The trade off theory states that the company's cash level is optimal by balancing the marginal costs and marginal benefits of holding cash (Ferreira & Vilela, 2004). Dittmar, Mahrt-Smith, and Servaes (2003) explain two costs of holding cash, (1) if managers maximize shareholder wealth, the costs that arise are the low rate of return on other investments at the same level of risk, this kind of cost namely the cost of carry; (2) if the assumption of maximizing shareholder wealth is ruled out, then the cost of holding cash increases because managers have the opportunity to spend capital expenditure and acquisition spend or even in some countries corrupt. The benefits of holding cash according to Dittmar et al. (2003) arise from two motives. First, according to the motive of the transaction, the company holds a lot of cash when the cost and opportunity costs of cash shortages are higher. Second, the precautionary motive cash is based on the impact of asymmetric information about the ability to obtain funds.

b) Pecking OrderTheory

Companies will first fund investments with retained earnings, then with debt, finally with equity. The purpose of this funding sequence is to minimize the cost of asymmetric information and other funding costs. This theory suggests that companies do not have a specific cash level target, but cash is used as a support for retained earnings and investment needs. When operating cash flows are currently sufficient to fund new investments, companies will pay off debts and collect cash. Furthermore, if the retained earnings are not enough to fund the current investment, the company will use the cash that has been collected and if necessary, issue debt to fund the investment (Ferreira and Vilela, 2004).

c) Free Cash Flow Theory

Free cash flow predict that agents or managements will rather increase investment than returning cash to shareholders. Managers prefer cash because it can reduce risk and increase the authority of managers in making decisions. Companies that are more concerned with managerial authority tend to hold more liquid assets than are needed to maximize shareholder wealth (Opler et al., 1999). This kind of managerial authority can trigger agency costs. Agency costs are defined as costs arising from conflicts of interest between shareholders, bondholders, and managers that include incentive costs for managers to maximize shareholder wealth and monitoring costs for shareholders to observe whether managers work according to shareholders' desire (Jerzemowska, 2006).

Hypothesis Development

Based on the research that has been done before, it can be specified the variables that contribute to the determination of the corporate cash holdings as follows: growth opportunities, firm's size, cash flow volatility, leverage, capital expenditure, research and development expenditure, net working capital, profitability, dividend payment, and corporate governance. However, this study refers to the survey conducted by Powell (2018). The survey results found that around 70% of managers agreed to a positive relationship between growth opportunities and cash holding. Firms with abundant growth opportunity tend to hold higher level of cash to segregate capital expenditures from the volatility of future internal cash flow. Another finding is that firms with higher growth opportunity hold higher level of cash because these firms want to maintain their competitive position and in accordance to

free cash flow theory, when a firm has greater investment opportunities, managers prefer to hoard large cash balances to provide discretion in their firm's spending and capital expenditure decision.

Further, survey results indicate that 57% of managers agreed on a positive relationship between leverage and cash holding. This positive finding supports the view of trade off theory, which states leverage increase the possibility of financial distress or bankruptcy (Ozkan & Ozkan, 2004). Hence, firm with high level of leverage should hold high level of cash to reduce the default risk. The survey also found that 80% of managers agreed that cash flow volatility and cash holding had a positive relationship. The higher the variability of cash flow, the higher level of cash will be hold by a firm. The purpose of holding such high level of cash is to prevent the possibility of cash shortages in the future when profitable project is available. Managers want to reduce the underinvestment problem where as in the condition they have to give up on profitable project because there has no enough internal funds.Another important finding that underlying the selection of this research variable is that 12% agreed managers increase cash holdings to increase the freedom of expenditure and capital expenditure decisions.

This finding concludes that the higher the company's cash level, the higher the capital expenditure. It can happen because the cash is used to finance capital expenditure. Furthermore, if cash is used to finance capital expenditure then firms will be likely to have fewer resources to collect cash. Bates et al.(2009) asserts if capital expenditure creates assets that can be used as collateral, then capital expenditure can increase debt capacity and reduce demand for cash. According to Harford et al.(2008), cash allocation policy related to managers and shareholders. It is important to examine whether this cash will be distributed to the shareholders, spent by the company, for external procurement or held as a firms' safety margin. Because of these considerations, it is interesting to study how corporate governance can influence the company's cash management policies. Lastly, to sum up, we then focus to test whether growth opportunity, leverage, cash flow volatility, capital expenditure, and corporate governance are the determinants of corporate cash holding.

a) Growth Opportunity and Corporate Cash Holding

Trade off theory postulates and predict a positive relationship between growth opportunity and cash holding (Ozkan & Ozkan, 2004). Firms with high level of growth opportunities tend to have higher bankruptcy cost. Hence, these firms will hold more cash to reduce the possibility of cash shortages and prevent uncertainty of internally generated cash flow. Growth opportunity is measured by by dividing (book value of total assets - book value of equity) plus the market value of equity and book value of total assets, where the market value of equity (MVE) is calculated by multiplying the closing stock price with the number of shares outstanding (Frank & Goyal, 2004). Then we can formulate the alternative hypothesis as follow:

H1: Growth opportunity is positively related to corporate cash holding.

b) Leverage and Corporate Cash Holding

Firms with higher level of leverage will face higher cost in liquid assets investment. This context explains if leverage is used up to increase cash balances. Thus, to reduce the cost, firms has to lower the cash balances. Therefore, by following the pecking order theory we assume that there is a negative relation between leverage and cash holding. Leverage is measured by total liabilities of total assets. Then we can formulate the alternative hypothesis as follow:

H2:Leverage is negatively related to corporate cash holding.

c) Volatility and Corporate Cash Holding

Volatility of cash flow implies that there is possibility to have cash shortages in the future. Trade off theory postulates there is positive relationship between cash flow volatility and corporate cash holding. Higher cash flow volatility of a firm will hold higher cash to reduce the possibility of cash shortages in the future. This positive result was found in Guizani (2017) research. Cash flow

volatility is measured by dividing standard deviation of 5 years operating cash flow and average total assets. Then the alternative hypothesis could be formulated as follow:

H3: Cash flow volatility is positively related to corporate cash holding.

d) Capital Expenditure and Corporate Cash Holding

Generally, one of the cash allocations is capital expenditure. In accordance with pecking order theory, firms with high level of capital expenditure will be financed by cash. As explained before, if capital expenditure creates assets that can be used as collateral, then capital expenditure can increase debt capacity and decrease demand for cash (Bates et al., 2009). And hence, the higher the capital expenditure the lower the cash holding. Capital expenditure is measured by the ratio of net fixed assets to total assets. Then the alternative hypothesis could be formulated as follow:

H4: Capital expenditure is negatively related to corporate cash holding.

e) Corporate Governance and Corporate Cash Holding

The weaker the corporate governance, the lower the cash will be held, and vice versa, the stronger the corporate governance, the higher the cash holding (Harford et al. 2008). Strength or weakness of corporate governance can be determined by board independence (ratio of total independent directors and total directors) and board size (ratio of total directors and logarithm of total assets). If a firm owned at least 1/3 of independent directors and on average 9 directors overall then the firm has strong corporate governance (Osei, 2014). Then we can formulate again the alternative hypothesis for two proxies of corporate governance respectively as follow

H5a: Corporate governance by board independence is positively related to corporate cash holding.
H5b: Corporate governance by board size is positively related to corporate cash holding.

Methodolgy and Data

a) Data

This study employed manufacturing firms listed on Indonesia Stock Exchange as data with period spanning from 2015 to 2017. The purposive random sampling method was adopted in this study. Samples used in this study has to fulfilled few criterias as follows (1) listed in IDX; (2) listed at least since 2011 till 2017; (3) listed have audited financial statements since 2011 till 2017; (4) financial statements denominated in Rupiah currency. Though the period of study is starting from 2015 but 2011 data are needed due to measure the cash flow volatility variable. Thus, based on the above criteria, 81 manufacturing firms chosen as sample out of 163 listed manufacturing firms. This study used the panel data as it combines time series of data for the 2015-2017 and cross section data of 81 companies. Since the study investigates 81 companies for three-year study period, the total number of observations of the study was 243 years observations.

b) Variable Measurements

This study conducted five main independent variables (growth opportunity, leverage, cash flow volatility, capital expenditure, and corporate governance) and one dependent variable (corporate cash holding). The measurement of each variable is presented in Table 1.

Table 1: Variable Measurements

Variables	Measurements	References
Cash Holding	$\frac{Total\ CE}{(TA - Total\ CE)}$	Guizani (2017)
Growth Opportunity	$\frac{BV\ of\ TA - BV\ of\ Equity + MVE}{BV\ of\ TA}$	Wasiuzzaman (2014); Frank & Goyal (2004)
Leverage	$\frac{Total\ Liabilities}{Total\ Assets}$	Wang& Chang (2014)
Cash Flow Volatility	$\frac{Std\ of\ Annual\ OCF\ (5\ years)}{Average\ TA\ (5\ years)}$	Wasiuzzaman (2014); Ozkan & Ozkan (2004)
Capital Expenditure	$\frac{NFA}{TA}$	Arfan *et al.* (2017)
Corporate Governance	$BS = \frac{Total\ Directors}{Log\ TA}$	Harford, Mansi, & Maxwell (2008)
	$BI = \frac{Independent\ Directors}{Total\ Directors}$	

Note: Where CE is Cash and Equivalents; TA is Total Assets; BV is Book Value; MVE is Market Value of Equity; Std is Standard Deviation; NFA is Net Fixed Assets; BS is Board Size; and BI is Board Independence. All the measurements used in this study was adapted from few references as written in Table 1.

c) Analysis Method

This study adopted the Generalized Least Square (GLS) panel regression analysis based on fixed effect model estimation. Since this study using panel data which combines time series and cross section, so the regression equation was structured as follow:

$$CH_{it} = \beta_{11}D_{1i} + \beta_{12}D_{2i} + \cdots + \beta_{1,81}D_{81i} + \beta_2 GO_{2it} + \beta_3 LEV_{3it} + \beta_4 CFV_{4it} + \beta_5 CAPEX_{5it} + \beta_6 CG(BI)_{6it} + \beta_7 CG(BS)_{7it} + e_{it}$$

Where CH represents corporate cash holding, β_1 is the constant of the equation, GO represents growth opportunity, LEV is the leverage, CFV is the cash flow volatility, CAPEX is the capital expenditure, CG(BI) is the corporate governance measured by board independence, and CG(BS) is the corporate governance measured by board size.

In addition, this study will provide descriptive statistics of each variables, hypothesis testing, and multicollinearity and autocorrelation diagnostic. And also, to control the autocorrelation and heteroscedasticity problem, we conducted cross section weight and heteroscedasticity-consistent standard error in the regression analysis by using Eviews 3 and 9 version.

To test the hypothesis, p-value will be shown, and if the p-value is lower than the significance level, the formulated alternative hypothesis is accepted. In contrast, if the p-value is higher than significance level, alternative hypothesis is rejected. In order to diagnose multicollinearity, this study using correlation coefficient between each independent variable, if the correlation coefficient below 0.8 then we assume regression is free from multicollinearity (Gujarati & Porter, 2010). Finally, to

check the autocorrelation problem, we use Durbin Watson statistics, if the result around two, then it is free from the autocorrelation problem.

Empirical Results and Discussion

a) Descriptive Statistics

In this section will be presented the results of descriptive statistic tests of all variables both dependent and independent. Descriptive statistical measurements include mean and standard deviation as shown in Table 2**.** In the following table, the average value of cash holdings from 81 companies is 0.149187 with a minimum value of 0.000416 and a maximum value of 1.721276. Variation of mean value might be influenced by the different cash management policies of each company. Some companies may hold too little cash, but other may hold too much cash. Judging from these varied values, it also increasingly convinced us that it was necessary to conduct research on corporate cash holding. Next will be discussed the descriptive statistics of other independent variables expected to having an influence on the corporate cash holdings.

As shown below, differences in mean and standard deviation of each variables are not significant, unless the growth opportunity (GO). The large standard deviation in this independent variable compared to other variables is caused by fluctuations in closing stock prices and including stock splits (splitting the number of shares into more with lower nominal prices) by several companies. For example, the highest growth opportunity value (60.66348) owned by MYOR company in 2015, then it dropped to 3.36138 in 2016. This drastic decline was due to the year of 2016, MYOR company did stock split. Standard deviation of the growth opportunity variable is much larger because there are fluctuations in the closing price in some companies and some of them did stock split during the period in this study. The growth opportunity which then calculates the market value of equity is certainly influenced by those two incidents.

Descriptive statistical values that must be considered are corporate governance variables measured by board independence. Board independence in this study is measured by dividing the total independent directors by the total directors in a company. So that the minimum value of this variable which shows the number 0.000000 also means that some certain companies in the study period spanning from 2015 to 2017 reported no single independent director in their audited financial statements.

