economic theory.

To reach the main objective of the paper, I used the Estimated Generalized Least Squares (EGLS) method weighted with the Period SUR option. This option was used to support the efforts for validating the model, respectively to avoid the occurrence of heteroskedasticity and of the general correlations between cross-sections.

In the process of identifying the method for estimating the effects , I initiated the Hausmann test (which verifies the compatibility with the Random Effects Model) and the Redundant Fixed Effects - Likelihood Ratio (which checks the compatibility with the Fixed Effects Model). The probabilities associated with the tests confirmed the compatibility with both models, which did not facilitate the

choice of an optimal estimation method, especially, since the Fixed Effects Model does not allow the use of the Period SUR option. In this context, I used an estimation method without effects that allowed the use of the mentioned option.

The data used in the paper have an annual frequency and covers the 2010-2017 period, for all 28 Member States of the European Union, in order to facilitate a comprehensive analysis of the human development. The statistical data used in the analysis are published by United Nations, Transparency International, Eurostat and AMECO, as shown in *Table 1*. Following the introduction of these variables in the model, 196 observations resulted.

Table 1: Structure of the model

Variable	Source
Human development index	United Nations
Life expectancy	AMECO
Early leavers from education and training (18-24 age %)	Eurostat
Corruption perception index	Transparency Internationals
Employment in agriculture (% of total employment)	Eurostat
Gross fixed capital formation (% of GDP)	Eurostat

Source: *Own processing using Microsoft Office 2016*

In order to verify the heteroskedasticity I used the Breusch-Pagan-Godfrey test, for which I estimated the equation manually, given that Eviews does not display this test result in the panel window. In this respect, I estimated the following equation:

$$hdi100 = \alpha + \beta_0\, life_expectancy + \beta_1\, early_leavers + \beta_2\, corruption(-1) + \beta_3\, \text{employment_agriculture}(-1) + \beta_4\, \text{gfcf} + \varepsilon_t$$

, where *hdi100* is represented by the human development index multiplied by 100, *life_expectancy* is represented by life expectancy expressed in average age at born, *early_leavers* is represented by the share of early leavers from education and traning, *corruption (-1)* is represented by corruption perception index lagged by 1 year, *employment_agriculture (-1)* is the share of employment in agriculture in the total occupied population lagged by 1 year and *gfcf* represents the share of gross fixed capital formation in GDP, while ε_t represents the error ter.

Following the estimation of the equation, I used the "CHISQ.DIST.RT(n*R2, Ω)" function from the Microsoft Office Excel software [where n is the number of observations (in this case, 196), R2 is the coefficient of determination, and Ω is the number of degrees of freedom (in this case, 5)], to determine the probability associated with the Breusch-Pagan-Godfrey test.

In order to check the autocorrelation of the residuals, I used the Durbin-Watson test, even if it is not a significant issue when using panel data (more details were presented in the next section). Lastly, in order to verify the maximum verisimilitude of the estimators, I have examined the Gauss-Markov hypotheses, as expressed in *Table 2*.

Table 2: Econometric tools used for validating maximum verisimilitude of the estimators

Tool used	Hypothesis checked
Fisher test	Valid model
Jarque-Bera test	Normally distribuited residuals
Durbin-Watson test	Absence of autocorrelation
Breusch-Pagan-Godfrey test	Heteroskedasticity
Cross-section Dependence Test (Breusch-Pagan, Pesaran CD, Pesaran scaled LM)	Absence / existence of cross-section dependence
Pearson correlation	Existence / absence of multicolinearity

Results and Interpretations

In this section, I analysed the impact of the human development drivers in all Member States of the European Union, at the same time verifying the verisimilitude of the obtained results, as I mentioned in the methodology.

In *Annex 1*, I have illustrated the situation of human development in 2017 in all the Member States of the European Union. As can be seen, the highest values of human developments index were recorded in Ireland (0.938), Denmark (0.936) and Sweden (0.933). At the opposite pole were Romania (0.811), Bulgaria (0.813) and Croatia (0.831). The main reason for their position consists in the fact that they were the last countries joining the European Union, which had also lower benefits from structural funds, compared to the first blocks of accession. On the other hand, as can be seen in *Annex 1*, the states with the highest levels of this indicator are those from the Western Europe, which have adopted inclusive economic policies, being also supported by the European funds.

Figure 1: Human development index in the European Union member states in 2017
Source: *Own processing using United Development database*

In *Figure 1*, I have clustered the Member States of the European Union depending on the level of the human development index in four categories, with an equal number of countries. In the first category are the states having the highest values of the human development index, respectively those registering a value between the 0.920-0.938 interval. This category includes: IE, DE, SE, NL, DK, UK and FI. Then, in the next category were included BE, AT, LU, FR, SI, ES and CZ, which registered values between 0.888-0.916. The third category is represented by the IT, MT, EE, EL, CY, PL and LT, with a level of the human development index between 0.858-0.880. The last category of countries (lowest values of HDI, between 0.811-0.855) is composed by SK, LV, PT, HU, HR, BG and RO. As can be seen in *Figure 1*, the northern, western and central states of the European Union are the most developed countries, with the highest values of the HDI, excepting Portugal; Eastern and Southern European Union Member States, respectively Portugal form the group of developing Member States, bearing in mind the lower levels of indicator.

The results obtained following the calculation of the impact of human development drivers were attached in *Figure 2*. As can be seen, the estimators are statistically significant, given that their probabilities are below the significance threshold of 5%. The value of R-squared (0.613271) confirmed the linearity of the regression and the appropriate choice of the regressors, their evolution explaining the fluctuation of the endogenous in a proportion of 61.32%. Also, the probability associated with the Fisher test is 0.00% (below the 5% significance level), which confirmed the validity of the econometric model from a statistical point of view.

Source: *Own processing using Eviews 9.0*

Next, I have presented the impact of exogenous variables on the human development index. According to the results, the increase of life expectancy by one percentage point led to a growth of the human development index with 0.552012 deviation points in the analysed period. The reason is that countries with a higher life expectancy, have also an educated and healthy population, while the situation of developing Member States is at the opposite.

On the other hand, an increase of the early leavers rate by 1 percentage point led to a reduction of the human development index by 0.136158 deviation points. The underdevelopment generates the inability of adolescents to access or continue the university studies, which creates the premises of a lower level of education. Further, this limits the opportunities of people on labour market and, implicitly, the wage expectations, which may cause a fall in human development level.

From another point of view, when corruption perception index register a hike by one deviation point, the human development index increases by 0.065563 deviation points. The high values of the corruption perception index are associated with a lower level of corruption. Reducing corruption leads to a higher confidence of the population in government institutions, which provides economic stability in terms of production, consumption and investment, this favoring development gains. In this context,

high quality government institutions may have an positive effect on different forms of development, implicitly on human development.

As regards the employment in agriculture, expressed as a percentage of the total employment, its increase by one percentage point led to a reduction of the human development index with 0.1516625 deviation points. A high employment rate in the agricultural sector determines a decline in the human development due to the fact that population employed in agriculture is facing issues related to their standard of living. Moreover, in the case of this category of population, human emancipation is limited and stationary, or in some cases, is growing slowly.

This paper, also demonstrated that, an increase in the gross fixed capital formation (expressed as % of GDP) by one percentage point of GDP caused a HDI growth of 0.058070 deviation points. This can be explained by the fact that investments generates higher opporunities on the labour market for the active population by creating jobs and increasing wages channels, which increase the level of development.

The results shows that the greatest impact of HDI drivers was obtained for the exogenous related to life expectancy (0.552012 pp). The increase in life expectancy is achieved by facilitating the access of population to a well-developed health system and, therefore, to a better life, which finally drives up the human development level. On the other hand, the employment rate in agricultural sector has the greatest negative impact on the HDI (0.156625), which confirms that the reduction of the employed population in this sector and their reallocation to better paid jobs leads to an increase in the standard of living, which favors the positive evolution of the dependent variable.

Regarding the autocorrelation of the residuals hypothesis, I used the Durbin-Watson test. In this case, I checked the values of dU and dL for 196 observations with 6 degrees of freedom, as follows:

dL = 1.7035

dU = 1.8296

Given that the value of the Durbin-Watson test (1.763401) is between dL and dU statistics, I concluded that the test is inconclusive, which cannot recommend any decision related to the autocorrelation of the residuals. However, the problem of autocorrelation loses its importance in the case of panel data, and I chosed to ignore it, bearing also in mind the result of the Durbin-Watson.

Further, according to the methodology, I processed the Breusch-Pagan-Godfrey test (*Figure 3*). For 5 degrees of freedom, the result of the test provided a probability of 9.06%, which confirms the hypothesis related to the model homoscedastic feature (the probabilities of exogenous variables have values higher than the significance threshold of 5%), this result being also in accordance with Gauss - Markov theorem.

Conclusions

Through this analysis, I identified a positive relationship between life expectancy and human development. This also confirms the fact that high life expectancy of the population, which can be ensured by reducing poverty, improving the health and education systems determines human development.

From another perspective, I demonstrated that the increase of corruption perception index (which reflects a fall in the incidence of corruption) impacts positively the human development index. In countries where corruption incidence is low, citizens and resident corporates, but also investors have more confidence in the policies adopted by the government, which ensures a favorable environment for development.

Moreover, I found a positive relationship between gross fixed capital formation and human development index. In this case, a high level of investment creates more opportunities for population, which drives human development on a upward trend.

This paper also demonstrated the negative impact of early leavers rate and employment in agriculture on human development. This fact shows that, people leaving studies early are more exposed to a low quality of life and poverty, compared to the young people with higher education. A high employment rate in agricultural sector leads to the categorisation of a significant part of the employed population in a lower income category, which causes a decrease in the standard of living and therefore a reduction in the human development index.

Abstract

This paper, based on a brief outline of theoretical aspects of competence and project management in public universities – using the methods of analysis, descriptive and graphical data presentation – addresses the problem of the level and expectations of students of the last year of public university studies (studying finance and accounting) in terms of their competences, with particular emphasis on language competences and acquiring / expanding professional experience. The analysis also covered the assessment of the level of fulfillment of expectations in the scope of competences development, resulting from the participation in the „Be Creative – staff development for the business services sector" project, planned for implementation in 2018-2020. The project is co-financed by the European Social Fund under the Operational Programme Knowledge Education Development 2014-2020 and is implemented in a partnership formula by the Częstochowa University of Technology and Syntea S.A.

Keywords: Competences, EU Project, Project Management

Introduction

Competence is a concept of high-capacity meaning with no explicit, universal definition. Given numerous approaches, especially interesting is the one treating competence as a disposition in the field of knowledge, skills and attitudes allowing for the implementation of professional tasks at an appropriate level (Filipowicz, 2016).

The review of the subject literature enables to state, that numerous presented definitions of competences (and also qualifications) depend on the scientific perspective adopted by a given researcher (Kupczyk and Stor, 2017). However, as noticed by J. Rzempała, most of the competence approaches refers mainly to issues related to the effectiveness of using an organization's human capital and should constitute the basis for human resources management (Rzempała, 2017).

It should be emphasized that „competences" and „qualifications" concepts are often used interchangeably, while there are some approaches that significantly differentiate them and indicate that competences are primarily expressed by a strong emphasis on independence and responsibility in task implementation. Thus competence covers those characteristics (knowledge, skills, way of thinking, thought patterns, etc.) which applied in practice (individually or in various combinations) result in a successful completion (of work or task). Qualification, on the other hand, equals a valuable activity, which leads directly to the most efficient completion of organizational objectives. In this approach qualifications are based more on skills while competences (resulting mainly from acquired

qualifications) on conducts (Kupczyk and Stor, 2017; Orczyk, 2009; Mantura, 2016). This is one of the approaches. There are also approaches indicating that qualifications are education, professional experience and skills (confirmed by documents) and competences are a conglomerate of knowledge, skills, attitudes and personality traits (Kubat, 2015).

Competences, related to the human potential, are a dynamic and situational concept. They also constitute a set of knowledge and skills, typical conducts, standard procedures, ways of reasoning that can be applied with no new learning and can be constantly improved (Müller, et al, 2020). They became the key capital and success factor, both on the individual and organization level. Also the awareness of the necessity to acquire/expand (Chadi, et al, 2019) them seems to be more and more common, which is demonstrated by both corporate investment in human capital and individual / employee / staff level initiatives.

An important role in this regard is assigned to educational institutions, including universities, which are increasingly expanding their educational offer with additional programs, co-financed with the European Union funds. Those activities are seconded by the „Be Creative – staff development for the business services sector" (hereinafter referred to as „Be Creative") project, proposed to the students of the Faculty of Management at the Czestochowa University of Technology (studying at the last year of the second degree of finance and accounting studies), aimed at enhancing the competences of 101 students. Project of this type is one of the examples of such the activities improving students labor competences.

Projects, due to the long term associated with the preparation of co-financing application, its evaluation, co-financing decision, implementation and maintenance of results durability, become an element of university strategic management (Szczepaniak, 2017). The common use of projects – not only by universities – forced the searches for adequate methods and tools, which can ensure their effective implementation. Those needs are met by project management, that on one hand is equipped with its own procedures, methods and frameworks, and on the other hand has to be included in the management processes of universities and governing legislation. Project management goal is to ensure the achievement of objectives adopted in the project, measured in this case with product and result indicators, project completion within assumed time, within the given budget while maintaining the eligibility of costs. In addition, given the impact on the effectiveness of the EU funds absorption, it also becomes an element that condition the implementation of the university strategy (Szczepaniak, 2017; Szczepaniak, 2018).

Projects implemented by universities require the engagement of certain resources (material, financial and human), the use of certain management methods integrated with the management processes present at the university, on levels of planning, implementation and performance control (Chluska and Szczepaniak, 2015). Their effective implementation is supported by cooperation with external entities (enterprises and public entities, called the triple/quadruple helix model. It is a specific form of innovation involving, inter alia, the activities of universities and scientific units that adapt their research and teaching programs to national and regional assumptions, smart specializations, responding to contemporary challenges of the labor market (Etzkowitz and Leydesdorff , 2000; de Almeida Borges, et al 2020; Zhang, et al., 2019).

The Aim of the Article and its' Methodical Bases

The purpose of this study was adopted as an analysis of selected competences (expectations and the level of their fulfilment) of public university students – participants of the project co-finances by the ESF funds ("Be Creative"). Due to the fact that motives for undertaking additional activity (besides didactics resulting from the course of the study) emphasized by students included primarily the will to acquire language competences and practical use of acquired qualifications through various forms of cooperation with employers, selected competences were made subject to the main part of considerations. In order to achieve this purpose the paper included mainly the results of questionnaire studies addressing the expectations of students covered by the support and the assessment of the level

of their fulfilment resulting from the participation in the project, using the methods of analysis, descriptive and graphical data presentation.

Presented results were developed on the basis of questionnaire studies addressed to the first group of participants (students of Czestochowa University of Technology: 40 individuals, including 36 women and 4 men). Questionnaire studies were carried out in five stages: after completing the recruitment to the project, but before applying the first form of support (February 2018, initial questionnaire), during the first and the last classes of the module „English for accountants" (February-April 2018), before the start and after the completion of work placements (June-September 2018) and after completing all tasks – completion of the project participation (August-October 2018, final questionnaire) as well as 6 months after the completion of the project (January-March 2019).

The study used anonymous questionnaires including mainly closed questions addressed to all project participants. In the case of trainings (including the module „English for accountants") knowledge and skills tests (initial and final) were also used. This study is also a result of the experience of the authors, who were members of the project management team, responsible primarily for its organizational and financial aspects.

Managing the Competence-enhancing Project – Theoretical and Practical Background

Economic practice, globalization and growing competition confirm the increasing demand for qualifications and competences, which is accompanied by the increase in the importance of projects being the response to those needs. Therefore, the demand for project knowledge and competences in project management grows. The development of competences in the area of project management refers both to the individual and organizational perspectives, which are subject to a mutual feedback: organizational competences are the resultant of acquired individual competences, while employee competences and their development often depend on the organization internal conditions, ie. its needs, organizational culture, management system, resources, leadership. The existing relationship enables the mutual improvement and development of competences (Rzempała, 2017). Such relationship in the assessment of the authors of this study is also present in the case of the described „Be Creative" project. Its scope is the resultant of the cooperation between the university and the employers as well as consultations (conducted before the formulation of the educational scope of individual tasks and the application for the ESF funds) relating to expectations of both students (regarding their needs) and employers in the area of preferred competences of future employees. The project is also correlated with the university's strategy. The fundamentals of the project included proposing additional classes that would allow to acquire/expand competences reflecting the needs of the economy, labor market and society.

The main objective of the project was identified as the improvement of students' competences. Its achievement, while preparing staff for potential employers that is compliant with their expectations, is about to be ensured by the implementation of the support program, covering four consecutive tasks:

- task 1. certified trainings resulting in obtaining professional, language and IT qualifications;
- task 2. additional practical tasks implemented in the project form (workshop classes conducted by the scientific staff of the Faculty of Management at the Czestochowa University of Technology and the employers' representatives, focused on the ability to solve featured problems of a specific company);
- task 3. two-day study visits in companies;
- task 4. 1-month work placement in companies of BPO/SSC/IT industries, allowing to acquire professional experience.

Under the project, the university initiated cooperation with four companies from Czestochowa, which in July-September 2018 provided project participants with the opportunity to increase their professional competences during 1-month professional work placements, namely:

- ZF European Shared Services Center – one of the largest employers in Czestochowa, providing financial and accounting services for the corporation's production plants located in Europe; the countries served include: Poland, Germany, Great Britain, Spain, Portugal, Italy, France, the Czech Republic, Slovakia and Romania,

- S24 Management – a company providing services in the area of law, accounting, finance and management for many entities with production, service, and trade profiles, including large listed companies,

- „LEW" Group SA – a leader on the terminal solutions market, having the status of National Payment Institution and providing financial and payment services; in 2013 the company became the owner of a majority stake in mPay SA and entered the FinTech industry,

- Firma Konsultingowo-Doradcza, Agnieszka Całus – a provider of complex services in the area of accounting, human resources and payroll, as well as tax and economic consulting.

For the proper implementation of the „Be Creative" project a management team was created, and the tasks assigned to its members (and responsibilities) were focused on following issues:

- organizational (securing the implementation of individual stages of the project according to the co-financing agreement, reporting on material progress),

- financial (implementing financial schedule, handling current payments, reporting on financial progress),

- administrative (public procurement issues, proper circulation of documents).

The base of the project staff (trainers) consists of the educational personnel of the Faculty of Management (selected by the management team, on the recommendation of the Dean of teaching, based on acquired competences and the analysis of current didactic workload of individual employees) and trainers (with appropriate university degree, minimum two-year teaching experience and VCC accreditation), selected by the Partner (Syntea S.A.), according to the procedure required in this type of projects. In the case of work placements, each student does it under care of a caregiver appointed by the employer, who provides educational supervision over its organization and course.

Expectations of University Students Related to the Participation in the Project and their Verification – Research Results

Before starting the project the participants determined (in the initial questionnaire; February 2018) their expectations associated with its implementation and the scope of acquired own competences. Then those expectations were verified in the final questionnaire, made after completing all forms of support (August-October 2018). The results reflecting the motives for participating in tasks under the project were presented in Figure 1. According to it the most important incentive was the will to complete professional work placements – 35 individuals out of 40 indicated that reason as the most significant (the possibility of providing more than one answer was assumed). A slightly less importance was assigned to the will to expand knowledge and skills in the area of professional English use. 34 respondents identified the acquisition of English for accountants competences as an important incentive to participate in the project. Given those two factors were the most important for students, the objective of this study was adopted as the evaluation of language competences acquired in the project and the analysis of experience resulting from professional work placements.

* percentages indicated in the chart represent the fraction of all answers given (174)

Fig. 1: Motives of student participation in the project

Source: Own elaboration.

In this context it is important to closely illustrate the level of knowledge and skills of students at the initial and final stages of the project which was done in Figure 2. Respondents, using a 5-point weight scale, where 1 represented low importance and 5 – high importance, were about to assess their knowledge and skills in seven research areas, thematically related to the scope of tasks the project was dedicated to. The adoption of weights facilitated the evaluation which area of knowledge, according to the respondents, was the most significant in the moment of starting the participation in the project, and which was finally the most improved. This is an important indication for project managers, as it allows to effectively direct the consecutive projects to tasks, that will bring the most tangible benefits to the participants.

* values indicated in the chart represent averaged results within the 1-5 weight scale

Fig. 2: Assessment of students' knowledge and experience before and after the project

Source: Own elaboration.

Assuming that answers given the weight of 4-5 are the most important for the respondents, it should be definitively stated that greatest development of students' knowledge occurred in areas, where the difference between average importance of a given competence in the initial and final questionnaires was the highest. Those areas included:

- completed professional work placements (difference in average values at 2.05),
- knowledge of sales techniques (1.37),
- knowledge of computer accounting standards (1.22).

The significance of expanding competences in the area of professional English, that was initially signalled important by the students, did not resulted to be the most effective in the end (difference in average values – 0.65), as well as the professional computer skills (0.65). Therefore, a detailed evaluation of completed professional work placements and language classes was made below in order to determine the reasons for this.

Analysis of Students' Language Competences Before and After Participating in the Project

As indicated by the initial questionnaire results, the will to expand knowledge and skills in English was one of the key incentives that made students participate in the project. In the same questionnaire (and again in the final questionnaire) students also assessed the level of their knowledge and professional experience related to professional English. The results of this process are presented in Figure 3.

Fig. 3: Assessment of students' knowledge and experience in English before and after the project

Source: Own elaboration.

During the phase preceding the start of the education under task 1 (which included the „English for accountants" module) the participants were evaluating their language competences in the range of weak to average – 87.5% of the respondents (35 of 40 students) declared such level of their abilities, while only 4 individuals considered their knowledge to be good. The results of the final questionnaire confirmed the desired (and assumed in the project's objectives) progress in this area, as there is an evident switch in students' abilities from mediocre and sufficient level to good level – after

completing all the tasks, as much as 17 individuals assessed their language skills as good. It is thought-provoking that before starting the education one person considered his/her abilities very good, while in the final questionnaire there was no such answer, and also that no respondent after completing the education declared very good language skills. It may suggest that already at the start of the project the participants represented poor language abilities, which however were possible to be improved to some extent through the participation in the project.

This fact is also indicated by the analysis of Figure 4, which presents the number of tests with a given score (max 15 points) as well as average results of the initial and final tests.

At the moment of starting the project the average score fluctuated around 4 points and only 3 students achieved the highest at that moment 7-point score. 80% of those who approached the initial knowledge test scored in the range of 2 to 5 out of 15 possible. After completing classes the average score was significantly improved (from 3.925 to 13.075), which was mostly affected by the fact that 23 students achieved a very high 14-point and 15-point score.

Fig. 4: Results of the initial and final tests checking knowledge in the area of "English for accountants"

Source: Own elaboration.

In summary, the level of students' knowledge and skills since the start of first English for accountants classes in February 2018 (ex ante questionnaires) until their completion in April 2018 (ex post questionnaires), on a 5-point scale, increased to a similar extent – on average from 2.60-2.65 to 3.83 (Figure 5).

Fig. 5: Results of ex ante and ex post questionnaires in the area of knowledge and language skills of project's participants

Source: Own elaboration.

Fig. 6: Results of ex post questionnaires in the area of the "English for accountants" overall assessment

Source: Own elaboration.

In the ex post questionnaire concluding classes of this module the students assessed also the subject in general, expressing their opinion ia. on the method of sharing the knowledge and trainer preparation, usefulness of classes, as well as the increase in the awareness of own strengths and weaknesses and motivation for further development (Figure 6). The most apparent is a very good assessment of the person giving classes as well as the usefulness of those classes, which is a significant indication for the project's management team, signaling the subject is needed and implemented at the high level.

Evaluation of Professional Experience of Project's Participants After Completing Work Placements

In the initial questionnaire 35 of 40 students indicated the will to complete paid work placements as a most important determinant of their decision to participate in the project. Task 4 of the „Be Creative" project provided for the completion of 1-month work placements in companies of BPO/SSC/IT

industries by the participants, which would allow to acquire professional experience even before they enter the labor market.

Given the results of the initial questionnaire regarding the level of students' knowledge and experience before and after completion of the work placements (Figure 7), it is noticeable that probably those 35 individuals who indicated the completion of the work placements as the most important incentive to participate in the project were also the same group, who assessed their professional competences in the range of very weak to average. The analysis of the chart illustrating the students' opinions reveals the occurrence of the desired „mirroring" effect of the bars representing input and output results – acquisition of experience decreases the number of individuals with lower self-esteem at almost the same rate as the number of students with higher self-esteem increases, while the intersection point is the sufficient assessment of their skills. After completing the work placements 37 of 40 respondents declared that 1-month work placement in the company allowed them to increase competences from average to very high level – while 75% of them assessed their competences to be at least good.

Fig. 7: Assessment of students' knowledge and experience in professional competence before and after the project

Source: Own elaboration.

Finally, the average level of the project participants' knowledge and skills in terms of professional competence was improved, however, to a smaller extent than in the case of English. The outcome of this process were presented in Figure 8. Those results slightly oppose the results of the initial and final questionnaires presented in Figure 2, where work placements were identified as the most developmental. However, it is possible that when evaluating each task individually students were more judgmental than during the total evaluation of all tasks.

Fig. 8: Results of ex ante and ex post questionnaires in the area of professional skills of project's participants

Source: Own elaboration.

Fig. 9: Results of ex post questionnaires in the scope of the overall work placement assessment

Source: Own elaboration.

The overall evaluation of this task, which results are illustrated on Figure 9, is also lower than in the case of the „English for accountants" module. The usefulness of classes stands out with a good assessment, however the other elements of the evaluation, such as trainer preparation or the method of sharing the knowledge, indicate some disappointment of students with this task. It can be assumed that in a situation where a person responsible for the implementation of the task from the company side is also obliged to perform his/her professional duties at the work placement location, he/she also has higher expectations about the independence and the rate of acquiring new skills by the student – a potential employee. At this stage there occurs a collision of employers and employees expectations. The employer, when employing, expects self-reliance, creativity and willingness to learn, while the employee expects an educational support. Its absence may lead to the loss of motivation, which was also signaled in the results of ex post questionnaire.

Conclusions

The fundamental objective of the implementation of the project described in this paper was adopted as an increase in the competences of 101 students, entering the labor market after completing the project. It should translate into greater ease in finding a satisfying job in the profession, especially with the employers operating in the modern financial services industry. The level of achieving the objective, besides tests and questionnaires which results were presented in the paper, is measured by beginning the work (in particular with an employer operating in BPO, SSC or IT sector – within 6 months from completing participation in the project). Result indicators also include starting employment in other industries and continuing education. Obtained results – despite relatively high assessments by students of individual support forms and educational staff, as well as meeting their expectations, despite the results of competence tests clearly indicating the expansion of knowledge and skills, and a good position on the labor market – place themselves far below expectations, both of students – project participants, and project management team. This is evidenced by the fact. that only 29 project participants (72.5%) started any employment after completing their studies (and the project), and the others (almost 1/3) within 6 months did not show any professional activity, nor undertake education. Only 7 individuals was employed (under a contract of employment or a civil-legal contract) by BPO sector employers, most of them by employers cooperating in work placement programs. Direct interviews with those employers and with students (project participants), conducted by the authors of this study after the completion of the first edition of the project, reveal the still-existing employment needs, however in individual cases job offers presented to students did not meet their acceptance. Existing employment and competence gaps can be potentially „filled" with the participants of the second and third edition of the project (61 students).

The Impact of Informal Credit towards Poverty: Evidence from Indonesia

Nicolas E. DARMAWAN

ericdrwn85@gmail.com

Chaikal NURYAKIN
University of Indonesia, Depok, Indonesia
chaikal.nuryakin@ui.ac.id

Abstract

Poverty has been a recurring problem in Indonesia, where credit access is one of the determinants that could affect poverty alleviation. However, for most of the poor, the only available credit for them are informal credit, which charges them with a high interest rate. By using Ordered Logit Regression, utilizing data from IFLS 3 & IFLS 4 to evaluate the short-term effect of informal credit towards poverty, and utilizing IFLS 3 & IFLS 5 to see the long-term effect. It is found that credit access decreases poverty incidence in both the short-term and the long-term. However, informal credit in Indonesia increases poverty incidence in both the short-term and the long-term. From these findings, it can be concluded that informal credit in Indonesia is not yet able to make the poor get out from poverty, due to the practice of loan sharks. Should informal credit in Indonesia be regulated to be like Vietnam's for example, then informal credit may be able to help Indonesians to live a better life.

Keywords: Poverty, Credit Access, Informal Credit

Introduction

Indonesia has continuously been trying to alleviate poverty throughout these past years. However, the speed of poverty alleviation has been slowing in the last few years (Exhibit 1.), (y-axis: proportion of poor people, x-axis: year). There are several causes that may affect poverty dynamics, such as household dynamics (Widyanti, Suryahadi, Sumarto, & Yumna, 2009), education (Biewen, 2003), et cetera including credit access (Lal, 2017), which has been overlooked in researches about Indonesia.

Fig. 1: Poverty Head Count in Indonesia (1996-2014). *World Bank*.

In Exhibit 1, the graph is flattest bewteen 2013-2016, while from Exhibit 2, Indonesia has shown approximately a 10% increase in its financial inclusion index[i]. This indicates more people have credit access, meaning that people should be better off. But in previous studies, lack of credit is proven to be a main cause as why the poor stay poor (Yunus, 1998), yet with the improvement in credit access from

Exhibit 2, poverty alleviation gets slower. This data raises the question whether credit access really helps in alleviating poverty.

There are three credit sources for Indonesians, which are formal, semi-formal, and informal credit institutions. Formal credit institutions include banks[ii], semi-formal credit institutions include microcredit institutions, and informal credit institutions are institutions that give out loans from their private equity (Mohieldin & Wright, 2000). In order to gain credit from banks, it would require collateral and documents as the loan is more secure. The poor cannot fulfill the collateral and could not gain access to formal credit. Semi-formal credit has less requirements, but the lack of regulation allow microloan-sharks to lurk in microcredit firms, which will further hamper the poor (Lewis, 2008). So, the poor turn to the informal sector, where they do not have to provide anything if an agreement is made. As the loan is risky due to the chance of default, the lender will charge high interest rates. However, in Indonesia's Civil Code there are no regulations regarding the interest rate ceiling, which will make borrowers unable to return the loan and be stuck in debt. As their debt increases, they are more likely to be stuck in poverty (Anuchiworawong, 2007). It is interesting to see whether credit access and informal credit specifically affect poverty and may explain the contradiction between Exhibits 1 & 2.

Fig. 2: Financial Inclusion Index in Indonesia in 2013 & 2016. ***Indonesia's Authority of Financial Services***

This research's novelty is derived from other studies regarding formal credit such as Nigeria (Obisesan & Akinlade, 2013), Peru (Schmied & Marr, 2016), India (Lal, 2017) and Indonesia (Sipahutar, Oktaviani, Siregar, & Juanda, 2016), which have all shown that formal credit helps in alleviating poverty. However, contradicting results appear where a study in Vietnam shows that informal credit helps poverty alleviation (Viet & Berg, 2011), and studies in Thailand (Anuchiworawong, 2007) and Ghana (Schindler, 2010) shows that informal credit makes the poor stay poor due to high transaction costs and unpaid debts. Studies about poverty determinants in Indonesia (Dartanto & Nurkholis, 2013; Dartanto & Otsubo, 2016) did not include informal credit. This research aims to confirm the previous studies that credit access in general helps in poverty alleviation and evaluate the impact of informal credit in Indonesia.

Section 2 will include theoretical foundation that is used for this research. Section 3 will elaborate the research data and methodology. Section 4 will explain the result and implications of the research. Section 5 will conclude with recommendations and limitations of the research.

Theoretical Foundation

Poverty

Poverty is deprivation in well-being; the inability to function properly in a society (Sen, 1987). There are different types of poverty based on the spell approach: chronic poverty, transient poverty, and never poor (Jalan & Ravallion, 2000). Chronic poor is people that stay poor for an extended period (Hulme & Shepherd, 2003). Transient poor is the people that move in and out of poverty, which can be divided into transient poor (+) and transient poor (-) (Gaiha & Deolalikar, 1993). Transient poor (+) are people

that got out from poverty. Transient poor (-) is the opposite. The never poor are people who constantly live above the poverty line.

Chronic poor people have a hard time to get out from poverty because they are in the poverty trap. Poverty traps are self-reinforcing mechanism that promotes never-ending poverty (Mas'Oed, 1997). A way to get out from the poverty trap is through credit access (Soederberg, 2013).

Previous studies have found several poverty determinants These can be divided into two categories: demographic and socioeconomic. For the demographic variables, it has been found that household dynamics (Widyanti et al., 2009), gender of household head (Muyanga, 2008), and education (Okojie, 2002), significantly affect poverty. While for the socioeconomic variables, it has been found that employment sector (Rapsomanikis, 2015), proportion of education expenditure (Dartanto & Otsubo, 2016), physical asset ownership (Dartanto & Nurkholis, 2013), and health of household head (Smith, 1999) significantly affects poverty. Credit access was also found to significantly affect poverty (Lal, 2017), but the effect of informal credit towards poverty still differ between researches. In Anuchiworawong (2007) and Schindler (2010), informal credit has negative effects for the poor, yet in Viet & Berg's (2011) research, it was found that informal credit helps the poor get out from the poor.

Financial Inclusion

Financial inclusion are initiatives to eliminate barriers from formal financial services. The barriers mentioned here are either in transaction costs or non-transactional costs for financial services. It has been found that not having credit access significantly affect poor households making them stuck in the poverty trap (Banerjee & Duflo, 2010).

Methodology

This research utilizes data from Indonesia Family Life Survey (IFLS) 3, 4, and 5 to find the effect of credit access and informal credit towards poverty. To evaluate the short-term effect, IFLS 3 and IFLS 4 are used, while for the long-term effect, IFLS 3 and IFLS 5 are used. IFLS is being used due to its high recontact rate. To categorize poverty, additional data from Indonesia Statistic Bureau (*Badan Pusat Statistik)* was used to compare per capita expenditure to areal poverty line.

For this research, two ordered logit regression models will be used, with each model being used twice to evaluate the short-termand long-term effect. The first ordered logit regression will use credit access as the dependent variable. For the second ordered logit regression, the observations that did not gain credit access are dropped, and the dependent variable is people who secured a loan from informal credit institutions. The model used will closely follow Dartanto & Otsubo's (2016), as follows:

$$Y_i = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + \beta_9 X_9 + \beta_{10} X_{10} + \beta_{11} X_{11} + \beta_{12} X_{12} + \beta_{13} X_{13} + \varepsilon \quad (3.1)$$

Explanation of the variables are provided in Table 1 below:

Table 1: Description of Variables.

No.	Variable (*Notation)*	Description	Hypothesis	Source of Data
1.	Poverty (Y_i)	The data to calculate this variable is all available on IFLS and poverty line statistics by Indonesia's National Bureau of Statistics. It is to normalize poverty line and household income over time to see	-	IFLS 3, IFLS 4, IFLS 5, Indonesia's National Bureau of Statistics

		households' poverty categorization. Where 0 implies chronic poor, 1 implies transient poor (-), 2 implies transient poor (+), and 3 implies never poor.		
Variables of Interest				
2.	People that successfully secured a loan in 2000 (X_1)	People that successfully secured a loan in 2000 ;1 implies the person succeeded, 0 implies otherwise.	Securing a loan decreases poverty incidence.	IFLS 3
3.	*People Who Secured Credit from Informal Credit Institutions in 2000* (X_1, *Second regression)*	People that successfully secured a loan from informal institutions in 2000; 1 implies the person succeeded, 0 implies otherwise.	Borrowing from informal institutions increases poverty incidence.	IFLS 3
Demographic Variables				
4.	Household size in 2000 (X_2)	Number of family members in 2000.	Larger household size increases poverty incidence	IFLS 3
5.	Age of household head in 2000 (X_3)	Age of the household head in 2000.	Older household head decreases poverty incidence.	IFLS 3
6.	Square of age of household head in 2000 (X_4)	Square of age of the household head in 2000	The nonlinear effect of age increases poverty incidence.	IFLS 3
7.	Household head' education in 2000 (X_5)	Years of household head's education	Household heads with higher education decreases poverty incidence.	IFLS 3
8.	Gender of household head in 2000 (X_6)	Gender of the household in 2000; 1 implies male, 0 implies otherwise.	A male household head decreases poverty incidence.	IFLS 3
Socioeconomic Variables				
9.	Proportion of smoking expenditure to total expenditure per capita in 2000 (X_7)	Proportion of monthly smoking expenditure to monthly expenditure per capita in 2000.	A larger proportion of smoking expenditure will increase poverty incidence.	IFLS 3
10.	Proportion of education expenditure to total expenditure per capita in 2000 (X_8)	Proportion of monthly education expenditure to monthly expenditure per capita in 2000.	A larger proportion of education expenditure will decrease poverty incidence.	IFLS 3
11.	Health status of household head in 2000 (X_9)	Health status of the household head; 1 implies the household head is healthy in 2000, 0 implies otherwise.	A healthy household head will decrease poverty incidence.	IFLS 3
12.	Total physical asset owned in 2000 (X_{10})	Total physical asset ownership in 2000.	More physical asset ownership will	IFLS 3

			decrease poverty incidence.	
13.	Employment sector in 2000 (X_{11})	Household head's employment sector in 2000; 1 implies that the household head was working in agriculture in 2000, 0 implies otherwise.	A household head that works in the agriculture sector will increase poverty incidence.	IFLS 3
Change in Variables				
14.	Larger household size in 2007/2014 (X_{13})	Growth of household size between periods; 1 implies a household is larger in 2007/2014 than in 2000, 0 implies otherwise.	Larger household size in the second period will increase poverty incidence.	IFLS 3, 4, and 5
15.	Increase in household head's education in 2007/2014 (X_{14})	Increase of household head's education between 2000 and 2007/2014; 1 implies there is an increase in parents' education, 0 implies otherwise.	An increase in household head's education in the second period will decrease poverty incidence.	IFLS 3, 4, and 5

Result and Analysis

First Regression (Long-Term): Effect of Credit Access Towards Poverty Incidence

The regression results for the long-term effect of credit access are described in Table 2, while the marginal effect analysis is explained in Table 3 below:

Table 2: Ordered Logit Regression Results for People Who Secured A Loan on 2000 Towards Poverty Incidence in the Long Term[iii]

Employment Sector in 2000 (1=Agriculture, 0=Other)	0.209	0.881	0.825	-1.912
Change in Variables				
Larger Household Size in 2014 (1=Larger Household Size, 0=Other)	0.397	1.670	1.564	-3.633
Increase in Household Head's Education in 2014 (1=Increased Educational Attainment, 0=Other)	-0.361	-1.522	-1.426	3.301

The first regression found that credit access significantly affects poverty at a 5% significance level, which is consistent with the findings of Yunus (1998), Obisesan (2013), Schmidt & Marr (2016), and Lal (2017), and confirms this research's first primary hypothesis. From Table 4.6, we can see that credit

access reduces the probability of being chronic poor by 0.3% and increases the probability of being never poor by 2.77%.

The significant demographic variables are household size in 2000, education of the household head in 2000, and gender of household head. A larger household size reduces the probability of being never poor by 3.17% for each additional household member, which is consistent with our hypothesis and previous studies (Meenakshi & Ray, 2002' Widyanti, et al., 2009; Dartanto & Otsubo, 2016). Meanwhile, when a household head has an increase in his/her education, the probability of being never poor increases by 0.53%. This is also consistent with previous studies (Jansen, 1950; Awan et al., 2011). While gender of the household head significantly affects poverty at the 5% significance level, where a male household head will increase the probability of being never poor by 3.86%, which also aligns to previous studies (Bourreau-Dubois, Jeandidier, & Berger, 2003).

All socioeconomic variables except health of the household head and share of education expenditure to total expenditure significantly affects poverty incidence at 10% significance level, but proportion of smoking expenditure and employment sector in 2000 are significant at a 1% significance level. A higher smoking expenditure increases poverty incidence, since the money used for smoking could be used to increase the quality of human capital. From the marginal effect analysis, a higher proportion of smoking expenditure decreases the probability of being never poor by 6.13%. When people work in the agriculture sector, the probability of being chronic poor increases by 0.2%, and probability of never poor decreases by 1.91%, which is caused by the lower income the agriculture sector has compared to other sectors.

Lastly, the change in variables are all statistically significant at a 1% significance rate. It is shown from Table 4.6. that if a household is larger in the second period, the probability of being transient poor (-) increases by 1.67%, which means a larger household increases the chances of falling into poverty. This is consistent with the findings of previous studies (Meenakshi & Ray, 2002), due to more household members mean a higher living cost. While an increase in parents' education will increase the probability of being never poor by 3.301%, which even emphasizes the importance of human capital investment, and is consistent with the findings of the previous studies (Okojie, 2002; Awan, et al., 2011).

Second Regression (Long-Term): Effect of Informal Credit Towards Poverty Incidence

After the first regression, the observations that did not secure a loan are dropped. The regression results for the second regression are in Table 4, while the marginal effect analysis is in Table 5 below:

Table 4: Ordered Logit Regression Results for People Who Secured A Loan from Informal Credit Institutions on 2000 Towards Poverty Incidence in the Long Term

Table 5: Estimation of Marginal Effects for Regression 2 in the Long-Term

Variable	Estimated Marginal Effects			
	CP	TP (-)	TP (+)	NP
Variable of Interest				
People Who Secured A Loan from Informal Credit Institutions in 2000 (1=Informal, 0=Other)	0.468	2.601	1.585	-4.655
Demographic Variables				
Household Size in 2000	0.276	1.532	0.934	-2.742
Age of Household Head in 2000	-0.057	-0.319	-0.194	0.571
Square of Age of Household Head in 2000	7.13e-06	0.004	0.002	-0.007
Household Head's Education in 2000	-0.027	-0.153	-0.093	-0.571
Gender of Household Head in 2000 (1=Male, 0=Other)	-0.099	-0.552	-0.337	0.988
Socioeconomic Variables				
Proportion of Smoking Expenditure to Total Monthly Expenditure per Capita in 2000	0.903	5.013	3.055	-8.971
Proportion of Education Expenditure to Total Monthly Expenditure per Capita in 2000	-0.244	-1.353	-0.823	2.422
Health of Household Head in 2000 (1=Healthy, 0=Other)	-0.085	-0.473	-0.288	0.847
Total Physical Asset Owned in 2000	1.34e-11	7.42e-11	4.52e-11	-1.33e-10
Employment Sector in 2000 (1=Agriculture, 0=Other)	-0.023	-1.262	-0.769	2.258
Change in Variables				
Larger Household Size in 2014 (1=Larger Household Size, 0=Other)	-0.160	-0.889	-0.542	1.590

Increase in Household Head's Education in 2014 (1=Increased Educational Attainment, 0=Other)	-0.297	-1.651	-1.006	2.954

Informal credit is significant in increasing poverty incidence at 5% significance level. This is consistent with the findings of previous studies (Zeller & Sharma, 1998; Anuchiworawong, 2007), and proves the second primary hypothesis of this research is true. This indicates that informal credit in Indonesia has not reached its full potential in helping the poor to become not poor. From the marginal effect analysis, borrowing from the informal sector increases the probability of being chronic poor by 0.468%, and increases the probability of being transient poor (-) by 2.601%, while reducing the probability of being never poor by 4.655%.

Most of the control variables have become insignificant due to the amount of observations that were deleted. Only two variables remain significant, which are household size and proportion of smoking expenditure to total monthly expenditure, both increase poverty incidence. In the second regression, an increase in the household size will reduce the probability of being never poor by 2.742%, while an increase of proportion of smoking expenditure will reduce the probability of being never poor by 8,971%.

First Regression (Short-Term): Effect of Credit Access Towards Poverty Incidence

The first regression results for the short-term evaluation are explained in Table 6, while the marginal effect analysis is in Table 7 below:

Table 6: Ordered Logit Regression Results for People Who Secured A Loan on 2000 Towards Poverty Incidence in the Short-Term

Age of Household Head in 2000	-0.059	-0.086	-0.179	-0.324
Square of Age of Household Head in 2000	-6.79e-06	-9.89e-06	-0.002	0.004
Household Head's Education in 2000	-0.229	-0.334	-0.693	1.257
Gender of Household Head in 2000 (1=Male, 0=Other)	-0.610	-0.889	-1.841	3.340
Socioeconomic Variables				
Proportion of Smoking Expenditure to Total Monthly Expenditure per Capita in 2000	1.040	1.514	3.139	-5.694
Proportion of Education Expenditure to Total Monthly Expenditure per Capita in 2000	-3.342	-4.868	-10.088	18.298
Health Status of Household Head in 2000 (1=Healthy, 0=Other)	-0.316	-0.459	-0.952	1.728
Total Physical Asset Owned in 2000	-3.59e-10	-5.23e-10	-1.08e-09	1.97e-09
Employment Sector in 2000 (1=Agriculture, 0=Other)	0.312	0.455	0.942	-1.709
Change in Variables				
Larger Household Size in 2007 (1=Larger Household Size, 0=Other)	0.672	0.979	2.028	-3.679
Increase in Household Head's Education in 2007 (1=Increased Educational Attainment, 0=Other)	-2.076	-3.024	-6.266	11.366

Credit access significantly affects poverty incidence at 5% significance level. This shows that credit access consistently affects poverty incidence in the long-term and the short-term. Credit access increases the probability of being never poor by 2.43%, while decreasing the probability of being chronic poor by 0.44%, which is approximately the same effect as the long-term effect of credit access.

The demographic variables are all significant in affecting poverty at the 10% significance level. Variables household size and square of age of household head increases poverty incidence, while variables age of household head, gender of household head, and household head's education in 2000 all decreases poverty incidence. It can also be seen that size of the household consistently affects poverty in the short-term or the long-term.

The socioeconomic variables are also all significant on the 10% significance level. Health of the household head is significant on the 10% significance level. This shows that health of household head is significant in the short-term in affecting poverty incidence, but not in the long-term. When the health of a household head is good, then the probability of being chronic poor will fall by 0.452%, and the probability of being never poor will increase by 1.728%. This proves that the hypothesis is consistent with previous studies (Benzeval, Judge, & Shouls, 2001) Proportion of smoking expenditure consistently affects poverty at 1% significance level, making it a consistent poverty determinant. Proportion of education expenditure towards total expenditure is significant in the short-term, but not in the long-term, which differs from Teguh & Otsubo's study in 2016. An increase in proportion of education expenditure will increase the probability of being never poor by 18.298%, showing the importance of investing in human capital. Employment sector consistently affects poverty in the long-term and the short-term at 5% significance level. Total physical asset owned also consistently affects poverty at the 10% significance level. All variables have the same effect as the long-term regression.

Lastly, the change in variables, which are larger household size in 2007 and an increase in household head's education in 2007, are both consistent in affecting poverty incidence in the long-term and short-term regression, making them a good poverty determinant as found in Dartanto and Otsubo's research in 2016.

Second Regression (Short-Term): Effect of Informal Credit Towards Poverty Incidence

The regression results are in Table 8, and the marginal effect analysis is provided in Table 9 below:

Table 8: Ordered Logit Regression Results for People Who Secured A Loan from Informal Credit in 2000 Towards Poverty Incidence in the Short-Term

Table 9: Estimation of Marginal Effects for Regression 2 in the Short-Term

Variable	Estimated Marginal Effects			
	CP	TP (-)	TP (+)	NP
Variable of Interest				
People Who Secured A Loan from Informal Credit Institutions in 2000 (1=Informal, 0=Other)	0.864	1.562	2.560	-4.986
Demographic Variables				
Household Size in 2000	0.493	0.891	1.461	-2.845
Age of Household Head in 2000	-0.016	-0.028	-0.046	0.090
Square of Age of Household Head in 2000	2.16e-06	3.90e-06	6.40e-06	-0.001
Household Head's Education in 2000	-0.204	-0.370	-0.607	1.182
Gender of Household Head in 2000 (1=Male, 0=Other)	-0.850	-1.537	-2.520	4.908
Socioeconomic Variables				
Proportion of Smoking Expenditure to Total Monthly Expenditure per Capita in 2000	0.792	1.432	2.347	-4.571
Proportion of Education Expenditure to Total Monthly Expenditure per Capita in 2000	1.256	2.269	3.721	-7.246
Health of Household Head in 2000 (1=Healthy, 0=Other)	-0.179	-0.323	-0.529	1.032
Total Physical Asset Owned in 2000	-1.75e-10	-3.17e-10	-5.20e-10	1.01e-09
Employment Sector in 2000 (1=Agriculture, 0=Other)	0.254	0.459	0.753	-1.466
Change in Variables				
Larger Household Size in 2007 (1=Larger Household Size, 0=Other)	0.598	1.080	1.771	-3.448
Increase in Household Head's Education in 2007 (1=Increased Educational Attainment, 0=Other)	-1.203	-2.174	-3.564	6.941

From the second regression, it is found that informal credit consistently affect poverty the same way in the short-term and the long-term, but the short-term effect is more statistically significant, at 1% significance level. Borrowing from informal credit institutions increases the probability of being chronic poor by 0.864%, while reducing the probability of being never poor by 4.986%.

The difference in the short-term second regression is that a lot of control variables are still significant. The demographic variables that are significant in this regression are household size and household head's education. Household size in 2000 is statistically significant in increasing poverty incidence in all the regressions done. Household head's education reduces poverty incidence in this regression, where an increase in the household head's educational attainment will increase the probability of being never poor by 1.182%.

The only significant socioeconomic variable in this regression are proportion of smoking expenditure to total expenditure and total physical asset owned in 2000 at 1% significance level. Proportion of smoking expenditure is significant in increasing poverty incidence in all the regressions done, joining household size in 2000 as one of the best poverty determinants. An increase in total physical asset owned in 2000 reduces poverty incidence, which is consistent with the long-term effect of total physical asset owned.

Change in variables are both significant at 5% significance level, where a larger household will increase poverty incidence, and an increase in household head's education in the next period will decrease poverty incidence.

Conclusion

This study is expected to provide some new insight regarding informal credit in Indonesia, how both credit access and informal credit can affect poverty incidence so the right policies can be made in fighting the malpractices in informal credit that happens in Indonesia.

From this research, the hypotheses that were made were proven to be true. Credit access significantly and consistently affects poverty incidence in the short-term and long-term, where people who has credit access have a better chance of being never poor. Informal credit is found to also significantly and consistently affect poverty incidence in the short-term and long-term, where people that borrow from informal credit institutions are more vulnerable to being poor or being stuck as chronic poor.

Vietnam is a good example that can be followed in regulating informal credit, because in Vietnam, informal lenders are not immune to public policies, which is a major difference compared to Indonesia where informal lenders are invincible. A clear interest rate policy is needed in Indonesia in order to alleviate loan shark practice.

There are several limitations in this research with the first one being the unclear nature of informal credits that does loan shark practice. With the right dataset, a research can dive deeper into Indonesia's informal credit and find out whether these loan sharks are causing poverty. Second, the data being used is not the most recent data, as IFLS is conducted once every seven years. The third limitation of this research is the comparison method in determining poverty, where the comparison was done only using two periods. This research still can be developed, yet hopefully it will shed a light regarding credit access and informal credit's effects towards poverty in Indonesia, and a policy can be implemented to alleviate poverty even further.

Abstract

The use of ICT in the household can be a force to increase financial inclusion. Especially if mobile phone and Internet is used in a way that it will gain user information and knowledge about finance. ICT could create a demand pull from the user side because of its nature to create a massive flow of information and knowledge (Sarma & Pais 2008; Ouma, Odongo & Were, 2017; Kabakova & Plaksenkov, 2018). In 2018 a survey by APJII stated that 64,8% (171.17 million people) of Indonesian have access to Internet with mobile phone as the most popular gadget to access it. The Indonesia's digital base continues to grow. But the digital base mainly uses mobile phone and Internet for a social purposes and entertainment, not really reflecting any information flows about financial education. Therefore, this study is interested in seeing whether the use of mobile phone and Internet in Indonesia households can improve the flow of information and knowledge about finance. That in the end will increase financial inclusion. This study uses Susenas 2017 and 2018 Podes with data at the household level for all cities/districts in Indonesia. The method use in this research are Poisson Regression and Logistic Regression methods. This study found that ownership of mobile phones and Internet access in Indonesian households can significantly increase ownership of savings accounts in formal financial institutions as a proxy for financial inclusion.

Keywords: Financial Inclusion; Internet; ICT; Mobile phone.

Introduction

Financial inclusion or having access to formal financial institutions is an important indicator in determining a country's economic development (World Bank 2014, IMF 2014). This is because an inclusive financial system can help people from all economic level gain the ability to save, develop and improve the assets and improve the quality of living (Demirgüc-Kunt and Klapper, 2012). Financial inclusion can be seen with the three indicators: ownership of the account at a formal financial institution, savings in a formal financial institution, and loan in a formal financial institution (Demirgüc- Kunt and Klapper, 2013).

Not only it will promote economic growth (McKinnon, 1973; Shaw, 1973; Stiglitz and Weiss, 1981), financial inclusion through the instrument Information, Communication, and Technology (ICT) can reduce the gap that exists economically and socially (Hannig & Jansen, 2010). Mobile phones and the Internet are one of the forms of ICT that can be used as a tool in promoting financial inclusion. Here's how ICT affects the financial inclusion: (1) on the supply side in the form of digital financial services to reduce transaction costs of formal financial institutions and (2) on the demand side where ICT can improve the flow of information and knowledge of finance (Sarma & Pais, 2008; Ouma, Odongo & Were, 2017; Kabakova & Plaksenkov, 2018; Demirguc-Kunt et al., 2018). Thus, mobile phones and

the Internet can reduce barriers in the category of unbanked population[1] to gain access to formal financial institutions.

Indonesia has a gap in access to formal financial institutions as well as digital access. The research by APJII (2018) shows the gap. Even though most of the population have access to Internet (64.8%). Java island, where most of big cities are, still hold the highest rate of Internet penetration which is 55,7%. For other area the internet penetration is as big as 21.6% (Sumatera) and as little as 5.2% (Nusa Tenggara). This was previously confirmed of research by Sujarwoto and Tampubolon (2016), where it was found that the spread of Internet access is uneven in every district in Indonesia with a tendency to agglomerate in big cities.

At the same time, there are 62.3 million adults in Indonesia who don't have a bank account but have a mobile phone (Demirgüç-Kunt et al., 2018). Mobile phone with Internet access can be a tool to improve financial inclusion, especially in developing countries (Ozili, 2018).

The digital potential in Indonesia is clearly stated, but the question is whether the ownership of mobile phones and Internet access have some effect on increased financial inclusion in Indonesia? There are previous studies, especially in Sub-Saharan Africa with mobile money services, where the mobile phone and the Internet can be used as a tool to enhance financial inclusion (Dupas and Robinson, 2013; Jack and Suri, 2014; Prina 2015, Brune et al., 2016). China has also proved that the innovation and development of the financial sector by using the Internet will increase the participation of the underbanked and unbanked population in the formal financial services (Guo, Kong, & Wang, 2016; Loubere, 2017; Demirguc-Kunt et al., 2018)

Indonesian who connected to the Internet using most online activity to access social media, entertainment and purchasing goods online (McKinsey, 2016; APJII, 2018). The use of social media can encourage financial inclusion as long as there is a flow of information to educate users about the formal financial institutions and financial services. But these flows are highly dependent on the network and connectivity of users and the country itself (Sarma & Pais, 2008). Since the use is mainly for social purposes and entertainment, not to access financial services, the relation between ICT and financial is still unclear and needed further research.

The Indonesia financial inclusion program by the government prefers banking channels (bank-based digital financial inclusion) to become major players of digital financial services provider (Nuryakin, Aisha, and Massie, 2019). Supply of financial service in Indonesia hasn't been maximized yet. But the high ICT adoption in Indonesia is an opportunity push financial inclusion. The role of information and knowledge flows about finance are becoming crucial to encourage user demand for formal financial services. Thus, it will push the financial inclusion.

In this study the authors will see how owning a cellular phone and Internet access in a household may affect the level of financial inclusion. The research aims to analyze the relationship between financial inclusion and ICT indicator in Indonesia household. With these objectives, this study used national data from the Survei Sosial Ekonomi Nasional (Susenas) 2017 and Potensi Desa (Podes) in 2018 through the household approach. This study has a hypothesis that adoption of mobile phones and Internet access in the household will increase the flow of information and knowledge of finance. In the end it will increase the probability of these households to have a savings account at a formal financial institution as an indicator of financial inclusion

Literature Review

Financial inclusion is a process where there is an ease of access, availability, and use of formal financial institutions for the entire community (Sarma, 2016). Access, availability, and the use of formal financial institutions can be viewed through three indicators, namely: ownership of the account at a

formal financial institution, savings in formal financial institutions, and loan in a formal financial institution (Demirgüc- Kunt and Klapper, 2013). Ownership of an account at a formal financial institution shows the access aspect, while savings and loan show activities in using formal financial service.

According to some studies, there are some factors that could affect financial inclusion in a country. These factors include ICT, age, education, gender, location, and economy (Sarma & Pais, 2008; Ouma, Odongo, & Were, 2017; Kabakova & Plaksenkov, 2018). Elaboration of these factors can be seen in Table 1:

Table 1: Determinant Factors Financial Inclusion

Factor	Description
ICT	ICT or technology can help to reduce the barriers in obtaining formal financial services. It can be influenced by the formal financial institutions that use ICT in offering his services and ICT facilitate the flow of information, thus increasing financial education.
Age	People in productive age increase their chance to save more. Following the Life-Cycle Hypothesis, this situation applies until it reaches non-productive age (retirement). When it reaches the retirement age individual will stop saving and use savings (dissaving).
Education	Education refers to the level of formal education. It is more likely that someone with higher level of education has information/access to information about formal financial institutions.
Gender	There is a greater tendency for men to use the services of formal financial institutions.
Locations	Differences in locations. Such as rural-urban differences and access to infrastructure that may affect the ease of access to services of formal financial institutions.
Economy	There is a positive relationship between financial development and economic growth. Where households with better economic circumstances are more likely to gain access to formal financial institutions.

Source: Sarma & Pais (2008), Ouma, Odongo, and Were (2017), Kabakova and Plaksenkov (2018), produced by the author

Research by De Koker and Jentzsch (2013) found that for some time, the initiation of financial inclusion in developing countries relies on the use of ICT. Some of these initiations are the use of digital payments, mobile banking, and fintech. The use of ICT as an instrument of financial services is one way that ICT can enhance financial inclusion. With the use of ICT in the supply side of financial services, financial institutions can provide services at a lower cost and higher accessibility. Thus, financial institutions can reduce bottlenecks and inefficiencies of the market (Kabakova and Plaksenkov, 2018).

Through the demand side, ICT could increase the demand of financial services for its users. ICT has a nature to improve the flow of information and education. Therefore, the user is more likely to gain a financial education that will increase their chances to use formal financial institution services. This illustrates the flow of an information network that can educate users about financial institutions and financial services. The role of ICT in enhancing demand of financial services depend on the type of information in the user's network (Sarma & Pais, 2008). If people get the right information, then the consumer pull will increase the digitalization of financial services.

There are some impacts to overcome poverty because of digitization in the financial sector for mobile money users: (1) The poor can manage financial risk (Jack and Suri, 2014); (2) The poor can accumulate savings and increase spending on basic necessities (Dupas and Robinson, 2013; Prina, 2015, Brune et al., 2016); (3) The Increase of revenue potential and a chance to reduce poverty (Suri & Jack, 2016). Table 2 elaborates on the findings in previous researches in Sub-Sahara Africa about financial inclusion and ICT.

Table 2: Literature Review

Findings	Author
Research in Kenya. Mobile money users didn't decrease consumption when there was a drastic reduction in income.	Jack and Suri, 2014
Research in Kenya. Market vendors that majority consists of female invest 60% more for their businesses.	Dupas & Robinson, 2013
Research in Kenya. Household of mobile money users with a woman as their head of household increase shopping for nutritious food up to 15% and shopping education to up 20%.	Prina, 2015
Farmers that were mobile money users in Malawi spend 13% more on agriculture equipment and experience increase in harvest price up to 15%	Brune et al., 2016
Research in Kenya. Mobile money user family with a woman as their head of household increase savings by 20%. 185,000 women develop a business or move to retail from sector agriculture. Also, a decrease of extreme poverty to 22%	Suri and Jack, 2016

For the last few years, financial services via the Internet or Internet Finance (IF) has developed rapidly in China. In 2015, the IF development index reaches 386 with 100 bases, the index showed a rapid growth (Guo, Kong, & Wang, 2016).

Innovation and capitalization of formal financial institutions through ICT in China enhance the development of financial services offered. Financial services are changing the target consumers to enhance financial inclusion. This innovation targeted diverse consumers, starting from the poor people in rural areas to large businesses looking for capital investment (Guo, Kong, & Wang, 2016). Research by Demirguc-Kunt et al. (2018) supports the statement of Guo, Kong, and Wang (2016), it finds that in 2014 there are 77% of the adult population in rural China who have accounts in formal financial institutions. The percentage rose sharply from 2011 which only accounted for 58%.

Fintech Singapore (2018) do a research about the development of fintech in Indonesia. Fintech with payment and loan categories have the largest percentage compared with other categories with 38% and 31%. Other than that, it is predicted that the number of transactions through fintech will grow by 16.3% annually. Fintech company in Indonesia has been concentrated on lending services. This concentration is due to the legal issues in which banking activities primarily in the form of savings is not allowed to be done by a private company (Nuryakin, et al., 2018).

To improve financial inclusion, Bank Indonesia and Otoritas Jasa Keuangan (OJK) issued two types of branchless banking: (1) bank based branchless banking, this program is called Laku Pandai and (2) telecommunication based branchless banking, this program is called Digital Financial Services (DFS). According to OJK regulations POJK No. 19/POJK.03/2014 branchless banking or Layanan Keuangan Tanpa Kantor (Laku Pandai) providing banking services and/or other financial services without having to go through an office. The government design it to go through cooperation of other parties and supported by the use of technology. Meanwhile, according to Bank Indonesia through Bank Indonesia regulation No. 11/12/PBI/2009, DFS is electronic money formally registered and provided by third parties via a mobile phone or website.

Nuryakin, et al. (2018) in his research found that financial inclusion through access and the use of DFS and Laku Pandai reaching 28% and 48%. But the financial inclusion through the ownership of the account only reached 5% and 25%. The study also found that Laku Pandai is more efficient to increase access to financial services for the poor and in rural areas. While DFS have a higher likelihood to be used by people with higher education and incomes. Therefore, the financial inclusion program in

Indonesia tends to be more dependent on bank-based branchless banking than telecommunication-based.

Financial services offered by DFS and Laku Pandai is considered less than ideal, especially because it is not reducing the cost of access and transactions. The cost of branchless banking is relatively still more expensive than informal financial services. This is because DFS and Laku Pandai agents are further away than informal financial services agents. It is also important to note that there is a cost of services that are considered too pricey. In this case, the use of ICT from the supply side is not maximizing the potential for financial inclusion.

Research Methods

The hypothesis in this study stated that the ownership of mobile phones and Internet in the household will increase the probability of these households to have savings account at a formal financial institution as an indicator of financial inclusion. To prove this hypothesis the authors used two methods: Poisson Regression and Logistic Regression.

The model used in this study refers to the model developed by Ouma, Odongo, and Were (2017). The model has the original formula as follows:

$$s_i = \alpha_i + X_i\beta + Zi\gamma + \varepsilon_i$$

In the model, it is explained that the proxy of ability to save in individual i (s_i), can be explained by the digital financial service or the Internet (X_i), and variable control (Zi) such as gender, age, income, and education. This model using logistic regression method to process the data.

In this study, the indicators used are at the household level. The author will look at how the availability of households savings account influenced by household access to mobile phone and the Internet with control of demographic characteristic, an indicator of access to formal financial institutions and indicator of access to informal financial institutions.

Here are the two main models to be used in this study:

1. $SavingAccount_j = \beta_0 + \beta_1 Mobilephone_j + \beta_2 Internet_j + \beta_3 Education_j + \beta_4 Gender_j + \beta_5 Age_j + \beta_6 NonPoor_j + \beta_7 InformalCredit_j + \beta_8 ATM_j + \beta_9 Bank\ Office_j + \beta_{10} Cooperative_j + \mu_{oj}$
2. $DummySaving_j = \gamma_0 + \gamma_1 DummyMobile_j + \gamma_2 DummyInternet_j + \gamma_3 Education_j + \gamma_4 Gender_j + \gamma_5 Age_j + \gamma_6 NonPoor_j + \gamma_7 InformalCredit_j + \gamma_8 ATM_j + \gamma_9 Bank_j + \gamma_{10} Cooperative_j + \mu_{oj}$

- *SavingAccount* : The number of savings per household member
- *DummySaving* : Ownership of savings in the household (1= household have savings account at least one, 0= household don't have a savings account)
- *Mobilephone* : The number of mobile phones owned per household member
- *DummyMobile* : Ownership of mobile phones in households (1= household have mobile phone at least one, 0= household don't have a savings account)
- *Internet* : The number of Internet users per household member
- *DummyInternet* : Internet access in households (1= there are at least one household member who has access to the Internet, 0= household don't have Internet access)
- *Education* : The last formal education attained by the head of the household
- *gender* : The gender of heads of households
- *Age* : Age of head of household

- *NonPoor* : Households with per capita income above the province poverty line
- *InformalCredit* : Households with a loan provided by an individual with interest.
- *ATM* : How easy it is to find ATM in the district (1= easy, 0=hard)
- *Bank* : The number of bank branches office in the district
- *Cooperative* : The number of cooperatives in the district

Model 1 will use Poisson regression while Model 2 use Logistic regression. Poisson method is used because of *SavingAccount* as the dependent variable in Model 1 is a count-data type, namely the amount of savings account per household member. Logistic regression is used in Model 2 dependent variable (*DummySaving*) in Model 2 is dichotomous variables.

Research Analysis

According to Susenas 2017, around 139,989 (51%) households in Indonesia don't have any savings account in a formal financial institution. Even if the household is marked as having access to formal financial institutions, it's not necessarily means that everyone in the family has their own savings account. The average proportion of household members who have a savings account is 0.214, in other words on average only 21.4% of total family members have a savings account. This proportion has a range of zero to one, where zero indicates the absence of household members who have a savings account and a 1 indicates each member of the family is represented by one savings account. Not everyone in the household have a direct access to formal financial institutions.

Authors use two proxies for ICT, the ownership of a mobile phones and Internet use in households. When compared to household access to the Internet, households in Indonesia have more access to a mobile phone. As much as 89.53% of households in Indonesia have access to a mobile phone. This figure is much larger than Internet access, where only 52.26% of households in Indonesia have access to the Internet. The same thing occurred in the proportion of ICT access to household members. The average proportion of family members who have mobile phones is 54.5% while the average proportion of household members who have Internet access is only 15.1%.

Households who have access to ICT is not entirely covered by formal financial institutions. There are households with no savings account but have access to ICT.As much as 47% of households with at least one mobile phone and 34% of households who have Internet access don't have any savings account. These characteristics match with findings by Demirguc-Kunt et al. (2018) where there are people with access to ICT that are still uncovered by the formal financial institutions. It is further explained that the ICT access of household is considered as an opportunity to push financial inclusion from the demand side.

Table 3 lists the results of Poisson and Logistic regression. Model 1 shows the incident rate ratio (IRR) while Model 2 displays the odds ratios of the regression results.

Table 3: Results of Poisson regression and Logit

Source: produced by the author

In both model *p-value* of the chi-squared is 0.000. Therefore, the overall model is statistically significant. In Model 1 All independent variables used, affects the dependent variable significantly up to 99% significance level. In the Model 2 Age variable is not significant at 0.05 and 0.01. Both regression results in Table 3 show that the sign of the variable of interest, namely mobile phones and the Internet, remain consistent after using control variables in the model. The variable of interest remains positively affects dependent variable. This shows that the use of ICT in Indonesian households increases the probability of those households to have a savings accounts, thus increase the rate of financial inclusion.

The majority of the independent variable (ownership of mobile phones, Internet access, educational level of head of household, household poverty level, the number of bank branches, the number of cooperatives, and informal credit) affect the dependent variable in accordance to the hypothesis that has been predetermined. In model 1, there are two control variables with coefficient results that are not following previous hypotheses. These variables are *Gender* and *ATM*. While on the Model 2 variables *Age* and *ATM* have different results with previous hypotheses.

In model 1 coefficient will be interpreted with the IRR. Each variable has an IRR determine the effect of the variable to the dependent variable, with the assumption that all other variables in the model are held constant. Here is the analysis of Model 1 Table 3.

1. For every increase of 1 household members who have a mobile phone, the proportion of savings accounts per household member will be increased by 3,484 times.
2. For every increase of 1 family members who have Internet access, the proportion of savings accounts per household member will be increased by 2,256 times.

Odds ratio in Model 2 explained the probability of household to has access to formal financial institutions if independent variables occur or not. Here is the analysis of the results of the regression odds ratio Model 2 in Table 3, with the assumption that all other variables in the model are held constant.

1. When the household has a mobile phone, then the probability of household to has a savings account is 2.653 times greater than households without a mobile phone.
2. When the household has access to the Internet, then the probability of household to has a savings account is 2.622 times greater than households without Internet access.

Through the analysis, it can be seen that the variable of interest in both models is positively and significantly affect the account ownership in the household. This is consistent with research Sarma & Pais (2008), Ouma, Odongo, and Were (2017), and Kabakova and Plaksenkov (2018). Based on the IRR analysis and odds ratio of mobile phone and Internet, ownership of mobile phone is more likely to enhance financial inclusion of household compared to Internet access. The difference can be seen by the amount of IRR and the odds ratio for each variable. It could be interpreted as Internet is one of the important factors to increase the level of financial inclusion of households, but the mobile phone can improve the level of financial inclusion further.

In this study, the mobile phone and the Internet are a more appropriate proxy for measuring the demand side of ICT influence on financial inclusion. Mobile phones and the Internet represent a form of ICT adoption in the household. As has been discussed previously in research Sarma and Pais (2008), Ouma, Odongo, and Were (2017), and Kabakova and Plaksenkov (2018) ICT can improve the flow of information and education, formal financial institutions and financial services to its users. Mainly in Sarma and Pais (2008) where it was found ICT is network that create connectivity for its users that will allow the mobilization of information.

It is predicted that ICT as its user's network makes education and poverty as variables that have a considerable influence on financial inclusion. Because the level of education and poverty will affect what type of information contained in the network itself. Especially with most of the Internet users in Indonesia use it for social purposes. The content of social media itself depends on the user's social circle, people, communities, and organizations that are available and accessible around the user. Therefore, the type of information and knowledge on social media highly depends on the socio-economic conditions due to different sources of information that will be available in the network.

Authors predicts that there is an endogeneity problem between the dependent variable (*SavingAccount*) and the variable of interest (*Mobilephone* and *Internet*). Through Durbin-Wu-Hausman test, it was found that there is an endogeneity problem in the variable of interest. Therefore, the authors conducted a robust on both models to address the minor violation in the assumptions as of the problems of endogeneity

Conclusions and Recommendations

Using Poisson regression and Logistic regression, this study found that in Indonesia household mobile phone ownership and household Internet access may increase household account ownership in a formal financial institution as a proxy of financial inclusion. Internet and mobile phones as an indicator of ICT affect your ownership positively and significantly. But mobile phone has a greater influence than the Internet. It is concluded without decreasing the important role of the Internet to increase financial inclusion. Mobile phone and the Internet are the adoption of ICT in the household, this study sees the impact of ICT on financial inclusion from the demand side.

The study also found the importance of education and the economic situation of households in influencing the level of financial inclusion. Education has a positive and significant effect to increase account ownership in the household. On the other hand, a household that categorized as non-poor will be more likely to have an account in a formal financial institution. The authors predict that the level of education and poverty influence the type of information in the user's network. Mainly because the

majority of the Indonesian population use the Internet for social purposes. So that the information obtained on the network is strongly influenced by socio-economic characteristics of users of ICT.

Based on the results of this study the authors provide suggestions for policymakers to consider the approach to ICT in the efforts to increase financial inclusion. ICT development in Indonesia is not maximized yet, while ICT become one of the major factors that have a big influence in increasing financial inclusion. ICT becomes an opportunity that has not been completely used. The ICT development needs to be focused mainly on the development of financial services by the formal financial institutions through the medium of ICT to improve the supply side. Also, the development of financial literacy levels of ICT users is badly needed. Especially since many households have adopted ICT in Indonesia. In the end, more education is essential for ICT user, so the use of ICT is not limited for entertainment or social activities, but actually can accelerate financial inclusion,

With the rapid ICT developments on a global scale, more research will be needed to gain a comprehensive understanding of the dynamics of the economy and ICT. Further studies are expected to use proxies better and more accurate. Especially in ICT where the proxy in this research is only limited to Internet and mobile phone.

The Level and Dynamics of Economic Development Versus Employment Structures in Economic Sectors and Sections in EU Countries

Danuta STRAHL

WSB University in Dąbrowa Górnicza, Dąbrowa Górnicza, Poland
dstrahl@wsb.edu.pl

Abstract

The purpose of the paper is to assess the relationship between the level and dynamics of economic development expressed in GDP per capita, and the employment structure in clusters of EU states in 2008 and 2018. These clusters are formed on the basis of two criteria: the employment share in economic sectors (Agriculture, forestry and fishing, mining and quarrying; Manufacturing; Electricity, gas, steam and air conditioning supply; water supply and construction; Services) and the employment share in industry sections of various technological advancement, and in knowledge-intensive services. The clustering of countrie was obtained by complete linkage method. The average GDP per capita and GDP dynamics were compared between these clusters of countries. The procedure proposed in the paper made it possible to: identify clusters of EU states with similar employment structures in selected sectors and sections, and assess the relationship between the analysed structures and the level and dynamics of economic development.

Keywords: Employment, Structures, Sectors, Sections, EU States, Level Of Development, Clustering

Introduction

Economies of European Union contries differ between themselves with respect to many characteristics. The employment structure is one of the important features, because of its influence on economic development. (Pasinetti, 1981; Laitner, 2000; Hartwig, 2012). The importance is also due to mutual relations between employment structures, their dynamics and technological and productivity development (Fagerberd, 2000). Between 2008 and 2018 slight increase in the employment figures was observed (Table 1), but as far as the sectoral structure is concerned, the only increase happened in service sector.

Table 1: UE employment in economic sectors, in 2008 and 2018

Sector	Year	
	2008	2018
Employment in millions (percentage share)		
Total:	222.8 (100.0%)	229.8 (100.0%)
- services	149.4 (67.0%)	164.1 (71.4%)
- industry	38.1 (17.1%)	35.4 (15.4%)
- electricity, gas, steam and air conditioning supply and in water supply and construction	21.7 (9.8%)	19.0 (8.3%)
- agriculture, forestry and fishing, mining and quarrying	12.3 (5.5%)	9.8 (4.3%)

Source: Eurostat (2019)

Total employment in five biggest EU countries covered 60.7% of EU employment in 2008 and 62.3% in 2018 (Table 2).

Table 2: Five UE countries with the highest employment, in 2008 and 2018

Country	Year	
	2008	2018
Employment in millions (percentage share in UE total)		
Germany	35.8 (16.1%)	41.7 (18.1%)
United Kingdom	29.5 (13.2%)	32.2 (14.0%)
France	26.5 (11.9%)	27.1 (11.8%)
Italy	23.0 (10.3%)	23.1 (10.0%)
Spain	20.5 (9.2%)	19.3 (8.4%)

Source: Eurostat (2019)

Each section of knowledge-based services saw the rise in EU employment, in 2008-2018: less knowledge-intensive market services – from 57.8 million to 62.1 million (25.9% of the total number of employees in 2008 and 27.0% in 2018); other knowledge-intensive services – from 57.3 million to 63.9 million (25.7% of the total number of employees in 2008, and 27.8% in 2018); knowledge-intensive market services (except financial intermediation and high-technology services – from 12.4 million to 15.0 million (5.6% of the total number of employees in 2008 and 6.5% in 2018); knowledge-intensive high-technology services – from 5.8 million to 7.0 million (2.6% of the total number of employees in 2008 and 3% in 2018). The increase of the number of employees was observed also in medium high-technology manufacturing – from 10.7 million to 10.9 million people (4.8% of the total number of people in employment). In other industry sections singled out in terms of technological advancement, the number of people in work decreased: from 14.4 million (6.5% of the total number of employees) to 12.3 million people (5.4%) in low-technology manufacturing; from 10.5 million (4.7%) to 9.6 million people (4.2%) in medium low-technology manufacturing); from 2.5 million to 2.4 million people (1.1% of the total number of people in employment) in high-technology manufacturing.