In addition, when collecting data to test H5b, the number of directors from 81 companies during three study periods was an average of five directors. Based on the explanation in the hypothesis development section, that the range of total directors for a company to be said having strong corporate governance should have an average number of directors of nine people. Hence, it is concluded that the majority of manufacturing companies in Indonesia still in a weak corporate governance system.

Table 2: Descriptive Statistic

Variables	Mean	Std. Dev.	Min.	Max.
Cash Holding (CH)	0.149187	0.259722	0.000416	1.721276
Growth Opportunity (GO)	2.115853	4.782888	0.304145	60.66348
Leverage (LEV)	0.447742	0.198206	0.091390	0.917341
Cash Flow Volatility (CFV)	0.062915	0.053227	0.000237	0.443634
Capital Expenditure (CAPEX)	0.385734	0.196335	0.035695	0.907350
Board Independence (BI)	0.124596	0.132790	0.000000	0.666667
Board Size (BS)	0.423451	0.196222	0.163892	1.296652

Note: Std. Dev. namely standard deviation of the data collected; Min. is the minimum level from all data collected; while Max. is the maximum level from all data collected.

Multicollinearity is a phenomenon of perfect correlation between one independent variable and another independent variable. The criteria used in this test, if the correlation value between independent variables has been tested < 0.8, this study is free from the problem of multicollinearity. Shown in Table 3 that the correlation value between independent variables is less than 0.8 so it is concluded that the sample of this study is free from multicollinearity problems. In addition, in Table 4 this regression model produces a DW value of 2.191951, the DW stat is around two, so it is free from the problem of autocorrelation.

Table 3: Multicollinearity

Variables	GO	LEV	CFV	CAPEX	BI	BS
GO	1.000000	0.012226	0.127362	-0.053242	-0.135987	0.114998
LEV	0.012226	1.000000	0.175918	0.192262	0.028946	-0.132280
CFV	0.127362	0.175918	1.000000	-0.095452	-0.054979	-0.101320
CAPEX	-0.053242	0.192262	-0.095452	1.000000	0.179557	0.023673
BI	-0.135987	0.028946	-0.054979	0.179557	1.000000	-0.113618
BS	0.114998	-0.132280	-0.101320	0.023673	-0.113618	1.000000

Note: GO is the Growth Opportunity; LEV is the Leverage; CFV is the Cash Flow Volatility; CAPEX is the Capital Expenditure; BI is the Board Independence; and BS is the Board Size. With 5% significance level, all variable independents show no multicollinearity problem.

b) Panel Regression Model Results

As explained before, to test the developed hypothesis in this study, we conducted few estimation models including common effect, fixed effect, and random effect. Each of the estimation model was then tested with no weight and cross-section weight method namely Generalized Least Square (GLS), except for the random effect estimation, because the estimation itself is a GLS model. By going through five model testing (two common effect model, two fixed effect model, one random effect model) as seen in Table 4, we then sum up fixed effect model with GLS method is the best fit to test all formulated hypothesis. Lastly, we apply White Heteroscedasticity-Consistent Standard Errors and Covariances to the regression analysis which according to Hayes and Cai (2007) the Heteroscedasticity-Consistent Standard Errors can be used to minimize the autocorrelation and heteroscedasticity effect of regression analysis.

Table 4: Different Panel Regression Model

Variables	(1)	(2)	(3)	(4)	(5)
GO	0.0004 (0.8879)	0.0010 (0.0003)	0.0005 (0.6883)	0.0010 (0.0193)	0.0005 (0.7076)
LEV	-0.4951 (0.0000)	-0.3820 (0.0000)	-0.1293 (0.1061)	-0.0928 (0.0000)	-0.2364 (0.0006)
CFV	-0.0755 (0.7864)	-0.0213 (0.6697)	-0.0225 (0.9541)	0.1144 (0.3488)	-0.1337 (0.6581)
CAPEX	-0.4051 (0.0000)	-0.3136 (0.0000)	-0.8977 (0.0000)	-0.8318 (0.0000)	-0.6830 (0.0000)

BI	-0.0760 (0.4938)	-0.0554 (0.0230)	0.4063 (0.0003)	0.3108 (0.0000)	0.2686 (0.0052)
BS	-0.0432 (0.5644)	0.0518 (0.0063)	0.0082 (0.9508)	0.0019 (0.9481)	-0.0033 (0.9714)
DW Stat	0.186397	0.177350	2.221518	2.191951	0.131291
	Significant at 5%			No autocorrelation	

Note: (1) common effect-no weight; (2) common effect-cross section weight; (3) fixed effect-no weight; (4) fixed effect-cross section weight; (5) random-effect. If only assess significant influence, then model (2) is the best suit, but we also consider the problem of classical assumptions, namely autocorrelation, so that model (4) is the most suitable model to be applied among other models. Then to test the hypothesis empirically, model (4) was developed again by applying the White Heteroscedity-Consistent Standard Errors to minimize the impact of heteroscedasticity problems in the regression model.

In Table 5 we present the coefficient and p-value to shows the effect of each independent variable on the corporate cash holding variable. The positive and negative effects of each variable are seen from the sign of the coefficient value, if the value of the coefficient is positive then the change in the independent variable will increase the dependent variable, and if the coefficient value is negative then the change in the independent variable will decrease the dependent variable. Where as to see whether the influence is significant or not can be seen from p-value, if the p-value is less than the level of significance (Sig. Level), the alternative hypothesis is not rejected, but if the p-value is more than the level of significance, the alternative hypothesis is rejected. In the following paragraphs, discussion of hypothesis testing results will be presented.

Table 5: Results of Hypothesis Testing

Variables	Coefficients	P-value	Diagnostic Test
GO	0.001005	0.0000	F-test = 0.0000 Adj. R^2 = 0.929586 DW = 2.191951 Sig. Level = 0.05
LEV	-0.092839	0.0000	
CFV	0.114427	0.0042	
CAPEX	-0.831820	0.0000	
BI	0.310810	0.0000	
BS	0.001914	0.8240	

Note: GO is the Growth Opportunity; LEV is the Leverage; CFV is the Cash Flow Volatility; CAPEX is the Capital Expenditure; BI is the Board Independence; and BS is the Board Size. The coefficient explains the sign of the influences of each independent variable toward corporate cash holding. P-value is the probability value which determined whether each independent variable has significant impact toward corporate cash holding. F stat is the probability value of Anova test. Adj. R^2 is the value of Adjusted R Square which determine proportion of corporate cash holding explained by all independent variables. DW is the Durbin Watson Stat to detect autocorrelation problem. Sig. Level is the level of significance applied in this study.

c) Each Alternative Hypothesis Testing Result

c.1) Growth Opportunity and Corporate Cash Holding

From the results of data processing, we can not reject the alternative hypothesis that growth opportunity is positively related to corporate cash holding so that H1 is supported . Growth opportunity as measured by market-to-book ratio, shows a company investment opportunity in projects that have a positive NPV. The positive relationwas found because companies with high growth opportunity are expected to have high bankruptcy costs and hence tend to hold more cash.

Companies that have many investment opportunities will also have a high risk so that the possibility of financial difficulties is also high. Therefore, companies will hold large amounts of cash to avoid the possibility of the crisis. Next reason for the firms with high growth opportunity will hold more cash is to avoid future cash shortages when the cash planned to be spent. This too support to the precautionary motive of holding cash, which states the company holds cash to avoid future cash shortages. If the company lacks cash which is so called source of internal funds, the company must look for external funding sources that are expensive. Therefore, companies with high growth opportunity will hold more cash in order to reduce the risk of cash flow shortages and reduce the cost of acquiring expensive external funding sources.

c.2) Leverage and Corporate Cash Holding

Leverage as a reflection of a company that relies on debt as one of the funding sources measured by total liabilities divided by total assets, is found negatively related to corporate cash holding as supported H2. This negative relationship shows that leverage is seen as a substitute for holding cash because leverage is considered as a measure of a company's ability to issue debt. Firms that are too focused on using debt as their main funding source, tend to hold less cash. In line with the pecking order theory that companies with high leverage will pay more expensive fees when the debt is used to invest in liquid assets and therefore must reduce cash holdings. Companies with high leverage will hold less cash because the purpose of obtaining the debt is not to be invested in cash but to increase their own capital needed to increase the company's sales. To strengthen the results of hypothesis testing, researchers added data on manufacturing companies from sub-sectors of consumer goods. Data added in the form of growth values from accounts payable and sales. Researchers want to prove that the increase in account payable (debt) aims to increase the company's sales.

As shown in Table 6**,** it can be seen that increases and decreases in account payable can increase and decrease company sales as well. For example, the CEKA company, from 2015 to 2016 there was an increase in payable accounts from minus 15.12% to 25.39%, sales of the company also increased in the same period from minus 5.84% to 18.07%. This proves that companies increase debt to increase sales not only to increase cash. So that the results of the study concluded that the increase in leverage reduces the ownership of cash because the debt aims to increase sales.

Table 6: Additional Data for testing Relationship Between Leverage and Corporate Cash Holding

	Account Payable (Growth)			*Sales (Growth)*		
KODE	**2015**	**2016**	**2017**	**2015**	**2016**	**2017**
APLI	-50.61%	171.22%	69.16%	-11.36%	33.20%	10.09%
CEKA	-15.12%	25.39%	20.60%	-5.84%	18.07%	3.46%
FASW	-54.83%	48.30%	39.34%	-9.11%	18.44%	24.89%
IMAS	-8.17%	-36.78%	92.43%	-6.98%	-16.85%	2.06%
INCI	70.04%	92.32%	42.38%	24.22%	28.83%	53.18%
MYOR	24.31%	30.02%	29.15%	4.58%	23.83%	12.35%
RICY	-10.20%	51.90%	185.38%	-6.28%	9.94%	31.02%
ROTI	27.12%	8.01%	-12.98%	15.65%	15.98%	-1.22%
VOKS	-19.95%	23.58%	39.17%	-20.25%	26.58%	11.67%

c.3) Cash Flow Volatility and Corporate Cash Holding

Cash flow volatility, which is defined as the level of uncertainty in the cash inflows and outflows of the company, is predicted to have a significant effect with a corporate cash holding at a 5% significance level and is positively related to corporate cash holding. So we can support H3. Volatile cash flows reflect financial uncertainty in the future, firms with high volatility in cash flows will hold more cash to anticipate future financial shortages. Cash flow volatility can also mean that a company

cannot allocate cash usage appropriately, especially for company operating activities because the variable cash flow volatility is calculated by the standard deviation of cash flows generated from the company's operations. Companies with high volatility in cash flow will hold more cash to avoid a cash shortage that can be used to finance the company's operations. If a company fails to generate cash that can finance operational activities, then the company is at risk of failing to achieve business continuity goals.

c.4) Capital Expenditure and Corporate Cash Holding

Capital expenditure is used to invest in certain fixed assets that can generate profits for the company. With a 5% significance level, we do not reject the fourth hypothesis that the capital expenditure variable was found to have a negative and significant effect on the company's cash holding. Thus H4 is supported. This negative influence is in line with the predictions of the pecking order theory, which states that companies will use the cash they have to finance capital expenditures. Companies with high levels of capital expenditure tend to be financed with cash, and therefore the company's ability to collect cash is also reduced. Additionaly, capital expenditures are often used to produce assets that can be used as collateral, so a high level of capital expenditure consumes more cash. The illustration reflects the negative influence of capital expenditure variables on corporate cash holdings.

c.5) Corporate Governance and Corporate Cash Holding

The results of the study indicate that the hypothesis of the effect from corporate governance as measured by board independence, H5a is not rejected at the 5% significance level. Corporate governance variables with board independence measurement have a positive effect on cash holding. Our findings support the view that stronger corporate governance tended to hold more cash. Companies with more independent directors will hold more cash. The tendency to hold more cash is due to the company's operational activities. Board independence provides better shareholder protection, thereby reducing agency costs from holding cash. So that companies with more independent directors will hold more cash and therefore have a positive effect on cash holdings. But the contradictory results were found by Wasiuzzaman (2014) who stated that there was a negative influence, arguing that the more independent directors on the board, the managers were subjected to further checks and could not accumulate cash for personal gain. This result shows the effectiveness of independent directors in controlling the level of cash held by the firm.