The average GDP per capita (in purchasing power standards – PPS) in the European Union was 26100 Euro, on average in 2008 and 31000 Euro in 2018. The dynamics of changes in the EU in 2008 as compared to 2000 was 131.8%, and 118.8% in 2018 as compared to the data of 2008.

Changes that occur in the EU labour market are similar in the selected countries both in terms of the number of employees and their share, which makes possible to identify clusters of such countries with the use of multidimensional data analysis methods. Processes that occur in the changes of shares of employees in sectors and sections are, on one hand, the product of the level and pace of development and, on the other hand, they entail it.

The purpose of the paper is to assess the level and dynamics of development measured based on the value of GDP per capita in clusters of EU states singled out with respect to similar shares of people in employment in sectors and sections.

Literature Review

The results of research on the employment structure presented in the literature, show that employment structures in the arrangement of sections and sectors are changing. It results, among other things, from the necessity of the structure to adapt to the changes that occur in manufacturing methods, market needs, challenges of the knowledge-based economy, industry 4.0 and the general condition of the economy (The employment, 2016; Cho et al., 2017; Hofäcker, 2017; van Treeck, 2017; Understanding, 2017; Berg et al., 2018; Building, 2018; Transition, 2018; Paterson at al., 2019; World, 2020). Researchers are particularly interested in changes of structures in the context of their impact on technological development and capacity improvement (Fagerberg, 2000). References to economic growth are of key importance (Pasinetti, 1981; Laitner, 2000; Hartwig, 2012). Studies are conducted on different sets of territorial units: 1/ countries, including EU states, with the use of dynamic multidimensional scaling (Markowska et al. 2014, 2019a, 2019b), dynamic classification

(Strahl and Markowska, 2019); 2/ selected countries, such e.g. Visegrad group states (Hlavacek et al. 2019); 3/ regions, for example in the regions of the Czechia (Markowska, 2017), China (Fan et al. 2003; Zheng and Kuroda, 2012), Great Britain (Chadwick et al. 2008); 4/ cities (Rubalcaba, et al. 2013).

The assessment of change in structures requires dynamic approaches (Strambach, 2008; Strahl and Markowska, 2019). Markowska and Sokołowski (2016, 2017, 2019) assessed employment structures in individual sectors, in EU states, in 2008-2017, and the employment in sectors in Warsaw and neighbouring districts in 2005-2014 - applying the structural change decomposition method.

It has been pointed out that employment structures in sectors or sections may be used to specify specializations (Marelli, 2004; Zheng and Kuroda, 2012; Markowska et al. 2016), concentration (Alecke et al. 2006; Merino and Rubalcaba, 2013) or agglomeration (Zhang, 2016; Alonso-Villar et al. 2004) of countries and regions.

Method

The completion of the goal of the study required a definition of the set of variables for clustering (employment in sectors and sections), the analysis period and study objects. Once data had been collected and missing information imputed, a final data matrix was prepared and a preliminary data analysis was performed. Structure dissimilarity measure (Chomątowski and Sokołowski, 1978) was applied as a distance measure, and it was used separately for each of analysed structures and periods. The complete linkage method makes possible to single out clusters for which the intra-cluster distance is not larger than the cut-off distance which is established through the analysis of dendrogram. Finally we can determine mean values of variables in the clusters as well as calculate reference means concerning the dynamics and pace of development for the identified clusters.

Data and its preliminary analysis

The assessment of the labour market situation from the point of view of changes in the employment is possible on the basis of data available in Eurostat, arranged by sectors and sections (Eurostat, 2019). For the purposes of clustering, the following employment sectors have been taken into account (for years 2008 and 2018) (as percentage of total employment):

P_1 – employment in agriculture, forestry and fishing, mining and quarrying,
P_2 – employment in manufacturing,
P_3 – employment in electricity, gas, steam and air conditioning supply, water supply and construction,
P_4 – employment in services,

and the following sections:

S_1 – employment in medium high-technology manufacturing,
S_2 – employment in high-technology manufacturing,
S_3 – employment in medium low-technology manufacturing,
S_4 – employment in low-technology manufacturing,
S_5 – employment in knowledge-intensive high-technology services,
S_6 – employment in knowledge-intensive market services (except financial intermediation and high-technology services),
S_7 – employment in other knowledge-intensive services,
S_8 – employment in less knowledge-intensive market services.

In order to assess the level of development, data concerning GDP per capita (p.c.) was used (Eurostat, 2020):

GDP_2008 – purchasing power adjusted GDP per capita in 2008,
GDP_2018 – purchasing power adjusted GDP per capita in 2018,

and in order to determine the dynamics of changes, data of 2000 for the first year of assessment and GDP per capita of 2008 for 2018 respectively:

DYN_GDP (2008/2000) – the dynamics of GPP per capita in 2008 (2000 = 100),
DYN_GDP (2017/2008) – the dynamics of GPP per capita in 2018 (2008 = 100).

The ranges of variable values and general differences between 2008 and 2018 are summarized in Table 3.

Table 3: Highest, lowest and median employment shares, in 2008 and 2018

Variable	Highest share				Lowest share				Median	
	2008	Country	2018	Country	2008	Country	2018	Country	2008	2018

Results and Discussion

With cluster analysis, eight groups of countries similar in employees shares in the sectors have been identified for the data of 2008 and six for 2008 (Markowska, Strahl, 2020). The composition of the clusters and mean values of the shares of people in employment in the sectors for the data of 2008 are presented in Table 4, and for the data of 2018 – in Table 5. The average GDP is also provided in both tables, and the clusters are arranged in an order from the highest to the lowest average GDP per capita. The applied cluster numbering is derived from the position in the dendrogram.

Table 4: Classification results – cluster composition and average employment shares in sectors, in 2008

In both partitions of EU countries identified with respect to the share of employment in the sectors (2008 and 2018), clusters with the highest share of employees in the service sector (P_4) are also characterized by the highest average GDP per capita. Four countries are the core of both clusters: Luxembourg, Sweden, Great Britain and the Netherlands. At the other extreme, there is a single-country cluster with Romania. It has the highest share of employment in agriculture, forestry and fishing, mining and quarrying as percentage of the total employment, and at the same time, the lowest GDP per capita. The low development level in this country in both years is accompanied by very high dynamics, due to low GDP in the base year.

The analysis of section structures produce eight clusters in 2008 and nine in 2018. The xomposition of clusters and mean values of employment shares for 2008 is presented in Table 6, and for 2018 – in Table 7. Clusters have been sorted from the highest to the lowest average GDP per capita, as in the case of the partitions for sectors described in Tables 5 and 6.

Acronyms – as in table 4.
Source: author's compilation.

Two last clusters, (arranged according to the average GDP per capita) include the same countries in both years. The second from the bottom are Latvia and Lithuania (the average GDP per capita of 15900 Euro in 2008 and 23050 Euro in 2018). Thay have one of the lowest shares of employment in knowledge-intensive high-technology services as percentage of total employment and employment in knowledge-intensive market services (excluding financial intermediation and high-technology services) as percentage of total employment). The last group consist of Bulgaria and Romania (with the average GDP per capita of 12200 Euro in 2008 and 17900 Euro in 2018).

In the further analysis, the natural logarithm of GDP was also considered. It mitigates the right-hand asymmetry of the distribution and slightly flattens the effect of the outlier – Luxembourg. The correlation of the structure elements with GDP, lnGDP and dynamics has been calculated separately for the years 2008 and 2018, and separately for sectors (Fig. 1) and sections (Fig. 5). Statistically significant correlation coefficients are marked in red. Scatter diagrams have been prepared for the strongest correlations, and the nature of the relationship has also been checked to assess whether relation is linear or non-linear. Where the correlation is linear, the correlation coefficient (r) is provided, and where it is non-linear, the value of multiple correlation coefficient (R) obtained as a root of a coefficient of determination for parabolic regression is given. The presented diagrams (Fig. 2, 3, 4 and 6) are categorised with obtained clusters marked.

Countries from the same cluster are usually located close to each other in the scatter diagram. One can conclude that in 2008 universal mechanisms were dominant in the case of shares of employment in sectors and sections, whereas in 2018 the employment structures and GDP per capita were more diversified (Fig. 4). In the analysis of the relationship between employment structures in sectors and income, the share of people in employment in services was the most significant. The relationship with GDP per capita logarithm is non-linear. In Fig. 2 the identified clusters of countries are clearly visible. There are two outliers – Romania and Luxembourg, at the extremes of the variability of the employment share in services. In general, the income is greater in countries where employment in services is higher. However, this effect is visible only when the boundary of 70% of people in employment is exceeded.

Fig. 4: Employment shares in services versus ln GDP in 2018

Source: author's compilation.

The opposite tendency appears in the the relationship between the employment share in services and income dynamics 2008/2000 (Fig. 3). Here, countries from the same clusters are also visibly located close to each other in the diagram. The negative relationship was caused by the so called base effect. Countries with low GDP per capita in 2000 managed to reach high GDP dynamics at the beginning of the 21st century quite easily, taking into account the base effect, after they had freed themselves from the "fetters" of the command economy.

In section-wise analysis the greatest correlations are observed for S_4 variable (employment in low-technology manufacturing) in both years (Fig. 5).

Source: author's calculations

Fig. 6: Employment shares in low-technology manufacturing versus ln GDP (left) in 2008 and GDP dynamics (right)

Source: author's own compilation

The highest, but negative correlation (-0.913) was observed between the employment in low-technology manufacturing and lnGDP in 2008 (Fig. 6). The linear regression provides a very good description of this relationship. Countries even with extreme results, such as Luxembourg and Bulgaria, are located close to the regression line. Generally, the same relation is observed in 2018, but with higher variability around regression line (Fig. 8). Fig. 7 illustrates a curvilinear correlation between the share of people employed in industry sections with poorly developed technology and GDP dynamics 2008/2000. Good dynamics (more than 160) have been observed for low technology countries with shares of people in employment of more than 8%.

Summary

The similarity of the identified clusters of EU states, both in terms of the shares of people employed in sectors and sections of industry of a different technological advancement and knowledge-intensive services, compared in two years – 2008 and 2018, is high, as stated also in the paper (Markowska, Strahl, 2020). The similarity of partitions measure (Sokolowski, 1976) for the assessed "arrangements" was 0.839 for sector structures in 2008 and 2018 and 0.913 for section structures in 2008 and 2018.

For the analysed sector employment structures, negative and statistically significant correlations in 2008 and 2018 were obtained both for GDP per capita and for the logarithm of this characteristic, with the share of employees in: agriculture, forestry and fishing, mining and quarrying (P_1), manufacturing (P_2), electricity, gas, steam and air conditioning supply, water supply and construction (P_3). Negative and statistically significant correlations are also observed in the employment share in services and in the dynamics of GDP per capita. Positive and statistically significant correlations for sector employment structures were observed for the data of 2008 and 2018 in the case of the relationship between:

– the level of GDP per capita (and the logarithm of this characteristic) and the share of people employed in services in 2008 and 2018,
– share of people employed in electricity, gas, steam and air conditioning supply, water supply and construction as percentage of total employment.

The results were generally similar for the data of 2008 – between the share of people employed in agriculture, forestry and fishing, mining and quarrying and the GDP dynamics.

In both analysed years, negative and statistically significant correlations were obtained for shares of employees in: low-technology manufacturing section and GDP per capita and the same characteristic expressed as a logarithm, and in knowledge-intensive market services as compared to GDP dynamics.

The positive tendency was observed in the relationship between GDP per capita and the logarithm of GDP per capita and the share of employment in the following sections:
– knowledge-intensive high-technology services,
– knowledge-intensive market services,
– other knowledge-intensive services.

Positive and statistically significant correlations are also observed in the employment share in low-technology manufacturing with GDP dynamics.

As a result of the conducted study, one can find that the employment structure in both sectors and sections of industry affects not only the level of GDP per capita and GDP dynamics, but also shows, through the tendency of the studied relationships, a particular role of economic sectors and sections that are based on knowledge and innovative technology.

Further studies may lead to the assessment of dynamic relationships between employment structures and entrepreneurship, unemployment, as in the paper by J.M. Plehn-Dujowich (2010). It is interesting whether the employment structure in sectors and sections of industry is a stimulus for the dynamisation of innovation in economy, and entrepreneurship rise.

Abstract

Economic freedom means the ability and rights of people of a country to take any economic actions. The concept of economic freedom is a key term during many political debates and in the philosophy of economics (see for example Bronfenbrenner 1955). To measure economic freedom whole number of indicators (quantitative and qualitative from four main categories) are taken into account. These indicators are then combined to build an economic freedom index. The main aim of the paper is to present the results of symbolic ensemble clustering and ensemble linear ordering of selected European countries according to their economic freedom. In the empirical part of the paper results of linear ordering and symbolic clustering ensemble are presented (where different clustering results are combined using Leisch's approach). Besides that linear ordering multidimensional scaling for symbolic data (with symbolic-numeric approach) is used to visualize results. Both approaches allow discovering countries that share similar patterns of economic freedom.

Keywords: Economic Freedom, European Countries, Symbolic Data, Ensemble Clustering

JEL codes: C38, C01, O52.

Introduction

Economic freedom in general means the ability of people in a particular country to take any kind of economic activity. The idea of advancing economic freedom is strongly connected to the empowerment of people. Usually stronger and expanding freedom improves chances to archive individual goals (see for example Miller et. al. 2014).

To measure economic freedom whole number of indicators (quantitative and qualitative from four main categories) are taken into account. These indicators are then combined to build an economic freedom index.

Economic freedom in general means the ability of people in a particular country to take any kind economic actions. The idea about advancing economic freedom is strongly connected to the empowerment of people. Usually stronger and expanding freedom improves chances to archive individual goals (see for example Miller et. al. 2014).

To measure economic freedom whole number of indicators (quantitative and qualitative from four main categories) are taken into account. These indicators are then combined to build economic freedom index. Most important freedom indices include:

1. Index of Economic Freedom developed and published by Heritage Foundation.
2. Indicator of the Economic Freedom of the World developed and published by the Fraser Institute.
3. Freedom survey that is published as World of Economic Freedom by Freedom House.

Besides that, many different authors present different aspects of economic freedom, like concepts of measurement by Gwartney and Lawson (2003), relationship of the income, economic freedom and the BMI by Lawson, Murphy and Wiliamsnon (2016), the role of economic institutions by Dutta and Williamson (2016), and the impact of the crisis on economic freedom by Bjørnskov (2016).

The main aim of the paper is to present the results of symbolic ensemble clustering and ensemble linear ordering of selected European countries (mostly the members of the European Union) according to their economic freedom. In the empirical part of the paper results of linear ordering and symbolic clustering ensemble are presented, where different clustering results are combined using Leisch's approach (Leisch 1999). Besides that linear ordering multidimensional scaling for symbolic data (with symbolic-numeric approach) is used to visualize results. Both approaches allow discovering countries that share similar patterns of economic freedom.

Ensemble Linear Ordering and Clustering for Symbolic Data

As usually in data analysis objects are described by single-valued variables, so they can be represented as a vector of qualitative or quantitative measurements, where each column represents a variable. Such data representation is too restrictive if we want to represent more complex data, that will take into account the uncertainty and/or variability. To represent such data variables must assume sets of categories or intervals, including in some cases frequencies or weights. Such kind of data has been mainly studied in Symbolic Data Analysis (SDA).

The main aim of Symbolic Data Analysis is to provide suitable methods for managing aggregated or complex data described by multi-valued variables, where cells of the data table contain sets of categories, intervals, or weight (probability) distributions, see for example (Billard, Diday 2006; Bock, Diday et al. 2000). Figure 1 presents general information about types of symbolic variables.

In the case of symbolic data, two types of data aggregation can be used to obtain symbolic variables and objects (see Billard and Diday 2006; Diday and Noirhomme-Fraiture 2008; Noirhomme-Fraiture and Brito 2011).

The first one is the temporal aggregation, where information for classical objects (individuals) are aggregated over time. In this case, we have first-order symbolic objects (simple objects, individuals). The second one is contemporary data aggregation, where other information than time is used to obtain symbolic objects (e.g. consumers buying the same product). In this case, we get second-order symbolic objects (super-individuals, complex objects).

In order to obtain the interval-valued symbolic variable, while aggregating the data, four different approaches can be used. The first one is to use minimum and maximum values from the initial data as the lower and upper bounds of the symbolic interval-valued variable. The second one is to take the first quartile from the data set as lower bounds of intervals and the third quartile from the data set as upper bounds of intervals. The third approach is to take the 10th percentile from the data set as lower bounds of intervals and the 90th percentile from the data set as upper bounds of intervals. And the last approach is to use some arbitrary knowledge (e.g. from experts) to obtain lower and upper bounds of a symbolic variable.

In general ensemble learning means combining results obtained by different models in order to get one aggregated model. In that sense ensemble approach can be applied in linear ordering for symbolic data, where multidimensional scaling is used for visualization.

Fig. 1: Types of symbolic variables.

Source: own elaboration based on Bock and Diday (2000) and Billard and Diday (2006).

The concept of the pattern of development and anti-pattern of development as well as concepts of development measurement were proposed by professor Z. Hellwig (see Walesiak 2017a). A two-stage, hybrid, procedure that allows visualizing the results of the linear ordering was presented by professor Walesiak (see Walesiak 2016, 2017b). This procedure can be also applied to symbolic data, were different distance measures will be used, and such procedure involves:

1. Choice of a complex phenomenon that cannot be measured directly. This phenomenon is considered among a set of objects A.
2. Choice of objects.
3. Selection of symbolic variables and collecting the data and the construction of a symbolic data table.
4. Identification of preferential variables – stimulants, destimulants and nominants. Variable is a stimulant when for every two of its observations v_{ij}^{S}, v_{kj}^{S} for two objects A_i, A_k there is a reference $v_{ij}^{S} > v_{kj}^{S} \Rightarrow A_i \succ A_k$ ($\succ$ means that object A_i dominates over object A_k). Variable is a destimulant for every two of its observations v_{ij}^{D}, v_{kj}^{D} for two objects A_i, A_k there is a reference $v_{ij}^{D} > v_{kj}^{D} \Rightarrow A_i \prec A_k$ ($\prec$ means that object A_k dominates over object A_i). A variable is a unimodal nominant when for every two of its observations v_{ij}^{N}, v_{kj}^{N} for two objects A_i, A_k if $v_{ij}^{N}, v_{kj}^{N} \leq nom_j$ then $v_{ij}^{N} > v_{kj}^{N} \Rightarrow A_i \succ A_k$ and if $v_{ij}^{N}, v_{kj}^{N} > nom_j$ then $v_{ij}^{N} > v_{kj}^{N} \Rightarrow A_i \prec A_k$ (where i, k are object's numbers and j is the variable's number).
5. Transformation of nominants into stimulants. There is no need to transform destimulants into stimulants.
6. Normalization of variable values.
7. Calculation of distances between objects. For a symbolic data case many different distance measures can be applied. They are chosen upon the type of symbolic variables.

Multidimensional scaling for symbolic data is done. This method allows representing objects from a *m*-dimensional space on a *q*-dimensional space (usually $q = 2, 3$). In the case of symbolic data two approaches for multidimensional scaling can be carried out:

a) the symbolic-symbolic approach, where for symbolic data a table containing symbolic interval-valued data only, interval-valued distances are calculated. The interval-valued distances are used to carry out multidimensional scaling with one of three approaches – InterScal, SymScal or I-Scal (see Groenen and Terada 2015; Goenen et. al. 2005; Groenen et. al. 2006). This approach allows to represent symbolic objects as rectangles, in the case of a 2 dimensional plane, or cuboids (hyperrectangles) in the case of a 3 dimensional plane,

b) symbolic-numeric approach, where for a symbolic data table containing any symbolic variables distances for all objects are calculated. There are many different distance measures for symbolic data. The choice is usually limited to the symbolic variables (see for example Gatnar and Walesiak (eds.) 2011). The iterative procedure called smacof was used in this paper (Borg and Groenen 2005, pp. 204-205). The symbolic-numeric approach allows representing symbolic objects as points.

In the multidimensional scaling for symbolic data, when using either of the mentioned approaches, multiple distance matrices can be used, leading to an ensemble result of the MDS. To build one distance matrix from multiple distance matrices two approaches can be used. The first one involves using new STRESS function, that allows applying different distance matrices (see Bai et. al. 2017).

This approach has been developed for the classical data matrix. However, it can be also applied for symbolic multidimensional scaling based on interval-valued distances by modifying either STRESS-Sym or I-STRESS functions (see Groenen and Terada 2015; Goenen et. al. 2005; Groenen et. al. 2006 for details on I-STRESS and STRESS-Sym functions).

The second approach uses the approach proposed by Melssen et. al. (2006) to combine dissimilarities. The dissimilarities in each dissimilarity object are scaled so that the maximum dissimilarity in each object is 1. The scaled dissimilarity objects are then weighted according to the supplied weights. If no weights are supplied the dissimilarity objects are weighted equally (Melssen et. al. 2006):

$$D_{fused}(j,k) = \sum_{i=1}^{N} w_i D_{ijk,} \qquad (1)$$

where: $D_{fused}(j,k)$ − combined (fused) distance matrix, obtained by merging distance matrices *j* and *k*; w_i −weight assigned to the *i*-th distance matrices; D_{ijk} −distance matrices *j* and *k* to be combined.

In this paper, symbolic-numeric multidimensional scaling will be applied. Besides that multiple distance matrices will be used (namely: Ichino-Yaguchi, normalized Ichino-Yaguchi, de Carvalho distance based on description potential, normalized de Carvalho based on description potential, de Carvalho distance that extends Ichino-Yaguchi distance and Hausdorff). The final distance matrix will be obtained using the approach proposed by Melssen et. al. (2006).

8. Graphical representation and interpretation of the results (multidimensional scaling and linear ordering results). For the multidimensional scaling results a straight line that connects pattern and anti-pattern (so-called axis of the set) is added. Isoquants of development are determined and based on a pattern object – e.g. by dividing the axis of the set into four equal parts. The objects that are located between isoquants represent a similar level of development that can be archived by different objects.

Normalized distances of the i-th object from the pattern of development are calculated as follows (see Hellwig 1981, p. 62):

$$d_i^+ = \frac{\sqrt{\left(z_{ij} - z_{+j}\right)^2}}{\sqrt{\left(z_{+j} - z_{-j}\right)^2}}, \quad d_i^+ \in [0;1], \qquad (2)$$

where: $\sqrt{\left(z_{ij} - z_{+j}\right)^2}$ − Euclidean distance between the *i*-th object and the pattern object; $\sqrt{\left(z_{+j} - z_{-j}\right)^2}$ − Euclidean distance between the pattern and the anti-pattern object; i is the object's number; j is the variable's number; − means the anti-pattern object; + means the pattern object.

The objects are ordered by the increasing values of distance measure (1). The linear ordering results are presented in the figure.

When considering ensemble clustering for symbolic data following solutions are possible:

1) Clustering based on multiple distance matrices that was proposed by de Carvalho, Lechevallier and de Melo (de Carvalho, Lechevallier and de Melo 2012). Multiple distance matrixes are used to calculate relevance weight vectors. Then these vectors and distance matrices are used to obtain final clustering.
2) Consensus functions that are used in clustering ensembles – e.g. mutual information, co-clustering matrix, hypergraph, finite mixture models (Ghaemi et. al. 2009).
3) Adaptations of well-known bagging procedure for clustering (see Hornik 2005, Leisch 1999, Dudoit and Fridlyand 2003). In this paper, Leisch's adaptation of bagging will be used. This procedure involves (Leisch 1999):

a) division of initial data set into *M* subsets. These subsets a drawn from initial data set with replacement – in this paper 25 subsets with 10 objects each will be used,

b) clustering of each subset. In the classical data case centers of clusters are obtained. In the case of symbolic data medoids will be used,

c) medoids (cluster centers) are used as the data matrix for some clustering method – e.g. *k*-means, pam, DIANA, etc., and final clusters are obtained. In this paper well-known *k*-means will be used with silhouette index for cluster selection (see Kaufman and Rousseeuw 1990),

d) for the final clusters new medoids are obtained,

e) all objects are assigned to the nearest medoid.

Analysis of the economic freedom of selected European countries

The empirical study uses the statistical data obtained from the Heritage Foundation (https://www.heritage.org/index). This dataset is freely available to download on their website. The index used by the Heritage Foundation covers 12 aspects of freedom, from property rights to the financial freedom, for 128 different countries. The measurement of economic freedom done by the Heritage Foundation is based on 12 quantitative and qualitative factors grouped into four categories. The categories (pillars) include rule of law (property rights, governmental integrity, judicial effectiveness), government Size (government spending, tax burden, fiscal health), regulatory Efficiency (business freedom, labor freedom, monetary freedom) and open markets (trade freedom, investment freedom, financial freedom).

In this paper data from 2016-2019 was used to obtain symbolic interval valued data for selected European countries using temporal data aggregation.

The dataset was descried by following variables that covered all pillars of economic freedom (more about all pillars and their more detailed description can be found at: https://www.heritage.org/index/pdf/2019/book/methodology.pdf):

v_1 – property rights is a component that assess the extent to which country's legal framework allows an individual to acquire, hold and utilize property. The final score for this component is derived by averaging scores for the following equally-weighted sub-factors: physical property rights, intellectual property rights, strength of investor protection, risk of expropriation and quality of land administration.

v_2 – judicial effectiveness. This component is derived by averaging scores for equally-weighted sub-factors: judicial independence, quality of the judicial process and favoritism in decisions of government officials.

v_3 – government integrity is a component that covers following areas that were averaged equally: public trust in politicians, irregular payments and bribes, transparency of government policymaking, absence of corruption, perceptions of corruption and governmental and civil service transparency.

v_4 – tax burden is a composite measure that covers the marginal tax rates on both personal and corporate income and the overall level of taxation (including direct and indirect taxes imposed by all levels of government) as the percentage of the gross domestic product (GDP). The component score is calculated from three quantitative sub-factors: the top marginal tax rate on individual income, the top marginal rate on corporate income and the total tax burden as the percentage of the GDP.

v_5 – government spending is the component that covers the burden imposed by government expenditures, which includes consumption by the state and all transfer payments related to various entitlement programs.

v_6 – fiscal health that is associated with macroeconomic instability and economic uncertainty. The score of the fiscal health is based on two sub-factors that were equally-weighted: average of deficits as the percentage of the GDP for recent three years (80% of the final score) and debt as the percentage of the GDP (20% of the final score). In most cases the index covers government deficit and debt data that include all levels of government such as federal, state and local.

v_7 – business freedom is a component measure that captures the extent to which the regulatory and infrastructure environments constrain the efficient operation of business. The final score is based on 13 sub-factors that are weighted equally.

v_8 – labor freedom component is a quantitative measure that considers various aspects of the legal and regulatory framework of a country's labor market, including regulations concerning minimum wages, laws inhibiting layoffs, severance requirements and measurable regulatory restraints on hiring and hours

worked plus also labor force participation rate as an indicative measure of employment opportunities in the labor market.

v_9 – monetary freedom combines a measure of price stability with an assessment of price regulations (controls). The final score is based on two sub-factors: the weighted average inflation rate for the most recent three years and price controls.

v_{10} – trade freedom is a composite measure of the extent of tariff and nontariff barriers that affect imports and exports of goods and services.

v_{11} – investment freedom covers a variety of regulatory restrictions that typically are imposed on investment.

v_{12} – financial freedom is an indicator of banking efficiency as well as a measure of independence from government control and interference in the financial sector.

All key pillars (factors) take value from 0 (minimum) to 100 (maximum). Variables $v_1, v_2, v_3, v_5, v_6, v_7, v_8, v_9,$
v_{10}, v_{11}, v_{12} are stimulants, variable v_4 is destimulant. Variable v_5 (government spending) is a nominant with a nominal level equal to 30. As the government spending is nonlinear, it means that spending that is close to 0 is penalized, while spending that exceeds 30 percent of the GDP leads to much worse scores in a quadric fashion (see https://www.heritage.org/index/pdf/2019/book/methodology.pdf for further details). To change the nominant variable into stimulant following equation was used for initial data:

$$v_{ij} = \frac{min\{nom_j; v_{ij}^N\}}{max\{nom_j; v_{ij}^N\}}, \qquad (3)$$

where: nom_j – nominal value for *j*-th variable; v_{ij}^N – value of the *j*-th variable for *i*-th object.

Figure 2 presents the results of the multidimensional scaling for 29 objects (27 countries, the pattern and the anti-pattern object). Objects 28 (pattern object) and 29 (anti-pattern object) were connected with a straight line to obtain the so-called axis of a set. Seven isoquants were added by dividing the axis of a set into seven equal parts.

Fig. 2: Results of multidimensional scaling in the two-dimensional space for 29 objects – 27 European countries, pattern object (28) and anti-pattern object (29).

Source: own elaboration using R software.

The distances of each country from the pattern object were calculated according to the formula (2). Countries were ordered by the growing values of this measure. The results are presented in table 1.

Table 1: The ordering of 29 objects regarding their level of economic freedom

Object no.	Object's name	Distance	Object no.	Object's name	Distance
28	pattern	0.0000	10	Germany	0.4166
27	United Kingdom	0.2600	17	Lithuania	0.4231
6	Denmark	0.2608	2	Belgium	0.4362
26	Sweden	0.2772	12	Hungary	0.4565
5	Czech Republic	0.2861	9	France	0.4595
18	Netherlands	0.2864	20	Poland	0.4599
8	Finland	0.2900	21	Portugal	0.4994
7	Estonia	0.2925	4	Cyprus	0.5004
19	Norway	0.3371	23	Slovakia	0.5027
16	Latvia	0.3557	25	Spain	0.5141
3	Bulgaria	0.3670	24	Slovenia	0.5505
14	Ireland	0.3674	15	Italy	0.5566
1	Austria	0.3728	11	Greece	0.6011
13	Iceland	0.3887	29	anti-pattern	1.0000
22	Romania	0.4133			

Source: own elaboration based on R software.

The top five European countries when concerning their economic freedom include United Kingdom, Denmark, Sweden, Czech Republic and the Netherlands. The five worst countries include Slovakia, Spain, Slovenia, Italy and Greece. Poland is not doing so great, as it is the 21-st country in the whole group.

For the same data set symbolic ensemble clustering, that uses Leisch's adaptation of bagging was used. As the final solution, three cluster solution was obtained with silhouette index equal to 0.6287997. The first cluster contains eleven countries: Austria, Belgium, Denmark, Estonia, Finland, Germany, Iceland, Ireland, Netherlands, Norway and Sweden. The second cluster contains ten countries: Bulgaria, Cyprus, Czech Republic, Hungary, Italy, Latvia, Lithuania, Poland, Romania and Slovakia. The third cluster contains France, Greece, Portugal, Slovenia, Spain and United Kingdom.

To find out which variables have the most significant impact on cluster membership a symbolic decision tree was built using symbolicDA package for R software (see Dudek, Pełka and Walesiak 2019). Figure 3 presents the final decision tree.

Variable v_9 (monetary freedom) has the most important impact on cluster memberships. Variable v_8 (labor freedom) is the second one when considering importance and variable v_5 (government spending) is the last one. Variable v_9 (monetary freedom) takes value from 79.8 to 91.6 in cluster 2, 78.7 to 87.1 in cluster 3 and from 74.7 to 87.5 in cluster 1. Variable v_8 takes values from 50.7 to 77.9 in cluster 2, 43.7 to 73.9 in cluster 3 and 47.8 to 86.1 in cluster 1. Variable v_5 takes value 0.45 to 0,98 in cluster 2, 0.08 to 0.92 in cluster 3 and 0.03 to 0.89 in cluster 1.

Fig. 3: Decision tree obtained for three clusters.
Source: own elaboration using R software.

Final Remarks

The proposed extension of the linear ordering that is combined with multidimensional scaling allows taking a deeper look into linear ordering results. When merging different distance measures into one (single distance matrix) we allow taking a look from different angles (perspectives) at the same problem. Such an approach allows using different approaches (distance measures) combined with different normalization methods in case of classical data.

When analyzing countries with similar levels of economic freedom three clusters were obtained with silhouette index equal to 0.62879997. This means there is a strong cluster structure in the data set. The most important variable, when considering clusters, is the variable v_9 (monetary freedom), then labour freedom. This means countries with high values of monetary and labour freedom are considered to have higher economic freedom in general and are more likely to be found in cluster 1 ("core UE countries with high economic freedom"). Second cluster contains mainly post-communist countries from eastern Europe that are low- and medium free when considering their economic freedom. The third cluster contains also high and medium-high countries with economic freedom.

When looking at linear ordering results we can find out that there are countries with similar levels of economic freedom, but with different position when looking at the axis of the set (see fig. 2) – for example Czech Republic (5) and Estonia (7), Latvia (16) and Ireland (14), Germany (10) and Lithuania (17), Spain (25) and Slovakia (23), Italy (15) and Greece (11). They share quite similar levels of economic freedom but they have different positions on the map as there are different reasons for them to be on such places.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

Business as A Career Choice for Women

Silvia MATÚŠOVÁ

Vysoka skola ekonomie a manazmentu verejnej správy v Bratislave, Bratislava, Slovak Republic, silvia.matusova@vsemvs.sk

Abstract

In spite the fact that the entrepreneurship in Slovakia is carried out mostly by men, women have also started to develop entrepreneurial activities in the market as successful entrepreneurs and managers. The entrepreneurship represents the area of the unutilised potential for career self-fulfilment and economical assurance of women. The businesswomen and female managers contribute, specifically by innovations, to business and entrepreneurship. In most cases, the women run business alone or as sole-traders and self-employed persons, mostly in branches as health, fashion, social-work, services, administration, education and training. The study analyses entrepreneurial activities of women in Slovakia and provides information on the system of support on behalf of entrepreneurial activities of women. The paper includes the results from survey on the entrepreneurial activities of women in Slovakia as well as the identification of factors contributing to disadvantaging position of female entrepreneurs and mangers in the market.

Keywords: Women, Legal Acts, Economic Stimulus, Challenging Career

Introduction

The status of women in society has been principally changed. The original role of women as mothers primarily caring after family has been changed and the women have started to act not only as mothers, in numerous cases as breadwinners (Alma Mater) but also as entrepreneurs in the market. The country which is economically successful is characterised by the capability to fully utilise the potential and talents of all population in productive age and at the same time able to raise new generations. The share of women in the labour market in Slovakia is lower than of men. Employed women usually work less hours than fulltime job, in sectors with lower earnings and occupy lower positions compared to men which effects the significant difference in remuneration and incomes between women and men.

The differences can be, to a certain degree, ascribed to deeply rooted, traditional gender roles as well as to economic stimuli. At present, however, the share of female entrepreneurs in the market has increased. They, the women, have often to cope with numbers of problems in the world of business and entrepreneurship which traditionally is the world of men. Women, however, do have an unsubstitutable place in entrepreneurship, management of corporations and politics. They, the women, contribute by their labour, creativity and female esprit to the cultivation of all above areas.

The paper has focused on the issues of entrepreneurship of women in their entrepreneurial activities with the intention to identify individual obstacles that women usually encounter and has identified factors positively influencing the harmonisation of labour (entrepreneurship) and personal obligations (family, further education, leisure time). The primary sources of statistics utilised in the paper were the databases of the Statistical Office of the Slovak Republic.

Representation of women in the market

The Annual Report on the State of Entrepreneurial Environ in the Slovak Republic, regularly elaborated by the Ministry of Economy of the Slovak Republic, provides monitoring on various aspects of the topical state of entrepreneurship environ. The report informs that in 2018 there was an increase by 51 586 entrepreneurs that run business activities in various legal forms as natural persons. The Slovak women entrepreneurs showed the biggest interest in running businesses based on trade certificate. The second place was represented by freelance occupations, i.e. the entrepreneurial activities not based on

the trading authority certificate (3654 persons). The majority of natural persons was registered in Prešov region (9112 subjects) and Žilina region (7529 subjects). On the contrary, the least natural persons were registered in Trnava region (4847). The share of female entrepreneurs and managers represents 29 % on the market. The biggest share of Slovak female entrepreneurs do business in Bratislava region.

The women, compared to men, are underrepresented in central state administration bodies with the exception in the sector of education and justice. The share of women in the sector of justice is 1,7 times higher compared to men. In the Supreme Court the share of female judges represents almost 60 % and the president and the vice-president of the Supreme Court are women. In the Constitutional Court the share of women in the position of judges represented 36,4 % in 2018.

It is a well-known fact that in the top company bodies the men are significantly represented compared to the women, and thus there is a higher probability of the narrow "group thinking" (Commission, 2012).

The representation of women in decisive positions in the Slovak Republic is very different, varying from the total absence of women in top decisive positions (e.g. the Banking board of the National Bank of Slovakia). The political representation of women has reached a turning point in 2018 when during the government reconstruction as many as 5 ministerial chairs out of total 15 were taken by women which was registered so far as the highest share of women in the Slovak Government since 1993, thus representing 33,3 %.

In the management of Slovak business companies the women proved to be competent in personal/human resources departments (82,5 %), informatics departments (56,2 %) and marketing departments (50,7 %). The least share of women was observed in the management of IT departments (6,7 %). Among the most significant 1 375 corporations in Slovakia the share of women in the position of directors general represented only 9 %.

The overall unemployment rate of women in 2019 in all eight Slovak regions was higher than the overall unemployment rate in the country and the unemployment rate of men specifically. For example, the unemployment rate of women in Prešov region (Eastern Slovakia) was three times higher than the rate in the capital Bratislava. Due to the Statistical Office of the Slovak Republic, the highest unemployment rate of women was registered in districts with relatively high shares of Romany ethnic groups, as e.g. Revúca (17,92 %), Kežmarok (17,15 %), Rožňava (16,29 %) and Vranov nad Topľou (15,54 %).

Success stories of women entrepreneurs acknowledged internationally

There are several well-known success stories referring to entrepreneurial activities of women acting and acknowledged internationally. There are, however, few examples of women who founded and managed really big companies, in some cases with international impact. In this group, e.g. Margaret Steiff can be ranked as a well-known German business woman, the founder of a toy factory *Spielwarenfabrik Steiff GmbH.*

Gabrielle Bonheur Chanel, better known as Coco Chanel, can be ranked among well-known female personalities enjoying international reputation. The fashion guru Coco by her talent and creativity created inimitable style of haute couture, perfumes and accessories. As back as in 1936 her company provided employment to 4000 employees and her vogue achievements were the success as she designed outfits for film stars (Audrey Hepburn, Grace Kelly) and the First Lady of the USA Jacqueline Kennedy.

Among the women personalities of the fashion world the undeniable significance is ascribed to Aenne Magdalena Burda who founded in Germany one of the biggest publishing houses for fashion journals, the Burda-Moden. In 1950 the first number of a new edition Burda Moden was published and in the short time the journal achieved the circulation of one million copies. At present, it is printed in 89

countries and 16 languages. Burda media concern publishes 239 journal titles all over the world. The flagship is represented by a news weekly Focus and a societal journal Bunte.

The world of business women with international reputation is represented by Elisabeth Arden, creative, visionary and well-balanced smart entrepreneur who has had courage and talent to transform dreams into reality. She opened her first beauty parlour in 1910. Her business activities included beauty salons and industry in the USA and Europe, with the representation in Australia and the South America, over 100 of Elisabeth Arden salons. The brand name Elisabeth Arden includes over 300 cosmetic products and relaxors.

At present, Victoria Beckham belonging to significant entrepreneurs was awarded by readers of the British Glamour as the Woman of the Year and the symbol of successful business woman and mother. She is active in the field of fashion and cosmetics.

Due to the estimate of the magazine Fortune 500, the share of women in the top management of the most significant corporations and public corporations represents 4,5 %. The ranking elaborated by Fortune includes 500 American private and public corporations due to the annual GDP.

Equal position of women in the market

The European Union and other international organisations, in the framework of their objectives and values, claim to the advocacy of equal opportunities and social rights protection. In their documents, they continuously require from their members to respect the principle to ban any discrimination. Economic integration as the process in which the economic relations are deepened and the economic collaboration is coordinated in the interoperation of all participating countries (Nováčková, 2014).

The European Union requests from its members to respect obligations set in EU primary and secondary legislation. The article 157 para 3 of the Treaty on Functioning of the European Union represents a legislative basis for all obligatory measures which aim to assure the application of the principle of equal opportunities and equal treatment of men and women in the issues of employment and occupation, including the measures of positive discrimination.

Based on the principle of loyal cooperation, embedded in article 4 para 3 of the Treaty on the European Union, the member states are obliged to adopt all necessary measures of general and specific substance, in order to assure the fulfilment of obligations emerging from the treaties and other legal acts of the institutions of the European Union. Pursuant to this principle, the member states must not adopt any other measures which could jeopardize the achievement of the EU goals. In the Slovak Republic, besides the Treaty of the Functioning of the European Union, the Slovak Constitution is applied, where in article 38 the particular status of women is embedded, in relation to the rights for increased health protection at work and special work conditions. The most significant legal act in labour relations is the Labour Code that has embedded the rights and obligations of subjects in labour relations, based on the labour (employment) contracts or emerging from labour relations based on temporary employment contracts.

The Labour Code directly bans the discrimination in remuneration of women and men. Both genders are entitled to equal earnings for equal work or equal value, respectively. The equal work is considered as the work of the same or comparable complexity, responsibility and work difficulty (labouriousness) which is carried out in equal or comparable working conditions, by accomplishing equal or comparable production rate and work accomplishments in labour relation at the same employer.

The principle of equal treatment is also set by the Act 265/2004 Coll. (subsequently amended) on equal treatment in some areas and on the protection against discrimination. Besides that, also the Constitutional Law 460/1992 Coll. (subsequently amended) in article 12, para 2 guarantees fundamental rights and freedoms to all, irrespective of sex, origin, nationality or ethnic group, property, kinship or other status (Bérešová, Nováčková, 2017).

Globalisation and international movement of persons

Globalisation fosters the economic development as well as the movement of labour force. The removal of barriers of free movement of persons is represented as the commitment of numerous international organisations.

Globalisation is the phenomenon of the present era and it effects economic, financial, social and cultural relations as well as the legal relations (Mičátek, 2019). In consequence of globalisation the mobility of labour force of women increases. The effects of globalisation are reflected in particular in the inflow of foreign investments, growth of interdependence, and in the deepening of global division of labour (Geistlinger, Nováčková, 2018). In 2017, the stock of EU-28 movers in the main destination countries increased by 5 % compared to 2016, with an increase of 14 % in the UK, 4 % in Germany, and between 1 % to 3 % in France, Italy and Switzerland. Aside from these, there were large increases in Portugal (12 %) and Poland and Lithuania (both 14 %). Hungary saw an 8 % decrease in EU-28 movers residing there (European Commission, 2018).

Entrepreneurial activities of women in Slovakia

In spite of the fact that the Slovak Republic by its territory is a rather small country, the regional disparities are manifested, including geographic and economic differences. Thus the conditions for entrepreneurial activities of women in Slovakia also differ. Therefore we will consider and analyse basic factors influencing women in professional life. The entrepreneurship of women in Slovakia is determined by several determinants, including the capital, without no doubts. Women can be motivated to start entrepreneurial activities also by ambitions to actualise themselves in labour markets.

The necessary prerequisites of entrepreneurial activities include:

- Social maturity: character maturity, will-power ripeness, cognitive maturity, creative maturity, the ripeness of temperament, emotional maturity, physical maturity, spiritual maturity.
- Cognitive efficiency: general and vocational knowledge efficiency related to the object of the work and the management and their substance, knowledge proficiency on management functions, knowledge on sources, contents and classification of information in management processes.
- Application skills: communication skills, motivation skills, team work skills, self-management and time-management skills (Slovenská akadémia manažmentu, 2019).

The decision to become an earner is an act of self-actualisation requiring a high level of commitment. Increased level of responsibility usually leads to the longer working time. The advantage of a woman in entrepreneurship is the possibility to harmonise the family life and the work, provided the external circumstances permit.

Table 1: Comparison of shares in female entrepreneurs in 8 Slovak regions

Region	2018	Age interval (Biggest share)	Branch	Average monthly salary in region (in euro. 2017)
Bratislava region	17 181	24-56	Services Industry Education	1 243
Trnava region	10 295	30-45	Services	903
Nitra region	12 591	40-49	Services	852
Banská Bystrica region	10 892	33-45	Industry Services	868
Trenčín region	10 378	34-45	Services	868

Žilina region	12695	40-49	Services Industry	864
Prešovský region	11 440	40-49	Services	819
Košický region	10 987	35-50	Services	912

Source: author, based on statistics of the Statistical Office of the Slovak Republic (cut-off day 31 December 2018)

The Table 1 illustrates the numbers of women who carry out entrepreneurial activities in 8 Slovak regions. Considering the acquired data, it is possible to say that there is a certain degree of dynamics in wiping away regional differences in earnings. Women carry out entrepreneurial activities mainly in the sector of services (such as gastronomy services, cosmetic services, garment repair, bakery services, auditing, accountancy, legal advice, health care, education, etc.). In the sector of industry the women mostly act in chemical industry.

In relation to age cohorts of women in entrepreneurial activities, the largest number of women is active as entrepreneurs in the age interval 40 to 49, which can be assessed as a ripe age.

Compared to other statistical sources we can formulate the assumption that in Slovakia with its 5,3 million of inhabitants, women in productive age compared to men show the tendency to prefer the status of employees. Out of 1 251 000 economically active women only 106 000 (8,4 %) carried out entrepreneurial activities in 2018, compared to 260 000 men entrepreneurs.

Identification of factors disadvantaging the position of women in the market

As one of the aims of the paper is to identify problems and obstacles in entrepreneurship of women, we administered a questionnaire in order to obtain relevant information. The questionnaire was administered from October 1, 2019 to December 31, 2019 to 330 participants. The respondents provided replies which were analysed and evaluated. The outcome of survey facilitated the identification of factors disadvantaging the position of women in entrepreneurial activities. We identified the following factors:

a) The traditional form of entrepreneurship in many women is the self-employment which usually neither brings big earnings nor profits. This group of women is at risk during their working life as well as in the old age as they are exposed to the risk of poverty.
b) Compared to men, women in entrepreneurship are not willing to get into debt or broaden the portfolio of entrepreneurial activities, probably because of lower level of self-confidence.
c) A significant problem of women in entrepreneurship is the access to finances and loans.
d) Women were primarily motivated to entrepreneurial activities because of the dissatisfaction at work. At present, they are motivated by acquired independence and possibility of autonomous decision-making.
e) They carry the entrepreneurial activities in majority cases in their own premises.
f) They offer their goods and services by internet and by other ways of marketing.
g) The branch of study (at secondary school or university) is usually not connected with the substance of their entrepreneurship.
h) They encounter and have to cope with traders in the market.
i) They are affected by unstable legal environ.

Based on the answers, the typical female entrepreneur in Slovakia could be characterised as a woman of 35, married, living in a municipality, mother of children, graduate of a secondary school or a university, carrying out entrepreneurial activities namely in the sector of services. The women usually act as natural persons, in some cases as legal entities. The entrepreneurship of women flourishes in municipalities and in the countryside where the focus of entrepreneurial activities lies in agricultural production and processing goods from biomass and relatively high share of services.

The support to entrepreneurship of women

The Central Office of Labour, Social Affairs and Family of the Slovak Republic is entitled to provide financial allowances to start entrepreneurship, namely the self-employment that will partly cover expenses associated with the business. The amount of the allowance is determined by several factors as e.g. the unemployment rate in the region and the overall cost of labour. The allowance is not paid out to full extent. At the start of the entrepreneurship, the 60 % of the approved allowance is paid out, the rest 40 % is paid after 12 months of the operation of self-employment. The women with the entrepreneurial activities based in the Bratislava region may receive the maximum allowance of 3 325,90 EUR. The women in regions with the average registered unemployment rate which is lower than the Slovak average unemployment rate and with the triple overall cost of labour may receive the allowance of 3 991,08 EUR from the governmental scheme as the entrepreneurship support assistance. In Slovak regions with the average rate of registered unemployment which is higher than the overall average in Slovakia and with the quadruple overall cost of labour the entrepreneurs may obtain the starting capital. The necessary condition for all above financial stimuli and allowances is the continuous operation of business for minimum three years (Central Office of Labour, Social Affairs and Family, 2019).

Conclusions

The entrepreneurial activities of women in Slovakia are effected by several determinants. The scope and the way of operation of economic activities is also determined by the harmonization of family and professional life and the amount of authorized capital. The relatively short history of entrepreneurship of women in Slovakia shows that women carrying out entrepreneurial activities do not give up and in spite of obstacles do persist in their entrepreneurial activities. They significantly contribute to the creation of new development opportunities, the decrease of social exclusion and the strengthening of social cohesion. We also identified that the share of women in entrepreneurship is still lagging behind in Slovakia as well as in many of EU member states. They, the women, they all represent the hidden, unutilised potential of growth and prosperity. The women in entrepreneurship often focus on branches which are less profit-making which was confirmed by statistics on entrepreneurship of women in Slovakia.

Abstract

Nowadays, Local Accommodation is one of the main types of accommodations, not only seen in Portugal, but also worldwide. The huge growth of this subject and the strong commitment to new concepts has fostered new trends and needs in the consumer. The present study aims to identify the national tourist perception, living in the North of Portugal, in relation to local accommodation, characterizing the main influence and motivation factors in the choice of this type of accommodation in Portugal and abroad. Taking this into consideration, after a literature review, an inquiry was carried out through an online questionnaire, composed mostly of closed questions and evaluation scales, to all Portuguese living in the north of Portugal, who had travelled at least once over the past 5 years. A random sample of 239 participants was collected, between May and July 2019. The collected data was treated through the SPSS software. An exploratory descriptive analysis, an inferential analysis and a factor analysis were then conducted using the information gathered. The study seems to point out that there is a significant relationship between the national tourist's adhesions to touristic accommodation in Portugal with the national adhesion to touristic accommodation abroad. The adhesion to local accommodation in Portugal is not related to the reasons for the trip/travel and the adhesion to local accommodation abroad, is mostly motivated by leisure. In what concerns the perception of the national tourist about touristic accommodation the location (Portugal/abroad) is not relevant.

Keywords: Tourism, Local Accommodation, Touristic Accommodation, Motivations

Introduction

Tourism is a social phenomenon defined by the consequence of the temporary movement of people, from one place to another, far from their usual place of residence (Sharpley, 2014). The study of tourism involves the motivation and experience of tourists, as well as the expectations and adjustments on the destination community, adding all stakeholders. Foreign tourism and domestic tourism are an integral part of people's lives (Chang & Katrichis, 2016) and tourism products should exhibit solutions oriented to customers/market, with focus on quality and designed in an innovative way to satisfy needs and expectations of tourism/travel and increasing intentions of return and loyalty (Mwinuka, 2017). Tourism is a strategic sector, considered as an economic giant and the most important factor of social and economic development in the world (Weaver & Lawton, 2010), with unavoidable and transversal impact to several sectors, creating jobs and wealth. Technology applied to the tourism sector is able to achieve results that exceed people's expectations, allowing big connections, exchange of information and achievement of results in real time (International Tourism Highlights, 2019 Edition, 2019). In Portugal the tourism sector is the largest export economic activity in the country, being responsible, in 2019, for 52.3% of exports of services and for 19.7% of total exports, with tourist revenues registering a contribution of 8.7% in Portuguese GDP (Turismo de Portugal,

2020). The Northern Region of Portugal (NUTS 2) accounts for 23% of the country's total surface area and approximately 35% of the national resident population. This region concentrates in itself 18.4% of the Local Accommodation units of Portugal, clearly highlighting the district of Porto, with 69.4% of the units in this region (INE, 2018). The promotion of tourism in the North as a whole is based on five strategic products namely: i) business tourism; ii) city breaks; iii) touring and cultural landscape; iv) heritage; v) gastronomy and wine; vi) health tourism; vii) nature tourism and viii) religious tourism (Oliveira, 2014). New patterns and new profiles of tourists appear, requiring research in order to analyze whether the evolution of tourism and the new forms of accommodation accompany the needs of the portuguese tourist. The present study aims to understand the perception of the national tourist in relation to local accommodation in Portugal and abroad and also to understand what motivates and influences them, when choosing accommodation while travelling.

Literature Review

Tourism

Tourism is a service industry with high potential growth and a major concern in the international community as a whole (WTTC, 2017). The concept has evolved over the past few decades, being tourism evolved as a decisive link in accelerating the pace of global socioeconomic development (Joseph, 2013). It has different meanings for different people (Pruthi, 2004) and may be seen as the total sum of phenomena and relationships triggered from trips and stays of non-residents, insofar as they do not lead to permanent residence and are not linked to any earning activity (Robison, 1976). In a more holistic approach, referring to an integrated and complete analysis of tourism, Leslie (2000) defends the need to include all the key characteristics of tourism, namely, movement of people, transport, stay and activities at destination and determinants of demand and supply. In a first instance, the tourist is influenced by the destination itself, and the destination encompasses the regions, countries, cities and other areas that attract tourists. However, tourist destinations suffer great impact from tourism including economic, social, environmental and cultural, among others (Chetthamrongchai, 2017).

Collaborative Economy

The concept of collaborative economy is widely used in literary with multiple interpretations, often appearing as the sharing economy or collaborative consumption (Botsman & Rogers, 2010). Accordingly to Lamberton & Rose (2012) collaborative consumption is a system in which consumers enjoy a certain good without actually owning it. Collaborative economy is an economy built on individual or community knowledge networks *versus* centralized institutions (Botsman & Rogers, 2010) and can be defined in four dimensions: i) collaborative production, ii) collaborative consumption, iii) collaborative financing and iv) collaborative education. In essence, collaborative economy is based on transactions that happen between business-to-business (B2B), business-to-consumer (B2C) and peer-to-peer (P2P), where the contact between the service provider and the final consumer is established through a digital and online medium (Botsman & Rogers, 2010). Some examples of collaborative economy platforms or "peer-to-peer accommodation" are, among others, Airbnb, Stayz, 9flats, alterkeys and Roomorama (Mahadevan, 2018). In recent years, the local accommodation market has been growing sharply and this new economic concept presents the Airbnb platform as a leader in the local accommodation market (Mahadevan, 2018) with more than 2 million properties spread across the world (Airbnb, 2015). Although there is no consensus, researchers like Zervas et al. (2017) defend that the existence of platforms such as Airbnb that provide low-cost accommodation, encourage tourism and the consequent increase in the number of travellers, as well as opportunities for new jobs. On the other hand some other researchers argue that the impact is low or null (Haywood, Wilson, Hennis & Alvarado, 2016; Wroten, 2017).

Consumer Psychology

Consumer psychology is the scientific study of the behaviour of consumers (Mullen & Johnson, 1990, p. 1). Foxall (1990) and Foxall &Goldsmith (1994) emphasize the significance of the cognitive consumer as a basis for this scientific understanding of consumer behaviour in that "consumer choice

is portrayed as an ego-involving sequence of cognitive, affective, and cognitive changes which precede and predetermine the purchase/no purchase outcome" (Foxall 1990, p. 9). The practice of tourism is entirely related to the act of meeting new people, sharing customs and cultures that can often result in conflicts between tourists and also between tourists and inhabitants of the visited places (Šimková, 2014). it is crucial to understand the factors that influence consumer behavior when choosing a product or service, subdividing them into 6 different steps for their acquisition: i) the recognition of the need, the search for information, iii) the alternative assessment, iv) the acquisition, v) the post-acquisition assessment and vi) the divestment (Blythe, 2005). These steps have the presence of cultural, social, personal and psychological factors that determine the choice of a product/service over another (Kotler, 2000; Kotler & Amstrong, 2011). In light to the above it seems possible to argue that the competitiveness of a destination depends largely on the experience that the tourist had in that same destination (Pavlovic, 2016).

Motivations and influences when choosing accommodation

For tackling the hotel establishments scarcity on times of great affluence and events in cities, new types of accommodation inserted in a collaborative economy have emerged (Bardhi & Eckhardt, 2012; Botsman & Rogers, 2010), becoming major competitors of hotel establishments and the services they provide (Freitag & Haywood, 2015). There are many reasons that lead consumers to opt for this type of hosting. There are authors who argue that the main reason that leads consumers to choose this type of collaborative economy is their monetary benefits (Bellotti et al., 2015; Botsman & Rogers, 2010; Gansky, 2012; Lamberton & Rose, 2012; Möhlmann, 2015; Sacks, 2011). But many more factors are relevant as social needs (Botsman & Rogers, 2010; Möhlmann, 2015), good quality services, amenities and location (Tussyadiah & Zach, 2015), sustainability and authenticity (Hamari, Sjöklint, & Ukkonen, 2016), reduction of environmental impacts and relationship with communities (Botsman & Rogers, 2010; Gansky, 2012). In fact, authenticity and the sharing of new cultures are something that is in high demand (Lewis & Bridger, 2000) and local accommodations such as hostels and "Airbnb" highlight those concepts. The behaviors of tourist is changing and tourists when staying in private and local housing tend to stay more nights, spend more money and travel more frequently (Tussyadiah & Pesonen, 2015). Larger hotel establishments need to adapt their services to this new reality (Byers, Proserpio, & Zervas, 2013) and these new accommodations are seen as places where tourists have the opportunity to make new friends, creating connections that can stay for life (Botsman & Rogers, 2010), socially interacts with the host of the accommodation and have opportunity to explore places that are outside the conventional routes (Guttentag, 2015). Local accommodations also allow being in contact with historical landmarks works as an important mechanism to experience the authenticity of the heritage (Chhabra, Healy, & Sills, 2003).

Research questions, Hypotheses and Methodology

The main objective of the study is to characterize the influences and motivations of the national tourist, residents in the North of Portugal, when travelling while choosing accommodation in Portugal and abroad. To complement and sustain the main objective, the secondary objectives were also identified as follow: i) describe the motivations of the national tourist in the North area when travelling in Portugal and abroad, relating them to the type of the chosen accommodation, ii) describe the influences in the choice of accommodation in Portugal and abroad by the national tourist and iii) describe the differences and relationships in the search for local accommodation and touristic accommodation in Portugal and abroad. Taking into account these objectives, following Research Hypotheses (RH) were defined:

- RH1 - The adhesion of national tourists to local accommodation abroad is related to adhesion to local accommodation in Portugal.
- RH2 - The adhesion of the national tourist to touristic accommodation abroad is related to the adhesion to touristic accommodation in Portugal.
- RH3 – The adhesion to local accommodation in Portugal is related to the motivations of the trip.
- RH4 – The adhesion to local accommodation abroad is related to the motivations of the trip.

As a methodology a quantitative study was used and a single duly designed questionnaire survey was applied according to the collected literature on the subject. All the survey questions were closed-ended, including dichotomous questions, multiple-choice questions, rank order questions and Likert-type scales in a five-point scale of agreement (from 1-Strongly disagree to 5- Strongly agree) and of frequency (from 1 – Never to 5 – Always). A random sample was collected, between May and July 2019, from national tourists residing in Porto and north of Portugal, over 18 years old and who had travelled at least once in the last 5 years in Portugal or abroad. The questionnaire was conducted through the Limesurvey and distributed to a list of more than 5,000 personal e-mails. It was also publicised through *social media* as Linkedin and Facebook. 239 of the collected questionnaires were considered valid, representing a sampling error of 6,3%, assuming a 95% accuracy level.

The questionnaire was divided into three sections, namely: i) information about respondents, supporting the relation between the components of the individual profile with local accommodation; ii) characterization of respondents, according to what motivated them to travel in Portugal and where a question based on 14 items was applied, aiming to identify the greatest motivations for travelling in Portugal in the last 5 years, iii) understanding what type of accommodation respondents looked for the most in Portugal in the last 5 years, with application of a question about the frequency with which they stayed in local accommodation in Portugal in the last 5 years and another question about how often they stayed in touristic accommodation in Portugal in the last 5 years. All questions from section two and three are repeated in sections four and five, but specifically for respondents when travelled abroad. The collected data was treated through the SPSS software. The exploratory descriptive statistical analysis allows to study the observed characteristics, as well as to analyse the main influences on the choice of accommodation, in Portugal and abroad, and the motivations while travelling.

To analyse the validity of the hypothesis of the research, an inferential analysis was chosen and different tests were used to confirm or refute the hypotheses of investigation. The chi-squared independence test allowed us to understand whether or not there is a significant relationship between two or more categorical variables and the non-parametric Mann-Whitney U test to compare differences between two independent groups. The considered level of significance throughout the analysis was 5%. To uncover the underlying structure of a set of variables it was applied a factorial analysis, a multivariate statistical method, with the purpose of identifying the key factors that determine the motivations to tourist travel in Portugal and abroad. To check the reliability of the questionnaire, the internal consistency was analysed using Cronbach's Alpha coefficient.

Results and Analysis

Sample Characteristics

In what concerns gender, 58.2% of the respondents were female and 41.8% male. With regard to age, 71.9% of respondents belong to age group from 18 to 35 years old, where the most representative are respondents between 18-25 years (37.2%). Only 8.0% of the respondents have more than 65 years. Respondents showed high levels of education: bachelors (49.4%), masters (22.6%), and PhD (3.3%). About 40.6% of the respondents have a monthly net income between 501€-1,000€ and 24.3% between 1,001€-2,000€. However, 15.5% of respondents have incomes less than €500 monthly and only 10.1% more than 2,001€. 9.6% of the respondents did not want to answer this question. Respondents are mostly single, with 95.5% of singles between 18 and 35 years old and 79.5% between 26 and 35 years. Most of them do not have children (between 18 and 25 years old, 98.9% and between 26 and 35 years old, 89.2%).

All respondents live in the North of Portugal, comprising 8 sub-regions or level III units (NUTS III). The majority, 70.2%, live in the metropolitan area of Porto, 11.8% in Braga and the remaining 18% in the remaining sub-regions.

Figure 1 shows the frequencies of accommodation in local accommodation in Portugal and abroad by the respondents. The values indicate that 113 of 233 respondents (48.5%) did not stay in local accommodation in Portugal, and 110 of 212 (51.9%) have not stayed in local accommodation abroad.

They stayed in local accommodation in Portugal 120 (51.5%), and 102 (48.1%) in local accommodation abroad. The data indicate that the percentage of individuals who did not stay in local accommodation in Portugal is close to the percentage of individuals who did not stay in local accommodation abroad, with the same trend for those who have already stayed in local accommodation in Portugal and abroad.

Figure 1: Frequency of accommodation in local accommodation in Portugal and abroad
Source: Own elaboration

In spite of not having relevant differences, a higher percentage value of the sample under study chose to stay in local accommodation in Portugal, in contrast when travelling abroad. Comparing the frequency of accommodation between touristic accommodation and local accommodation in Portugal, there were significant differences in their adherence. In fact, in Portugal only 47 (20.2%) of the respondents did not stay touristic accommodation, while 48.5% did not stay in local accommodation. Figure 2 shows the comparison between those who have stayed and those who have not stayed in local accommodation and touristic accommodation in Portugal.

Figure 2: Frequency of accommodation in local accommodation and in touristic accommodation in Portugal
Source: Own elaboration

It was also made a comparison between those who have stayed and those who have not stayed in local accommodation and in touristic accommodation abroad. Abroad, only 24.1% of respondents' didn´t stay in touristic accommodation, while 51.9% didn´t stay in local accommodation.

Regarding the factors that the national tourist from the North most valued when staying in local accommodation in Portugal, the price stood out with 43.4%, followed by hospitality (23.4%) and location (6.6%). Those same factors when abroad are also price and location (respectively with 44.3% and 37.1%), followed by facilities and support conditions, with 28.6%. The study seems to point out that the most valued factors by the national tourist in the northern zone are very similar when looking for local accommodation in Portugal and abroad. An attractive price and a favourable location of the accommodation at the destination place largely influence the adhesion by the local accommodation. In fact, price was chosen as the main factor that influences the national tourist from the North to stay in local accommodation in Portugal and abroad. This is supported by other studies, evidenced in the bibliographic review, namely by Hamari, Sjöklint, & Ukkonen (2016), Möhlmann (2015), Botsman & Rogers (2010), Gansky (2012), Tussyadiah & Zach (2015), Guttentag (2015), Bellotti et al. (2015), Lamberton & Rose (2012) and Sacks (2011). As opposed to what happened with the price, authenticity was the least valued factor in the choice of local accommodation in Portugal and abroad, by the national tourist. This result highlights non concordance with what previously was mentioned in the literature review and following Bardhi & Eckhardt (2012), Botsman & Rogers (2010), Gansky (2012) and Hamari, Sjöklint, & Ukkonen (2016). It seems to demonstrate the existence of some conservatism as well as the weight of cultural values in Portugal' society (Kotler, 2000), making it impossible for individuals to live the experience in an authentic way.

Regarding the motivations for the national tourist in the northern zone to travel in Portugal and abroad, the study shows that in a general way they feel motivated to travel, presenting an average of 3.60 for Portugal and 3.39 for abroad, on a scale 1-5. Table 1 shows the obtained percentages for each of the variables and by level of satisfaction, for Portugal (P) and for other countries (O), as well as the average degree of satisfaction and the standard deviation.

Table 1: Motivations for the national tourist to travel in Portugal and abroad

Level of satisfaction	1		2		3		4		5		Mean ± SD	
Item	P %	O %	P %	O %	P %	O %	P %	O %	P %	O %	P	O

Analysis of Research Hypothesis

Answers to the hypothesis of research were obtained through non-parametric tests in accordance to what was previously mentioned. Responses for joining local accommodation and joining touristic accommodation were grouped into two groups: No (1-never; 2-rarely) and Yes (3-sometimes, 4-often and 5-always). The results of the chi-squared independent test (Table 2) suggest that there is a significant relationship between the national tourist's adhesion to local accommodation abroad with the adhesion to local accommodation in Portugal ($p < 0.001$) (RH1).

Table 2: Chi-squared independent test

		Local Housing Accommodation abroad		
		Not Hosted n(%)	Hosted n(%)	p - value
Local Housing Accommodation in Portugal	Not Hosted	68 (69.4%)	30 (30.6%)	< 0.001
	Hosted	40 (37.0%)	68 (63.0%)	

Source: Own elaboration based on SPSS output (N =206, due to omitted cases)

The results of the chi-squared independent test allows us to concluded (RH2) that there is a significant relationship between the national tourist's adhesion to touristic accommodation in Portugal with the national adhesion to touristic accommodation abroad ($p < 0.001$), as is shown in Table 3.

Table 3: Chi-squared independent test

		Touristic Accommodation abroad		
		Not Hosted n(%)	Hosted n(%)	p - value
Touristic Accommodation in Portugal	Not Hosted	19 (48.7%)	20 (51.3%)	< 0.001
	Hosted	31 (18.6%)	136 (81.4%)	

Source: Own elaboration based on SPSS output (N =206, due to omitted cases)

To validate RH3 and RH4, it was applied a factorial analysis in order to find dimensions not directly observable, but maybe able to explain what motivates the tourist from the North of Portugal when travelling in Portugal and abroad.

For motivations to travel in Portugal, the factorial analysis (Table 4) showed that the 14 studied initial items were explained in 59.13% for 4 common factors obtained from a Varimax rotation with Kaiser Normalization, indicating a reasonable correlation between the items (0.798). Also the Bartlett's Test of Sphericity showed that variables under analysis are statistic and significantly correlated (p-value < 0.001). The analysis can explain that the Portuguese tourists' motivations for travel in Portugal are: Leisure (30.02%), Attractiveness (10.67%), Reason for travel (10.54%) and Price (7.90%). Cronbach's alpha is 0.798, indicating good internal consistency reliability.

Table 4: Factorial Analysis

Factor	Variable included in the factor	Loadings	Eigenvalues	% of explained variance
1 (Leisure)			4.20	30.02
	History/Culture	0.740		
	Nature	0.684		
	Gastronomy	0.648		
	Hospitality	0.613		
	Search for Adventure	0.565		
2 (Attractiveness)			1.49	10.67
	Accessibility and ease of travel	0.771		
	Attractive climate	0.762		
	Sun and beach conditions	0.733		
	Country's safety	0.595		
3 (Reason for travel)			1.48	10.54
	Need (work, visiting family and/or business)	0.753		
	Health reasons	0.661		
	Attractive airline prices	0.653		
4 (Price)			1.11	7.90
	Price	0.799		
	Accommodation	0.706		
Total				**59.13**

Source: Own elaboration based on SPSS output

To see if there are significant differences in each of the factors that motivate tourists to travel in Portugal by joining local accommodation in Portugal (RH3), the Mann-Whitney nonparametric test was used (Table 5).

Table 5: Mann-Withney tests

		Leisure	Attractiveness	Travels' Purpose	Price Accommodation
Frequency in Local Accommodation	Yes	3.84 ± 0,.06	4.26 ± 0.06	2.52 ± 0.09	3.63 ± 0.08
	No	3.74 ± 0.07	4.16 ± 0.07	2.44 ± 0.08	3.46 ± 0.09
		MW-U	MW-U	MW-U	MW-U
		7039.500	7394.000	7039.500	7364.500
		(0.399)	(0.228)	(0.612)	(0.247)

Note: MW- U – Mann-Whitney U test
Source: Own elaboration based on SPSS output

For motivations to travel abroad, the factorial analysis showed that the 14 studied initial items were explained in 66.49% for 5 common factors obtained from a Varimax rotation with Kaiser Normalization, indicating a reasonable correlation between the items (0.7368). Also the Bartlett's Test of Sphericity showed that variables under analysis are statistic and significantly correlated (p-value < 0.001). The analysis can explain that the Portuguese tourists' motivations for travel abroad are: Attractiveness (27.51%), Hospitality (10.67%), Price (10.01%), Leisure (9.48%) and Reason for Travel (8.21%), as seen in Table 6. Cronbach's alpha is 0.798, indicating good internal consistency reliability.

Table 6: Factorial Analysis

Factor	Variable included in the factor	Loadings	Eigenvalues	% of explained variance
1 (Attractiveness)			3.85	27.51
	Sun and beach conditions	0.852		
	Attractive climate	0.843		
	Nature/Landscape	0.664		
2 (Hospitality)			1.57	11.21
	Accommodation	0.770		
	Gastronomy	0.751		
	Hospitality	0.712		
3 (Price and facilities)			1.41	10.01
	Price	0.599		
	Accessibility and ease of travel	0.790		
	Country's safety	0.647		
	Attractive airline prices	0.560		
4 (Leisure)			1.33	9.48
History/Culture		0.671		
Accommodation		0.768		
5. (Reason for travel)			1.15	8.21
	Health reasons	0.726		
	Need (work, visiting family and/or business)	0.854		
Total				66.49

Source: Own elaboration based on SPSS output

To what concerns RH4 the only validated factor is "Leisure" and may, in fact, interfere in the choice or not of a local accommodation abroad, as seen in Table7. The remaining motivating factors for traveling abroad are significantly different between the people who joined and those who did not join the local accommodation abroad.

Table 7: Mann-Withney U tests

		Attractiveness	Hospitality and Gastronomy	Price and facilities	Leisure	Reason for travel
Frequency in Local Accommodation - abroad	Yes	3.75 ± 0.09	3.22 ± 0.08	3.67 ± 0.07	4.18 ± 0.07	2.22 ± 0.10
	No	3.76 ± 0.10	3.16 ± 0.09	3.61± 0.08	3.65 ± 0.08	2.07 ± 0.10
		MW-U	MW-U	MW-U	MW-U	MW-U
		5295.000	5595.000	5805.500	7668.500	6079.500
		(0.477)	(0.973)	(0.660)	(0.000)	(0.282)

Note: MW- U – Mann-Whitney U test
Source: Own elaboration based on SPSS output

Conclusion

The study seems to point that the adhesion of tourists from the north of Portugal to local accommodation in Portugal is related to adhesion to local accommodation abroad, with the existence of a relationship between the demand for local accommodation in Portugal and abroad. It was observed that 63% of the respondents who stayed in local accommodation in Portugal also stayed in local accommodation abroad and 69.4% who were not staying in local accommodation in Portugal also did not stay in local accommodation abroad (Table 2). The national tourist's perception of local accommodation does not change depending on the location (Portugal/abroad).

In what concerns the adhesion of tourists from the north of Portugal to touristic accommodation in Portugal, it was also found that it is related to the adhesion to touristic accommodation abroad, verifying the existence of a relationship by the demand for touristic accommodation in Portugal and abroad. Of the 81.4% respondents who stayed in touristic accommodation in Portugal, also stayed in touristic accommodation abroad and 48.7% who were not lodged in touristic accommodation in Portugal also did not stay in touristic accommodation abroad. It was again checked that the perception of the national tourist about touristic accommodation does not change depending on the location (Portugal/abroad).

It was also verified that the adhesion to local accommodation in Portugal is not related to the reasons for the trip/travel. This means that none of the four travel motivation groups appear to interfere with the demand for local accommodation. Regarding the adhesion to local accommodation abroad, only Leisure appears to be a relevant motivation group. The other remaining motivation groups were not validated.

With this study it was possible to have a sampling of the global perception about the new type of accommodation that is rising nowadays: the local accommodation. It was possible to portray the sample through an exploratory descriptive analyzes and statistical tests, demonstrating the behaviors, motivations and influences of the national tourist in the northern part of Portugal when adhering to local accommodation in Portugal and abroad. The study aims to support local accommodation owners and managers who wish to strategically attract the national tourist by going against what they are looking for when looking for this type of accommodation both in Portugal and abroad.

Abstract

The digital infrastructure of the economic system is viewed as one of its subsystems, enhancing the innovative activity of economic entities and ensuring the emergence of a new economy. The advocates of the key role of digitalization in economic development argue that innovation and digital technology are at the core of technological advances and economic growth. This article presents evidence of the fact that digital infrastructure is a prerequisite for the country's innovation policy implementation to obtain a technological breakthrough and the transition to a new type of economy.

Keywords*:* Innovation infrastructure, digital infrastructure, digital technologies, technological breakthrough, digital economy, digital resources, digitalization, digital sector, economic development.

Introduction

Russia needs to make a technological breakthrough and implement transition to the digital economy to become a leader in the global economy. The massive application of digital technology can be expressed in qualitative changes in business models, the nature of doing business, its manageability and flexibility. Addressing the challenges related to the expanded application of digital technologies requires a favorable environment - a specific infrastructure, promoting the formation of a new type of economy, which is built in accordance with the tasks being performed. As an economic system element the infrastructure is a favorable environment for shaping and developing the digital economy that is formed while innovation process is regulated and innovation activity is activated (Vavilina A.V., Kalashnikov I.B., Gladysheva I.V. (2018)). It becomes especially acute in case of a high level of technical, industrial, financial, commercial and other risks. Thus, the study of the digital infrastructure content comes down to determining its structure, which is able to ensure the technical and technological development of the electronics industry and IT technologies, the implementation of professional competencies by the entities and institutions that are parts of its structure. A more profound understanding of digital infrastructure involves clarifying areas for reducing risks that arise during the transfer of the economy to a new technological base and ensuring its innovative and competitive advantages. A special feature of the fourth industrial revolution is Smart Manufacturing, which is possible through the convergence of key digital technologies. Today, smart manufacturing is a new paradigm for business development. The rapid development of smart manufacturing technologies leads to a widening of the digital divide between developed and developing countries. At the present stage, many areas of the development of smart industries are at the level of conceptual

models, which suggests that the digital divide is only just beginning to take shape. That is why it is so important for Russia not to miss irrevocably the opportunity to integrate into the processes of the initial stages of the formation of Smart Manufacturing taking place in the global world.

Research Methodology

Literature Review

The influence of infrastructure and its assets on the development of economic systems has been studied in various aspects since the middle of the last century; but this issue has been most vigorously discussed in the scientific literature since the late 1980s. Technological innovation has always been considered the main driver of economic growth. High-speed Internet access through broadband infrastructure has developed rapidly since the late 1990s. due to the deployment of both stationary and mobile technologies. The ongoing transformation of economic relations supported by information and communication technologies (hereinafter - ICT) - primarily the Internet - is termed as digital economy. This "digital" transformation is undergoing a certain evolution, influencing in some way various aspects of the socio-economic activity in the society. The main studies and the results of assessing the impact of ICT infrastructure development based on publications by Kramin, T.V., Klimanova, A.R. (2019) are presented in Table 1.

Table 1: Research into the impact of ICT infrastructure evolution on economic development

Authors	Object of research	Findings
Roller & Waverman (2001)	21 OECD countries, 1970 -1990	It was demonstrated that GDP growth per capita (0.59 out of 1.96% per year) is explained by investments into telecommunication infrastructures.
Datta & Agarwal (2004)	22 OECD countries	It estimated the impact of telecommunication infrastructure (accesslines per 100 inhabitants) on economic growth.
Gillet et al. (2006)	USA 1998-2002	It proved the fact that broadband connection can explain significant gaps in growth and employment.
R. Crandall et al. (2007)	USA, 2003-2005	A strong link was identified between the introduction of broadband (BB) and economic prosperity in the United States. According to their estimates, an 1% BB increase in its introduction led to an increase in the annual rate of employment in industrial sectors from 0.2 to 0.3 percentage points regarding the impact of the BB deployment on GDP.
Castaldo at al. (2018)	23 OECD countries 1996-2010	It was shown a continuous numerical relationship between broadband diffusion and economic dynamics in the short, medium and long terms.
D. Nipo at al. (2018)	149 countries divided into five regions (in Africa, America, Arab, Asian and European regions), 2006-2014	ICTs have a significant impact on economic growth, especially in regions such as America, Asia and Europe.

R. Pradhan, G. Mallik, T. Bagchi (2018)	G-20 countries, 2001-2012	The development of ICT infrastructure - both for fixed broadband users and for Internet users - leads to an increase in per capita GDP.
T. Niebel (2018)	59 countries, 1995-2010	The impact of information and communication technologies on economic growth in developing, developed countries and transition economies.
E.A. Kolomak (2011)	Russia	The contribution of transport infrastructure is insignificant, the influence of communication infrastructure is positive and significant, the effects of spatial externalities differ for the western and eastern parts of the country.

The general conclusion made by authors studying the role of the infrastructural factor in the development of economic systems is that the use of the Internet, new technologies and, in general, "digitalization" broadens the range of forms and directions of socio-economic development.

Data Processing Methods

The methodological basis for the study of digital infrastructure is seen as the provision that it acts as an integrated part of the infrastructure of the national innovation system, which in turn is a combination of legal entities, organizations and institutions providing material, technical, financial, organizational and methodological, informational, consulting and other services for the innovative activity of entities and supporting their innovative activity.

The analysis of this population was carried out on the basis of several approaches:

– a system-functional approach to identify the quality, properties, consequences of its systemic actions aimed at creating opportunities for technological breakthrough;
– a reproductive one to identify the logic of economic processes that ensure the continuity of technological changes in the reproduction system based on new discoveries and inventions;
– a formation approach to analyze the main technological changes when changing stages of the economic formation, identifying their causes and effects.

The study was carried out on the basis of the analysis and comparison of theoretical principles of the "digitalization" origin , the formation of infrastructure, including the identification of the digital infrastructure features, its role in economic and innovative development, comparison and evaluation of statistical information on the dissemination of ICT at the national and international levels, international rankings (competitiveness, innovative development, quality of infrastructure), materials of the Federal State Statistics Service (Rosstat), its bulletins on the science of information-oriented society compiled in collaboration with the NRU HSE.

Paper Results

A technological breakthrough is a fundamental, accelerated pace of restructuring the technological base of the existing economy based on the use of innovations, technical achievements, professional competencies of entities and institutions. Such logic (Fig. 1) indicates the need for a close relationship between the processes of economic system development and its infrastructure, which will ensure the transition to a new technological structure. Examples of network company priorities say that a new type of infrastructure is emerging today, which are designed to solve a number of problems and challenges facing different countries, regions, cities and by an individual (Schedrovitsky P., (2013)).

Fig. 2. Digital Infrastructure Characteristics

Fig. 1: Logic of technological breakthrough

At the same time, to successfully bring about the technological breakthrough, it is necessary to have, within the framework of the general economic system, an innovation-oriented, digital in essence infrastructure, having a powerful development potential, clearly organized and adequately oriented, purposeful, i.e. adequate persistent digital economy (Fig. 2). In continuing the development of the theme identified in an earlier publication (Vavilina, A.V, Kalashnikov, I. B., Yakubova, T..N. (2018)), we affirm that in a certain sense, the digital infrastructure in the economic system performs a number of important functions (Fig. 3).

Fig. 3: Digital Infrastructure Functions

Digital infrastructure includes all the informational, organizational, marketing, educational, network and other institutions that help the new innovative idea to get implemented and find its consumer. The infrastructure is very large in size. It comprises a part (probably the biggest one) of the country's economic system. Therefore, the digitalization of infrastructure is the digitalization of the economy as a whole. Digital infrastructure includes enterprises and organizations that have become digital, producing innovative benefits, working in the manufacturing, trade, communications, transport, management, planning, and optimization of economic processes. Global experience in the article of Mohamad A.S. (2016) indicates that the more substantial the infrastructure, the more successfully it develops, the higher the degree of influence of the data used in doing business, the higher the level of coherence and conformity of the economy system and its infrastructure (Table 2).

Table 2: Global country ranking by quality of infrastructure

Country	Infrastructure quality (position on ranking list)	Specific GDP (current USD prices)	Competitiveness factors, %		
			basic	effectiveness	innovations

If we look into the quality of Russia's infrastructure with a analogous indicator in countries that have a similar level of welfare (Poland, Hungary, Greece, Kazakhstan), we can see that the level of infrastructure quality is comparable. In general, international assessments of the quality of key Russian infrastructure indicate that it is currently not adequate to the tasks of modernizing the economy, let alone its transition to an innovative development path. In the world ranking, according to the World Economic Forum (WEF), Russia was ranked 35th in 2017 and 43rd in 2019. The assessment of Russia's infrastructure is higher than in African and Latin American countries, but significantly inferior to European countries and North America. One of the key elements of digital infrastructure is digital information resources and systems containing information on the results of innovative activities, products, services, technologies, scientific and innovative organizations, intellectual property, and technology transfer processes. The effectiveness of the information component of digital infrastructure is manifested in the multiplication of scientific and technical results and an integrated approach to the use of investments and innovations in the scientific and industrial sphere (Biktimirov M. R., Syuntyurenko O. V. (2017), Andrushchak G.V., Artemov S.V., Vakhstein V.S., (2017)), which affects the level of competitiveness of the country (table 2). For the period 2015–2019 Russia has managed to significantly develop its innovative potential against a global background, having improved its position in the GII from 62nd (2013), 48 (2015) to 46th place. At the same time, in recent years there has been a trend towards a slowdown in the growth rate of innovation indicators (table 3). The weaknesses of innovation in Russia include: the loan portfolio of microfinance institutions (73rd position) and transactions using venture capital (77) - indicators of innovation resources, as well as a group of indicators of innovation results - ICT and the creation of business models (91), development print and other media (78), compliance of quality management systems with ISO 9001 (111). If we look at the institutional readiness of Russia for innovative and

technological transformations, then according to the annual World Bank study The Global Competitiveness Report-2019, the conclusions for Russia are not yet encouraging in all respects. Indeed, compared with 2018, Russia improved its innovation potential by 2.2 points (32nd place) due to the improvement of the quality of its research institutes (9th place) and constant R&D expenses (1.1% of GDP, 34th a place). Innovation is also supported by the growth in the introduction of information and computer technologies (+4.9 points, 22nd place) due to the especially rapid spread of the Internet, reaching 81% of the population (39th place). At the same time, Russia was in the lower half of the ratings by the level of development of such an indicator as "Public Institutions": Russia ranks 74th. According to the criterion of "technology management", how quickly the country's legal framework adapts, in particular digital business models? - Russia has 51st place (3.9 points out of 7 possible) (WEF, 2019). A comparative analysis based on data from such sources as "Global Innovation Index – 2019" and "Innovative regions ranking Version 2017. Association of innovative regions in Russia, 2018" demonstrates that Russia lags behind developed and many rapidly developing countries in respect of almost all metrics that characterize the efficiency of resource utilization and the degree of impact of the results of scientific, technical and innovative activities on the economy and society. It should be noted that in contrast to digital technologies themselves, which are distributed mainly evenly, the benefits from their use - "digital dividends", are mainly received by developed countries - technology developers, which leads to deepening global inequality, increasing unemployment in developing countries (Digital dividends, 2016).

Table 3: Dynamics of Russian Federation positions in GII: 2015-2019

Year	GII (position)	Ranking for individual items	
		Innovation resources	Innovation results
2019	46	41	59
2018	46	43	56
2017	45	43	51
2016	43	44	47
2015	48	52	49

Information technology systems and related services are key elements of digital infrastructure in Russia and other countries. This list of elements includes information on innovative products, services, technologies, scientific and innovative organizations, intellectual property, etc. Such systems include the following: CORDIS (since 1990) - a database system in which information on research activities in the EU countries is accumulated; ARIST - scientific and technological information service, which is an information tool for obtaining data about existing markets for innovative technologies, which is used to provide a number of information services, to establish contacts between innovative organizations and potential customers; EPIDOS - European Patent Information and Documentation System, Japanese PATOLIS Database - Japanese Patent Data Source. Among the Russian organizations developing information technology systems in order to provide information on innovative technologies, the All-Russian Institute of Scientific and Technical Information (VINITI), the All-Russian Scientific and Technical Information Center (VNTIC), etc. stand out.

Experts from different countries associate the successful development of digital infrastructure with integration processes that under the new conditions allows achieving a synergistic effect by combining and coordinating the actions of various infrastructure elements. An example of such integration was the creation of the European network of innovation and business centers - EBN. This network was created in 1984. According to experts, including Kazakova M.V., Pospelova E.A., (2017) and analysts of the Eurasian Economic Commission currently, the European network includes 160 innovation and business centers from 21 countries and 70 associate members that share the goal of promoting and developing small and medium enterprises.

Digital infrastructure is as a kind of systemic basis for building the entire socio-economic life of society (Tab. 4).

Table 4: Structural Elements of Digital Infrastructure

Infrastructure Subsystems	Elements of individual infrastructure subsystems
material (production and technology)	industrial clusters, investment and technology centers, business incubators, transfer centers, technology, etc.
financial	different types of financial foundation and financial institutions
social	institutions, organizations, centers of culture, leisure, health, education, communications, transport, etc.
informational	proper databases, knowledge and access centers, as well as analytical; statistical, information centers
personnel	educational institutions for training and retraining personnel in the field of scientific and innovative management, technological audit, marketing, etc.
expert and consulting	organizations engaged in the provision of services in the fields of intellectual property, standardization and certification; centers, both general ones and those that specialize in certain areas (finance, investment, marketing, management, etc.), consulting. Their activity in processing and utilization data results in the emergence of qualitatively new socio-economic relations
organizational and methodological	data based on digital technologies, marketing, statistical research, practice of building business models, scientific and social networks, cooperation ties

All of these subsystems are designed to deal with specific tasks and have their specific effects. Such tasks include: information support of ongoing economic processes and current changes; ensuring the growth of economic value in the field of data transmission, processing and storage; manufacturing, technological and financial support for innovation; certification and standardization of innovative products; assistance in promoting effective development and implementing innovative projects; arranging exhibitions of innovative projects and products; providing practical and consulting assistance in training, retraining, and professional development of personnel for innovative activities. The successful harmonizing effect of infrastructure is achieved through the formation of the digital economy in the form of an integral, systemically functioning, and effective whole (Table 5).

Table 5: Characteristics of digital infrastructure as a factor of the digital economy development

Elements	The content and effects of the constituent elements action
Digital technologies and digitalization	contribute to the formation of fundamental grounds of a new-type society, digital models of technological and economic processes,
Data its reliability	create conditions for planning and forecasting economic processes at all levels of management, for a reliable assessment of the performance of entities and institutions, optimizing the utilization of all types of resources
Data communication network	provides a link between various sectors of the economy, affects the formation of a new economic content
Electronics industry	manufactures microchips, computers telecommunication and electronic devices
Digital sector companies	become the growth points in the digital economy, provide services in the field of digital technologies, use digital means of production, storage, and

	data management
Digital capacity of a company	provides the profitability of the digital resources, the necessary level of transaction costs, organizational efficiency, market opportunities

Reports "Summary statistics on geographic information system for technology clusters. RF Ministry of Industry and Trade 10.07.2018" show and experts of Association of innovative regions in Russia confirm the current state of Russian infrastructure is characterized by a number of problems that impede the progress in digital technologies and the digitalization of economic procedures: small and medium-sized innovative companies are not sufficiently integrated into innovative networks; cooperative ties, which are to ensure the formation of innovative chains «science and education - innovative small and medium business - large business» are insufficient. According to Rosstat, the number of organizations implementing technological innovations is declining both in Russia as a whole and in individual regions (Fig. 4). In Russia, there is a significant differentiation of the digital maturity of the regions. The main indicator determining the possibility of developing "smart manufacturing" in the region is the development of information and communication technologies (ICT). Based on a study of the possibilities of developing smart industries in the regions of Russia (Tkachenko I.N., Ramenskaya L.A., 2019), very contradictory trends are noted. Thus, an analysis of the change in the number of organizations that used personal computers for the period from 2007 to 2017 allows us to see a paradoxical picture. Despite the increase in the functionality of ICT, the conversion of a number of business processes to digital format, a decrease in the use of ICT occurred in half of the federal districts and in more than half of the constituent entities of the Russian Federation (50 out of 85), which can certainly be considered a negative trend. The leader in the use of ICT is Moscow, in which this indicator has remained equal to 100% since 2005. Among the federal districts, the Siberian region has the highest value, the use of ICT for which has grown most dynamically. The negative trend was most pronounced in the Ural Federal District, in which all subjects showed a decrease, the worst values in the northern regions - the Khanty-Mansiysk Autonomous Okrug - Ugra and the Yamalo-Nenets Autonomous Okrug, as well as in the Kurgan Region. Among the analyzed districts, an increase in the indicator technological innovation was observed only in the Central Federal District. This prevents the dissemination and capitalization of knowledge in the Russian economy.

Figure 4: The share of institutions that carried out technological innovation in the total number of institutions surveyed by constituent entities of the Russian Federation, % (Source: Federal State Statistics Service)

Without resolving these and other problems it is impossible: to ensure the transfer of the of the research and development results to the economy; development of entrepreneurship in the innovation field; performing technological update of fixed assets. Achieving specific results through intensifying the improvement of infrastructure effectiveness requires some measures, including: the formation of a

unified digital environment through adequate services - identification and authentication of interacting entities, protection against unauthorized access and modification of documents; activation of the latent potential in economic activity; reformation of the legal regulation in information risk management processes and provision of cybersecurity; actualization of innovation activities of infrastructure institutions.

Discussion

In 2019, Dell Technologies, in collaboration with Intel and Vanson Bourne, compiled a digital transformation index. Based on a survey of 4,600 business executives from more than forty countries, they analyzed the initiatives of digital transformation companies. The analysis showed that most companies in the world do not keep pace with the trends of digital transformation. However, Russia follows the global trends in digital transformation: in Russia, 7% of companies can be attributed to leading companies, 19% of companies are digital innovators, and only 1% of companies (compared with 9% of companies in the world) are companies that lag behind digital transformation. The dynamically developing situation in the formation of the digital economy demonstrates the scale and complexity of the new infrastructure functioning. Overcoming them involves: a) increasing the throughput of communication channels; b) expanding access to mobile Internet; c) enhancing the work of data centers; d) increasing investment resources for the implementation of projects and further maintenance of the operability of IT systems; d) the removal of the problem of staffing for the "digital revolution"; f) stimulating demand from suppliers and consumers for advanced technologies; g) the implementation of broad government support for digital technologies implementation.

Abstract

The article analyses the historical aspects of the development of lean production, briefly describes modern concepts for improving production efficiency, and identifies the main tools and methods used in lean production and the application possibility in micro, small and medium enterprises in the Russian Federation. The article shows the possible advantages of introducing tools and methods in microenterprises. Also this article presents the barriers of the lean project implementation from the owners' side and the employees. Authors of the article offer a cycle for the implementation of a complex of projects at the enterprise.

Keywords: lean production, lean manufacturing, small enterprises, micro enterprises, project implementation, barriers, staff resistance

Introduction

One of the key tools to solve the problem of increasing the efficiency is lean production. Lean production includes principles, norms, rules, methods, tools for developing lean organization management. All of the above allows owners to use all the capabilities of the enterprise on the basis of reducing wastes. Many companies, implementing elements of lean manufacturing, are able to improve the quality of products and services. At present, there is a lot of research on this topic in relation to large and medium-sized enterprises, while the analysis of the effectiveness of the lean approach in small enterprises is extremely scarce. At the same time, many regional development programs proclaim the growth of the importance of small business. Therefore, this article takes the first step in analysing the applicability of modern methods and principles of organizing production for small businesses (both in terms of individual implementation of tools and principles, and the main types of wastes).

To solve the problems, such scientific research methods as the comparative method of analysis, questioning, generalization, abstracting, statistical method, and the method of expert evaluations were used.

Literature Review

The idea of lean production gained fame in the late 1980s after the research of the 19th century global automotive industries was made. That research revealed that Japanese automobile factories had higher performance and quality than their western competitors. Researchers gave the name of the Japanese manufacturing model to lean manufacturing or lean production.

The first prerequisite was in 1850 when Eli Whitney introduced the term "mass production". Henry Ford talked about strategy in 1900, while Frederick Taylor and Frank Gilbert dealt with rationalization and standardization of processes (Table 1). In the mid-1950s Tahiti Ono introduced the Kanban control system created at the Toyota factory, which eliminates the main types of wastes *(Ono, n.d.)*. The illustrated glossary on lean manufacturing gives the following definition of the Toyota production system: "The production system developed by Toyota and aimed at ensuring maximum quality, minimizing costs and lead time by eliminating wastes" *(Assemblymag.com, 2020)*. The goal of the Toyota Production System is to provide products at world class quality levels to meet the expectations of customers, and to be a model of corporate responsibility within industry and the surrounding community [Toyota Production system handbook] *(Ono, n.d.)*.

Table 1 presents the results of the main literature sources concerning different stages of lean instruments' development.

Table 1: development of the Lean production concept

Period	Author	Main milestones in developing of lean production
1920	Kaom Ishikava	Graphic method for the analysis of causal relationships "Fishbone Diagram" *(Osipov, 2018)*
1924	Walter Andrew Shewhart	Shewhart control charts
1950-1970	Taiichi Ohno	Toyota production system; Kanban system; Seven wastes in production; SMED – Single minute exchange of die

1962	Kaom Ishikava	Quality circles
1964	Joseph M. Juran	AQI (Annual Quality Improvement)
1982	William Deming	"Deming Wheel" – PDCA (Plan – do – check – act)
1986	Masaaki Imai	Kaizen
2003	James P. Womack, Daniel Johnson	Make lean production known worldwide 5 principles of lean production
	Meier David, Jeffrey Liker	Allocation of the eighth type of wastes: non-utilized talent *(Liker, 2013)*

(Source: compiled by the authors)

Lean production is an approach to management (principles, norms, methods, rules, standards) that focuses on cutting out wastes, whilst ensuring quality and continuous improvement. Owners of the enterprises, managers and CEOs can fully apply this approach to all aspects of business, starting from design, through production process, to distribution and customer service. The lean philosophy allows using capabilities of the enterprise to improvements and reducing waste losses.

Lean manufacturing allows you to achieve a competitive advantage by increasing productivity, improving the quality of products or services, reducing costs and the production cycle time. Lean manufacturing is a management philosophy based on the principle of doing more with less investment: fewer human resources, reducing time and space, reducing the use of equipment *(Assemblymag.com, 2020)*.

This concept is a system of solutions that should be applied at a time in order to focus not on individual aspects of the processes, but on the process as a whole: improving the production process in order to reduce costs (SMED, just-in-time, Kanban, SOP, TPM, 5S, VSM); continuous improvement of quality (Kaizen, Jidoka); staff training and motivation (Kaizen, 5S); creation of a "pulling system" from the final consumer of the product (Just-in-Time, Kanban, VSM). As part of the implementation of lean manufacturing, the use of additional tools, borrowed from other spheres, is possible *(Assemblymag.com, 2020)*.

Methodology: Functional fields of the enterprise and the use of various tools and principles of lean production

Nowadays, there is a trend in recent years the number of large enterprises has been decreasing in the territory of the Russian Federation. Moreover, a classification of enterprises today has an additional category such as micro enterprises along with small and medium-sized enterprises.

The criteria for referring to a particular type of enterprise are 3 groups: legal criteria, criteria for number of staff and criteria for income. Legal criteria are mostly cut-off or personal in nature (for example, enterprises with a share of foreign capital of more than 49% will not fall into small and medium-sized enterprises).

As for the criteria for the number and income, according to them there are:

- microenterprises - an enterprise with a marginal value of income for the year -120 million rubles for all types of activities and the average number of employees up to 15 people,
- small enterprises - an enterprise with a marginal value of income for the year - 800 million. for all types of activities and the average number of employees from 16 to 100 people
- medium-sized enterprises - an enterprise with a marginal income for the year of -2 billion for all types of activities and the average number of employees from 101 to 250 (and from 251 to 1000 if they are included in the list of light industry enterprises approved by the Ministry of Industry and Trade in the manner prescribed by the Government Decree dated November 22, 2017 No. 1412).

The final category of the enterprise is determined in accordance with the largest condition. If, for example, in terms of number, an LLC that meets the legal criterion can be considered a microenterprise, but its revenue over the past year is in the range of over 800 million rubles to 2 billion rubles inclusive, such an LLC will be considered a medium-sized enterprise.

According to statistics presented by the Federal State Statistics Service, the following conclusion was made (see Fig. 1): the share of micro-enterprises is stable and has a tendency to increase, in addition, micro-enterprises account for more than 95% of the total number of registered enterprises in the Russian Federation, while the share of small and medium-sized enterprises declining slightly.

Fig. 1: Share of the enterprises of different sizes

(Source: compiled by the authors on the basis of stats (Rmsp.nalog.ru, 2020)

The number of small and medium enterprises during 2018-2020 in the Russian Federation (Table 3*) (Rmsp.nalog.ru, 2020).*

Table 2: number of enterprises in the Russian Federation (excluding large enterprises)

Date of formation of the statistical base	Registered enterprises			
	Total number	Micro	Small	Medium
10.01.2018	6 039 216	5 751 885	267 033	20 298
10.01.2019	6 041 195	5 771 626	250 758	18 811
10.01.2020	5 836 910	5 594 309	225 910	16 691

(Compiled by the authors based on stats (Rmsp.nalog.ru, 2020)

Fig. 2: The ratio of the number of different forms of enterprise
(Compiled by the authors based on Rmsp.nalog.ru, 2020)

In August 2016 the number of registered micro, small and medium-sized enterprises was 5 523 765. This number increased to 5 542 782 enterprises in August 2017. While by August 2018 there was a significant increase, which amounted to 6.8% compared to August 2017. Table 3 shows the share of small and medium-sized businesses in the Russian economy.

Table 3: share of the contribution of small and medium-sized businesses to the Russian economy

Year	Share in Russian economy, %
2014	19
2015	19.9
2016	21.6
2017	22

(Source: compiled by the authors according to RBC, 2018)

By order of the President of the Russian Federation in 2018, a strategic goal was set - to achieve a 40% contribution of small and medium-sized businesses in the economy of the Russian Federation. Today the reference point is 2024 (the year of the end of the national project "Small and medium-sized enterprises and the support of individual entrepreneurial employment"), when the contribution rate should be 32.5%.

Today, there is a tendency to increase the number of enterprises, but still the question remains of increasing the contribution of these enterprises to the country's economy. The development potential of the sector of small and medium enterprises can be increased by applying the principles and tools of lean manufacturing. To do this, in the framework of this study, the tools of lean production were analysed and the functional fields of the enterprise were identified.

Functional fields are areas of activity in which departments and units of an organization are functioning to gain the interests of the organization as a whole. Although functional fields have certain boundaries, they are cross-functional in nature.

Fig. 3: Functional fields of the enterprise

(Compiled by the authors)

Certain functional fields may sometimes not present within some enterprises, especially if this does not apply to large enterprises. In this regard, authors select the fields, after group into 3 blocks according to the frequency of finding in micro, small and medium enterprises: personnel, mechanisms and equipment, production planning, analysis and control.

Table 4 shows lean production methods and tools which were considered in the context of the following functional fields and their applicability.

Table 4: lean production tools and techniques depending on functional application

Functional fields	Lean production tools and methods
Personnel	Kaizen
	Qualification Matrix
	Methods for calculating staff rotation
	Lean-leadership
	Motivating pay system
	TWI – Training Within Industry
	SFM – Shop floor management
	OPL – One Point Lesson
Mechanisms and equipment	TPM – Total Productive Maintenance
	SMED – Single-Minute Exchange of Dies
	Poka-Yoke
	MES – Manufacturing Execution System
	Rational loading / arrangement of equipment
Production planning, analysis and control	Standartization
	5 why?
	VSM – Value stream map
	A3 Value stream mapping
	MCT – manufacturing critical path time
	Desciption of business process BPMN, Swim-line
	Spaghetti diagram
	Line balancing. The Jamazumi chart
	One-piece flow
	Pull system
	Principle of “3 do not”: Do not take junk! -Do not make junk! -Do not pass on junk!
	Heijunka (Product levelling)

	Jidoka
	A3 problem solving
	PFMEA - Failure Mode and Effects Analysis
	TRIZ - theory of the resolution of invention-related tasks
	7 new instrument in quality management

(Compiled by the authors)

Practice shows that lean manufacturing methods and tools may not be equally applicable to large and small organizations. If the successful experience of implementing lean production at a large enterprise can still be adapted to the medium, then it is completely unsuitable for small and micro enterprises.

This article investigates existing lean manufacturing methods for further use in micro, small and medium enterprises. The results of the preliminary study should demonstrate the existing hidden potential in small enterprises and the possibility of choosing suitable methods for them. Because of their flexibility and innovative capabilities, small and medium-sized enterprises are more suitable for introducing innovative tools in contrast to large and multinational enterprises.

In the literature you can find many examples of the implementation of lean production in large and medium enterprises, however, there is no information on the implementation of tools in small and micro enterprises. According to the authors of the article, the introduction of individual tools and lean manufacturing methods for enterprises with fewer than 100 people can improve the company's productivity and competitiveness in the market.

Lean thinking inherent in lean production ceases to work at the stage of work with suppliers. Small business owners are not confident in their business partners and are not ready to transfer their planned needs. Although in many cases, close cooperation with suppliers and customers can reduce the amount of waste for processing, reduce the amount of waste in the supplied components, reduce the time for delivery and processing of the application *(Liker, 2013)*.

One of the main goals of this study is to present a list of suitable or recommended methods and tools for increasing productivity in small enterprises (Table 5).

(compiled by the authors)

* Large enterprises can be adopted as an ideal example, since all tools and methods can be applied at large enterprises, and almost all tools can be sold to varying degrees in medium-sized enterprises. This is due to several points: the availability of sufficient funding, the existence of a separate department engaged in lean production and the development of lean projects.

This study is based on the findings of foreign authors presented in scientific papers, as well as practical results obtained when working with enterprises of the Chelyabinsk region.

According to the study, it was concluded that for micro-enterprises it is possible to effectively use a limited number of tools and methods: kaizen, qualification matrix, methods for calculating staff

rotation, Leadership, motivating pay system, production briefing, SMED, Poka-Yoke, standardization and TRIZ.

Results and Discussion

A study of the literature on lean manufacturing shows that various authors are of the opinion that one of the reasons for abandoning lean manufacturing is the costly and time-consuming implementation, in addition, often small business owners are not convinced of the tangible results and benefits that they can achieve. Compared to larger enterprises, small businesses have fewer resources and less available capital *(Jørgensen, Boer and Gertsen, 2004)*. At the same time, it can be concluded that small enterprises that have introduced that lean manufacturing can benefit from increased competitiveness through faster implementation of innovations and production, while increasing flexibility and reducing costs.

As part of this study, a survey was conducted of the owners of the enterprise and the managerial staff of the enterprises in order to identify the main barriers and constraints in the implementation of lean production and connected projects (Fig. 4).

In this questionnaire, questions were grouped into the following categories:

- description of the company (revenue ranges, field of activity, number of employees, share of standardized goods / services)
- Lean manufacturing (whether fully implemented in the enterprise, whether individual tools have been implemented, degree of implementation, who initiated the implementation process)
- problems with the implementation of lean manufacturing (problems of implementation by management, staff resistance, barriers)
- success of implementation (stage at the moment: projects have been successfully implemented and further development has been suspended, continuous improvement continues)

More than 115 representatives of companies were interviewed, of which a sample of 57 representatives of micro, small and medium-sized enterprises was made to analyze problems.

Fig. 4: The main difficulties that suspend work on lean manufacturing projects
(Compiled by the authors based on the survey)

Based on the results of the responses to the questionnaire, possible barriers were grouped in the following areas: staff knowledge and skills, management, finances, resources and conflicts (Fig. 5).

Fig. 5: Barriers arising from the implementation of lean manufacturing projects
(Compiled by the authors based on the survey)

Events that allow you to work with objections from employees when implementing the principles and tools of lean production

According to the results of the survey, it was revealed that one of the most frequently indicated reasons for refusing to introduce lean production (or the risk associated with implementation) is the resistance of the enterprise personnel. The reasons for these resistances can be of a different nature, but for the most part they come down to fear of job loss, as the growth of labor productivity is often perceived by employees as a prospective decrease in the number of employees. Moreover, the notes on the part of the owners indicated that the concept of lean production does not give direct answers and recommendations on working with such objections. Therefore, it was decided to find out how top management generally works with the objections of its employees. When conducting open interviews, many of the respondents found it difficult to formulate answers (what methods of persuasion they use), therefore, typical forms of overcoming resistance were proposed for assessment:

-logical form (action through logic, arguments are suggested, the interlocutor is given time to think, while it is desirable to have a structured list of arguments),

-emotional form (impact through emotions, mood, in this case, emphasis is placed on feelings, surprises, doubts, confidence, laughter, for example, “without you we can’t cope, and you can do it easily”),
-shift to the past (using the past experience of a person illustrating the effectiveness of such changes),
-shift to the future (the idea is to form an attractive vision of the future),
-link to authorities (using the principle of social evidence when we push others to follow, for example, those who have already done this),
-link to the standards (we refer to some patterns, trends, relevant situations, for example, the introduction of lean production in most companies led to such and such results),
- sayings and sayings (using sayings it is necessary to explain and decipher them, for example, the saying "Who gets up early, God gives it to him" can be provided with explanations about the possible primacy of both the company and the specialist among similar ones on the market),
metaphors and allegories (metaphorical influence sometimes has a stronger effect than direct evidence),
-boomerang (using the energy of resistance for their own purposes, giving the statement the opposite direction),
-concentration on the positive (when the focus of attention is shifted from difficulties to positive results, it can also fix "small victories" and other tricks),
- substitution of resistance (for any doubt there is some reason, for example, past experience, lack of training, etc., that is, more constructive reasons need to be found and discussed),
-game provocation (for example, you can offer to change responsibilities, but you need to do this without aggression in a game manner),
-change of role (the point is. To put a person in another role - yours, customer, supplier, etc.)
Work on the implementation of projects related to improvements and the implementation of individual tools can be presented in cycles. The authors proposed a cycle that consists of 4 main phases:

• search for weaknesses in the implementation of lean manufacturing projects;
• selection of areas and facilities for the implementation of improvement projects;
• the expected effect of the implemented improvements;
• identification of strengths and positive results that should be recorded as a standard and basis for starting a new cycle of improvements.

Fig. 5: Identification of the elements of the cycle of implementation of projects for the implementation of a set of improvements

(Compiled by the authors)

In large enterprises, a separate office or unit (department) is usually formed to work with improvements, which is directly involved in project activities, improvements and development. As an example, in this study, we will consider the cycle of work with staff resistance during the implementation of the lean manufacturing project, and also predict the possible effect of the implemented measures.

- Weaknesses of the enterprise in the implementation of lean manufacturing projects
- Possible effect obtained
- Strengths of the enterprise after the implementation of projects
- Choosing the direction of improvements

Fig. 6: Identification of elements within the implementation cycle of a complex of projects on work with personnel resistance

(Compiled by the authors)

Conclusion

The scientific literature on lean manufacturing has revealed that most of the companies that have introduced lean manufacturing are large and medium-sized enterprises. The current economic conditions in Russia require that micro and small enterprises actively engage in the implementation of tools and principles of lean manufacturing at their sites. However, the study showed that in existing realities the owners of micro and small enterprises refuse this in connection with various problems: distrust of outside experts, lack of qualified personnel, lack of free financial resources or time for implementation measures.

One of the main tasks posed before the study was to identify tools and methods depending on their functional application. This was done by the example of the following areas: personnel, mechanisms and equipment, planning, analysis and control, which allowed us to identify the most appropriate methods that can be implemented in micro and small enterprises.

Abstract

Business Process (BP) development can be defined as the process of constructing a workflow application by composing a set of services performing BP's activities. In this respect, Cloud Services (CSs) are being increasingly used in BP development to ensure a high level of performance with a low operating cost. Although large companies may benefit from CSs' advantages, Small and Medium-sized Enterprises (SMEs) and startups are falling behind in cloud usage due to missing Information Technology competence, (IT-competence). The crucial challenge facing SMEs and startups in cloud-based BP development is to effectively address the so-called business and IT alignment issue. It presents the alignment between two different domains; one that entails technical cloud resources requirements and another comprising business-level. Formerly, we present this issue as a discovery challenge of suitable CSs performing abstract BP's activities. To address this challenge, firstly, we introduce the concept of cloud-aware BP by proposing a Domain-Specific Language (DSL) named "BP4Cloud" to enrich BP modeling and cover both business and technical requirements. Secondly, we propose an Activity-Services Matching algorithm that automates the discovery of CSs performing BP's activities. As a part of the evaluation, we set up by clarifying the specification of BP4Cloud elements through a proof of concept implementation applied on a real BP. Then, we proceed by evaluating the precision and recall of our Activity-Service Matching algorithm.

Keywords: Cloud services discovery, Business process development, Activity-Services Matching.

Introduction

A business process is the combination of a set of activities which are performed in coordination within an organizational and technical environment. These activities jointly realize a business goal [Carrillo and Sobrevilla, 2017]. The BP development leads to define a workflow application which consists of coordinated executions of multiple activities that require access to high performance IT services [Carrillo and Sobrevilla, 2017]. For this reason, companies are interested in cloud computing environments which provide on-demand high performance IT services based on a pay-as-you-go model, allowing them to reduce the management costs, improve their productivity and decrease the time to market.

Despite these advantages, SMEs and startups are falling behind in cloud usage due to missing IT competences. In fact, BP designers and technical developers usually have to cope with alignment challenges between business aspects and CSs needed for BP development. This challenge is, practically, conducted, in our work, through two perspectives, on the one side, we introduce the concept

of cloud-aware BP which presents an enrichment of BP by supporting cloud requirements modeling. On the other side, we handle the mapping of BP's activities to concrete CSs required to perform the BP. Despite the existence of two widely adopted standards for process models and execution like Business Process Model and Notation "BPMN" [Geigera et al., 2018] and Web Services Business Process Execution Language "WS-BPEL" [Sun et al., 2019], there is no general agreement on the mapping and alignment between the business modeling side and the performing of abstract business's activities side. Several efforts have investigated the business and IT alignment challenge in cloud environments such as[Nacer et al., 2019], [Martino et al., 2018] and [Nagarajan et al., 2018]. However, fundamental issues remain for further investigations, mainly, a discovery process ensuring an automatic mapping from business activities to CSs.

The contributions of this paper can be summarized as follows:

- Introducing the concept of cloud-aware BP by proposing a DSL named "BP4Cloud", an extension realized in full compliance with BPMN meta-model in order to cover both business and technical requirements and pave the way to the CSs discovery step.
- Proposing an Activity-Services Matching algorithm to automate the mapping between business activities and CSs.
- Demonstrating the effectiveness of the proposed algorithm through experimental evaluation.

The remainder of this paper is organized as follows: Section 2 presents a motivating scenario. Section 3 details BP4Cloud language. Section 4 presents the Activity-Services Matching algorithm. Section 5 illustrates the evaluation of our contributions. In Section 6, we discuss the related work. Section 7 provides concluding remarks and outlines our ongoing works.

Motivating Example

Our main focus in this paper is to assist the modeling and discovery of cloud resources required for BPs development. To effectively achieve our purpose, we need to outline a substantial interaction between business designers and technical developers during the resources modeling and resources discovery.

The resources modeling presents the specification of abstract entities that carry out the work related to activities which are in our context CSs [Carrillo and Sobrevilla, 2017].

The resources discovery presents the identification of concrete CSs needed for (i) the deployment and (ii) the performing of abstract BP's activities. The deployment of the BP requires to identify suitable infrastructure and platform services. These services provide virtualized resources and software tools needed for application development. The performing of BP activities requires a mapping between abstract business activities and concrete software services.

To illustrate, let us suppose the following scenario presented in Figure 1. This scenario describes a simple BPMN process for online bank accounts opening which initiates with an application request sent from a customer. The first activity consists on checking the customer summary, if a similar request is already in process, his/ her request will be rejected. Otherwise, the process evaluates the customer application, if the application is approved, a provisional account Id is generated and sent. In order to develop the bank account opening process using CS, two major steps should be conducted:

First, we need to define technical cloud resources, essentially, IaaS and PaaS requirements. For instance, the evaluation application activity requires a compute resource to evaluate the customer's application. The check customer summary activity requires a database server to verify if the customer has already an account Id. The whole process may require a load balancer to distribute the application traffic across the allocated compute resources. However, BPMN, which is the most used standard for the high-level description of BPs, supports neither the modeling of the required cloud resources nor their configuration features. This fact presents an important challenge for business designers.

The second step consists of the discovery of software services performing abstract activities. For instance, the sending account Id activity can be performed by a service which sends notifications or emails. Our main purpose is to assist business designers in the aforementioned steps.

Fig. 1: BPMN Process Example

BP4Cloud Language

BP4Cloud consists of a set of extension elements that allow the attachment of cloud resource perspectives to the BPMN standard. By enriching BPMN with CSs covering both business and technical requirements, we define a cloud-aware BP. BP4Cloud considers two aspects:

- First, technical resource requirements which are IaaS and PaaS services allowing to define the run-time environment.
- Second, business specifications which assist SaaS services discovery to perform abstract business activities.

Concretely, we specified these proposed extension definitions in an xsd document derived from the BP4Cloud meta-model. By importing our xsd extension in the BPMN document, we extend the BPMN document by putting into the core of its tag the corresponding extension elements.

Technical Cloud Resources Requirements

The first aspect considered by BP4Cloud is the modeling of IaaS and PaaS requirements. IaaS requirements cover three types of resources which are: computing, storage, and network resources.

- The computing aspect provides resources able to deploy and run service activities or execute script activities (e.g. virtual machines) [Nacer et al., 2019].
- The storage meta-class presents the requirement of information recording resources in data storage devices. There are different ways to use the storage resource depending on activities requirements. Namely, the online storage state manages the shared data. The backup state manages private data.
- The network meta-class presents network resources providing mechanisms that are used for communication [Nacer et al., 2019]. The network type denotes an interconnection resource (e.g. a virtual switch).

The PaaS requirements cover the virtual appliances' requirements that present the middleware components needed for the execution of activities such as; web server, application server, etc. Figure 2 illustrates the meta-model presenting the infrastructure requirements.

It is worth pointing that our presumption consists on assisting non-cloud experts in identifying their technical requirements. Thus, we specified the main cloud technical requirements which can be exhaustively extended.

Fig. 2: BP4Cloud Meta-Mode

Software Cloud Resources Requirements

The second aspect considered by BP4Cloud is the required software/application services. In practice, these services are identified using our proposed Activity-Services Matching algorithm. In order to upgrade the performance and the results of the algorithm, we need accurate specifications related to the business logic of BP's activities. For these reasons, we introduce the Business Logic meta-class which classifies activities according to their business logic. This classification is, basically, inspired by Workflow Pattern Activity (WPA) [Workflow Resource Patterns, 2018]. WAP describes a business function frequently found in BPs [Martino et al., 2017]. In fact, BP can be seen as several connected process fragments each one presents a particular business function. Thom et al. [Lucineia et al., 2009] performed a manual analysis to identify relevant WAPs as well as their cooccurrences within a collection of 214 real wold BPs. Based on the frequency of appearance and potential reuse of a business function in the analyzed models, the authors define seven WPAs which are; which are Approval, Question-answer, Uni/Bi-directional Performative, Information Request, Notification, and Decision Making.

In our proposal, a CS classification is conducted based on WPAs in order to identify candidate services for a particular business logic. This fact can upgrade the precision of the algorithm by identifying service classes that share the same business logic as the activity. To do so, we propose a modified K-means algorithm based on CS descriptions. In order to have meaningful classification adapted to our context, first, we left frequent and rare words extracted from services description unclassified in order to avoid overfitting.

Second, we enhance the cohesion and correlation conditions defined in the standard K-means algorithm by quantifying the cohesion and correlation of classes based on a semantic functional similarity (which is presented in the next section) instead of Euclidean distances used in the standard K-means algorithm.
Third, to ensure that we obtain classes with high cohesion, we only add an item (in our case a service) to a class if it satisfies a stricter condition, called cohesion condition. Given a class C, an item 'i' is called a kernel item if it is closely similar to at least half of the remaining items in C. Our cohesion condition requires that all the items in the class be kernel items. Formally;

$$i \in C \implies (\forall j \in C, i \neq j), Sim(i,j) \geq \frac{||C|| - 1}{2}$$

We illustrate the major steps of the modified K-means algorithm as follows:

Modified K-means Algorithm:
Input: classes scopes set (S = s1, s2, ..., sn) k the number of classes
Output: k classes
Let sim be the similarity function
C = {c1, c2,... , ck } (set of classes centroids)
L = {L(si)|i = 1, 2, ..., n}(set of classes labels)
for all ci in C do
ci <-- sj {Initialize Centroid (ci) }
end for
for all si in S do
l(si) <-- index_max_Sim(si,cj)
end for
Centroid_Change <--False, cohesion_condition() <--True
srepeat
for all ci in C do UpdateCentroid(ci)
end for
for all si in S do
M <-- index_max_Sim(si,cj)
if M /= l(si) then
l(si) <-- M
Centroid_Change <-- True
end if
Verify(cohesion_condition(si, sl))
l in (1, 2, ..., n) l /= i
end for
until (Centroid_Change == False and Verify(cohesion_condition()))

Figure 3 illustrates activities' business logics.

Fig. 3: BP4Cloud Meta-Model

Activity-Services Matching Algorithm

After modeling the required cloud resources, we need to particularly discover concrete services that will be invoked to perform BP's activities. To do so, we propose the Activity-Services Matching algorithm which is accomplished through two main steps: the technical matching and the business matching. Figure 4 illustrates an overview of the matching algorithm steps.

Fig. 4: Activity-Services Matching steps

Our algorithm uses real services referenced in a cloud registry. We propose a consistent registry, named ULIT (Unified cLoud servIces regisTry), where services offered by different cloud providers, such as Amazon, IBM, and Google, are collected, unified and classified based on their functional features. ULIT was reviewed and accepted by Elsevier Mendeley Data [Elsevier Mendeley Data , 2019]. It is publicly available on [ULIT , 2019].

Technical Matching

The main purpose of the technical matching is discovering the infrastructure environment based on technical requirements specified by BP4Cloud. To do so, we establish, first, a mapping relationship between "agnostic cloud resources" specified in BP4Cloud and "concrete cloud resources" referenced in ULIT. Figure 5 illustrates this mapping.

Fig. 5: Technical Matching

However, this is not enough to precisely define the infrastructure environment. Indeed, IaaS services need to be correctly configured. Several and conflicting criteria have to be considered such as; VCPU, RAM, etc. No single service exceeds all other services isn all criteria but each service may be better in terms of some of the criteria. Therefore, we consider IaaS services discovery and configuration as a MultiCriteria Decision Making (MCDM) problem. In our previous works [Gabsi et al., 2018] and [Gabsi et al., 2019], we have clearly addressed the technical matching.

Business Matching

The business matching is conducted through two steps. The context matching and the functional matching. Figure 6 illustrates the business matching steps.

Fig. 6: Business Matching

Context Matching

The context matching discovers CSs sharing the same business context as BP's activity. To identify the business context of BP's activities, we annotate each activity by scope & objective that clearly define the business context such as Send Notification, Database Access. The scope & objective are defined by the business designer.

Defining the business context of a CS is more challenging due to its heterogeneous description and the abundant use of adjectives for commercial purposes. To deal with this challenge, we extract relevant keywords presenting the functional features of CSs from its provided descriptions in supplier's web portals. We use a natural language processing tool named Stanford Parser [Marneffe and Manning, 2015]. The Stanford Parser can identify the grammatical structure of each sentence of service descriptions by creating grammatical relations or type dependencies among elements in the sentence. These dependencies are called Stanford Dependencies SDs [Marneffe and Manning, 2015]. In our work, we model keywords as a set of binary relations < action, object >, where the action is a keyword presenting a verb, which denotes the functional feature of the service. The object is a keyword presenting a noun, which denotes the entities affected by the action. Then, we use the SD sets to properly identify the grammatical relations between < action, object >. In fact, each SD is a binary relation between a governor (also known as a regent or a head) and a dependent [Marneffe and Manning, 2015].

After defining services functional features, the context matching is based on the semantic similarity between service's keywords and activity's scope & objective. The semantic similarity $SIM(S_1, A_1)$ is inspired by [Lin, 1998a]. Indeed, the authors prove the relevance of the proposed similarity formula in the context of words pairs similarity. The main asset of this work is defining similarity in information theoretic terms which ensure the universality of the similarity measure.

We denote $S_1 = \{S_{1,1}, S_{1,2}, S_{1,3}, \dots, S_{1,N}\}$ *a* service business features, where $s_{1,i}$ is the pair < action, object > and $|S_1|$ the cardinality of S_1, (the number of pairs $s_{1,i}$). We denote $A_1 = \{a_{1,1}, a_{1,2}, a_{1,3}, \dots, a_{1,N}\}$ *the* activity's scope & objective. The similarity $SIM(S_1, A_1)$is the sum of the similarities between each pair s_{1i} of S_1, and the pairs $\{a_{1,1}, a_{1,2}, a_{1,3}, \dots, a_{1,N}\}$ of A_1, normalized by the cardinality of S_1. Formally, we obtain;

$$SIM(S_1, A_1) = \frac{\sum_{i=1}^{|S_1|}\left(\frac{\sum_{j=1}^{|A_1|} SIM\ (s_{1i}, a_{1J})}{|A_1|}\right)}{|S_1|}$$

where $S(s_{1i}, a_{1j})$ is the pairs similarity. We define the pairs similarity as follows:

- Let A_{s1} and A_{c1} respectively denote the actions in the pair s_1 and a_1;
- OS_{i1} and OA_{i1} respectively denote objects in the pair s_1 and a_1;
- ω_1, ω_2 denote the weight of the action part and the object part. We suppose that some predefined action has a higher weight such as; offer, provide, deliver, etc.;
- *m* is the minimum number of objects of the pair s_1 and a_1 (min number objects(s_1 ,a_1)) whereas n is the maximum number of objects of the pair a_1 and s_1 (max number objects(a_1 ,s_1)).

The pair similarity is calculated as :

$$SIM(a_1, s_1) = \omega_1 SIM(A_{S1}, A_{c1}) + \omega_2 \frac{\sum_{i=1}^{m} SIM(OS_{i1}, OA_{i1})}{n}$$

where $SIM(OS_{i1}, OA_{i1})$ is words similarity. We use Jacard Similarity Coefficient [Niwattanakul et al., 2013] to calculate the word similarity. In fact, the Jaccard coefficient measures similarity between finite sample sets, and is defined as the size of the union divided by the size of the intersection of the sample sets.

$$J(E,F) = \frac{E \cup F}{E \cap F}$$

where E and F are two given sets of words. We create a feature set F(w) for each word 'w' (i.e for each object which is presented by a word in our context) containing the synonym set, generic word and interpretation of the word w. F(w) is created using BabelNet. Based on [Lin, 1998b], we define the similarity between the two words as follows:

$$SIM(\omega_1, \omega_2) = \frac{2 \times I(F(\omega_1) \cap F(W_2))}{I(F(\omega_1) + F(W_2))}$$

where I(S) represents the amount of information contained in a set of features S. I(S) is calculated as:

$$I(S) = -\sum_{f \in S} logP(f)$$

The probability $P(f)$ can be estimated by the percentage of words that have the feature f among the set of words that have the same part of speech in the entire BabelNet library database. If the semantic similarity $SIM(S_1, A_1)$ is greater than a specific threshold (experimentally fixed in our work as 0.5), S_i is considered as candidate for the functional matching.

Functional Matching

The output of the context matching is a set of candidate CSs that share the same business context as the activity. The functional matching aims to identify the CS's operations that can perform the BP's activity. Inspired by [TRAN et al., 2009], we perform the functional matching by evaluating how a service operation fulfills an activity requirement. This is performed by answering two symmetric questions: (1) how the activity can fulfill required inputs for the service operation; and (2) how the service operation can fulfill expected outputs of the activity. To do so, first, we classify CSs operations and business activities into two categories: information request (IR) and manipulation request (MR). Information requests (IR) aim to retrieve diverse information regarding a particular request such as get attributes(), list methods() etc. Manipulation requests (MR) present several modification functions such as: create(), recommend(), etc. Based on this classification, we identify candidate operations according to the activity request type. We define a matched operation if two main elements are verified: a matched context and matched inputs/outputs.

A matched context is defined through two steps. First, we take advantage of the structure of CSs operations' naming, which is typically action object, to calculate the semantic similarity between the operation action and the activity action. If this similarity is greater than a fixed threshold, the second step consists on verifying if the operation object is a generic word of the activity object, that means the activity object satisfies the relationship *"is a"* an operation object. We consider an operation is a candidate for the inputs/outputs matching if it satisfies the two abovementioned conditions.

The input/output matching consists of a matching level and matching degree. The matching degree consists of four elements: SIF: service operation input fulfillment, AIR: activity input redundancy, AOF: activity output fulfillment, and SOR: service operation output redundancy. SIF and AOF are, respectively, the ratio of the fulfillment of the service operation inputs and activity outputs by the activity inputs and service operation outputs. AIR and SOR are, respectively, the ratio of redundancy (unused) of the activity inputs and service operation outputs in fulfilling the service operation inputs and activity outputs. SIF, AIR, AOF, and SOR have values in [0.1]. Formally;

$$SIF = \frac{Matched_Input_Count}{Operation_Input_Size}$$

$$SOR = \frac{Unused_Operation_Otput}{Operation_Otput_Size}$$

$$AIR = \frac{Unused_Activity_Input}{Activity_Input_Size}$$

$$AOF = \frac{Matched_Output_Count}{Activity_Output_Size}$$

A matching level can be precise, over, partial, or mismatch and it is specified based on SIF, AIR, AOF, and SOR in the following rules:

- Precise: if (SIF = 1 ∧ AOF = 1) ∧ (AIR = 0 ∧ SOR=0)
- Over if (SIF=1 ∧ AOF=1) ∧ (AIR>0 ∨ SOR> 0)
- Partial if (SIF >= iMT ∧ SIF < 1) ∧ (AOF >= oMT ∧ AOF < 1)
- Mismatch if SIF < iMT ∨ AOF < oMT

iMT and oMT are customized matching thresholds. Depending on a particular business context, we can set suitable values for iMT and oMT to get more or less partial matched services, e.g. they can be set to 0.5. If there are more than one service operations which are matched with the activity then the list of matched service operations is sorted according to the following rules:

- Precise>Over>Partial>Mismatch
- If two operations are both over match then
    - The smaller the value SOR is the better the matched operation is.
    - If they have the same value SOR then the smaller the value AIR is the better the matched operation is.
- If two operations are both partial match then
    - The larger the value AOF is the better the matched operation is.
    - If they have the same value AOF then the larger the value SIF is the better the matched operation is.
    - If they have the same values AOF and SIF then we apply the rules of the values SOR and AIR as in case of over match above.
- If two operations are both mismatch then they are considered the same.

The following algorithm illustrates the Activity- Services Matching process.

```
Activity-Services Matching Algorithm
Let S be a Cloud Service.
Resources.
{Context Matching}
Select S where S.Class == A.BusinessLogic
If (Sim (A.Scope_Objective, S.Keywords_Set)>=0.5) then Add(Candidate_Services,S)
{Functional Matching}
For each S in Candidate_Services do
Select S.Operations_Set where A.Request_Type == S.Operation_Category
If Sim(A. Verb, S.Operation_Verb) >= 0.7 then
If (A.Object is_a (S.Operation_Object) Add(Candidate_Operaton , S.Operation)
Endif
Endif
Endfor
matchCount=0
unusedCount = 0
For each op in Candidate_Opererations do
```

```
For each inp in op.Input_set do
m = match (inp, A.input) (the match function checks the compatibility between
data types.)
if m != "mismatch" then
matchCount ++
Endif
Endfor
Endfor
For each a_input in A.input do
If a_input.used == "false" then
unusedCount ++
Endif
Endfor
(Service Input Fulfillment)
Sif = matchCount /S.Input.size();
(Activity Input Redundance)
Air = unusedCount /A.Input.size(); IfSif==1andAir==0 then matchingInput.Level =
"precise"; elseifSif==1andAir>0then matchingInput.Level = "over";
elseif Sif < 1 and Sif >= iMT(0,5) then matchingInput.Level = "partial";
elseif Sif < iMT(0,5) then
matchingInput.Level = "mismatch";
Endif
(We apply the same algorithm for matching
the outputs as matching the inputs.)
If (matchingInput.Level == "precise" and matchingOuput.Level == "precise") then
matchingOperation.Level == "precise";
elseif (matchingInput.Level == "precise" and matchingOutput.Level == "over") or
(matchingInput.Level == "over" and matchingOutput.Level == "precise") or
(matchingInput.Level == "over" and matchingOutput.Level == "over") then
matchingOperation.Level = "over";
elseif (matchingInput.Level == "partial" and matchingOutput.Level != "mismatch") or
(matchingInput.Level != "mismatch" and matchingOutput.Level == "partial") then
matchingOperation.Level = "partial";
elseif (matchingInput.Level == "mismatch" or matchingOutput.Level == "mismatch") then
matchingOperation.Level = "mismatch";
Endif
```

Application and Performance Analysis

In order to illustrate our approach, we set up, firstly, by clarifying the specification of BP4Cloud elements applied on the use case, ”Online Bank Accounts Opening”. Then, we proceed evaluating the overall performance of our Activity-Service Matching Algorithm.

BP4Cloud Evaluation

We present an extract of BP4Cloud file specifying the activity ”Check customer summary” requirements. The activity requires a compute server, as IaaS requirement, and a database server as PaaS requirements. Its business logic is ”Datachecking and Analytics.

```
1 <is_composed_of
2        xsi:type="CloudBusinessProcess: Service_Task"
3        name="Check customer summary"
4        description="Verify if a customer has already made an application earlier"
```

```
    key_words="Check summary" , "Verify application", "Validate
        Summary"
    preconditins=""
    effects=""
    id="1">
<use_data
    href="Data.xmi#/" input_data_type="
        String" output_data_type="Boolean "/>
<requirements
    xsi:type="CloudBusinessProcess: Data_Base_Server"
    href="Data_Base_Server.xmi#/">
<requirements
    xsi:type="CloudBusinessProcess:Compute"
    href="Compute.xmi#/" id="1" vmsize="
        Meduim">
<business_logic
    href="Datachecking_and_Analytics.xmi #/"/>
```

To practically evaluate our specification, we measure the complexity of two process models, one using the standard BPMN and the other using BPMN extended by BP4Cloud. The complexity of a process model can be defined as the degree to which a BP is difficult to analyze and understand. [Huber et al., 2018]. Huber et al. [Huber et al., 2018], propose to categorize BP complexity metrics. We consider the following metrics:

- The number of activities and control flow elements in a process metric (NOAC). It counts the activities and control flow elements of a process, which are the gateways in BPMN.
- McCabe's Cyclomatic Complexity metric (MCC) measures the number of control paths through the process. MCC is defined to be $e - n + 2$, where e is the number of edges and n is the number of nodes in the control flow graph.
- Control flow Complexity metric (CFC) is defined as the number of mental states that have to be considered when a designer develops a process. It is calculated as $C_{XOR} + C_{OR} + C_{AND}$, where C_{XOR} is complexity of XOR-split (equals to number of branches that can be taken), C_{OR}complexity of OR-split (equals to number of states that may arise from the execution of the split), and C_{AND} complexity of AND-split (always equals 1). The higher the value of C_{XOR}, C_{OR}, and C_{AND}, the more complex is the process design.

The online bank accounts opening process designed using BP4Cloud has the same control flow elements (NOAC), activities elements (NOA, control paths (MCC) (in our use case e=15 and n=15) and the control-flows (CFC). Using the presented metrics, we can clearly demonstrate that using BP4Cloud is not in any view more complex. In fact, BP4Cloud does neither modify the control-flow elements of the BP nor its activities.

Activity-Service Matching Algorithm Evaluation

In order to evaluate the effectiveness of our algorithm, experiments were conducted to evaluate its precision and recall on the BP presented in the motivating scenario section. The precision evaluates the capability of the algorithm to retrieve top-ranked services that are most relevant to the activity. The recall evaluates the capability of the algorithm to get all the relevant CSs [Davis and Goadrich, 2006]. Formally;

$$P = \frac{|S_{Rel}|}{|S_{Ret}|}, \qquad R = \frac{|S_{Rel}|}{|Rel|}$$

$$P_k = \frac{S_{Rel,k}}{k}, \qquad P_r = \frac{S_{Rel,|Rel|}}{|Rel|}$$

where Rel denotes the set of relevant service, S_{Ret} is the set of retuned services, S_{Rel} is the set of returned relevant services and $S_{Rel,k}$ is the set of relevant services in the top k returned services. Among the above metrics, P_r is considered to most precisely capture the precision and ranking quality of the algorithm. We also plotted the recall/precision curve (R-P curve). In an R-P curve figure, the X-axis represents recall, and the Y-axis represents precision. An ideal discovery result presents a horizontal curve with a high precision value. The R-P curve is considered by the IR community as the most informative graph showing the effectiveness of the discovery algorithm [Davis and Goadrich, 2006].

In order to evaluate our proposed algorithm, we asked several BP designers and technical developers who are familiar with CSs uses to identify the relevant services meeting the business activities. Table 1 illustrates the online bank account process results. For reason of space restraint, we display some relevant services related to the activities ”check customer summary” and ” send account id”.

TABLE I: Activity-Services matching algorithm evaluation

Activity	Business Logic	Scope / Objective	Relevant Services	Relevant Operation	Context Matching			Business Matching	
					Returned Services	Extracted keywords	SIM (S.KW, A.Scope/Objective)	Returned Operation	Matching Level
Check summary ,	Data checking & Analytics	Database Access / Availability Check	Amazon SimpleDB Amazon DynamoDB Amazon RDS Amazon Aurora Amazon Neptune Amazon Redshift Oracle Database	elect() Query() Describe events() Select () Select () Describe events() Query()	Amazon SimpleDB	(’query’, ’data items’) (’storing’, ’data items’) (’serving’, ’requests’)	0.796	Query()	Over
					Amazon RDS	(’query’, ’data items’) (’replicate’, ’databases’) (’scale’, ’database setup’)	0.796	-	Over
					Amazon DynamoDB	(’handle’, ’requests’) (’Create’, ’table’) (’handle’, ’data’)	0.642	Query()	Over
					Amazon Neptune	(’build’, ’queries’) (’querying’, ’database’)	0.597	Select ()	Over
					Oracle Database	(’retrieve’, ’information’)	0.503	Query()	Over
Send account ID	Notification	Send/Receive Message	Amazon SQS Amazon SNS Amazon SimpleMail Amazon WorkMail IBM	Send Message () Publish() Send Email() Send Message ()	Amazon SQS	(’send’, ’messages’) (’receive’, ’messages’) (’losing’, ’messages’)	1	Send Message()	Over

We evaluated the precision of the proposed services and report the average top-2, top-5, and top-10 precision. To ensure the top-10 precision is meaningful, we selected activities for which we can identify more than 15 relevant services over different providers. Figure 7 illustrates the results. The top- 2, top-5, and top-10 precisions related to the context matching of our algorithm are, respectively, 91%, 87%, 74%. The precision related to the functional matching can be 1 or 0. Finding the suitable operation

performing the activity is considered as 1 in terms of precision value, else the precision is estimated to 0.

The evaluation demonstrates that taking into account the context of both the business process and activity using their business features during the context matching can effectively provide acceptable precision values (91%, 87%), which means, we can identify suitable candidate services. The discovery of suitable service operation can more challenging since the functional matching involves different matching level. The inputs/outputs matching is considered as the main important step to validate if a candidate operation can perform the activity.

Fig. 7: Top-k precision for retrieved services

We plot the average R-P curves to illustrate the overall performance of the matching algorithm. As mentioned previously, an appropriate discovery result has a horizontal curve with a high precision value. Typically, precision and recall are inversely related, ie. as precision increases, recall falls and vice-versa. A balance between these two needs to be achieved. As illustrated by Figure 8, for a recall average equals to 0,63 we have 0,85 as precision value. As an example, for the service activity " Check customer summary ", we have 20 services considered as relevant in ULIT i.e $|Rel| = 20$, the matching algorithm returns a total of 16 services i.e $|S_{Ret}| = 16$, among them 13 services are considered relevant i.e $|S_{Rel}| = 12$. We obtain a precision value $P = 13/16 = 0,81$ and a recall value $R = 13/20 = 0,65$.

Fig. 8: R-P Curves

It is worth pointing out that in some cases, depending on particular context, high precision at the cost of a recall or high recall with lower precision can be chosen. Thus, evaluating a matching algorithm for services discovery must be related to the purpose of the discovery. In our case a compromise between the recall and the precision values is necessary. Therefore, we can announce the proposed algorithm provides accurate results for CSs discovery.

Related Work

Despite various efforts for cloud resource integration in BPs modeling, it remained poorly described and operated [Nacer et al., 2019]. In [RamosMerino et al., 2019], the authors proposed extensions to support new features such as the possibility to describe the workflow behavior, the activities performed and the context of the application in a machine understandable way. Even though, this works can simplify the BPs modeling, it did not take into consideration several resources required for the development and execution of the BP, particularly, cloud resources perspective. In [Heidari et al., 2013], the authors proposed the use of BPSim, which is a standard that provides a framework for structural and capacity analysis of BP models specified by the use of BPMN or XPDL (XML Process Definition Language). However, it is limited to introduce BPMN extensions to enhance its expressive capabilities without considering the runtime environment. In fact, the resource perspective may change depending on the runtime environment, notably, cloud environments require specific resources that are different from other runtime environments.

Other approaches investigated the discovery of concrete CSs performing BP's activities. In that respect, several semantic approaches are scientifically interesting such as [Martino et al., 2018], [Nagarajan et al., 2018]. However, most of these works are depending on the preexistence of providers' specific ontologies (OWL-S services description) that require mapping techniques to coordinate the difference between agnostic (abstract) and vendor dependent concepts to support interoperability. Moreover, from the business designer perspective, it requires to have intimate knowledge of semantic services and related description and implementation. The business designers may not be aware of all the knowledge that constitutes the domain ontology. As a result of which many relevant services may not be considered in the service discovery process. Therefore, proposing an atomic mapping from business activity to CSs based on available services description that does not make any assumptions about the description standard languages of CSs, presents valuable insights to improve BP development.

Conclusion

This paper aims to provide efficient support to discover cloud services required for business process development. To achieve our aim, we define a cloud-aware BP by proposing BP4Cloud which is a BPMN extension that supports the design of cloud resource perspective requirements. BP4Cloud offers a solution for coordinating cloud resources between business designers and technical developers. Following the modeling of the required cloud resource, we propose an Activity-Services Matching algorithm to assist technical developers in discovering the required cloud services. Our proposed algorithm is conducted through two steps; the context matching which aims to discover services that share the same business context as the business activity and the business matching which aims to identify the suitable operation performing the activity. Our experimental evaluation has demonstrated that the Activity-Services Matching algorithm can potentially assist technical developers owing to its precision. Although we believe that our algorithm leaves scope for a range of enhancements, yet it provides suitable results. As ongoing work, we intend to conduct the composition of the discovered cloud resources in order to develop the cloud workflow application.

Abstract

This article attempts to construct a sociocultural matrix of an ecological-tourist landscape in order to promote the image of the territory. It is shown that the social construction of the ecological-tourist landscape is based on the ideas of the correlation of the environment, image, action and narrative. Today, the landscape fits into our identity, relationships and life scenario and suggests an active position in the sequence of life events. To a certain extent, the design of ecological-tourist landscapes is designed to overcome the growing emancipation of man from the place, to restore the coherence and meaningfulness of the spatial organization of life that we lose in separation, lack of commitment and unlimited freedom. At the same time, representing a positive, "elevated" from an axiological point of view and at the same time very varied image, the constructed ecological-tourist matrix of the region is an important element of strategic planning of the image of the territory.

Keywords: Sociocultural Matrix, Tourism, Ecological Tourism, Landscape, Image Of The Region.

Introduction

The field of ecological tourism, in comparison with other areas of world tourism and industry, is currently characterized by the most powerful and rapid development. One of the main reasons for this phenomenon of our time is that environmental problems have now become global. The increased interest in the field of ecotourism in the world and in the Russian Federation indicates that this phenomenon has a significant impact on the political, economic, social and spiritual spheres of society. The experience of regions where ecotourism is thriving can lead to positive socio-cultural and economic trends.

The development of eco-tourism is currently creating favorable conditions for the formation of a new, modern tourism culture. Its highest priority is environmental protection, preservation of the natural ecosystem, the formation of environmental awareness and environmentally conscious behavior for each participant in ecological tourism activities. Moreover, such a culture is a reliable foundation for the development of not only ecological tourism, but also the tourism industry as a whole.

Research Methods

The theoretical and methodological foundations of the study are based on the subject field of tourism sociology, whose main interests are concentrated in the intersection of the concepts of consumption, identity and tourist experience. In accordance with the formulation of research tasks, the work uses elements of the theory of social mobility J. Urry, as well as his ideas regarding the practice of managing tourist attention. The activity-structural approach predetermined the research orientation on the use of the case study strategy of a particular place / places, which allows us to identify the logic of the relationship between local practices of constructing the sociocultural matrix of the ecological-tourist landscape and the processes of their capitalization developing on this soil with a wider social context, reflecting the formation of the territorial structure society.

The research methodology is based on the use of general scientific methods of a systematic approach, typological techniques, social construction, a method for assessing the reliability of qualitative and quantitative statistical indicators.

Results and Discussion

Currently, there is a rapid increase in the number of people for whom daily trips, travels and relocation are becoming the norm. As A. Toffler rightly remarks, today we are “witnesses to the historical process of destroying the significance of a place in human life” (Toffler, 1997, p. 57). This circumstance determines the turn of research interest in the problems of mobility in the sociocultural environment. More and more often, scientists are wondering how and why tourism has turned from an elite type of vacation for a very small group of people into a symbol of mass consumption and has become one of the trendsetters for standardized pleasures. In turn, modern tourist practices actualize the problem of the production of new tourist places and attractions, images and brands. Tourism and travel create their own system of significations, creating ways of constructing themselves and others.
Recent studies have revealed a wide range of problems related to the tourist image of individual territories (Kryukova, Pechorina, 2014; Cherifi, 2014; Lai K., Li Y, 2012, Chen Lei, 2019).

It should be noted that the development of tourism in the regions has some growth restrictions that depend mainly not so much on the availability of developed tourism infrastructure, but on the degree of generation and accumulation of tourist narratives in the region. Thanks to these narratives, places of interest are perceived by visitors and the local population as objects of tourist interest (Leukhin, 2018, p. 41)

In the context of the indicated problems, the vector of “tourist reflection”, which, according to J. Urry, “makes it possible to identify a specific place in geographical, historical and cultural coordinates, and to determine its existing and potential material and semiotic resources” is of particular importance (Urry, 2005) The surge of "tourist reflection" has led to the emergence of various technologies, procedures, and evaluation criteria for any point on the planet from the standpoint of global tourism standards. Now any city, locality - by and large, any place - can be studied and modified in the context of a rapidly changing world order. Such procedures, according to J. Urry, were the basis for the invention, production, sale and distribution (by telecommunications) of new or newly “packaged”, different from each other or occupying a separate niche places and their visual representations, offering models of global spatial arrangement (Urry, 2005).

First of all, we are talking about the actualization of the processes of constructing the sociocultural matrix of a particular place or object endowed with meanings, associations and memories. As a result, we have the opportunity to create (form) a holistic tourist landscape, which is not only a natural form created and changed by man, but also a kind of cultural product with many layers of meanings that require thoughtful “reading” and comprehension.

The modern development of ecological tourism, the tourism industry and activities is indisputable evidence and confirmation of the thesis of modern scientists on the need for official recognition of global (transnational) citizenship. Going beyond the usual borders of the national state, such

citizenship objectifies the need to take into account the rights and obligations of a citizen of the global community, which, in our opinion, should be considered any ecotourist as a traveling person.

Scientists identify a number of duties of a citizen of such a global community (Kimelev, 2001, p. 131-152):

- ✓ to be aware of the state of the planet using not only national but also international sources of information;
- ✓ demonstrate the installation of cosmopolitanism in relation to other cultures, environments, people;
- ✓ comply with behaviors that are consistent with the standards of stability and sustainability;
- ✓ respond to information, images, etc. as a citizen of the planet, and not as a citizen of a certain country or as a member of a certain ethnic group, class, etc.;
- ✓ strive to convince others to act in the name of the planet as an integrated and unified system;
- ✓ act in terms of global public interest, and not in terms of local or national interests.

In our opinion, the following rights are rightly recognized as the rights of a citizen of a reputed global community:

- ✓ to migrate from one society to another and stay there for a while, having received rights comparable to those of indigenous people, to return home without losing citizenship and other rights;
- ✓ bring your own culture with you, as well as meet in a new place with a "hybrid culture" that also contains elements of tourist culture;
- ✓ culturally participate in all social groups in world society (ownership of information, knowledge, communication, representation);
- ✓ buy services and goods produced in other cultures and use them within their own culture;
- ✓ form social movements with citizens of other countries to counter any state or group of states, as well as corporations;
- ✓ migrate around the planet for leisure and consumption of various places;
- ✓ live in an environment relatively free of risks and threats to health and safety.

It is in the context of the presence of the above duties and rights that it is necessary to talk about a sociological interpretation of the place, which now seems to be a social construction. Due to the emergence of new technologies, modern socio-economic processes, the network of high-speed travels, there has been a significant increase in regional and global ties. The consequence of these processes is a noticeable increase in attention to a place that has ceased to be a simple locus. Sociocultural transformations in modern societies with obligatory dislocations, movements that significantly compress the time frame of social actions carried out in various places, which inevitably cause a feeling of soil loss, contribute to such attention. All this has a significant impact on a person's perception of a place, since it acts as a recognizable and changing reality (Culture, Power, Place, 1999, p. 12).

In addition, the concept of a place focuses on relations in the format of "a person traveling - the natural environment", and not just refers to geographical localization. This is because the world embodies something that is experienced and acquires significance as a human construct, because people live in the world, creating, using and transforming the image of the world. A place does not exist as a simple given, since it is subjectively perceived and experienced differently depending on the perspective of observation, the strength of emotional experiences, and the readiness to perceive it.

In this connection, an interesting theory is M. Aude, in which he proposed his original concept of non-place (Aude, 1997, p. 51-52). The scientist clearly distinguishes between a place filled with historical sights and the work of social life, and a non-place where no form of organic social life is possible.

By non-place, this scientist understands "interesting places that are everywhere and nowhere," that is, contexts in which people spend a significant part of their time (supermarkets, airports, hotels, roads, watching television, sitting at a computer, etc.), where the consciousness is fragmented and leads to the loss of the unity of the world. In his opinion, the existence of non-place allows you to clearly define a place as both a concrete and symbolic construction of space, which serves as a reference point. The place is endowed with a basic meaning for its inhabitants and has three mandatory properties: correlation with identity, relationships, history (Aude, 1997, p. 77).

The significance of the place is also explained by the fact that it is symbolically embedded and reproduced in a unique tourist landscape, which focuses on the practice of tourism consumption and virtual design, ensuring its originality.

As the analysis shows, the landscape is understood in the social sciences as a social construct, as something that is experienced and endowed with meanings, associations, and memories.

In the context of ecological tourism activities, it is advisable to define the sociocultural landscape as the multiplicity of relative places that embody (directly and indirectly) the emotions, memories, associations received in individual and group experience in a general historical and cultural context. Moreover, the sociocultural landscape is embodied not only in natural forms created by man or changed by him, but also in the meanings embodied in them (Pokrovsky, 2008, p. 172).

Interesting, in this context, is the opinion of K. Girtz that between "what our body says and what we need to know in order to function, there is a vacuum that we ourselves must fill, and we fill it with information (not misinformation) provided by our culture. The border between what is controlled by innate mechanisms in human behavior and what is controlled by cultural mechanisms is an undefined and unstable border" (Girtz, 2004, p. 62).

It is important to emphasize that in this sense, the concept of a sociocultural landscape clearly indicates that the geographical characteristics of a place are not determining components of its existence. That is why scientists identify three main approaches based on various cultural practices of landscape use (Kagansky, 2001, p. 3-18):

1. Aesthetic. It involves the perception, description, emotional assessment of the surrounding beauty, harmony, aesthetic characteristics.
2. Naturalistic. It is based on the understanding of the eternity of nature and its supremacy over human activity, which, being a derivative, builds ecological relations with the landscape.
3. Escapism. With this approach, the landscape acts as a special environment for the activities of socially marginalized groups that unfold a peculiar theatrical action that contrasts or even conflicts with the life of the main part of society.

Obviously, it is advisable to agree with scientists who are convinced that the methods for distinguishing the landscape directly depend on the sphere of activity of people who differently inhabit it and represent culturally and socially significant experience (Kagansky, pp. 3-18).

It is in this sense and context that it is advisable, in our opinion, to talk about the official recognition of another approach to the use of the landscape through the prism of ecological tourism activities.

We believe that this fourth approach should be called "educational and enlightening", since its essence is to obtain new additional knowledge about the environment and, accordingly, the landscape and the place. It is important to emphasize that obtaining additional knowledge cannot be an end in itself, since it is necessary, firstly, to expand existing practices of relationships and interaction in the format "environment-sociocultural landscape, tourist-sociocultural practice-behavior".

Secondly, the acquired knowledge must necessarily be disseminated in order to create a kind of "knowledge bank" about existing sociocultural landscapes and the accumulation of their so-called "institutional memory", common to all tourists as representatives of the global community.

This is especially important because the perception of the environment is determined by the semantic connections that a person puts, including the perceptual image, into the structure of his life experience. This process is accompanied by various emotional experiences, correlating individual concepts with existing cultural themes. That is why culture as a system of established well-known signs becomes both power and a context within which various social events, institutions or processes, people's behavior can be described and understood (Pokrovsky, 2008, p. 173).

People create, use, and transform landscapes using sign systems with which they identify themselves and understand the world around them.

Landscape as a cultural product becomes a text with many layers of meanings, which requires thoughtful reading (Brueggemann, 1997, p. 5). We share the opinion of scientists that the landscape is a complex grid - a network of relationships, connections and sequences, “physical, social and cultural conditions that describe my actions, my reactions, understanding, and this gives the form and content of life itself, which I am "(Brueggemann, 1997, p. 5).

In this regard, we believe that the use of technologies for the social construction of ecological and tourist landscapes will contribute to improving the management of the development of the field of ecological tourism in Russia.

By creating an ecological-tourist landscape, we understand the process of constructing a sociocultural matrix of a certain unknown place or object with the mandatory use of a number of successive phases, namely (Pokrovsky, 2008, p. 174):

1. Identification of the place. The purpose of passing this phase is to choose a place as an object of construction and determine its main characteristics.
2. The formation of sociocultural connotations. This phase provides for the confirmation of the historical, sociocultural, ecological value of the chosen place by using various means for this.
3. Visualization and virtualization. The purpose of this phase is to create an attractive positive image of the chosen place or object using various modern technical means (photos, videos, media), and create legends and myths about it.
4. Distribution of the image and distribution of the created texts using the media, advertising companies, tourists.
5. Development of the tourist infrastructure of the place. The emphasis is on creating conditions for excursions, recreation and other types of tourist activity, possible in these conditions.

We believe that taking these phases into account is an essential element in the landscape design process that is carried out to manage the tourist presentation and aimed at creating a message that needs to be perceived, understood, learned in a certain way to trigger further feedback and actions that form the basis of the visual organization of the space being transformed in his image.

According to J. Urry, such an organization defines the physical (movement), psychological (interest, attention, surprise), social (communication, perception of social information, interaction) components of action (Urry, 1995, p. 78-79).

In this context, the concept of indexing representations of C. Roger deserves attention. In his opinion, the structure of tourist perception is a combination of visual, textual and symbolic representations placed and presented in various guides, film, television, video shows, stories of tourists, etc. That is why, according to this scientist, each person has a socially constructed range of ideas composed of various elements. Since sights, like tourist places, do not have any of their own or initial values, it is necessary to create their frames, be sure to index the elements of culture, using various means of visualizing their image, namely: cinema, video, television, media, etc. (Rojek, 1997, p. 70-71).

In this context, it is necessary to take into account the fact that the ecotourist perceives a certain version of reality that has developed on the basis of images created by modern technology, powerful for shaping the perception of a place.