While corporate governance variables measured by board size, the results of the study indicate that the hypothesis, H5b was rejected at the 5% significance level. The reason for rejecting the hypothesis is because the probability value shows a non-significant effect but produces the same direction as the hypothesis formulated in the previous section. In the context of Indonesia's manufacturing firm which shows to have weaker corporate governance system, with a positive influence on corporate cash holding, we support our hypothesis that weaker governance tended to hold less cash. This is due to the way how a company would allocate its cash. The more boards of directors of a company reflects the more agents a company has. Agents will prefer to hold lots of cash in order to increase the freedom making cash allocation decision. Thus, this positive effect is explained that companies with large board size (the number of directors) are increasing their cash holding because it can increase agents' discretionary power for the investing decision making that benefit themselves but disserve the shareholders.

d) Discussion of Hypothesis Testing Result

In this section we will discuss the comparison between current research with previous research by three researchers, namely: 1) Ozkan and Ozkan (2004) conducted a study of the determinants of cash holding in companies in the UK using the Generalized Method of Moment (GMM) regression; 2) Arfan et al. (2017) conducted a research on the determinant factors of cash holding in manufacturing companies in IDX using the GLS model; 3) Harford et al. (2008) which examined the effect of corporate governance on corporate cash holding on US companies.

Table 7: Comparison of Recent and Previous Studies

Each Variables of Hypothesis Testing	Our Study (2020)	Ozkan & Ozkan (2004)	Arfan et al. (2017)	Harford et al. (2008)
GO → CH	0.001005 *0.0000	0.027 *0.010	0.546 **	
LEV → CH	-0.092839 *0.0000	-0.324 **0.042	-0.197 **	
CFV → CH	0.114427 *0.0042	0.084 *0.125		
CAPEX → CH	-0.831820 *0.0000		-0.198 **	
BI → CH	0.310810 *0.0000	-0.037 *0.033		-0.021 0.33
BS → CH	0.001914 *0.8240			-0.035 0.99

*Note: Recent study is comparing to Ozkan & Ozkan (2004); Arfan et al. (2017); Harford et al. (2008) by the coefficient value and p-value in different significance level which * shows 5% level and ** shows 10% level.*

The growth opportunity variable as shown in Table 7 which provide a comparison of the results between current research findings and previous researchs turned out to have the same effect on the corporate cash holding which is positive. So that the change in one growth opportunity unit will increase cash holding by the coefficient value presented according to each study. The results of this study are similar to the results found by Ozkan and Ozkan (2004) and Arfan et al. (2017). The leverage variable also shows the same negative effect on the corporate cash holding either recent study or previous study conducted by Ozkan and Ozkan (2004) and Arfan et al. (2017). However, both previous studies were significant at 10% level. The higher the significance level it means the less percentage that the hypothesis is true. So, comparing to both previous studies, we are sure that our findings are more accurate. Looking down to the cash flow volatility variable, which comparing to Ozkan and Ozkan (2004), it shows the same direction from the coefficient value and significant at 5% level. Cash flow volatility proved to have positive effect on corporate cash holding.

Next up, the capital expenditure variable shows the negative influence towards corporate cash holding both recent study and Arfan et al. (2017) study. Yet both study's result conducted in two different significant level which recent study using 5% level and Arfan et al. (2017) used 10% level. On the contrary, corporate governance which measured by board independence, compare to Harford et al. (2008) shows the different sign on coefficient value. Harford et al. (2008) found that the more independent directors in a firm the less level of the cash holding. Lastly, corporate governance which measured by board size, compare to Harford et al. (2008) also show the different effect on corporate cash holding. We find positive effect however Harford et al. (2008) found negative effect. To sum up, the influence of corporate governance on corporate cash holding still can not be precisely predicted.

Conclusion and Suggestion

Conclusion

This study was conducted to determine the factors that determine the level of cash holding manufacturing companies listed on the Indonesia Stock Exchange in the period 2015-2017. Through sample selection techniques, purposive sampling, with the criteria needed by researchers in completing this paper, produces 81 manufacturing companies with various sub-sectors. The total observations found in this study were 243 observations with 81 companies in three years.

The determinants of corporate cash holding examined in this study consisted of growth opportunity, leverage, cash flow volatility, capital expenditure, and corporate governance. The measurement of corporate governance variables used in this study to explain the effect of corporate governance on

corporate cash holding is board independence and board size. Thus, it has been proven the hypothesis that the growth opportunities variable has a positive influence on corporate cash holding, leverage has a negative influence on corporate cash holding, cash flow volatility has a positive influence on corporate cash holding, capital expenditure has a negative influence on corporate cash holding, and corporate governance with board independence proxy has a positive effect on corporate cash holding.

a) Suggestion

Regarding the results of this study, the researcher will provide some suggestions that could be useful for other researchers, namely as follows:

1) For other researchers, it is recommended that the selection of research subjects not only be limited to one company sector, so as to strengthen and complement previous research.
2) For other researchers, it is suggested that examining the independent variables other than those that have been proven to have a significant effect in this study.
3) For other researchers, if you want to examine the effect of the leverage variable on a corporate cash holding can show data that increased leverage is used to increase sales and not to collect cash.
4) For other researchers, it is suggested that separate corporate governance variables and other independent variables in determining the level of the company's cash holding. Related to the context of corporate governance variables themselves are very broad and very many measurements.
5) For companies, it is recommended that they be able to work with other academics in providing a real picture of what determinants have an important role in the policy of determining a company's optimal cash level.

Annotation

The essence of the price is expressed in its functions; one of the most important of them is the distribution. With pricing established national income is distributed between the market actors. This distribution is multiplicative. Fiscal multipliers show the impact of discretionary changes to core budget indicators and allow you to form sound economic policy. The purpose of the study to determine the optimal allocation mechanism established the national product among the market agents based on price ad valorem, specific and complex taxes. Authors in the study used a VAR model to calculate the magnitude of the fiscal multiplier generated by the value added tax (VAT) and excise duty (A).
Existing pricing models no longer cope with the emerging challenges of efficient distribution and modalities for the accounting of internal and external factors. Therefore, when creating a pricing policy increasingly turn to the tax agreements, providing for a deviation from the tax pricing.

Keywords: Fiscal Multiplier, Pricing, Budget Rule Pricing Models, Taxes, National Product.

Introduction

Price is the monetary expression of costs and benets plus social, political, and other effects, as wrote A. Marshall. The essence of the price is expressed in its functions; one of the most important of them is the distribution. With pricing established, the national revenue is divided by market actors. This distribution is multiplicative. Fiscal multipliers show the impact of discretionary changes in the main fiscal indicators. Knowledge of fiscal multipliers allows generating an optimal economic policy, since for the last decade, there has been a weakening of the budgetary policy in many countries. Fiscal multipliers show the direct impact of fiscal policy on the change (growth) of GDP.

Over the last decade in the world, there are many methods of calculation of fiscal multipliers. However, so far not identified the benchmark. Gimpelson V. and others, (2015) believe that the research results largely depend on the used class of models for the estimation of fiscal multipliers. Among empirical methods of evaluation, there are two basic vector autoregression (VAR), the model that was used by the authors, and dynamic stochastic General equilibrium model (DSGE). In one of the most famous works of J. E. Arias, Rubio-Ramírez J. F., D. F. Waggoner (2014) uses the theoretical concepts of the authors to construct the structural shocks and the determination of their impact on GDP growth. Favero, Giavazzi (2012), Baum A., Poplawski-Ribeiro M., Weber A. (2012), summarized the researched features of various countries, and identified non-linear behaviour of fiscal multipliers in different phases of the business cycle is Auerbach, Gorodnichenko (2012). Anderson D., B. Hunt, M. Kortelainen, M. Kumhof, Laxton D., Muir D., Mursula S., S. Snudden (2013) investigated the VAR model and the "average" response of GDP to shocks of fiscal policy and the multipliers obtained through them, they are usually used when the economy is close to "normal". When the state of the economy is significantly different from "normal", the more effective can be the estimates obtained using DSGE models.

Methods of Research

An overview of DSGE models is presented in Gechert S., Will H. (2012). The presence of a significant number of countries that do not have a sufficient number of observations for qualitative analysis prompted the IMF to create a simplified method of calculation of the total fiscal multiplier based on the evaluation of a set of determinants that determine its value.

Authors in the study used a VAR model to calculate the magnitude of the fiscal multiplier generated by the value added tax (VAT) and excise duty (ED):

$$Y_t = \mu_t + nB(F_i) * Y_{t-1} + \mu_{t-1} \quad (1),$$

Where, Yt - GNP;
n - Fiscal multiplier calculated according to the methodology of the Ministry of Finance;
F_iendogenous and exogenous variables: state of the business cycle; development of financial markets; reaction to monetary policy shocks; exchange rate regime; amount of debt; the effectiveness of tax administration, etc. .;
μi is a constant at each time lag.

As noted above, one of the price distribution functions. In the price model, there are taxes that cause the strongest animated effect; this is the value added tax (VAT) and excise tax (A). Price models cover all areas of activity. Let us dwell on the most common. The Tax Code, Figure 1, determines the first two models and their elements

C	P	Pcp	ED	VAT	CCH	TN
Price for calculating the commodity products of the organization (enterprise)						
Amount for excise duty (A)						
Wholesale price of the organization (WP)						
Intermediary price (IP)						
Retail price (RP)						

Fig . 1: Tax pricing model or price model for industrial товаров economic goods.

Designations in the figure[1]:

C - Costs or cost;
Pcp- Price for calculating the commodity products of the organization (enterprise)
P - profit;
ED - excise tax;
VAT - value added tax;
CCH - premium intermediary;
TN - retail chain premium.

An entrepreneur (seller) can set any price level, but cannot change model elements. The taxes laid down in the model form the tax multiplier. Consider the process of pricing according to the system shown in Figure 1. The calculation is summarized in table 1.

[1] Tax code of the Russian Federation (part two) " from 05.08.2000 N 117-FZ (as amended from 29.12.2019)

Table 1 – Price calculation for goods of various categories

Name of goods	**C**	**P**	**P %**	Pcp	ED **%**	ED **rub.**	**A**	VAT**, %**	**WP**	**CCH**	IP	TN	**RP**
Conditional product	100	10	10	110	23		135,3	10	148,83	25	186,0375	5	195,3394
Cahors wine, 750 ml capacity.	236,76	71,03	30	307,79		18 rub\ for 1 l	321,29	20	379,12	35	511,8	10	563
Millet grits	38,62	9,27	24	47,89	0	0	47,89	10	52,68	16	61,11	8	66
the drug Quprenil	13819,62	3316,71	24	17136,33	0	0	17136,33	0	17136,33	1	17307,69	4	18000

This model, used for the domestic market, allows you to solve marketing and fiscal problems related to the distribution of profits between the participants of the transaction and taxes for the budget. Considered example[2].

PC "Tire" sells waste rubber crumb to the small business enterprise "Technologist". The cost of crumbs - 50 rubles \ kg. LLC "Technologist" makes rubber hoses from rubber crumbs and sells them at the price of 154 rubles\kg. VAT = 18%. There is no excise tax.

Let's determine at what price PC "Tire" sells the crumb, if the organizations agreed to divide the profit and loss in equal proportions.

Table 2:Source data

C (PC)	**P** (PC)	Pcp	**VAT**	**WP**	**C** (LLC)	**P**(LLC)	Pcp	**VAT**	**WP**
50	32.8					32.8			154

To solve it, you must use a system of equations:

$$\begin{cases} (50+P)*1.2=СМП \\ (СМП+P)*1.2=154 \\ 59+1.2P=СМП \end{cases} \qquad (2)$$

59+1.18P+P= 130.5

2.2П=71.5

П=32.8

Table 3: Results of calculations

C (PC)	**P** (PC)	Pcp	**VAT**	**WP**	**C** (LLC)	**P**(LLC)	Pcp	**VAT**	**WP**	**taxes**
50	32,82	82,8	14,904	97,704	97,704	32,8	130,504	23,49072	153,99472	38,39
50	5	55	9,9	64,9	64,9	65,600001	130,5	23,49	153,99	33,39
50	60	110	19,8	129,8	129,8	0,6999992	130,5	23,49	153,99	43,29

[2] Gryzunova N. V., Lukashevich A. B. Workshop on the discipline "taxes and taxation". Taxes in trade. Moscow.: PRUE im. G. V. Plekhanova, 2016.

Based on a simple example can be seen that the largest fiscal effect will be of the maximum profit in the initial stage of distribution.

The third type of models are implemented in the case of actions of international relations, prices, the pledged taxes and risks are subject to Incoterms[3]. Depending on the price of the group's transport costs are divided between seller and buyer. According to Incoterms 2020, a group of E- "self" - transport costs and risks are on the buyer. Price group F, the word "free." This pricing structure assumes that the seller transfers under certain conditions. Their products to the international carrier. After this fact–the «transfer of goods" the seller is not under any obligation. The third group-C. This design of prices implies that the seller not only signed a contract with the international carrier. However, the risks paid. Group D - "delivery" - all costs borne by the seller.

The fourth group of the classification prices - the selling prices are contractual, exchange, prices, fairs and auctions. The fifth group, the stages of the sales forms of bid, proposal and implementation. The sixth group of models determines the price according to the degree of regulation. Respectively are rigidly fixed, adjustable and free. The seventh level of classification characterizes the stability of prices in time by determining the moving and sliding prices with subsequent fixation[4].