However, these images may not coincide with their own images, feelings, assessment of the place. In this case, the feelings and expectations of ecotourists from the place visited by him personally are not justified, and the place or attraction creates an anti-experience.

In our opinion, this fact should be especially taken into account in the process of preparing and distributing printed advertising materials about ecotourism places and sights. It is important at the same time not to impose on a potential tourist an opinion about a place or attraction, but to create opportunities and prerequisites for him to become interested in a place or attraction and a desire to see it with his own eyes. In this context, ecological tourism acquires the importance of spatial self-realization, self-identification and self-actualization of the personality of a tourist.

We believe that in the process of social construction of tourist landscapes, increased attention requires the process of focusing attention. According to J. Urry, a tourist's view always includes relationships between bodies that are in motion. Bodies present themselves in the space of sensations of others and in diverse sensual landscapes. The bodies pave the way between the direct perception of the outside world, in which they either physically move or lie motionless on the beach waiting for a bronze tan, and discursively, mediated by sensual landscapes in which their social tastes and differences, ideology and significance are articulated. That is why an important task for landscape design is the establishment of links between discourse and the body, providing a fixation of the tourist point of view [Sokolova, 2006].

Scientists rightly, in our opinion, identify a number of ways that contribute to the social construction of the tourist landscape, namely (Pokrovsky, 2008, p. 175-178):

1. Novelty and surprise. Z. Bauman explains this state of things by the fact that the purpose of the tourist's movement is a new experience, since the tourist consciously and systematically searches for adventures, new, not like the old ones, experiences (Bauman, 1995, p. 146).
2. Archetypal symbolism and disconnection of everyday life. Scientists have proven that the perception of “magical lands” like Disneyland is based on a standard set of social frames, organizes the view of tourists thanks to essential, archetypal symbols that excite, initiate a sense of mysterious, sacred, sacred, magical (Urry, 1995, p. 86-87). The organization of magical spaces gives rise to specific bodily experiences that switch the tourist's attention from ordinary to magical, wonderful. In addition, K. Rogek is convinced that the pleasure and excitement that tourists experience during travel is directly related to their temporary disconnection from the daily routine. Magic places, activating mental symbols, introduce elements of the essential and significant into the chaos of everyday life, thereby increasing the value of the experience gained (Rojek, 1997).
3. Image attack. This path is gaining importance now, since information technologies and Internet communications are beginning to play an increasingly important role in shaping the visual and emotional perception of the landscape. The appearance of different versions of the same landscape is considered as a strategy for the victory of the tourist services producer over the consumer. Victory begins already with a forced visual selection of an object (place, attraction, transport) and / or determining a route and ends with a triumph - possession of a set of visual confirmations (Pokrovsky, 2008, p. 177).
4. Entertainment and interaction of feelings. It has been proven that acoustic and visual (spectacular) effects have an extraordinary effect on travelers. At the same time, the culture of the event turns into a culture of participation, which is impossible without the acoustic and optical component of the “sound light” type. For example, in Rome tourists visiting the Coliseum is accompanied by sound effects: you can hear the emperors' speeches, the noise of the fire of the Nero era (Papiryan, 2000, p. 27), although history is often written in many places, and not just in a single city, like a way of creating a tourist-city (Urry, 2002, p. 86-87).
5. Programming narratives. Scientists rightly note that the meaning of a place is impossible without a word, a story, because “words are complex systems of metaphors and symbols that translate experience into our pronunciations or feelings that come out. This is the technology

> of explicitness. By translating direct sensory experience into voice characters, you can awaken and reproduce from memory at any time" (McLuhan, 2003, p. 74).

In this context, particular attention should be paid to narratives associated with any landscape that bears a name or title. The name itself gives it a unique meaning, and it is not chosen spontaneously. Of course, each toponym is a code of something once understandable that opens up a whole world of associations and stories, because "all human experience is a story with which we figuratively reconstruct it, and every encounter with the sacred is rooted in a place, in a socio spatial context, rich in myths and symbols "(Lane, 1994, p. 19).

Conclusion

The social construction of the ecological-tourist landscape is based on the ideas of correlation of the environment, image, action and narrative. Today, the landscape fits into our identity, relationships and life scenario and suggests an active position in the sequence of life events. To a certain extent, the design of ecological-tourist landscapes is designed to overcome the growing emancipation of man from the place, to restore the coherence and meaningfulness of the spatial organization of life that we lose in separation, lack of commitment and unlimited freedom. At the same time, representing a positive, "elevated" from an axiological point of view and at the same time very varied image, the constructed ecological-tourist matrix of a certain place / places is an important element of strategic planning of the image of the territory.

The analysis shows that the creation of an ecological-tourist landscape should now be the process of constructing a sociocultural matrix of a particular place / places. This process must necessarily occur due to consecutive phases, and the previous task is a prerequisite for the next phase.

Their primary task should be to conduct a SWOT analysis (analysis of strengths, weaknesses, opportunities and threats) and determine the regional specifics of the development of the tourism industry and related industries. This is followed by the development of a geo-information system (catalog of natural and cultural attractions). It is about organizing the list of tourist sites and making it convenient for use. The next step in this direction is the creation of a comprehensive strategy for the promotion of tourist services in the region, which involves the identification of target audiences, basic communication channels with them, the frequency and intensity of the relevant information impact. Thus, following a similar algorithm for increasing the tourist attractiveness of the region will contribute to bringing the region's ecological tourism industry to a new level.

Abstract

The technological transformation of the economic system contributes to the improvement of existing industries and the development of new ones. The main factor in the growth of the number of small and medium-sized industrial enterprises in developing countries is active state support, the formation of an effective infrastructure and the reduction of administrative barriers that impede the development of enterprises. Therefore, the formation of promising tools to support small and medium-sized industrial enterprises in the Russian Federation is a priority, both for state and private investors. The aim of the study is to analyze existing support tools for small and medium-sized industrial enterprises in terms of improving the economic situation in the Russian Federation and to increase their effectiveness. In the process of researching tools to support small and medium-sized industrial enterprises in the Russian Federation, methods of logical and statistical analysis were used, as well as a method of comparative and correlation analysis of indicators which characterize funding and development of small and medium-sized enterprises in the Russian Federation. The study has identified factors affecting the growth in the number of small and medium-sized industrial enterprises in developing countries. At the present time, state regulation of small and medium-sized industrial enterprises and support for entrepreneurial activity are not carried out at the necessary financial and systematic levels in the Russian Federation. To create rapid growth rate and sustainable development, small and medium-sized industrial enterprises should be regulated by the reasonable and rational impact of the state, and it should also contribute to the creation of favorable conditions for the development and maintenance of enterprises

Keywords: Small and Medium-Sized Industrial Enterprises, Financial Support, Efficiency.

Introduction

At the present time in the Russian Federation, less attention is paid to the study of the development of small and medium-sized industrial enterprises than in countries that are successful in this regard. For instance, American economists consider business to be an activity of creating and implementing bold, sometimes dangerous and difficult projects. Business is an activity voluntarily carried out by citizens

or their associations, which includes taking high-risk decisions on their own responsibility. In the modern world, business is closely connected with the willingness to do something new in society, to invent something or to improve an existing one. Entrepreneurship is the tool that helps to release the potential of citizens in terms of developing the society, improving the quality of life, increasing the number of innovations.

The interest of world scientists in researches on the development of small and medium-sized industrial enterprises is logical and explicable. Small and medium-sized businesses are the foundation for the development of the entire economic system; the stability of the economy, as well as the formation of favorable conditions for the society depends on the level and effectiveness of their activity (Vetakova et al., 2016).

The degree of knowledge of the problem of financial support for industrial enterprises is reflected in studies of the features of regulation of a market economy by the state. These issues were considered by a number of leading economists from EU, for example, J. Sachs, who studied the features of economic development taking into account the living standards of the population. In this work, he raises the topic of state support for business, including various kinds of grants. There are many studies of this problem in the EU countries, especially in countries with relatively low economic development such as Romania (Beldiman et al, 2016), Slovakia (Majdúchová et al., 2015), Hungary (Csata Andrea, 2018), Croatia (Kotarski, 2016).

Currently, state support for small and medium-sized industrial enterprises in the area of organizing project competitions and grants is mainly carried out at the federal level and to a much smaller extent at the regional and municipal levels. Thus, the involvement of representatives of regional and municipal authorities is one of the priority tasks in the formation of targeted support tools for small businesses. This is problematic for the economic development of our state. It is necessary to correct the present situation by involving municipal authorities in improving and developing the business.

Materials and Methods

The method of statistical analysis, namely the use of formulas and the calculation of the Pearson correlation coefficient has been originally used in this article. The Pearson correlation analysis index allows the authors to identify the strength of the correlation between the two indicators that were measured in a quantitative scale. It shows the strength of the existing relationship between the two indicators, whereupon it is possible to draw a logical conclusion concerning cause-and-effect relationships in the research field. According to statistical data, a quantitative analysis of information on small and medium-sized businesses has been carried out, indicators over the past few years has been compared, which gives a general understanding of the current situation; and on the basis of it, conclusions about the effectiveness of small and medium-sized industrial enterprises in the country have been drawn.

Results and Discussions

At the beginning of the study of promising tools to support small and medium-sized industrial enterprises in the Russian Federation, the authors have generated the hypothesis: the number of small and medium-sized enterprises is directly dependent on the amount of grant financing.

During the first stage of the study, the authors have conducted a comprehensive analysis of the volumes of grants allocated to support small and medium-sized industrial enterprises and analyzed the interdependence of this indicator and the number of small businesses. The comparison of data on financial support for small businesses according to the Central Bank of the Russian Federation and Rosstat is presented in Table 1.

Table 1: Data on the volume of grants and loans provided to small and medium-sized industrial enterprises

Year	the volume of grants provided to small and medium-sized industrial enterprises by the state, thousand of rubles	the volume of provided loans, mln rubles
2014	20 800 000	6 023 812
2015	19 815 042	6 933 243
2016	19 374 822	6 568 483
2017	18 528 287	4 540 710
2018	11 124 625	4 560 099
Growth rate, %	53.5	75.7

Source: Overview of the financial affordability in the Russian Federation [Electronic resource] -Access mode.— URL: https://cbr.ru/statistics/?PrtId=pdko

According to table 1, it is possible to talk about a significant reduction in funding, in particular, the volume of grants to support small and medium-sized industrial enterprises has decreased by 46.5% (the growth rate is 53.5%), the volume of loans has decreased by 24.3% (the growth rate is 75.7%). Negative factors also include the level of the interest rate for lending to small businesses; in the Russian Federation, it is 11%, while in many foreign countries the interest rate is 5%. At the same time there is a decline of 25% in lending.

At the next stage of the study, there has been made a comparison of the volume of grants issued and the number of small and medium-sized enterprises in the Russian Federation from 2014 to 2018 (Table 2). The growth rate for this indicator is 73.1%, which demonstrates an insufficient level of stimulation of the development of small and medium-sized industrial enterprises and the advisability of managing this process.

Table 2: Data on the volume of allocated grants and the number of enterprises in the Russian Federation

Year	The amount of grants for state support to small and medium-sized industrial enterprises, - X	The number of small and medium-sized industrial enterprises – Y
2014	20 800 000	258 895
2015	19 815 042	249 909
2016	19 374 822	250 905
2017	18 528 287	257 941
2018	11 124 625	189 224
Growth rate, %	53.5	73.1

Source: Federal State Statistics Service of the Russian Federation. - grant volume, number of enterprises - [Electronic resource] -Access mode. — URL: http://www.gks.ru.

To analyze the relationship between the amount of grant financing and the number of small and medium-sized industrial enterprises, the Pearson correlation coefficient has been calculated: X- The amount of grants for state support of small and medium-sized industrial enterprises, thousand rubles; Y - "the number of small and medium-sized enterprises."

As a result of calculations by formula 1, the value of the Pearson coefficient is 0.97, which indicates a strong relationship between the two indicators and their direct relationship. Thus, financing of small and medium-sized industrial enterprises and grant support directly affects the development of small businesses, i.e. first hypothesis is confirmed.

The authors address the second hypothesis: the indicator "ease of doing business" is a stimulant for a group of indicators: "global competitiveness" and "level of innovative development". In order to study this thesis, the authors have similarly defined the relationship between these indicators.

To confirm or refute the second hypothesis, the authors have analyzed the popular international ratings: 1. The Doing Business report, 2. The Global competitiveness rating, rating of countries of the world by the innovation index.

The Doing Business report, which is annually compiled by the World Bank and the International Finance Corporation, characterizes the level of creation of favorable conditions for doing business in different countries; in other words, it is the ease of doing business index. The rating covers 189 countries and consists of 10 indicators, the less, the better the conditions for doing business.

In 2018, New Zealand occupies the first place, Singapore- the second place, Denmark- the third place, Russia takes only the 35th place, but one can note positive trends. Compared to 2012, the situation has improved by 88 positions.

Table 3: Statistical data of Russia on ratings

Year	The Doing Business report- X	The Global competitiveness rating- Y1	Rating of countries of the world by the innovation index - Y2
2012	123	66	56
2013	120	67	51
2014	112	64	62
2015	92	53	49
2016	62	45	48
2017	51	43	43
2018	35	38	45
Change, %	81.6	42.5	19.7

Global innovation Index - Rating of the countries of the world by the innovation index - [Electronic resource] -Access mode. - URL: https://www.wipo.int/publications/ru/details.jsp?id=4330.

The next indicator under study, the Global Competitiveness Rating, compiled by the World Economic Forum, measures the level of citizens' well-being. According to 2018 data, Switzerland occupies the first place, Singapore -the second place, Finland - the third place; Russia occupies the 38th place, while its rate has improved by 28 positions.

According to the international statistics, a study has been conducted on the competitiveness of small and medium-sized industrial enterprises in ten countries. Competitiveness indicators included such elements as: price, quality or innovation (table 4).

Table 4: Small and Medium-sized Enterprise Competitiveness Indicators in Ten Industrialized and Developing Countries

Indicator	Great Britain	Brazil	The USA	Germany	France	Russia	Spain	China	Italy	Japan
Price	3.3	3.53	3.24	2.85	3.15	3.27	3.16	3.40	3.09	2.97
Quality	3.67	3.5	3.60	3.89	3.44	3.45	3.38	3.16	3.40	3.28
Degree of innovation	3.49	3.43	3.47	3.42	3.22	3.12	3.23	3.11	3.22	3.00
Recognition	3.48	3.50	3.28	3.17	3.40	3.22	3.20	3.07	3.22	2.79
Delivery time	3.43	3.51	3.19	3.75	3.24	3.30	3.30	3.31	3.25	3.31
Level of service	3.58	3.36	3.53	3.85	3.34	3.30	3.27	3.09	3.11	2.87
Personnel	3.32	3.22	3.14	2.55	3.00	3.01	3.07	3.44	2.92	2.77
General level	3.47	3.44	3.35	3.35	3.26	3.24	3.23	3.23	3.17	3.00

The global innovation index based on the methodology of the INSEAD International School (France) is calculated on the basis of two groups of indicators: available (existing) resources and conditions for innovations; practical results of innovations.

The leaders in this indicator are: Switzerland, Sweden, the Netherlands, the USA and Great Britain. Russia takes 45th place (the position has been improved by 11 places over the study period).

To analyze the second hypothesis, according to which the indicator “ease of doing business” is a stimulant for a group of indicators: “global competitiveness” and “level of innovative development”, the authors have defined the relationship between these ratings in a similar way by the Pearson coefficient. The following results are obtained: the correlation coefficient between the rating of “ease of doing business” and the rating of global competitiveness is 0.9907, the correlation between the rating of “ease of doing business” and the rating for innovation index is 0.7943.

However, in general, according to the results of the study, it can be concluded that the reduction in the number of small and medium-sized industrial enterprises in the country is directly related to the financial support tools, and the development of small business in turn affects the socio-economic development of the country as a whole.

At the present time, existing programs to support small and medium-sized businesses are poorly developed both at the state and regional levels. This is mainly due to the lack of dissemination of information on forms of state support; thus the result of surveys of representatives of small and medium-sized businesses, shows that 79% of respondents heard about forms of state support, but only 7% of respondents (mainly from the agricultural industry) used these forms. This proves the necessity of a general popularization of various forms of state support for small and medium-sized enterprises. It is necessary to expand the sources of informing entrepreneurs about existing support programs and the areas within which they can be implemented. It is also worth not only making such information more accessible, but also giving a kind of “advertising” to foundations and companies that are ready to provide entrepreneurs with financial support for a promising project. At the moment, such advertising is not given everywhere and for everyone. A vivid example is the “You are an Entrepreneur” program, which covers mainly educational institutions through a course of lectures from entrepreneurs. However, billboards with business lecturers now can be noticed on the streets of cities during the program.

The analysis of the number of registered representatives of small and medium-sized businesses (table 5) shows a positive trend in all categories. Nevertheless, one can notice the Central Federal District takes the first positions in all quantitative indicators, but at the same time, the farther the region moves away from the central part of the Russian Federation, the smaller the number of registered representatives of small and medium-sized businesses is. This situation is quite logical, since the Central Federal District possesses more resources and opportunities for creating a small business. However, state programs to support small and medium-sized enterprises are currently aimed at creating favorable conditions for development, regardless of the region; one can take part in them in absentia.

Table 5 : the Dynamics of Registered Small and Medium Enterprises in 2018 in the Russian Federation

Territorial units	Total	Legal Entities				Individual Entrepreneurs			
		Total	Micro-enterprises	Small enterprises	Medium enterprises	Total	Micro-enterprises	Small enterprises	Medium enterprises

The authors suggest considering the rating of the effectiveness of state grant support by federal districts (table 6). This will give a broader picture of the effectiveness of state support for small and medium-sized enterprises in the federal districts of the Russian Federation.

Table 6: the total rating of the effectiveness of state support of small enterprises in the Federal districts of the Russian Federation

№	Indicator	The rating of Federal Districts							
		1	2	3	4	5	6	7	8
1	**Federal Districts**	**The Siberian Federal District**	**The Northwest Federal District**	**The Central Federal District**	**The Southern Federal District**	**The Volga Federal District**	**The Ural Federal District**	**The Far Eastern Federal District**	**The North-Caucasian Federal District**
2	The percentage of small businesses in the total set of entrepreneurial business structures.%	56.6	54.31	30.21	52.07	48.14	50.88	48.82	39.08
3	The percentage of employees in small enterprises.%	15.9	19.4	17.7	13.9	16.8	15.7	15.7	8.1
4	Percentage of ongoing small enterprises support programs.%	6.08	5.82	5.72	5.5	5.43	11.5	4.56	5.14
5	The degree of effectiveness of small enterprises	Effective	Effective	Effective	Effective	Effective	Medium effectiveness	Medium effectiveness	Ineffective

Source: MCC. Microfinance Fund NSO [Electronic resource] - Access mode. — URL: https://www.microfund.ru/

According to table 6, it is clearly seen that the activities of small and medium-sized industrial enterprises are directly dependent on the level of state support. It can be concluded that in most regions, and especially in the North-Caucasian Federal District, it is necessary to strengthen measures and apply effective instruments of state support.

The analysis of the largest grantors in the Russian Federation for the period 2016-2018 (table 7) has shown that the largest amount of money was operated by such grantors as the “League of the Health of the Nation”, the “National Charitable Foundation”, and the “Zhnanie” Russian Association.

Table 7: The largest grantors of the Russian Federation

Firms	2016		2017		2018	Total, mln rubles
	The first competition (№115-po 2016) mln rubles	The second competition (№348-po 2016) mln rubles	The first and the second competitions (№11-po 2017) mln rubles	The third competition (№243-po 2017) mln rubles	The three competitions (№79-po 2018) mln rubles	
League of the Health of the Nation	570	-	474	350	519	1 913
National Charitable Foundation	500	25	474	200	585	1 784
the "Zhnanie" Russian Association.	320	25	400	250	695	1 690
Russian Youth Union	320	-	340	200	695	1 555
Civil dignity	-	200	500	-	528	1 228

Source: Bulletin of NKOs - information resource center of NKOs - reports - [Electronic resource] -Access mode. - URL — URL: https://vestnik-nko.ru/press-tsentr/biblioteka-nko/biblioteka-12/
Thus, in connection with a sharp increase in the volume and dynamics of the grants distribution, one could expect a significant increase in interest in obtaining state support for organizations close to the authorities, NPOs.

Therefore, beginning and experienced entrepreneurs can conclude that at the moment both the state and private investors are ready to sponsor promising business ideas. This is shown by the amounts of money allocated for grant support. However, it can be noticed that many amounts of subsidies and grants do not change for several years and remain fixed, which does not have a very positive effect on the development of small and medium enterprises. Prices are growing every year; that is why it will be possible to implement less and less points of a business plan for the allocated grant every year.

Conclusions

After the calculations and analysis, it was revealed that the number of small and medium-sized enterprises is growing depending on the increase in the amount of grants allocated for their support; as well as an improvement in the ease of doing business index leads to improved global competitiveness and economic development in terms of innovation. For a stable increase in the effectiveness of state support, it is necessary to improve the municipal component of this system. Support programs at this level are currently unstable and do not bring the desired results.

Assessing the quality of the provided state support for the development of small and medium enterprises in Russia, the main attention should be paid to the information coverage of all participants of the business environment. Currently, weak indicators include 1) the amount of costs to overcome administrative barriers; 2) distribution and availability of credit resources. This was clarified by statistical indicators of the number of small and medium-sized industrial enterprises and the amount of taxes received by the state budget for 2016-2018. From the point of view of the country's economic development, grant support was most successful in 2017, when there was the largest

amount of financing for three years and the largest amount of taxes paid; 3) the number of inspections by the regulatory authorities.

The creation and maintenance of small and medium enterprises leads to an improvement in the economic situation in the country, since such enterprises perform significant macroeconomic tasks, among which the most relevant are: treatment of social issues; increase in the revenue component of budgets through taxes at the municipal level; increase of the flexibility of the state economy and reduce of the reaction rate to market fluctuations; increase in the share of participation of small and medium-sized companies in the structure of the domestic market of goods and services; increase in the level of employment of the population and the standard of living in general.

According to the rating of directions in business development, the three leaders have been defined: 1) social entrepreneurship; 2) scientific, technical, innovative entrepreneurship; 3) entrepreneurship in the sphere of agriculture.

Based on the foregoing, it can be concluded that the effective regulation and promotion of the development of small and medium-sized businesses is one of the key priorities of the state at this stage of economic development.

Acknowledgement

The study was supported by a grant from the President of the Russian Federation for state support of leading scientific schools of the Russian Federation No. NSh-2702.2020.6 “Conceptual foundations of a new paradigm of economic development in the era of technological and social transformation”

Abstract

The article is devoted to research of influence of digital transformation of economy on project management of the organization. The basic purpose - revealing of specificity and principles of project management of the organization in the context of digital transformation of economy. Achievement of the set purpose has predetermined the decision of following problems: to prove high penetration of digital technologies in all areas of society life; to analyze State support measures of digital economy development of leading countries; to investigate level of digital economy development of countries on the basis of the rating approach, and introduction and use of information and communication technologies in activity of the organizations. In the article were used general scientific methods of comparative analysis, methods of rating estimation. As a result of research, the authors identified basic principles of project management of the organization in the context of digitalization of economy.

Keywords: Digitalization, Digital Transformation, Project Management.

Introduction

In today's world, the digital transformation of socio-economic and production processes is actively carried out in the conditions of transition to a new technological mode. At present, there are six levels of development of productive forces, i.e. the technological stage, reflecting a set of related productions with the same technical level and synchronous development. At the same time, transition from one mode to another is closely linked to scientific and technological progress and transformation of social thinking based on accelerated emergence of new technologies. The modern world is characterized by the transition to the fifth technological mode, the specifics of which is the active introduction in all spheres of life of information and communication technologies, nano- and biotechnology, genetic engineering, new types of energy and materials, high humanities technologies. For the Russian Federation, the transition to this mode is based on the development of priority areas of science and technology. Transition to the fifth order implies individualization of production and consumption in the conditions of globalization, rapid growth of communication speed and movement. At the same time, qualitative transformations of the above-mentioned technologies and human capital are prerequisites for the formation of the sixth technological mode. Its essence can be broadly described through intensive development of individualization of production and consumption, creation of materials and organisms with predetermined properties, sharp reduction of energy and material intensity of production to improve the quality of life. At the same time, the formation and development of technological patterns is carried out on the basis of digitalization of all socio-economic processes, in the conditions of digital economy development.

Scientific works of such scientists as A.V. Babkin (Babkin A. & et al, 2019), S.D. Bodrunov (Bodrunov S. & et al, 2019), Y.V. Vertakova (Vertakova Y. & et al, 2020; 2019), A.E. Karlik (Karlik A. & et al, 2019), V.A. Plotnikov (Plotnikov V. & et al, 2019), A.V. Polyanin (Polyanin A. & et al, 2019) and others are devoted to research of digital economy problems. The term "digital economy" can be presented as an important component of economic relations, which uses the global Internet network, cellular communications and other information and communication technologies (ICT) for its implementation. Digital economy focuses on the development of an economy based on new methods of generating, processing, storing, transferring data, as well as digital computer technologies - digital economy. Examples and analysis of successful digital transformations are presented in published works on the digitalization of the economy of such scientists as Matt C., Hess T., Benlian A. (Matt C. & et al, 2015), Wiesbock F. (Wiesbock F. & et al, 2016), Karapetyants I., Kostuhin Y., Tolstykh T., Shkarupeta E., Krasnikova A. (Karapetyants I. & et al, 2017). This accumulated research experience shows that it is from the transformations or transformations of specific areas and businesses in the country that the GDP of the digital economy grows and develops, digital leaders grow.

Results and Discussion

Cloud and other digital technologies that store and analyze continuous data flow are already changing the nature of many industries. The active development of the Internet, its further penetration into all areas of society should be taken into account at the state level to justify the strategic direction of the economy, which, in particular, is defined in the China Development Strategy "Made In China 2025" (MIC 2025), which aims to make China a world leader in production. At the same time, the first of the ten priority directions of China's economic development, indicated by the State Council, is information technology of the next generation (Fig. 1).

Fig. 1: Made in China 2025 aims at substitution. Semi-official targets for the domestic market share of Chinese products (in per cent)

Source: Just Wubbeke, Mirjam, Meissner, Max J. Zenglein, Jaquline Ives, and Bjöm Conrad, (2017)"Made in China 2025: The making of a hight-tech superpower and consequences for industrial companies" URL // https://www.uschamber.com/sites/default/files/final_made_in_china_2025_report_full.pdf

In particular, MIC 2025 notes that "active use of the Internet contributes to the digital development of the Chinese economy and society. "The development of information technology, including cloud computing, large volumes of data, e-commerce and Internet of Things (IoT)," which will play an important role in the future development of MIC 2025 industry. Information and communication technologies (ICTs) form the basis on which all future innovative solutions will be built. Embedded systems and global networks are the two main drivers of technological progress in ICT. Embedded systems are already playing a central, though invisible, role in our lives.

In the "smart, networked world", due to the Internet of things and services, the fourth industrial revolution will be felt in all key areas. This transformation is leading to the emergence of smart grids in energy supply, sustainable mobility of strategies (smart mobility, smart logistics) and the development of smart health care. In a production environment, a vertical working network, continuous design and horizontal integration across a network of increasingly intelligent products and systems have been established to move to the fourth industrialization level - "Industry 4.0".

Fig. 2: The Internet of Things and Services – Networking people, objects and systems

Source: Recommendations for implementing the strategic initiative Industrie 4.0 (2013) Securing the future of German manufacturing industry Final report of the Industrie 4.0 Working Group. URL // https://www.din.de/blob/76902/e8cac883f42bf28536e7e8165993f1fd/recommendations-for-implementing-industry-4-0-data.pdf

Professor Henning Kagermann, President of Acatech's National Academy of Science and Manufacturing, spokesman for the Communication Promoters Group of the Industrial-Scientific Research Alliance and co-chairman of the Industries 4.0 Working Group, says, "The Internet of Things is paving its way into production. The Machine-to-Machine communication model is transforming factories into decentralized management. The embedded software directs the flexible production flow of the smart enterprise, allowing complex products of small volumes to be produced in the most cost-effective way. The new generation of auxiliary industrial systems with the help of augmented reality and multimodal interaction will help factory workers to work in conditions of complex cyberphysical production and activate new forms of cooperation of digital social media.

Industrial Internet of Things (IIoT) refers to the expansion and use of the Internet of Things (IoT) in industrial sectors and applications. Focusing on communication between machines (M2M), BIG data and machine learning, IIoT enables enterprises and businesses to increase the efficiency and reliability of their operations. IIoT covers industrial applications including robotics, medical devices and software-defined manufacturing processes. IIoT goes beyond conventional consumer devices and the interconnection of physical devices typically associated with IoT. What makes it great is the intersection of information technology (IT) and operating technology (OT). OT refers to the networking of operational processes and Industrial Control Systems (ICS), including Human Machine Interfaces (HMI), Supervisory Control and Data Acquisition Systems (SCADA), Distributed Control Systems (DCS) and Programmable Logic Controllers (PLC). IT and OT convergence provides the industry with greater system integration in terms of automation and optimization as well as better visibility of the supply chain and logistics. Monitoring and management of physical infrastructure in industrial operations such as agriculture, healthcare, manufacturing, transportation, and utilities is simplified by the use of intelligent sensors and actuators, as well as remote access and management.

In the context of the fourth industrial revolution, called Industry 4.0, IIoT is an integral part of the transformation of cyberphysical systems and production processes using large data and analytics.

As part of the implementation of Presidential Decree No. 204 dated May 7, 2018 "On National Goals and Strategic Development Tasks of the Russian Federation for the Period until 2024", including the task to ensure accelerated introduction of digital technologies in the economy and social sphere, the Government of the Russian Federation formed a national programme "Digital Economy of the Russian Federation" on the basis of the programme "Digital Economy of the Russian Federation". Within the framework of the Federal project "Digital Technologies" it is envisaged to support Russian high-tech companies - leaders developing products and platform solutions for digital transformation of priority sectors of the economy and social sphere.

Further to the implementation of planned measures of state support for the digital economy development of the leading countries, a study of the development level of the digital economy of countries based on the rating approach was conducted.

IMD World Digital Competitiveness Ranking is made in three directions: "Knowledge" (quality of education and science), "Technology" (regulatory environment, financial capital in the IT industry, the state of Internet and communication technologies) and "Future readiness" (level of readiness to use digital transformation). The 2019 IMD World Digital Top 10 countries are shown in Figure 3.

Fig. 3: Top-10 in the 2019 IMD World Digital

Source: The 2019 IMD World Digital URL // https://www.imd.org/wcc/world-competitiveness-center-rankings/world-digital-competitiveness-rankings-2019/

The first place in the overall standings went to the USA, the former leader of the ranking Singapore moved down to the second position. Then come Sweden, Denmark, Switzerland and Norway. Compared to the previous version of the list, Russia moved up two lines and took the 40th position out of 63. Russia's weak points, according to the authors of the rating, are in the legislation on research and protection of intellectual property rights, in the level of financing of the IT industry (including venture capital) and high investment risks, as well as in "attitudes to globalization" and the ability of businesses to adapt to changes.

Global Competitiveness Report 2019 noted that governments must better anticipate the unintended consequences of technological integration and implement additional social policies that support the population during the fourth industrial revolution. The report shows that some countries with strong innovation potential, such as South Korea, Japan and France, or with growing opportunities, such as China, India and Brazil, need to improve their skills base and the functioning of their labour markets (Figure 4).

Fig. 4 : Speed of technological adaptation of legal framework of states to digital business models, 2019.

Source: Global Competitiveness Report 2019 URL // https://www.weforum.org/reports/how-to-end-a-decade-of-lost-productivity-growth

Based on how the legal framework in their countries adapts to digital business models, only four G20 countries are in the top 20: USA (1st place), Germany (9th place), Saudi Arabia (11th place) and Great Britain (15th place), China ranks 24th in this category.

According to the results of Bloomberg Innovation Index 2020, the first place in the ranking in 2020 was taken by Germany, which surpassed South Korea due to the decline in productivity in the Asian country (in this category it fell from 18th to 29th line). Germany took the lead in value-added production, high technology and patent activity. Russia moved up one place in the ranking of the world's most innovative economies and was ranked 26th, ahead of Malaysia. The data was released in January 2020. ING analyst Carsten Brzeski says that the lack of innovation in higher education leads to "growing concern," especially as the world economy is increasingly shifting towards services and production.

The top 10 countries of the Bloomberg Innovation Index 2020 ranking are shown in Figure 5.

2020 Rank	2019 Rank	YoY Change	Economy	Total Score	R&D Intensity	Manufacturing Value-added	Productivity	High-tech Density	Tertiary Efficiency	Researcher Concentration	Patent Activity
1	2	+1	Germany	88.21	8	4	18	3	26	11	3
2	1	-1	S. Korea	88.16	2	3	29	4	16	5	11

The Institute of Statistical Research and Knowledge Economy (ISRKE) of the National Research University Higher School of Economics has developed the Business Digitalization Index (hereinafter - the Index) to provide an integral assessment of the level of digitalization of the business sector. It characterizes the speed of adaptation to digital transformation, the level of use of broadband Internet, cloud services, RFID-technologies, ERP-systems, inclusion in electronic commerce of business sector organizations. The Index is calculated for Russia and European countries, the Republic of Korea, Turkey and Japan. The leading position among these countries is occupied by Finland with the Index value of 50 points (Fig. 6). Next come Belgium (47), Denmark (46), Republic of Korea (45). Russia (28 points) is on a par with such Central and Eastern European countries as Bulgaria, Hungary, Poland and Romania.

Fig. 6: Index of business digitalization, 2019

Source: Business Digitalization Index 2019. Institute for Statistical Research and Knowledge Economy (ISRKE) NRU HSE URL //https://issek.hse.ru/data/2019/02/27/1193920132/NTI_N_121_27022019.pdf

The analysis of intensity of using separate technologies in our country, taken into account at calculation of the Index, shows, that broadband access to the Internet is used by 82% of organizations, cloud services - 23%, ERP-systems - 19%, electronic sales - 12%, RFID-technologies - 6% (Table 1). The gap between Russian indicators and similar data for Finland, which has the highest Index value, ranges from 9 to 43 percentage points. The lowest gap is recorded for e-sales (9 percentage points) and RFID (17) and the highest for cloud services (43).

The Digital Economy and Society Index (DESI) is a composite index that summarizes relevant indicators on the performance of digital technologies in Europe and tracks the evolution of EU member states in the area of digital competitiveness. Ireland has the highest score on the Digital Integration Index, followed by the Netherlands, Belgium and Denmark. Bulgaria, Romania, Poland and Hungary have the lowest score (Figure 7).

Fig. 7 : Digital Economy and Society Index (DESI) 2019, Integration of Technology

Source: Digital Economy and Society Index (DESI) 2019 URL // https://ec.europa.eu/digital-single-market/en/news/digital-economy-and-society-index-desi-2019

The EU members most actively using e-commerce opportunities are Ireland, Sweden and Denmark, while the Netherlands and Finland are leaders in adapting and implementing e-business technologies.

The different segments of the ICT sector (from telecoms to the manufacture of computers) tend to be the most digitised sectors of the economy. However, other sectors such as travel agencies and the media sectors are also highly digitised. Some sectors are still impervious to digital changes: for example, in the construction sector only 6.5 % of the enterprises have a high or very high DII, while for transport and storage almost 10 % of enterprises have high or very high DII. The distribution of the DII by economic activity is similar across EU countries. Denmark, Finland and Sweden are over performing in many of the sectors. Some positive exceptions of higher digitisation exist in the following sectors: "travel agency; tour operator reservation service and related activities" (Slovenia, Lithuania, Romania, Hungary, Estonia, the Netherlands and Czechia), "professional scientific and technical activities" (Finland, Slovenia and Lithuania), "real estate activities" (Finland, the Netherlands and Ireland) and "transport and storage" (Malta).

Fig. 8: Enterprises with high or very high digital intensity by economic activity, EU, 2018 (% of enterprises)

Source: Digital Economy and Society Index (DESI) 2019 URL // https://ec.europa.eu/digital-single-market/en/news/digital-economy-and-society-index-desi-2019

The adoption of digital technologies varies strongly according to company size. There are still many areas for SMEs, where opportunities for digitization can be exploited.

Large enterprises have a scale advantage, thus 75 % of them employ internal ICT specialists. The share of SMEs employing ICT specialists decreased slightly (1.6 percentage points) during the last six years, however the share of SMEs where ICT tasks were carried out by external personnel increased since 2015 (1.7 percentage points) Electronic information sharing through Enterprise Resource Planning (ERP) software is much more common in large companies. SMEs are active on social media (47 % use any type of social media, 2017) and, to a limited extent, they try to exploit e-commerce opportunities by selling through online marketplaces (6.5 % of SMEs versus 8.3 % of large enterprises). Nevertheless, there are many technological opportunities yet to be exploited by SMEs such as cross-border ecommerce, cloud services and customer relationship management.

Fig. 9: Enterprises employing ICT specialist, EU, 2012-2018, (% of enterprises)

Source: Digital Economy and Society Index (DESI) 2019 URL // https://ec.europa.eu/digital-single-market/en/news/digital-economy-and-society-index-desi-2019

Orientation on innovations assumes not only creation of products demanded by the market, possessing new qualitative differences, or introduction of process allowing appreciably more effectively to reach necessary results. This is also the very ability to change, and to do it quickly in the conditions of digitalization of the economy. In this regard, the study of the specifics of project management in the era of digital economy is relevant. In opinion of the director of business applications department of the integration decisions center of company RedSys A. Semin from the point of view of design management projects of digitization and digital transformation differ nothing essential from each other. In his opinion, digitalization is the automation of individual business processes, and digital transformation is a set of digitalization projects that translate key business processes of the customer into a digital format.

Conclusions

Unlike digitalization projects, digital transformation is not a single act, but a continuous process that changes the way we do business to one extent or another. As a result of digital transformation, the dependence of business on uninterrupted operation of IT systems is increasing many times, and this requires rethinking approaches to building the entire software and hardware stack and the underlying IT infrastructure. Also it is necessary to mean that after end of the similar project of ways of returning to old business processes can't be or its cost can appear unacceptable.

The basic principles of project management remain basic also in the conditions of digital transformation as they prescribe and fix the need in the project office for constant monitoring, adjustment and adaptation of plans and tasks taking into account the specification of the original goals in an unstable environment. The basic principles are becoming more flexible, knowledge and competencies are essential to the success of the project, but they will not be enough. Project management must be refined in efficiency and ergonomics to the level of the tasks to which it applies. Basic principles such as planning, monitoring, teamwork remain. In a digital transformation

project it makes sense to pay special attention to risk management, including technological risks, taking into account a significant innovation component. For effective work with uncertainty and minimization of negative risks it is required to organize project management correctly. Change management as one of principles of classical design management, and following it will help to solve problems in the conditions of global updating of requirements and the purposes of projects in the conditions of digital transformation.

The so-called hybrid approach becomes relevant when it is recommended to bet on the symbiosis of the management model of the Stage-Gate Process type in the organization of project phases, which are logically combined works in the course of which some final result is achieved, and practices of the Scrum type, which allow to organize the effective work of a group of heterogeneous specialists within a short period of time. Thus, in the course of the project the advantages of different management models are used and "an important task is the seamless integration of these approaches within a single project", - believes Ilya Vinokurov (Svarni, P., 2019)

Project management becomes very flexible. At initial introduction it is necessary to adhere to the traditional approach which sets rigid frameworks on time of introduction and functional filling of system.

The study is allowed:

- a reasonable degree of penetration of digital technologies in all spheres of society;

- analyze measures of state support for the development of the digital economy;

- to study the level of development of the digital economy of states on the basis of the rating approach, as well as the activity of using and using information and communication technologies in the activities of organizations.

Thus, the main goal of the research that was achieved was achieved.

Acknowledgments

The study was supported by a grant from the President of the Russian Federation on state support to leading scientific schools of the Russian Federation No. NSh-2702.2020.6 «Conceptual Foundations of a New Paradigm of Economic Development in the Age of Technological and Social Transformation».

Abstract

The vast majority of government agencies and organizations actively implement and use information technology in their practice. It should be noted that the level of innovation diffusion in the public sector is still lower than in commercial business structures. This is due, first of all, to a certain inertia inherent in the traditional system of state and municipal government, especially at the initial stages of reform, the desire to maintain the stability of the existing structure, as well as considering innovations as a destabilizing factor. At the same time, it is important to fully understand the fact that the process of creating an electronic state should not act as an end in itself, since the priority goal in this process is to improve the quality of services provided, as well as the benefits derived by citizens, the public, representatives of the business community, and organizations in process of interaction with authorities. The transfer of managerial functions to the information environment as a result of the implementation of the E-Government concept will allow authorities to actively interact with other departments and solve not only current operational tasks much faster and more efficiently, but also to implement long-term programs and projects in various sectors of the economy and social sphere, making maximum use of the whole range of opportunities that will become available as a result of informatization of state and municipal government. The purpose of this article is to consider the problems and prospects for the development of digital public administration.

Keywords: Digitalization, Public Administration, E-Government, Information, Telecommunication Technologies.

Introduction

In our dynamic age, innovations in the provision of electronic state and municipal services are very relevant, which are now very popular and allow making the interaction between government structures, citizens and organizations more high-quality and comfortable.

The transfer of managerial functions to the information environment will allow the authorities to actively interact with other departments and to solve not only current operational tasks much faster and more efficiently, but also to implement long-term programs and projects, making maximum use of the whole range of opportunities that will become available as a result of state informatization and municipal government. The obvious advantage of converting public services to electronic form is the reduction of administrative barriers between the executive bodies and local governments that provide services, on the one hand, and citizens and organizations that need them, on the other hand.

Until recently, issues related to the provision of state and municipal services in electronic form were not adequately reflected in scientific research. This was primarily due to the insufficient level of development in our country of information and telecommunication technologies necessary to create information services that could provide high quality and convenience for users in the interaction of citizens with authorities. Nowadays, modern information technologies have become an integral part of the life of each of us, and with their widespread distribution, including in the field of management, the topic of converting state and municipal services into electronic form has become one of the most discussed.

The purpose of this article is to consider the problems and prospects for the development of digital public administration.

The theoretical foundation for comprehending the digital age, as well as the waves of digitalization of state administration, are considered in the works of Dunleavy & Hood (1994), Dunleavy & Margetts (2015), Helen Margetts & Dunleavy (2013), issues of digital government, its open architecture are devoted to the works of Fishenden and Thompson (2013). The study of open data and big data in the development of the digital era of the public administration is devoted to the research of Card (2015), Aggarwal (2016), while Höchtl, Parycek and Schöllhammer (2016) emphasize the increasingly important role of big data in the process of making government decisions. The problem of digital government also is one of the current problems in the Russian literature. The theoretical interpretation of the administrative paradigm of the state and the bureaucracy transformation that contributes to the crisis state of the modern state administration is devoted works of Barabashev (2016); open data as a new instrument of interaction between the state and society, tasks and prospects for the implementation of open data in Russia are considered in works of Babkin (2018), Dmitrieva (2014), Plotnikov (2018), Polyanin (2017), Vertakova (2019), Vidyasova (2014), and etc.

Problem Statement

Today, the Russian Federation is going through a “transitional” period from e-government, where in assessing the effectiveness of public administration, special attention was paid to adapting public services to the needs of individual citizens (their groups), to the stage of formation of a digital government, in which special attention is paid to issues of openness, transparency, and quality of governance and interaction, trust issues to authorities.

However, it is worth noting that the leaders in building e-government (Great Britain, Australia, South Korea and Singapore) have not been able to achieve full-scale digitalization today and switch to the digital government by default, which implies a digital interaction format and the maximum avoidance of paper circulation.

Today, the main requirement in building a digital government is to study the possibilities of moving from paper documents to records in authoritative databases. In this regard, the problem of data confidentiality and the accuracy of the processed information is becoming particularly relevant. In its solution, it can be very useful to use the technology of distributed data storage - the blockchain, the introduction of which will allow solving two key problems: preserving the history of changes and guaranteeing the authenticity of the entered data, as well as the identity of the data for all participants of the decentralized platform.

The creation of a national blockchain system will create a full-fledged platform for digital government, consisting of trusted basic information resources, personal identifiers of citizens and government bodies. The basis of this initiative can be successfully proven existing basic components of e-government infrastructure, such as a unified portal of public services and municipal services, a federal registry of public services, a unified system of identification and authentication, a system of interagency electronic interaction, a unified system of regulatory and reference information and state information system on state and municipal payments.

The main goal of implementing projects on digitalization of public administration is the rationalization and integration of work and production processes, the effective management of data and information, improving the efficiency of the provision of public services online, as well as expanding communication channels to involve and empower people (UN, 2014). However, a unified

understanding of the criteria and parameters of digitalization has not yet been developed either in the Russian Federation or internationally.

Results and Discussion

The research analyzed key trends in the development of digital government and examined global trends in the provision of electronic services based on the E-Government Development Index (EGDI).

One of the key indicators of the development of the information society in the countries of the world is the rating of the UN e-government. Since the UN's first attempt to mark the state of e-government in 2001, it has developed rapidly. Studies from year to year emphasize a constant positive global trend towards an increase in the level of development of e-government. 40 countries received a rating of "very high", with EGDI from 0.75 to 1. For comparison: in 2003 there were only 10 such countries, and in 2016 only 29. Since 2014, all 193 member states provide an online presence in one form or another.

The percentages of groups of countries with different EGDI levels for 2016 and 2018 are shown in Figure 1.

Fig. 1: Grouping of the analyzed countries by the e-government development index for 2016 and 2018

In 2018, there is an increase in the number of countries with high and very high EGDI or values from 0.50 to 1.00. As a result, the percentage of countries with high and very high levels of e-government development cumulatively reached 58% or almost 2/3 of the total number of UN member states.

The list of countries with the highest ratings in the field of e-government development according to the results of the Study for 2018 is presented in Table 1 together with the corresponding values of EGDI and its three components - OSI, TII and HCI. All 29 leading countries with very high EGDI ratings in 2016 remained in the same group in 2018.

Table 1: Leading countries in e-government development, 2018

Position	Position change 2018/2016	The country	Level of evolution	(EGDI)	Online services	ICT infrastructure	Human capital
1	+8	Denmark	Very high	0,915	1	0,7978	0,9472
2	-	Australia	Very high	0,9053	0,9722	0,7436	1
3	-	The Republic of Korea	Very high	0,901	0,9792	0,8496	0,8743
4	-3	Great Britain	Very high	0,8999	0,9792	0,8004	0,92
5	+1	Sweden	Very high	0,8882	0,9444	0,7835	0,9366

6	-1	Finland	Very high	0,8815	0,9653	0,7284	0,9509
7	-3	Singapore	Very high	0,8812	0,9861	0,8019	0,8557
8	-	New Zealand	Very high	0,8806	0,9514	0,7455	0,945
9	+1	France	Very high	0,879	0,9792	0,7979	0,8598
10	+1	Japan	Very high	0,8783	0,9514	0,8406	0,8428
11	+1	USA	Very high	0,8769	0,9861	0,7564	0,8883
12	+3	Germany	Very high	0,8765	0,9306	0,7952	0,9036
…	…	…	…	…	…	…	…
32	**+3**	**Russia**	**Very high**	**0,7969**	**0,9167**	**0,6219**	**0,8522**

The positions of the Russian Federation in the ranking of countries with the highest level of development of e-government were considered. A UN study is conducted every two years. Over this period, Russia has risen in this list in three places - from the 35th in 2016 to the 32nd in 2018. Our country also rose from 34th to 23rd place in the group with the highest level of citizen involvement by the criterion of electronic participation of citizens in the management and adoption of government decisions using ICT. In addition, Russia strengthened its position in the ranking of telecommunications infrastructure, gaining 0.6219 points in 2018 against 0.6091 two years earlier. The dynamics of the place in the overall ranking is determined by the dynamics of the relative position of the country in these three groups of indicators. An analysis of this dynamics shows that the main contribution to increasing Russia's place in 2018 was made by a significant increase in the Online Services Index (from 0.7319 in 2016 to almost the maximum value of 0.9167 in 2018), according to which Russia entered the group of 25 countries leaders (in 2016, it closed together with Brazil a group of 38 leading countries), while the index itself in Russia is now in 11th place (in a number of countries the values of this index are the same), rising from 22nd place in 2016. The online services index is calculated on the basis of a survey of official government portals and websites, which is carried out during the preparation of the next rating.

After reviewing the global development trends of e-government and the positions of the Russian Federation in the global ratings of countries, we analyzed the main indicators characterizing the efficiency of the process of converting state and municipal services into electronic form within the country. The results of regular monitoring of the quality of the provision of electronic services by the constituent entities of the Russian Federation were summed up on May 28, 2019 at a meeting of the Government Commission on Digital Development. Monitoring was carried out by the RANEPA IT Research and Expertise Center at the request of the Ministry of Economic Development of Russia in August-November 2018. In the course of the study, experts analyzed 1,143 priority services provided by executive authorities of the constituent entities of the Russian Federation and local governments on the Unified portal gosuslugi.ru and regional portals of state and municipal services. Services were examined for compliance with the provisions of the current legislation establishing requirements for the provision of state and municipal services in electronic form, in particular, Decree of the Government of the Russian Federation No. 236 "On requirements for the provision of electronic state and municipal services" of March 26, 2016.

Based on the monitoring results, we can conclude not only about the increase in the number of electronic services provided in the regions compared to the previous year (1100 and 1143 services, respectively), but also about improving the quality of their provision (Fig. 2). Successfully generate and send a statement to the department was possible in 89% of cases (1021 services). However, it was revealed that in almost half of the cases (49% or 556 services), the application was not properly reviewed by the department, and the user did not receive any feedback. Therefore, departments should pay particular attention to ensuring that applicants are correctly and timely informed, reflecting the actual progress of service provision.

Fig. 2: Results of monitoring public services

Regarding information on the procedure for providing services hosted on portals, it was revealed that often the user was not provided with full information (Fig. 3). The completeness of information on all regional and municipal services averaged 87%. That is, only 600 investigated regional and municipal services provided comprehensive information.

Fig. 3: Providing information on the procedure for obtaining regional and municipal services

It should be noted that users are not always provided with the opportunity to complete all the necessary procedures in electronic form. In particular, users do not always have the opportunity to make an appointment with the department, pay a fee, etc. Thus, the departments responsible for the provision of services do not fully comply with the applicable regulatory requirements.

Based on the analysis, it can be concluded that citizens use official websites of authorities mainly in order to receive information when they need to contact the appropriate state authority. This is a positive trend, since it is precisely this function that can be called one of the main ones for information portals of government bodies. The results of a survey of residents of the Kursk region regarding the level of reliability and usefulness of official websites of authorities allow us to draw certain conclusions. Firstly, the degree of attendance of the sites under investigation remains low, which is undoubtedly a negative trend. Secondly, the level of trust in information published on official websites should be brought to an extremely high level. Thirdly, it is necessary to take into account the opinion of users about the shortcomings of such sites and eliminate them in a timely manner. And, finally, to develop and improve the structure and interface of official sites, introduce innovative forms of communication between the population and government, as well as raise the rating for the use of electronic services.

Thus, having examined the main indicators characterizing the development of the system of providing public services in electronic form, at the global and Russian levels, you can get a holistic view of the state of e-government and make appropriate recommendations on the development of a comprehensive strategy to improve the quality and accessibility of electronic public services.

We should not lose sight of the fact that in the process of introducing modern information technologies into the sphere of state and municipal government, the bodies carrying out reforms in this direction, one way or another, encounter a number of difficulties at different stages of this complex process. These problems are the result of the inevitable opposition of the external and internal environment to the active introduction of innovations in the traditionally established system of government. All existing problems in this area for a more orderly and systematic consideration and their subsequent solution can be classified by source. According to this criterion, the following problems are identified that arise in the process of introducing new technologies, including in the process of converting public services into electronic form: managerial, technological, organizational and social. Consider each of these types in more detail.

1. To the managerial barrier, first of all, there are significant differences between the authorities of various sectors and levels of management in terms of the quantity and quality of information technologies used in everyday activities, the implementation results of which are only departmental in nature. Another manifestation of this problem is the lack of a single body responsible for the transition to e-government. This problem made itself felt in the early stages of a systematic transition to the provision of public services in electronic form. The powers in this area are distributed between the Ministry of Communications and Mass Media and the Ministry of Economic Development, the competence of which includes certain issues directly related to the informatization of public administration. Within the framework of the Government Commission on the use of information technology to improve the quality of life and the conditions for doing business, federal and regional authorities are coordinated, as well as specific actions of individual ministries and departments. This situation led to an interdepartmental struggle for control over budget funds allocated for the implementation of the transition to the electronic state, and inefficient work in this direction due to duplication of functions. Another factor that significantly impedes the process of improving the provision of public services in electronic form, especially at the initial stages of reform, is the inertia of the traditionally established administration system, as well as the unwillingness of some corrupt officials to lose the possibility of generating income by illegal means.

2. Technological barriers are manifested in the fact that the infrastructure of open access to the official websites of authorities and other means of information and reference support and services for citizens and organizations are currently underdeveloped for a complete transition to the provision of electronic services. Obtaining public services in most cases requires a personal appeal of the applicants to the appropriate authorities, which leads to large time and financial costs and creates significant inconvenience. In addition, all the necessary infrastructure has not been prepared that can ensure the information security of electronic forms of interaction between authorities, among themselves, with citizens and organizations, which also does not contribute to the transition to an electronic state.

3. Organizational problems, in turn, are due to the lack of a single regulatory and scientific and methodological base that regulates in detail the process of providing state and municipal services in electronic form using modern information and telecommunication technologies. Currently, normative legal acts adopted in the Russian Federation regarding the transition to e-government are advisory in nature, rather than strictly regulating the activities on the widespread introduction of information technologies in state and municipal government processes. In laws, it is necessary to clearly define resources, implementation mechanisms and responsibility for the implementation of the concept. Until this is fully reflected in normative acts, there will be constant contradictions regarding the interpretation of official documents, which, in turn, significantly reduces their practical significance.

A separate consideration deserves the question of the development of relevant administrative regulations. The process of automation of public administration involves the restructuring of the organizational structure of government bodies of various levels of government that has developed over the years. That is why the review of existing and the development of new regulations acts as a paramount operational task in the conditions of informatization of public administration.

4. In this area there are social problems that impede the process of informatization of management. First of all, they include the low level of computer literacy of a significant part of the population, the lack of access points to the Internet, as well as the stereotypes prevailing in society. One of the main inhibiting factors hindering the comfortable use of modern information technologies in everyday life is the insufficient level of informatization of society. First of all, this refers to populated areas far from large cities, where in fact there are not only terminals, but also access to the Internet, which is especially necessary here, since it is not always convenient to travel several kilometers to the right authority to receive a public service. In addition, the majority of Russian society, like the authorities, are often too slow to accept any innovations, especially when it comes to information and telecommunication technologies. Therefore, even now, in the age of Internet technologies, a significant proportion of the population is not completely ready for fully electronic interaction with power structures, even in those areas where all the necessary conditions have already been created for this. We should not lose sight of the fact that over decades of interaction with various government agencies, certain stereotypes have emerged in society regarding the bureaucratic system, of which paperwork was an integral part.

In modern Russia, the vast majority of government agencies and organizations actively implement and use information technology in their practice. It should be noted that the level of innovation diffusion in the public sector is still lower than in commercial business structures. This is due, first of all, to a certain inertia inherent in the traditional system of state and municipal government, especially at the initial stages of reform, the desire to maintain the stability of the existing structure, as well as considering innovations as a destabilizing factor. At the same time, it is important to fully understand the fact that the process of creating an electronic state should not act as an end in itself, since the priority goal in this process is to improve the quality of services provided, as well as the benefits derived by citizens, the public, representatives of the business community, and organizations in process of interaction with authorities.

Conclusion

As can be seen from the above, the problems that impede the efficiency of the use of information and telecommunication technologies in the activities of government bodies are complex and cannot be solved at the level of individual government bodies. Therefore, to solve the complex of identified problems, it is necessary to implement a program-targeted approach to ensure the compatibility of state information systems, develop standards and technologies for their interaction.

The transfer of managerial functions to the information environment as a result of the implementation of the E-Government concept will allow authorities to actively interact with other departments and solve not only current operational tasks much faster and more efficiently, but also to implement long-term programs and projects in various sectors of the economy and social sphere, making maximum use of the whole range of opportunities that will become available as a result of informatization of state and municipal government. After all, all these processes and current trends in the field of computer technology are designed to make people's lives and activities more comfortable. That is why one should not stop there, do not stand still, but continuously move forward, develop in this direction and make every effort to further improve information technologies in the provision of state and municipal services and management in general for the benefit of our state and society. Putting this concept into practice and putting it into practice by the country's population will bring the system of providing state and municipal services to a new level, and it will force employees of state institutions to provide these services efficiently and on time.

Acknowledgment

The study was supported by a grant from the President of the Russian Federation on state support of leading scientific schools of the Russian Federation No. NSh-2702.2020.6 “Conceptual foundations of a new paradigm of economic development in the era of technological and social transformation”.

Abstract

Crisis phenomena, complex external and internal economic conditions highlight the innovative component of the state economic entities modernization. One of the most important requirements of modern economic development is the need for innovation and the ability to innovate. This work is devoted to the innovative activity analysis of the European Union countries and Russia and their rating based on the integral innovative development index. The basis of the study was statistics for 2018, which allowed us to identify 16 indicators characterizing the level of states innovative development. These indicators are grouped into three blocks: “Socio-economic conditions of innovative activity”, “Scientific and technical potential” and “Innovative activity of organizations”. The obtained values of the integral index made it possible to divide the countries into 5 homogeneous groups, in each of which the strengths and weaknesses of innovative development were identified. The analysis of innovation indicators in the EU and Russia allowed us to formulate the main conclusions that reflect the innovation development level, as well as the specifics of main innovation types processes in the context.

Keywords: Statistics, Innovation, Integral Index, Rating, Clustering, FCM Clustering.

JEL Classification: C43; O30; O52

Introduction

In the conditions of international competition from not only economically developed countries, but also developing countries, increasing the innovative activity of enterprises and organizations is a necessary condition for further dynamic economic growth. There are various methods for evaluating innovative

development, which include various indicators that characterize the level of their innovative development. The methodology developed in the European Union for assessing the innovative development level includes 27 different indicators (EIS 2019). Data for 18 of the 27 indicators applied in the EIS 2019 are used to assess the innovative development of EU countries by region. In Russia, in order to assess the level of the subjects innovative development, a proprietary methodology has been developed based on a system of 29 indicators (AIRR, 2017), which is regularly updated. The methodology for assessing the level of innovative development of Russian regions, proposed by Bakhtin et al. (2017) contains 37 indicators, among which there are indicators that are not presented by official statistics. Due to historical, geographical, economic and cultural features, the European Union countries and Russia have differences in the innovative processes development. Therefore, for a comprehensive analysis of the main indicators structure characterizing the innovative potential of the state, it is necessary to divide countries into homogeneous groups. This allows you to strengths and weaknesses identify, determine the further development direction and improvement of the state innovative activities. The need for a differentiated approach to the regional development strategies development is reflected in research study by Gusev et al (2018), Khalimova (2016).

When conducting economic transformations, it is necessary to take into account the region existing specialization. The need to orient the region towards the use of local production is highlighted in studies Valentey et al. (2019), et al. Kolmykova (2017). Moreover, without the new production technologies at enterprises and organizations active introduction of and increasing their innovative activity, successful economic growth and the industrial production modernization are impossible.

Materials and Methods

The methodology for evaluating EU countries and Russian by the innovative development level is based on the Federal state statistics service of the Russian Federation (2019) official statistics published. The calculation of the proposed innovation index is based on 16 indicators system, which are grouped into three blocks that allow calculations of the corresponding sub-indices: "Socio-economic conditions of innovation activity", "Scientific and technical potential" and "Innovative activity of organizations". The choice of indicators is based on the availability of official statistics for all countries under consideration. Ranking is carried out for each of these indicators. The total integral innovation index is the average of the normalized all included in the rating indicators. The indicators system for the the final integrated innovation index formation of the EU and Russia is presented in table 1.

Table 1: Indicators System of the integrated innovation index

	Indicator Name	Measure Unit
1. Socio-economic conditions of innovation activity		
1.1	GDP per employed in the economy person	US dollar
1.2	Students quantity per 1000 population	human
1.3	Proportion of households with Internet access in the total households quantity	%
1.4	The proportion of organizations that used the Internet, in the total number of the business sector organizations	%
1.5	Percentage of organizations using broadband Internet access, in the total business sector organizations quantity	%
1.6	Percentage of organizations using cloud services in the total business sector organizations quantity	%
1.7	ICT Development Index	
2. Scientific and technical potential		
2.1	Domestic research and development costs as GDP percentage	%
2.2	The research and development staff quantity per 1000 the economy person	human

2.3	The publications in scientific journals indexed quantity in Web of Science, in 2014-2018	units
2.4	The citations in scientific journals quantity indexed in Web of Science, in 2014-2018	units
2.5	The patent applications for inventions filed in the country by national and foreign applicants quantity in 2017, per 1000 in the economy person	units
3. Innovative activity of organizations		
3.1	The proportion of organizations implementing technological innovations in the total organizations quantity	%
3.2	The proportion of organizations engaged in marketing innovation in the total organizations quantity	%
3.3	The proportion of organizations implementing organizational innovation in the total organizations quantity	%
3.4	The proportion of industrial production organizations engaged in technological innovation in the total organizations quantity	%

To the indicators used achieve comparability, the transition from absolute values to their normalized values by the formula was previously carried out:

$$\tilde{x}_i^k = \frac{x_i^k - x_i^{\min}}{x_i^{\max} - x_i^{\min}}, \quad (1)$$

$\tilde{x}_i^k$ – normalized value of the *i*-th indicator in the *k*-th country;

x_i^k – initial value of the *i*-th indicator in the *k*-th country;

$x_i^{\min}$ – minimum of the *i*-th indicator;

$x_i^{\max}$ – maximum of the *i*-th indicator.

Before performing normalization, a procedure was carried out to assess the asymmetry of each rating indicator relative to its average value. To smooth out the influence of extreme values on the final result with an asymmetric distribution, the value of each rating indicator was transformed according to the following rule:

$$\tilde{x}_i^k = \sqrt[r]{x_i^k}, \quad (2)$$

$\tilde{x}_i^k$ – the adjusted of the *i*-th indicator in the *k*-th country;

x_i^k – initial value of the *i*-th indicator in the *k*-th country;

r – the degree of adjustment (takes from 2 to 4, is selected so that the distribution asymmetry coefficient of the indicator is less than 0.5). For a symmetric distribution, the adjustment of the corresponding rating indicator is not carried out.

We give a sequence of stages in the formation of the final integral innovation index.

Stage 1. Formation of indicators of the innovation index system of the EU and Russia, the collection of statistical data.

Stage 2. Rationing of indicators according to formulas (1), (2).

Stage 3. The total integrated innovation index calculation as the average of the normalized all included in the rating indicators.

Stage 4. Ranking of the EU and Russia by the calculated total integral innovation index calculation.

Stage 5. Isolation of 5 groups of countries according to the innovative development level. The division of Russian regions by the level of innovative development into similar groups is proposed in the AIRR methodology (2017).To classify the EU and Russia participating countries, we define 5 groups according to the level of innovative development according to the following rule:

Group 1 – strong innovators. The innovation development index exceeds 140% of the average.
Group 2 – medium-strong innovators. The innovation development index is from 110% to 140% of the average, inclusive.
Group 3 – medium innovators. The innovation development index is from 90% to 110% of the average, inclusive.
Group 4 – medium-weak innovators. The innovation development index is from 60% to 90% of the average, inclusive.
Group 5 – weak innovators. The innovation development index is below 60% of the average.

Stage 6. The use of the fuzzy clustering algorithm for the automatic classification of the EU and Russia according to the innovative development level and comparison with the obtained at stage 5 results. The FCM (Fuzzy Classifier Means, Fuzzy C-Means) clustering algorithm assumes that all objects belong to all clusters with a specific membership function. Moreover, the clusters are represented by fuzzy sets and the boundaries between these clusters are also fuzzy sets. The degree of membership is determined by the distance from the object to the corresponding cluster centers. The FCM algorithm calculates cluster centers and new ownership of objects degrees. Fuzzy clustering is carried out according to three subindexes that define the set of input vectors x_1 = {Socio-economic conditions of innovation activity}, x_2 = {Scientific and technical potential}, x_3 = {Innovative activity of Organizations} and 5 allocated clusters v_j, $j = 1, \ldots, 5$. In this case, we assume that any vector x_i, $i = 1, \ldots, 3$ belongs to any cluster v_j with membership u_{ji}, moreover $0 \le u_{ji} \le 1$. For the membership function, the following normalization conditions are true:

$$\sum_{j=1}^{5} u_{ji} = 1, \forall\, i = 1, 2, 3,$$

$$0 < \sum_{i=1}^{3} u_{ji} \le 3, \forall\, j = 1, \ldots, 5.$$

The algorithm purpose is to minimize the sum of all distances weighted $\|x_i - v_j\|$:

$$\sum_{j=1}^{5} \sum_{i=1}^{3} u_{ji}^{q} \|x_i - v_j\| \to min, \tag{3}$$

q – fixed parameter before iterations.

Results

The final innovation development rating is the ranking result the EU and Russia in descending order. The ranking leaders are Finland, Germany and Denmark. The group of “strong innovators” also included the Netherlands and Sweden. The medium-strong innovators group includes seven EU: Belgium, Austria, France, Great Britain, Luxembourg, Ireland and Italy. The average innovators group is represented by five states: Portugal, Spain, Slovenia, Czech Republic and Estonia. The medium-weak innovators include eight EU: Lithuania, Greece, Croatia, Cyprus, Latvia, Malta and Poland. The weak innovators group according to the rating results are Slovakia, Hungary, Russia, Bulgaria and Romania. The distribution of countries according to the innovative development level is presented in Figure 1.

Fig 1. Countries Distribution by group

The final innovation development rating results are presented in Figure 2.

Fig 2. The Rating Results

The leaders in terms of the negative impact degree on the final position in the ranking are the indicators blocks "Socio-economic conditions of innovation activity" and "Scientific and technical potential". According to these indicators blocks, 15 states from the EU and Russia participating countries have sub-indices below their average values.

The average values comparison of all 16 indicators for the selected innovative development groups shows the development heterogeneity of the EU countries and Russia (Figure 3). As can be seen from Figure 3, a strong innovators countries group surpasses the rest of the countries in all indicators, with the exception of 1.1. "GDP per employed in the economy person" and 3.3 "The proportion of organizations implementing organizational innovation in the total organizations quantity".

Fig 3. Average indicators scores by innovative group

Consider the strengths and weaknesses of the leading countries in the innovative development final rating. A comparison of the normalized indicators values that form the final integrated assessment is used in Figure 4.

Fig 4. Comparison of relative values indicators of the rating leading countries

As can be seen from Fig. 4, for all countries strong innovators, with the exception of Germany, the weak side of innovative development are indicators such as 2.3 "The publications in scientific journals indexed quantity in Web of Science, in 2014-2018", 2.4 "The citations in scientific journals quantity indexed in Web of Science, in 2014-2018" and 2.5 "The patent applications for inventions filed in the country by national and foreign applicants quantity in 2017, per 1000 in the economy person". The

most strong side of the innovative development the leading countries is the indicators that form the block "Socio-economic conditions of innovation".

For all countries included in the group of strong innovators, all three main groups of indicators are uniformly developed, while for Germany, the indicator 1.6 "Percentage of organizations using cloud services in the total business sector organizations quantity" showed a value below its average. For Sweden, all rating indicators turned out to be higher than their average values, with the exception of the indicator 3.3 "The proportion of organizations implementing organizational innovation in the total organizations quantity". It should be noted that in the group of strong innovators among the 16 indicators presented, only 5 indicators show negative deviations from the average. So, according to indicators 2.3 "The publications in scientific journals indexed quantity in Web of Science, in 2014-2018" and 2.4 "The citations in scientific journals quantity indexed in Web of Science, in 2014-2018", the values of innovative Finland's development shows values below average. In terms of indicator 3.3 "The proportion of organizations implementing organizational innovation in the total organizations quantity", the values of innovation development sub-indices in the Netherlands and Sweden could not exceed their average value. According to indicator 3.4 "The proportion of industrial production organizations engaged in technological innovation in the total organizations quantity" did not allow to exceed the average value of this sub-index.

Consider the strengths and weaknesses of the final ranking of innovative development countries, which were in the groups of medium-weak and weak innovators. A comparison of the normalized indicators values that form the final integrated assessment is presented in Figure 5. As can be seen from Figure 5, for countries of weak innovators, except Russia, not one of the indicators exceeds its average value. In countries with medium-weak innovators, most indicators of all three blocks take values below their average.

Fig 5. Comparison of relative values of the indicators medium-weak innovators countries and weak innovators countries

One of the key indicators characterizing the conditions for the innovation development is the cost of research and development. In the EU and Russia, there is a high variation in indicator 2.1. "Domestic research and development costs as GDP percentage". Figure 6 shows the distribution of internal research and development costs.

Fig 6. The distribution of internal expenditure on research and development by science sectors in 2017

Let us consider in more detail the positions of the EU and Russia in certain groups of indicators that form the system of indicators for the final integrated innovation index of the EU and Russia.

According to the indicator "Socio-economic conditions of innovation", the leaders group are Denmark, Netherlands, Finland and Sweden. The weak innovators group includes Greece, Russia, Bulgaria and Romania. According to the indicator "Scientific and technical potential" 10 EU countries were included in the group of strong innovators, the leaders among which are Germany, Great Britain and France. The weak innovators group are made up of 9 countries, including Estonia, Croatia and Lithuania. In the EU and Russia, there is a high scatter in the level of scientific and technological potential that characterizes the initial stage of the innovation life cycle. However, even with a developed infrastructure of innovation, a key problem for some states remains the technology transfer low efficiency. According to the indicator "Innovative activity of organizations" the following states are leaders in the level of innovative activity development: Finland, Belgium and Portugal. The leaders group strong innovators also included Austria, Luxembourg, Germany, Ireland and Greece. The country's rating is completed by weak innovators. This group includes 7 countries including Slovakia, Latvia, Hungary, Bulgaria, Poland, Romania and Russia. The distribution of EU and Russian countries by sub-ratings is presented in table 2.

Table 2: Distribution of EU countries and Russian countries by sub-ratings

Group	Countries Distribution by sub-rating "Socio-economic conditions of innovation activity"		Countries Distribution by sub-rating "Scientific and technical potential"		Countries Distribution by sub-rating "Innovative activity of Organizations"	
	Number of Countries	Countries	Number of Countries	Countries	Number of Countries	Countries
Group 1. Strong innovators	4	Sweden, Finland, Netherlands, Denmark	10	Italy, Belgium, Netherlands, Finland,	8	Greece, Ireland, Germany, Luxembourg,

				Austria, Sweden, Denmark, France, United Kingdom (Great Britain), Germany		Austria,, Portugal, Belgium, Finland
Group 2. Medium-strong innovators	8	Estonia, France, Germany, Austria, United Kingdom (Great Britain), Belgium, Luxembourg, Ireland	2	Spain, Luxembourg	6	Denmark, United Kingdom (Great Britain), Sweden, Netherlands, Italy, France
Group 3. Average innovators	6	Italy, Latvia, Czech Republic, Lithuania, Slovenia, Spain, Estonia	3	Czech Republic, Slovenia, Russia	4	Estonia, Czech Republic, Croatia, Lithuania
Group 4. Medium-weak innovators	7	Hungary, Croatia, Poland, Slovakia, Cyprus, Malta, Portugal	5	Hungary, Ireland, Greece, Poland, Portugal	4	Spain, Malta, Cyprus, Slovenia
Group 5. Weak innovators	4	Romania, Bulgaria, Russia, Greece	9	Malta, Cyprus, Latvia, Romania, Bulgaria, Slovakia, Lithuania, Croatia, Estonia	7	Russia, Romania, Poland, Bulgaria, Hungary, Latvia, Slovakia

The final ranking results of the EU and Russia by the level of innovative development and sub-ratings for the three selected indicators blocks are presented in Table 3.

Table 3: The Rating Results

Country	Integral Index of Innovation	% from the average	Group by Integral Index of Innovation	Rating by Integral Index of Innovation	Rating by Indicator 1	Rating by Indicator 2	Rating by Indicator 3
Finland	0,763	154,25%	1	1	3	7	1
Germany	0,755	152,71%	1	2	10	1	6
Denmark	0,737	149,04%	1	3	1	4	14
Netherlands	0,705	142,56%	1	4	2	8	11
Sweden	0,696	140,88%	1	5	4	5	12
Belgium	0,691	139,71%	2	6	7	9	2
Austria	0,688	139,19%	2	7	9	6	4
France	0,677	136,85%	2	8	11	3	9
United Kingdom (Great Britain)	0,674	136,24%	2	9	8	2	13
Luxembourg	0,658	133,03%	2	10	6	11	5
Ireland	0,598	121,03%	2	11	5	19	7
Italy	0,549	111,11%	2	12	18	10	10
Portugal	0,527	106,66%	3	13	19	16	3
Spain	0,495	100,08%	3	14	13	12	22
Slovenia	0,491	99,28%	3	15	14	14	19
Czech Republic	0,480	97,16%	3	16	16	15	17
Estonia	0,465	94,01%	3	17	12	21	18
Lithuania	0,430	86,99%	4	18	15	23	15
Greece	0,422	85,39%	4	19	26	18	8
Croatia	0,372	75,17%	4	20	24	22	16
Cyprus	0,339	68,56%	4	21	21	28	20
Latvia	0,338	68,39%	4	22	17	27	24
Malta	0,331	67,02%	4	23	20	29	21
Poland	0,330	66,78%	4	24	23	17	27
Slovakia	0,318	64,23%	4	25	22	24	23
Hungary	0,292	59,07%	5	26	25	20	25
Russia	0,245	49,60%	5	27	27	13	29
Bulgaria	0,185	37,44%	5	28	28	25	26
Romania	0,087	17,57%	5	29	29	26	28

We apply the fuzzy clustering algorithm of the EU and Russia. The input parameters are the number of allocated clusters v_j, j = 1, …, 5 and the sub-index vectors x_1 = {Socio-economic conditions of innovation activity}, x_2 = {Scientific and technical potential}, x_3 = {Innovative activity of Organizations}. The FCM algorithm results implementation are presented in Figure 7. The selected clusters and their centers are marked in different colors.

Fig. 7: Clustering result of EU countries and Russia by FCM method

Based on the fuzzy clustering results, we obtained cluster centers, a fuzzy membership matrix of vectors x_i, i = 1, …, 3 to each of the clusters v_j, j = 1, …, 5 and the objective function value, the minimum value of which was obtained at 31 iterations and is 0.4340. Table 4 shows the distribution of EU and Russian member states by cluster as a result of applying the FCM clustering algorithm.

Table 4: Distribution of EU countries and Russian by cluster as result of the FCM clustering algorithm

Group	Cluster center	Number of Countries	Countries
Group 1. Strong innovators	(0.7004; 0.5100; 0.8250)	6	Germany, Denmark, Netherlands, United Kingdom (Great Britain), France, Sweden
Group 2. Medium-strong innovators	(0.7574; 0.6331; 0.6622)	6	Austria, Belgium, Ireland, Luxembourg, Portugal, Finland
Group 3. Average innovators	(0.5465; 0.3392; 0.5331)	6	Greece, Spain, Italy, Slovenia, Czech Republic, Estonia
Group 4. Medium-weak innovators	(0.4805; 0.1049; 0.4149)	6	Cyprus, Latvia, Lithuania, Malta, Slovakia, Croatia
Group 5. Weak innovators	(0.2319; 0.2276; 0.1567)	5	Russia, Bulgaria, Hungary, Poland, Romania

As can be seen from table 4, the fuzzy clustering results differ from the rating results. Note that the rating leader – Finland – according to the FCM clustering results belongs to the second group - medium-strong innovators. This is easily explained by the fact that a positive influence on the final position in the ranking of countries on the development of innovative activity was exerted by the fact that for some indicators of the "Socio-economic conditions of innovation activity" group their absolute maximums were obtained. Finland showed maximum values for all indicators of the "Innovative activity of organizations". Among the strong innovators were Great Britain and France, which, according to the rating results, were in group 2 – medium-strong innovators. Austria, Belgium, Ireland and Luxembourg retained their positions, while Portugal improved its position and moved from the average innovators

group to medium-strong innovators. Greece and Slovakia also improved their overall ranking position and moved from group 4 to group 3 and from group 5 to group 4. Spain, Italy, Slovenia, Czech Republic and Estonia maintained their positions in the average innovators group, and Cyprus, Latvia, Lithuania, Malta and Croatia in the medium-weak innovators group. Among the weak innovators were Russia, Bulgaria, Hungary and Romania, while Poland lowered its final position and moved from group 4 to group 5.

Conclusion

Innovative development states problems may be associated with insufficient socio-economic conditions for innovation, among which are low investment attractiveness, lack of human and financial resources. Efforts to create innovative infrastructure coordination and improving the interaction of the state with educational and research centers, innovation financing infrastructure and innovative companies becomes a key task in implementing the innovation strategy. For this it is necessary: stimulating demand for innovative activity in the economy and the effectiveness of scientific research, creating the prerequisites and conditions for the formation of sustainable scientific and production cooperation links, innovation clusters and networks; creating favorable conditions for technological modernization of economic sectors based on advanced technologies and integration with world-wide complexes of technological innovations in order to create an innovation market for the research and development sector; the formation and implementation on the basis of public-private priority areas partnership for the development of science, engineering and technology, within which the competitiveness of individual economy sectors can be achieved mainly through national technological developments.

The analysis of indicators of innovation in the EU and Russia allowed us to formulate the main conclusions that reflect the level of innovation development, as well as the specifics of processes in the context of the main types of innovation. Based on the findings, it is possible to develop management recommendations that must be considered when stimulating innovation.

Government Bonds and Their Role in Polish Economy

Mariusz TOMCZYK

War Studies University, Warsaw, Poland
E-mail address: m.tomczyk@akademia.mil.pl

Abstract

Government securities such as government bonds are considered as safe assets. The safe assets term is understood as securities that give a reliable, stable profit and, above all, which are guaranteed by the state. State securities give the government "fuel" to act (e.g. by stabilizing the state's liquidity). However, their supply is not dependent on demand, as is with the case of private securities, but on the financial needs of the state. In addition, the interest rate on state securities does not necessarily meet market expectations for safety assets. The purpose of this article is to present the issue of Polish treasury bonds (10 years government bonds) and their role in the economy. The author of the article will attempt to identify the determinants affecting profitability on Polish treasury bonds and relation between their profitability and public finance balance.

Keywords: Financial Security, Financial Stability, Government Bonds, Budget Deficit

Introduction

Treasury securities are a cumulative category of securities that is created by various types of financial instruments. From the point of view of this article, the most appropriate criterion for the division of state securities will be the criterion of their redemption. In the above context, it is worth to point out that treasury securities are divided into two groups. The legislator referring to the classical for financial science division of financial instruments into financial instruments specific to the money market (with maturity up to one year - up to 364 days inclusive) and to financial instruments characteristic of the capital market (with a maturity of at least year - at least 365 days).

The first category, known as short-term treasury securities, includes, in particular, securities such as treasury bills, while the second category consists of securities such as government bonds.

The purpose of this article is to present the issues of government bonds with their role they play in the Polish economy and the relationship between their profitability and the (Polish) public finance balance.

Tax competition in EU Member States - analysis of CIT tax rates

Focusing further considerations on government bonds, it is worth to start with a few introductory remarks. The legal act defining government bonds is the Public Finance Act. According to art. 92 paragraph 1 of the Public Finance Act. a government bond is a security offered for sale in the country or abroad, bearing interest in the form of a discount or interest rate. The above legal definition of a government bond indicates its most important features, which in practice individualize government bonds within the category of treasury securities. It should be noted, that government bonds are complex category, which includes various specific categories of securities. A common element for them is that they are issued by the State Treasury, they are based on monetary claims, they are issued for a period of not less than one year (at least 365 days) and are offered for sale in the country or abroad . Treasury bonds are type of debt securities in which the seller (State Treasury) borrows a given sum of money from the buyer of the bond and undertakes to return it within a predetermined time period. However, individual types of treasury bonds are distinguished by such elements as:

• the group of entities to which the bond purchase offer on the primary market is addressed;

• the method of their distribution on the primary market;
• the form of the cash benefit associated with the bond.

Government bonds are included in the collective category of treasury securities, and as a consequence they are characterized by the above-mentioned features that all treasury securities have. When personalizing treasury bonds as part of treasury securities, it should first of all be pointed out, that the treasury bonds is a security that has a monetary claim. Thus, the only entity that has the right to issue government bonds is the Minister of Finance. The cash benefit incorporated in the content of government bonds may take the form of a discount or interest rate. Government bonds may be offered for sale at home or abroad and may be issued as securities with an original maturity of not less than a year.

The mentioned above elements describing government bonds in the category of treasury securities indicate at the same time the possibility of flexible use of government bonds in the process of raising capital by the Minister of Finance to finance the medium and long-term needs of the Treasury. On the other hand, it should be emphasized once again that, in accordance with the regulations contained in the Public Finance Act, treasury bonds may be issued only within the limits specified in the content of the Budget Act. The combination of the above elements makes government bonds flexible from the point of view of the Minister of Finance and a safe way of raising foreign capital by the State Treasury from the investor's point of view.

In the above context, it is worth to emphasize that the considerations contained in the content of this publication will be devoted only to 10-year government bonds offered on the financial market.

Determinants of Government Bonds Yield

The purpose of making investments by business entities is to achieve specific material benefits in the future, related to the allocation of capital to another entity in temporary management. The measure of the effectiveness of implemented investments is the rate of return, informing about the proportion of capital allocated to the investment that will be returned to the investor in the form of profit. There are many ways to allocate financial resources to investments in the financial market. It should be noted, that the choice between alternative methods of allocating cash results are the sovereign decisions of investors. This chapter presents a set of factors affecting the profitability of 10-year government bonds. The presented scientific material is the result of author's own scientific research enriched by the synthesis of the results of scientific research raising the discussed issues by other scientists. It should be noted, that the factors listed below deter-mining the yield on government bonds can be also used to assess the profitability of other securities.

Government debt to GDP. In the opinion of many experts and investors, this feature is one of the key factors for government bonds yield. The deterioration of the financial situation of the state is associated with an increased demand for capital, which increases the interest rate on treasury bonds. In addition, an increase in debt leads to a worsening of the country's risk assessment. With higher risk, investors expect higher rates of return. Scientific research has confirmed this phenomenon (L. Oliveira, J.D. Curto, J.P. Nunes, 2012 and P. De Grauwe, Y. Ji, 2014). In addition, the high Treasury demand for capital, associated with an increase in interest rates on government bonds (or simply state securities), may cause the phenomenon of investment capital being pushed out of the private market to the state. Such a phenomenon will have an impact on the economic slowdown (J. Siwińska-Gorzelak, 2015).

Tax revenues in relation to GDP. This is another factor affecting government bond profitability, related to the ratio of public debt to GDP. Effective fiscal policy of the state - perceived as the ability to collect tax liabilities is important for assessing the country's ability to pay its debts, and thus affects the profitability of treasury bonds. Even a country with a low debt-to-GDP ratio may have problems with its debt servicing if its ability to collect tax liabilities is limited (J. Aizenman, M. Hutchison, Y. Jinjarak, 2013).

GDP dynamics. Lowering the GDP growth rate will result in an increase in government bond yields. The economic crisis will create uncertainty about the profits in the private investment market and lead

investors to allocate capital to government securities that are considered safer. In addition, as the economic downturn, the country may have problems with collecting taxes, and thus with debt service. **Inflation**. An economy with high inflation is becoming uncompetitive. High inflation is associated with high volatility of relative prices, which weakens the information base of financial institutions on which investors base their decisions. In addition, high inflation may cause a deficit, which is the reason for the increase in public debt (P. De Grauwe, Y. Ji, 2013). High inflation is accompanied by an increase in government bonds yield. It should be noted, that this trend is not clear. In the conditions of high economic growth, an increased level of inflation may not lead to an increase in government bond yields (P. Gajewski, 2014).

VIX index. The volatility index measures market expectations for S & P500 index volatility over the next 30 days. The high value of the VIX index is associated with the high volatility of the S & P500 index - both increase and decrease in the index, which may affect the yield on government bonds (Y. Duran, 2018). The VIX index is commonly called the fear index because it expresses investors' expectations of future returns based on their own (more or less accurate) premises. The increase in the value of the VIX index (implied volatility for the S & P500 index) indicates intensification of tensions in global financial markets.

CDS indicator[1]. Credit Default Swap is a derivative instrument functioning on credit markets. The purpose of CDS is to transfer the risk of insolvency of the debtor - the issuer of the underlying instrument. The underlying instrument may be, for example, government bonds. CDS is collateral in which the issuer (investment bank) can sell to the holder of the underlying instrument (e.g. government bonds) a "collateral" in the event of the debtor's insolvency. In this way, the bank accepts the risk of insolvency of the issuer of the underlying security, while the bond holder accepts some type of "insurance". At the same time, however, investors must pay an annual rate for such collateral - a percentage of the value of the hedged instruments. The price of CDS depends mainly on the perception by large players from the financial market of the risk that the issuer of the underlying instrument (e.g. Poland with its bonds) will not be able to pay interest on time (e.g. 10 years) and on the maturity does not repay the capital due. CDS may affect bond yields - as an indicator of the expected financial position of the underlying issuer. If big players put an increased risk of repayment of the country's debt, then the CDS contract rates will increase. The consequence of such a situation or accompanying phenomenon may be an increase in the demand of the capital hedge issuer, which may ultimately lead to an increase in government bond yields. This also applies to securities issued by companies, because the poor fiscal situation of the country increases the risk of unforeseen government actions in the field of taxation or freedom of economic activity. As a rule, the local currency is also weakening, which is a consequence of the increase in investment risk in a given country and the outflow of some portfolio investments.

Exchange rate. The exchange rate affects the rate of return on investment when the financial instrument in which the investor invests his financial resources (e.g. treasury bonds) is denominated in a currency other than the currency of the investor's country. Therefore, exchange rate changes mean that rates of return expressed in two different currencies are not the same. Exchange rate fluctuations can have positive or negative investment effects. If there is a depreciation of the exchange rate in which the collateral is expressed, the return on investment after conversion to another currency will be lower. In the event of appreciation of the currency in which the value of the financial instrument is expressed (treasury bonds), the potential profit of the investor will be greater. The exchange rate reflects the stability and strength of the economy (D. Maltritz, 2012).

Summing up the considerations on the factors determining the profitability of government bonds, it should be noted that the attractiveness of investing in government bonds depends on the overall economic situation and economic policy of the country. This applies in particular to the central bank's policy in the area of interest rates, exchange rates, tax and budget policy of the government, the expected money supply on the market, shaping individual balance of payments items as well as

[1] The Credit Default Swap is the research subject of article's author. The results of the research will be published in the near future.

inflation and growth of the economy. Political aspects are also important. Sometimes this field is the dominant factor in assessing the profitability of not only government bonds, but also other securities.

Budget Deficit and Government Bonds Yield

Government bonds are popular and effective financial instrument used by the Treasury to manage public debt and budget deficits. In this part of the article author decided to present the results of his own scientific research and prove the existence of a relationship between the level of budget deficit in Poland and the profitability of 10-year Polish government bonds. As mentioned earlier in the paper, interest on treasury bonds is a premium on investment risk undertaken by the investor. The profitability of government bonds, which are securities, also has an impact on the cost of servicing public debt (public debt) and the overall cost of capital in the economy.

The time range used in the survey is 2008-2018. The adoption of such a time period was dictated by the occurrence of the Global Financial Crisis in 2008, which was considered the appropriate benchmark for beginning proces of improving economic situation in the country and in the world. The characteristics of the budget balance for Poland and the profitability of 10-year government bonds are presented in the table below.

Table 1: The balance of the Polish budget in 2008-2018 and the profitability of Polish 10-year treasury bonds

Year	Balance	*R**	Year	Balance	*R**
2008	- 3.6%	6,07 %	2014	- 3,6 %	3,52 %
2009	- 7,3 %	6,12 %	2015	- 2,6 %	2,70 %
2010	- 7,4 %	5,78 %	2016	- 2,4 %	3,04 %
2011	- 4,9 %	5,96 %	2017	- 1,5 %	3,42 %
2012	- 3,7 %	5,00 %	2018	- 0,2 %	3,20 %
2013	- 4,2 %	4, 03 %			

** Yield on 10-year government bonds*

A preliminary analysis of the information contained in the table shows that in all years in the period under consideration the Polish economy generated a budget deficit. The highest deficit fell during the global economic crisis, which confirms that this situation has also affected the Polish economy. The slow exit from the economic crisis also illustrates the size of the budget deficit. The highest general government deficit falls in 2008 and 2009 - the summit years of the global economic crisis. Over time, the deficit falls. According to Eurostat, the general government deficit in Poland in 2018 was 0.2%. This is one of the lowest deficit results in the country's economic history (after 1989).

The table clearly shows that the highest interest rate on government bonds also falls during the global economic crisis. The growing demand for capital from the state coincides with the investors' expectation of higher rates of return on government bonds. As a result, the highest government bonds profitability was gained in 2009. The figure below graphically presents the considered issues.

Fig. 1: Chart for data from Table 1

Graphical presentation of the data from Table 1 shows that at a first sight it can be stated that along with the decrease in the budget deficit in Poland in the years 2008-2018 the profitability of 10-year treasury bonds also decreased.

The figure below presents the distribution of data on the general government balance and government bonds yield over the considered period.

Fig. 2: Data dispersion of general government balance in relation to government bonds yield for Poland in 2008-2018.

The above chart presents the dispersion of data from the discussed issues. The values that deviate most from the trend line fall in 2008 and 2015. The R2 determination coefficient is 0.59, which can be considered a satisfactory result, but with a high risk of incorrect forecasting. It can be assumed that about 60% of the variability of government bonds yield is explained by the general government balance.

The table below presents the results of the Pearson and Spearman correlation tests for the discussed issues.

Table 2: Pearson and Spearman correlation coefficient for the convergence between general government balance and government bonds yield for Poland in 2008-2018.

Poland	Pearson's correlation coefficient	Spearman's correlation coefficient	Critical t value α=0,05, n-2
Saldo general government/ government bonds yield	-0,77	-0,76	2,262
t statistic	-3,57	-3,47	

Pearson's correlation coefficient between the general government balance and the yield on 10-year government bonds in 2008-2018 was -0.77. Such result means a strong relationship between the state budget balance and the yield on 10-year treasury bonds in Poland. It confirms the accepted assumption that the financial situation of the state affects the profitability of treasury securities. However, this relationship is negative over the period under review, which means that the increase in the budget deficit is accompanied by increase in the yield on treasury securities (10-year government bonds) and vice versa. Importantly, for the adopted significance level $\alpha = 0.05$, the result is statistically significant. This relationship was also confirmed in the Speraman's correlation study. The correlation coefficient was -0.76. As in the case of Perason's correlation, this value indicates the existence of a strong relationship between government bonds yield and general government balance. A negative coefficient result indicates the opposite relationship of these two variables. The result is also statistically significant.

Budget Deficit and Government Bonds Yield

The presented results of the research on the relationship between the Polish budget balance and the yield on 10-year treasury bonds in 2008-2018 confirm the general assumptions about the functioning of treasury securities. According to these general assumptions, during the financial crisis and increased demand for capital (also higher costs of servicing public debt) by the state, the yield on government bonds should increase. Another factor impacting the increase in the profitability of these securities during the financial crisis is investors. They are able to accept higher risk in change of higher rates of return. In discussed period for Polish economy, the assumptions of existing relation between general government balance and general government bonds yield is true. Pearson and Spearman correlation coefficients are negative and show strong relation between these factors.

Table 3: The balance of the Polish budget in 2008-2018 and the profitability of Polish 10-year treasury bonds

	General government balance	Deficit dynamic t+1 - t	Deficit economically	Mathematically	Government bonds yield	Bonds dynamic t+1-t	Yield increase /decrease	Pearson's/ Spearman's realtion
2008	-3,60%	-	-	-	6,07%	-	-	-
2009	-7,30%	-3,70%	increase	decrease	6,12%	0,05%	increase	negative
2010	-7,40%	-0,10%	increase	decrease	5,78%	-0,34%	decrease	positive
			decrease					

2011	-4,90%	2,50%	increase	5,96%	0,18%	increase	positive
2012	-3,70%	1,20%	decrease increase	5,00%	-0,96%	decrease	negative
2013	-4,20%	-0,50%	increase decrease	4,03%	-0,97%	decrease	positive
2014	-3,60%	0,60%	decrease increase	3,52%	-0,51%	decrease	negative
2015	-2,60%	1,00%	decrease increase	2,70%	-0,82%	decrease	negative
2016	-2,40%	0,20%	decrease increase	3,04%	0,34%	increase	positive
2017	-1,50%	0,90%	decrease increase	3,42%	0,38%	increase	positive
2018	-0,20%	1,30%	decrease increase	3,20%	-0,22%	decrease	negative

In the period under review, the highest dynamics in the increase in the budget deficit were recorded in 2009. The general government balance was -7.3% and was as much as 3.7% higher than in the previous year. At the same time, in 2009, the dynamics of change in government bonds yield was the lowest in the entire period - it increased only by 0.05%. In 2010, the general government balance increased by 0.1% to -7.4%, while the yield on 10-year government bonds fell by -0.34%, which is evidence of the economy's behavior different from generally accepted canons. The year 2011 is also characterized by a positive relation: general government balance to government bonds yield. However, during this year, the decline in the budget deficit was accompanied by an increase in government bonds yield. In subsequent years from the audited period, the relationship between general government balance and government bonds yield was 5 times positive (opposite to results of the evaluation) and 5 times negative, as shown in Table 3.

The considerations presented in this article concern an important area for the economy. The article characterizes the determinants of government bonds profitability and proves the existence of a relationship between general government balance and government bonds yield for Poland. The scope of research was limited in time to 2008-2018 and concerned only the Polish economy. For more reliable results and conclusions, however, longer time series and a wider spatial approach are needed. In the next few or more years it will be possible to verify the hypotheses presented today. The existence of dependencies between these variables would seem obvious. Also, the mechanism of the functioning of this relationship seems to be clear. The presented research confirms that the shape of the whole is determined by the details.

Abstract

Digital technologies now provide opportunities for inclusive and sustainable economic growth, in all sectors of the economy. The digital transformation is helping companies discover and monetize new business models. That might mean delivering new value added services for the fleet of products forming installed base. Or it might mean creating entirely new revenue streams for a company. The article highlights how to obtain the benefits of digital economy in order to realize greater job creation, increase country competitiveness, and allow for diversification and innovations in service delivery to improve the lives of people. The development of industrial ecosystems is one of the methods for economic growth. The authors propose to evaluate the effectiveness of industrial ecosystems using KPI methods based on corresponding of industrial ecosystems aims from the standpoint of global benchmarking. The authors concluded that in modern economic conditions it is necessary to consider new approach - digital innovation ecosystem, which has a number of important advantages.

Keywords: Digital Ecosystem, Innovation System, Economic and Social Benefits, Accelerating Global Development, Metallurgical Industry.

Introduction

The statistics of recent decades have shown that the dynamic and structural characteristics of the Russian economy development are quite different from those in most developed and largest developing economies. Over the last decade (2009-2019), the Russian economy has grown by 5%,

while the growth of the world economy during this period was 25%, and, for example, China's GDP more than doubled. Among the twenty largest economies of the world and the Eurasian Economic Union (EEU) countries in 2017, Russia ranked 17th in terms of GDP growth. Slower growth rates than in Russia in 2017 were observed only in 3 leading EU countries (Great Britain, France, Italy), Japan, Brazil, Belarus and Saudi Arabia. The lag in growth rates from the average world level leads to a consistent decline in Russia's share in the global economy. According to the Russian Academy of Sciences, Russia's share in world GDP is expected to decline to 2.8% in 2022. The development of industrial ecosystems is one of the methods for economic growth. The industrial ecosystems contribute to extension of infrastructure, increasing employment in the manufacturing industry and the share of industrial production in GDP, use of environmentally technologies, enhancing scientific research and raising the technological potential of industrial sectors.

The concept of digital economy is evolving all the time because of its multifaceted and dynamic nature and due to the transformational power of digital technologies. For instance, the Australian government defines a digital economy as "the global network of economic and social activities that are enabled by platforms such as the Internet, mobile and sensor networks"1. Digital economy is defined by Oxford Dictionary as "an economy which functions primarily by means of digital technology, especially electronic transactions made using the internet" [1] .The digital economy is sometimes called the Internet Economy, the New Economy, or Web Economy It is often perceived as conducting business through markets based on the internet and the World Wide Web. According to OECD, the digital economy enables the trade of goods and services through e-commerce on the internet [2]. European Union considers digital economy as the most important driver of innovation, competitiveness and growth in the world. The Economist Intelligence Unit and IBM joint study defines digital economy as one that "can provide a high quality of ICT infrastructure and harness the power of ICTs to benefit consumers, businesses and governments" [3].

According to the UK Government, digital economy includes the manufacture of digital equipment, publishing, media production and computer programming [4]. The recent studies highlight diffusion of the digital economy within the whole economy and claim that "it can no longer be described as a separate part, or subset, of the mainstream economy" [5]. It goes beyond e-commerce and e-business and includes doing business, conducting communications and providing services across all sectors including transport, financial services, manufacturing, education, healthcare, agriculture, retail, media, entertainment and business using digital technologies (fig. 1). Digital economy has an important role in accelerating global economic development, enhancing productivity of existing industries, cultivating new markets and industries, and achieving inclusive, sustainable growth.

At the same time, the digital economy is becoming a powerful catalyst and a driver of inclusiveness, by linking communities to each other in a sort of "global village" [6], sharing information, ideas and products, and allowing countries to rise up the value chain.

Economic and Social Benefits of Digital Economy Development

Today, people around the world rely on mobile communication, internet access and social media for interactions with each other, sharing information and obtaining new knowledge and services, while governments and businesses increasingly prefer the internet for disseminating information, delivering services, communications, marketing and doing business in general. According to the World Development Report 2016: Digital Dividends recently released by the World Bank, digital technologies have boosted growth, expanded opportunities, and improved service delivery. Digital technologies can transform the economy as a whole and across different sectors. As shown by the successful practices, the more efficient use of digital technologies is a key driver for a more competitive economy, growth and jobs.

Source: McKinsey Global Institute analysis

The global digital economy is experiencing high growth, rapid innovation, and broad application to other economic sectors. An Accenture study estimates that digital transformation of the top ten economies of the world is a $ 1.36 trillion. According to BSG, it will reach $4.2 trillion in the G-20 economies by 2016 and contributes up to 8 % of GDP [4, 9]. It is estimated, that the digital economy accounts for about 6 percent of GDP in OECD countries and in Sweden it reached to almost 8 percent of GDP due to significant competitive advantage in digital services and platforms the digital

economy growth. The UK's digital economy has the largest proportion of GDP among G-20 countries (close to 10 percent of GDP) [4, 5]. It led by a strong e-commerce sector and includes online retailing, sales of Internet-related devices, IT and telecommunications investments, and internet-related government spending. The economic contribution of the digital economy in terms of Gross Value Added was £118 billion, 7% of the UK total in 2014 [6].

According to BCG in Russia, the share of the digital economy in GDP is 2.8%, or 75 billion US dollars. Most - 63 billion US dollars - accounted for the sphere of consumption (e-commerce, services, and online search and offline purchases). The share of online commerce in all sales was 1.7% (12 billion US dollars) in 2010, and then in 2017 it rose to 3.9% (48 billion US dollars). IT technology exports amounted to 8.4 billion US dollars.

Digital innovation drives the development of the digital economy and society, enables applications in many areas, and leads to transformations. Digital technologies can affect businesses' dynamism, which supports the emergence and growth of firms. The Internet lowers barriers to entrepreneurship and makes it easier to start, grow and manage a business. It also supports "lean start-ups" that leverage the Internet to lower fixed costs and outsource many aspects of the business to stay agile and responsive to the market. The Internet further affects the broader business environment by lowering transaction costs, increasing price transparency and improving competition. It is now easier for businesses to communicate with suppliers, customers and employees using Internet-based tools. Improved communication is also leading to the emergence of new and transformed business models.

Digital innovation and applications transform not only products, business models and markets, but also jobs and trade. In some sectors ICT investment has led to job losses while in others it has led to job creation.

Creating new jobs. The digital economy in UK employed 1.3 million people in 2014, 5% of all employees. There were 204,000 digital economy businesses, 9% of the UK total in 2015. Over the last five years, the development of mobile applications alone has created nearly 500 000 new jobs in the US, implying strong employment growth prospects [5,7]. It is estimated that 1.5 million additional jobs could be created in the EU digital economy if it mirrors the performance of the US or Sweden. According to a BCG study, European countries that are leaders in digitalization, such as Denmark, Sweden, Finland etc., between 2015 and 2020 the number of new jobs will exceed the number of those phased out by 1.6–2.3 million [12].

Improving Public Services. As highlighted by Mckinsy, "innovative governments are making it easier for citizens to access public services" and shifting from simply administering services to regularly engaging and empowering citizens to participate in the design and the delivery of these services. This helps not only increasing choice and wellbeing but also boosting government productivity and efficiency of public administration. For instance, the UK government's 2012 Digital Efficiency Report suggested that transactions by government channels are 20 times cheaper than by phone, 30 times cheaper than by post and as much as 50 times cheaper than by face-to-face contacts. Shifting 30% of government service delivery "front office" contacts and transactions to digital channels would deliver gross annual savings of more than £1.3 billion a year, rising to £2.2 billion a year if 50% of contacts and transactions shifted to digital channels [7, 13, 14].

The methodology for assessing industrial ecosystems KPI

The authors propose to evaluate the effectiveness of industrial ecosystems using KPI methods based on corresponding of industrial ecosystems aims from the standpoint of global benchmarking. The methodology for assessing KPI of industrial ecosystems in the digital economy differs in the structural composition of KPIs used for analytical purposes. KPI (indicators, ratios) allows evaluating progress in industrial ecosystems, to identify and justify the prospects of this process due to comparison estimated KPIs with similar ones in developing and new industrial countries.

In order to implement global benchmarking, the KPI assessment methodology should be consistent with the goals and indicators adopted in 2015 by the UN General Assembly [16] :

№ 8 "Promoting sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all";
№ 9 "Creating resilient infrastructure, promoting inclusive and sustainable industrialization and innovation";
№ 10 "Reducing Inequality within and between Countries";
№12 "Ensuring the transition to rational consumption and production patterns".

In existing methodologies, the achievement of sustainable development goals is proposed to measure.

Goal № 8 "decent work and economic growth" - through seventeen indicators, of which Rosstat does not develop five, one indicator is in the process of development, eleven indicators are developed;
Goal № 9 “industrialization, innovations and infrastructure” - through twelve indicators, of which three are not developed by Rosstat, nine are being developed;
Goal № 10 “reducing inequality” - through eleven indicators, of which eight are not developed by Rosstat, one is under development, two are being developed;
Goal № 12 “responsible consumption and production” - through thirteen indicators, of which Rosstat does not develop any.

The problem of indicators lack developed by Rosstat can be solved by using the database of the UN Department of Economics and Social Threats.

The authors correlated the presented indicators with the goals of the industrial ecosystem (IE) development in the digital economy and identify key KPIs (Table 1). The KPI assessment methodology includes the following steps for evaluating all 15 indicators.

Table 1: The key KPI for IE

The purpose of the IE management	UN Indicators	Measurements	Inclusion in KPI
Maximizing the level of global leadership (competitiveness) in high-tech markets	"Research and development expenses as a percentage of GDP" (9.5.1 SDG)	%	KPI-1
	"The share of value added products of medium-tech and high-tech industries in the total volume of value added" (9.b.1 SDG)"	%	KPI-2
	"Total official international support (official development assistance and other official funding flows) allocated to infrastructure" (9.a.1 SDG)	$ mil., 2016 prices	KPI-3
	"Number of researchers (in full-time equivalent) per million inhabitants" (9.5.2 SDG)	number of people	KPI-4
Labor productivity growth	"Annual growth rate of real GDP per employed person" (8.2.1 SDG)	%	KPI-5
	"The share of the industry value added " “Manufacturing” in GDP for the year preceding the previous one" (9.2.1 SDG)	%	KPI-6
	"Internal material consumption of raw materials per unit of GDP" (8.4.2 or 12.2.2 SDG)	kg / $, 2016 prices	KPI-7
The growth of the	"Annual growth rate of real GDP per capita"	%	KPI-8

The purpose of the IE management	UN Indicators	Measurements	Inclusion in KPI
level and quality of life of the population	(8.1.1 SDG)		
	"CO2 emissions per unit of added value" (9.4.1 SDG)	kg CO2 eq. / $	KPI-9
	"Proportion of population covered by 4G mobile networks" (9.c.1 SDG)	%	KPI-10
	"Value Added Industry Manufacturing Per Capita" (9.2.1 SDG)	$	KPI-11
	"The growth rate of per capita income among the least affluent 40% of the population" (10.1.1 SDG)	%	KPI-12
	"Internal material consumption per capita" (8.4.2 or 12.2.2 SDG)	tones	KPI-13
Employment growth in non-primary industries	"The share of young people (aged 15-24) who do not study, do not work, and do not acquire professional skills" (8.6.1 SDG)	%	KPI-14
	“Employment in the manufacturing industry as a percentage of total employment" (9.2.2 SDG)	%	KPI-15

Source: developed by the authors using materials [1]

By 2017, the RF IE reached the world level in KPI-4 (number of researchers), KPI-14 (employment among young people) and KPI-15 (employment in the manufacturing industry), despite the presence of downward trends in these indicators, due to including, patterns of change in industry. According to KPI-1, KPI-2, KPI-5, KPI-6, KPI-7, KPI-8, KPI-9, KPI-10, KPI-11, Russian IE didn’t reach the world level.

We offer to use the rating of V.L. Quinta [17], when conducting a global benchmarking of countries in terms of IE development, as well as the term “emerging market country”, which means “society moving from dictatorship to a market-oriented economy, with a growing level of economic freedom, consistent integration into the world market space, a stronger middle class, improved living standards, social stability and tolerance, as well as increased cooperation with international institutions "[18].

V.L. Quint algorithm classification of countries based on the Benett algorithm and integrated indicators (the industry modern index, knowledge economy index, industry index, economic freedom index and per capita GDP) and offers a systematic rating of countries technological development.

Let's analyze a number of significant KPIs in more detail.

KPI-1 "Research and development costs,% of GDP."

R & D expenditure as a percentage of GDP in Russia declined from 2010 to 2018. (as of 2018, the figure was 1.1%). The European Union (EU), for example, has set a goal to invest 3% of GDP in scientific research, while the EU is investing 1.97% of GDP (in 2017) [19].

International statistics show that in the past twenty years, there has been an outpacing growth in spending on research and development relative to the growth of global GDP. So, according to the UN [18], for the period 2013-2018 global spending on research and development grew by 30.5%, and the global economy - by 20%. The main share in the expenditures is occupied by countries and regions with high per capita incomes - primarily the United States (25.5%) and Western Europe. However, this share is decreasing due to a significant increase in research and development costs in the

countries of the Asia-Pacific region, primarily in China. If in 2007, the share of China in world expenditures on research and development was 10.2%, in 2018 it was twice - 20.8% [16].

It is expected to maintain sustainable values of global economic growth, an increase in the number of countries in which science support is among the main priorities of long-term development. This creates favorable conditions for the growth of global spending on science, which will be observed in the future. According to the Russian Academy of Sciences, in the period up to 2035, the total amount of scientific expenditures in the world will increase from 1.7 trillion dollars in 2016 to 3.3 trillion dollars in 2035, that is, almost doubled, and knowledge intensity of world GDP will grow from 2.2% in 2016 to 2.3% in 2035.

KPI-1 below the world level, below the level of developed countries.

Target KPI-1 in 2030: 10% of GDP.

KPI-2 "The share of high-tech and knowledge-intensive industries in GDP for the year preceding the previous one,%." In 2016, Russia had the 51st place in the world in the share of high-tech and medium-tech industries in manufacturing.

KPI-2 is above world level, but below the level of developed countries.

Target KPI-2 by 2030: 50%.

KPI-3 "Total official international support (official development assistance and other official financing flows) allocated to infrastructure, million US dollars". *Data for the calculation of KPI-3 in Russia are not available.*

The target value of KPI-3 by 2030: achievement of world indicators.

KPI-4 "Number of researchers (in the equivalent of full employment) per million people (person, value of the indicator per year)". The number of researchers in the Russian Federation has decreased since the 2000s. In European countries, on the contrary, there is a significant increase in the number of researchers per million people. Russian indicators are above world level.

Target *KPI-4: 4500 people* by the year 2030.

KPI-6 "The share of the value added of the industry "Manufacturing production" in GDP for the year preceding the previous one (percentage, value of the indicator for the year)". There is a global tendency to reduce this indicator. However, it should be noted that the share of manufacturing in global GDP in dollars with constant purchasing parity (in US dollars), calculated using different sectoral conversion factors, has not changed significantly [25].

KPI-6 below the world level, below the level of developed countries.

Target KPI-6: 26.51% by 203

KPI-9 "Volume of greenhouse gas emissions (tons of CO2-eq.) per unit of gross domestic product ". Russia's KPI-9 indicators significantly exceed world values, which is a negative factor.
Target KPI-9: Achieving the world level by 2030.

KPI-10 "Share of population covered by 2G mobile networks, %". Russia's KPI-10 figures are below world level. It is necessary to note the breakthrough world dynamics to the growth of this indicator. Mobile networks and LTE technologies are an example of disruptive innovations and technologies that have taken over the world in the last ten years.

The target value of KPI-10 by 2030: 100%.

KPI-15 "Employment in the manufacturing industry as a percentage of the total number of employees, %". As a rule, in high-income countries, the share of manufacturing in total employment, as well as the number of people employed in manufacturing in absolute terms, is reduced. The decline in employment in the manufacturing industry is due to structural changes occurring in it. Thus, the Russian indicator (14.35% in 2016) corresponds to the global trend of reduction, but is at a level higher than the global one.

Target KPI-15: 28.2% by 2030

The choice of the RF IE development target level should determine the country's ability to take a leading position in the global industry [20-24]. A summary table of KPI goals for the development of IE in a digital economy is presented in table 2.

Table 2: The summary table of KPI goals

KPI	RF/The world	2015	2016	2017	by 2030 г.
KPI-1	RF	1,10	1,04	1,05	**10**
KPI-1	World	1,70	1,70	1,72	
KPI-2	RF	25,60	22,46	22,15	**50**

Digital Transformation in the Steel Industry as an integrator of industrial ecosystem

The global steel industry is the critical backbone of the industrialized value chain. An essential base material for significant sectors, such as automotive and aerospace, steel is a centerpiece of innovation and economic growth. The steel industry is facing significant challenges due to cost, regulatory, product and service requirements (fig. 2)

Figure 2: Metals business challenges

Source: PwC's Digital Services

Steel producers face continuing challenges to improve EBITDAs which is only possible by pushing the productivity, flexibility and innovation envelope continuously. One such opportunity to transform operations and alter the cost structure is by creating the digital workshop serves as a working and communication platform for multidisciplinary collaboration when tackling tasks that involve various disciplines. By making use of the native data and data exchange formats (IGES, JT, WRL) available in the 3D CAD systems used in the engineering departments, it links simulation data with actuations of plant components and movements of products.

Today, virtual technologies are used as a tool to back planning and designing. Proven fields of application are, for example, interactive product presentations used in sales departments, integration tests as part of the project implementation process or virtual technologies used by service departments for training purposes. Making the customer part of a virtual, multi-discipline working environment shared by several users facilitates effective coordination and agreement processes that will minimize corrections at a later stage, saving project time and costs.

The basic instrument of Supply Chain Management, for example, is the consistent mapping of the production and material flows and the complete order handling process, including the customer order, the manufacturing order and the suppliers. The employees rely on digital simulation and optimization tools operating in real time to be able to plan production more effectively and at shorter notice and predict production processes or energy consumption more reliably. They expect flexible, cooperative logistics solutions implemented together with their raw material, consumables and spare parts

suppliers. Here, cost reduction potential is tapped from economies of scale resulting from the combination of several spare part portfolios.

Sales departments request digital tools that facilitate pricing and provide for transparency in delivery date setting as well as solutions enabling "digital shadowing" of products and processes, serving as documentation for the customer. Providers of IT and automation solutions as well as the IT departments of the manufacturing companies are presented with the challenge of having to capture all data and information arising from the production activities (plants, processes, products) in a consistent form, at all process stages. At the same time, the correct information has to be processed in a way suitable for all involved (humans and machines), while being accessible at any place and time and guaranteeing a maximum of data security.

Today there is a large choice of innovative technologies that not only save time and resources, but also ensure employee safety. This allows metallurgical enterprises translate into digital format the most important functions (fig. 3).

Figure 3: The digital enterprise combines vertical and horizontal integration with customer access & business models

Source: PwC's Digital Services

Our approach to the digitization of the metallurgical plants:

1. Comprehensive expert research, including analysis of business problems, business processes, IT infrastructure and assessment of the current level of automation and compliance of existing equipment with the requirements of Industry 4.0.
2. Formation of the customer's digital business model based on the target parameters of the enterprise's efficiency, compliance with the criteria of Industry 4.0, as well as industry and business characteristics of the business.
3. Formation of a strategy for the implementation of a digital enterprise model, which takes into account the economic feasibility of the entire digitalization process and each of its stages, in priority.

4. Clear implementation of the approved strategy, based on the principles of openness and interactive feedback mode.
5. Assessment of the actual performance of the digital enterprise model in the context of each project or complex of projects.

Conclusion

1. Data-driven innovation, new business models, and digital applications are changing the workings of science, governments and industry. Policies to support digital innovation tend to focus on innovation networks, access to finance, and data use, but pay less attention to investment in ICTs, knowledge-based capital and data analytics.
2. Digitalization is the new competitive instrument. It is the key differentiator in manufacturing today.
3. Companies should also take advantage of established innovation networks around universities and R&D centers that give the steel industry an opportunity to develop new technologies and products. Besides, industry requires employees with the advanced skills and technical know-how to master complex equipment and take products beyond the concept stage.
4. Trust underpins most digital relationships and transactions and depends on the management of risk. A few are listed here.

– Risks associated with the speed of labor market changes and the destruction of traditional jobs;
– Risks associated with changing nature of work and the quality of internet enabled jobs, such as micro work or jobs in the on-demand economy;
– The risks associated with widening income inequality.

5. The authors tested the methodology for KPI assessment of IE development goals in a digital economy based on the Sustainable Development Resolution adopted by the UN General Assembly in 2015. It was proposed to use fifteen KPIs, for each KPI a calculation method was developed in accordance with the Rosstat methods. All KPIs are estimated in dynamics since 2000 and correlated with international and global values. Target KPI values by 2030 have been developed.

Abstract

The article examines the influence of the main characteristics of the open procurement procedures for the supply of motor vehicles from Romania on the savings achieved. In this regard, from the Romanian Public Procurement System was extracted a sample of 165 lots of vehicles that were awarded in 126 procurement procedures carried out in 2019 (open tenders and simplified procedures). The research verifies for the analyzed sample if there is an inverse proportional relationship between the number of offers received and the savings achieved. Also, the research tries to determine the point from which the offered price no longer decreases and the efficiency of the use of budgetary funds becomes maximum. By carrying out 8 unifactorial and multifactorial linear regressions, the research verifies whether the number of offers received depends on the type of procurement procedure and which of the following characteristics of the procedures most influence the achieved savings: the type of procurement procedure, the number of offers received and the estimated value of the procedure.

Keywords: Public Procurement Procedure, Savings, Type Of Procedure, Number Of Offers, Estimated Value.

Introduction

The biggest challenge in the field of public procurement is the efficient use of public funds, with the level of competition being one of the factors affecting the efficiency of the spending funds (Hanak and Muchova, 2015).

In a procurement procedure, the criteria for the qualification and selection of offerors must be established in such a way as to fulfill two objectives: firstly, to allow the qualification of economic operators which may carry out the procurement contract (similar experience, facilities, qualified personnel etc) and secondly, to facilitate sufficient competition in the procedure leading to the greatest possible efficiency in the use of public funds.

Papers such as “Surgical team and surgical communication” (Dutu, C., Luchian, A., Starcu, E., Savulescu, F., 2015), “Internal Medicine Papers” (Popescu, A. L., Costache, R.S., Savulescu, F.,

Jinga, M., Ionita-Radu, F., 2019), "Patient-centered innovative monitoring system and smart personalized health care services using ICT" (Ianculescu, M., Alexandru, A., Radulescu, C/Z., 2018), "A Pilot Study on Management Systems Implemented within Romanian Organizations" (Popa, I., Stefan, S.C., Popescu, D.I., 2015) and "A Parametric Approach for Filling the Gap between Raw Data and Knowledge Based Engineering in the Aerospace Industry" (Alexandru, T.-G., Pupaza, C., 2018) reveal two areas in which public procurement is large and in which the efficiency of the use of public fumds is essential, respectively medicine, and aerospace industry.

The most important way to increase the savings achieved and implicitly the efficiency of procurement procedures is to increase competition.

Research by Thai et al. (2009) concluded that in order to achieve significant savings in a procurement procedure at least four economic operators must participate. According to the authors, the situation becomes unfavorable to the contracting authority to three offers or less, and when only one offer is received, the situation is catastrophic (Thai et al., 2009).

An explanation of this conclusion is that when there are multiple bidders, it is very difficult to reach any non-competitive agreements between them. Also, the potential profit that can be obtained by a bidder decreases greatly when the competition is high, the lower gain not justifying taking the risk that the non-competitive agreement poses. The reduced profit may even be a reason for economic operators not to participate in the procedure.

The amounts that are allocated annually in Romania for public procurement represent about 7% of GDP. Thus, in 2018 were completed procurement procedures with a total value of 42,484,208 thousand lei, VAT excluded, meaning 50,556,207 thousand lei, VAT included, respectively 10.5 billion euros, VAT included (ANAP - Romanian National Agency for Public Procurement, 2019).

Table 1 presents the final values of completed procurement procedures and the number of procurement contracts concluded in Romania in 2018 for each type of procurement procedure.

Table 1: The awarded values of completed procurement procedures and the number of contracts concluded in Romania in 2018

Type of procedure	Awarded value (thousands of lei, without VAT)	The weight from the total awarded value	Number of contracts
Open tender	16,809,037.12	39.56%	8,480
Simplified procedure	24,567,230.52	57.83%	20,478
Accelerated open tender	30,040.57	0.07%	71
Restricted tender	102,796.39	0.24%	13
Competitive dialogue	393.97	0%	1
Competitive negotiation	974,709.93	0.01%	26
Total	**42,484,208.49**	**100%**	**29,069**

Source: (ANAP, 2019)

As can be seen, most contracts with the highest total value have been concluded following the application of simplified procedures followed by open tenders. In view of this situation, research will continue to analyze only these two types of procurement procedures.

Simplified procedures differ from the open tenders by the fact that the estimated value of the products / services to be procured is lower, the documents that are requested from offerors are less and with shorter deadlines (for submission of tenders, submission of appeals, etc).

As a result, the duration of open tenders is higher than the duration of simplified procedures.

For example, in 2018 in Romania, the average duration of the 3,626 open tenders was 118 days and the average duration of the 14,874 simplified procedures was 90 days. If the open tenders were ex-ante controlled by ANAP, the average duration of the open tenders was 143 days, meaning a very long period of about 4 and a half months (ANAP, 2019).

Literature Review

Gupta (2002) analyzed the competition in a sample of US works auctions (investments) from 1981 to 1986 and found that after receiving 6 to 8 offers, the price no longer decreases and the maximum spending efficiency is achieved (Figure 1).

Figure 1: The level of maximum competition (X)
Source: Gupta (2002)

Brannman et al. (1987) confirmed the results of Gupta (2002) and found that the maximum level of competition is reached when 5 to 8 bids are received.

Gineitiene and Serpytis (2011) concluded that in some procurement procedures where 2 tenders were received instead of 1, savings were achieved between 10% and 20%.

Pavel (2010) concluded that in the case of procurement procedures for the construction of Czech railways and motorways from 2004 to 2009, each additional offer received led to an average reduction in the final price achieved by 3.2%.

Ilke, Rasim and Bedri (2012) found that each additional offer led to a 3.9% reduction in the final price and that the number of offers received depends on the estimated value of the procurement procedure.

However, Rose-Ackerman (1999) concluded that there are a number of procedures in which only 3 offers were received and where savings were obtained in the same size as 6 offers.

In times of economic crisis, the trade mark-ups of the offerors were smaller due to the increase of the competition because of the reduction of demand (Gugler, Weichselbaumer and Zulehner, 2014).

Most research in this area has concluded that if competition increases, then the final price decreases, and if 5 to 8 offers are received, then the price will no longer decrease and the efficiency of the use of budget funds becomes maximum.

Research Methodology/Working Hypotheses

The study objectively analyzes the specialized literature on the field of competition and the factors that influence the savings achieved.

A representative sample of lots awarded in motor vehicle procurement procedures will be drawn from the Romanian Electronic Public Procurement System (SEAP). The data extracted from this system presents the advantages of being accurate, relevant data and covers the whole territory of Romania.

Using unifactorial and multifactorial linear regressions, the possible correlations between the main characteristics of the procurement procedures will be determined.

As the number of offers received may depend on certain characteristics of the procurement procedure, the following working hypotheses have been defined:

H1: The number of offers received depends on the type of procurement procedure;
H2: The number of offers received and the estimated value of the procedure influence the size of the savings achieved.

Analysis of the influence of procurement procedures characteristics on savings achieved on the purchase of motor vehicles

In Annex 1 are presented the main characteristics of the motor vehicles procurement procedures carried out and completed in Romania in 2019. The sample of data was extracted from SEAP and contains the data of 165 lots of motor vehicles that were awarded in 126 procurement procedures (open tenders and simplified procedures). Out of the 165 motor vehicles lots, 95 lots were awarded by open tender and 70 lots were awarded by simplified procedures.

The main characteristics that were extracted for each lot were: the number and date of the award notice, the object of the procurement, the type of procurement procedure, the number of offers received, the estimated value of the procedure, the final value of the procedure, the savings achieved and the weight of the savings achieved from the estimated value.

Products and services subject to procurement procedures are classified according to a Common Procurement Vocabulary (CPV) code. Motor vehicles are in CPV class No 34 - Transport equipment and auxiliary transport products.

In 2018, in this CPV class, 1,210 supply contracts were awarded in Romania and the average number of offers received in each procedure was 2 (ANAP, 2019).

For the sample analyzed of 165 lots, the average number of offers received was 1.72, which is very close to that recorded at national level. For the selected sample, the average number of offers received at the 95 open tenders was 1.92 and the average number of offers received at the 70 simplified procedures was 1.42.

Figure 2 shows the average number of offers received by type of contract in 2018 in Romania.

Figure 2: The average number of offers received within the procurement procedures carried out in Romania in 2018

Source: (ANAP, 2019)

As far as can be seen, the average number of offers registered at national level in product procedures (for all product types) was 4 in open tenders, respectively 5 in simplified procedures. By comparison, for the sample analyzed of 165 lots of motor vehicles, the average number of offers received was much lower (1.92 in open tenders and 1.42 in simplified procedures). It is interesting that **the trend of economic operators to submit more offers in simplified procedures is not confirmed** for the sample under consideration.

In 2018, in Romania, at CPV class no. 34 were concluded 735 contracts based on a single offer received (out of the total of 1,210 contracts awarded), representing a weight of 60.74% of the total (ANAP, 2019). In the sample analyzed, 103 lots were awarded on the basis of a single offer received, which represents 62.42%. It is observed that for the sample under consideration, the weight of contracts concluded on the basis of a single offer (62.42%) is very close to the weight registered at national level for the entire CPV class (60.74%).

A plausible explanation for the reduced competition is that in Romania many national motor vehicle manufacturers' representatives participate in the procurement procedures but do not allow smaller dealers of the same manufacturer to participate in the procedures. These are in reality "anti-competitive agreements" that reduces competition and increases the inefficiency of spending public funds.

The weight of savings achieved (column 10 of Annex 1) by the number of offers received (column 6 of Annex 1) for the sample analyzed is presented in Figure 3.

Figure 3: The weight of savings obtained according to the number of offers received
Source: Based on the data in Annex 1

As can be seen, there is an inversely proportional relationship between the savings and the number of offers, but it is not possible to establish the point from which the price no longer decreases and the efficiency of the procedure becomes maximum due to the small number of offers received.

In order to verify hypothesis H1 for the sample analyzed by 165 lots, that is, if the number of offers received depends on the type of procurement procedure, we will use a linear unifactorial regression model of the form:

$$y = a + bx \quad (1)$$

where:

y – number of offers submitted (column 6 of Annex 1);
x – type of procurement procedure (column 5 of Annex 1);
a – residual variable;
b – factor of independent variable x.

In Table 2 are presented the results of the linear unifactorial regression model.

Table 2: The results of the linear unifactorial regression model (y – number of offers submitted, x – type of procurement procedure)

Source: author's calculations

As can be observed, the correlation ratio (R) is 0.2122 and it shows that between the number of offers received and the type of procurement procedure exists a weak link.

The coefficient of determination (R^2) is 0.0450 and it shows that only 4.5% of the variation in the number of offers received (y) is explained by the type of procurement procedure.

Thus, according to the results of the regression model for the sample analyzed, **it is not possible to establish a significant, strong link between the number of offers received and the type of procurement procedure**.

Hanak and Muchova (2015) analyzed a sample of procurement procedures which resulted in 256 public works contracts and found a moderate positive correlation between the number of offers received and the relative reduction of prices offered.

The same conclusion was reached by Man, Matejkova, Jurcik and Heidu (2014), who analyzed 197 procurement procedures. The authors found that there was an inversely proportional relationship between the number of offers and the price offered. Furthermore, the authors also analyzed the influence on the final price of two more independent variables, namely the type of procedure (open or restricted) and the estimated value of the procedure. Following the successive application of several linear multifactorial regressions, the authors found that the savings of the procurement procedure depends on the type of procedure and its estimated value.

It is easy to see that more offers will be received in open procedures and thus the final price obtained will be lower than in restricted procedures. More difficult to see is how the number of offers will vary if both types of procedures analyzed are open, namely open tenders and simplified procedures.

For the verification of the H2 hypothesis for the sample analyzed, meaning to verify if the savings obtained depend on the type of procedure (open tender or simplified procedure), the number of offers and the estimated value of the procurement procedure, we will use a multifactorial linear regression of the form:

$$y = a + bx_1 + cx_2 + dx_3 \quad (2)$$

where:

y – savings achieved (column 9 of Annex 1);
x_1 – type of procurement procedure (column 5 of Annex 1);
x_2 – number of offers submitted (column 6 of Annex 1);
x_3 – estimated value, in lei, without VAT (column 7 of Annex 1);
a – residual variable;
b, c, d – factors of independent variables x_1, x_2 and x_3.

In Table 3 are presented the results of the linear multifactorial regression model.

Table 3: The results of the linear multifactorial regression model (y – savings achieved, x_1 – type of procedure, x_2 – number of offers submitted, x_3 - estimated value)

Source: author's calculations

The correlation ratio (R) is 0.5897 and it indicates that there is a medium-intensity link between the obtained savings and the three independent variables.

The coefficient of determination (R^2) has the value 0.3477 and it shows that 34.77% of the variation of the obtained savings (y) is explained by the three independent variables.

In order to determine which of the independent variables most influence the achieved savings (y), we will try to improve the regression model, by excluding one or two of the independent variables used.

Therefore, 6 multifactorial and unifactorial linear regressions have been performed and their results are presented in Table 4.

Table 4: Extract from the results of the 6 multifactorial and unifactorial linear regressions performed

Independent variable (x)	**The correlation ratio (R)**	**The coefficient of determination (R^2)**	**The mean square error deviation**
Multifactorial linear regression $y = a + bx_1 + cx_2$, where y = the savings achieved (in lei, without VAT) (column 9 of Annex 1)			
x_1 = type of procurement procedure (column 5 of Annex 1) **x_2 = number of offers (column 6 of Annex 1)**	0.294229	0.086571	5,800,265.50

x = number of offers (column 6 of Annex 1)	0.274999	0.075624	5,816,991.63
x = estimated value (in lei, without VAT) (column 7 of Annex 1)	0.588008	0.345753	4,893,785.84

Source: author's calculations

From the comparative analysis of the results of these regressions, respectively of the correlation ratios - R and of the coefficients of determination - R^2, it can be found that they have higher values when the independent variable is the estimated value of the procedure (cells highlighted with yellow color in Table 4).

These results show that in the case of the analyzed sample, **the savings achieved are most influenced by the estimated value of the procurement procedure**, the other two independent variables, respectively the number of offers received and the type of procedure (open tender or simplified procedure) having an insignificant influence.

Conclusions

The article analyzes the influence of the main characteristics of the procurement procedures on the savings achieved for a sample of 165 lots awarded in 126 procurement procedures for motor vehicles carried out in Romania in 2019.

The study found that in the case of the sample under consideration, competition in motor vehicle procedures is lower compared to competition in procedures for other product types. The research also concluded that in the procedures with lower estimated values (simplified procedures) do not significantly submit more offers. A explanation may be the existence of anti-competitive agreements between the national representatives and the dealers of car manufacturers.

The research found that there is an inverse proportional relationship between the size of the savings and the number of offers, but it is not possible to establish the point from which the price no longer decreases and the efficiency of the procedure becomes maximum due to the small number of offers received.

According to the results of linear regressions performed in the case of the analyzed sample, no significant connection could be established between the number of offers received and the type of the procurement procedure (open tender or simplified procedure) and it has been demonstrated that the savings achieved are influenced most by the estimated value of the procurement procedure, the other two independent variables, respectively the number of offers received and the type of procedure having an insignificant influence.

Future research should examine other types of products in a similar way. The comparative analysis of the obtained results should emphasise a number of characteristics of the observed differences that can be exploited by identifying and implementing measures to improve the procurement procedures and

to increase the savings achieved (simplifying the minimum requirements of qualification / selection for offerors, increasing competition, changing value thresholds, etc).

Abstract

Spatial arrangement of human activity by territorial planning is a highly relevant problem for many countries throughout the world. A problem of an optimal population settlement distribution network is always drastically crucial for Ukraine due to a number of reasons, some of which have been taken into account upon the administrative and territorial reform provided. The determination of structural and dynamic characteristics of the population settlement network gets more and more topicality in the mentioned aspect. Our paper focuses on methodical and procedural issues of the agglomeration spatial structure regional research by the modeling of Integral Function of Impact (IFI). This approach is grounded on the concept of some "area of impact" for any socio-economic geographic feature. Modelling builds the series of IFI-surfaces with spatial distribution of population settlement by the IFI-function itself, by the population settlement potential, and by the averagely weighted with the IFI population settlement potential. These surfaces represent various sides of interactions according to a parameter selected. The IFI-surfaces built are a user-friendly tool for the definition of initial agglomerations and promising region growing points, which stimulated development would contribute to an optimal usage of a territorial potential, while increasing economic, human, and investment potential too. The paper demonstrates the results of the IFI-approach application within a case study of Kharkiv region (Ukraine). The outlined approach of the agglomeration spatial structure regional research can be in demand for evidence-based territorial planning and managing, for effective policy of regional development, etc.

Keywords: regional development, population settlement, agglomeration, territorial planning, IFI-modeling, Ukraine.

Research Problem Introduction

The population settlement system is a conservative constituent of the mankind due to its historical development. It not only represents all singularities of former socioeconomic formations, but also the population settlement system permanently stays in contradiction with those newly entities of social production, which have been generated recently. The increased pace and rapid development of the urbanization process during the industrial age was caused by the growth of manufactures in cities and by the following necessity of their labor potential increasing. As the result, the urban population concentration reached acritical level in the biggest megalopolises all over the world in the twentieth century. This circumstance caused much higher specifications to the urban infrastructure functioning, citizen life support systems, social security, etc. However, the beginning of postindustrial development of human civilization initiated the definite decentralization of the productive industry with relocation of productive units from urban territories to suburbs and even to rural areas. Hence, the countryside obtained the higher development priority in comparison with a traditional urban area, what was reasoned by the rural labor market promptly developed due to agriculture demand, and this trend was followed by corresponding spreading of various services for rural residents. All mentioned above drastically altered existing requirements with respect to a population settlement system and to the medium of communication. As a result, the territorial planning of agglomerations obtained the highest priority.

All processes and phenomena described above are relevant to Ukraine. The existing structure of the population settlement distribution were implemented upon Soviet times. This out-of-dated structure is unable to provide the flexibility of the spatial organization of the society upon contemporary transition to the free market economics. Because of this the regions pertained to the monocentric class of the population settlement began losing their labor force. Distal parts of regions began to expose a significant decay, while the countryside fell in the drastic decay. The disbalance between the regional center and almost all distal part of a region grew more and more, and that continually distorts the spatial organization of regions and makes all components of regional development be more complicated. Thus, there is an evident necessity for new approaches to territorial planning as to a tool, which can provide an optimal balance between a region center and its periphery (distal parts).

A category of "urban agglomeration" was officially used in the research domain of population settlement since some time. This category possesses quite a few definitions for the time being. The most frequently it means a big city (as an agglomeration center) with its suburbs and with all nearest townships. All these settlements are, as a rule, associated among them by various relations and interconnections, which all together finally produce a new entity of common functioning for this big city and small towns and villages around. Such territorial compact entity of settlements can be considered as a spatial systemic formation with all relevant properties of the social geographic system – socio-geosystem [10, 11]. As they were investigated, it appeared, that agglomerations as spatial structures of various hierarchical level are a widespread mode of the territorial arrangement. Taking this into account, it is possible to suggest the following hierarchy of these agglomerations for the administrative and territorial division of Ukraine (Table 1).

Table 1: The agglomeration hierarchy of the population settlement in Ukraine

(implemented by the authors)

#	*Agglomeration hierarchical level*	*Agglomeration center*	*Topical sociogeosystem*
1	Mega-level	A large city (almost or over 1 million of residents)	Interregional, regional
2	Macrolevel	A city as a center of an oblast – a larger administrative unit	Regional
3	Meso-level	A town as a center of a rajon – a smaller	Under-regional

		administrative unit	
4		A town, a township (a center of UTC)	United territorial community
5	Microlevel	A township, a large village	Local

Thus, a regional population settlement system is a mosaic of all five agglomeration levels, which either partially, or completely overlap each other in the spatial extent. That is, the local agglomerations are the elementary ones, while various hierarchical levels of the population settlement spatial structure can be distinguished – from microlevel to mega-level. If summarized, this structure of the population settlement network can be represented at any place of a populated territory by the vector, which components are a cluster of agglomerations of different levels. Therefore, the delineation of agglomerations with further research is a topical issue of the population settlement system optimization (territorial management and planning), this stipulates the importance and necessity of its structural-systemic analysis.

Key singularities of the contemporary structure of the population settlement network have been defined by the long history of its formation. A settlement agglomeration initiation is a complicated process of numerous stages, and which is caused by many factors. This process should be considered as the consequent implementation of the development and the self-organization functions of the geographical space. The latter is the origin domain of the future key environmental factor and an initiator of future civilizations – a biological species *Homo Sapiens.* The allocation function was the initial function of the geographical space. Implementation of this function led to creation of distinguished single settlements, which made an initial framework for further population settlement distribution. Afterwards several other functions of the geographical space were consequently implemented (*distance function, gradient function, transference function, interaction function)* [9]. It is necessary to emphasize, that quite a few preventing factors, both natural (mountains, impassible marshes and forests, big lakes and rivers), and artificial (e.g., state boundaries) ones impeded implementations of these functions. The biggest and most rapidly developed settlements gradually became accepted leaders and the agglomeration centers upon the interconnections with respect to the development of industrial and business specialization, trade growth, and cultural advancement. Agglomerations were initiated as soon as newly originated settlements attempted to enter into already existing spatial infrastructure of a number of settlements in a given area. Further alterations of initial agglomerations were determined by demographic processes of "population-depopulation" (increasing / decreasing number of residents), as well as by a migration process upon the procedure of the continual territorial self-organization.

The optimal usage of the integrated territorial potential is one of the key tasks in the regional development management for the time being. This task requires the composite research on the agglomeration spatial structure as well as on their evolutionary potential for indication of possible development distortions and for optimization of the regional production spatial structure. The delineation of the mentioned spatial structure and consequent estimation of agglomeration interactions – from local level to mega-level – is the first step of the mentioned key task solution.

This paper deals with the methodological substantiation of the regional research of the agglomerations spatial structure using the method of integral influence function modeling (IIF modeling), the presentation of the results of the grounded methodology application on the materials of Kharkiv region (Ukraine), which may be useful for the determination of scientifically-based planning measures and managing the territories of other countries and regions.

Literature Review

Many various topics in the domain of territorial planning have been examined in publications issued for years by both scientists, and managers. Agglomeration issues were considered by many well-known researchers. In particular, J. Coppolani once suggested to consider an urban agglomeration as a system of towns and villages interconnected by functional relationships, which exposes a definite

trend of unification into one common urban territory [2]. According to P. McCann, the existence, allocation, and repartition of the labor force is the determinant of the agglomeration development [7]. B.H. Baltagi B.H. proposes to accept purely economic criteria of research on the development of agglomerations (general level of a national economy, rate of salaries and wages, productive specialization, existing transportation infrastructure) [1]. According to A. Pujiati with coauthors the questioning survey with further analysis of its results can be highly effective method in agglomeration research if the following criteria are taken into account: characteristics of city management, urban housing development, urbanization level and a population number, housing supply ratios, possible environmental hazard, if there is an embankment in an area, local economy with its informal sector, urban green space and volume, if there are sources of renewable energy, the possibility of environmental harmful contamination [14].

Some issues of the regional development spatial models have been presented by the authors and discussed on the former IBIMA conferences [12, 13]. The authors have explored the agglomerations of Kharkiv region for quite a long time by applying the structural systemic approach and some other methods of the information theory and the systemic analysis [5, 6, 9]. This text has summarized the regional research of the agglomeration spatial structure methodological issues and represents key results of the relevant analysis of Kharkiv region.

Research Approach

The IFI-modeling method is quite applicable for pursuing the outlined research goal. This method is based on the series of publications made by L. Niemets and K. Niemets, which introduced the concept of "the Impact Zone" of a human geographic feature [10, 11]. An interaction between two settlements is possible according the mentioned concept, if impact zones of these settlements obviously overlap, thus they share a common part of the geographical space. If a distance between them is a historically given constant, their interaction force is determined by the radius R of impact zones. The latter in its turn depends on the potential of an analyzed entity (a number of residents), which is a settlement. Changing R sequentially on the systemic basics (for all analyzed entities simultaneously), it is possible to explore various according to the rate of summarization "profiles" of the interaction field for two settlements. These profiles can be accepted as the views of some historical stages of the agglomeration development. Finally, the series of IFI-surfaces of interaction fields is computed. These surfaces represent the distance function and the interaction function of the geographic space bounded to different historical benchmarks [10].

Presentation of research results

The alteration of the social relation in Ukraine, transition of our country to the postindustrial society, structural improvements in regional developments, all these factors cause the current changes in the territorial organization of the society. The geographic space polarization, spreading of deprived areas, low competitiveness of some regions and the absence of the effective regional policy, all this is intrinsic for the majority of regions. The population settlements as a mode of the society territorial organization cause singularities of the population social activity. The administrative territorial reform has been provided in Ukraine since 2015. Its essence lies in a delegation of more power credentials to the local self-governments and self-authorities. The changes in administrative territorial divisions took place too. This reform has to become a crucial tool of optimal changes in the spatial organization of the society, a factor of the regional development acceleration, and a condition of upgrade for the population settlement and the economy [3]. Generation of united territorial communities in Ukraine in 2015-2019 demonstrated two opposite trends. The first trend: rural territorial communities in distal areas were united around county ("rajons" – in Ukrainian) centers – small townships and villages [4]. The second one: rural communities around big cities of regional scale attempted to organize UTCs without this city involvement. The placement of UTCs throughout Ukraine is quite uneven. UTCs in some regions such as Khmel'nyts'ka Oblast', Zhytomyrs'ka Oblast', Ternopil's'ka Oblast', Dnepropetrovs'ka Oblast' already possess the bigger parts of the corresponding areas. At that very time, Zakarpats'ka Oblast' and Kyyivs'ka Oblast' present a quite slow process of

UTCs generation. Kharkiv region - Kharkivs'ka Oblast' can be described by the regional center exaggerated development and by the conservation of the center-peripheral models of development. There are only 23 UTCs in the region [4], that only emphasizes both timeliness, and necessity for our research to be done.

Computing of IFI-surfaces has been provided in our research with *R*-parameter sequential increasing from 2 till 30 km with a step of 1 km. In this way, a cluster of IFI-surfaces models consequently the relationship origination among settlements with increasing interaction forces. In some way this describes the dynamics of a process of agglomeration generation, changes of agglomeration size and configuration, spatial interrelationships, overlapping, etc.

The series of IFI-surfaces have been modeled for 993 settlements within the boundaries of Kharkiv region. These surfaces display spatial distribution of population settlement by the IFI-function itself, by the population settlement potential (*P*), and by the averagely weighted with the IFI population settlement potential (P_w), These surfaces represent various sides of settlement interactions according to a parameter selected. The most pictorial surfaces are introduced on Fig. 1.

Fig. 1: The IFI-surfaces modeled with the basic impact radius $R_0 = 2$ and 10 km by the averagely weighted with the IFI population settlement potential (P_w), (made by the authors according to modeled results)

It is necessary to emphasize, that IFI-surfaces for $R_0 = 2 - 4$ km display clearly the origination of the initial local agglomerations with the centers of large villages. We can easily trace the microlevel / meso-level agglomeration origination upon $R_0 = 10 - 12$ km, while the macrolevel agglomeration origination - upon $R_0 = 19 - 22$ km. The IFI-surfaces relevant to the initial stages of the mega-level agglomeration origination are distinctive for rather big R_0 values.

The built IFI-surface can be accepted as the efficient tool for the definition of initial agglomerations and promising region growing points (the areas expected for the socio-economic growth), which stimulated development would contribute to an optimal usage of a territorial potential, while increasing economic, human, and investment potential too. The delineation of region growing points contributes to the regional development acceleration, in general, and can speed up the peasant farming, in particular. These processes can be supported by both the central, and regional authorities, since there is a sustainable perspective of the regional manufacturing industry and various services further developing. In its turn, the development of promising region growing points as the areas expected for the socio-economic growth contributes to decreasing external migration as well as to enhancing investment attractiveness of the region. Also, it can be taken for granted, that gradual development of promising areas within the region strongly contribute to the territorial distortion diminishing with respect to the regional socio-economic growth.

Conclusions

A problem of an optimal population settlement distribution network is always drastically crucial for Ukraine due to a number of reasons, some of which have been taken into account upon the administrative and territorial reform provided in our country recently. Thus, the accomplishment of the regional population settlement research can be considered as an extremely topical issue. The outlined approach can be demanded for evidence-based territorial planning and managing, for effective policy of regional development, etc. Our paper focuses on the results of the IFI-approach application within a case study of Kharkiv region. The following conclusions can be made: 1) the polarizing impact can be traced within the region, which is related to not only Kharkiv-city, but also to such cities as Lozova, Izym, and Kup"yans'k; 2) the model of basic radius of 20 km displays an origination of some elongate impact zone of organizational cores of population settlement distribution and significant distortion in the relevant regional development; 3) the population concentration phenomenon can be traced at the locations, which can be considered as the "region growing points" mentioned above; 4) the rural areas with the lowest averagely weighted potential of population settlement can be accepted as the most promising ones for the priority development. The authors' research will be continued in this thematic domain.

Abstract

The country's food security is an important indicator of socio-economic development, a component of social and physical health of the population. Ukraine having got high quality black soil is a potential contender for growing ecologically clean food. Land market can start working in the country in the near future, which potential business is interested in. Food security is an integral part of many economic and political transformations in Ukraine. This issue requires comprehensive research, including scientists. The paper analyzes the current state of food security in Ukraine, indicators of physical and economic availability of food by main foodstuffs have been calculated. It was found that the highest level of food security by the indicator of physical accessibility is characterised for certain products, in particular, it is oil, potatoes and sugar, and by the indicator of economic accessibility - for potatoes and bread products. Volumes of food production by domestic producers fully meet the solvent demand of the population, however, due to the low incomes of the majority of Ukrainian citizens, the consumption of practically all foodstuffs (except potatoes and bread products) is lower than rational norms. In order to solve the problems of food security of Ukraine, it is necessary first of all to raise the level of population's income, which will stimulate increase in consumption of foodstuffs and rise the capacity of the internal food market.

Keywords: Food Security, Indicator Of Food Physical Availability, Indicator Of Food Economic Accessibility, Rational Rates Of Consumption, Agri-Food Complex Of Ukraine.

Statement of the Problem

Food security is one of the indicators of the socio-economic development of the country. It characterizes the level of satisfaction of one of the basic human needs - the need for food. Achieving

a sufficient level of food security is a major factor in social stability and a guarantee of social peace in society.

Since 2014, the crisis processes in the Ukrainian economy have led to a sharp deterioration in the standard and quality of population's life, which has been reflected primarily in meeting the basic needs of the vast majority of people. In this view, the study of Ukraine's food security problems is extremely relevant and important in today's context.

The purpose of this study is to identify Ukraine's food security problems and determine ways to address them.

Review and analysis of previous research materials

According to the Methodological Guidelines for the Calculation of the Economic Security Level of Ukraine (2013), food security is "… a status of foodstuffs production in a country able to fully meet the needs of every member of the society for good quality food, provided that it is balanced and accessible to every member of society».

According to Kwasha S.M. (2000), three essential aspects of the concept of food policy are identified: political, economic and social.

According to Shchekovich O.S. (2009), food security necessarily includes not only the consumer aspect (taking into account physiological norms), but also production (due to the development of own production, and only then - the necessary imports of agricultural products and food).

Golikova K.P. (2012) proposed a food security structure consisting of resources coming from the environment.

Problems of population provision with agricultural products (mainly crop production) at the regional level are considered by Dobrovolskaya N.V. and Kostrykov S.V. (2016).

In the study of regional competitiveness the issues of agricultural development are considered by Niemets L.M. and Sehida K.Yu. (2017), in particular, its innovation and investment potential is determined as a factor of the food security formation.

Ungureanu, G., Leonte, E., Chiran, A., Costuleanu, L. C., Ignat, G., Donosă, D., Boghita, E., Petrea, E. (2019) showed understanding of the concept of food security and nutrition in the XX and XXI centuries.

There are different methods of assessing food security. The Global Food Security Index (GFSI) considers such key factors related to such indicators as the economic and physical availability of food (sufficiency diet, infrastructure development level, GDP, level farmer financing, etc.), as well as their safety and quality (dietary norms; presence of micronutrients in food) (Global Food Security Index).

The Food and Agriculture Organization of the United Nations uses 30 indicators to monitor food security, which are formed into four groups: availability, access, stability, use of food (FAO's web site).

According to the methodology of the Cabinet of Ministers of Ukraine and the Ministry of Economic Development and Trade of Ukraine, food security is considered as one of the indicators of economic security. The status of food security is characterized by an integral index consisting of 9 weighted average subindices.

Banach O.I. (2017) describes the features of food security and its problems at the individual, national and global levels.

Fachrudinawati F. and Handayani D. (2019) investigate gender-based food security in Indonesia's households.

Some issues of population trading service of regions of Ukraine as a component of food security and features of food security as components of regional development were discussed by us at previous IBIMA conferences and some papers (Kobylin, P.O. (2015), Kobylin, P.O. (2016), Kobylin, P.O. (2017), Niemets, L.M. et al. (2018), Niemets, L.M. et al. (2019).

Research Methodology

Determining the food security of Ukraine, the authors propose to consider it in terms of the physical and economic availability of food.

The indicator of food physical availability (I_{pa}) proposed by the authors can be represented as a ratio of food production and consumption:

$$I_{pa} = \frac{\text{Volumes of production}}{\text{Volumes of consumption}} \quad (1)$$

This indicator reflects the development level of the food complex of a country or region, its ability to meet the population's needs in food in general. In fact, this is an indicator of *food availability* produced by domestic producers.

The indicator of food economic availability (I_{ea}) proposed by the authors is defined as the ratio of food consumption and its rational norms:

$$I_{ea} = \frac{Volumes\ of\ consumption}{Rational\ norms\ of\ consumption} \quad (2)$$

In fact, it is an indicator of *food consumption sufficiency*, which depends on the level of purchasing power of the population.

Statement of The Study Materials

The calculated indicators of the food physical and economic availability in Ukraine are shown in Table 1.

Table 1: Ukraine's Food Security Indicators, 2017
(Source: based on data from "Agriculture of Ukraine: Statistical Yearbook", 2017)

The main food stuffs	Consumption per 1 person per year, kg	Rational norms of consumption, kg	Indicator of the food economic availability, I_{ea}.	Production per 1 person, kg	Indicator of the food phisical availability, I_{pa}
Meat and meat products, including offal and raw fat	51,7	80	0,65	54,6	1,06
Milk and dairy products	200	380	0,53	242	1,21
Eggs, pcs.	273	290	0,94	365	1,34
Bread products (bread and pasta in terms of flour; cereals, flour, legumes)	100,8	101	1,00	No information available	-
Potatoes	143,4	124	1,16	523	3,65
Vegetables and melon food crops	159,7	161	0,99	219	1,37
Fruits, berries and grapes (without wine processing)	52,8	90	0,59	48	0,91
Fish and fish products	10,8	20	0,54	No information available	-
Sugar	30,4	38	0,80	46,9	1,54
Oil	11,7	13	0,90	123,5	10,56

The calculations of the indicator of food physical availability show that the level of of agricultural production development and food industry in Ukraine provides a sufficient level of food security for most food products, especially oils (I_{pa} = 10,56), potatoes (I_{pa} = 3,65), sugar (I_{pa} = 1.54). Volumes of domestic production of vegetables and melons, eggs, milk and dairy products, meat and meat products also exceed their consumption (I_{pa} exceeds 1). Only production of fruits, berries and grapes provides about 90% of the population consumption (Fig. 1).

The indicator of food economic availability in Ukraine has greater variability of values than the indicator of food physical accessibility (Fig. 2).

Fig. 1: Indicator of the food phisical availability,
(Source: based on data from "Agriculture of Ukraine: Statistical Yearbook", 2017)

Fig. 2: Indicator of the food economic availability in Ukraine,
(Source: based on data from "Agriculture of Ukraine: Statistical Yearbook", 2017)

According to this indicator, the highest and sufficient economic availability is characterized for such foodstuffs as potatoes (I_{ea} = 1.16) and bread products (I_{ea} = 1). For other basic foodstuffs, the indicator of food economic availability is less than 1, indicating a lack of consumption of certain foodstuffs in accordance with rational standards. The lowest indicators of economic availability are characterised for milk and dairy products (I_{ea} = 0.53), fish and fishery products (I_{ea} = 0.54), fruits, berries and grapes (I_{ea} = 0.59), meat and meat products (I_{ea} = 0.65).

The greatest imbalance in terms of physical and economic accessibility is characterized for oil, sugar, milk and dairy products, meat and meat products, eggs. The indicator of physical accessibility shows that these products are produced excessively in Ukraine, but their consumption levels are less than normal. This indicates that population due to low incomes cannot generate sufficient solvent demand for basic foodstuffs.

The authors analyze the level of food security of Ukraine for each of the basic food products. During 2015 – 2017, the volume of meat production per person remained virtually unchanged and exceeded 54 kg, its consumption slightly increased from 50.9 kg to 51.7 kg *("Agriculture of Ukraine: Statistical Yearbook", 2017).* That is, domestic production actually provides consumer demand for meat and meat products, but their consumption is only 65% of the rational consumption rate which is 80 kg. This situation is explained, on the one hand, by the low purchasing power of the population and, on the other, by the constant rise in prices for livestock products. The number of cattle stock in Ukraine decreased from 9.4 million heads to 3.5 million heads, and the number of pigs - from 7.7 million heads to 6.1 million during 2000-2017. *("Agriculture of Ukraine: Statistical Yearbook", 2017)*. Therefore, it is extremely problematic to achieve a sufficient level of food security using a domestic livestock resource base.

The volume of milk production decreased from 248 kg to 242 kg per person, as well as its consumption - from 210 kg to 200 kg during this period. Although the population of Ukraine is provided with surplus dairy products, their consumption is almost twice less than the normal rate (380 kg). This is due to the same reasons as in the meat situation.

The situation is the same with fish and fishery products, whose consumption is twice less than rational rate, although during 2015 - 2017 their consumption increased from 8.6 kg to 10.8 kg per person.

Egg production for the period from 2015 to 2017 decreased from 392 pcs. up to 365 pcs per one person, and their consumption - from 280 pcs. up to 273 pcs., which provides almost adequate food security for this foodstuff with a rational consumption rate of 290 pcs. Poultry breeding in Ukraine is better compared to other livestock industries due to its higher profitability, faster payback on production costs.