The eighth model group rates –tariff. The rate is the price rate at which the settlements, for example, the electrical and thermal energy, including related services. A major role in the determination of tariffs plays a form of the financial statements: "statement of cash flows". The time interval of validity of the established rate, usually equal to one year. The current system of tariffs for thermal and electric energy includes:

• limit and (or) maximum levels of tariffs for thermal energy (capacity 25 MW or more) supply of thermal energy to the end user;
• Tariffs for the consumed heat energy generated by the organizations who supply to the wholesale market.
In determining the forecasted levels of values, costs and tariffs, which implements the unit of production (works or services) use the information contained in the official sources of information, namely:
• depending on the consumer group set tariffs, subject to state regulation;
• The price formed as a result of the auction (tenders);
• The forecasts reflected in the program socially economic development of the Russian Federation for the next financial period in the base scenario, which reflects:
• The predictive value of CPI (consumer price index);
• Level of natural gas prices;
• limit growth of tariffs.
Creation and calculation of the tariff level for electric energy involves the implementation of the following algorithm of actions[5]:
• Determination of the expected (required) of gross revenue:
GS = (CCapex – Vcapex/2) / (1- T) x ROIC + VCapex + capex x (30 + 1 – 2 x n) /30 x Tp + Cexp x12 (3)

Where, gross sale (GS) - the amount of gross revenue required breaking even;

-Cost of capital expenditure (Ccapex) - costs for the reimbursement of capital costs at the beginning of the reporting period;

-volume of capital expenditure (Vcapex) - the amount of capital costs recoverable in the reporting period, in value terms;

-tax of profit (T) - the amount of tax on profit in value terms payable to the federal budget and the budget of the subject of the Russian Federation;

[3] International rules for the interpretation of trade terms " incoterms-2020

[4] Kiseleva I. A., gryzunova N. V., Bui N. A., Simonovich N. E. Analysis of pricing factors for the cost of tourist services \\ Izvestiya Kabardino-Balkarian state agrarian University. V. M. Kokova. 2016. No. 1 (11).

[5] The RF Government decree of 29.12.2011 No. 1178 (ed. by 19.10.2018), "On pricing in sphere of controlled prices (tariffs) in electric power industry " (together with "Bases of pricing in sphere of controlled prices (tariffs) in electric power industry", "Rules of state regulation (revision, application) of prices (tariffs) in electric power industry")

-return on invested capital (ROIC) - the rate of return on invested capital, set at 14% per annum;
-capex - the value of specific capital costs for MW of installed capacity of the generated facility;
-number (n) - serial number of the period starting from the year in which the supply of electric energy and power of the generating facility began;
-Tax of property (Tp) - amount of tax on the property of the company, valid in the period n;
cost of exploitation (Cexp) - the volume of operating costs in the year n.

Pricing in the housing sector is a set of principles and methods of forming and establishing the price range for the following activities:

• The contents of the housing;
• Housing repairs
• hiring of premises
• Utilities (rates).

Within the aforementioned pricing policy in the housing are formed rules for the regulation of prices, develop methodological recommendations by definition of the structure of prices and tariffs, the basis for revising the recommended level of prices and tariffs, the establishment of the period of regulation.

Costs in housing and utilities include the following elements: the cost of using cold water, hot water, electric energy, thermal energy, gas (including the supply of gas in cylinders), solid fuel, and the discharge of wastewaters, municipal solid waste management. The change in the value of these articles in the dynamics is regulated using marginal indexes.

Depending on the tariff structure and allocation base costs are:

• straight-line rate, assuming the costs for the consumption of cold water, Sewerage and wastewater treatment of the calculation for 1 cubic meter of cold water, 1 cubic meter of wastewater disposed 1 cubic meter of treated wastewater, respectively;

• two part tariff involving cost recovery organizations and utilities on the two bases of allocation, namely: rates of payment for consumption of cold water, Sewerage and wastewater treatment (a natural measure of the act of 1 cubic meter of hot water, 1 cubic meter of cold water, 1 cubic meter of wastewater disposed 1 cubic meter of treated wastewater), and the rate of payment for the content of all allocated water systems.

Single-rate tariffs in the sphere of cold water supply is defined as the quotient of the magnitude of the financial requirements for the relevant type of goods on the estimated volume of goods[6]:

$$T_{cw} = (C_1 + C_2 + C_3 + C_4 + C_5 + C_6) / V_{cw} \quad (4)$$

Where, Tcw - tariff for a product (service), rubles / cub. m.;
C1 - the cost of raising water in part;
C2 - the cost of water purification in part;
C3 - the cost of transporting water;
C4 - non-operating expenses;
C5 - expenses from profit in part;
C6 - adjustment of the value of financial needs for this type of product;
Vcw is the estimated sales volume of this type of product.

In the particular case when the company is involved only in the provision of services and the performance of work in only one category, it is allowed to set a tariff according to a simplified scheme:

[6] Resolution of the Government of the Russian Federation No. 1075 of October 22, 2012 " Fundamentals of pricing in the field of heat supply" as amended on 08.02.2018.

Single-rate tariff calculated according to a simplified scheme[7]:

$T_{cw} = (c_1 + c_2 + c_3 + C_5 + C_6) / V_{cw}$ (5)

Where Tcw - the rate at which the product (service), RUB./sq. m.;
C1 — costs associated with the production and sale of goods (services);
C2 - non-operating expenses;
C3 — the cost of profits;
C5 - reinvestment of profits;
S6 - adjustments for financial needs;
Vcw - the estimated volume of sales of this type of product.

At regulation of tariffs in sphere of housing and communal services (HCS) using the following methods of calculation and determination of the rate used in organizations, utilities:

- Method of establishing fixed tariffs;
- The method of setting maximum tariffs;
- The method of indexation of the established tariffs.

Discussions

However, whichever method of calculation was not chosen, the result should remain the same. Since the level of tariff for different consumer groups is fixed, so far the chosen method only allows redistributing income via institutional market participants.

Existing pricing models no longer cope with the emerging tasks and modalities for the accounting of internal and external factors. Therefore, when creating a pricing policy increasingly turn to the tax agreements on the procedure for determining prices and applying pricing methods for transactions subject to price control. These aspects of price policy arise only from the largest taxpayers, which (for the Russian Federation) have defined limits[8]:

- The total amount of accruals of Federal taxes — 300 million rubles;
- Total volume of revenue (income) exceeds 20 billion rubles.
- The total assets exceed 20 billion rubles.

A statement on the agreement can address organization — the largest taxpayers subject to tax administration of tax service. The level of control can be, at both the Federal and regional levels. The opportunity to apply to FTS of Russia with the statement for the conclusion of an agreement on prices is only for residents, foreign organizations can use this tool. Methodological basis of the agreement on price is the theoretical development of the organization for economic cooperation and development (OECD). The process of agreement involves conducting tax due diligence and tax risks for the FTS, as well as the appearance of additional responsibilities for the taxpayer:

1. Analysis and identification of controlled transactions;
2. Preparation and submission of transfer pricing documentation;
3. Canceling 20% of the allowable deviation from market prices;
4. introduction of penalties in the amount of 40% of the unpaid amount of tax payable, but not less than 30,000 rubles.

The first two groups of pricing models are designed so that the final sale price is practically independent of the chosen pricing strategy. So often, use methods:

- Least Cost Method
- Target pricing method
- Method of accounting for return on investment

[7] in the same place

[8] The order FNS of Russia from 16.05.2007 № MM-3-06/308@ "ON amendments to Order of Ministry of Russia from 16.04.2004 № SAE-3-30/290@".

- Price markup method
- Cost plus method
- Method for determining selling prices in determining the minimum margin of profit and loss
- Regression analysis method

The first four price groups depend on the type and type of taxes laid down in them: taxes are ad valorem (ad valorem means "noble", constant interest), specific (in the money rate) and complex (both interest and money are applied).

The price of goods, work, and services is formed through the interaction of supply and demand. Taxes are always a supply factor, except for taxes on personal income. Consider the effect of tax changes on the price level. Figure 2.34 shows the law of supply and demand in canonical form and the shift of the supply curve under the influence of ad valorem or specific taxes.

Fig. 2: Law of supply and demand. P — price; D-demand; S-supply

A formalized record of supply and demand curves can be presented in the following form:

$$\begin{cases} y = a \mp bx; \\ P = a + bQ \text{ — supply curve; (6)} \\ P = a - bQ \text{ — demand curve.} \end{cases}$$

The first equation is the equation of the line. To simplify, we will present the supply and demand curves in the form of a straight line. In equation (6), (a) is the point where the line intersects the [OX] axis, and (b) is the angle of the curve. If a specific tax is entered, then a parallel transfer is performed from the supply curve, as shown in figure 2.

Figure 3: Introduction of a specific tax

After the introduction of the tax t, the equations of the system (7) will take the form:

$$\begin{cases} P = (a \mp t) + bQ; (7) \\ P = a - bQ. \end{cases}$$

When an ad valorem tax is introduced, the supply curve will change its slope, as shown in figure 4.

Figure 4: Introduction of ad valorem tax

After the introduction of the tax t, the equations of the system (8) will take the form:

$$P = \begin{cases} a + (b \pm * t) * Q; \\ P = a - (b)Q. \end{cases} \quad (8)$$

Instead, we introduce the notion of the interval of market prices (profitability interval), within which should be the price of the controlled transaction in order to admit the market. When applying for an agreement, a state fee (in Russia it is the size of 1,5 million rubles.). Issues of tax control over pricing in most cases affect the foreign trade transaction. The pricing agreement may be concluded by one or more transactions (group of homogeneous transactions), with the same subject matter of the transaction, for a period not exceeding three years. The effect of pricing agreements can be extended for a period ending on the first day of the calendar year in which the taxpayer appealed to the FTS on the day of its entry into force. It should be noted that the taxpayer in compliance with all conditions of an advance pricing agreement might apply to the tax authority, authorised on control and supervision in the field taxes and fees, a statement on the extension of the term of the agreement on pricing. The renewal term of the agreement can be no more than two years. The main advantages of the agreement for the taxpayer are as follows:

• if the taxpayer complied with the terms of the agreement, the tax authorities are not entitled to take decision on additional taxes, fines and penalties with respect to those controlled transactions, prices which were defined in the agreement;

• subject to the provisions of the agreement the taxpayer can with a higher degree of confidence to estimate the size of future tax liabilities related to controlled transactions;

• in the case of an agreement on pricing, the taxpayer is exempt from the obligation to prepare transfer pricing documentation for purposes of establishing the conformity of the applied prices market level in relation to those controlled transactions that are covered by the agreement.

Results

There are two types of agreements — unilateral and bilateral. The first is used for any agreements that are concluded without the participation of the competent Executive authorities of a foreign state, with the participation of the relevant authorities of a foreign state.

During the preliminary discussion, the taxpayer may be in the form of presentations or in any other convenient form allow:

1) The circumstances warranting the conclusion of the controlled transaction;
2) Description of the business activities of the parties to the controlled transaction tax residents;
3) The intended methodology for determining prices for tax purposes, information sources and other information that taxpayer considers necessary to specify.

It should be noted that a preliminary discussion of the award process and the rationale for key provisions of the agreement between the taxpayer and the tax authorities is widely used in international practice and is included in the list of recommendations contained in the OECD guidelines. The results of the preliminary discussion of the FTS of Russia may notify the taxpayer of its position regarding the appropriateness of application of the agreement, as well as on their assessment of the time expenditure necessary for the conclusion of a specific agreement. Consideration of the draft agreement after its official submission to the tax bodies should be completed in a period not exceeding six months from the date of receipt of documents FTS. This period may be extended to nine months.

Financial and economic activity of each subject of tax legal relations can be diverse. Estimates show that the multipliers of the costs are much lower multiples of income. On financial and economic activity of each entity can be influenced by various conditions: seasonality, location, international politics, etc. a Significant part of these terms is considered the subject of legal relations at the stage of tax planning at formation of accounting policy and tax accounting system.

Conclusion

We define the value of fiscal multipliers as the maximum size of the response of GDP to fiscal shock of the price variable. Values are statistically significant. Analysis of the determinants of fiscal multipliers showed a relatively low degree of influence of the main indicators of public finances on GDP growth in Russia. The increase in government spending by 1 percent of GDP causes GDP growth in the next after shock quarter of 0.28%. Raising taxes on 1% of GDP leads to a gradual decrease of GDP and reaches a peak of 0.75% after eight quarters after the shock. With 2017 and the need to reduce the budget deficit has a negative direct effect on GDP growth. The planned reduction of expenditures relative to GDP as the main measure of fiscal consolidation is consistent with the results of the evaluation of fiscal multipliers, allowing you to expect a relatively small negative impact on GDP growth slowing (for 2018-2020 cumulative of about 0.3 p. p.), and in addition may allow to increase the efficiency of budget expenditures. In addition, the negative direct effect on GDP could be more than offset by a substantial positive indirect effect of increasing the confidence of economic agents in the long-term stability of the budget.