The highest level of food security among vegetable products of plant origin, according to the indicator of food physical availability, has oil, whose production is in 10 times higher than the volume of consumption and they are constantly growing. Ukraine ranks first in the world on the production of sunflower oil. However, consumption of vegetable oil below rational norms was approximately 10% and in 2015-2017 decreased from 12.3 kg to 11.7 kg per person *("Agriculture of Ukraine: Statistical Yearbook", 2017)*.

The similar situation with the sugar supply: its consumption has decreased from 35.7 kg to 30.4 kg and it is 80% of rational rates, but its production is in 1.5 times higher than the consumption (Agriculture of Ukraine, 2017).

The highest level of food security for both indicators of (physical and economic) accessibility is characterized for potatoes, its production exceeds the consumption in 3.6 times, and the consumption increased from 2015 to 2017 from 137 kg to 143 kg and on 16% higher than rational rates (*"Agriculture of Ukraine: Statistical Yearbook", 2017*). Potatoes for Ukrainians have traditionally been one of the key foodstuffs called "second bread".

The same situation is with bread and bread products, their consumption generally meets or exceeds rational rates, and the baking industry fully provides the population with this "strategic" food product based on a powerful flour-milling industry. The developed olericulture in Ukraine creates a sufficient products supply which covers 137% of domestic consumption of vegetables, which is almost in accordance with rational rates of nutrition.

The lowest level of food security among crop products is characterized for fruits, berries and grapes, their production provides consumption for about 90%, and the level of consumption of these products is only about 60% of rational rates.

Conclusions

Summarizing the conducted research, it should be noted that in general, the agro-food complex of Ukraine has a sufficient level of production of food products to ensure population consumption, except fruits, berries and grapes, and partly - meat and meat products. However, the level of population consumption of the majority of basic foodstuffs is lower than the rational norms and at the same time decreases over time, which indicates deterioration of the population's living standard. In turn, the decline in solvent demand for foodstuffs is a deterrent to the development of certain branches of the agro-food complex of Ukraine. A way out of this situation for food producers may be increase of their exports, which will stimulate the development of the agricultural sector of the economy and related branches of the food industry, promote economic growth and raise of population's social standards, in particular it is regarded to the balance of foodstuffs consumption.

The analysis in this study is based on the real status of economic development of Ukraine. Complex institutional and economic processes are held, which raises many important issues, including Ukraine's food security. The authors continue to investigate this problem, including in particular the improvement of research methodology, statistical data collection, etc.

Abstract

The article describes the relationship between the central and peripheral regions of the Kharkiv region, which are manifested, as a rule, in the form of labor and educational migration. On the basis of the "growth poles theory", it has been proved that cities become a place of concentration of economic, social, financial, intellectual, labor resources. Such "growth points" provide wide opportunities for the population to receive higher incomes and, therefore, attract migrants from peripheral areas. The purpose of this article is to analyze the current migration situation in the Kharkiv region in order to identify factors, directions and characteristics of migration. Based on the migration trends identified by the authors in the Kharkiv region, it can be noted that urbanization processes are intensifying in the region due to the influx of rural residents, but settlement within the city occurs in semi-peripheral areas, thereby creating a suburbanization process. An increase in the urban population, its employment in the tertiary sector and high-tech sectors of the economy, a high proportion of youth and students speaks of its post-industrial development.

Keywords: Labor Migration, Educational Migration, Post-Industrial Development; Center-Periphery, Growth Pole, Kharkiv.

Relevance of the Research

Differentiation of the socio-economic development of the region often leads to the concentration of a number of resources: production, human, financial, transport and communications, infrastructure, innovation, investment, etc. in some territories, mainly large cities, and the lack of these resources in other territories. Large-scale urbanization processes have long led to rural depression, and the migration of people from villages to cities causes decline and even the elimination of many villages throughout Ukraine. Only those rural settlements, which are located in close proximity to large cities, and also have good transport access to them, benefit. There are close ties between such settlements and a large city, which are supported by peripheral-center population migrations. The relevance of this topic is that the city of Kharkov, which is the center of the Kharkiv agglomeration with a post-industrial city, daily, receives tens of thousands of migrants from peripheral areas who are mainly employed in the tertiary sector of the economy, while this process is typical of most post-industrial cities of Eastern Europe.

The ***purpose*** of the study is to analyze the current migration situation in the Kharkiv region in order to identify factors, directions and characteristics of migration. The main ***research questions*** are: How have the main directions of migration in the Kharkiv region changed? Why is the city of Kharkiv a center of attraction for migrants? Do migration processes affect the post-industrial development of the city?

Methods

This article is based on a set of philosophical, general scientific and concrete scientific research methods. The main methods: analytical, synthesis, inductive-deductive, problem-searching (identifying the impact of population migration on the post-industrial development of the city), retrospective (analysis of the main periods of the city's development, changing its functions and factors of migratory attractiveness) statistical (operating with statistical data), graphic (when visualizing the results of the study in the form of graphs, charts, cartographic diagrams).

The research database consists of data from the State Statistics Service of Ukraine, the Main Department of Statistics in the Kharkiv Region, materials from the Kharkiv Regional State Administration and the Kharkiv City Council. Analytical reviews and reports, scientific articles and publications of foreign and Ukrainian authors were studied.

Analysis of Previous Studies

At the beginning of the XX century, many scientists, in particular economists, sociologists, philosophers and futurists in their studies talked about the upcoming transformations of society and its individual components. The founders of this concept were A.J. Penty (Penty, 1922) and D. Bell (Bell, 1967), who, as the main agent of these changes, considered the level of technological development of society, in particular, the method of production. E. Toffler called such transformations “technical revolutions” and in the book “The Third Wave” (Toffler, 1980) described in detail the current and future technical, economic and social transformations, calling the new period of development of society – post-industrial, and the previous ones: industrial and agrarian (pre-industrial). The industrial revolution was followed by scientific and technological, which entailed a complex of changes in society. If in industrial society the main driving force was labor productivity, now human capital has come to the fore. For most post-industrial or those that are in the process of transformation to post-industrial cities of the world, the predominant mechanism for replenishing the quantity and quality of human capital is migration in all its manifestations. Perhaps the most important and visual form of migration during the post-industrial transformations of the city is migration from the periphery to the center, if we consider the city as part of an agglomeration, and from the center to the periphery, if we talk specifically about the city itself.

Demographic transformations have formed a territorial unevenness in the settlement of Ukraine, since the density of urban and rural populations varies significantly against the background of the

concentration of significant economic and labor resources in cities and territories adjacent to them with high economic activity. The processes of polarization of socio-economic development of settlements in the center-periphery direction on the background of depressiveness of rural areas and small towns due to a significant outflow of youth.

In the middle of the twentieth century among economists, the "growth poles theory", was emerging. Jacques Boudeville (Boudeville, 1966), continuing the idea of François Perroux (Perroux, 1970), in his studies, in addition to focusing on the particular concentration of enterprises in certain industries, an important role is given to the territory in which this concentration occurs, calling large industrial cities the main "growth poles" of the territory. For the first time, based on the "growth poles theory" urbanization processes are analyzed by H.R. Lasuean (Lasuean, 1969). In his opinion, the regional node of enterprises associated with the export of the region may be the "growth pole"; "growth poles" grow due to impulses generated by nationwide demand, these impulses are transmitted to peripheral secondary industries through market saints and connections between enterprises, taking into account the factors of their location. In addition to this, P. Pottier (Pottier, 1963) noted that territories located between "growth poles" and providing transport links receive additional development impulses due to the growth of cargo flows, the spread of innovations, and the development of infrastructure, thereby turning into development axes (corridors). Such territories are suburban areas of cities and settlements that are part of the agglomeration.

A critic of the "growth poles theory" was J. Friedmann, who associated the concept of a "growth center" directly with geographical space, and his concept of "center-periphery" suggested that the uneven economic growth of the regional system and the process of spatial polarization create imbalances between the center and the periphery (Friedmann, 1979). In the process of relations between the center and the periphery, the center constantly dominates due to the emergence of innovations and the constant use of resources from the periphery, including human resources, increasingly generating migration from the periphery.

Center-peripheral and peripheral-center migration of the population is a subject study of socio-economic geography, economics, sociology and political science, since they affect various components within the socio-territorial system, therefore, they need an integrated approach to their study. Within the framework of human geography, this approach is widely used in the works of W. Crystaller (Crystaller, 1966) and C. Friedmann (Friedmann, 1966), and in the center-peripheral concept of A. Frank, the center is seen as a concentration of economic political, military power that exploits the peripheral regions.

Presenting Main Material

Suburban zones have long been formed around large cities, the relationship of which with a large city is greatly enhanced. This connection is manifested mainly due to the migration of the population, since large cities are a system of concentration of production, investment, intellectual, educational and other resources, which allows the population to get better job opportunities, increase their own incomes and receive quality social services. One of the striking examples of the city-growth pole, which is at the stage of transition to post-industrial development in Ukraine, is the city of Kharkiv, in the past a powerful industrial city.

According to the legislation of Ukraine, the main criterion for the status of a city is a population of at least 10 thousand inhabitants, and 2/3 of the population is employed outside agriculture. In this regard, in the Kharkiv region there are 17 cities, 7 of which are cities of regional subordination (Cities and areas…). The increasing role of cities is evidenced by the fact that the urban population over the past 30 years has increased from 78.6% to 81.0% (Fig. 1) (Cities and areas…).

Kharkiv agglomeration is the second largest agglomeration of Ukraine, located in the Kharkiv region, formed around the city of Kharkiv. According to the "Demographia World Urban Areas", in 2019 Kharkiv agglomeration takes 340th place in the world with a population of 1,585 million people and a population density of 4,000 people/km² (Ukrainian society: the migration dimension). 54.04% of

the total population of the region lives in Kharkov, no more than 5% in other cities of the region, this indicates the monocentric city of the Kharkiv region. The centers of spatial distribution of the population of the Kharkiv region depend on the number of people in the city of Kharkiv (Fig. 2). This is especially true of the arithmetic center and the center of gravity of the population. The calculations presented on the map of Figure 2 indicate that the regional center – the city of Kharkiv – Is the center of gravity of the population of the region, and the maximum concentration of the population is in the neighboring administrative regions of the region. Thus, around Kharkiv – the "center", a "semi-peripheral region" was formed – the Kharkiv, Chuhuiv and Zmiiv districts, and the rest of the region is the "periphery".

In contradistinction to the cities and districts of the Kharkiv region, which lose their population every year, the population of the city of Kharkiv due to the influence of migration processes decreases slightly, since the city is a center of regional attraction for potential migrants from smaller cities and villages of the region and other regions of the country. The relatively high migration attractiveness of Kharkiv as a regional center is naturally caused by a high level of socio-economic potential, a better situation on the labor market, a large concentration of training and research centers, industrial enterprises and service organizations, which, in turn, causes the formation of new labor flows and educational migration to the city (Ukrainian society: the migration dimension). These two types of migration (labor and educational) can be called one of the most important signs of the transition to the post-industrial development of the city (Suptelo, 2019). Moreover, the scale of migration flows could be of different levels, both international or interregional, and local, within the city itself.

Figure 1: The dynamics of the urban and rural population of the Kharkiv region for the period from 1989 to 2019 (built by authors according to the (Cities and areas of the Kharkiv region in 2018)

In 2018, the migration balance of the population in Kharkiv was positive in the amount of 5755 persons. Emigration from the city amounted to 22,736 people, immigration – 28,491 people. Mostly among immigrants, a population of 18 to 50 years old, that is, an active working population predominates (Kharkiv region in 2018. Statistical Yearbook). Thus, the migratory replenishment of the young population to some extent compensates for the depopulation losses and the scarcity of regional labor markets, which creates favorable conditions for the socio-economic recovery of the city.

One of the positive effects of migration processes in cities is the centralization of human resources, which is manifested in the territorial concentration of labor and intellectual resources. The greatest potential for the development of human capital, in our opinion, is concentrated in such a group as applicants and students, since it is they who are promising qualified personnel, therefore the effectiveness of the socio-economic system depends on the quality and quantity of this group in the region. The reason for the migration of young people from the regions and the reason not to return is the location in the city of 52 higher education institutions (Fig. 3).

Figure 2. The spatial distribution of the population of the Kharkiv region as of January 1, 2019
a) taking into account the city of Kharkiv, b) excluding the city of Kharkiv)

Figure 3: The dynamics of the number of students in the Kharkiv region and in Kharkiv

In Ukraine, there is no comprehensive data on internal educational migration, although a certain part of the information is collected at the national level. So, in the Unified Electronic Database on Education of the Ministry of Education and Science of Ukraine, admission commissions of higher educational institutions enter data on enrollment in the first year of full-time education for residents of the region where the educational institution is located, as well as residents of other regions. However, in the Register of subjects of educational activities, these data are not freely available (in particular, separately for higher educational institutions and regions), which complicates detailed monitoring of youth migration flows.

Since there are no statistics on the volume of educational migrations between and within regions, it is reasonable to use the indicator of the number of visiting full-time students who need to be accommodated in a hostel, which can be used for approximate volumes of migration in the region. Of the total number of enrollees in Ukraine who needed a settlement, 15% were settled in hostels in Kharkiv and the region. 49.5% of all city enrollees are directly from Kharkiv, 50.5% are residents of the Kharkiv region, other regions and foreign students (Official website State Statistics Service of Ukraine).

According to the data on educational migration, in 2018, 90% of all school graduates began to study in their region, 10% chose another region for higher education, mainly Kiev, Dnipro, Lviv, Odessa, and some of the graduates wished to receive education abroad. Of the 32871 enrollees who entered higher educational institutions of the Kharkiv region in 2018, 5941 were residents of other regions of Ukraine, which makes up 18% of all enrollees. The increase in applicants in the Kharkiv region occurred mainly due to migration from the Luhansk and Donetsk regions, which in 2018, 45% and 35%, respectively, which were selected by higher educational institutions of the Kharkiv region (Official website Kharkiv Regional State Administration).

In order to identify the positive impact of population migration on the development of the city, we created a periodization of migration processes in the city of Kharkiv, depending on the functions that the city performed at different periods of the development of society (table 1). It should be noted that throughout the entire period of the city's development, labor migrations predominated, only during the period of pre-industrial and industrial development of the city were these mainly migrations from the central regions of Ukraine and the peripheral regions of the Russian Empire, and post-industrial -

peripheral migrations from the districts of the region, having the form pendulum migrations. With the opening of Kharkiv University in 1805, the city became the center of educational migration. These two types of migration (labor and educational) prevail in the city to this day, replenishing the city with highly qualified labor resources. Since 2014, the population of the city is replenished by internally displaced persons from the Donetsk and Luhansk regions, which are also potential resources for the socio-economic development of the city, having a certain financial, economic and intellectual potential (Niemets, Husieva and etc., 2018).

Table 1: Periodization of migration processes in Kharkiv (compiled by the authors (Bahalei, Myller, 1905; Mazurova, Virchenko, 2014; Niemets, Husieva and etc., 2020))

Period	City functions	Types of migration and composition of migrants	Migration attractiveness factors
Pre-industrial (agricultural)	Defense	Forced migrations due to war and peace – the heirs of the Cossacks and the military of the Moscow state	On the ruins of the Wild Field appears Kharkiv Fortress – the defense center of the Moscow state; the beginning of the construction of roads that connected Kharkiv with Poltava, Sumy, Moscow
Industrial	Administrative, industrial, transport	Voluntary labor migrations, forced labor migrations, both permanent and episodic, educational migrations.	Transformation of Kharkiv into a large provincial city; opening of Kharkiv University; development of trade fair and crafts; the beginning of the development of the financial, commercial, cultural and educational spheres of the city; expansion of urban development; open rail links; the emergence of the first educational institutions and the development of theater, cinema, art. Kharkiv – the largest transport center with a high level of economic development, attracts workers to industrial enterprises and service industries; wide connections with the Donetsk-Kryvyi Rih region; the availability of jobs; Kharkiv is the first capital. During the Second World War, the city suffered tremendous damage, many enterprises were irrevocably evacuated or destroyed, so in the post-war period a large number of both the local population and migrants were sent to restore the city.
Post-industrial	Multifunctional center	Educational, labor, both permanent and pendulum, forced migration of immigrants from Donetsk and Luhansk regions	Departure of industry to the 2nd plan, priority development of the services sector: financial sector, trade; the development of high-tech industries; IT industry, a high level of development of science, education (Kharkiv is the student capital of Ukraine), positioning the city as a Smart city; wide transport links both within the city and with the periphery attracts a completely different qualitative composition to the city. This is mainly a young population with a high level of education.

Conclusions

Of course, the level of development of the territory affects the qualitative and quantitative composition of the population, which changes under the influence of both natural and mechanical movement of the population For countries and territories that have moved to a post-industrial level of development, a feature of population reproduction processes is a reduction in natural growth and an increase in migration flows. The main reason for the reduction in the rate of natural growth is the ability of the population to comprehensive development and self-realization. At the same time, this is the main factor in the migratory attractiveness of the territory. The transformational processes of the territory in the economy and technical features of production are primarily displayed on its population, at the same time. The population itself is the agent of these transformations.

For Ukraine, the Kharkiv region and the city of Kharkiv, in particular because of events in the east of the country, are strategically important for the development of the country's economy. As a powerful industrial city in the past, Kharkiv is now at the stage of an active transition to post-industrial development. At the same time, not only the features of the economic life of the city are changing, but also the composition of its population. As for most other post-industrial cities, in Kharkiv, migration flows change the composition and quantity of the population more intensively than the processes of natural population growth.

Compared with other cities in the eastern region of Ukraine, Kharkiv is a rather young city that developed intensively and changed its functions (Table 1), while the composition of the city population changed. A retrospective analysis suggests that it was migration processes that had the greatest impact on the population of the city. The relationship between the level of development of the city, its functions, features of migration and its direction is also traced. In the Kharkiv region, Kharkiv has always been a “pole of attraction”, both economically and demographically. In the first two periods: pre-industrial and industrial, as for most cities in eastern Ukraine, the prevalence of labor migrations, both forced and voluntary, as well as migrations due to war and peace, was characteristic. The duration and extent of such migration flows were mostly constant. In the modern post-industrial period, the causes of migration in the Kharkiv region have not changed, their nature has changed. Labor migrations have become predominantly pendulum. Educational migrations were added, which in most cases from a temporary phenomenon develop into a permanent one, students do not return, but remain in the city for permanent residence.

Given the fact that more than 50% of the region’s population lives in Kharkiv, one cannot ignore its impact on both economic and migration processes. Supporting the main theses of the concepts of “cent-periphery” and “growth poles”, it can be argued that for the Kharkiv region and Eastern Ukraine the city of Kharkiv is a “center” and a “growth pole” in which the maximum number of population and production, which is migratory, is concentrated attractive and attracts all kinds of innovations in production, economics, science and education.

At the same time, a number of unresolved issues remain in need of further research. First of all, these are the problems of methodological support of migration studies at the local and regional territorial levels, associated with the lack of most of the necessary statistics on the number, quality of migrants and the direction of migration. Available statistics do not provide a complete picture of the impact of migrants on the development of individual sectors of the city’s economy. To obtain such information, most likely, it is necessary to apply sociological research methods.

Linking migration with the transition of the main city of the region to the post-industrial stage of development, it is necessary to study these processes on a city-wide scale. The results of such studies, on the one hand, will confirm or refute the theory of its post-industrial transition, and on the other hand, they will give an idea of the pattern of population distribution. Until the post-industrial transition is completed, the city is under threat in optimal development: from full-fledged industrial development to the complete decline of the city. In their further research, the authors intend to

reasonably consider the indicated options based on an interdisciplinary approach, drawing up conceptual models of possible development directions

Abstract

Migration of the population is becoming increasingly important, their directions are diversified. There is an increase in the volume and impact of migration on the population, economy, culture, and politics of almost all countries of the world in the 21st century. The migration crisis has become a major challenge for the European Union and has disturbed its integrity, because every state has interests that do not always coincide with the needs and interests of the EU as a coherent integration union. Migration challenges of the 21st century regard many European countries, affect their stability, determine the relevance and timeliness of migration studies, taking into account the geopolitical, demographic, sociocultural and economic capabilities of countries. They require studies of the causes, volumes and consequences of migration processes, as well as their impact on security and social transformations, which can be useful to increase the effectiveness of migration policy both within one state and at the interregional and global levels. This publication analyzes the positive and negative socio-economic effects of migration processes for both recipient countries and EU donor countries. The spatio-temporal features of migration processes in the EU countries are determined, push-and-pull factors, migration movements are determined based on the analysis of official data and analytical reports. The main migration trends are investigated, the socio-economic consequences for the countries of departure and acceptance of migrants are determined, measures to resolve the migration crisis in the EU are identified. The experience that will be gained depending on the success of these issues in the European Union will be of great value for the further development of the world society, the world economy, the movement of labor and the international division of labor.

Keywords: Migrants, Migration, Migration Crisis, Positive and Negative Migration Effects, Migration Policy, European Union.

Relevance of the research topic

Intensification of migration processes is observed in the world, which has led to significant social changes and shocks in the last ten years, especially in the most developed and developed countries of the European Union. The relevance of this study determines the powerful economic, social and political effect of migration processes in the countries of the European Union. Of great interest are interregional and interstate migrations in modern scientific research, the result of which can be significant economic consequences not only for countries in which there is significant emigration of the population, but also for those states in which there is immigration of the population from other countries. Changes in the structure of the population, social characteristics and the relationship between the strata of the population emerging as a result of migration open up new opportunities for states that accept migrants to solve existing problems, and at the same time create a whole series of new social problems and conflicts. The emerging issue of changing migration policy has become a very serious challenge for each state of the world's largest integration association. The experience that will be gained depending on the success in resolving these issues by the European Union will be of great value for the further development of world society, the world economy, the movement of labor resources and the international division of labor.

Analysis of previous studies

Studies of individual aspects of migration processes in the European Union and its individual countries are sufficiently covered in the scientific literature. The issues of migration processes in the EU are presented in the works of B. Dmitruk [2], H. Lutsyshyn [11], O. Malynovska [12], M. Martsinyk [1], R. King, E. Zontini [17]. This topic was also discussed at previous IBIMA international conferences. In particular, the determinants of migration flows from the «new» member states of the European Union to the «old» member countries of the European Union, which have accompanied the process of enlargement of the European Union since 2004, followed by the liberalization of migration by removing restrictions on labor markets at different time periods in different member countries represented in the work of S. Franca, A. CehCasni, A. Barisic [5]. Demographic effects of labor migration in European countries presented in the work of researchers A. Cristea, D. Cristea, A. Bobocand, E. Samoila [1]. Features of the impact of the refugee crisis on EU economic diplomacy are analyzed in the work of A. Ilieand, D. Dumitriu [7]. An analysis of the dynamics of labor force and population employment in the European space, as well as the implications for the Romanian labor market was discussed in a scientific study of M. Stefan, M. Oancea, A. Diaconu, O. Buzoianuand, M. Mitrita [20]. Some issues of migration processes in the world and in Ukraine in particular were discussed by us at previous IBIMA conferences [15, 16, 18].

The purpose and objectives of the study

This publication identifies the positive and negative socio-economic consequences of migration processes for both recipient countries from the EU and donor countries. To carry out the study, the tasks were set to establish the spatiotemporal differences of migration processes in the EU countries, determine pushandpull factors of migration movements, consider the main trends, determine the socio-economic consequences for countries of departure and acceptance of migrants, determine measures to resolve the migration crisis in the EU based on analysis of official data and analytical reports.

Information base and research methods.

The information base for the analysis of migration processes in the EU countries is official data of European Union [3], United Nations (UN) [21], United Nations High Commissioner for Refugees (UNHCR) [23], United Nations Fund For Population Activities (UNFPA) [22], International Organization for Migration (IOM) [9], International Labour Organization (ILO) [8], open data of Eurostat [4] and Migration Database [10], analytical reviews, reports, scientific articles, data from

sociological studies, materials from the specialized and socio-political press, and the results of our own research by the authors. In the research process, analysis and synthesis methods were used (to identify the structural features of migration processes), systematization (to group the positive and negative effects of migration), a comparative historical method (to identify the dynamic features of migration processes in the EU countries), a comparative geographical method (to identify regional differences in migration processes and EU countries), generalization method and others.

Main Exposition

There are several directions of migration in the European Union now. In general, only a small fraction of Europeans migrate to North America, and all other migrant flows are directed to the EU.

The main directions of migration flows in the European Union, which can be represented as follows [19]:

- from the Middle East through the Mediterranean to Greece, Italy, Spain, and then to Hungary, Germany, France, Great Britain, Sweden;
- from Eastern Europe to Central Europe;
- from Central Europe to Western and Northern Europe;
- from Western Europe to Canada and the USA;
- from the countries of the Balkan Peninsula to Central and Western Europe;
- from the countries of the Baltic region to Western Europe.

It should be noted that the magnitude of migration from Eastern, Central and Southeastern Europe to Western Europe was very large in 2000-2010, after which there was a decrease in their intensity. This is confirmed by data on changes in the working-age population of individual states as a result of emigration. There was a recession of more than 3 % in Lithuania, in Latvia – by 2 %, in Poland - almost 4 %. The global economic crisis slowed down the pace of mechanical movement in Europe itself, but it had almost no effect on migration from North Africa and the Middle East [9, 13]. In general, migrations from the countries of the Middle East have received the greatest intensity in recent years [14]. In addition, the intensification of forced migrations over the past ten years is typical. Note that the most attractive regions for immigrants, including refugees, are among the countries of Europe and the Middle East: Western and Northern Europe, including Germany, France, Austria, Denmark, Sweden. The transit states include Spain, Italy, Portugal, Malta, Greece, Bulgaria, other Balkan states and Hungary. Bulgaria, Romania, Slovakia, Croatia, Hungary, Czech Republic, Poland, Lithuania, Latvia, Estonia are considered to be the countries where emigrants predominate. These states are the least attractive for migrants and pursue such an economic and social policy that gravitates toward the countries of Western Europe, one of the world development centers [19].

The positive investigation of migration processes for the economy can be evidenced by information from countries that have become new members of the European Union after 2000: unemployment rates have declined there since 2007. But in this case the main factor is the migration of citizens from these states to the more developed states of Western Europe. The decrease in the number of unemployed is due, first of all, not to changes in the domestic economic policy of these states, but to the departure of people to work in Germany, France, Great Britain, Spain, Portugal, Italy, Sweden. The positive role of economic transformation through membership in the European Union should not be reduced, because the sharp economic growth in the new EU member states has led to the phenomenon of reverse migration.

The report of the Special Rapporteur on the human rights of migrants of the UN General Assembly highlights the results of recent studies by scientists at Oxford University, which found that an increase in the share of migrants in the low-skilled labor segment by 10 % reduces wages in these professions by only 2 %. It is also noted that such a decrease in salaries can have a positive effect: University of California researchers studied the labor activity of refugees who arrived in Denmark from 1991 to 2008, and found that migrants really drove the poorly educated indigenous population

out of the low-paid professions. But instead of staying on unemployment benefits, most of the citizens who were laid off found places with higher wages [21].

A new migration problem can be attributed to the refusal of new migrants from the Middle East to return to their homeland if a stable peaceful political and economic situation is established in the states from which they came. The experience of previous migrants will not be very useful in assessing the impact of the current wave of refugees on the European economy. Migrants in Germany have become an additional burden on the budget in past years, because among them there were many pensioners. The current migrants from North Africa and South-West Asia are mainly young people, which means they will work for a long time throughout their lives. It is these immigrants who require a special political and economic approach to satisfy both their needs and the needs of the indigenous inhabitants of the European space [9, 14].

Both positive and negative effects of migration processes from the positions of the European Parliament, EU leaders and leaders of the governments of the participating countries are highlighted. Among the positive results (fig. 1) are the solution to the demographic problems of depopulation, the solution to the problems of the lack of cheap labor resources (following the concept of a new demographic transition), the solution of economic problems and overcoming crisis phenomena in the economy (in particular, the prevention of economic stagnation).

Fig. 1: Effects of migration processes for recipient countries (summarized according to [2, 3, 11, 12, 14, 17, 21])

At the same time, experts identify a significantly larger number of negative effects of the influx of refugees: despite the solution of some demographic problems, others may appear, the basis of which is a significant change in the national composition of member states with a decrease in the influence of state-forming nations. The spread of terrorism, interethnic and religious conflicts, a decrease in the general income level of the population (disproportionate increase in income and population growth rate (including – children and older people)), as a result, the public reaction to such a change will be impoverishment of the population, increase in unemployment. The cumulative negative impact will result in a violation of the integrity of the European Union. Most of the projected consequences have been fully or partially confirmed, and some influential states intend to exit the European Union (Great Britain).

The effects of migration on the countries of destination can be considered. The positive effects include a decrease in social tension, because there is a decrease in the pressure of excess labor. As a result of this, the solvency is partially increased, but the most important factor in this case is the

receipt of funds that citizens earn abroad. If a migrant returns, he is an important skilled worker. Negative consequences have an impact: the loss of most of the qualified resources (young people usually do not plan to return), the decrease in investment due to the loss of investor confidence in the reliability of their investments. The loss of part of the national income occurs because migrants produce goods and services for other states, which also increases the competitiveness of other states, especially if the migrant is highly skilled worker.

Fig. 2: Consequences of migration processes for donor countries (summarized according to [2, 3, 11, 12, 14, 17, 21])

Migration problems in developed countries were exacerbated at the end of the twentieth century, but current migrants have completely different qualities than those that prevailed until 2010 [3, 10]. It was believed that globalization should solve this problem, because the disappearance of borders should not cause intolerance in a tolerant society. But in reality globalization exacerbates existing interethnic, national, and religious conflicts. The modern migration wave is a direct consequence of globalization and one of the types of reactions of other civilizations to the spread of economic, political, cultural influence of the European Union and the USA. An example of the transition of regional problems to the global scale are migrants, who migrated to them in connection with military operations and economic problems and generate crisis situations in their territories.

The main problems associated with migration processes include cultural inequality, the problem of integrating migrants into the European community, and lack of consensus on the issue. It is the fundamentally different positions between the states that are the reason for such a long search for a solution to the migration crisis. Some states are in favor of introducing a hard migration policy with

full control over irregular migration processes and emphasizing the unification of the procedure for returning irregular migrants to the donor country [11, 21].

The emphasis is that the cultural and social integration of migrants always has two sides: it depends not only on the desire or unwillingness of the newcomer to integrate into society, but also on the attitude of society itself towards it. Recently, the attitude of society towards migrants of a new wave has intensified, which is one of the decisive indicators of the possibility of further acceptance of illegal migrants and their legalization as refugees. The difference between EU residents and refugees is too big at the civilizational level. This led to the consideration of several ways of integrating migrants into the European community, which present opposing views on the migration problem:

- isolating migrants through the creation of closed ethnic and religious communities;
- assimilation, which goes through complete voluntary identification with European culture (speech, mentality, religion).
- multicultural approach: immigrants receive the same rights and privileges as a citizen of any state within the EU.

The first approach is a partial restriction of the rights of migrants, therefore, it cannot be used to conduct migration policy at the regional level. The EU is trying to maintain a multicultural approach, which is the best option for refugees, but there is increasing support for ultra-right, nationalist movements in society. These include organizations such as «SYRIZA», which is significantly represented in the Greek Parliament, the National Front (represented in France and the European Parliament). Radical-nationalist parties in the elections to the European Parliament received more than 14 %, which was an important indicator and a signal to search for new approaches that would satisfy everyone [3].

The priority is to strengthen the protection of the external borders of the EU among further actions aimed at solving the migration crisis. This task was determined by the European Council. The result of this decision was to check the activities of the Rapid Response Teams regarding the violation of the external borders. With the help of such a decision, it is planned to overcome illegal migration and remind everyone, who plans to immigrate to any country of the European Union, about the opportunities provided to legal migrants. The result of the migration crisis is an increased focus on border protection, which indicates the beginning of the dominance of more radical positions that have been lobbied by states such as Hungary, Slovakia and the Czech Republic [3, 11, 19]. Migration problems and methods for solving them will become those indicators with the help of which tests of willingness to yield to interests will continue to be tested in order to find a compromise and make informed decisions.

The results of the study

Migration processes intensified in the late 1990s, but by 2010 they had a regional aspect: most of the migrants were from Europe. Immigrants from the Middle East began to prevail among the immigrants only after 2010. After the influx of migrants from South-West Asia and North Africa, including refugees and illegal migrants, into the European Union in 2015, the economic and domestic political situation intensified. It was called the «migration crisis». Some states have come out of the demographic crisis, but new problems have arisen: the unstable economic and labor market conditions, the rise of terrorism, cultural, ethnic and religious conflicts against the background of the general consolidation of migrants on religious and ethnic grounds. The increase in radical nationalist and separatist movements was a reaction to multicultural politics. The continued existence of all countries in harmony and unity was threatened [9]. Several mechanisms were proposed to stabilize the migration crisis, none of which found full support in society, since most of the representatives of indigenous nations believe that this violates their rights, national and cultural identity. An important and promising is the study of the impact of refugees on the national composition of the population, changes in the role of the state-forming nation in world globalization processes and social resistance to such changes. Ideas for integrating migrants from Syria, Iraq, Libya, Algeria, Afghanistan, Iran,

Morocco into the European space so far remain only ideas, therefore, conflicts in society will arise with periods of powerful exacerbations [3]. The experience of the European Union as a leading integration entity will become an example for all other countries of the world and regional organizations, including Ukraine, which is part of Europe and announced its intention to become a member of the EU in the future.

Abstract

One of the most important aspects in the evolution of the human being is the use of tools that simplify his physical work. The man imagined intelligent mechanized devices that would take over a significant part of the physical effort. Thus, he built automatic toys and intelligent mechanisms or imagined robots in "SF" drawings, books, movies. In general, robots are a class of technical systems that mimic or substitute human motor or intellectual functions. This is achieved by combining different types of handling systems or locomotives, determining the anthropomorphic character of the robot, with different types of computing or logical equipment, which determines its intellectual functions. Robots operate in a specific environment, whose characteristics may remain constant or variable over time. The proposed application is a variant of experimental study with signal acquisition for a uniform rectilinear motion where the LabView package and a DAQ U 6008 data acquisition board were used as a programming medium, with particular emphasis on the movement and speed control.

Keywords: Driving System, Mobile Robot, Microcontroller, Programming Controller, Sensor System.

Introduction

An advanced industrialized society requires a flexible automation of the production processes. Given that industrial robots are flexible and versatile, providing freedom of movement similar to those of the upper limb (human-arm), their use ensures a number of economic and social benefits. These include: increasing productivity, humanizing labor activity in heavy sectors of production, preventing accidents at work, increasing product quality and speeding up investment.

A study by the British Robotics Association (BRA) shows that Japan ranks first among the industrialized countries in the production and use of robots in industry, a situation confirmed by the American Institute of Robotics (RIA), which states that even excluding robots with manipulation simple, the base of robots used in the Japanese industry remains three and a half times greater than the American one. Only the production of industrial robots of the company " MOTOMAN ", in 1991 was 500 robots / week, the installed capacity of the company being 1.000 robots / week.

After RIA and BRA one can observe, nowadays, a strong upward trend, especially in USA, Japan, but also in Europe. In this sense, the problem of developing methodologies for testing robots as well as of a device for determining their performances was posed, especially since, at the time, this problematic issue was under study at the world level, with only a few norms, specific to some countries, with project character.

The robot is an automatic manipulation mechanism, serviced in position, reprogrammable, versatile and capable of positioning and orientating specialized materials, tools or devices, during variable and programmed movements, destined to perform various tasks.

The German standard DIN 2801 defines: "Industrial robots are mobile automatic with universal applications, with multiple axes, whose movements are freely programmed on the trajectories or angles with certain sequence of movements and in certain cases, controlled by sensors. They are

equipped with pre-tensioning devices, tools or other means of manufacture and can carry out handling and manufacturing activities. The industrial robot can be fixed, in one place or it can be moved to an assembly".

Japanese standards state: "The robot is a mechanical system, equipped with flexible motor functions analogous to those of living organisms or their imitations, with intelligent functions, systems that act according to human will."

The Robotics Institute of America (RIA) states that: "The robot is a reprogrammable, multifunctional manipulator, designed to move materials, parts, tools or devices through variable programmed movements, in order to perform different tasks. The robot is an advanced component of automation, which combines computer-type electronics with advanced mechanical actuation systems, to achieve highly flexible independent equipment. The robot is an equipment with automatic functioning, adaptable to the conditions of a complex environment - in which it evolves - by reprogramming being able to prolong, amplify and replace one or more of the human functions in its actions on the environment".

According to the definition of the British Robot Association (BRA), the robot is a reprogrammable device, made for manipulating parts, tools and other means of production, through variable, programmed movements, to perform specific manufacturing tasks.

Company A.S.E.A. from Sweden, in 1971, he produces the industrial robot with electric drive IRB6 for arc welding operations. In 1975, the Cincinnati Milacron (US) machine tool company built a family of industrial robots powered by T3 (The Tomorrow's Tool), now widely used.

In Romania, beginning with 1980 the first RIP63 robot was manufactured at Automatica Bucureşti after the A.S.E.A. model and the first industrial application with this robot was welding an electric arc of a component of the bus chassis and was made in 1982 at the Bucharest Bus. Another indigenous robot is REMT-1 used in a flexible manufacturing cell at the Timisoara Electromotor for cutting through the shaft of electric motors.

Statistics on robot types suggest significant increases in the number of robots responding to non-industrial applications. If during the year 2000 the number of units installed was 112.500, at the end of 2004 it was estimated that their number was almost 825.000. In these years one can said that the number of robots in the world has reached 2.000.000 units. This development, even spectacular, in the direction of non-industrial applications justifies the review in the following of the main sub-domains in which non-manufacturing robots or service robots can find their applicability.

These areas are: construction, rehabilitation of the sick, trade, transport and movement of goods, local administration, environmental protection and agriculture; surveillance, inspection, radiation protection and disaster intervention; hotels and restaurants; in medicine, household, hobby and leisure.

Rădoi, C. (1997) said that the robot is currently the point of intersection of the top results in a number of fields: mechanical, automatic, computers and drive systems. This congruence of so many different scientific and technological branches is explained by the special complexity of the robot, both in terms of mechanical architecture and in terms of the driving system.

Of course, the robot is the natural result of the evolution from the automated machine tools, the machines with program control, the automatic lines of manufacture etc. when their rigidity and inflexibility no longer corresponded to the current requirements of productivity and quality, and the man tried to execute direct, direct actions on the processes taking on a supervisory and control role. Therefore, the robot, as a result of these technical - scientific developments, can be defined as a technological system capable of replacing or assisting the human being in performing various actions on the machines or production lines. In this context, the complexity of the problems regarding both

the construction and the operation of the robots, and in particular their management, is evident, as Armas I. (2011) said.

The original contributions in this paper are making a Robot Driving System trying to implement to an Auto Platform, building a car concept able to officially compete in a Formula 1 race, for example.

Presentation of the Mobile Robots

The robot, the basic component of this system, consists of two parts: the information processing unit and the operational unit. The information processing unit is a compliant hardware-software that receives data on the instructions defining the executed operations, measurements on the status of the operational unit, observations on the operating space of the robot, data based on which it determines according to the established management algorithms, decisions on how to operate the operational unit. The basic function of the robot is represented by its movement in space, so the static and dynamic regimes of the mechanical structure will represent the starting point in defining the robot as a driving object, as Borangiu T. and Ionescu F. (2002).

Mobile robots represent, the most spectacular and representative category of mechatronic systems, especially because of the attempt to copy and approach the models of the living world. A mobile robot has a complex mechanical structure, drive motors that ensure movement in the environment, sensors that allow it to orient, identify and avoid obstacles and a "brain", consisting of one or more numerical processors, which provides control of the entire system.

Intelligent systems and control

An exact definition of intelligent control is still a problem today. In May 1993, the IEEE Control Systems Society's Technical Committee for Intelligent Control formed a working group to determine what attributes can be encompassed in the area of intelligent control, what features and what role intelligent control systems play, how to recognize them. systems and how they differ from conventional control systems and at the same time to identify those problems for solving which only intelligent control techniques give results. It was estimated at that time that a single definition would not be possible, given the multiple facets of intelligent control, so several points of view expressed by specialists were analyzed and debated in order to extract the essential features.

The notion of "intelligent control" cannot be debated outside that of "intelligent system", which in fact means a nuance of the term "intelligent" used in the two terms. In fact, this term is found in the specialized literature and in relation to "artificial intelligence". It is obvious that intelligent controllers are also designed to emulate faculties of mental behavior such as adapting and training (learning), planning in inaccurate conditions (uncertainty), associating various information. Perhaps an alternative definition to that of "intelligent control" could be that of "autonomous control", to underline the degree of autonomy that an intelligent control system must provide, as Berian S. and Maties V. (2011) uses in their research.

An intelligent system has the ability to act appropriately in incomplete defined environments, by appropriate action understanding an action that maximizes the probability of success, the success being the achievement of one of the partial objectives whose overall objective is the end.

An intelligent system can be characterized by a series of attributes, or dimensions. These are degrees or levels of intelligence. A minimum level would be that of the capacity for environmental recognition, decision making and action to execute them. A higher level of intelligence may involve the recognition of events or objects, their representation in a model (for example a knowledge base), and a long-term plan. The highest levels involve the ability to perceive and understand, to choose wisely and to act appropriately in all circumstances, including under hostile environmental conditions.
An intelligent control system must be designed in such a way that it autonomously achieves high-level objectives, even if the system or process-driven model and even the structure and objectives of

the system are not completely defined, either due to partial knowledge or unanticipated changes, as Dutta A. (2015) said.

According Margineanu I. (2005), a system is considered autonomous when it has the ability to act correctly in incomplete defined environments without external intervention over a long period of time. There are several degrees of autonomy, which could be associated with the control functions included in the intelligent control: a control system with fixed parameters has the minimum degree of autonomy; adaptive control systems have a higher degree of autonomy.

To the extent that a system has a higher degree of autonomy, it is accepted that it also has a higher level of intelligence. In order to differentiate the degrees of intelligence, other criteria can be adopted such as: the computing power of the system; the degree of complexity of the algorithms used for the acquisition, processing and evaluation of the data obtained from the surrounding medium; data storage capacity in memory. In most artificial systems, increasing the level of intelligence reflected by computing power and storage capacity is done by increasing the complexity of the hardware structures and thus can become an obstacle in the application either by too high a cost or by the impossibility of real-time processing of the stored information.

The Hardware Configuration

To realize these application one choose some hardware parts, which authors want to explain below.

Fig. 1: Internal block diagram of the PIC16F877 microcontroller

PIC16F877 microcontroller

The manufacturer best placed on the PIC microcontroller market is Microchip. Another major manufacturer of PIC microcontrollers is Motorola. There are several families of PIC microcontrollers: PIC12, PIC16, PIC17, PIC18. The microcontroller used in this application is PIC16F877, like one presented in figure 1, from above, like Patic P. C. and Zemouri R. (2018) said.

Proximity sensor SHARP GP2Y0A21YK

GP2Y0A21YK, used in this application, is an analog proximity infrared sensor. It can be used to detect obstacles. This sensor has an LED that emits infrared waves. The infrared wave has an interesting property to reflect on the surface of objects. In front of the sensor, near the infrared emitter, is a photodiode sensitive to infrared waves.

This will have a variation of the output voltage depending on the infrared train it will receive. Thus, the more it receives pulses, the closer the object is to the sensor and the output voltage generated by the photodiode is higher, like Munteanu O. (2003) said.

Configuration: High immunity to ambient light and color of objects; Does not require control of the external circuit; The sensor includes mounting bracket; Compatible with ATMEL and Microchip microcontrollers; Digital output; The duration of the LED pulse cycle is: 32 ms; Range of action: from 10 to 80 cm; Response time: 39 ms; Delay on start: 44 ms; Power consumption: 30 mA; The diameter of the detection area at 80 cm: 12 cm.

Applicability: Robotics, Television, Personal computers, Cars, Copiers.

Calibration: Because the output of the GP2Y0A21YK sensor is not linear, one must determine in a way which distances correspond to certain voltages. A variant of sensor calibration is to measure the output voltage of GP2Y0A21YK at fixed distances, in centimeters. Once the authors get this information one will know what the voltage is given by the sensor in relation to the distance it is to an object.

Interconnection of the GP2Y0A21YK sensor with the PIC16F877 microcontroller

If the output voltage is connected to a microcontroller with the possibility of converting from analog to digital, such as PIC16F877, it is possible to transpose this voltage into numerical values. Figure 2 shows that these values can be used to determine whether or not there are obstacles near the sensor and how far they are from the sensor.

Fig. 2: The GP2Y0A21YK sensor. The characteristic of the distance to the output

A brief overview of the Lab View programming environment

LabVIEW is a programming environment used especially for measuring and monitoring automated processes. For writing programs in LabVIEW, the graphical language G, 5th generation programming language is used, the LabVIEW environment containing several predefined function libraries for data acquisition, processing, display and transmission.

According with Borangiu T. and Dumitrache A. (2010), the programs created in the LabVIEW environment are called, as I mentioned above, virtual tools (IV). An IV has three component parts:

- Front panel, as one shown in figure 3, the left one;
- Block diagram, as one shown in figure 3, the right one;
- Icon and connector, like one presented in figure 4, as example.

Fig. 3: Block Diagram in Labview

Fig. 4: Example to measure temperature, using Labview Interface

In figure 3 and figure 4, from above one tried to represent software interfaces used to develop presented application.

Robot Driving System Applied to an Auto Platform - General presentation

In a research study by Cojocaru M. G. (2010) the movement control, of the application is made according with next figure, presented below, in figure 5.

Fig. 5. Application interfaces for movement control

Fig. 6. The block diagram of the application

The Block diagram of application was shown in figure 6.

The proposed application is a variant of experimental study with acquisition of signals for a uniform rectilinear motion. In the real system, the mobile is a car that moves in a circuit of Formula 1, for example figure 7.

Fig. 7. Application Interface for speed control

The sensors used to monitor the movement of the car on the rectilinear portion of the route are coils in which a voltage pulse appears during the passage of the mobile equipped with a strong magnet, underneath them. The DAQ acquisition board and Lab View programming environment were used to study the movement, as Patic P. C. and Zemouri R. (2019) said.

Fig. 8. Final application assembly

The final assembly of our application was shown in figure 8 and 9, where one discover the link between the mobile robot (the car) and the LabVIEW acquisition board.

Fig. 9: Final application assembly, top panoramic view

Conclusions

Most industrial robots and manipulators operate in practice under conditions known in advance, operating cyclically in accordance with the technological requirements imposed. As a result, it is possible to synthesize a nominal management, a programmed control, which implements the desired movement for a particular initial state considering that no disturbance affects the movement. Such control can be synthesized using the centralized (global) model of the robot. Since these models are, in general, quite accurate, it is expected that the trajectory achieved by the robot by exercising this control will be quite correctly executed. One consider that present practical realization can be used on auto platform for racing circuits and can provide an alternative to a multitude of these application, maybe more of them expensive, complex etc.

The synthesis of this control is usually performed offline by first defining the motion trajectory in accordance with the technological requirements of the robot's operation and then calculating the control quantities necessary for its operation.

This solution is generally unanimously accepted in the industrial applications of robots and manipulators, the off-line control calculation being carried out in a sufficiently powerful computer,

covering a large number of management systems, while the effective control of robots at the executive level it falls to the task of local machines, microprocessors or specialized microcomputers.
A special problem, in the synthesis of tactical control, arises due to the redundancy of the mechanical structure. This problem can be eliminated by introducing additional criteria that penalize and restrict the movement possibilities of the robot. In this way, optimal or suboptimal management meets on the one hand certain performance criteria and removes, on the other hand, the redundant management aspects. Obviously, such an approach requires an approach at higher hierarchical levels, the respective algorithms requiring substantial hardware and software support.

Driving robots by measuring moment-forces is also required in assembly operations when the robot comes in direct contact with certain objects. In this case, driving by force control allows a better adaptation to the fluctuations of the operating space parameters while also achieving satisfactory dynamic performances.

Abstract

Potential trafficking in Indonesia from the beginning until now unresolved problems. However, this happens because of a lack of attention and involvement of the government in anticipation of potential trafficking growing transaction mode via offline and online. This study aims to determine the form of anticipation and government involvement in suppressing the emergence potential trafficking of children and women to prevent the early occurrence of trafficking. Such engagement is defined in terms of regulation on the policies made by the government. The method used in this research is a descriptive qualitative approach by taking a sample in one of the provinces in Indonesia. Data were collected through observation, interviews, and documentation. The results show that in the context of regulation, government involvement is still very minimal. It is evident there is no single mechanism of rules that can be directed to anticipate the potential trafficking in Indonesia. As a recommendation the need for regulation and the action more real and touching at the root of the problems that exist in the entertainment industry.

Keywords: Potential Trafficking, Government Involvement.

Introduction

Indication of the phenomenon of trafficking, in the Kalimantan region refers to the results of previous research, it turns out the mapping of potential trafficking in South Kalimantan indications are quite clear, especially when seen from South Kalimantan region in the form of areas of the coal industry, the number of facilities that provide services hotel Cheap, karaoke parlors and entertainment venues, as well as being the region route providing dimly lit stalls or even prostitution. Of these factors are most susceptible to potential trafficking is an area of the coal industry which in the region is also facilitated by means of cheap hotels, entertainment venues and saloons, and also there is the area of prostitution, as well as dimly lit stalls (Mansur, H., 2019).

The setting of the problem of trafficking contained in the formulation of article 297 of the Penal Code which this chapter is the only chapter that regulates the trafficking of women and boys. While setting the law No. 23 of 2002 on the protection of children such as Article 68 paragraph (2); article 78; Article 83; Article 84; Article 85; and Article 88. In terms of protecting victims of crime, there are no rules on the granting of compensation to victims and witness protection in the criminal code. While the law No.

23 of 2002 on the protection of children also has drawbacks, among others: the type of sanctions / criminal, old criminal, and criminal threats formulation system. (Ambarsari, RR, Andiyansyah, FA, & Soewandy, AA, 2016).

If this understanding is used as a reference to assess whether there is trafficking in the region such as South Kalimantan, the opportunity and the indication in that direction have been there. This is supported by the results of the mapping is done in the field shows that in the area of the sample is no indication that there has been syndicated trafficking in the region. An indication of the results of the mapping of trafficking is seen from 1) places that are prone to trafficking, such as: hotels, karaoke-karaoke, salons and practice legal CSW (commercial sex workers), 2) the area crossing (transit), 3) The region's coal industry (Mansur, H., 2019).

As data on potential trafficking on previous studies have shown that in the region of the sample has a considerable potential for the emergence of trafficking. This has been indicated by some sectors that support the emergence of such cases. The purpose of this study is:

a. To determine the shape of local government involvement in anticipation of potential trafficking
b. To determine the activities that have been carried out by local governments on sectors vulnerable to potential trafficking.
c. To find out the attitude of local authorities to act to anticipate trafficking in Indonesia.

Referring to the above research objectives, the benefits to be gained from the study are as information for the public on what has been done by the local government in anticipation of potential trafficking, so that there are preventive measures that are preventive of society. Then the emergence of a permanent regulation of the local government, so that potential trafficking does not develop in Indonesia.

Literature Review

Foucault, Michel (1985) suggests that the potential for human trafficking, especially of children and women occur due to personal motivation and comfort just to be able to meet the demands of their daily needs. The renewal of social democracy should be followed up by local governments in efforts to improve the motivation and purpose in life is wrong to hold moral counseling (Giddens, 1999). Perspectives of people who sell themselves for the sake of momentary comfort and gain a bit of self-interest will be transferred to another person if it is not followed up by the local government in a planned and gradual (Haralambos, 1980). Perspectives of people who are happy to sell himself for a moment convenience and gain a bit of self-interest is referred to as an outbreak of social pathology (Kartini, 2001). Economic factors and poverty as a cause of trafficking practices located in the border area between Indonesia and Malaysia (Niko, 2016). Implementation of the model of social services tackle the problem of trafficking need to be developed by the local government (Dianayati, 2018). International cooperation in combating social service model and Illicit Arms Trafficking in Southeast Asia should be the reference implementation of design models preventing potential trafficking (Parici, AA, AK, S., & Idris, A., 2016). Model trafficking in Indonesia coping strategies have been implemented gradually in every province and district (Minin, 2011). The result is the handling of trafficking in East Nusa Tenggara run up through preventive measures by way endorse the rules or regulations of local governments related to the handling of potential trafficking. (Daniel, ESR, Mulyana, N., & Wibhawa, B., 2017). Efforts to tackle trafficking in the United States is something that is risky and requires the involvement of all elements of society and stakeholders (Fedina, L., Williamson, C., & Perdue, T., 2019). The black-market trafficking is a potential trigger perpetuating trafficking and alien smuggling (Hughes, DM, 2019). Unnecessary debates occur between elements of society who always blame the victims of trafficking, should be more focused on preventive measures through moral education (Kelly, L., 2019). Anti-trafficking organization in the Netherlands, revealed that there has been a new person trading model in the form of evasion of immigrants become slaves (Bruinsma, GJ, & Meershoek, G., 2019). The United States government crackdown on the fence / brokers cases of trafficking in persons (Soderlund, G. (2019). Victims of trafficking need to be further identified in the system of support which they can obtain physical and psychological treatment that is

needed (Sanchez, R., & Stark, SW, 2014). the development model of handling of potential trafficking need to be implemented in the regulation / International regulations that bind all citizens of the world, because of the potential trafficking occurred in almost all countries (Laczko, F., & Gramegna, MA, 2019).

Methodology

The research method is descriptive qualitative that emphasizes the recording element. Emphasizes qualitative descriptive methods to researchers to be able to describe on data and facts and be able to build the full involvement of the researcher (Muhadjir, 2002). Description The location was done by taking samples in the region of South Kalimantan in places such as nightclubs, hotels, and the area provides many crossing the dimly lit stalls. Data collected through library research, field research, interviews, and photo documentation. Data analysis technique is done by using interactive model approach developed by Miles and Huberman, with three procedures, namely data reduction, data presentation, and conclusion and verification.

Fig. 1: Model Interactive Data Analysis Techniques Miles and Huberman

Results and Discussion

One of the problems lately often discourse by many is associated with problems of children and women trafficking (trafficking) either mode both online and offline transactions. This is a pretty basic humanitarian issue. Preventive measures must be carried out with the involvement of local authorities, considering the development and deployment of this trafficking problems spread so fast. Trafficking in human beings have relevance to the issue of development where development gaps, cultural influences and exposure to globalization increases the vulnerability of people to trafficking in more developed regions. Since trafficking involving international criminal,

Human trafficking is happening in Indonesia due to many factors, among others: the conditions of the community that is not fully conscious, caring and knowledgeable enough about human trafficking, corruption that has access to the institution of legal government, and the low effort of legal instruments to combat human trafficking was own (Daniah, R., & Apriani, F., 2018). This is in line with efforts to protect victims of crime, there are no rules on the granting of compensation, and also for the protection of witnesses in the Criminal Code. While Law No. 23 of 2002 on the protection of children also has drawbacks, among others: the type of sanctions / criminal, old criminal, and criminal threats formulation system. One of the causes contributing factor is the lack of coordination and cooperation among members of the task force,

As revealed in the plan of action mandated by the national action plan for the elimination of trafficking in persons that tackling trafficking in addition to do with the integrated approach, should also be carried

out with a bottom-up approach that is considered as an approach to accommodating the aspirations from below by actually building the pillars of openness, transparency, open access to information, and develop a civil society based management in the handling of human trafficking. Based on previous research, that the South Kalimantan, there is the potential occurrence of trafficking who are at places such as karaoke, beauty salons, hotels, dimly lit stalls, and places of prostitution. Entertainment venues and the hotel is very prone to trafficking. Survey of the three places of entertainment (karaoke) like Grand Discotheque, HBI and Barito. The Ladies who work in three places of entertainment in Singapore are mostly from outside the region, such as Surabaya, Bandung, Jakarta and Manado (Mansur, 2010: 61).

As mandated by the Law of the Republic of Indonesia Number 21 Year 2007 concerning the Eradication of Trafficking as set out in Chapter VII, Article 29 Paragraph (1) states for the effective implementation of the prevention and eradication of trafficking in persons, the Government of the Republic of Indonesia is obliged to carry out international cooperation , whether they are bilateral, regional and multilateral. In the aforementioned article shall include the words mean this is a requirement by the government. The government is meant to be understood that not only the central government but also for the purpose of government is a government that Provincial, District and City. What was expressed by Head of Tourism, Culture, Youth and Sports of the the measures undertaken by the respective local governments. These measures, if linked to the Regional Regulation No. 20 Year 2008 on the Amendment of Regional Regulation About Licenses Public Recreation and entertainment, then it cannot be found in the rules on prohibitions or restrictions that can be categorized as a precaution against trafficking.

Governments in preventive medicine or anticipation should always refer to the clear legal umbrella. So that in every action there is an element of the amplifier. This is as expressed by the Head of Social Services Tanah Bumbu, that: "For places where prostitution like in Batu Ampar Batu Ampar I and II We always provide coaching and social counseling. One of our real effort is to provide health services to sex workers to always check their health to the officer. Besides coaching we are doing is in the form of mental guidance to bring the preachers. From the results of the coaching there are some who are aware and change their work ". Referring to the explanation, preventive measures to prevent trafficking, especially for places where prostitution has been no action is emphatic. The activities undertaken by the Government are the actions it has taken, but to anticipate in order to prevent (preventive) before referring to that direction.

Table 1: Result and Discussion

Factors	Description	Implementation
Regulation	There are no regulatory mechanisms preventive	The government will soon issue regulations / rules related to the prevention of potential trafficking by listening to the aspirations of the people and involve the relevant stakeholders
Government Involvement	Only limited guidance and counseling activities which are not effective	The government immediately organized the training for the prevention of potential trafficking by listening to the aspirations of the people and involve the relevant stakeholders

Conclusion

Referring to the findings and discussion we can conclude the government's involvement in the potential of trafficking in Indonesia are: In the context of regulatory involvement, government involvement is still very minimal. It proved none of the regulatory mechanisms that can be directed to anticipate the potential occurrence of trafficking. Regulation is in the form of rules in the form of Local Government Regulations or legislation but do not yet have the power to anticipate the potential trafficking, this is because the contents of the rule does not lead to preventive measures or anticipation of potential trafficking. Actions taken by the government against vulnerable sectors of potential trafficking, such as places where prostitution is still within the range of guidance and counseling to the perpetrators of prostitution, while for the indication has not been touched, or in other words the counseling that has been done is not right on target. In the broader sector, such as hotels and places of entertainment performed by the government is still within the limits of surveillance, but the sector is even smaller in scale that is dimly lit stalls absolutely nothing for any actions taken by the local government.

Acknowledgment

As an input that can be advised of the results of this research is the need for clear regulations, especially from the government in terms of the adjustment to the entertainment industries continue to employ women. The need for action more real and touching at the root of the problems that exist in the entertainment industry.

Abstract

The main purpose of the present paper is to identify new solutions for prevention and, at the same time, to stop certain actions whereby man leaves his mark on the natural space. Nowadays, the economic power has become greater than the ecological one, so that the man no longer appreciates the natural space and prefers to think about the benefits that he adopts for a short period of time, neglecting important aspects that in the long term produce certain disasters. natural. We have tried to highlight the most important issues that arise when man does not respect nature, but also its effects. We also analyzed the figures that appear in the statistical yearbook to see their evolution.

In the last part of the paper are highlighted the solutions that should be imposed to save the nature and improve the condition of the forests. Also topics from this paper such as the structure of the forestry fund, the distribution of forests on relief forms and climatic floors, but also on the functional groups will be reproduced and exemplified in the following.

Keywords: population, globalization, resources, biodiversity, earth, development.

Introduction

There is an increasing tendency in recent years, once the concept of sustainable development and management of forests in Romania has been introduced, namely that of regulating the forestry field in the defense of forest functions and on the national or state forest fund (Bran et al., 2019). It is a fact that we enjoy and choose these steps. However, there are situations when implementing the proposed measures, especially those with a financial character in the state budget (Jianu et al., 2019).

For example, ensuring from the state budget the amounts for forest management for owners with areas less than 100 hectares is new, as well as the fact that for owners of forests over 100 hectares, the necessary funds for forest management are insured. by them, if the management of the total national forestry fund, regardless of the model of ownership, is ensured by targeted and authorized forestry structures (Burlacu et al., 2018). This measure is not really implemented, it has been created a regulatory framework for implementation, but it depends a lot on the budget allocation (Dima et al., 2020). According to the analyzes that have been done on the cutting of trees in the last years, they have revealed that the owners with private properties did not provide an adequate protection from the sludge of funds, and out of about 500,000 hectares, 400,000 were already destroyed, according to certain reports of the Court of Accounts. This reflects a clearer regulation on the obligations of forestry operators made to reduce the effect of illegal logging. (Cogălniceanu, 2007).

The new forest code enforces the obligation to set up a conservation fund of its own regardless of who is the owner, which until now applies only to the administrator of the state steps, and thus obligatory is allocated funds for different things that are meant to ensure a regeneration. quality of the forest, as well as the afforestation and care of the trees that constitute it (Negescu Oancea, et al., 2019). Also, the introduction of the wood mass limitation, related to the annual possibility, represents an additional value compared to the regulations that were before and established this volume by which the government decided (Burlacu et al., 2019). All these regulations, which are considered welcome, concern only the surface on which the racial cuts are applied, which has decreased from 5 hectares to 3 hectares at the present time. Moreover, in natural and national parks, racial cuts are strictly forbidden, except in certain cases where natural regeneration can only be done through such cuts (Callicott, 1985). There are also some regulations that may be risky in our opinion and which endanger the integrity of the forestry fund, as for example: the permanent removal of some territories from the private forestry fund for the arrangement of housing or rental villas, detailed and unsatisfactory provision that can thus, it allows a massive fragmentation of the forests near the villages, or the law according to which the owners who have forest areas less than 10 hectares are no longer obliged to make forestry arrangements helps the small forest owners to use a quantity of wood up to at 3 cubic meters per year per hectare, but having a forest management contract concluded with a certain forest bypass, but here there is a quite high risk of abuses or violations in this context, this provision being discriminatory at a at a certain time and to a certain extent (Bran et al., 2018).

Perhaps a more efficient solution, which would ensure a complete control and record over the small properties, would have been for their owners to conclude a forestry arrangement at the level of the entire administrative territory of the belonging communes, which would constrain them as well. to hold everyone accountable and to be carried out by the mayors, from the budgets that are representative of this norm. (Moga & Rădulescu, 2005)

It should be noted that there is now a bureaucracy that is sharpened and quite stubborn in the process of approving and approving forest management, without the existing endorsement stages having decisive beneficial effects for the conservation and sustainable use of forests (Bodislav et al., 2019). The checks are based only on the written analysis of the documentation submitted by the companies specialized in forest management and most of the time the necessary checks are not performed (Alpopi et al., 2018).

Methodology Used

The methodology used in the work below is based on the study of the behaviors of forests in Romania and was taken for the analysis of the period 2017-2018 regarding the division by groups and species, but also by the phytoclimatic floors. The forests under evaluation will be constituted and delimited according to the norms in force regarding the establishment of indicators and criteria. In general, the plot boundaries should not necessarily overlap with the natural boundaries, and here we have bridges, valleys and secondary peaks or artificial boundaries such as railways, permanent roads. It also aims to identify by certain specific methods the surfaces that are anthropically affected and that meet the criteria of naturalness. At the same time, an evaluation of the indicators is done through a photo documentation, and depending on the case, certain biodiversity elements can be identified. By the presence of certain rare or exemplary species of forests with exceptional dimensions.

Elements of characterization of forests in Romania

The national forest fund of Romania is made up of all the forests, of the lands destined for afforestation, of those that represent aid to the needs of culture, production or forestry administration, of ponds, of streams, or of other lands with forest destination, even if they are not productive, included. in forestry arrangements as of January 1, 1990, including surface changes, according to certain operations performed in accordance with the law, regardless of the form of ownership. The national forest fund represents, as the case may be, a public or private space and is of good interest at national level (Rădulescu et al., 2018).

The total area of the national forest fund of Romania is about 6,564 thousand hectares and represents 27.5% of the country's surface. The European average at the moment is about 32%.

Source: IFN

Figure 1: Distribution of forests by relief

As can be seen in the graph above most of the forest cover is represented by the mountain area, 59.7%, followed by the hill area, in our case we talk about Subcarpathian where the proportion is 33.8%, and the smallest part as it is normal to happen is the plain area where we have a 6.5% forested percentage.

Source: IFN

Figure 2: Distribution of forests on phytoclimatic floors

According to the graph above, it is observed that predominant in our country are mixtures of beech and gorse with a percentage of 24.9% followed immediately by the mix of spruce with a percentage of 20%. the highest percentages, as we can see, are in the mountain area, it is a favorable area for the development of these species, but neither the hilly or the sub-Carpathian area can be neglected, because 12.8% is a considerable percentage, even if in many zoos in Romania, deforestation is becoming more and more present.

Source: IFN

Figure 3: Distribution of forests by species and species groups

The beech forest is distributed on the largest surface in Romania, with a percentage of 31.51%, followed by the spruce forest with 19.95%, which shows us that these two essences are specific to the continental temperate zone, especially in the mountain area from the submontana.

Depending on how a forest is managed, forest resources may be either depleted or inexhaustible. If the exploitation of the forest resources is done in an unsustainable (unsustainable) manner, then the regeneration capacity of the forest is affected and can even be canceled, these resources having a (depletable) character. The application of a sustainable management ensures the continuous regeneration of the resources, these having an inexhaustible (infinite) character.

Managing forests in a sustainable way requires an assessment of the impact of the works applied in the medium term but also in the long term, in which it is imperative to anticipate the effects of any intervention not only for a certain period of time, but for the entire production cycle. existing. This is why, when intervening in the forest, a high degree of forest awareness is needed, but also a special training on this branch, because the effects of negligent action persist for long periods of time, are major, extend over the long term and resemblances are very difficult to remedy. (Bran et al., 2011).

There was no possibility yet that in a single generation of foresters we would drive an orchard from the phase where it was at the beginning, that is, from seedlings to exploitation, which is why the forest is a good that we take over and it is necessary to offer it more. away to future generations. In order to sustainably manage the forest, certain principles must be taken into account or should be the basis of any forest management action, and they are:

- The primordiality of the ecological objectives of the forestry;
- Ascension of the role of forestry in rural and regional development;
- Promoting the fundamental natural type of forest and
- ensuring an ecological diversity of the natural cdr;
- Correlation of relations between forestry and other fields
- of activity that underlies them;
- Promoting practices that ensure management
- sustainability of forests;
- Ensuring the integrity of the forestry fund and the forest;
- Increasing the area of land occupied by
- continuous forests;
- Stable medium- and long-term forest policies;
- Ensuring an adequate level of legal continuity,
- Institutional and operational in the management of forestry and certain compensations.

It is known that worldwide, the Earth has a limited capacity to meet the increasing demand for natural resources from the socio-economic system and to absorb the destructive effects of their use. Climate change, erosion and desertification, soil, water and air pollution, reduction of the surface of forest systems and wetlands, disappearance or destruction of an increasing number of species of aquatic animals and plants or on land, The continuous depletion of non-renewable natural resources has begun to have negative, quantified effects, especially on the socio-economic development and quality of life of people in wider areas of the planet. For the moment at the declarative level, the principles of sustainable management have been adopted by all the states that want to apply an advanced forestry based on technology. This is precisely why there are various methods based on the sustainable management of the forest. At national level, it is important to promote certain actions that respond to the national strategy for sustainable development. (Jacobs, 2012).

Another common situation, very visible, in fact, taking into account the species composition of the forest fund in Romania, is the high percentage of trees regenerated vegetatively from shoots or cuttings that rises to about 56.7%, ultimately leading to a reduction in quality and the annual growth of wood from these forests. Thus, the average annual growth is 3.3 m3 / year / hectare, resulting in a possibility of harvest in a year of approximately 577.5 thousand m3. Under the current conditions, the legally harvested wood according to the calculated possibility cannot have the capacity to completely cover even the fuel needs for the whole humanity, this fact causing an exponential increase of the anthropic pressure on the forest. The possibility of harvesting determines the volume of wood mass to be harvested from a forest, based on the forest bypass, to reach a normal capacity. The volume of wood harvested annually means the possibility of annual harvesting, and the one to be harvested over a period of time - the possibility of periodic harvesting. (Lane, 2010)

For these situations to have a solution is very it is important to establish and respect a forest strategy that contains:

- Promoting a seed regeneration of species of the fundamental natural type of forest;
- The increase of the areas covered with forest by works of afforestation and ecological reconstruction at certain periods of time;
- Use of acacia crops in separate areas (but not in the natural forest), so as to eliminate the risk of acacia spreading in the natural forests,
- The more detailed use of wood by developing small industries by craftsmen showing the capacity that was created of added value for this resource.

To what extent is climate change a major threat to our forests?

For a country like Romania with a high agricultural potential, the role of the forest is also a paramount one. Although it started, the forests were the first meadow for the growth of agricultural areas, while it was found that they play a special role in the development of the agricultural sector. Also, the forest often has the capacity to change agricultural production in a positive way, by maintaining and developing networks of forest curtains that would greatly contribute to the development efforts of urban areas. Forest camps are stretches of forest vegetation, located at a certain distance from each other, to protect against the effects of harmful factors or for the climatic, economic and sanitary improvement of arable land. (Satbyul et al., 2014).

From the climate point of view, these networks that are formed improve the cultivation conditions of the agricultural plants during the dry periods during the summer by:

Lowering the air temperature is especially beneficial in high summer summers when the sun's radiation is low in the leaf layer of the trees and uses the radiation energy to create the transpiration process. Increased humidity due to the evaporation capacity of the leaf mass of the trees. Through this process, in the dry periods, the water from the precipitations dropped in excess during the periods with large amounts of water, the decrease of the direct and the refracted solar radiation due to the crowns of the trees shading the agricultural areas in the immediate areas. The decrease of the intensity of the winds that during the dry periods intensifies the process of aridization of the plants.

During the winter season, the forest curtains help protect the snow from blurring and implicitly eliminate it from the agricultural fields, ensuring a water supply to the melting of the snow for agricultural crops and protecting the localities from the snow phenomena. Strong winds also support soil particles that can cause damage to crop plants. Also, since the protective curtains are most often assembled in areas where forests are not found, they also contribute to their specific functions such as: providing wood for burning, carbon storage, shelter for agricultural workers. . The appreciation that the existence of the networks of the forest protection curtains of the field does not emphasize the degree of development of the agriculture for a certain country must be brought into the spot. (Cândea și Bran, 2001). Many of us know that forests will be affected, but we do not know exactly how and to what extent. Climate change can have both positive and negative effects. As the climate becomes warmer and the global warming is increasing, it is expected that the growth rate of the trees will be lower, generating a negative impact on the wood production. Climate change can also have an effect on the geographical spread of forests, advancing to higher altitudes and to more northern latitudes as it began to happen. At the same time, however, forests may face a greater number of threats from pathogens, newly emerging diseases, pests and harmful species.

For example, as a result of the hotter and drier summer and spring periods, the species native to Europe from the large bark of the spruce bark reaches maturity in a much shorter time and can be reproduced several times during the same season. , which leads to the growth of the population of this pest, in the medium and long term certainly affecting this species. Changing weather conditions can add to the change of forests against the background of the proliferation of weather phenomena of the type. Changing the annual and quarterly precipitation regime could lead to the replacement of some current tree species with other species more apt for survival and development in the new climatic conditions. Even though most forest fires in Europe are created by humans, extreme drought and dry weather can increase their risk of production, especially in southern Europe, and can be devastating for forest ecosystems, trapping by themselves and what is happening in Romania. (Păun, 2012).

Measures proposed

According to those identified in this article for better protection of forests it is necessary that:

- a whole range of means of protection should be focused on the sphere of economic interests;
- placing natural warnings to visually remember the destruction of the planet - global warming;
- Annual replanting of young;
- Fragmentation of certain areas where clearing is allowed.

Conclusions

Protected areas are essential in the conservation of natural and cultural capital as well as in the sustainable development of forests, as they include the most representative and significant methods in terms of biodiversity, natural values and associated crops. Management measures in these areas are developed and implemented in such a way as to maintain or even restore, where necessary, natural ecosystems and populations of wild species, while maintaining at the same time or seeking solutions for the sustainable use of natural resources. The establishment of sustainable development and their efficient management are a necessity in our day because, they are the most effective way of conservation, as they are often designated on relatively large areas, they can include representative natural and semi-natural ecosystems that allow their conservation and monitoring. Also represented are areas followed, where the efficient actions of conservation of natural and semi-natural ecosystems, including through sustainable use, can demonstrate that, maintaining in a proper state of the components of the natural capital allows to ensure all services and resources that underpin the social development. sustainable economies and represent true "entities", in which the actions of protection or active management for the purpose of biodiversity conservation allow the accumulation of valuable knowledge either on the natural processes or on finding efficient parameters to ensure the transition from a concentrated economic development. on profit to a new model of sustainable development.

Abstract

This paper tries to analyse the relation between the Russian Federation and the European Union to foresee who is better positioned in the trade battle with its nearby commercial partners and how they would develop towards the 2030, where also both of them should meet the criterias for sustainability.

Keywords: Trade, Emerging Economy, Development

Introduction - The relation between the European Union and Russia

The European Union represents an economic union for 28 Member States. The EU covers an area of 4,475,757 km2 and a population of approximately 513 million inhabitants. The process of forming a European Union began to flourish after 1945, with the US model, in order to reduce the involvement of European states in a new world conflict. When the French Minister, Robert Schuman, in French, Robert Schuman, proposed that France, Germany and other European countries combine coal and steel production at the behest of a supranational authority, 5 years after the end of World War II. avoids a new war between France and Germany.

Russia is the largest country in the world, it has an area of 17.125.200 km2 - representing an optimum of the inhabited surface of the Earth. In terms of population, it ranks 9th in the world, with over 144 million inhabitants in December 2017 (excluding Crimea). The capital of Russia is Moscow, one of the largest cities in the world.

In 2017, Russia's economy recovered from the recession and turbulence of 2014-2016 in the banking sector, benefiting from increased revenues from oil and raw material exports. The economic system is concentrated in only a few sectors, investments with transformative effects are lacking, and large companies close to the state dominate the market (Ioniță, F. et al., 2009). Despite sanctioning policies, the EU remains Russia's first trading partner, and Russia is the fourth for the EU. However, trade and economic relations are disrupted by many factors, such as Russia's embargo on EU agricultural

products, WTO disputes and serious constraints on EU companies to participate in public tenders in Russia.

Since March 2014, the EU has gradually imposed restrictive measures against Russia, in response to the illegal annexation of Crimea and destabilizing Ukraine. EU sanctions widened substantially following the collapse of the MH17 passenger plane on June 17, 2015, over territory controlled by Russian-backed rebels in eastern Ukraine. The sanctions are periodically updated and extended.

EU vs. Russia Living Standards

In the graph below we analyzed GDP per capita in Russia and compared with the EU 28 average. This indicator helps us analyze the living standards in the EU and Russia. For both economies, GDP per capita grew slightly in 2018 compared to 2017. Numerically Russia has a GDP per capita below the EU average28, but we must mention that they are EU member countries. which have a GDP per capita lower than that of Russia, for example: Bulgaria and Romania (Romania recorded in 2018 a GDP per capita approximately equal to that of Russia, $ 11,433, compared to 2010 prices).

Chart 1: Comparative analysis of GDP per capita - Russia vs EU

Source: Own data processing: United Nations Conference on Trade and Development

Renewable Resources

There is no doubt that renewable energy sources will play a strategic role in fueling the global economy of the future. For the moment, oil is still the undisputed champion of the energy world. In 2018 we consumed more oil than any other year in history - about 99.3 million barrels per day, globally. It is estimated that this number will increase again in 2019, reaching up to 100.8 million barrels per day.
In the chart below we have illustrated the top 15 countries that have the largest oil reserves. As we can see, Venezuela is in first place with 300.9 billion barrels in reserve. Russia ranks 8th, with 80 billion barrels in reserve. Russia is one of the main producers of oil and natural gas and is also a leading exporter of metals such as steel and primary aluminum.

Chart 2: Oil reserves (billion barrels)

Source: Own data processing: United Nations Conference on Trade and Development

It is important to note that although supplying billions of barrels of oil can be a natural mother's advantage, they are only a factor in assessing the potential value of this crucial resource. Russia is among the countries with the lowest cost of oil production, ranking 4th, with a total cost of $ 19.21 per barrel, and the 1st place is Saudi Arabia, which produces a total cost of about $ 9 a barrel.