Chinese initiative One Belt, One Road – the Implications for the European Economy

Karolina LOPACINSKA

Wroclaw University of Economics and Business, Wroclaw, Poland
lopacinska.karolina@gmail.com
The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

Abstract

Initiative of the Chinese government, *One Belt One Road*, focused on the expansion of the network infrastructure linking China, the countries of Central Asia, the Middle East, Africa and Europe is meant to expand the cooperation of these countries in the implementation of infrastructure and finance related projects. Therefore the initiative will be of crucial importance to the development of the Chinese economy, its partner countries and regions in the world. The aim of the article is to present the essence, significance and the expected impact of this strategic economic project, both on the European market and the world market. The basis of conducted analyzes are mainly experts' opinions obtained from the press and Internet portals, consulting agencies and so-called *think tanks,* specializing in economics and international economic relations, such as: European Council on Foreign Relations, Bruegel and McKinsey's Podcasts. Preliminary statistical data on the implementation process of the *One Belt, One Road* project has also been included. Analyses have been conducted in two key areas: regarding trade between China and other countries, and in the field of the investment activity in the countries covered by the initiative.

Keywords: One Belt One Road, China, European economy;

Introduction

Over the past four decades, the People's Republic of China has undergone impressive transformation from a poor farming country to a global economic power. "Opening of China to the world" started by, the leader of China at that time, Deng Xiaoping in 1978, allowed for recovery of the country from the economic collapse it had been left in by the Chairman Mao TseTung. This was due to the socio-economic reform program initiated by Xiaoping, that started the development of Chinese economy and affected a gradual change in both the economic and social image of the country. Thereby People's Republic of China could rebuild its economic and political relations with many countries while developing the basis for economic growth at the same time (Guthrie, 2012).

Implementation of the *Go Global* strategy resulted in a huge progress reported by Chinese economy. Currently, Chinese investors are active in more than 132 countries and regions all over the world. It results from reports of the United Nations, that the value of Chinese foreign investment grew from USD 2.7 billion in 2002 to USD 84.2 billion in 2012. This allowed China to advance from the sixth position in 2011 to the third position among the most active countries in terms of conducting foreign direct investment in 2012 (Pinkerton, 2014).

Increase in investment activity of China in the international arena has been especially observed since the global financial crisis of 2007/2008. This resulted from the fact that, even though the overall value of foreign direct investments in the world declined during this period, the level of investments of Chinese enterprises showed a significant increase. Their value of USD 55.9 billion in 2008 doubled in comparison with USD 26.5 billion obtained in 2007, and then it reached the value of USD 68.8 billion in 2010. This gave China the fifth position in terms of the scale of direct investments conducted all over the world, and allowed for overtaking Japan and Great Britain in this respect.

Currently in the face of the economic slowdown, China is constantly seeking new incentives that might stimulate the pace of its growth and development.

Analysing the projected development prospects of Chinese market, the importance of one of China's main initiatives, *One Belt, One Road*, aiming at reactivation of the Silk Road and providing a better transport and trade links within China, as well as between China and the countries of Europe, Asia and Africa should be emphasised**.**

Within the framework determined by the *Belt and Road*, Chinese investors, will have a better chance to conduct business activities and build relationships with foreign partners.

According to experts, success of the project is of fundamental importance, as in the case of many areas, also including the western part of China, it will not only contribute to easing regulations concerning capital flows between states and internationalization of Chinese yuan, but above all to significant civilizational progress (The State Council The People's Republic of China, 2015).

One Belt One Road - main assumptions of the project and its significance

The purpose of the paper is to present the essence, importance and predicted impact of the strategic economic project, that is *One Belt One Road*, both on the European market and on the global market. The first part of the article is devoted to the presentation of the essence of the project and the premises that prompted the Chinese government to undertake this initiative. Further in the article the general objectives of the *One Belt, One Road* project and its anticipated implications, for the European economy in particular, have been presented. The conditions, that are necessary to meet for the successful implementation of the project‘s objectives have been addressed. Lastly potential threats and challenges that may arise from the inevitable growth of Chinese influence and domination on the international arena in connection with the implementation of the objectives of the project have been presented.

The project of *One Belt One Road* initiative was presented for the first time by China’s President Xi Jinping in September 2013 during his visit to Kazakhstan. In his speech at Nazarbayev University, Jinping officially presented the idea of creating a land-based trade and transport route linking China and Europe within the so-called *Silk Road Economic Belt*. On the other hand, in the same year, in October, during a visit to Indonesia, the President presented the vision of creation of *Maritime Silk Road*, within which establishment of connections between Asia, Europe and Africa is planned. Both routes are to be developed simultaneously within *One Belt One Road* initiative and represent construction of new, or redevelopment of already existing transport and rail infrastructure networks (European Parliament Think Tank, 2016).

Analysing the routes of both the Land and the Sea Routs, they can be seen as a coherent system of communication covering the whole of Asia. This is the main assumption of *Belt and Road* initiative. For the homogenous network created in this way will not only facilitate trade with existing foreign partners, but also create new opportunities for making investments in areas previously poorly penetrated or not penetrated, while enabling investors to transport goods safely.

Furthermore, it is predicted that implementation of *Belt and Road* initiative will contribute not only to modernization of tracks for high-speed rails, land and sea ports and airports, but also to considerable progress in the development of transmission infrastructure, including gas pipelines, oil pipelines and telecommunication infrastructure. Developed facilities will further allow for the creation of various, not mutually exclusive, but complementary options of routes, connecting China with European countries, and facilitating the establishment of a dialogue between the Middle Kingdom and foreign partners (TłustyKot, 2016).

It should be emphasized that *Belt and Road* initiative is aimed not only at the creation of transport and trade links of a physical nature, but also, and even above all, at the creation and development of relations between the participants in the analysed project. This is because it will allow for economic,

political and socio-cultural cooperation between China and the countries included in New Silk Route, while contributing to creation of the world's largest international cooperation platform (Jinchen, 2016).

Thus, it results from the analyses that the main assumptions of *One Belt One Road* initiative are focused on:

- increasing investment activity of China and the countries involved in the project, as well as trade between these countries,
- stimulating undertaken investments in infrastructure,
- achieving higher effectiveness of land transport, i.e. higher quality transport at lower cost and simultaneous reduction of time.

A special USD 40 billion fund was established in 2014 for implementation of the Silk Road assumptions and initiatives, and moreover USD 10 billion was allocated to the BRICKS New Development Bank.

In 2016, the government of China declared development of activity of the Asian Infrastructure Investment Bank (AIIB), which will be responsible for implementation of *Belt and Road* initiative. The capital of the bank amounts for USD 100 billion, and China is its main shareholder (30%). Declarations of support for the initiatives of the Bank have been made with various shares by almost all the world's richest countries, except for the United States and Japan (finanse.wp.pl, 2015; Aiib.org, 2020).

The major task of the bank is to provide support for the poorer Asian countries neighbouring with China, such as Vietnam, Cambodia, Bangladesh, Birma and Laos, for development of industrial infrastructure in these countries. For construction of new factories and production halls will create opportunities for foreign investors (especially from China and Europe) to transfer their production there. Increase in foreign investments in these countries will create new employment opportunities, which, in turn, will have a positive impact on reducing the level of unemployment, and will strengthen their competitiveness.

Furthermore, the AIIB's task is to develop infrastructure facilitating trade and transport of goods within the New Silk Road. Russia, Mongolia, Kazakhstan, but also Middle East and Balkan countries, i.e. the countries of strategic position for China and of poorly developed car and railway infrastructure are among the major beneficiaries of these investments (Chiny Powołują Do Życia AIIB, 2015).

Implementation of the project was preceded by a thorough analysis of the relations between the countries included in the New Silk Route and China. These relationships were assessed in terms of economic, political and historical contexts. For the government of China plans to establish strategic free trade agreements with each of these countries. So far, agreements have been signed with Hong Kong, Singapore, Taiwan, Pakistan, Switzerland, Iceland, Peru, Chile and Costa Rica, among others. Agreements with such countries as Japan, South Korea, Australia, Sri Lanka, Norway, the countries associated within Regional Comprehensive Economic Partnership (RCEP), Association of Southeast Asian Nations (ASEAN) and Gulf Cooperation Council have still been under negotiations.

As of 2017 it is estimated that *Belt and Road* initiative reached 4.9 billion people from over 68 countries, which represents 40% of the total world economy, and over half of the world's population. It is predicted that implementation of this strategic initiative will allow for generation of 55% of global GNP and 75% of energy resources reserves. *One Belt One Road* is therefore perceived as the project of greatest importance with a long-term development potential, and its implementation will have an impact both on domestic and foreign policy of China, and on its economy and international relations (SCMP, 2015, European Council on Foreign Relations, 2015; Godement and Kratz, 2015)
The success of New Silk Road initiative is in the interest of the countries located along the designated routes, whereas the regions of Europe, especially of Central and Eastern Europe are of the key

importance for the development of *Belt and Road* initiative. For the implementation of this project will contribute to the substantial development of their infrastructure, and thus their economic growth. The government of China declared its willingness to respond to the needs of the countries of Central and Eastern Europe by proposing cooperation within the *16+1* agreement in 2012. This was one of the stimuli that led to the development of direct links between China and Europe.

In 2013, the first direct railway link between China and Poland was established. This had impact on a significant increase in trade between these countries, as transportation time was shortened from 40 days needed before for sea transport, to only two weeks by rail. Therefore, the possibility of rail transportation contributed to increase in efficiency while reducing the costs in comparison with air transport.

Furthermore, in 2015, a direct air link was created between Prague and Beijing. It contributed to enhancement of cooperation both in trade and investments, as well as tourism and health protection, and it strengthened ties between the two countries (Jakóbowski, 2015).

It is predicted that especially the development of railway links will allow for a significant increase in the speed of flow of goods and money between the countries of *Belt and Road* initiative, which will affect industry growth, activation of trade, as well as urban development and population growth. According to reports from the Ministry of Commerce, trade between China and the countries of *One Belt One Road* initiative reached USD 995 billion in 2015, which represented about a quarter of the national trade turnover. However, not only opportunities but also threats to Belt and Road project ought to be indicated.

This is because on one hand, the concept of the New Silk Road is perceived as another step in China's political and economic evolution, but on the other hand, the difficulties that investors face, and the risks that this initiative can bring may not be neglected. Successful implementation of the project will therefore require considering its broad range of impact and the level of complexity of the initiative (Godement and Kratz, 2015).

Additionally, the size and scope of the projected investments in infrastructure allow for assuming that the Asian Infrastructure Investment Bank will start cooperation with other international development banks in the world.

Determinants of One Belt One Road project implementation

Implementation of the objectives and assumptions of the project needs taking a series of determinants into consideration. They include political, economic, logistic, as well as social and cultural determinants.

One Belt One Road initiative is primarily perceived as an opportunity to obtain economic support from China, and for the participating countries it means entering new economic paths. Estimates developed by Asian Development Bank show that until 2030 the region needs to be supplied by investments worth an estimated USD 26 trillion. Within *Belt and Road* initiative, the Export-Import Bank of China announced financing of one thousand projects in 49 countries, whereas the Chinese Development Bank informed about implementation of over 900 investments in 60 countries in 2015. (Tomański, 2017) Therefore, it can be concluded that on one hand the economic determinants of the implementation of the *Belt and Road* perform the key role in stimulating the development of the economies of the countries involved. However, looking from the perspective of political determinants, many countries are concerned about growing expansion and power of the Middle Kingdom influence, as well as the rise of China‘s power brought by the New Silk Road project.
Attention should also be paid to dangers associated with intensification of problems related to serious territorial claims of the People’s Republic of China concerning the area of South China Sea. This is because currently, there has been a dispute between China and the states of ASEAN community about the archipelagos located in the area. Beijing explains its expansion with the intention of ensuring safety to sea transport within the Sea Silk Road.

Countries such as Indonesia are afraid of hegemony of China in the region (Tjhin cited Tomański, 2017). On the other hand, Russia is anxious that involving post-Soviet states by China in cooperation within *Belt and Road* is an expression of Beijing's aspiration to reduce the influence of Moscow in the area of Central Asia (Kaczmarski & Rodkiewicz cited in Tomański, 2017). India also expressed its critical view on the issue of Chinese investments in Kashmir, while explaining its objections with security reasons (Tomański, 2017).

Concerns are also raised by the announcement related to financing investments within *Belt and Road* in the form of loans to partner countries, which will result both in the increase in economic dependence of their governments of Chinese and the political burden on the partner countries.

In view of the observers, China is obviously trying to change the political structure of functioning of the region and reduce American influence in the world. *Belt and Road* initiative will help to achieve these goals (Callahan cited in (Tomański, 2017). Furthermore, withdrawal of the United States from the Trans-Pacific Partnership Agreement (TPP) is a significant opportunity for China to fill the gap created by the United States and to increase its influence in South East Asia region.

Despite the concern of many states about growing global dominance of China, the country assures that the goal of the policy pursued by the government is not to gain control over the states, but to develop cooperation that will bring mutual, both financial and strategic benefits over the long term (Xiaoli cited in Tomański, 2017). The initiative is focused on making China "a power of a new type", that is, neither striving for confrontation, nor having hegemonic aspirations. (Bondaz cited in Godement and Kratz, 2015)

During the May 2017 summit on *Belt and Road* that has been held in Beijing, the President of China, Xi Jinping, declared that within the next three years China will provide food and crisis support to countries in need and already in 2018 it has become an important donor in these areas to developing countries. China's readiness to help developing countries as well as to expand and improve its aid programmes have been supported by the Development Cooperation Agency that China has established earlier in 2018 (Neuweg, 2018).

However, successful implementation of *Belt and Road* initiative, demands from all its participants development of strategies of effective solutions, both in the sphere of transport and logistics as well as transfer of knowledge and products between China and the countries of Asia, Europe and Africa.

It ought to be stated that making investments in foreign markets also often brings complex results of social nature that may arise at all stages of conclusion of agreements, especially between companies coming from different countries and diverse backgrounds. Therefore, performance of a thorough analysis of the market environment before starting a business activity on a particular market is a fundamental element for the success of *Belt and Road* initiative. This analysis requires a multidimensional approach, while considering the situational context of the transaction, its premises, its objectives, the scope of its cooperation and its nature, as well as the benefits to all parties involved (Hajduk, 2016).

Apart from economic, political and social determinants, it is also necessary to take into consideration cultural determinants that affect attitudes, mentality and the way in which the new phenomena and processes are perceived, and thereby have impact on organizational culture of enterprises. Despite special, comprehensive trainings in the area of international management that emphasise extreme importance of corporate culture, the managers still have the habit of neglecting this factor in favour of hard factors. However, cultural mismatch is a strong determinant for the success of many investments and with as broad range of impact in terms of territory as *Belt and Road* initiative, it is particularly important to apply an appropriate model of intercultural management, based on intercultural cooperation and focused on the use of valuable resources of cultural diversity to achieve synergy effect, improve the level of efficiency and develop both sides to the agreement. (Kostera, 2005; Adler, 1980; Koźmiński, 1999; Zając, 2006; Szczepankowski, 2000)

The importance of logistics in coordinating international flows should also be emphasised. It is an important instrument in coordinating actions by companies from countries that make a decision to be actively involved in the development of *Belt and Road* initiative. (Szymczak, 2004) This finds reflection in plans of China's government related to creation of modern logistic centres alongside the Belt and Road routes. One of such centres is going to be established on the Polish-Belarusian border in Małaszewicze town (Money.pl, 2015).

That is why it is important to ensure that agreements within One *Belt One Road* project are appropriately prepared in terms of content, and consider political, economic, logistical, social as well as cultural determinants.

Challenges resulting from Chinese expansion on the European market

The inflow of Chinese capital into markets all over the world, also including the European market, plays a vital role in the process of stimulating economies of the countries most affected by the financial crisis of 2007-2009. For the increased activity of Chinese companies also in Europe contributed not only to lowering the costs of infrastructural ventures and creation of new workplaces, but also provided local companies with opportunities of greater and easier access to Chinese market. It also increased profitability of conducted research and development activity resulting from significant interest of Chinese companies in European technology (Millner, 2012). This gives hope that intensification of foreign expansion of China and the involvement of Chinese investors on international arena within *Belt and Road* initiative will contribute to favourable changes in the sphere of regulations that facilitate making investment by foreign enterprises in Chinese market.

However, it must be remembered that increased investment activity of Chinese companies in the markets of countries covered by *Belt and Road* project implies numerous problems and challenges for the countries receiving the incoming capital.

According to experts, the concerns of European countries are mainly related to a different attitude of Chinese companies to the allocation of resources and the investment risk management. For in China, they are dependent on the applied model of state capitalism, and not on the principles of the market mechanism. This, in turn, results in violating the principles of free-market competition operating in Europe. Decisions of Chinese investors are therefore less predictable and raise concerns about their impact on the process of implemented investments (Owen, 2012).

Several negative effects brought by activities of Chinese companies on the markets of countries included in the *Belt and Road* also need to be indicated. They are expressed by social reluctance of these countries, additionally strengthened by the application of the so-called dumping, i.e. selling Chinese goods on foreign markets at prices lower than the prices at which those goods are sold on domestic market, or at prices lower than their manufacturing costs. In this way, Chinese companies contribute to the rise of unfair competition on foreign markets, and thus weaken the position of companies offering the same goods in these markets.

Another factor disturbing competition in the future is related to the presence of Chinese state-owned conglomerates in Europe that because of their dominance may bring the threat of oligopolisation of the European market. Therefore, all Chinese state-owned companies, i.e. those under the control of the State-owned Assets Supervision and Administration Commission (SASAC), are perceived by authorities of the European Union as a single economic entity, and in the assessment of its operation, its overall market share is taken into account (European Commission, 2011).

Furthermore despite the high openness of European countries to the inflow of foreign investment within *Belt and Road* initiative, they try to approach the actions of Chinese companies with caution, especially when they involve the key sectors of the domestic economy of the host country. For there is a risk that while implementing the adopted model of China's economy development, the investors will liquidate European companies that have been taken over, and transfer assets of strategic importance from Europe to China. However, analysing the existing agreements established by

Chinese companies not only on the European market, but also all over the world, it is clear that investors are more inclined to expand the size of production and increase employment in acquired companies while trying to benefit from their experience, technology and prestige, rather than concentrate on the liquidation of acquired companies. For in this way, Chinese companies can achieve a synergy effect from development of cooperation with European partners within the New Silk Road. In fact, the European market creates conditions for them to develop those areas of conducted business activity in which explicit deficiencies are observed, i.e. first of all in the sphere of new technologies and acquisition of highly qualified staff. Nevertheless, in order to avoid the danger related to facilities of strategic importance, European countries are starting to apply the policy of economic protectionism (Hanemann, 2012). It is obvious that the threat to European partners will increase together with levelling the largest weaknesses in Chinese business activity. However, before this happens, investing in the development of companies overtaken on the European market is in the best interest of China.

While analysing the intensified investment expansion of Chinese companies in the countries involved in the Silk Road, cultural differences seem to be a serious challenge, for Chinese managers often lack the relevant experience and preparation to conclude business agreements with partners from other cultural circles (Gao, 2012). Whereas the lack of such preparation, starting from a good command of English, through lack of sufficient knowledge about local determinants of business activity in a particular country, low flexibility, difficulty in adopting to international standards and finishing with thorough preparation on the details of the very transaction, makes it impossible to build long-term relationships and to develop investment activities of companies (Tung and Luo, 2007).

The practical application of the regulations concerning intellectual value, environment protection or labour rights, applicable in the European Union states and in other regions involved in *Belt and Road* initiative, also seem to be a big challenge. (Shambaugh, 2012).

Assessing the economic consequences and motivations of *Belt and Road* initiative, experts indicate the concerns of Chinese scientists, analysts and other representatives of the intellectual elite regarding unreasonable allocation of limited resources of China, when its economy is slowing down. Therefore, successful implementation of *Belt and Road* initiative is perceived as an opportunity to strengthen the weakening power of Chinese export (Kratz, cited in Godement and Kratz, 2015).

It should be emphasized here that, despite the economic slowdown, China has not remained passive in the situation, but on the contrary, the Middle Kingdom has been working on the integration of sixteen Asian economies within the framework of proposed RCEP. This agreement would include ten most dynamically developing countries of ASEAN and five countries with which ASEAN countries have free trade agreements, i.e. China, Japan, South Korea, New Zealand and Australia. Because of the large share of these countries in world trade, this partnership, that is to be sign in 2020, would have a very positive impact on foreign trade, while enabling China to establish its own sphere of influence, both in the area of economy and in politics (Zadrożna et al., 2016; Lee, 2019).

To assess the development prospects for the expansion of China, it is necessary to indicate the impact of global economic downturn on weakening of domestic demand in countries that are the major business partners of China. This is reflected in the weakening of exports (by 1,3% in 2019), which before has played a key role in driving the growth of the Chinese economy (Tomański, 2019). Therefore, expectations related to strengthening of the declining power of Chinese export are so strong. This can be achieved through successful implementation of *Belt and Road* initiative because China is currently focused on searching for new stimuli for growth, and on reforming the national economy towards (Mercator Institute for China Studies and Rhodium Group, 2016):

- ⇒ more modernized and environmentally friendly industry,
- ⇒ modernization of the existing production base (departure from the image of the manufacturer of cheap goods of low quality),
- ⇒ increase in expenditures on research and development,
- ⇒ implementation of new technologies,
- ⇒ making investments in design,

⇒ increased consumption, both domestic and worldwide.

According to experts, increased openness of both the Chinese market to foreign investors, as well as of Chinese enterprises to start business activity with foreign partners within implementation *of Belt and Road* concept, as a part of *Go Global* policy of the government, are conducive to the process of transformation of the country and creation of a new economic reality of China (The State Council The People's Republic of China, 2015; García-Herrero and Xu, 2016).

Conclusions

Intensified activity of Chinese companies in the markets of European countries and globally within implementation of *One Belt One Road* initiative will contribute to growth of the scale of foreign direct investments conducted in these markets and related inflow of new capital. While establishing links with global value chains and export markets, it is anticipated that *Belt and Road* will contribute to increased expenditures on research and development, formation of development clusters and improvement of workers' qualifications. Furthermore, the scale and pace of growth, and the complementary nature of Chinese economy offer unique opportunities for development of the economies involved in the New Silk Road. However, it must be remembered, that the nature of economic and political system of China can raise some concerns, and constitute challenges for markets of partner countries, including the European market. As an emerging market in which financial system is not fully stable yet, China may put the countries where they invest in danger of capital flow variability and instability. Although Chinese entrepreneurs appreciate the freedom offered by the European Union countries, they retain many formal restrictions concerning foreign investments, and European companies are still discriminated in Chinese market. It should also be remembered that Chinese companies, particularly the state-owned enterprises, are still largely supported financially by the government, which provides them with a significant advantage over other companies operating in the market. This forms a threat to development of competition. Additionally, there is a risk of diffusion of bad practices into the countries of *Belt and Road* initiative in which Chinese investments are located.

However, despite apparent challenges that *Belt and Road* initiative can bring, it is generally perceived by the countries involved as an opportunity to create new platforms of cooperation. They include new technologies, scientific exchange, support for young researchers, the creation of a "big data" exchange platform and implementation of solutions aiming at protection of the climate and improvement in ecological solutions in economy among others (Tomański, 2017a).

At the May 2017 Summit on *Belt and Road*, that has been held in Beijing, Xi Jinping emphasised the importance of development of cooperation between the states within *Belt and Road* initiative in the face of rising global challenges that individual countries may not be able to deal with independently. It is crucial to coordinate the strategies applied by countries, and at the same time to search for development prospects at a global level. This is the main objective of the Chinese initiative *One Belt One Road* (Kaczmarski, 2016; Polska-azja.pl, 2020).

Abstract

The scientific community, rating agencies and news media pay close attention to the issue of corporate conflicts, which affect company's operations, business reputation and capitalization. The research conducted by the authors of this article is devoted to the search for answers to questions about corporate conflict resolution tools. In our research mediation is regarded as an instrument for resolving corporate conflicts in Russia. The article presents the content of the mediation process and emphasizes the importance of this method in resolving persisting corporate conflicts that are witnessed in current Russian practice. The authors analyze the characteristics of corporate conflicts and highlight the fundamentals of mediation in resolving them in Russia. The article concludes that the institution of mediation in Russia does not match the essence of mediation as an extra-judicial form of conflict resolution.

Keywords: Corporate Governance, Corporate Values, Corporate Interests, Corporate Conflicts, Forms and Types of Corporate Conflicts, Mediation, Intercession, Conflict Resolution.

Introduction

The corporate history of Russia substantially is a history of conflicts between business structures. The conflict map detects the formation of the largest groups, their management styles, the amount of administrative resources and their position in the hierarchy. Corporate conflicts lead to an increase in corporate disputes number. In Russia, in 2018, the amount of corporate claims increased 3 times compared to 2017 and 9 times compared to 2016. No other type of entrepreneurial dispute is growing at that rate. And this is a new steady trend: companionship, joint business on the basis of conceptual agreements, investments in start-ups, refusal to disclose sales contracts for expensive fixed assets by creating joint legal entities, the desire to hide interdependence in a group of companies are potentially dangerous, prolonged and latent conflicts that the business has not yet learned to prevent or solve without complete elimination of the joint business. Statistics of the Judicial Department of the Supreme Court of the Russian Federation confirms the above (Fig. 1.)