Greenhouse Gas Emissions

One of the goals of the European Union is to reduce carbon dioxide emissions to combat climate change. Since 1965 it is estimated that over 1.35 million metric tons of greenhouse gases have been released into the atmosphere, and over a third can be caused by 20 companies. Both the European Union and Russia are bad at this indicator, being in the top 4 countries with the highest carbon dioxide emissions - the European Union has annual CO2 emissions of 3,115,125 thousand tonnes (meaning 11.4%), and Russia 1,524,993 thousand tonnes. (meaning 5.6%).

Below we have added a graph that highlights the companies that have been responsible for the most carbon emissions for the last half century. We note that in the list of the 20 companies that produce the highest amount of CO2 emissions, we find both companies in Russia and companies in the European Union (France, UK, Netherlands).

Table 1: Biggest oil companies in the world and their emissions (2019)

Company	Country	Ownership	All Emissions, $MtCO_2e$
Saudi Aramco	Saudi Arabia	State-owned	59,262
Chevron	U.S.	Investor-owned	43,345
Gazprom	Russia	State-owned	43,230
Exxon Mobil	U.S.	Investor-owned	41,904
National Iranian Oil Co.	Iran	State-owned	35,658
BP	UK	Investor-owned	34,015
Royal Dutch Shell	Netherlands	Investor-owned	31,948
Coal India	India	State-owned	23,124
Pemex	Mexico	State-owned	22,645
Petroleus de Venezuela	Venezuela	State-owned	15,745
PetroChina	China	State-owned	15,632
Peabody Energy	U.S.	Investor-owned	15,385
ConocoPhillips	U.S.	Investor-owned	15,229
Abu Dhabi National Oil Co.	UAE	State-owned	13,840
Kuwait Petroleum Corp.	Kuwait	State-owned	13,479
Iraq National Oil Co.	Iraq	State-owned	12,596
Total SA	France	Investor-owned	12,352
Sonatrach	Algeria	State-owned	12,302
BHP Billiton	Australia	Investor-owned	9,802
Petrobras	Brazil	State-owned	8,676

Foreign Direct Investment

The value of foreign direct investment (FDI) stocks has increased considerably over the entire period analyzed, from 1995 to 2018. As can be seen in the graph above, the value of internal FDI stocks is significantly higher than that of stocks. external to FDI, in 2018 reaching even double value. This fact can be explained by increasing the equity of foreign investors and the loans granted to entities in the Russian economy. The highest values of FDI stocks, both internal and external, are recorded in 2017, approximately $ 441k million, respectively $ 380k million.

Chart 3: Evolution of Foreign Direct Investment in Russia

Source: Own data processing: United Nations Conference on Trade and Development

The evolution of FDI as a percentage of GDP is a surprising evolution, recording high values, on average over 20% in the last 3 years analyzed. Compared to 1995, 2018 is surprising, the value of the external FDI stocks increased by 20 percentage points, and the value of the internal FDI stocks increased by approximately 23 percentage points.

Export and Import of Russia. Worldwide structure

In 2012 Russia became a member of the World Trade Organization (WTO) - an organization that works to reduce and abolish international trade barriers. Also, the Russian Federation is the leading member of the Commonwealth of Independent States (CIS) and one of the five members of the Eurasian Economic Union, along with Armenia, Belarus, Kazakhstan and Kyrgyzstan.

The figure below shows the evolution of imports and exports from Russia in the period 2013-2018. Between 2013 and 2016, including, there is a downward trend in international trade, against the backdrop of political and economic imbalances - inflation, modest GDP growth, reduction of foreign capital flows. Starting with 2017, exports from the Russian Federation have an upward trajectory, towards the end of 2018 increasing by 60% compared to 2016 and by 14% compared to 2017. The level of imports fluctuates around 200 billion euros in 2015-2018, being lower export level over the whole period analyzed.

Chart 4: Evolution of Export and Import in Russia, 2013-2018

Economic Freedom Index

We live in the most prosperous period in human history (Angheluta, S. P. et al., 2019). Poverty, disease and ignorance is diminishing throughout the world, due in large part to the advancement of economic freedom (Bran, F. et al., 2018). Economic freedom is the fundamental right of every man to control his work and his property. In an economically free society, individuals can work, produce, consume and invest in whatever way they want (Burlacu, S. et al., 2018). The Economic Freedom Index (ILE) 2 is an annual guide published by the Washington Heritage Foundation, which measures the principles of global economic freedom. The index covers 12 freedoms - from property rights to financial freedom - in 186 countries. Depending on the index level, the states are classified into 4 types: (0-50 points) - repressed, (50-60 points) - mainly free, (60-70 points) - moderately free, (70-100) - predominantly free. By 2030, the complexity of the global economy may look very different from today's. According to recent projections by Standard Chartered, a multinational bank based in London, in the next decade, emerging markets such as India and Turkey will climb the global economic scale to become tomorrow's power.

Below we can see the projected change for the biggest economies from 2018 to 2030:

Chart 5: Top 10 states by GDP (PPP) in 2018 vs. 2030

Source: https://www.visualcapitalist.com/animation-the-biggest-economies-in-2030/

Conclusion

EU restrictive measures have different forms. Diplomatic measures consisted in excluding Russia from the G8, suspending Russia's accession to the OECD and the International Energy Agency, and disrupting regular EU-Russia bilateral summits.

Economic sanctions target trade with Russia in certain economic sectors. They limit the access of certain Russian banks and companies to primary and secondary capital markets in the EU and impose prohibitions on the export and import of weapons and the export of dual-use goods for military or military end-users in Russia. The sanctions also restrict Russia's access to certain sensitive technologies and services, which can be used for oil production and exploration. Specific restrictions on economic relations with Crimea and Sevastopol apply, including a ban on the importation of goods from the peninsula, a ban on the export of certain goods and technologies, restrictions on investments and a ban on providing tourism services. The measures on economic cooperation suspend the new financing operations in Russia of the European Investment Bank (EIB) and of the European Bank for Reconstruction and Development (EBRD).

Individual restrictive measures are applied against 150 persons and 40 entities, whose assets have been frozen and have been imposed travel bans, because their actions have undermined the territorial integrity, sovereignty and independence of Ukraine. Their list includes the presidents of the two chambers of the Russian Federal Assembly (State Duma and the Federation Council), as well as the acting president of the Russian Delegation to the EU-Russia Parliamentary Cooperation Commission.

Since August 2014, Russia has responded to EU and Western countries' sanctions (including the US, Canada and Australia) by imposing counter-sanctions on agricultural products, raw materials and food, under the pretext of violating food security rules. This has strengthened Russia's policy of substituting imports into the agricultural sector. Also, Russia applies a "stop-list" (travel bans) to EU and US nationals who criticized their actions, denying them the right to enter the territory of Russia (on this list there are 18 MEPs). There is no legal remedy if a person is included in the list, as opposed to the travel ban imposed by the EU.

Abstract

Solid waste management is a major problem today. Defective waste collection and transportation as well as the low amount of their recycling and reuse has resulted in an increasing amount of waste being deposited, sometimes at will and most of the times under adverse conditions that may affect the health of the population and can lead to the destruction of habitats and ecosystems. In order to prevent and control the flow of waste, several management systems have been implemented, as well as modern waste recovery systems that allow the reuse of a large amount of waste and less and less storage.

Keywords: Management, Waste, Transport, Recycling

Introduction

Waste management includes the activities of collection, transport, treatment, recycling and storage of waste and aims to reduce their effect on human health, the environment or the appearance of a habitat, as well as saving some natural resources by reusing the recoverable parts (Oros V., 2002) (Bran, F. et al., 2019).

To come to the aid of the local authorities, national waste management plans were first developed, from which they subsequently derived county and local waste management plans (Rădulescu, C.V. et al., 2018). Waste management plans play a key role in the development of sustainable waste management (Negescu Oancea, M.D. et al., 2019). Their main purpose is to present the waste streams and their management options (Ackerman F., 2000). In more detail, the waste management plans present the planning framework for the following aspects:

- Compliance with the waste policy and reaching the proposed targets: waste management plans are important tools that contribute to the implementation of policies and to the goals set in the field of waste management (Bodislav, A. . et al, 2019).
- Establishing sufficient and characteristic capacities for waste management: Waste management plans outline the flows and quantities of waste that must be collected, recycled, treated and / or disposed of (Alpopi, C. et al, 2018).
- Control of technological measures: the presentation of waste flows ensures the identification of the areas where technological measures are needed to eliminate or minimize certain types of waste

- Presentation of economic and investment requirements: waste management plans are a starting point for establishing the financial requirements for operating waste collection, recycling, treatment and disposal schemes.

On this basis, the needs for investments in waste recycling, treatment and disposal facilities can be determined (Dima, C. et al, 2020). The PJGD is requested by the European Union as a planning tool on the basis of which financial assistance and support from the EU can be obtained (Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L., 2019). It is necessary to ensure that EU and national targets will be achieved and sustainable solutions tailored to specific regional conditions will be identified (Circular Economy Strategy, 2016).

Based on the County Waste Management Plan, Maramureş County must develop a waste management system valid and functional for the entire county. Due to the orographic barrier that divides the county into two parts, the waste management will be differentiated on the two parts of the county, respectively in the part of the municipality of Baia Mare and in the part of the city of Sighetul Marmatiei.

The proposed project wants the theoretical implementation of an ideal waste management system in the northern part of Maramures County. This ideal system is composed of all the stages included in the management of waste and focuses on the most efficient variants, but at the same time plausible collection, transport, sorting, recycling and storage of waste being to some extent a fully implementable system (Paunescu I., 2002).

The present paper proposes a description of the current situation of waste management followed by the proposal of a new management base with construction details and specialized site on the North Maramures region. We should mention that this management system includes only the solid municipal waste collected through the waste collection network in the cities, communes and villages of the northern part of Maramures County.

The Existing Situation in The Study Area

Calculation of the served population

Table 1: Served population

In order to estimate the future quantities of waste and their composition, the provisions of the Regional Waste Management Plan were considered:

- Evolution of the population until 2042.
- Specific factors for the generation of waste and an annual increase of 0.8%. According to the data provided by the National Institute of Statistics ("Population forecast in the areas of origin 2004 - 2005") and contained in the Regional Waste Management Plan for the period 2003 - 2013 the following trends have been identified
- Urban area: negative values -0.6154% per year
- Rural area: positive values of + 0.2981% per year

Average composition of waste

Regarding the composition of the collected municipal waste, it differs in the urban environment from the rural one, and the amount of waste eliminated per capita differs from the urban to the rural one. The graph below shows the average compositions of waste collected in urban and rural areas (Burcea S., 2009).

Figure 1: Average composition of waste

Source: INS

The most important amount of waste collected from the population, whether from urban or rural areas, is biodegradable organic matter.

In the conditions of the existing situation, in Romania it is recommended to introduce separate collection of biodegradable matter in the less dense urban environment, in the green areas of the big cities and in some rural areas, which represent 25- 35% of the population.

According to the report of the European Environment Agency "Management of municipal biodegradable waste", in the urban area the share is 69% and in the rural 60%. Currently, there is no separate collection in the county of Maramureş, at the source of the fraction of biodegradable waste from household waste.

The following assumptions reflecting the general trend of developing the economy and changing consumer habits (Bahor B., 2009) were taken into account for estimating the quantities of waste generated:

- decrease of the amount of organic waste by 1% per year;
- an increase in the amount of paper and cardboard waste by 3% per year;
- an increase in the amount of plastic waste by 2% per year;
- a decrease in the amount of waste from glass by 1% per year
- a constant tendency of the quantity of ferrous materials;
- an increase in the amount of textile waste by 1% per year.

Proposed Management Strategy

The proposed methodology envisages the creation of a unique center for collection, processing, recovery and storage of waste from the North Maramures region. Taking into account the directions of the European Union, of which Romania is a part, regarding waste management, it imposes a complex waste management based on reuse, recycling and avoiding waste production (Campeanu V., 2007). In the waste regime proposed by the EU, a regional centralization of the activities related to waste is also required, which means the elimination, namely the closure of all existing waste storage centers and the creation of a county-level center for waste collection and processing, creating locally - waste transfer stations for temporary storage until the time of accumulation of sufficient quantities to be transported to the county center.

Due to the orographic barrier raised by the Igniş - Gutâi Mountains, the county of Maramureş is the only one in the country where the construction of two county waste collection centers is necessary, the project proposing the construction variant for the center that will cover the North Maramureş region serving the communes and cities presented in the table. the next subchapter.

The design of such a center raises a complex problem that must be analyzed from all points of view, choosing the most optimal and favorable solution (Mertins L., 1999). Regarding the location, as it appears from the previous chapter, the location near the commune Ocna Şugatag was decided, this being contested by the inhabitants, but given the new jobs created as well as the subsequent economic development of the area this will be avoided. especially due to the fact that the center will be located at a legal distance from housing and will not have a negative effect on the population.

The center will consist of the following units:

- Unit for the temporary reception and storage of waste
- Primary waste sorting unit
- Waste treatment units
- Waste landfill
- Unit infrastructure

All units will be described in detail in the following chapters, with details of location, surface, construction, etc. Regarding the changes at the level of localities, they will be noticeable by the way the waste is collected.

Figure 2 : Waste flow diagram
Source: after Davidson, G., 2011, *Waste Management Practices: Literature Review*

Waste Collection

Waste collection is one of the most important factors in the entire waste management technology flow. This element is mainly felt by the population served because they are in direct contact. A correct and rational collection of waste leads to a normal and fluent technological flow without difficulties and without major problems as well as to direct benefits at the level of the local communities reflected through clean public spaces and avoiding uncontrolled storage (Hoornweg D., 2012).

A rational waste collection also facilitates the subsequent technological flow by reducing the amount of mixed waste by differentiated collection (Themelis N., 2003). The design of the waste collection system is thus an element of major importance and for its efficient implementation, several elements such as:

- Type of container
- The volume of the container
- Combination of containers
- Frequency of waste collection

The proposed waste collection system involves the acquisition and placement in the region of several types of containers and the bins described below.

Effective waste management starts from the phase of waste collection and extends throughout the technological flow through which waste passes. In the waste collection phase, differentiated collection

helps a lot and favors the following processes. Thus, the waste management system proposes a selective collection at the source of the waste.

The differentially collected waste will be as follows:

- Glass
- Paper
- Metals
- Lightweight PET packaging

For each type of waste collected differentiated will be placed in each commune and in each city, at acceptable distances specialized containers each having its own emptying regime and its own constructive characteristics.

Collection Systems

In practice, several methods of waste collection are applied and known, each of them having their advantages and disadvantages. Effective waste management involves several methods, or generically called collection schemes, generally depending on the type of waste collected or the amount of waste collected (Consonni S., 2005).

The collection in collection points is a more passive method from the point of view of the sanitation agents because in this case the citizens have to make their own contribution to the collection of waste by transporting personal waste to the collection points (McDougall F., 2001). The location of collection points is very important because too much distance between them will mainly lead to passivity from the user's point of view. However, this method has the disadvantage in the case of differentiated waste collection because it remains up to the user whether or not to sort their waste.

For certain types of waste, the door-to-door collection system can also be applied. This method is a more practical one for the users, but it is disadvantageous for the sanitation agent because it will make more effort and will consume more resources for collecting waste from each user. For this reason, this method will only apply in the case of waste collection of used electronic equipment in the case of the proposed management (Wilson D.C., 2006).

In this case, the sanitation agent will set a day when a collection machine will go from gate to gate and pick up the waste of used electrical and electronic equipment.

The main element in the collection stage is the users' awareness, because an effective selective collection starts from the source, and in this case each user has the responsibility to sort their waste.

In order to maintain a superior quality of the environment and to avoid some negative impacts, we suggest that the following be included in the monitoring of the future landfill:

- Monitoring the quality of the environment;
- Technology monitoring;
- Monitoring after closing the site.
  The system for monitoring the warehouse after closing consists of:
- Groundwater monitoring: tracking wells located one upstream and two downstream of the landfill; the chemical and biological parameters will be monitorized, the analysis will be carried out in the accredited laboratory according to the legal norms.
- Monitoring of the coating system: visual inspections of the warehouse in order to prevent and correct the landslides, clearing the final layer, uncontrolled growth of vegetation.
- Monitoring of gas emissions. Monitoring tasks regarding closed landfills are not included in future services, as it is the responsibility of the operator (in this case, the municipalities that hold the respective landfills) (Davidson G., 2011).

The necessary measures to prevent, reduce and eliminate the negative impact have been identified for each major environmental problem. The positive impact of each proposed activity was also underlined. The evaluation of the potential impact is based on the proposed conditions and the general characteristics of this development project. The impact on the environment is quantified as Zero, Not Significant, Moderate and Significant.

Conclusion

Waste management remains unknown in the decision-making landscape of communities. Problems get complicated quickly over time, and delays in their integrated resolution make things even more complicated. The organization of waste management is well developed as documentation but in the field the situation is aggravating. There are components that have not been taken into account and they are even more confusing elements. Integrated management solutions have a much broader scope and need to be considered in order to make a correct and realistic assessment of costs.

Waste recycling is a challenge for everyone. It is necessary for the local authorities to ensure, in stages, the separate collection of waste, having organized a sanitation service at the level of each locality. Separate collection must increase, and the transport of waste from the territory of the localities should be done on time, strictly applying the legislation regarding environmental protection. It is necessary to emphasize the awareness and education of the population, economic agents and local public authorities regarding the impact of waste on the environment.

In order to evaluate the situation in the field of chemical administration, highlighting the problems regarding their management it is necessary to develop an integrated monitoring program of the chemical substances in the environmental components.

In order to stop the processes unfavorable to nature, to exclude or minimize the effects of the influence of anthropic activities on the environment and population health, applying the "polluter pays" principle, as well as perfecting the normative acts regarding the increase of the efficiency of the ecological control in the field of environmental protection, stimulation and application in country of non-polluting technologies it is necessary to elaborate some norms, which would allow the prevention of pollution and make more efficient the compensation of the damage caused to the environment.

European Forest Areas Management

Carmen Valentina RĂDULESCU

Associate professor PhD, Bucharest University of Economic Studies, Romania,
cv_radulescu@yahoo.com

Abstract

Future generations will be able to meet their life and living needs by applying proper forest management. Decreasing the vegetation period is an effect of global warming. Tree health is also affected by the increasing acid rainfall. Deforestation leads to the decrease of the areas occupied by forests. For this reason, the article presents an analysis of the area of forested land for the European Union. Protecting forests can lead to improved human health. The importance offered by this function is also highlighted by the evolution of the forest surfaces, as well as of other forested lands, which fulfill the protective function. Also, cutting down forests is an additional pressure that leads to global warming. Thus, the article presents a situation of industrial roundwood removals as well as roundwood production.

Keywords: European Union, Environment, Forest Areas, Forest Protection

Introduction

The conservation of biodiversity also contributes to the application of sustainable management measures of forest areas. Following the research, it was found that there is the possibility of anticipating both precipitation and temperature (Voicu and Rădulescu, 2018). These measurements can be the basis of sustainable forest management.

Human health, but also the environment, is affected by pollution (Dima, C. et al, 2020). The balance of ecological systems can be maintained and restored by measures to combat pollution. The pollution manifested in the forest areas is a process that influences the capacity of the trees of regeneration and, in general, their state of health (Negescu Oancea, M.D. et al., 2019). The drying of trees before reaching maturity is determined by climate change (Bran, F. et al., 2018, 2019). Certain economic activities adversely affect the forests, through the emanated powders, but also through the appearance of acid rain.

The rational and prudent use of natural resources allows the application of measures related to environmental protection (Burlacu, S.; Alpopi , C.; Popescu, M. L. 2018). These measures lead to the improvement and conservation of the quality of the environment. Through them, the objective of protecting the health of the population is also achieved (EU, 2020). The landslides and soil erosion can be reduced by afforestation measures. Forests contribute to the absorption of carbon dioxide, but also to the production of oxygen needed for life (EP, 2013).

It has been found that afforestation can be applied on degraded land. Thus, afforestation programs contribute to the extension of forest areas. Forests can act as protection and absorption screens for different harmful gases . At the same time, the existence of the forest fund allows for additional protection of both soil, water and climate. Also, forests represent a favorable environment for the development of some plants, which allow the use of both fruits and flowers or leaves Burlacu, S. et al., 2018). Biodiversity and wildlife are preserved through forests. At the same time, in addition to these, forests also fulfill the recreational function (Lindahl et al., 2017).

Literature Review

To apply a good management of ecosystem services, it is necessary to know the complex socio-ecological systems. Forest areas provide renewable raw materials, clean air and rich biodiversity (Pynnönen et al., 2019).

The existence of the bidirectional flow of materials between the environment and the economy is offered by the economic activities. One result of this flow of materials is the production of goods, and another represents waste. Thus, we can divide the economic activities according to the degree of use of material resources, including those coming from the forestry field (Victor, 2018).

Even if clearing actions occur, over time, forests regenerate. This capacity should continue to be maintained. Another way to increase the areas covered by forests is by reusing those lands that can no longer be used in agriculture. Their afforestation increases the importance of those areas.

The types of trees that are today part of the forests, but also their distribution, can change over time due to climate change. More and more cases of desertification are emerging. At the same time, global warming can lead to the spread of forest areas to higher altitudes (EEA, 2017).

It must be kept in mind that the loss of ecological value and the decrease of ecosystem capacity can occur if there is a greater emphasis on water resources at the expense of species biodiversity (Weber, 2014).

Ecosystem services make the connection between human well-being and the natural environment a dynamic one. This category also includes forest areas (Ward et al., 2018). The production of oxygen, but also the absorption of carbon dioxide, represent functions of forests, which contribute to reducing environmental pollution.

Applying environmental legislation can lead to the protection of forests and the improvement of natural capital (EU, 2019).

The importance of forests is also given by their role with regard to the health of the environment. They also have an economic advantage for communities. Climate change also causes certain pressures on forest areas. Whether they are willing or not, deforestation actions lead to the reduction of areas covered with forests (WB, 2020).

The application of some legislative measures can lead to the reduction of the pressure exerted on the biodiversity and the ecosystems. Improving forest resilience can be achieved by applying effective management measures (EP, 2013). Also, timber production should also consider the application of biodiversity conservation measures (Ezquerro et al., 2019).

Another aspect that influences the way forest management is given is urbanization. The application of conservation policies for land use can be reflected in the wildlife and forest areas (Balukas et al., 2019).

Methodology of Research

It is necessary to have a balance between the cuts made in the forest areas and the quantity of wood that remains after these cuts (EEA, 2018). Illegal cuts, as well as other types of deforestation, can be controlled through local communities. Certain legislative measures can support them.

The article presents an investigation of the situation in the forest areas for the member countries of the European Union by analyzing the surface of the forest land. A comparative analysis of the data regarding the protective function of the forest surfaces, as well as of other forested lands is performed. Due to the economic activities carried out in the forest areas, the evolution of roundwood production is studied. The evolution used in forestry and logging for 2012-2016 was also analyzed.

Considering the importance of the cuts made in forests, the comparative situation of industrial roundwood removals is presented, for the period 2008-2017.

Results and Discussions

Forest ecosystems are a suitable environment for different species of plants and animals. In addition to the wood material provided, forests allow climate control and protection against natural disasters (EP, 2013). It becomes important to analyze the forest surfaces. Thus, the comparative situation of forest areas, as well as of other forested land, for the period 2000-2015 (thousand hectares) is presented in Table 1.

Table 1: Comparative situation of forest areas, as well as other forested lands, 2000-2015 (thousand hectares)

Countries	2000	2005	2010	2015
European Union	177,834	179,133	180,311	181,918.00
Austria	3,955.00	3,978.00	4,000.00	4,022.00
Belgium	694.40	704.20	714.00	719.10
Bulgaria	3,480.00	3,677.00	3,761.00	3,845.00
Croatia	2,300.00	2,387.00	2,474.00	2,491.00
Cyprus	385.47	386.72	386.13	386.19
Czechia	2,637.29	2,647.42	2,657.38	2,667.41
Denmark	721.45	599.30	634.08	657.69
Estonia	2,450.31	2,465.04	2,452.96	2,455.51
Finland	23,282.51	23,300.00	23,019.00	23,019.00
France	17,093.00	16,748.00	17,163.00	17,579.00
Germany	11,354.00	11,384.00	11,409.00	11,419.00
Greece	6,525	6,532	6,539.00	6,539.00
Hungary	1,907.00	1,983.00	2,046.39	2,190.43
Ireland	684.44	744.46	772.86	801.24
Italy	10,019.00	10,467.00	10,789.00	11,110.00
Latvia	3,364.00	3,415.00	3,467.00	3,468.00
Lithuania	2,103.00	2,194.00	2,254.00	2,284.00
Luxembourg	88.15	88.15	88.20	88.20
Malta	0.00	0.00	0.35	0.35
Netherlands	360.00	365.00	373.48	376.00
Poland	9,059.00	9,200.00	9,329.00	9,435.00
Portugal	4,560.61	4,577.18	4,742.20	4,907.21
Romania	6,600.00	6,743.00	6,919.00	6,951.00
Slovakia	1,921.40	1,931.60	1,938.90	1,940.00
Slovenia	1,271.00	1,272.00	1,272.00	1,271.00
Spain	27,336.96	27,540.76	27,525.38	27,626.65
Sweden	30,707.00	30,762.00	30,505.00	30,505.00
United Kingdom	2,974.00	3,041.00	3,079.00	3,164.00

It is noted that in 2015, the area of forests and other forested land was the highest in: Sweden (30,505 thousand hectares), Spain (27,626.65 thousand hectares), Finland (23,019 thousand hectares), France (17,579 thousand hectares), Germany (11,419 thousand hectares), Italy (11,110 thousand hectares). Compared to 2000, in 2015, it increased significantly in: Ireland (+17.07%), Hungary (+14.86%), Italy (+10.89%), Bulgaria (+10.49%). At the same time, compared to 2000, in 2015, the area of forests and other forested land decreased in: Denmark (-8.84%), Finland (-1.13%), Sweden (-0.66%).

In recent years, the protective function of forests is a predominant feature of forests. The table 2 presents the comparative situation of the forest areas, as well as of other forested lands, that fulfill the protective function, for the period 2000-2015 (thousand hectares). The table does not present the data for the countries where the forests do not have a protection feature, respectively the countries for which there was no data available on the Eurostat website.

At European level, the data extracted from the Eurostat website shows the growth of forest areas, respectively of other wooded lands, from 27,606.7 thousand hectares (in 2000) to 38,075.1 thousand hectares (in 2015). The countries where the largest areas for the protective function were allocated in 2015 were: Italy (9,349.31 thousand hectares), Spain (6,628.92 thousand hectares), Germany (5,500 thousand hectares), Sweden (5,328 thousand hectares), Poland (3,152.4 thousand hectares), Romania (3,087 thousand hectares).

Table 2: Comparative situation of forest areas, as well as other forested lands, which fulfill the protective function, 2000-2015 (thousand hectares*)*

Countries	2000	2005	2010	2015
European Union	27,606.7	34,117.5	36,180	38,075.1

Belgium	179.1	175	170.9	167.6
Bulgaria	665	597	583	569
Croatia	96	116	135	126
Czechia	179.97	251.56	281.25	312.27
Estonia	275.72	231.64	157.88	157.38
Finland	727	583	326	326
France	:	:	906.39	906.39
Germany	2,981	3,737	4,616	5,500
Hungary	218.24	181.46	197.82	200.65
Italy	8,547.45	8,811.87	9,080.91	9,349.31
Latvia	71	122	131	141
Lithuania	230	258	246	251
Netherlands	:	:	4.5	4.5
Poland	2,753	2,907	2,887.4	3,152.4
Portugal	:	:	:	380.09
Romania	3,009	3,013	3,087	3,087
Slovakia	316.9	344.4	357.8	354.7
Slovenia	74.14	94.84	249.4	299.9
Spain	6,510.21	6,566.68	6,600.71	6,628.92
Sweden	:	5,326	5,328	5,328

Above the European average growth is: Slovenia (from 74.14 to 299.9 thousand hectares), Latvia (from 71 to 141 thousand hectares), Germany (from 2,981 to 5,500 thousand hectares), Czechia (from 179.97 to 312.27 thousand hectares), Croatia (from 96 to 126 thousand hectares).

As Slovenia has the highest growth, the figure 1 shows the evolution of the forest area, respectively of other forested lands, between 2000-2015.

Fig. 1: Evolution of forest areas, respectively of other forested lands, between 2000-2015, fulfilling the protection function, for Slovenia (thousand hectares)

The increase from 74.14 thousand hectares (2000) to 299.9 thousand hectares (2015) is observed. Another important aspect regarding the management of the forest areas is given by the quantity of cut wood. The following figure shows the evolution of industrial roundwood removals for non-coniferous and coniferous, for the period 2008-2017 (million cubic meters).

Fig. 2: Industrial evolution of roundwood removals for non-coniferous and coniferous, 2008-2017 (million cubic meters).

The evolution of industrial roundwood removals for the two categories shows a different trend. Thus, for Non-coniferous, in the period 2011-2017, the tendency is to maintain constant values. The growth registered in 2017, compared to 2008, is 4.59%. On the other hand, for the coniferous, in the period

2012-2017, there is an increasing trend of values. Also, in 2017, compared to 2008, there is an increase of 7.94%.

The table 3 presents the comparative situation of industrial roundwood removals for the member countries of the European Union, between 2008-2017 (million cubic meters).

It is noted that, at European level, compared to 2008, in 2017, industrial roundwood removals increased by approximately 7.19%, from 261.81 million cubic meters to 361.28 million cubic meters. From the data presented, for all tree species, in 2017, compared to 2008, the highest increases were recorded in: Estonia (+84.52%), Slovenia (+68.30%), Ireland (+37.89%).

The situation is similar for the two species analyzed (coniferous and non-coniferous). However, in 2017, industrial roundwood removals had high values in: Sweden (65.38 million cubic meters), Finland (55.33 million cubic meters), Germany (43.56 million cubic meters), Poland (40.10 million cubic meters), France (25.36 million cubic meters), Czechia (17.01 million cubic meters), Spain (14.64 million cubic meters), Austria (12.74 million cubic meters). It should be noted that the volume of industrial roundwood removals registered in 2017 for the eight countries represents 75% of the volume given by all the countries of the European Union.

Each socio-economic system, whether it is regional or local, has a certain approach when it comes to the management of forest areas. Thus, adaptation and impact to adaptation measures may be different, even if the ecological forest areas are similar (Andersson and Keskitalo, 2018).

Table 3: Comparative situation of industrial roundwood removals for the member countries of the European Union, 2008-2017 (million cubic meters)

Thus, one of the economic activities that use the resources offered by the forest areas is given by the exploitation of the wood. Many of the ecosystem products and services required by the population are provided by forests. These include wood production (Lešo et al., 2019). The table 4 presents the comparative situation of roundwood production for the member countries of the European Union, between 2007-2017 (million cubic meters).

From the previous table, it is noted that, compared to 2007, in 2017, roundwood production increased significantly in: The Netherlands (+208.3%), Estonia (+121.07%), Italy (+60.64%), Slovenia (56.47%). Also, the values fell in: Germany (-30.28%), Cyprus (-18.66%), Austria (-17.22%), Sweden (-6.8%), France (-6.2%) %), Romania (-5.53%).

However, in 2017, the largest roundwood production was registered in: Sweden (72.88 million cubic metres), Finland (63.28 million cubic metres), Germany (53.49 million cubic metres), France (51.2 million cubic metres), Poland (45, 35 million cubic metres), Czechia (19.39 million cubic metres), Austria (17.65 million cubic metres), Spain (17.57 million cubic metres). Thus, in 2017, roundwood production for these eight countries represented about 72.5% of the roundwood production corresponding to the European Union.

Table 4: The comparative situation of roundwood production for the member countries of the European Union, 2007-2017 (million cubic metres)

Countries	2007	2009	2011	2013	2015	2017

Fig. 3: The evolution of roundwood production for the European Union (million cubic meters)

The evolution of roundwood production for the European Union is shown in the figure 3 (million cubic meters). For the period 2007-2009, a decrease in values is observed. We also find that the trend of recent years is increasing. Between 2012 and 2017, roundwood production in the European Union increased from 426.2 million cubic meters (2012) to 470.3 million cubic meters (2017). However, we must bear in mind that the decline of forest areas leads to additional anthropic pressures. Conservation of biodiversity is one of the advantages that forests offer.

The importance given to the forestry field is also given by the number of employees in this field. Thus, at European level, for the period 2012-2016, the evolution of employed persons in forestry and logging is presented in table 5 (thousand annual working units).

Table 5: Employee evolution, 2012-2016 (thousand annual working units)

Countries	2012	2013	2014	2015	2016
European Union	493.11	491.92	512.92	514.71	503.26
Austria	20.33	20.27	21.40	20.69	18.84

Italy	39.90	39.79	39.29	40.00	40.60
Latvia	16.60	16.87	17.55	18.80	17.85
Lithuania	12.63	12.17	13.73	13.75	12.69
Luxembourg	0.53	0.51	0.56	0.56	0.56
Malta	0.00	0.00	0.00	0.00	0.00
Netherlands	2.00	2.00	2.00	2.00	2.00
Poland	47.70	48.20	48.50	48.70	51.60
Portugal	10.82	11.13	12.02	12.86	13.46
Romania	60.30	57.90	47.03	46.69	44.78
Slovakia	8.86	8.11	22.79	21.43	19.98
Slovenia	5.34	5.81	7.44	7.50	7.49
Spain	19.00	19.00	20.60	21.90	21.20
Sweden	42.70	42.90	43.40	42.90	40.70
United Kingdom	15.00	14.00	16.00	17.00	17.00

The data presented show an increase at European level. In 2016, the highest values were registered in: Poland (51.60 thousand annual working units), Germany (48.89 thousand annual working units), Romania (44.78 thousand annual working units), Sweden (40.70 thousand annual working units), Italy (40.60 thousand annual working units). Also, compared to 2012, in 2016, significant increases were observed in: Slovakia (+125.51%), Slovenia (+40.26%), Germany (+26.14%), Portugal (+24.40%). Significant decreases were recorded in: Romania (-25.74%), Cyprus (-15.38%), Ireland (-14.98%), Bulgaria (-14.81%).

Since, in the period 2012-2016, the number of employees has decreased significantly in Romania, the following figure shows the evolution of the number of employees for this period.

Fig. 4: The evolution employed, between 2012-2016, for Romania (thousand annual working units)

The decrease from 60.30 thousand annual working units (2012) to 44.78 thousand annual working units (2016) is observed.

Conclusions

Sustainable management of forest areas can lead to the needs of future generations. Decreasing the vegetation period is an effect of global warming. Tree health is also affected by the increasing acid rainfall.

For local communities, sustainable forest management allows both the quality of the environment and the creation of new jobs (Buzoianu et al., 2018).

Between 2000-2015, the area of forests and other forested land increased. This increase was observed both at European level and in most of the member countries of the European Union. Also, it has been observed the increase of the forest surfaces, respectively of other forested lands, that fulfill the protective function. Regarding the evolution of industrial roundwood removals, at European level, there is a tendency of increasing values for coniferous. At the same time, the volume of industrial roundwood removals registered in 2017 for the eight countries represents 75% of the volume given by all the countries of the European Union. Growth trends were also observed for roundwood production. Regarding the evolution of employed persons, it can be said that the situation is different in the member countries. If in most of the values have increased, there are countries where the evolution has had decreasing trends.

In order for future generations to live in a healthy living environment, the way resources are used today needs to change. Natural capital is a wealth that must be preserved and passed on to future generations (EU, 2020).

Abstract

The basic idea that starts from this concept is the following: essential for business success, in a constantly changing world, is, first of all, an optimal organization of the activity, given to external priorities and rigor and not the availability of resources (financial). , materials, human, information, etc.). Business Process Reengineering (BPR) has become one of the most commonly used terms by management specialists and managers who want to increase the efficiency and effectiveness of their businesses. Officially launched in the 1990s (M. Hammer, J. Champy, 1993), the reengineering revolutionized the managerial theory and practice at the company level, with the emphasis placed on the fundamental, spectacular, profound and radical redesign of work processes and, in especially those of value added generators. The key notion around which this unique mode of change gravitates is the "process", which, we must admit, the Romanian management made little reference to until the emergence and promotion of quality management systems.

Keywords: Reengineering, Business, Start-Up, Organization

Introduction

Reeingineering is an increasingly common term, but not always better understood. It is a concept originating in America from the last recession, then spreading rapidly throughout the world (Dubois H, 2002).

The basic idea that starts from this concept is the following: essential for success in business, in a constantly changing world, is, first of all, an optimal organization of the activity, given to external priorities and rigor and not the availability of resources (financial, materials, human, information, etc.) (Jianu, I. et al., 2019).

The concept of reengineering finds its roots in management theories developed in the early 19th century in the USA (Ioniţă, F. et al., 2009a,b). The purpose of reengineering is to: "Make all your processes the best in the classroom," suggested Fredrick Taylor since the 1860s. Taylor revolutionized the workplace with his ideas on how to organize work. He believed that the same principles that brought success to solving technical problems could also be used to structure the jobs performed by individuals (Davenport T, 1993).

Taylor suggested that managers could discover the best way to perform the process and implement reengineering to the extent that it reflects the classic belief that there is a "best way" to perform tasks. The principles Taylor has developed have become known as scientific management. Scientific management has had a long-term effect on the organizational structures of workers 'work, the terms of content of the workers' workplace, their models of interaction with technology, as well as on the roles and relationships between workers and management.

Business process reengineering involves radical redesign of core processes to achieve dramatic improvements in productivity, cycles and quality. In the process of reengineering business processes, companies start with a blank sheet of paper and rethink existing processes to provide more value to customers (Bălan C., 2006).

The Reengineering Process

A business process in the above concept can be defined as a collection of activities that take one or more types of inputs and create something at the output, something that has value for the customer (Hammer M., 2006).

Three types of reengineering enterprises have been identified (Ionita, F., & Burlacu, S., 2009):

• The first type is represented by those companies that face great difficulties, which have no other solution. If, in an enterprise, the costs are of an order of magnitude greater than the competition or that would allow the model of production process in which they fall, if the service activity offered is so defective that the customers protest, if the failure rate of the products is twice, three or five times higher than the products of the competition, if, in other words, the company needs improvements in the scale of an order of magnitude, then that company needs reengineering;
• The second type is the one of companies that have no problems at the moment but whose management anticipates the emergence of these major difficulties. This leadership prefers to approach this solution before reaching the crisis situation.
• The third approach to the reengineering concept is even the companies on the wave, which have a very good position but which have an ambitious and aggressive management.
Adam Smith's theory, according to which industrial activity can be broken down into simple, fundamental operations, was the one that stood for two centuries at the basis of business organization and the concept of reengineering comes with the reunification of operations around business processes (Burlacu, S., 2010) (Costache, G., et al., 2015).

The division of labor is no longer the reality of our day, it simply does not work anymore. Clients, competition, change are the driving forces behind another approach (Al-Mashari M., 2001).
Business reengineering means starting from the beginning, from the ground up, to let go of much of the wisdom gathered during two hundred years of industrial management, to look at how to work in the mass production era and to decide how best to currently operated (Bran, F. et al., 2018).

The need for reengineering

In 1990, Michael Hammer, a former computer science professor at the Massachusetts Institute of Technology (MIT), published in the Harvard Business Review the article "Reengineering Work: Don't Automate, Obliterate," stating that "the biggest challenge for managers is eliminating forms of work that add no value, rather than using technology to automate it" (Hammer M., 2006).

Hammer's proposal was very simple: most of the work done by companies does not add any value to customers, and this activity should be eliminated, not accelerated by automation. His proposal was to companies: they should reconsider their inability to meet the needs of their clients and to redo their processes. Hammer said that BPR (business process reengineering) will bring more value to customers; will accelerate their processes; the focus will only be on what matters BPR basically aims to maintain

long-term profitability and strengthen competition in line with transforming the market reality (Hammer M., 2006).

BPR can represent an effective management approach, adopting a wide range of use and can have very successful results, if it is put in the right conditions. Before proper and careful implementation, consideration can be given to the factor care and can be significantly included in the BPR project (Ozcelik Y., 2010). Their commitment and support are the main success factors in the re-engineering project. Peak administration cannot provide strong and consistent support in terms of capital, resources, or life-long leadership, this is very important for BPR design.

At the same time, the top management should ensure constant control over the design of the BPR for a monitoring of the modality in the effective care works and for taking measures before a problem for any problem (Dubois H., 2002).

Figure 1: The objectivs of BPR

Define Start-Up

A startup is a type of temporary organization, which aims to look for a repeatable and scalable business model, in response to an existing unresolved problem, and which constitutes the transition from a simple idea to a business (Lewis L.V., 1983). Although there are many definitions for the concept of start-up, some very technical, some less specialized, there is still no unanimously accepted explanation (Zeleny M., 2005).

In the case of Romania, the following approach is identified with an optimal application:

- a startup is a company that has less than 10 employees and activates for a maximum of 5 years (from other sources, maximum 2 years) only that this variant takes more of technical aspects instead of taking into account the part of innovation, novelty and so on. completion also appears;

- a startup is a company that has noticed an existing problem and has designed a creative solution that has not been encountered until then, in response to that problem. More efficient solutions can be framed here, for problems already "solved" by other methods.

Figure 2: A framework for increasing entrepreneurship

Startup financing programs

At present, there are several programs for financing, supporting and accelerating start-ups. These programs are supported by the Government of Romania, by certain investment funds (eg: GapMinder, recently launched venture capital fund in Romania), by certain banks (eg Romanian Commercial Bank, Banca Transilvania).

In order to be able to access these funds, each person must take certain information, development and training courses to help them develop and sustain the business (internships in companies with the same field of activity as the one of the company they wish to access. o set up, personalized mentoring and mentoring sessions, "business school" type events, support for setting up the business and monitoring the implementation of the business plan and the expenditure of the financial aid received) (Rădulescu, C.V. et al., 2018a,b). The conditions and requirements differ from one funding program to another. Structural Consulting Group has started projects on the financing line Romania Start Up Plus, through which new businesses are financed.

Their involvement is made in four geographical areas as follows:

- Start-up @ CENTER - project addressed to the Centru region (Alba, Braşov, Covasna, Harghita, Mureş and Sibiu counties), more specifically for people with a residence or residence in this region and who wish to set up a business in this region;
- Entrepreneurs' Workshop - project addressed to the West region (Timis, Arad, Caras-Serverin and Hunedoara counties);
- Start UP Smart 2.0 - project for the South-East region (Galaţi, Brăila, Constanţa, Tulcea, Vrancea and Buzău counties);
- Plus for the start-ups of the North-West region - project addressed to the North-West region (Cluj, Bistriţa-Năsăud, Maramureş, Satu Mare, Bihor and Salaj counties);

The conditions regarding the business provided under this program are the following:

- To be new businesses (companies will be set up after the selection of business plans by the selected contractors);
- To be business in non-agricultural fields and to be set up in the urban environment, in one of the counties of the region to which the project is addressed;
- To create at least 2 jobs (per business);
- The entrepreneurs selected to receive the financial support for setting up and developing the businesses will no longer have the status of majority partners in other businesses;
- Financing can be obtained for the proposed businesses in most areas of activity.

The Start-up Nation program is a program to encourage and stimulate the establishment and development of small and medium-sized enterprises, implemented by the Ministry for the Environment of Business, Trade and Entrepreneurship "through the Territorial Offices for Small and Medium Enterprises and Cooperation, according to with the provisions of Emergency Ordinance No. 10/2017 for stimulating the establishment of new small and medium-sized enterprises approved by the provisions of Law No. 346/2004 on stimulating the establishment and development of small and medium-sized enterprises, with subsequent amendments and completions, as well as Government Decision no. 23 / 2017- regarding the establishment, organization and functioning for the Business, Trade and Entrepreneurship Environment.

Start-Up Nation is a program through which the Romanian state commits to offer up to 200,000 lei to those who want to start an SME. The 200,000 RON (the maximum amount that can be accessed by one person through this program) are non-refundable and represent 100% of the value of the eligible expenses.

In short, unlike other financing programs, the state no longer requires the entrepreneur to pay part of the expenses that arise with the opening of a new company. The state wants this program to be successful because this funding program could lead to the establishment of 10,000 SMEs and the creation of new jobs: every person who starts a business as a result of this program will have to hire at least a man and hold the post (not the employee, the employee can be changed) for a period of at least two years after the end of the implementation period.

Conclusion

The concept of reengineering involves recasting and redesigning the activity of a company to achieve significant and lasting improvements in terms of costs, revenues, quality. The purpose of reengineering is to optimize the development of all the processes involved in the activity of the company, maximizing the results with an optimal consumption of resources.

In this context, my work on the topic "Reengineering in business models for start-ups" is part of the modern management approaches regarding new businesses and how they can be successful in the Romanian economic market.

I can say that the Romanian entrepreneurship has a favorable evolution and is very receptive to the opportunities existing in the economic environment. Entrepreneurs share a common set of features that help them start their own business and increase their chances of success with start-up programs.

In conclusion, I can say that the private environment can make a significant contribution to the development of entrepreneurship by implementing quality programs: training sessions, events and competitions for entrepreneurs at the beginning of the road, mentoring programs and support for start-ups or information sessions about existing financing opportunities.

Abstract

This paper tries to underline the evolution of the three pillars of the Romanian pension system and the support developed by the European Commission and midrange entities that are designed to grow the real convergence between EU Member States and reduced development delays between the East and the West.

Keywords: Pension System, European Union, Development, Sustainability

Introduction

The aging of the population is a major problem found in the pension systems of all the countries of the European Union. By 2050, the life expectancy at birth for men is expected to increase by 7.4 years, and for women by 6.1 years, compared to 2010. Due to the increase of the retirement age of the baby-boom generation the active age of Europe will it begins to decline, thus leading to annual growth of approximately 2 million elderly people over 60 years of age. Also, the active persons between the ages of 20 and 59 will decrease each year during the following decades.

Increasing longevity and phasing out the baby-boom generation will have significant economic and budgetary repercussions in the EU, limiting the potential for economic growth and putting pressure on public finances.

The pension policy is established and implemented by the European Union countries at national level (Profiroiu, A. et al., 2019). The EU supports national efforts to ensure a high level of social protection, pension allocation and exchange of best practices.

Fig. 1: Demographic changes from the previous year, EU-27, 1996-2060

The Pension System in Romania

The World Bank supports and promotes the reform of the pension systems in the EU countries. The system promoted by the World Bank, implemented by Romania, is based on three pillars:

1. Pillar I - It is the pension offered by the public system and is represented by the state pension
2. Pillar II - It represents the privately administered pensions - the obligatory private pensions
3. Pillar III - Represents optional private pensions, consisting of additional contributions of employees and employers

Pillar II and III assume the private administration of the pension money.

The role of the Member States and the EU in the field of pensions

For the sustainable functioning and efficiency of the pension system it must be supported by the people with a job through taxes, contributions and savings (Bran, F. et al, 2018). The way of financing the pension fund must be supported in a fair way by the conditions on the labor market in order to have a balance between the active taxpayers and the beneficiaries, ie the retired persons (Bodislav, A. et al, 2019).

Each Member State has the power to develop its own pension system according to their context. According to the Treaty on the Functioning of the EU, it provides for the support and completion of the activities of the Member States in the implementation of policies and social protection (Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L., 2019).

The European Union has a plethora of political instruments to support Member States in ensuring and maintaining adequate sustainable pensions (Burlacu, S. et al., 2019). However, it is recognized that

pensions play a vital role in supporting EU citizens, but the largest public expenditures are allocated for pension funding (Jianu, I. et al., 2019).

In order to postpone retirement, some Member States resort to different factors such as increasing the number of years required for the contribution to obtain a full pension; adapting the retirement ages in direct relation to the increase in life expectancy (Ioniţă, F. et al., 2009).

Increasing the retirement age as well as phasing out the early retirement system requires measures to allow workers to continue their work over an extended period, health-related measures, employment and the work environment (Rădulescu, C.V. et al., 2018).

The value of pensions in relation to the GDP of the European average is increasing, contributing to the increase of public spending, currently being at 10% of GDP, and by 2050 it will reach 12.5%.

During the last decade the pension system has undergone various structural reforms. Most EU countries have adapted the pension system to cope with any demographic changes. A series of changes to the pension system reforms include the inclusion of mandatory financial support pillars and the transition from predefined benefits systems to predefined contributions systems.

Average life expectancies at EU level

According to Eurostat in Europe average life expectancy is constantly increasing for all states. Life expectancy for men grows exponentially from decade to decade so that by 2050 the country with the highest life expectancy is Switzerland with 85.3 years, and at the opposite end is Latvia with an average life of 78.4 years.

Table 1: Average life expectancy for men

Switzerland	85.6	86.0	87.1	88.1	89.1

Source: Eurostat, 2019

Conclusion

At the level of the European Union, the aging of the population is an important factor, more precisely a negative element due to the decrease of the number of active persons and the increase of the number of old people, having effects on the economic evolution, limiting its potential.

At the level of Romania, the pension system promoted and implemented is based on 3 pillars, being supported both from the public space and from the private space, through various taxes, contributions and savings, forming a balance between active taxpayers and pensioners.

Regarding the role of each state, they have the duty to create their own pension system, according to the needs of each one. The European Union offers support to the Member States in support of these pensions, being shown that the largest public expenditures are made to finance these pensions. Having the opportunity to make their own pension system, some states postpone retirement by calling on various forms of age extension as well as ending the early retirement phenomenon.
Looking at the demographic estimates on the increase of the number of pensions and the decrease of the young generation due to the decrease of the birth, a future problem of the states is evaluated, the

coverage of these pensions. Specialists support the move to private pensions to avoid problems in the public environment.

Abstract

Technological progress, automation, digitization, lead to changes in the demands of the labor market. Vocational education and training systems are forced to keep up with these changes. The acquisition by young people and adults of skills that are as relevant to the labour market as to provide them with increased employment opportunities is the basis of investments in education. Objective 4 of sustainable development pursues these aspects. The article analyzes the progress made in reaching the targets proposed by the Member States of the European Union. Depending on the degree to which young people acquire new knowledge, skills and competences, their capacity to integrate them into the labour market increases. Subsequent integration into the labour market of young people may be affected by the early departure of vocational education and training systems. Throughout life, adult education measures may be hindered by their refusal to participate in vocational training programs. Comparative analyzes regarding both basic education and tertiary education are presented, as well as comparative analyzes regarding adult education.

Keywords: European Union, Education, Training, Employment

Introduction

The United Nations agenda for sustainable development for 2030 aims at both poverty reduction and combating climate change and addressing inequalities. To meet these issues, 17 sustainable development goals were set, for which 169 targets were associated (EC, 2020). The Treaty on European Union stipulates that the European Union assumes the principles of the Charter of the United Nations (EC, 2012).

At EU level, through the reflection paper „Towards a sustainable Europe by 2030", the European Union recognizes that for its political agenda it is necessary to prioritize the 2030 Agenda for sustainable development, as well as the 17 goals of sustainable development (EC, 2019) . It is also proposed that the overall objective in the next strategic plan of the European Union for the period 2019-2024 and subsequently be represented by the implementation of the 2030 Agenda for sustainable development (ECR, 2019).

Achieving a sustainable future for the Member States of the European Union is closely linked to achieving these goals. One of the goals of sustainable development concerns the quality of education. The Member States of the European Union, with the intention of providing new opportunities for young people, given the special importance of improving the quality of education and vocational training (EC, 2016).

All the Member States of the European Union aim at increasing the quality of their own education and training systems. The exchange of experience in the steps to achieve this objective constitutes advantages in preparing young people and their transition to the labour market (CEDEFOP, 2018).
Changing the qualification needs leads to the need to update the skills. Loss of contact with the labour market diminishes the chances of getting a job (CEDEFOP, 2018b). Workplace practice becomes a necessity in the youth's quest to acquire new knowledge, skills and competences (OECD, 2017). In this context, dual education has the advantage of partnerships between companies and the education system. In the labour market, persons trained in the dual system benefit from high mobility (Koudahl, 2010).

Investments in education allow the overcoming of the mismatches between the competences required in the labour market and the competences with which the young graduates are presented for employment (EC, 2018a).

The implementation of digitization has made the mobility of the population increase. Both professional insertion and social inclusion are influenced by the existence of reading, math and science skills (EC, 2017b).

Reducing social inequities can be achieved through adequate education. In this way, changes can occur both at the level of individuals and communities they belong to (OECD, 2019).

Modern technologies have also emerged as a consequence of investments in innovation and research. Economic growth, based on productivity growth, is influenced by employment rates. The structure of the labour markets changes according to the level of education of the recent graduates. Thus, new jobs appear based on new skills (EC, 2019).

It cannot be said that the protection of young people against social exclusion or poverty can be based only on employment. The low levels of pay or the long periods affected by unemployment lead to the need to complete the competences by acquiring higher level qualifications (Maguire, 2015).

Companies are becoming more and more mobile and digital. This is why it is necessary to identify new ways of education and vocational training, through which those skills required by the labour market can be acquired (EC, 2017).

The changes manifested on the labour market, due to the financial crisis, influence the structure of the economy. Thus, a motivating salary can make graduates choose a job in public administration to the detriment of small or medium-sized companies, with unattractive salaries. Also, the segmentation of the labour market, as well as the regional differences, make the graduates to occupy jobs in certain occupations, respectively in less developed regions (Xiaohao and Changjun, 2013).

Literature Review

In recent years, there is an increase in population in urban areas to the detriment of population in rural areas. These changes influence the way in which the planning of educational systems should be carried out (UNESCO, 2016).

The objectives of the early childhood education programs should include aspects related to the development of children in general, namely self-care skills, as well as issues related to their preparation for a higher level of education (Ahi and Kildan, 2013).

In many countries of the European Union the education and training systems have also changed as a result of European law (Dias, 2014).

In view of demographic, social and economic changes, most EU Member States promote quality in adult education (Pozdnyakova and Pozdnyakov, 2017).

Many young people are tempted to put a job first, to the detriment of acquiring skills. It is often proven that such an approach in life can be harmful (Burlacu and Jiroveanu, 2009). Under the current changes in the labour market, the acquisition of a qualification, as well as the updating of competences, allow to eliminate the risk of social exclusion and represent advantages in the steps of employment (Maguire, 2015).

Increasing the ability to take a job can be achieved through education (Costache et al., 2015). The information is becoming more and more diverse and diverse. Therefore, lifelong learning has an important role to play (Burlacu, 2011). Economic growth can occur through the application of investment measures in education and training (Jianu et al., 2019). In this way, the number of low-skilled people can be reduced and the number of people with the required qualifications in the labour market can be increased (Burlacu et al., 2019).

For regions facing low-skilled workers, regional economic development can be achieved either by increasing the employment rate of these workers or by using high-tech sectors. In this case, increasing productivity can be achieved by improving workers' skills (Lee and Clarke, 2019).

By ensuring quality in education, knowledge is promoted, but opportunities are created to promote creativity (Burlacu et al., 2019b). In this way, literacy and numeracy skills are of particular importance. Poor results in basic reading, math and science skills can lead to situations of social exclusion (Rădulescu et al., 2018b). Also, the professional insertion is done with weight. One measure by which these limitations can be eliminated is digitization (EC, 2017).

Due to the evolution of the labour market, the connection between education and training, on the one hand, and employment, on the other, will be based on the interconnection of some activities (Dubois and Rousset, 2017).

Vocational education and training systems may undergo changes due to economic trends. In this way, the need for new education and vocational training programs emerges, at the end of which the graduates acquire the skills required by the labour market (Sava and Bădulescu, 2016).

The chosen field of study influences the further professional development (Burlacu and Jiroveanu, 2012). Also, a better transition of graduates also depends on the degree to which they identify and occupy suitable jobs (Stojanová and Blašková, 2014). The educational trajectory of the students is influenced by the employability of the parents. Thus, parental unemployment has negative consequences on family life and implicitly on children (Lindemann and Gangl, 2019).

Lifelong education and training should encompass both the context of formal education as well as the context of non-formal and informal education (Aleandri and Refrigeri, 2013).

It is considered that the young people who fall into the category of neither in employment nor in education and training (NEET) do not have a portfolio of vocational training adapted to the new needs of the labour market. Belonging to this state influences both professional and personal life (Bodislav et al., 2019). Also, their possibility of participating in vocational training programs is affected (Angheluta et al., 2019). These people are often marginalized and have a high risk of social and economic exclusion. For this reason, measures are needed to support this category of people (RCT, 2017).

Methodology of Research

Although for many companies it is easier to acquire ready-made specialists than to invest in vocational training, however, the areas that offer more jobs also allow for easier skills building (Rădulescu et al., 2018).

The article presents research on achieving the targets proposed by the Member States of the European Union for the Sustainable Development Goal 4 - Quality Education. A comparative analysis is performed for each indicator of this sustainable development objective. Thus, the research was conducted for: early leavers from education and training, tertiary educational attainment, participation in early childhood education, underachievement in reading, maths or science, employment rates of recent graduates, adult participation in learning, young people not in employment nor in education and training. Indicator developments are also presented for some Member States which have had results in reaching the targets. The analyzes are based on the data existing on the EUROSTAT website.

Results and Discussions

One of the indicators is Early leavers from education and training. It takes into account the share of the population between the ages of 18 and 24, who has at most lower secondary education (level 0-2 ISCED). In addition, the comparative situation of Participation in early childhood education is presented in Table 1. The indicator shows the share of children between the ages of four and the age required for compulsory primary education. Table 1 presents the comparative situation of the indicator Young people neither in employment nor in education and training. This indicator refers to personnel between the ages of 15 and 29 who are not employed and are not included in vocational education and training programs.

Table 1: Comparative situation for Early leavers from education and training, Participation in early childhood education, Young people neither in employment nor in education and training, 2002-2018 (%)

Countries	Early leavers from education and training (%)				Participation in early childhood education (%)				Young people neither in employment nor in education and training (%)

The target for 2020 for early leavers from education and training is 10% maximum. For early leavers from education and training, from table 1 it is observed that, in 2018, the share of population aged 18 to 24 was over 10% in 11 countries. The highest values were observed in: Malta (17,4%), Spain (17,9%), Romania (16,4%), Italy (14,5%), Bulgaria (12,7%), Hungary (12,5%). However, compared to 2002, in 2018, in Malta, the values decreased by 35,8%.

Being the biggest difference registered, in figure 1 is presented the evolution of this indicator for Malta, for the period 2002-2018 (%).From the presented figure it is observed that for the period 2002-2018, the share of population aged 18 to 24, for the indicator early leavers from education and training in Malta, had a decreasing tendency, from 53,2% (in 2002) to 17, 4% (in 2018).

The target of 2020 for participation in early childhood education is over 95%. From table 1, it is observed that, in 2017, almost half of the countries of the European Union did not reach this percentage. The countries with the lowest weights are: Slovakia (78,2%), Greece (81,5%), Croatia (82,8%), Bulgaria (83,9%), Finland (87,8%), Romania (89,6%).

Fig. 1: Early leavers evolution from education and training, for Malta (%)

However, in Poland, in 2017, there was the highest increase compared to the values of 2002. Figure 2 shows the evolution of the age group between 4-years-old and the starting age of compulsory education, for the period 2002- 2017, for Poland (%).

Fig. 2: Evolution of participation in early childhood education, for Poland (%)

For the period 2002-2016, figure 2 shows an increasing trend. Also, in 2017 the values decreased slightly from 93,1% (in 2016) to 91,9% (in 2017).

In 2018, the indicator of young people neither in employment nor in education and training had high values in: Italy (23,4%), Greece (19,5%), Bulgaria (18,1%), Romania (17%), Croatia (15,6%), Spain (15,3%).

Although Bulgaria had high values in 2018, however, compared to 2002, it registered the most significant decrease among the countries of the European Union. The evolution of the indicator is shown in figure 3.

Thus, in the period 2008-2013, there is an increase in the values of this indicator. For the period 2002-2008, respectively 2013-2018, the share of population aged 15 to 29 from Bulgaria, which falls in the category young people neither in employment nor in education and training, decreased by 12,9%.

Fig. 3: Evolution of young people neither in employment nor in education and training, for Bulgaria (%)

Table 2 presents the comparative situation for a set of three indicators: tertiary educational attainment, adult participation in learning and employment rates of recent graduates.

Table 2: Comparative situation for Tertiary educational attainment, Adult participation in learning, Employment rates of recent graduates (%)

Countries	Tertiary educational attainment (%)				Adult participation in learning (%)				Employment rates of recent graduates (%)

Sweden	28,3	41	47,9	51,8	18,4	19	27	31,4	83,3	83	85	88,1
United Kingdom	31,5	38,3	46,9	48,8	21,3	20,5	16,3	14,6	86,3	81,3	83,2	86,7

The tertiary educational attainment indicator refers to the share of the population between the ages of 30 and 34, who graduated from tertiary studies (level 5-8 ISCED). For this indicator, the target of 2020 is that at least 40% of population aged 30 to 34 be a graduate of tertiary educational attainment. From the data presented in table 2, it turns out that, in 2018, only 10 countries did not reach the proposed target: Romania (24,6%), Italy (27,8%), Bulgaria (33,7%), Croatia (34,1%), Portugal (33,5%), Czechia (33,7%), Hungary (33,7%), Malta (34,7%), Germany (34,9%), Slovakia (37,7%).

Compared to 2002, in 2018, the largest increases were recorded in Lithuania (+34,2%). Figure 4 shows the evolution of tertiary educational attainment, for Lithuania, for the period 2002-2018 (%).

Fig. 4: Evolution of tertiary educational attainment, for Lithuania (%)

Between 2002 and 2016, there is a relative increase from 23,4% (in 2002) to 58,7% (in 2016). Between 2016 and 2018, this indicator shows a slight decreasing trend.

The adult participation in learning indicator aims at 2020: at least 15% and refers to the share of people between the ages of 25 and 64 who have participated in vocational education and training programs. In 2018, this value was reached in: Sweden (31,4%), Finland (28,5%), Denmark (23,5%), Estonia (19,7%), Netherlands (19,1%), France (18,6%), Luxembourg (18%), Austria (15,1%). The lowest values were recorded in: Romania (0,9%), Bulgaria (2,5%), Croatia (2,9%), Slovakia (4%), Greece (4,5%).

The importance given to this type of education, through the reforms implemented in 2013 in France, has led to the increase of the share of population aged 25 to 64 who participated in learning in 2018 compared to 2002. The evolution of this indicator is shown in figure 5.

Fig. 5: The evolution of adult participation in learning, for France (%)

We observe the results of the reforms introduced in the education system in France, in 2013. Thus, adult participation in learning increased from 2,7% (in 2002) to 18,6% (in 2018).

For employment rates of recent graduates, the proposed target is that over 82% of population aged 20 to 34 with at least upper secondary education, after graduation, take a job. Table 2 data shows for 2018 percentages below 82% in 11 countries: Greece (55,3), Italy (56,5), Croatia (71,2), Spain (75,4), Romania (77,4), France (78), Bulgaria (78,6), Cyprus (78,9), Portugal (80,6), Estonia (81,7), Finland (81,7).

With a percentage in 2018 of 83,1%, Poland is the country with the highest difference between the values of 2006 and those of 2018. The evolution of the share of population aged 20 to 34 with at least upper secondary education in Poland, for the period 2006-2018 is shown in Figure 6.

Fig. 6: Evolution of employment rates of recent graduates, for Poland (%)

From the presented data it is observed that, between 2008 and 2013, employment rates of recent graduates had a decreasing trend. Also, between 2006-2008 and 2013-2018, respectively, the values of this indicator increased.

For the underachievement indicator in reading, maths or science, the targets for 2020 are given by obtaining a percentage of less than 15% of 15-year-old students. Table 3 shows in alphabetical order, for 2015, the countries for which the percentages are below 15% or close. This indicator is updated every 3 years. The results for 2018 will be published this year.

Table 3: The situation of underachievement in reading, maths or science, weights below 15%, 2015 (%)

Countries	Reading	Mathematics	Science
Denmark	15	13,6	15,9
Estonia	10,6	11,2	8,8
Finland	11,1	13,6	11,5
Ireland	10,2	15	15,3
Poland	14,4	17,2	16,3
Slovenia	15,1	16,1	15

It is noted that for reading the lowest values have: Ireland (10,2%), Estonia (10,6), Finland (11,1). For mathematics: Estonia (11,2%), Denmark (13,6%), Finland (13,6%). The lowest values of 15-year-old students with underachievement in science are in: Estonia (8,8%) and Finland (11,5%).

Also, Table 4 presents the countries in which the share of 15-year-old students with underachievement in reading, maths or science, corresponding to 2015, was very high.

Table 4: The situation of underachievement in reading, maths or science, high weights, 2015 (%)

Countries	Reading	Mathematics	Science
Bulgaria	41,5	42,1	37,9
Cyprus	35,6	42,6	42,1
Greece	27,3	35,8	32,7
Malta	35,6	29,1	32,5
Romania	38,7	39,9	38,5
Slovakia	32,1	27,7	30,7

Thus, the worst results for reading were recorded in: Bulgaria (41,5%), Romania (38,7%), Cyprus (35,6%), Malta (35,6%), Slovakia (32,1%). For the mathematics the worst results were recorded in: Cyprus (42,6%), Bulgaria (42,1%), Romania (39,9%), Greece (35,8%). Countries where the share of 15-year-old students with the highest underachievement in science were: Cyprus (42,1%), Romania (38,5%), Bulgaria (37,9%), Greece (32,7 %), Malta (32,5%), Slovakia (30,7%).

Conclusions

A correlation of the demands of the labour market with the educational offer should also be achieved in higher education. This can be achieved by participating in partnerships of all providers of education and training.

From the analysis, it is observed that the Member States of the European Union are making progress towards achieving the proposed targets regarding the Sustainable Development Goal 4 - Quality Education. Thus, in 2018, for early leavers from education and training, the target was reached in 11 countries, and for tertiary educational attainment, only 10 countries did not reach the proposed target. For participation in early childhood education, in 2017, almost half of the European Union countries did not reach this proposed target. In 2018, the target for the adult participation in learning indicator was reached in 8 countries. Also, for employment rates of recent graduates, the target was not reached in 11 countries.

Even though secondary education is the basis of education systems, it is becoming increasingly clear that lifelong learning becomes very important (Dias, 2014).

Abstract

Globalization is a complex system or phenomenon that can be analyzed differently. Although it has both negative and positive opinions, it is extremely difficult to decide which of the two inclines more balance. According to the information analyzed, the number of optimists on the problem of globalization has increased compared to that of the pessimists. A good example given by optimists is that of increasing life expectancy from 46 years to 66 years in the last 50 years.
Another optimistic example is the fact that due to globalization, namely the progress in health, at the end of the 21st century we will be able to live 200 years according to scientists. But pessimists sound an alarm because many countries, areas, territories and peoples of the Earth will not have any of these discoveries of science. Due to the fact that the progress of globalization is taking place at the planet level, the areas left behind are enhanced by their deposits, raw material resources, energy and human resources. Beyond these, globalization is a living, real fact that we must face regardless of our will. Through this article we disseminate the results of our documentary research by highlighting the main trends and opinions expressed today.

Keywords: Globalization, Poverty, Market Space

Introduction

Human need to exchange goods generated a new activity "trade", which comes from the Latin word "commutatieo mercium" meaning exchange of goods. The notion of trade has an extremely complex content that involves the exchange of goods, currencies and services, determining an economic function that consists in the purchase of goods, currencies or services and to sell them and make a profit convenient to the seller (Bodislav, A. . et al, 2019).

The history of trade is a very old one, its presence has been necessary since the time people started communicating with each other. In the beginning, the first form of trade was the "dumb" in the form in which the exchanges of goods took place (Ioniță, F. et al., 2009). The exchanges of goods that were made at the beginning were those produced against the product and thus replaced the so-called barter (Ioniță, F. et al., 2009). Thus, in order to obtain what they needed, the man gave in his things to those who gave in exchange what they had as surplus (Bran, F. et al., 2018). The exchange became easier when it went from barter to the use of intermediate goods called currency. The barter split in two into selling and buying, truly marking the beginning of true trading (Bran, F. et al, 2012). If at first people were satisfied with a few things and endeavored to produce all that was needed, over time, as the

civilization developed, needs increased and could no longer be met. Which led to the continuous development of trade.

The specialists in the commercial theory have analyzed the evolution in time of the exchange and have noticed a true commercial civilization whose beginnings have to be looked for in a past of more than four thousand years (Ionita, F., & Burlacu, S., 2009). Thus China, Mesopotamia, Northern Europe have been trading internationally ever since. Several Mediterranean peoples were also more navigators and traders. Later the Greeks and then the Romans built empires genuine commercial advantage of improving land and sea transport and the development of trade and economy.

After the Second World War in the second half of the twentieth century, world trade was marked by a series of events such as:

- the collapse of the colonial system
- the appearance of over 150 national states
- US propulsion as leader of the Western world
- the emergence of transatlantic trade
- the appearance of NAFTA (North America) and EU (Europe) alliances

Global trade comprises two distinct entities, namely transnational corporations and regulatory institutions (Jianu, I. et al., 2019). World trade, the most widespread international economic form represented by transactions with goods and services that take place between residents of different countries (Alpopi, C. et al, 2018).

World trade is a human activity that concerns us all and involves us every day. It has effects on citizens in at least two ways, namely:

- first of all the international trade diversifies the offer of available goods and services and leads to the decrease of the price of the products due to the increase of the competition
- secondly, access to raw materials, cheaper materials, more efficient technology and a broader market leading to the growth of local companies, economic growth, creation of new jobs and increased investment rate.

A series of events and changes marked the evolution of international-global trade, namely:

- increasing the share of developed countries in world trade (reaching 70%)
- cross-sectoral exchanges have led to an independence between nations
- parallel existence of financial flows (which determine the interest rate, exchange rates) that stimulate world trade
- changing the structure of world trade
- the growth of international trade

The global market represents the assembly of international flows of products, services, capital, goods and labor (Costache, G., et al., 2015). This is the starting point in the protection of goods and services designed to meet the needs, representing the relationships established on the basis of the demand and the supply of goods, goods and services from different countries that resulted in international economic transactions. In global markets countries meet from different levels of development or different product structure (Rădulescu, C.V. et al., 2018).

Research Aim / Question

Regulations and Deregulations in World Trade

Over time, in the evolution of world trade, the following manifestations of protectionist type and global trade order are highlighted. Protectionism appeared at the end of the seventeenth century - with the objectives of maximizing the export and minimizing the import, objectives that were achieved through the development of the national industry, limiting the import through various instruments (taxes,

restrictions). This is a customs policy of a state that aims to protect the national economy against foreign competition.

The global trading order represents a fixed system of exchange rates and marks the beginning of the global trading order. And it represents the follow-up to the 1944 Bretton Woods Agreement, concluded after World War II. After that, the General Agreement on Tariffs and Trade (GATT), designed to negotiate tariffs, appears. In 1995 it is replaced by the World Trade Organization (WTO), adapted to the reality of today's world. As a result of the adoption of these treaties, the tariff barriers were lowered but the non-tariff ones appeared.

The World Trade Organization is a first instrument in the process of globalization, especially in the liberalization of markets. This is considered to be guilty of failure to implement the anti-dumping order.

Findings

Market Liberalization

Price liberalization is influenced by a number of positive and negative effects, namely:

Positive effects:
- consumers benefit from new, more efficient services
- consumers benefit from lower prices
- consumers are free to choose what they want
- The European economy is becoming more and more competitive
- liberalization of the international movement of goods and services
- disappearance of commercial borders
- disappearance of customs duties
- expansion of markets
- creation of new interdependent markets

Negative effects:
- reducing the number of jobs in developing countries
- stagnation of raw material prices
- outsourcing of some economic activities
- the liberalized black market operates in parallel with the illegal market with great effects on the state budget

The effects of the process of globalization differ depending on the degree of development of the respective country and the typology also:

- the appearance of the e-tarifari barriers
- multiplication of non-tariff barriers
- company policies focus on products that offer price advantages on the world market
- the inter niche trade remains unaffected by the globalization and liberalization of the markets. This reduces the pressure of the impact on the budgets of the small urban and rural communities.

The effects of globalization led to the modification of the physical structure of export and import after 1989. Absolutely all the products had decreases in the volume of production which led to a decrease in the volume of export. To highlight these decreases we will analyze several product groups in turn.

The first group of products and certain machines, machines and means of transport, production was at the level of the 1950s-1960s. The group of chemicals, fertilizers and pesticides are not very much found in the export offer nor in the domestic market. Regarding the wood, its exploitation is done by grinding, and its processing has yielded the place of export of raw wood.

The food group registered in Romania a food export of about 2.35 billion euros in 2010 and an import of 3.34 billion euros, a rather large gap. Romania thus becoming a net importer of food.

The group of services has developed their commercial activities, financial services, real estate and insurance. Reducing those for health, education and military. In the case of utility services, namely energy, natural gas, water, telephony, and heating, they have experienced a continuous increase..[1]

Debates: Externalities of The Globalization Process

Poverty

Poverty is a state of permanent lack of the necessary resources to ensure a way of life considered acceptable at the level of a given community (Dima, C. et al, 2020). The World Bank calculates the poverty line after the consumption of calories, as being "the average level of the income at which the consumption expenses allow to satisfy the nutritional requirements and to ensure a consumption of calories accepted according to FAO recommendations.

We have absolute poverty when the total earnings are insufficient to meet the minimum needs to maintain the physical performance of a person. That person is exposed to various risks and humiliations that go beyond the imagination of the privileged world, representing his threshold of survival. Poverty is the product of the power structure existing in society and the way in which certain social processes create poverty.

Poverty can never be eliminated from society even if there was enough wealth for everyone because other reasons are responsible for this process and not the lack of needs.

Poverty legitimizes the existing structure because the poor are responsible for their situation, they have "a perspective of sustainable poverty". That is why they will always be the most prone to the disasters of life than the rich. The continued lack and shortcomings make them more unreliable, isolated, vulnerable, powerless associated with the idea that they can do nothing to improve their situation.

Poverty makes them forget fundamental things like:

- discipline
- order
- politeness

Interpreting in his own life style.

Poverty is present in all countries and its causes are numerous:

- individual crisis: the psychology of poverty according to which the poor are guilty of poverty
- political explanation: the cause of poverty results in the institutional dysfunctions of the society
- economic and social explanation: according to which the poor are the victims of society and not the culprits
- cultural explanation: we say that it creates its own culture, an own world from which they do not want to escape

[1] Florina Bran, Gheorghe Manea, Ildiko Ioan, Carmen Valentina Radulescu, Globalizarea Manifestari si reactii, Editura Economica, Bucuresti, 2012, pp. 173.
George Postelnicu, Catalin Postelnicu, Globalizarea Economiei, Editura Economica, Bucuresti, pp. 321.

- the theory of social labeling: Today they are labeled as lazy, immoral, incompetent, in which they will never be able to overcome their condition.

The most important barrier to overcoming poverty is motivation and hope, the lack of which diminishes the chances of escaping poverty. Poverty is present in all countries of the world. More than 50% of the population in sub-Saharan Africa and Latin America lives on less than $ 1 a day, 9% in Denmark, 12% Slovenia, 20% Italy and 17% of the EU population. But the proportions of poverty in the world are much higher than trying to express official statistics.

Beyond the official statistics, the economic reality whose accents are extremely painful must be highlighted. Thus, according to UNDP data, about 3 billion people live on only $ 2 a day, of which 1, 3 billion with 1 dollar a day, and about 70% of them are women.

In Sweden 70 phones per 100 inhabitants return, in Kenya only 0.8 phones return, and in Hungary only 0.1. According to statistical data, only 0.1 of the sub-Saharan African population uses the Internet. Because of this percentage, sub-Saharan Africa's doctors do not have access to all the data needed to fight certain diseases. It is noted that the library of the University of Medicine of Nairobi, an institution of higher education in East Africa has only subscriptions for 20 specialized magazines. In contrast, a US medical school has approximately 5,000 specialist journals. Considering that the population of the Earth is growing, with about 80 million a year, in the next 30 years we will have 5 billion people living with only $ 2 per day. Due to the fact that I live for only $ 2 a day or even less, the population of Earth suffers from anemia. According to the United Nations Development Program, only 4% of the income of the rich (ie 225 rich people) would be sufficient to meet the essential needs (regarding food, water, health and education) of poor countries.

The geography of poor countries means not only Africa but also Asia. According to some analysts, about 70% of the world's poor live in Asia. Such results were much worse 30 years ago, when more than half of the territory of Asia was covered by a glossy poverty, where life expectancy did not exceed 48 years, where only 40% of Asia's adult population was schooled.

Today, the proportion of the poor population has dropped by one third, and life expectancy has increased from 45 years to 65 years, and the adult school population has reached 70%.