Fig. 1. Corporate disputes (ratio of tried and upheld claims[1]

Fig. 2. The ratio of the claimed and collected money according to legal actions[2]

Of course, everything is comparative, and 504 555 disputes related to non-performance or improper performance of obligations under sales contracts were heard in arbitrations in 2018, while the amount of money involved exceeded 1.2 trillion rubles. In such a context, though corporate disputes seem rare, but very costly, and the results of such disputes are often fatal for business.

Interestingly, corporate disputes overshadow tax disputes, as the amount of their claims is "only" 19 billion rubles.

At the same time, let us draw attention to the fact that in 2018 the share of collected funds for corporate disputes turned out to be 9 times less than the amount of claims. That is, many corporate

[1] www.cdep.ru
[2] ibidem

disputes simply do not end up in court, because business owners do not see this as a solution to the conflict eventually brought before a court are resolved 9 times less efficiently, as plaintiffs suggest. The most significant and high-profile corporate conflicts in Russia in 2019 are presented in Table 1.

Table 1: The most significant and high-profile corporate conflicts in Russia in 2019

Parties to a conflict	Content and status of conflict
Rosaviatsia against the developer GC "Filatov Lug"	The conflict between the Federal Air Transport Agency and the developers of the residential complex Filatov Lug (GC Ingrad) was the most unexpected. In 2017, the federal agency issued a permit to the developers to construct a complex near the Vnukovo airport. However, in 2019, when the construction was well in the way and deals were being concluded, the government department reconsidered and canceled the previously granted permission, believing that the RC still interferes with the airport operations. Developers had to right wrongs in court. The court of the first instance came down in favor on the side of the developers, canceling the rescinding of the permit issued by the Federal Air Transport Agency. The federal agency tried to appeal the judgment, but the appeal only reinforced it. But the government department does not intend to give up so easily: in 2020, the cassational instance will pursue the case. **Status of conflict:** The Federal Air Transport Agency is trying to challenge the judgment of the Moscow Region Arbitration Court appealing to a court of cassation. . The hearing of the complaint of the federal agency is scheduled for February 6, 2020.
Investigative Committee against the founder of Rolf automotive dealer	The past year turned out to be not very successful for the Rolf car dealership network: in June, security forces rushed into the company with searches. The reason for the operational events was the allegedly illegal activity of the founder of the network - Sergey Petrov and a number of top managers. The Investigative Committee suggests that Mr. Petrov and his colleagues withdrew about 4 billion rubles abroad. The purchase of shares of the Cypriot Panabel Limited by the Rolf structure was considered illegal. Under the guise of a sales contract, Sergey Petrov and his colleagues allegedly withdrew abroad the funds earned by car dealerships. Sergei Petrov strongly denies the accusations against him. To turn aside the blow from the company, he hastily left the board of directors of the company. Whether this will help Rolf to get out of the delicate situation we will find out in 2020. Conflict status: according to the latest data, Sergey Petrov was put on the international wanted list, he was charged in absentia under part 3 art. 193.1 of the Criminal Code of the Russian Federation ("Conducting currency transactions to transfer funds to accounts of non-residents of the Russian Federation using forged documents") The Rolf car dealership network continues to operate as usual.
The public against Rostec waste incineration plants	The problem of waste disposal for the Moscow region is one of the most acute. Last year, the public "fought" with the authorities over a landfill site in Volokolamsk, because of which schoolchildren were poisoned; this year a protest was launched against Rostec incineration plants, planned to be constructed in the Moscow region.

	In July 2019, Kommersant, citing a study by the NRU HSE, published data on the inefficiency of enterprises under construction. Allegedly, they pollute the air with waste combustion products, and the ash that remains after processing will be at least 70% of the waste. Later on this information was called unreliable, and Deputy Chairman of the Moscow Region Government Evgeny Khromushin spoke up for the Rostec plants. He emphasized that the garbage recycling plants being built in the region will have the most modern equipment, the quality of which is monitored by the Japanese Hitachi Zosen Inova, a world authority in the field of garbage processing. As for ash, it, as the deputy chairman noted, is primarily formed from the burning of plastic and glass, which will not be delivered to plants - these materials are planned to be sorted and sent for recycling. Conflict status: despite the absence of active "centers of resistance", the public continues to be wary of the idea of Rostec. Fuel is added to the fire by Incinerator No. 4 (operated by Charter LLC,owned by the son of the Prosecutor General of the Russian Federation), which doesn't bring out the best. Residents of the region rightly fear that Rostec enterprises will also poison them with fetid smoke.
Rospotrebnadzor versus AnderSon cafe network	In 2019, the Russian consumer protection agency (Rospotrebnadzor) attacked the AnderSon network of cafes with numerous inspections, during which in several Moscow cafes they found "systemic violations of sanitary and epidemiological requirements" and Bacillus thuringiensis. All this resulted in 10 lawsuits against Anderson, which the cafe network is now trying to challenge. AnderSon's owner Anastasia Tatulova believes that the attack of the government department against her business is connected with her participation in the election campaign in the Moscow City Duma. In addition, sources close to Mrs. Tatulova believe that the owner of the network could provoke the anger of Rospotrebnadzor by criticizing the department. Conflict status: the first instance and the appeal recognized the right of Rospotrebnadzor in all claims against AnderSon and ordered the network to pay fines for violations revealed during the inspection. The defendant does not agree with this situation and will appeal the decision in cassation: AnderSon's complaints will be considered in 2020.
Leonid Reiman, Ex-Minister of Communications of the Russian Federation, against the Angstrem-T plant	The bankrupt Angstrem-T plant near Moscow gives no peace to Leonid Reiman, ex-Minister of Communications of the Russian Federation, who at various times was the stockholder of this enterprise. The former official is trying to recover a considerable sum of money from the plant and its affiliates - both on his own behalf and through one of the companies affiliated with him. Mr. Reiman has already managed to "shove" 423 million rubles of debt into the register of creditors of Angstrem-T with the help of the appeal. The court will consider another 2-billion-ruble claim of his Alternative Capital LLC to Angstrem JSC in 2020. Conflict status: in October 2019, Angstrem-T JSC was declared bankrupt and entered into bankruptcy proceedings, the financial claims of Leonid Reiman were included into the statement of creditors' claims: there is nothing he can do but wait for payments. The consideration of the financial dispute between

	Alternative Capital and Angstrom will take place in January next year. A third party to the case was the Federal Financial Monitoring Service.

No conflict can last forever. What tool can be used for effective and rapid resolution of the conflict? Four out of five top managers prefer to agree under a pre-trial process, therefore such a tool as mediation can successfully cope with the task.

Mediation as a type of brokerage in the resolution of disputes has existed for as long as conflicts, therefore, now this process is well-established, has its own requirements and principles of conduct, as well as specific features in various countries. A mediator only directs the negotiations, his/her interest is to resolve the conflict, he/she has no personal or business relations with either side, he/she should not have a material interest in the conflict. The decision to terminate the dispute under certain conditions is always made by the parties themselves. In addition, the mediator does not have advisory functions (does not have expertise in the field that is the subject of conflict), but creates only conditions for dialogue, with a view to further cooperation.

In Russia, it has become possible to use mediation procedures in resolving the conflict since 2011 with the adoption of Federal Law No. 193 “On an Alternative Dispute Resolution Procedure with the Participation of a Mediator (Mediation Procedure)”.

In Russia mediation is an novelty, but abroad mediation is popular and successful among many companies and citizens. So, the first countries that legislated the mediation procedure were the USA, Canada, a little later the countries in Europe and Latin America. The effectiveness of mediation can be witnessed in the United States, which is the founder of this method. Nowaday in the United States up to 80% of conflicts are resolved using the procedures of out-of-court settlement of disputes, and of all such settlement 30% are provided by arbitration (arbitral tribunal in Russia), and 70% - mediated (Parinsky A.I. ,2010) Since 2004 the European Code of Mediators has been applied, which defines the basic principles of mediators’ activity.

The main condition for using mediation is the intention of the parties to agree to a compromise and constructively solve the problem. According to T.V. Letuta, for the successful implementation of mediation in Russian corporate relations, it is necessary to address the problem for mediator services payment in local acts of corporations, where the principle of forming a guaranteed fund should be laid down, the funds of which should cover legal and other costs of out-of-court dispute resolution (Letuta T. V. 2009). The main disadvantage of the mediation procedure is the impossibility of enforcing the mediation agreement, the execution of which is based on the good will of the parties. Therefore, it may be advisable in developing this institution to give mediation agreements the force of an executive document. We should agree with the opinion of C.A. Shamlikashvili, that “the specificity and at the same time the advantages of mediation are such properties as its informal, confidential nature: as it is a process, in which the parties participate on an equal footing, while retaining full control both over the decision-making process and its content”(Shamlikashvili C.,2010).

For example, in the United States, approximately 800 companies, including Time Warner, UPS, General Electric, the Prudential, and Coca-Cola, try to resolve a dispute using alternative dispute resolution methods before suing (Runesson E. M. and Guy M. L. Mediating Corporate Governance Conflicts and Disputes, Focus 4). Thus, in order the mediation to become an element of the corporate governance of a company, it is necessary to:

1) adopt a policy providing for the assessment of each dispute regarding its mediaability; require managers to make maximum efforts to resolve disputes through negotiations or mediation, without continuing with a lawsuit; 2) include a clause on mediation in all contracts, namely, providing that before going to court, the parties to the dispute should try to resolve the conflict through mediation; 3) regularly train employees in mediation or negotiation skills based on interests rather than positions; 4) establish that all disputes between parties should be resolved without judicial

procedures. It is possible to regulate the mediation procedure within a large company with the help of internal documents, rules, regulations, and instructions developed by specialists.

At the same time, the effectiveness of this institution is confirmed by international practice. Thus, the United Nations Commission on International Trade Law adopted a model law on international commercial conciliation, in Canada the procedure for conciliation in resolving labor disputes is established as mandatory (Alexander N.M.,2006). Mediation is used in countries of continental Europe, in Canada, Australia, Great Britain and other states. Since 1947, a special federal body has been operating in the USA - the US Federal Mediation Conciliation Service (FMCS) (Ralko V.V., 2009). In Germany, the Federal Union for Mediation in Economics and Labor (Bundesverband Mediation in Wirtschaft und Arbeitswelt) actively operate and develop (Abolonin V. , 2010); and in the UK there is the advisory service for arbitration and conciliation (Asac Codes of Practice), the main function of which is to promote the development of industrial relations and offer, at the request of the conflicting parties, of assistance in resolving the dispute (Voronkova E. R. ,2007).

The effectiveness of the mediation process lies in the fact that it assumes the existence of future relationships between the conflicting parties, and confidentiality. Mediation is applied in cases where the dispute raises issues that are sensitive to the business or the parties, for whatever reason, do not want their dispute to be considered by the court. In addition, the mediation process lasts less than a month, when in the arbitration court the proceedings will take from one to three months, and in arbitration from nine to ten.

Research Methodology

The theoretical and methodological basis of the study is a systematic and structural-functional approach to the analysis of corporate conflict, a sociological and conflictological view of it as a holistic, dynamic, differentiated system of social actions, relationships and processes. The resolution of corporate conflicts is considered in close connection with the specific role of this process in the system of well-established corporate relations.

The principle of unity of the objective and subjective is realized in the study. The objective need for resolving corporate conflicts is defined as a process determined by the real external environment and existing corporate relations, which are influenced by subjective assessments, opinions and ideas of people.

Results

The current development of corporations in Russia is accompanied by an endless series of corporate conflicts, some of which are given in Table 2

.