One of the reports presented by Mark Malloch Brown, administrator of the United Nations Development Program, presented some rather large economic differences that described today and show that:

- the first three richest people in the world have assets that, in terms of value, exceed the gross domestic product of 43 developing countries
- the number of computers connected to the internet was 36 million in 1998, while ten years ago it was only 100,000
- 97% of the computers connected to the internet were in the highly industrialized states
- an employee in Bangladesh must save his entire salary for 8 years in order to buy a computer
- more than 80 countries today have a lower per capita income than ten years ago
- In Cambodia a phone returns to 100 inhabitants, while in Monaco 99 phones return to 1000 inhabitants
- 74% of the total world telephone lines are owned by 1/5 of the population
- Tanzania spends nine times more to pay its foreign debt service than it spends for health and four times more than it spends for education.

With such data, particularly suggestive for the creation of an economic picture of the contemporary world. According to these predictions, in 2017 about 70 million children worldwide will remain completely out of school. As of now, at least 45 million children in Africa have never seen the inside of a school. Another 5 million children die daily due to malnutrition or other diseases.

A scary statistic that should make us think and shame us. For example, in the UK a person is expected to live an average of 77 years, while in Sierra Leone in West Africa he is expected to die at the age of 37. Another problem that should concern us in these underdeveloped countries is the HIV virus, which has a high percentage. In Africa, the percentage reaches even 30% of people infected with HIV. Worldwide, according to statistical data, about 40 million people are infected with this virus, at a rate of 16,000 per day. Besides avest virus there are other diseases such as tuberculosis which mainly affects poor countries because there is no access to treatments and information to prevent, fight against these diseases. If these diseases do not have access to the necessary ones, the ones mentioned above will expand rapidly and will result in the loss of an impressive number of the population.

Another major problem of poor countries is the high degree of indebtedness, in relation to their level of economic development. Thus, after long discussions, the need for an external aid of the comet and the investments in solving these problems and canceling the debts has been realized,

An example is the one from 1965, when the aid granted to the poor states amounted to 0.48% of the gross domestic product of the developed countries. But in 1998 it decreased, reaching only 0.23% of the gross domestic product of the developed countries. The Group of Seven or G7 recently decided to cancel the $ 100 billion total from the poorest countries.

In terms of world trade, it has declined considerably in recent decades in the case of developing countries, with poor countries being the most affected. While developing countries have opened markets for the goods of rich countries, the latter have introduced many restrictions. One thing is very clear and that developing countries could have gained more if they could access the markets of the world's poorest countries (Postelnicu, G.& Postelnicu, C., 2000).

Globalization and Poverty

Poverty - this dramatic concept of history has been perceived over time. Globalization has not always had the same impact on it (Burlacu, S. et al., 2018). In the nineteenth century, the economic progress generated by globalization resulted in visible things, which meant more steel and more electricity.

In the 21st century, the general progress of globalization is materialized in less visible things, such as technological information focused on education and people's motivation (Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L., 2019. Globalization is not the cause of poverty in the world, but it has a major contribution to this process for about two billion people.

There are also favorable effects of globalization, increasing the standard of living of the population (Bodislav, A. . et al, 2019). That is why the liberalized capital market allows developing countries access to direct investments, which has led to the following positive effects such as:

- creation of new jobs
- Increase of population incomes
- high level of qualification
- infrastructure improvement
- access to management knowledge

The liberalization of the labor market is easily transformed into the safety valve for the working population in the poor countries of the world, who cannot find a job in their country. Thus, those who leave their native country return to send money to the family's country. Or they remain permanently in the host country as citizens, but they bring a loss for the sacred country from which they come. This process favors increasing the productivity of economic activities in all fields and accumulating professional knowledge.

Another point of view within the globalization-poverty relationship is that poverty is an effect of the globalization process. An example is that according to which an employer of a company that finds a

better place of operation and positioning with respect to the resources and the market will move its activity, thus reducing the number of employees.

Another very common example is the large number of supermarkets, growing hypermarkets, which does nothing but eliminate jobs because it covers small farms, medium-sized, small firms and local and traditional producers.

Thus, all these are gradually but surely leading to a poverty of our traditional products and the importation of the necessary products to the population.

Conclusions

It is noted that, the biggest problem of globalization remains the dehumanization of some of those whom this wave simply swallows, conquered by the market, television and the Internet, they live against a general crisis of the meanings of life. The globalized or globalized man, centered only economically risks becoming the atomized man, living only for production and consumption, lacking: culture, policy, religion, consciousness, meaning. Despite all the effects of globalization and warnings, none of us can avoid or eliminate the process of globalization.

Abstract

Globalization has begun to take shape once the history of mankind, namely since the population migration to a better life. This is a result of the development of technologies, services and trade, the population wanting to discover more and more places. History globalization intensifies along with the industrialization process, outlining the emergence of large migration flows, new continents, territories and empires.In terms of economic and financial globalization is defined as strengthening and broadening relationship between national economies in the global market of goods, services and capital. In other words, the phenomenon represents the international integration of both the goods, services and capital markets. This article presents the results of research documentation on globalization trends with a focus on the causes, risks and effects of economic globalization.

Keywords: economic and financial globalization, internetional integration, poverty

Introduction

The term globalization appears in the late 1960s under the auspices of Canadian specialist Marshall McLuhan, a professor at the University of Toronto, and Zbigniew Brzezinski of Columbia University, a specialist in communism issues, one of the founders of the Trilateral Commission (1973), who defines himself. as "a group of private citizens" made up of over two hundred personalities from North America, Europe and Japan, aiming to reflect on the crisis of "accidental democracy governance". Brzezinski saw the unfolding of the technotronic revolution, the fruit of technological convergence, the consecration of the American superpower as "the first global society in history" (Bran, 2012).

Literature Review

Globalization is a complex process of multidimensional and correlative ordering of the world, whereby people accept what they look like. This process is based on the liberalization of access to efficiency and modernity, on free information, permissive finances and modern technology, the free access to honest accumulation of wealth (Alpopi, C. et al, 2018). Globalization is the process of ensuring the functioning of the global economy within a global society, capable of creating a global decision structure, capable of solving global problems (Dima, C. et al, 2020). Even if the term of globalization belongs to the "economic lexicon", essentially manifesting the phenomenon at the level of the global space, from the temporal perspective it has led to the creation of new advanced concepts such as:

- globalism;
- globality;
- it was knowledge;
- the information society;

- the era of wealth.

In short, globalization is described as giving up territorial boundaries, namely:

- unlimited growth of technology;
- unbalanced circulation of information;
- free movement of capital;
- free movement of the platform;
- uniformization of the economy.

The Canadian A. Ayoud uses instead of the term globalization, the notion of globalization and states that “globalization is far from being a novelty or an unusual phenomenon. In terms of concepts, globalization is, in essence, just a name of an old concept that simply is the leader of exchange. ”In conclusion A. Ayoud considers that globalization represents the leader of exchange extended on the planetary scale, ie the extension of the free movement of of goods and services, capital, people and ideas between all countries.

The French economist J. Percebois uses the whole phenomenon of globalization instead of the one of globalization, considering that globalization, as a process leads to the setting up of transnational decision networks in the motor fields of growth such as:

- information;
- research - development;
- finances.
- cutting-edge technologies.

In the specialized literature, there are three major approaches to this process:

- a phenomenon reached, analysts manifesting over-optimism about the possibilities and potential of the new process;
- that all important process, we can distinguish and contrary current, that of pessimists, who is minimized, if not deny the advantages of globalization, or insist on its negative consequences, particularly social;
- a moderate line, characterized by promoting a balanced approach in which to regain and novelties brought by globalization but expensive precesele you enter.

British professor P. Worsley says that "to date, there has been no human society", meaning that only today can we talk about forms of association that are spread all over the world, in the sense that until now, they have never been on the stage all the possible actors of globalization. The actors of globalization are the following: the state, a political entity consisting of a territory delimited by borders, from police and from an institutional power; international organizations; global organizations (United Nations: International Monetary Fund, World Bank, International Transparency, Medecins sans Frontieres, Greenpreace); macroregions (NAFTA, ASEAN, CSI, MERCOSUR, APEC, African Union, other organizations); International Monetary Fund; transnational corporations ; USA; Russia ; China.

Today's globalization is in full swing, transformed from process into phenomenon, served by four support pivots:

- capital market;
- market for information and knowledge;
- free movement of human resources;
- liberalization of product and service markets.

Its vectors are the transactional corporations and the capital banks that power the globalized system, giving it viability.

Globalization is a reality of the contemporary world, a component of human, economic history, which puts its mark on the present and future of the Earth (Negescu Oancea, M.D. et al., 2019). It operates in the economy and produces economic, financial, social, informational changes of human components and models of production and consumption (Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L.,

2019). The driving forces driving globalization are inspired by the concepts of the market economy in general, the liberalization of capital and the labor market (Jianu, I. et al., 2019).

Concerns regarding the analysis of the globalization phenomenon highlighted the following definitions:

- globalization can be conceived as a process or assembly of processes that include the transformation into a spatial organization of social relations and transactions, expressed through transcontinental or inter-regional flows and networks of activities, interactions and power (David Held, Anthony Mr Grew);
- globalization meant for the very rich many opportunities to make money and this much faster. These people have used the latest technology to transport money anywhere in the world, in just a few seconds, to be able to speculate more efficiently (John Kavanagh);
- process with multiple transplanetary connections between people (J. A. Scholte);
- globalization is the global integration of financial markets, nation states and technologies within a free market capitalized, on a scale unknown until now (J. A. Scholte);
- globalization refers to all the processes by which the peoples of the world are incorporated into a single world society - the global society (Martin Albrow).

Methodology

Since the 1960s, the term globalization began to be used more and more often, which required that the debate on this topic be "structured along the following points of discussion, as:

- how to conceptualize the reality called term;
- adequate tools and methods for measuring the phenomenon;
- its temporal classification;
- its normative evaluation;
- its impact on states.

The consecration of the notion of globalization will take place in the 80s under the auspices of geoeconomics and not under those of geopolitics, under the rule of market pragmatism (Bran, F. et al., 2018). Opportunity given to the transformation in international management of corporations as well as the globalization of the financial sphere (Ioniţă, F. et al., 2009). A sector of the international economy that has achieved the interconnection of its activities and its information and communication networks (Androniceanu, A. et al, 2017). From the documentary research, it seems that the term globalization was used for the first time by Theodorow Levitt in the work "Globalization and Marketing" since 1980. An answer to the question "What is globalization? "Is given by Friedman, a supporter of globalization, who says that" globalization is not a mere tendency or a fantasy but rather, an international system. " He also argues that globalization has its own laws, its own logic that can influence politics, the environment, geopolitics and the economy of every country on the globe.

FINDINGS

Positive definitions of globalization:

Globalization is defined according to the World Bank as the freedom and ability of individuals and companies to initiate voluntary economic transactions with residents of other countries.

Negative definitions of globalization:

One of the pessimistic definitions of globalization is that: The planet is cut off today by a huge dividing line, on one side there are young societies that multiply rapidly, without resources, underdeveloped and under-educated and on the other side are rich populations, but old people with technological inventiveness but demographically dying.

UNDP defines globalization as one of the most discussed phenomena in the world, manifesting its effects on the simple population. It is a powerful force that enhances the world welfare of humanity. Solving these negative effects of globalization is represented by finding a balance between negative and positive effects.

Another definition proposed by Henry Kendill states that "if we do not stabilize the population through justice, humanity and mercy, then nature will do it for you."

The process of globalization depends on economic and cultural independence and less on economic and cultural domination, diversification rather than unification and integration (Costache, G., et al., 2015). Today, in the age of globalization, we face a harsh reality, namely an unfair international order that should be eliminated (Burlacu, S., 2011); at is why third world countries (Africa, Asia) do not have the opportunity to compete with those who own the monopoly on the most advanced technologies and unlimited resources. They already own the majority of the markets compared to the countries in the world of linden which represents the weakest market (Profiroiu, A. et al., 2019). Gradually these markets will be reduced to only some areas and not markets for the production of raw materials (Rădulescu, C.V. et al., 2018).

The second problem in the age of globalization is that of demographic and technological development (Burlacu, S. et al., 2018).. The historian Paul Kennedy states that our planet would be cut by a dividing line, on one side are the fast-growing, lacking resources and underdeveloped, underdeveloped young societies, and on the other side are the rich, elderly population with technological inventiveness. .

Globalization should be the relationship that would complete, standardize the two separated worlds (Bodislav, A. . et al, 2019). So it is obvious the gap between developed countries, protagonists of globalization and developing countries, victims of the effects of globalization (Rădulescu, C.V. et al., 2018). If developed countries will become richer as a result of globalization, developing countries will become increasingly poor and indebted (Bran, F. et al., 2018).

Globalization Objectives

To highlight the importance of the two terms, namely objectives - globalization, scientists and international specialized institutions have defined the following:

The Club of Rome: interdependence between countries on a global scale, without national borders.

UN (UNDP, 1999): Globalization with the human face, a concept that also involves the concepts of sustainable development, sustainable human development, balanced development and sustainable development of the environment. From all this, it is proposed to establish a set of principles that give consistency to the concept of globalization with the human face.

The objectives of the globalization process - selection are the following:

- formation of the global state, creation of the global civilization;

- modern colonialism;
- trade liberalization and promotion of free trade;
- solving the major problems of today's world;
- formation of a global supermarket;
- global institutional order, world governance;
- the spread of capitalism in the developed countries to the developing ones.

Principles of globalization

- the principle of market and commodity liberalization;
- the flow of people, the global labor market, migration having as its final objective the emergence of a homo globalism;
- liberalization of capital flows with the 3 components: credit flows, investments (direct and shares) and currency.

The tools of globalization that ensure its dynamics, direction and evolution are numerous, the most important being:

- labor force migration "brain theft";
- consolidation, improvement of education;

- protectionism: taxes, subsidies, quotas, norms, quality, impact on the environment;
- international credit institutions (BM *, IMF *);
- transnational corporations.

The effects, risks, causes and consequences of globalization (Pisleag, G.A .; Pisleag, T. & Postolache, M. n.a., pp. 30-34)

Positive effects:

- offers space for new systems of world governance;
- reduces production costs due to economies of scale;
- it emphasizes the transactions, the exchanges that are realized almost in real time due to the globalized communications systems;
- development of international trade;
- increases the speed of running commercial, financial and technological operations;
- expanding markets and creating new markets independent of certain resources or traditional areas;
- international aid offered in various forms to poor countries;
- reduction of production costs due to economies of scale;
- movement of capital;
- foreign direct investments;
- reducing the feeling of isolation of poor countries;
- freedom of travel;
- expansion of the information society and ease of access to information;
- technology development;
- development of communications.

Negative effects:

- demographic deficit (the national intellectual potential is restricted and the export of human resources increases);
- the loss of the individuality of a people;
- loss of social control;
- security deficit (poverty, personal insecurity, migration is transferred in threats to the national and global social horizon);
- ecological deficit (the natural environment of the world deteriorates rapidly depending on the national and global economic growth);
- social deficit;
- reducing the number of jobs;
- strengthening the commercial networks for drugs, weapons, people and money laundering;
- international terrorist networks;
- paralyzing national strategies for radical reforms;
- the traditional culture of societies disappears;
- deepening economic barriers;
- the danger of setting up branches;
- destabilizing the economic life.

The Causes of Globalization

Complex phenomena can only be explained if we consider several causes. This is the only point where everyone agrees on globalization. Depending on what acceptance of globalization is taken as a starting point, other causes and motive forces appear in the foreground. In the chart below are the most frequently mentioned causes. Without a doubt, technical innovations, especially those in the field of computer and communications, have played and still play a central role. The Internet is, in many ways, the emblem of globalization. A very important role, especially at the level of consciousness, has been played by global problems. Proof of this is not only "One World" type stores in industrialized and ultra-developed states. Global problems, however, also require internationalization of politics, stimulating the development of a global consciousness. Organizations such as GreenPeace or Amnesty

International, which are dedicated to global issues such as the environment or human rights, are "Global Players". Critics of the phenomenon of globalization such as the ATTAC network are increasingly drawing attention to the fact that globalization is not an inevitable process, but rather a consequence of the US de-regulation policy begun at the end of World War II. Without the liberalization of world trade within the GATT and the WTO, this development could not have really been possible.

DEBATE: Globalization of the Economy

Globalization broadly covers thre areas of the respective social life: economic, politics and cultural. This domain of globalization is also the most important, representing the backbone of globalization on the basis of which it develops 2 domains, political and cultural. In order to highlight the history of the evolution of the globalization of the economy, we must take into account that the components of globalization originate from the earliest forms of marketing, selling products, but this becomes evident only in the mid-1980s.

By economic globalization is meant an expansion of the markets of goods and services, of the volume of products but with lower consumption of natural resources. Thus, the globalization of the economy, essentially implies the globalization of the process of creating the gross domestic production of the states of the world. The globalization of the economy also implies a reduction or renunciation of the customs policy, the restrictions of circulation of the customs duties, restrictions of circulation of the services, of the technological information and of the capital.

Economic globalization implies the globalization of the process of creating the gross domestic production of the states of the world and of orienting the restoration of the free market production with a unique competition. From an economic and financial point of view, globalization is defined as the strengthening and widening of the links between national economies on the global market of goods, services and capital. In other words, the phenomenon represents the international integration of both the goods, services and capital markets.

The determining factors of the globalization of the world economy:

Determinants of globalization of the world economy led to deepening of economic globalization and includes:

- liberalization of trade in services;
- liberalization of capital markets;
- liberalization of foreign investments.

The liberalization of the trade in services in the field of telecommunications, banking insurance took place in the 1980s, then in the European Union and then in Japan, including the countries of Central and Northern Europe. The liberalization of capital markets as a result of obstacles to the movement of capital represents an important step towards forming global financial markets. The liberalization of foreign investments is another factor that has favored globalization. The '70s led to the emergence of concepts with global vocations, as:

- the common goods of humanity;
- sustainable development;
- ecological security.

Conclusions

We can say that globalization directly affects all of us, therefore, it is necessary to analyze the opportunities and risks that it implies. From my point of view, globalization is not responsible for all the problems that the population is facing today. It is true that this has had both positive effects, forced the countries to improve their efficiency, as well as negative ones, namely that the internal problems of certain countries or areas have increased. The opening of international trade has led to an increase or improvement of many countries, such as East Asia, through exports but it has also led to the reduction of markets in developing or underdeveloped countries due to the increase of interdependencies. In the case of multinational companies, the globalization from a positive point of

view has led to their growth and development, and in a negative sense it has acted by reducing or eliminating the domestic companies. Globalization should be seen as a process that helps open markets, create activities and new technologies. Developing countries are forced to accept globalization if they want to develop and combat poverty, although in most cases it has not brought any promised benefits. The impact of globalization on developing countries can be a positive one, through the effects of removing barriers, integrating national economies, with the role of improving the situation of the population economy.

Features of Electronic Public Services: Principles, Beneficiaries / Participants, Classifications

Sorin BURLACU, PhD, Lecturer,

Bucharest University of Economic Studies, Romania, sburlacu@amp.ase.ro

Abstract

The concept of Electronic Public Service includes two attributes: public and electronic. Starting from the understanding of the two attributes, we will continue to try to investigate what electronic public services are. The use of the term "e-Services" is found in various fields, but its predominant application is observed in the case of electronic commerce (e-Services provided in the private sector of companies and NGOs) and in the case of e-Government (e-Services provided). by citizens and businesses). In this paper by this term we will refer to the second situation. The public administration unit as a provider has the task of popularizing the e-Services offered, and the technical equipment, and the necessary training for the use of the technical means, could be returned to the government through programs to favor their acquisition by the population and small companies. The objective of the present paper is to present some essential characteristics of electronic public services as documented in the specialized literature.

Keywords: Electronic Services, Principles, Classifications, Public Services

Introduction

In the absence of a definition of the public service in the legislation, the working definition will be adopted according to which "the public service represents the activity organized or, as the case may be, authorized by a public authority of the central or local public administration, in order to satisfy a public interest or needs. social, having as characteristics continuity, equality and adaptability"[1]. We find in the specialized literature characteristics specific to public services: Public utility services must meet certain essential requirements: universality; continuity from the qualitative and quantitative point of view, under contractual conditions; adaptability to user requirements and long-term management; equal and non-discriminatory accessibility to the public service, under contractual conditions; transparency and user protection (Burlacu, S., 2009, 2010, 2011).

The State of Knowledge

The term e-Service (the prefix "e" means "electronic", as is the case with other uses), although difficult to classify, refers to electronic services in general. In the doctrine various definitions meet, but all agree on the role of technology in facilitating the provision of services, which makes them to be categorized as electronic (Ionita, F., & Burlacu, S., 2009).

Therefore e-Services include e-commerce, but may also include non-commercial (online) services that are usually provided by the government. Rowley J. (2006) defines electronic services as: "facts, efforts, or performances whose dissemination is mediated by information technology."

This definition reflects three main components - the service provider, the service receiver, and the service delivery channels (ie It is deduced that an example of e-Services is electronic public services. In these cases the public agencies are the service providers, the citizens as well as the companies are the recipients of the services, and the delivery channel is mainly the Internet, while other classical

[1] For a more elaborate explanation of the concept see Analysis of the legislative and institutional framework for the provision of public services at the level of public administration, SNSPA POCA Project

channels. (for example, telephone, call center, public kiosk, mobile phone, television) are also taken into account (Ioniţă, F. et al., 2009((Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L., 2019).

These electronic public services, e-Services, are added to the traditional ones provided by a traditional computerized public administration unit (PAU) and turn it into an electronic public administration unit (eUAP). The idea of electronification refers both to the provision of e-Services through electronic access channels (mainly the Internet) and to a reorganization of traditional UAPs, meant to adapt them to the new access channels and to bring in general, greater efficiency in operation. We agree that not all traditional public services can be fully electronic - so some services will be electronically only partially, while others will not. The computerization of a UAP (electronification, or automation) forms the technological basis, which, extended and adapted, allows the implementation of electronic public services". Vasilache states that "an eUAP is, in most situations, a 'UAP plus the Internet' if we consider the beneficiaries of public services, that is, citizens viewed as consumers (demand-side), and from the point of view of government (supply side). , an eUAP is a 're-organized and re-organized UAP', more efficient (lower costs, better services), and with more qualified staff. "And in this definition the three main elements (provider, receiver, channel) appear, in addition it is specified that electronic public services are added to traditional UAP services and run in parallel with them, although they can be accessed through various electronic channels (internet, telephony, interactive digital television, etc.). In fact, at present, most of the public services of the PAU are provided in the traditional form, with the beneficiaries coming to the counter and exchanging paper documents. An eUAP will therefore provide in parallel both traditional services and the same services (or part of them, or new ones) provided in electronic form.

For the "electronic" attribute of electronic public services some authors uses the term "electronified" to better distinguish them from traditional computerized public services, which involve the limited use of computer equipment (computer, printer, scanner, fax, etc.) in the back office work of to an office within a PAU in order to make this work more efficient (Vasilache, D, 2008). The limitation is given by the lack of interconnection between the various computer devices. Therefore electronic public services are not only computerized public services, computerization is the basis of them, but they are computerized and connected public services, using the Internet generating an exchange of information or data in a shorter time and obviously with lower costs, a reorganization. of the processes, but it also requires new skills from the officials. It is obvious how the concept of electronic public services meets the requirements of the "3E" (economy, efficiency and efficiency).

Returning to the architectural structure of an electronic public service, we have detailed some of their main features. The architectural structure includes, but is not limited to: provider (eUAP, government), gateway (site or portal), interaction and presentation (internet connection, access channels, interface or device owned by the client through which the web pages are connected and services), data (information), processing systems (data management and storage, etc.), exchange (applications for service integration), and receiver (beneficiaries: citizens, companies, eUAP other than the one who is the provider).

The beneficiary who accesses e-Services through the Internet uses an electronic access gate in the form of an electronic counter, eGhişeu (virtual counter). It appears in the form of a website created by the service provider, a site from which it can obtain information or through which it can interact bidirectionally (receiving and entering data) to perform more complex services.

An eUAP provider of e-Services can have a single site, which represents a single access point (one-stop shop, a store where they are all located), making it easier for the beneficiaries to search for the services they need, or for a single portal (the only central government site that can send all existing, central and local e-Services). All sites of the same type (eg town halls) can have a similar structure by applying standards.

In order to use the administrative e-office the beneficiaries must have the means of access to the Internet (a device used as an interface such as the computer and Internet connection) and have the

necessary knowledge - first to find out about the existence of e-Services, and then to know how to use your computer to use e-Services.

The public administration unit as a provider has the task of popularizing the e-Services offered, and the technical equipment, and the necessary training for the use of the technical means, could be returned to the government through programs to favor their acquisition by the population and small companies. Access channels to electronic services are electronic channels that eliminate the need to present the beneficiary in person at the counter, or reduce the number of such visits. These include: the Internet (the main electronic access channel to e-Services through a computer, laptop or tablet equipped with a modem or adapter, specific to the connection mode - dial-up telephone line, DSL, ISDN, cable, fiber optic or radio and browser), voice channels (landline, call centers / Call Centers), mobile phones (increasingly used for Internet access), small laptops equipped with a mobile phone modem (palmtop, handheld, PDA , smart watch), and interactive digital television (iDTV, Interactive Digital TV). They are considered as access channels and the so-called PIAP (Public Internet Access Point) equipped with one or more personal computers connected to the Internet, through which the beneficiaries who do not have a device connected to the Internet can have free access to e-Services at UAP locations , and those who do not have the necessary knowledge to use the computer and e-Services can be assisted by a guidance staff. When PIAP presents the public with a series of useful information about the services (not just electronic) of the administration unit they are in, it is called Information kiosk (Kiosk).

Findings

The information that flows between the beneficiary and the e-Services is in this case in electronic documents in various formats, such as .html, .XML, .doc, .pdf, SMS, or e-mail, which sometimes meet the requirements of security and confidentiality, can be accessed using a digital signature or a card equipped with a chip.

It is obvious that this structure of electronic public services describes their functioning, operating mode that responds to principles underlying the electronic governance itself. The following lines will outline some of these principles that we considered to be more representative:

1. User focused: means that a government builds its services based on understanding the needs of the users, around the needs of its citizens, and not vice versa.
2. Accessibility and ease of use: it means the ease with which citizens can make use of the possibility of electronic consultation of government information: finding, digesting and using it. Accessibility criteria: easy access, friendly, permanent, transparent, responsible, for information and participation, the ability to respond to special needs.
3.Standardization: by using compatible data formats, by using the same terminology, information exchanged between agencies can be understood by all applications in their information systems, including old ones that were not created for this purpose.
4. Automation: the provision of electronic public services is not done manually, but in an automated way which limits the possibility of human error.
5. Transparency and traceability: in the digital environment, everyone is equal, there is no personal favor because a computer cannot be bribed, transparency is real and all actions are traceable, regardless of whether they are related to accessing or modifying certain sets. data, etc.
6. Confidentiality, trust, security: the authenticity of the entities participating in e-Services, the integrity and authenticity of the data, the confidentiality, the prevention of fraud is essential.
6. Permanent re-design / reorganization: all services and their related processes are permanently re-analyzed and re-designed, old systems deleted and rebuilt, in order to streamline and streamline, to minimize the effort from the beneficiaries.
7. Interoperability, correlation between systems, integration: the data are provided by the beneficiary only once to a certain supplier and this is sufficient, they are not double collected if they are already available in the system (s); the principle of "one time data" applies, there is no additional burden on the shoulders of citizens to ensure that all authorities have new data available.
8. Multi-channel (multi-channel) provisioning: services are offered through various supply channels, providing online is just one of many other options.

9. Continuity, collaboration between front-office and back-office: seamless services, that is to say in one piece, uninterrupted, are more efficient than providing many separate services to the same user group.

The variety of electronic public services seems endless, with a wide range of them being offered in public administration, both locally and nationally (Rădulescu, C.V. et al., 2018). The following will be presented some of their possible classifications that reflect the above-mentioned principles. One of the criteria for classifying electronic public services that can be used is taking into account their beneficiaries. This criterion was also adopted by the European Union by defining it the List with the 20 public services considered basic. Thus, there is a set of 20 services monitored at European level (12 for citizens and 8 for economic operators)[2].

Public services for citizens

1. Services for collecting the income tax of citizens;
2. Looking for a job;
3. Service for tracking social assistance benefits (3 out of 4)
- Unemployment benefits
- Children's allowances
- Medical costs (reimbursement or direct settlement)
-Students for students
4. Issue of personal documents (passport and driving license);
5. Vehicle registration service (new, used or imported);
6. Issuance of building permits;
7. Service for monitoring police statements (eg in case of theft);
8. Service for public libraries (availability of catalogs, search tools);
9. Application and issuing of personal certificates (birth, marriage);
10. Enrollment in universities;
11. Home Change Announcement Service;
12. Health services for citizens (interactive consultancy regarding the availability of services in different hospitals; appointments for consultations);

Services for companies:

13. Payment and monitoring of social contributions;
14. Service for the payment of the tax on the profit;
15. VAT payment service;
16. Registration of new economic operators and modification of data of existing economic operators;
17. Statistical data of economic operators;
18. Service for customs declarations management;
19. Issuance of environmental permits;
20. Public Procurement Service.

Discussions

Another possible criterion for the classification of e-Services is deduced from this classification, namely according to their importance e-Services are distinguished: basic or fundamental and others.

As you can see, these services are essential in public administration, being used by almost all citizens and all companies. These were also the reasons why they were included by the European Commission in the list of fundamental services for the governance process, being monitored to offer these services online, within the e-Government programs.

[2] European Interoperability Framework for Pan-European eGovernment Services, EIF, v1.0, 2004, http://ec.europa.eu/idabc/servlets/Doc4ee4.pdf?id=18060, p.13

From the point of view of evaluating the online presence of these public services, the European Commission has established to use a model of the maturity of the service divided into five stages, also called sophistication stages, which are presented in Table 1. Within this model, which shows the increasing extent in which the service is offered in electronic form, from very little to fully electronic, it is essential to reach at least level 3, which is a standard in most European countries at the moment. . Stage 5 is most desirable, but not always possible.

Table 1: Sophistication stages used to measure the maturity of online public services

Stage	Stage description
0	No counter on the Internet or with a site containing only general information
1	Online information materials about the public service
2	Interaction with the unidirectional citizen (download forms that are completed and sent in paper format by post or fax)
3	Interaction with the two-way citizen (download, fill and send the form in electronic form, electronic processing of forms, authentication)
4	Included are methods of decision, notification, delivery and payment of online services (transactions, complete processing, payment)
5	Fully automated, personalized service (this is targeting or personalization)

Source: *Adaptation after European Commission*

Another classification related to the complexity of electronic public services is divided into: information services (unidirectional) and actual services (two-way), which carry out more complicated operations, such as paying taxes or registering new companies. Thus, the services in stage 1 and 2 of sophistication where the service provider offers information to the beneficiary, the flow of information flowing only from the supplier to the beneficiary are unidirectional, while the services that have reached the 3rd, 4th and 5th levels of sophistication are bidirectional (or interactive, or transactional), during their execution, the information flowing between the supplier and the beneficiary in both directions.
The four models of (re) organization of offices, described by Jeremy Millard (2004), which take into account the number of services (one, or more) and the number of stages (stages) can be used to describe the complexity of the way services are performed.) necessary in their realization, that is, by the number of offices (one, or more) in which the procedures finalizing the service are carried out, differentiated according to their degree of digitization

Table 2: Office organization models for the provision of online public services

Font-office / Back-office	One service	More services
One office	**Model A**	**Model B**
More office	**Model C**	**Model D**

Source: Adaptation after Millard[3] (2004).

Model A - one service and one office (the beneficiary sees a single service, and interacts with a single office, which performs that service),
Model B - more services and one office (beneficiaries see more services, but interact with a single office which makes them all),
Model C - one service and several offices (the service is performed by at least two offices, so the beneficiary interacts with one office 1, and offices 1,2,3 interact with each other), and
Model D - more services and more offices (more services are integrated with automatic re-entry data and more offices cooperate to a lesser or greater extent, including ancillary services).

Conclusion

If we take the example of the European Union, e-Administration services can be offered by one state and the other Member States. This is ensured by the government's strategy for each state to implement its own e-Government, a strategy that must also take into account a cross-border dimension, this dimension being already formalized in a normative document called the European Interoperability Framework (EIF). . In this context we can talk about e-Services: cross-border, national, central and local.

Furthermore, starting from the interoperability and interconnection feature of e-Services, it can be stated that, although in each country it is different, the transition of the services in electronic form leads to a certain degree of uniformity by sharing the successful experience from one country to another. countries, especially within the European Union. Thus another classification follows: international electronic services, pan-European and national.

The following principles, of a general nature, should be considered for any of the eGovernment services to be established at pan-European level: accessibility, multilingualism, security, privacy, subsidiarity, use of open standards, evaluation of the benefits provided by open source software, the use of multilateral solutions.[4]

Depending on how they serve a need of the beneficiary, the distinction is made between: direct services (they directly serve a need, but they may call during their implementation a series of auxiliary services), auxiliary (auxiliary services such as: the management service of electronic identity, eID, through which a declaration of the identity of the beneficiary is made followed by its authentication, and the electronic payment service, ePayment or ePayment, through which various payments required within a direct service can be made electronically).

Abstract

Following synthesis of theory evaluation studies were identified several issues criticized by academics and practitioners. Most problems occurred due to lack of appropriate theoretical fundamentals. Currently, evaluation theory is defined based on neoclassical economic theory, based on the concept of value-utility theory underwent considerable changes in recent decades. Theory evaluation, however, failed to comply with the changes, which created problems in practice.
The methodology of the combination (reconciliation) can be found in the specialized literature in three approaches - by cost, by income and by comparison. These approaches are focused on neoclassical economic theory, which could be derived from the idea of long-term market value matching with costs. Modern economic theory accepts that costs and market value over a long horizon may have a tendency to approach, but at the same time, he mentions that in reality there is no internal reason for ensuring this approach or long-term equivalence. The present article presents the results of our research regarding the analysis of valuation theory from the perspective of modern economic theory. A first conclusion was that the significance of the methodology of reconciliation of values could diminish and the theory of valuation could use probabilistic notions because the heritage markets are uncertain.

Introduction

One of the tendencies of theory evaluation assessment work is split into two areas: financial evaluation - investment (EFI) and professional estimation value (EPV) (Bran, P., 2009). In the EPV see two paths of development: assessing the likely selling price and second - limited boundaries of public and state interests - assessing the estimated value (fair value) (Costache, G., et al., 2015). The modern school of professional evaluation, in its turn, has been divided into two directions: technical-mechanical (measurement, examination, market reflection) and behavioral (modeling / simulation of active price formation processes).

Analyzing the logical chain of creation, estimation, management of value, we came to the need to explain the way of dimensioning the value, resulting from the way it appears (Burlacu, S. & Jiroveanu, D., 2011). The most explicit theory from this point of view, which explains the essence of the value and the mechanism of its creation, is, in our opinion, the value theory based on low entropy (Bran, F. et al., 2018). In the following, we will try to explain the evaluation method based on the value-entropy theory, as evidenced by the documentary analysis.

Problems Researched

The assessments should be used when receiving concrete decisions and be specially adapted to solve the problems specified by the beneficiary. These problems may require, and may not imply a market value (Bran, P., 2003).. The most acceptable way to forecast likely sales prices is by comparison approach. The modern statistical techniques (from the market position) and the techniques of market simulation (from the position of the transaction, of human behavior) must be applied. The use of the cost of reconstruction in the cost approach is focused on theoretic theoretical ideas. Adding the value of the land with the value of the improvements does not form the most likely selling price. Moreover, the division of the impairment into physical, functional and economic components is incorrect and misleading (Bran, P., 1992).

Findings

A Marshal's ideas became a landmark for the emergence and development of the entropic value theory, elaborated by Paul Bran (1941-2006). From this perspective, value-entropy theory generalizes existing directions defining value and indicates that the value is the result of changes taking place in economic processes (at least) the human activity is involved. These processes may include production, distribution, exchange and consumption. In these conditions, the value is the result of complex processes of transformations, conservation and transfers brought together in the dynamic states of production, consumption, liquidation (Ioniţă, F. et al., 2009. The physical support of value is the degree of organization of the elements of matter: substance, energy and information or, in other words, low entropy (Bran, P., 2003).. For the sake of clarity, we will mention the basic definitions of TVE:
Entropy is the measure of the degree of organization / disorganization of a system. The lower the entropy (low, negative), the higher the degree of organization, cumulating with the living systems (Bodislav, A. . et al, 2019). The potential represents the degree of organization (low entropy) held by a simple or complex system, the level of organization that makes it attractive to be consumed by a living system. In other words, that potential represents the ability of a system to provide organization (Dima, C. et al, 2020).. In the TVE model, the potential category is a basic category, used to generalize the ability to provide the organization of several types of systems: natural, biological, social, economic (Burlacu, S.; Alpopi , C.; Popescu, M. L. 2018).

The natural potential (Pn) is represented by the degree of organization existing in all systems in nature: systems at equilibrium, systems near equilibrium, systems far from equilibrium. Pn encompasses the entire low entropy existing in our reference system and conserved in the elementary forms of matter: substance (s), free energy (s), information (s)

The social potential (Ps) is the result of the transformation of natural potential attracted (Pna), biologically attracted (Pba) and economically attracted (Pea) in the complex system of the society. This degree of organization is included in the structure of the society system, but also in the products and services provided by this system through social activities, other than the economic one (administration, education, culture, defense, health, scientific research, etc.).

The biological potential (Pb) comprises the degree of organization existing in the living systems, being the result of the transformation - the conservation of natural potential attracted by the respective systems.

The economic potential (Pe) shows the degree of organization included in the economic systems and in the products and services provided by these systems and is the result of the economic type attraction of natural potential (Pna), biological potential (Pba), social potential (Psa), economic potential from other systems or from own results (Pea).

Taking into account that considered above relationship and definitions, will formulate the definition of value according to TVE. Value system (the property) is all attracted potential in this system.

Paradigms and Debates

The basic paradigms of economic theory have remained so far at the level of the two axioms: Value = Work and Value = Utility The path to a new paradigm was started by the late Professor Paul Bran even before 1989, when he was concerned about the measurement or financial distribution of value, by which he observed numerous clumsiness of economic theory. Explaining the economic reality from that period, as well as the major dysfunctions (unemployment, pollution, economic and social imbalances) that developed in society, both in us (where we used Labor-based Theory of Value) and in the countries that used the theory based on utility (marginal value) (Jianu, I. et al., 2019).

The foundations of the value-entropic theory (TVE).

In order to bring into economic theory concepts, assumptions, laws, definitions, etc., it is necessary to use a rich arsenal of tools, methods and processes in the economic field or borrowed from other fields of science. In order not to remain isolated between the narrow borders of the economic field, the working area of one's own science must be surpassed, thus widening the horizon (Negescu Oancea, M.D. et al., 2019). On the other hand, it must penetrate into the depths of the systems that contribute to the realization of the phenomenon of value (economic, society and natural environment) (Rădulescu, C.V. et al., 2018).

Thus, we reach the basic objective, which is:

• Finding and substantiating symbolic generalizations in the form of basic paradigms of value theory;
• Synthesis of partial models and the general model of the mechanism for obtaining and managing value;
• Use of paradigms and the general model of obtaining and managing value to explain and solve the complex problems of the economic activity.
In the action of defining the value, it is likely that solving the problem of physical support would be necessary (Profiroiu, A. et al., 2019). The scientific theory in the economic field has gone from the support called work, in the form of socially necessary work time, to utility or satisfaction (Androniceanu, A. et al, 2017). In entropic value theory (TVE), we choose another type of physical support, much more general, low entropy support or degree of organization existing in simple systems or complex systems.

Secondly, it was necessary to establish a defining relation that does not conflict with the requirements of the general laws of nature (the law of transformation and conservation of matter and the law of entropy). Using the classical notations for the inputs and outputs of the economic processes, the corrections were completed that supplemented the inputs with the potential attracted free from society and the environment, and the outputs with the useless results in the form of high entropy wastes.

The object of study of the value paradigm to understand the value theory based on low entropy is the need to know the mechanism of life, this myth of systems far from equilibrium (Bran, 2013). Living organisms maintain their life, only if, from the environment, they attract and transform low entropy from the primary elements of matter: substance, free energy, information (Burlacu, S., 2010,2011). Integrated into the natural circuit of matter, the living system of man is the beneficiary of an enormous low entropy potential, manufactured by the living and the nevi systems of nature. This potential allows it to exist, even if the processes it triggers in society and in the economy are very wasteful. In order to understand the mechanism of value, economic science must master the discoveries of the other sciences. It can no longer be sister to mechanics, but will have to be related to nonlinear thermodynamics, biology, cybernetics, etc.

The general model of entropic value theory (TVE) Having a new opening, economic science must build a complex model for the mechanism of obtaining value, a model that includes many cash. The construction of a model presupposes the existence of a well-structured project, in which the primary processes of transformation, conservation and transfer are present, all of which contribute to transforming the potential initially attracted into the real value recognized by TVE.

The TVE model does not exclude the final event from the life of a system, the moment of liquidation. The correlation of the TVE model with the models of the other theories of value emphasizes the differences, but also the fact that the model of the value based on entropy includes the other models, taking the knowledge further, to the real level of the potential conserved as value of the obtained product. Although, in TVE, the production process is only a process of transformation-preservation-transfer, and not of creating an additional value inputs, it is a decisive component of the TVE model. Therefore, understanding the model of the production process is essential for the knowledge and assimilation of the general model of obtaining and managing value.

The decoding of the primary processes of transfer-entry, transformation, conservation, transfer-exit brings additional elements of knowledge in economic theory and practice. Inbound transfer, as well as outbound transfer, occurs naturally through repartition or exchange(Burlacu, S. et al., 2018). The sources from which the transfer is made are of the most diverse, highlighting the possibility of restoring in the economic circuit the potential of waste. In turn, the primary processes of transformation and preservation contribute to the resetting of low entropy from inputs in accordance with the company profile and with the consumer's demands.

The transformed potential is conserved in the quantitative, qualitative and reliability dimensions of the product, at an always subunit efficiency. The Entropic Value Theory Model (TVE) The Entropic Value Theory model implies the recognition of service potential, taken out of the product by accepting this potential in a future production process. Only the level at which this potential is recognized becomes, according to TVE, the value of the product obtained in the production process. The model of the Entropic Value Theory TVE includes all the systems possible to train in obtaining and managing the value, as well as the channels of the transition of the natural, social and economic potential towards the real level of the value. In these passages, forces are manifested that bring the market value to dimensions that differ from the real value level.

Resolving the price deviations from the entropic value is another novelty for the economic theory, these solutions explaining the phenomena of inflation, of the environment and of entering the economic systems in the complex process of liquidation (Burlacu, S. et al., 2019). The construction of the general model of the Entropic Value Theory imposed a disciplinary matrix with many novelty elements or with totally different interpretations compared to the current content of some economic categories. The transition from the entropic support for the value category has brought, in the foreground, new symbolic generalizations, models, common examples (paradigms). The entropic value theory brings severe restrictions on the development of economic processes in the form of the entropic value law action. This law requires that economic processes, but also some processes in society and of environmental protection and restoration, be conducted within the limits of the economic potential preserved during the economic processes. If there is no sense of value in these systems, then the system in question enters into a state of fluctuation and goes to a fork, where the problem of disappearance or survival is posed by restructuring the system in the sense of obtaining and managing the value in other conditions, more effective. and more efficient.

The TVE model and the action of the Law of Entropic Value are verified in the system of human society in the four major stages: antiquity, middle age, industrial, post-industrial. Each stage went through periods of flowering, maturation and decline, largely determined by the way in which the mechanism of obtaining and managing the value worked. The level of the economic potential attracted and processed depended on the ways of attracting (work, science and technology, geographic discoveries, war, etc.), on the way of organizing and equipping the economic processes (property force, technical endowment, management), as well as on how useful results, products and services were distributed and used. The changes that have taken place in society and economy have made the mechanism of obtaining value, fertilizing a period of time, enter into difficulty, attracting the whole society in this situation. The productivity of this mechanism was reflected in the way of building the tools, in the evolution of the society, in the diversification of the economic and social activities, in the environmental impact, in the social and political events of the world. Through these effects on such a complex system, as the society, the TVE model verifies itself, its main paradigms succeeding, largely, the society's walk on

the arrow of time. This model allows us to foreshadow the economic aspects of the future human society, the postindustrial or information society.

Current economic theories are not built on the principle of increasing entropy. According to these theories, the value and the wealth depend on the work and the means of the economic activity, so, by developing them, the road to welfare is open! This model has proven to be inappropriate and even dangerous in the area of secondary activities, as a transformative activity of potential removed from the environment and society from primary activities. Through these reconsiderations, we will be able to adapt the system of economic activity to the countless restrictions that are in front of the bifurcation point, where the human society is now.

After verifying the TVE model based on the complex system of the company, it is necessary to see if this model explains the changes in the environment and the structure of the economic activity system. Given the fact that the most important partner of man in the economic and social activity, the natural environment, has been permanently neglected in the distribution of results and disadvantaged by eliminating the waste of the economy and society. As Professor Paul Bran states, "Nature had to die a little in order for 20th-century scientists to warn humanity that we are near the limits of economic growth. For these reasons, the construction of the economic activity system (either enterprise or other micro-, macro-, world- level) in the future society must comply with the restrictions required by environmental protection and the law of entropic value. Science has made available to the people the procedures, methods, instruments suitable for observing the mentioned restrictions; therefore, miniaturization, computer science, education, creativity".

Conclusions

The entropic value model requires documentation as to how this consumer, who has become a producer, will be able to use the services removed from the product they are about to sell. Only by discovering the source of the enormous potential brought by information in the economy, we will recognize that the whole natural environment is the number one partner in our economic activity and we will have to reward it with an increasing share of the economic results to which it contributes directly and through of the other elements of the structure of the company, including through information. The TVE model for changing managerial behavior.

The adoption of economic decisions greatly increases the responsibility and the risks that a manager assumes. A first change in the manager's behavior refers to the reconsideration of the processes involved in the mechanism of obtaining value. He must accept that, in addition to the economic processes such as production and consumption, he participates with decisive role also the processes in the natural environment and the processes in society. On the basis of this reconsideration, the manager will have to grant equal rights to all the mentioned processes, both in the mechanism of obtaining the value and in the division of value between the participants in the respective mechanism.

Therefore, the manager must be aware that the value is obtained through the obligatory contribution of both economic processes, the production and the consumption processes. A second change concerns the redesign of the entire decision-making process. Economic communication through money The economic language mediated by money is part of a broad process of communication in economy and society. At each stage, there is a risk of miscommunication and communication errors. Thus, four main moments are observed: knowledge of the phenomenon of obtaining value; coding the meaning and inscribing it in the content of a sign; decoding the sign by the recipient of the message; confirmation of the agreement to the sender of the message.

The first moment corresponds, in the process of money communication, to the knowledge of value through measurement. Second, the one by which the meaning obtained, the price, is discharged in money signs through the banking system and which presents risks. Third, it is about decoding the money signs. The value message brought by money does not specify the goods in which the value is to be placed, which the economy will put at the disposal of the holder of money signs. The decoder will identify the value based on its model, both in terms of the size of the standard and in terms of the goods

in which it thinks the value is. The fourth step is only achieved if the money holder uses them to buy the goods on the market. The money signs reach the bank, being able to reenter a communication circuit. If the money is kept for future payments, they will no longer have the same meaning, because both the value and the standard change daily. Born in the intimacy of processes and complexes, in systems such as environment, society and economy, the value is revealed, on the market, in the form of price. The information is mediated by the monetary standard, a standard undergoing profound changes, as well as the value and the sign-form of the currency.

Therefore, the price will reflect the conflict of interests of the participants in the mechanism of obtaining and managing the value, from the producer to the consumer, from the company to the natural environment! The use of money in the process of communication in the economy brings elements of ordering, but also of disorder, when the decoding models of the standards for measuring the value are not correct or permanently updated. Inflation fraud is an old tool of social management, at the same time, it is also the cause of social discontent and riots, inflation drastically reducing the amount of real value that reaches the systems in the state of consumption. In conclusion, the mechanism of obtaining value, through its complexity, deserves attention from all, whether they work in the economic, technical, cultural, political, or social field, "THE ENGINE OF THE SOCIETY" needing the input of each participant in the social life. The gain of value in the struggle with the laws of nature and of the economy proves to be the result of both the worker and the engineer, economist, teacher, sociologist or painter, etc.

Perhaps only by associating with the mechanism of obtaining value the processes from the natural environment and from society, we can give "value" to all processes and we can respect the activity of all the specialists and participants in the respective processes. Or maybe just in this systemic form, the value model recognizes us all, from humans to the natural environment, from plants and animals to tools, from physical work to scientific and educational activity, the contribution to obtaining value and the right to receive a parts, from the economic results.

Abstract

The decision represents a dynamic, rational process, in which a line of action is chosen, from a number of alternatives, in order to influence the activity of the performers and to obtain a certain result. The management and conduct of the financial activity in the economic unit is achieved through decisions with a financial content. The decision involves the transition "from power to act under conditions of efficiency", consciously, based on a scientific, psychological and purpose rationale and motivation. Adopting the strategic economic decision involves choosing an optimal solution from the set of possible solutions. In choosing this solution, the decision maker has at its disposal the consequences of a technical, economic, financial, social nature, present in the core of each solution that participates in the stage of choosing and adopting the economic decision. The objective of the present article is to highlight these elements in the specialized literature and, through an adequate documentary analysis, to make available to the specialists viable perspectives in order to make practical decisions.

Keywords: Economic Analysis, Resource Management, Economic-Financial Decision, Value Law,

Introduction

The decision represents a dynamic, rational process, in which a line of action is chosen, from a number of alternatives, in order to influence the activity of the performers and to obtain a certain result (Ioniţă, F. et al., 2009).

The following elements can be kept from the definition of the decision:

- it is regarded as a process of rational choice;
- represents the final act in establishing the direction of action of achieving an objective;
- the action bears the name of decision only insofar as it corresponds to a situation of choice;
- it directs the activity of the subordinates under the conditions in which the action of a leader is imposed by events without having the possibility to choose another alternative, it is not a decision.

Depending on the time horizon referred to, the financial decision may be (Ion-Trifoi, G. & Dinte, C. n.a.):

- *Strategic decision*, targeting a distant time horizon that foreshadows the framework of the company's activity.
- *Tactical decision*, which aims to adjust the conjunctural influences that can remove the company from the adopted strategy.

Financial Decision Making - Decision Making Process

The management and conduct of the financial activity in the economic unit is achieved through decisions with a financial content (Jianu, I. et al., 2019). The decision involves the transition "from power to act under conditions of efficiency", consciously, based on a scientific, psychological and purpose rationale and motivation (Costache, G., et al., 2015).

The financial decision is the result of a complex decision-making process comprising the steps of knowledge of financial reality and stages of acquiring the optimal solution (Burlacu, S. et al., 2019). The main steps to be taken in order to play the content of the financial decision are: establishing the financial objectives included in the line of development of the company, financial information analysis, adopting the financial decision, executing the financial decision (Profiroiu, A. et al., 2019).

The development line includes the most general and important objectives of the management of the economic activity (Burlacu, S. & Jiroveanu, D., 2011). These objectives include a synthesis of the main types of activities that take place in the respective unit: economic, technical, technological, organizational, financial, etc.

Research Methodologies

Information analysis is an action to know the economic reality with the help of methods and tools for collecting, processing and interpreting information. Starting from the information obtained, based on this analysis, the possible solutions for achieving the objectives of the development line are synthesized. Adopting the financial decision involves choosing the optimal solution from the set of possible solutions. The execution of the financial decision seeks the complete and operational satisfaction with financial funds of all economic and social activities in the economic unit, as well as the supply of the centralized financial funds from the national economy (Bran, P., 1980). In order to carry out our research, we used the documentary analysis that allowed us to highlight those particularities that present to the specialists in the field viable perspectives in order to make practical decisions.

Finding

Adopting the Strategic Financial Decision

The strategic financial decision involves a complex action to finance the economic, technical, social activities, required by the production process and the development of the elements of the economic structure of production (Litra, M., & Burlacu, S., 2014). The preparation of the financial allocation solutions that participate in the establishment of the strategic financial decision is carried out with the help of financial actions. These actions have the mission to establish the financial information around which the possible solutions are formed in the form of the variants of income and expenditure budget of the economic unit (Pricop, C., et al., 2016).

The synthesis and adoption of the optimum solution are achieved through the financial activity, of two categories of attributions: the knowledge of the reality of the economic unit and its environment and the intervention in the environments of defining the financial phenomenon represented by the production and consumption processes (Burlacu, S. & Stoica, A., 2012). The intervention of the financial activity in the economic activities depends on the qualitative side and is achieved through the connections of the reverse connection type: financial action - production process and financial action - consumption process (Alpopi, C. et al, 2018).
The choice and establishment of the optimal solution for the content of the strategic financial decision take into account the nomological motivation (based on the scientific knowledge of the reality), the psychological motivation (it concerns the interests of those who will make the financial decision), the axiological motivation (it takes into account the value judgments made in relation to the activities

required by the financial decision), and the teleological motivation of the decision's purpose (Rădulescu, C.V. et al., 2018).

a. Strategic financial decisions for economic activities regarding fixed assets. The financial action will adopt the optimum financial allocation solution for the strategic financial decision regarding the investment activity (replacement, training or development of fixed assets). The optimal solution is determined by the correlation between the need for funds and the financial sources.
b. Financial decisions strategic economic activities on public assets. Financial activity will adopt strategic financial decisions for financing economic activities of training and development inventory working capital and insurance of goods by insurance institutions. Financial decision will be adopted based on a correlation between the volume of necessary funds and financial funds to be mobilized from internal or external sources.
c. Strategic financial decisions for economic and social activities regarding the workforce element of the economic unit. The financial decision is made on the basis of the correlation of the company's own financial resources and of bank loans on the one hand with the need for financial funds for the investment expenses and for the repayment of the previously used credits, plus the related interests, on the other.
d. Strategic financial decisions for the information element activities. The strategic financial decision considers the need for funds arising from the quotations for the research-assimilation works, as well as the need for funds for the payment of financial obligations. On the other hand, the level of the internal sources, the allocations outside the unit and the credit for the technical assimilation plan are considered.
e. The strategic financial decision to pay the financial obligations to the state budget and to the finances of the economic center. This decision will include all the financial relations of the company with the respective financial links.

Results

Strategic Financial Decision Making

Making strategic financial decision is made by the execution of tactical financial decisions, through which the financial allocation envisaged by the strategic decision (Bodislav, A. . et al, 2019). These decisions are part of operational decisions taken in the financial service of the economic unit. These decisions are mobilizing funds from outside the enterprise or production results and then share to finance the establishment and payment obligations to the national economy Angheluta, S. P. et al, 2019).
The argumentation and the realization of the tactical financial decisions have implications both on the economic activities and on the strategic financial decision (Bran, F. et al., 2018). These decisions depend on the general competences of the economic unit within the self-management of workers through the economic-financial mechanism of the national economy, and specifically, what competences in the field of taking self-financing decisions from their own results (Bran, F. et al., 2018). Financial activity is an important factor in driving economic activities organized economic unit, methods, tools and high informational value of its information (Burlacu, S., Alpopi, C., Mitrită, M., & Popescu, M. L., 2019). Economic undertaking any decision should be based on fund financial information on funding needs, available resources, future financial results, financial indicators of economic efficiency (Bran, F. et al., 2019).

The Stages of Foundation of The Strategic Economic Decision

The first step is information. This involves investigating the sources of information in the areas that will influence or will be affected by the adoption of the strategic economic decision (Negescu Oancea, M.D. et al., 2019). To achieve this stage, the financial activity must contribute with the financial information fund regarding the internal situation of the company and the external environment requirements of the economic unit.

The second stage is information analysis. This ensures the obtaining of information regarding the adoption and the realization of the object in question of the development line, an objective that generates the strategic economic decision that must be based and adopted in the economic unit.

The purpose of the financial activity at this stage is that, through the financial information analysis, it will contribute to the financing sources, to the total financial and economic results obtained from the activities that accompany the adoption and the realization of the economic decision, to the financial obligations, and to the financial indicators of economic efficiency.

Conclusions

Adopting the strategic economic decision involves choosing an optimal solution from the set of possible solutions. In choosing this solution, the decision maker has at its disposal the consequences of a technical, economic, financial, social nature, present in the core of each solution that participates in the stage of choosing and adopting the economic decision.

To be comparable, the consequences of the multitude of possible solutions must be expressed by the same unit of measure. By the method of calculating the utility, it is used as a unit of common utility measure.

This method gives the value of 1 the utility of the most favorable consequence and the value 0 of the most unfavorable consequence for the decision maker. The choice of the optimal solution will be made taking into account the sum of the utilities on each solution, and the solution with the highest sum of the utilities will be chosen.

If several solutions have the same amount, the second method of calculation is used. The utilities granted previously, are multiplied by the coefficients of importance that have values between 0 and 1. The new amounts of utilities on each solution will allow to differentiate the solutions and adopt the optimal solution for the decision maker.

Abstract

Global warming is undoubtedly a fairly debated environmental issue, but the biggest environmental situation detected is the disappearance of forests, which is also a consequence of global warming, because the forest has the capacity to absorb tons of carbon dioxide at the moment. respectively. in which massive deforestation is made, the amount of greenhouse gases increases. In this paper we will be able to observe the economic-ecological dysfunctions, generated when the forest is destroyed, we will also perform a quantitative, but also qualitative analysis of the forest area, how a forest can be managed in based on SWOT analysis, as well as creating certain strategies for combating and reducing deforestation, also, the identification of new ideas in preventing and stopping certain actions by which man leaves his mark on the natural space. Nowadays, the economic power has become greater than the ecological one, so that man no longer appreciates the natural space and prefers to think about the benefits that he can have for a short period of time, neglecting important aspects that in the long run will it produces certain natural disasters for its descendants.

Keywords: Forest, Risks, Resources, Biodiversity, Earth, Development.

Introduction

If we look at the general level of our country, Romania has a forest fund of about 6.3 million hectares, which represents 26.6% of the country's surface compared to Europe, where the average is 32%, we do not have this percentage an encouraging one. , but we can't even say it's dramatic. When we talk about the role of the forest in the economy, we refer to the main factor of ecological stability according to the legal regulations, because it is in direct relation with the territorial administrative units. (Antonescu, P., 1992). Forests have always had and will have a significant economic role in economic and social development, producing revenues from the exploitation of wood products and forestry. Even though

we do not currently have an impressive volume of forests, they fulfill many functions of a social and ecological nature. For our country, the economic function of the forest is of particular importance, as it is an indispensable resource for sustainable development.

Through its diversity, the forest is united in a huge reservoir of genetic information. Its value cannot be calculated or estimated, because not all species that are housed in virgin areas are known. Many of these species and varieties of plants contain certain principles that help treat incurable diseases. (Alexandru, B. & Alexandru, R. 2001).

Regardless of the area we are talking about, the importance of the forest ecosystem that maintains an ecological balance is very well understood or outlined. As mentioned above, the role of the forest has often been ignored with or without good science, receiving economic interests. The direct or indirect consequences in relation to local conditions are major.

Economic and ecological malfunctions generated by the destruction of forest

If we look at the situation of deforestation in a superficial way and what are the immediate benefits, in the short term we can highlight a valuable result regarding the capacity of the wood and the free land. It is also mentioned that a very high profit can be obtained in a very short period of time and at low costs, and here we refer in particular to certain deforestations that are not legal and contribute to the growth of the underground economy. , most of the time, it has poorly trained staff, sometimes even unskilled and that is rewarded for the value of the work done and there are no costs related to replanting the areas that have been eliminated. Viewed as a whole, but at the same time, careful, the deforestation situation is very worrying for the world economy and this is what researchers from all over the world say. In this case, the destruction of forests, but also other situations related to the deterioration of the environment and especially of the forest area, can halve the standard of living for many poor countries in the world and has the capacity to reduce global GDP by about 6, 8 % by 2050. (Antonie., J.)

All forest products have played throughout life on Earth and continue to play a particularly important role in the development of today's society compared to the role played by arable land or water. Currently, developing or developed countries continue to use timber for the construction of certain terraces or homes or even for the manufacture of paper. In developing countries, over 3 billion people rely on this wood raw material for cooking and heating, this industry being a very important part of the economy in most countries. Short-term economic gains that turn forest-occupied land into land used for agriculture or sometimes through over-exploitation of timber products often lead to loss of medium- and long-term incomes due to decreased biological productivity. Therefore, many areas whose development has focused in the past on the use of wood, presently face a major decline due to the substantial decrease of the incomes obtained from the smaller timber harvests. Analyzing the low areas of Romania, but also some warm areas from the planetary level, the drought, contributes to the degradation of the tree vegetation. Often, instead of the forest we find savanna or steppe vegetation, and the protective effect on the soil is quite low. Modifying the floristic structure by afforesting with species that develop very quickly and, at the same time, that help to obtain exploitable plantations in half time produces dysfunctions by modifying the biocenetic structure, and for example we can think of replacing the beech in the spruce floor. or pine whose root system is shallow, will clearly have negative chain effects. (Stoiculescu, C.D ., 1999).

Analyzing the low areas of Romania, but also some warm areas from the planetary level, the drought, contributes to the degradation of the tree vegetation. Often, instead of the forest we find savanna or steppe vegetation, and the protective effect on the soil is quite low. Modifying the floristic structure by afforesting with species that develop very quickly and, at the same time, that help to obtain exploitable plantations in half time produces dysfunctions by modifying the biocenetic structure, and for example we can think of replacing the beech in the spruce floor. or pine whose root system is shallow, will clearly have negative chain effects.
Another main role of forests that disappears through the phenomenon of clearing, which also has immediate effects, is the retention of dust in the air. It has been shown that one hectare of forest filters an average of 19-20 million cubic meters of air over a year, retains about 80 tons of dust and produces

up to 3500 tons of oxygen in a year. If we mention between the medium and long term effects, we can specify that the forests create a soil rich in humus, which means that a land that is graded after it has been reforested, but also after a long period of time, becomes again fertile. Desertification occurs when the amount of precipitation decreases considerably, sometimes reaching the limit. If the massive deforestation will continue repeatedly, these will be a disastrous situation, and in time, causing damage where there are accumulation lakes or even dams destroyed, followed by flooding downstream areas. (Vlad, I., Chiriţă, C., Doniţă, N., Petrescu, L.,1997).

Quantitative and qualitative analysis of forests in Romania

Quantitative and qualitative analysis consists of gathering, organizing and analyzing data, which are fundamental to all studies that use statistical data as a research methodology. Quantitative analysis is based on quantitative or numerical data and is very useful in interpretation because it offers quantifiable results that are easy to understand. Below we have taken into consideration a database from 1990 to 2017 to observe what are the changes made at the level of Romania regarding the state of the forests and what were the trends in these segments. The data are retrieved and analyzed from the website of the National Institute of Statistics.

Source: National Institute of Statistics

Figure 1: The surface of the land from the forest fund is crossed by cutting by categories of cuts

Analyzing the graph above, it can be observed that the three categories analyzed throughout the period have the same trends. If at the beginning of the segment, the felled forests totaled about 72,915 hectares, the trend is increasing, but after the period of 2015, things became 177,296, approximately 3 times higher. From an increasingly complex desire for the recovery of wood, the grinding is an increasingly accentuated one for the purpose of industrializing and processing the wood in order to obtain cellulose, paper and furniture. Despite the clearing actions, the priority objective is the protection of forests and calls for an increasing number of forests and forest forests for their protection.

Source: National Institute of Statistics

Figure 2: The volume of wood harvested by species, macroregions, development regions and counties.

According to the graph above, we analyzed the evolution of the volume of wood that was harvested by species categories in the four regions of our country. Macroregion one is the most present on the graph, because here we refer to the North and West part of the country where the forest areas are still extended and here we find an important source of harvest. At the opposite pole is classified the region of the South West, because here the largest area of land is composed of plains and has not exceeded 4000 m3 harvested, only after 2004.

Analysis of the forest management practiced at national level

The promotion and recognition of certain complex values of the forest have become and continue to be a necessity especially after the way the technology evolved and the development of the transport infrastructure has allowed unlimited access to the forest resources. Over time, people from local communities have focused their attention on the resources acquired through forest ecosystems with a minor influence on the level of ecological balance. The local communities have used these resources that I mentioned earlier, for a good reason. The existence of resources such as construction, heating and food for food were the main reasons. Therefore, a shift has been made from the exploitation of forest resources that aim to meet subsistence needs, to commercial exploitation. Following this change, certain management principles were developed in the context of maintaining the forest environment as a provider of environmentally friendly products and services, not only as a raw material, as a wood source. Nowadays, wood represents the raw material that has been emphasized to a significant extent, the exploitation of wood being considered a controversial topic, discussed in depth among certain groups of people. (Oarcea, Z., 2016)

The economic development on a global level, especially in the last period, was done by ignoring certain effects it has on the environment (air, water, forest) and produces major changes in their entire structure. Human action that has been uncontrolled over nature, especially in recent decades due to the development of the industry, has sounded an alarm signal about the danger the environment is in and has tried to raise awareness of the global population to focus your efforts on maintaining a natural balance where the forest is the main instrument of the forest fund and plays a very important role. Also in the present situation have contributed the economic policies, which have been carried out in the last decades in this field and whose purpose was to reduce it by an abundant felling of forests that was

double-acted due to the fact that no measures were taken to reforest those areas, but also the existence of a legal framework for regulating specific modalities and actions carried out in this segment.

The efficiency of certain activities cannot be dissociated from a prior knowledge model of forestry situations. Wood contributes to the needs of the present population and future generations, influencing the life of the human being. All forest resources, regardless of the country of which they are a part, of their development stage or size, remain in the medium and long term, being vital from many points of view: ecological, social, economic, and in some situations, the survival of the community depends on they. In order for these assessments to be maintained for the generations to come, we need serious commitments from all those involved in forest management and its resources, but also to maintain a sustainable development concept. All the specialized studies that have been carried out internationally show that there is a close and dynamic link between economic development and forestry. The wood that is exploited and transported from the forest is marked and inventoried according to the forest rules in force and is attested by legal documents provided by government decisions. (Merce, O., 2016). In the specialized legislation, the forest regime is defined as a unitary type system with norms that have an economic, technical, forestry nature, protection against pests and regeneration of forests for a secure and sustainable management of forest ecosystems.

SWOT Analysis of Forest Management in Romania

STRONG POINTS	**WEAKNESSES**
• The value of natural capital that brings an added value in the quality of biodiversity; • We have very important sources of income due to the exploitation of forests ersity; • According to environmental factors, the existence of certain forest areas in our country is highly valued; • Arrangement of parks and natural reserves, while preserving the natural state of the forest bottom; • A network of forest roads that helps local communities; • • A very good property of the lands that are in the forest area.	• Treatment and establishment of inadequate policies to support environmental factors. • A rather low degree of environmental information management. • The landslides and soil erosion. • A very low price of the technical and economic indicators that contribute to the introduction in mountain areas and certain tourist destinations. • A very low irrigation concept, in this way, the water quality being compromised quite a lot. • Loss of productivity due to unfertile soils
OPPORTUNITIES	**THREATS**
• Adaptation of fiscal formalities for economic agents; • Creation of investments in environmental areas in ecological risk process; • Introduction and regulation of the environmental fund in Romania. • Continuous improvement of the quality of life; • Intensification of forested land to help protect and succeed with aid that reduces soil erosion processes.	• Impact and deterioration of the patrimony, if the existing regulations are not respected; • The increase of average temperatures in our country every year; • High costs to support environmental protection will affect the market economy; • Climate change and its impact on the green space that has been analyzed through several climate models globally. • After 2035, in the hill and low areas that are afforested at the present moor, there will be a significant decrease.

Regarding the above analysis, we can identify some major issues that we have to improve in the immediate period, if we want to save as much of Romania's forest territory as possible. Even if the statistics are worrying, every gesture we try to protect nature keeps us from disaster. Deforestation in the last period is very large and in areas of increasing extent, tens of thousands of hectares have been deforested, but even worse is the fact that the afforestation came with a delay of several years, and in some areas it is completely lacking.

Strategies to Combat Massive Deforestation

Romania is in the top of the European countries when the forested area is discussed, all of which take place under the eyes of the authorities. Our country has illegally cleared over 3,500,000 hectares of forest. All statistics show us the gloomy truth as we rank in the last place when the forested surface is brought into question. If we take the time back, at the beginning of the ninth century, Romania had a share of approximately 80% forest cover, and currently the area covered if it reaches 26%. With these conditions at hand, no one should be surprised by the fact that the weather names are from one extreme to another, floods and landslides more and more often, where many people have died. It is hardly possible to blame any particular person, but those who are in parliament even have a much greater power than any person who decides to act in this direction in a positive sense. At the moment there is no inventory to be carried out to keep the deforestation under control or a large national plan to combat this phenomenon. No one has any interest at this time for this data to be known by everyone, but the effects of deforestation can no longer be neglected. Due to the lack of a National Agency, illegal logging is encouraged. In the reserves of Romania natural resources are exploited, constructions are made, mass tourism, and the newest phenomenon is hunting. (Jalubă, Iuliana, 2013).

Pollution and deforestation are the main environmental situations that are felt by Romanians according to several studies. An objective that must come into view of Romania is to conserve the remaining or virgin areas regarding the implementation and promotion of sustainable management, in order to bring benefits in the medium and long term both to the environment and to the people. Many counties in the North and North West of the country have been cleared thousands of hectares, but no one received a certain punishment or if he received, it was not a very serious one. Wherever you try to explore the codri of Romania, it is close to impossible not to find without too much effort thieves who are in action. The authorities at the local level do not have the possibility to completely stop the clearing of illegal forests, because often, they are out of the situation or they are overlooked, which I think has determined to reach such statistics. Most of the times the commercial operators are protected by the court or personal property, where no one can access anyone, as long as there is no mandate issued by the specialized police bodies. For the poor areas, this phenomenon of clearing is the main source of economic growth. (Giurgiu, V., 1999).

Combating strategies for deforestation in Romania and a first solution that will have an effect is to stop the damage. World trade in mass volumes reached about $ 5 billion, and if anyone were to try to stop the flow, they would face many hostilities. It does not mean that a complete cut of the forest is necessary. All the schemes that are organized have a plan in place that helps keep them. Another very important step in stopping deforestation is informing and educating those people who directly or indirectly influence the fate of forests and subsequently of humanity. (Dinu, L., 2012).

Conclusions

The main causes that led to deforestation are a real ecological disaster that was produced by illegal logging of private forests, but also unprotected ones. Further measures must be considered to further prevent the destruction of what is left in the virgin or preserved areas of the environment, in particular forest areas. Looking back, the last 20 years do not have very good statistics, and the main reason from my point of view is the economic power that was much higher and viewed in the short term, without analyzing the consequences in the medium term, but more long-term choice. The dysfunctions related to the judicial system by analyzing the delay in resolving the cases and punishing criminal offenders

who commit certain crimes. From a managerial point of view it is necessary to create a new system of coordination and organization in the forest field by separating the activities.

Abstract

Cash holding is the most common form to reflect firm's liquidity. Most Indonesian firms' manager agreed that corporate hold an optimal amount of cash which maximizes shareholders' wealth and operational performance. According to the Powell (2018), most Indonesian's managers believe that there is relationship between growth opportunity, leverage, cash flow volatility, capital expenditure, and cash holding. Hence, werecognize to implement cash holding, required variables which has been examined by Powell (2018). Then this study is aimed to examine corporate cash holding determinants of manufacturing firms in IDX for period 2015-2017. The samples used are 81 manufacturing companies (243 firm-year observations) was selected using the purposive sampling technique. Our study find that leverage and capital expenditure have negative and significant impact toward corporate cash holding. While growth opportunity, cash flow volatility, and corporate governance with board independence as its proxy is found to have positive and significant impact to the corporate cash holding.

Keywords: Cash holding, CFO, Growth Opportunity, Cash Flow Volatility

Introduction

One of the most important financial management is to hold or use cash. As we have known, cash is the most liquid asset. And therefore, the amount of cash must be determined optimally. Financial management literature state if cash was excessive determined then firms has to bear the opportunity cost. Thus, with that amount of cash, firms will miss the opportunity to buy securities. On the other hand, if a firm deficit in cash then the firm fail to fulfill short term obligations. Therefore, optimal cash management is needed. To determine the optimum cash can be explained by three theories. First, the trade off model, the optimum amount of cash is when the marginal costs and marginal benefits of holding cash are the same or identical. Second, the pecking order theory, optimum cash determination is used to meet the availability of corporate funding sources. Third, free cash flow theory, the optimum determination of cash depends on the flexibility of the manager in allocating cash for projects that are considered still profitable.

As in other countries, it turns out that cash management contributes up to 75% of financial management functions. By the financial management functions, it includes investment management, which management uses cash to buy short-term securities, inventories, and recognizes the existence of accounts receivable. Investment management also means to meet capital budgeting needs or buy equipment and facilities that are long-term in nature. While to meet the cash needs, the company must be able to determine short term and long-term financing. In principle, financial management teaches in order to fulfill short-term investments, such as buying securities or cash equivalents, buying inventory and recognizing the existence of accounts receivable, it should be fulfilled with short-term obligations including trade debt and short-term bank loan. Meanwhile, to fulfill long-term investment needs, ideally it is fulfilled with long-term obligations, specifically the issuance of bonds

and fundraising from several creditors, both banks and non-banks for the long-term financing. Thus, the financial management principle adopted in cash management is to fulfilling short-term investment needs with short-term liabilities and in the same time, fulfilling long-term investment needs or capital budgeting using long-term obligations. This principle is often referred to as the principle of hedging, which means preventing the occurrence of congestion in investment financing both short and long term because the company could be wrong in using its types of obligations. The principle of hedging was also relevant to the precautionary motive of cash holding that had been known before.

In practice, Indonesian companies have made mistakes in cash management, that is during the 1997-1998 monetary crisis. Many CFOs from large companies tended to use short-term obligations to finance long-term investments. The severe condition is when short term liability used by those companies was denominated in foreign currencies. On the other hand, the types of long-term investments targeted were various projects that have a very high level of risk. The error in cash management mentioned above is also contributing to the bankruptcy of many companies listed on the Indonesian Stock Exchange in the era of the monetary crisis. Also, the bankruptcy of the company causing many banks and other financial institutions to collapse. Furthermore, after a period of economic recovery, many Indonesian companies began to reorganize their cash management policies by paying attention to the principles of true cash management. In practice, many companies have been asked to pay attention to the issue of current ratio when applying for loans to banks or when the company wants to issue debt or bond securities. The crucial point is, if the company wants to get credit, the position of the cash balance must be safe. Similarly, when you want to issue bonds, the company's liquidity position must also be safe. With the increasing number of companies that have managed to get loans from both local and foreign creditors along with the increasing number of companies that have successfully become bond issuers, it arises beliefs that some companies have successfully implemented ideal cash management.

Because of the progress in cash management that has been successfully carried out by Indonesian companies, it then encourages academics to do further studies. One of cash management progress is that many companies have succeeded in becoming debtors from several large foreign companies and also become bond issuers in IDX. One interesting study was conducted by Powell (2018) who did a survey of 250 companies in Indonesia to find out the determinants of cash management. This survey is very interesting because it was carried out towards the CFOs of the companies listed in IDX and found various determinants factors of cash management decisions. Based on the survey from Powell (2018), some important dimensions are found, companies tend to hold a lot of cash to avoid the risk of financial distress and bankruptcy. Also, companies with high future cash flow volatility tend to hold cash in excessive amounts to prevent underinvestment in profitable projects in the future. The most critical factor in cash management is balancing conditions where cash is not in the excessive or shortage level, which in practice the magnitude of its value cannot be observed directly. The amount of this value will depend on the company's unique characteristics, namely growth rates, debt position, volatility of cash flows, investment levels, and corporate governance issues. Thus, this research intends to prove the results of a study from Powell (2018) on the relationship between various unique characteristics of the company and cash management policies using empirical research designs. This should be done to reinforce the results of studies from Opler et al. (1999), Arfan et al. (2017), and Harford et al. (2008) in other countries that have succeeded in finding determinants of cash management, especially leverage and cash flow volatility. While in the case of Indonesia, based on the Powell (2018) survey, there were indications that capital expenditure and growth opportunities should be considered as determining factors for cash holding. Further, according to our opinion, it should also consider the issue of corporate governance as a determining factor because CFOs are in the ranks of decision making which have the power and authority to use or hold cash as the most liquid assets. Finally, as a differentiator with other studies we will pay more on manufacturing companies as the majority part of IDX to obtain a comprehensive picture of the profile and determinants of cash management policies. In general, this study will be divided into several parts, which the first sections are preliminary which have been discussed before, continue with an overview of the theories and relationships between variables, research methods, results and discussion, and last but not least the conclusions and implications of this study.

Literature Review

In this section, we provide the main theories of cash holdings. Then we highlight findings of Powell (2018) survey. Lastly, we develop alternative hypothesis to test empirically whether independent variables have impact towards cash holding.

Cash Holding Theory

a) Trade Off Theory