Table 2: The practice of using mediators in resolving corporate conflicts in Russia

Parties to a conflict	*The subject and cause of conflict*	*Intermediary (Mediator)*	*Mediator's interest*
JSC MMC "Norilsk Nickel" Majority shareholders of Interros V. Potanin and OJSC Rusal owned by O. Deripaska	• Criticism of the Norilsk Nickel strategy, dividend policy and operational management of the company; • CEO personality and the board of directors • different management styles of major shareholders.	Roman Abramovich - the guarantor of compliance with all conditions of the agreement between the shareholders of Norilsk Nickel	In 2012, MillhouseCapital bought from Interros and Rusal a 5.87% stake in Norilsk Nickel Rusal sold 3 million 873 thousand 537 shares of Norilsk Nickel (or 2.03% of the total number) to MillhouseCapital, another 5 million 420

			thousand 464 shares were sold to Interram owned by Potanin. MillhouseCapital manages approximately 20% of the company's stake, having the opportunity to act as an arbitrator to resolve conflicts between Norilsk Nickel shareholders
CJSC "Oil Company" Nobel Oil ", LLC" Kolvaneft ", CJSC" NeftUs "and OJSC" Lukoil "	OJSC Lukoil prevented the direct activities of CJSC NK Nobel Oil , LLC Kolvaneft, CJSC NeftUs by stopping the transportation of oil through the Kharyaga-Usa pipeline. During the conflict, the defendant used an illegal form of struggle that is contrary to corporate ethics.	Panel of Arbitrators of the Joint Commission on Corporate Ethics under the RUIE, composed of the chairman of the panel of arbitrators E. Somers, Arbitrators of the Commission - S.V. Generalova and S.A. Abramova, with the participation of the Executive Secretary of the Commission N.A. Ostarkova.	
IJSC Ingosstrakh Majority shareholders O. Deripaska (controlling more than 60% of the stake - 10% personally and about 50%) and A. Mamut (controlling 38.5% of the stake)	Different views on the strategy: A. Mamut wanted to turn the company into a transnational corporation, for which he proposed to attract as a partner the Czech businessman P. Kellner O. Deripaska rejected the proposals make by A. Mamut, since he believed that Russia and the CIS countries should become the main markets for Ingossrakh.	OJSC VTB proposals in 2001	A stake in a joint insurance company.
CJSC Tsvetmetservice and OJSC NK Yukos	CJSC and NK were shareholders of CJSC Rosskat. Yukos owned a controlling interest in it, and Tsvetmetservice - 25% of the shares. The company was suspended from participation in the management of Rosskat. In this regard, it demanded that Yukos either buy out its stocks or, conversely,	Commission on Corporate Ethics under the RUIE. Mediator - Chairman of the Commission, Mr. B.Yu. Titov. His decision did not help Petersburg metalworkers to feel like co-owners of Rosskat. He	

	sell part of its own at an affordable price.	decided that Yukos should simply redeem a blocking stake from Tsvetmetservice.	
In September 2004, Prosperity Capital Management and the Association for the Protection of Investor Rights filed a claim against CJSC Severstal-Group, OJSC Severstal-Resource, and personally, Mr. A.A. Mordashov.	As a result of the additional issue of shares, the package of minority shareholders was diluted, after which the assets of the company were transferred to a third party, which was under the control of the same main shareholder, CJSC Severstal-group. The claimant considered such actions a violation of corporate ethics. The claimants were minority shareholders of OJSC Severstal-Resource.	Joint Commission on Corporate Ethics under the RUIE, Mediator - Mr. E.L. Yuriev.

The majority shareholders of Lenta VTB and TPG on the one hand and August Meyer's Svoboda Corporation	Each co-owner proposed their own representative as the head of the company. Various assessments of the activities of the general director of the Lenta retail network, Jana Dunning; Disagreements of A. Meyer with the composition of the board of directors. Disagreement over development strategies.	"Mediator" - , member of the board and co-owner of «Ilim Pulp and Paper Group» Boris Zingarevich	Option to purchase 3.375 million common equity of Lenta at $ 25.086 per share. The peacekeeper's package amounted to about 3.2%. The peacekeeping mission is thus estimated at 2.6 billion rubles.

Analyzing the first and second columns of the table, we can conclude that disputes mainly occur between majority shareholders regarding inconsistencies in corporate development strategies, the composition of the board of directors and company boards. These conflicts are the result of a concentrated ownership structure and the merging of ownership and management, formed over the past twenty-five years in the Russian economy. In addition to conflicts between majority shareholders, there are also conflicts between majority and minority shareholders, and they are associated with the abuse of control of the majority and violation of the minority shareholders' rights as a result.

But these conflicts have common features: they all arise under the strong influence of personal relationships and emotions. And in some cases, the parties to the conflict even show aggressiveness towards their opponents, which tensions the situation and is not productive for resolving the contradictions between corporate entities. In such circumstances, the actual method of resolving corporate conflicts is the use of mediation, which in countries with a developed corporate governance

system has been practiced for over fifty years, is popular and effective. So, based on international statistics, 25–50% of all disputes go through mediation, and in 80% of cases the mediator resolves the dispute successfully.

Let us note that many businessmen believe that in Russian context mediation will not work - the aggressiveness and distrust of the parties are usually too great, although in our opinion, these are precisely the cases where mediation should help because of its advantages over other forms of resolving corporate conflicts. Despite the skepticism that prevails in business community about the use of the mediator institution in resolving corporate conflicts, mediators have been involved in Russian practice for a long time. Another thing is that these mediators far from meeting the professional requirements of the mediator, although they play a positive role in resolving corporate conflicts. Thus, a number of features of the Russian practice of mediation in resolving corporate conflicts can be highlighted.

Analyzing the second and third columns of the table, we can conclude that the mediators in resolving corporate conflicts are often oligarchs, who are respected in the business community and have a personal material interest in the subject of the conflict. Consequently, the invited intermediaries lack special professional knowledge, not to mention the professional qualities of a psychologist.

A number of authors propose to invite as a mediator - a member of collegiate bodies of corporate governance, for example, a member of the board of directors. But this can be argued, because corporate actions arise in Russian companies as a result of certain actions of the board of directors, although the steps of the board of directors should be aimed at minimizing them.

The requirement to assign personal responsibility to the mediator is also doubtful, when it is supposed that the mediators is accountable to the parties for the harm caused as a result of mediation, in the amount of full reimbursement. The question arises, how a mediator can describe the possible risks and negative consequences, as a result of which the party incurred losses, if his/her task is only to direct the dispute process and create conditions for resolving the dispute? After all, the mediators are not a consultant and they should not have professional knowledge in the field of conflict. The talent of a mediator possessing psychology expertise is crucial for the success of the mediation procedure, and legal knowledge can impede the progress of negotiations.

Conclusions

The costs associated with poor governance and corporate conflicts are too high. And when regulating corporate conflicts, attention should be paid to their emotional side. The advantage of mediation in resolving corporate conflicts is confidentiality, and therefore parties to disputes can “save face”. Mediation is designed to maintain relations between conflicting parties, which is undoubtedly important for corporate relations. But Russian business is characterized by atavisms of a planned economy, namely, CEO’s rude statements, incompetent task setting, lack of skills for developing feedback and constructive criticism, and a low culture of meeting. The use of mediation in such an atmosphere is limited and requires a special approach.

The first step for introducing a mediation approach into the real life of Russian organizations is the ability to communicate with the most short-sighted leaders, who still consider the method of the carrot and stick the only means of managing people. The second step is the need for the parties to explain to the mediator all the features of the corporate culture and company management. As a result, some disputes within the organization can be resolved by internal employees who are not involved in the conflict, but who know the specifics and culture of the organization. As a result, it is crucial today to build a whole system of mediation within the company, designed to help resolve internal conflicts.

To determine to which mediators, internal or external, it is necessary to turn in a specific situation, it is necessary: to distinguish between situations that can be resolved by internal experts or internal employees in the role of mediators; formulate mediation competencies and select the employees who

are most relevant to them; conduct training of internal mediators. The main thing is that the organization's employees are aware of the possibility of resolving conflicts through a similar procedure, and the highest corporate governance bodies have contributed to the maximum use of the internal mediation in the company.

Expectations of Generation Z from Perspective of Employers: The Delphi Method

Jiri KUTLAK

University of West Bohemia, Pilsen, Czech Republic
kutlak@kpm.zcu.cz

Abstract

This paper aims to identify the factors and areas that Generation Z expects from its employers. However, these expectations are not identified by the representatives of the Z generation themselves, but by the employers themselves represented by HR specialists from Czech companies. For the research was theoretically defined and practical used three-round questioning in the form of Delphi method. The results indicate that employers are able to identify areas that are crucial for Generation Z. However, this identification is not entirely accurate and there are areas such as the need for your own workspace, the importance of the corporate social responsibility concept (CSR), the emphasis on diversity or the business mindset that are important to the Z generation, but employers themselves have not identified them as important. On the contrary, there was a consensus between the expectations of both sides in the areas of learning & development, rewarding or attractive corporate culture. The need for a gradual shift of concentration from Milenialls towards the Gen Z is thus a necessary activity that will give businesses the needed advantage in labor markets.

Keywords: Generation Z; Expectations; Motivation; Delphi Method, Employer

Introduction

In recent years, the media, as well as companies and their human resources (HR) departments, have focused on the Millenials (the generation Y) that entered the labor market. Now is the time when representatives of the next generation, the generation Z (the Gen Z), are entering the labor market. The youngest economically active generation Z consists of individuals born between 1995-2010 and are currently (2019/2020) aged 24 years or less (Henley, 2019; Francis & Hoefel, 2018; Fratričová & Kirchmayer, 2018a, b; Monych 2017; Patel 2017). It means that attention is slowly but surely shifting from the mentioned Millenials towards the Gen Z, specifically to its characteristics. They consist of opinions, views, values, qualities, ideals and, last but not least, the expectations of the representatives of this generation. The necessity of a Gen Z‘s orientation is aslo based on an estimate of the global population according to which the Gen Z is the largest generation on the planet with population of 2.5 billion, the Millenials is about 1.7 billion (13%) (Kleinschmit, 2019; Deloitte, 2018).

Characteristics of Generation Z

The Gen Z growing up at the turn of the millennium is influenced, as it is based on the definition, by various cultural-historical, economic and social factors of the time. Specifically, it can be mentioned the 2008 World Economic Recession or the deteriorating security in the world, for example as a result of the terrorist attacks of September 11, 2001, which according to many sources have influenced mainly the Z generation in the Western Hemisphere (Deloitte, 2018; Merriman, 2018; EY, 2015). The fact that individuals grew up in families that may have been struggling with job loss or living standards in times of economic decline means that individuals are *realistic, pragmatic, self-sufficient and independent* (Deloitte, 2018; Monych, 2017; Patel, 2017; EY 2016; EY 2015

Another undisputed factor that influenced the formation of the Gen Z is *technology* and *digital world*. For this reason, the Gen Z is also called iGen, Gen Tech, Digital Natives or Net Gen (Baldonado, 2018). Since birth, this generation has been surrounded by mobile phones, unrestricted Internet access and social networks (Fratričová, & Kirchmayer, 2018b; Merriman, 2018). This context has the effect that the Gen Z considers its own the validation and retrieval of information anytime, anywhere and can be described as strongly cognitive. The Gen Z uses his smartphone an average of 15.4 hours per week, that supports the positive relationship of the Gen Z to technology (Kleinschmit, 2019). They also expect

the use of technology in their professional lives, for example in the area of learning & development (L&D) - in training, retraining or redeploy of employees (KPMG, 2018).

Other traits of the Gen Z include *self-reliance* and *independence* (Patel, 2017). Unlike the Millenials, which are characterized by shared work environment, collaboration and teamwork, the Gen Z is characterized by independent work (Half, 2015). They want to work on their projects, the results of which are of course fully responsible. This goes hand in hand with the fact that the Gen Z favors its own workspaces at the expense of the currently widely used open spaces (Miller, 2018; Puiu, 2017). This does not mean that the Gen Z is not in personal contact. Quite the contrary, according to Half (2015), three quarters of respondents prefer personal communication. Kutlák (2019) and Bejtkovsky (2016) confirm a similar tendency in their research.

Frequently mentioned characteristic of the Gen Z is a positive attitude towards *entrepreneurship* (Kleinschmit, 2019; EY, 2016). According to Patel (2017), the relationship to starting their own business is 55% higher than for the Millenials and even 72% of college students would like to start their own business. In addition, 61% of college students and more than 40% of high school students would become an entrepreneur rather than to be employed (KPMG, 2018). In general, entrepreneurship and innovation are among the main skills of this generation. At the same time, the Gen Z is aware, even on the basis of its pragmatic approach, that business brings possible failure. Less than three quarters of the Gen Z are aware, according to EY (2016), that their business may end in failure. But at the same time they want to learn from that mistakes. Entrepreneurship is also supported by the fact that almost 90% of the Gen Z wants to spend part of their free time productively and creatively (EY, 2016).

It is precisely *financial security* that is mentioned as the most frequent inspiration and motivation for the Gen Z and their professional life (Deloitte, 2018, Hppy, 2018; Half, 2015). Among the three most importnat work motivation factors is mentioned by Schwabel (2014) (2nd position); Half (2015) (2nd position); Deloitte (2018) (1st position) or Kubátová (2016) (1st position). According to a survey by Kirchmayer and Fratričová (2018b), one third of respondents (3rd position overall) evaluate the financial reward as an main motivation factor. However, great interest in financial security also brings issues in the form of overstated expectations of salary levels or growth. According to the PayScale (2019), the average expected wage is higher than the median of the actual wage in 10 out of the 12 sectors surveyed (with the exception of computer science and nursing). This is also confirmed by the fact that college students actually receive 23% lower wages than they initially expected (Henley, 2019).

For the representatives of the Gen Z is very important *meaningful work*, which can be expressed, for example, in feeling of satisfaction from the work done, but also in the *impact of the company* on the outside world. The activities of the company in which the Gen Z wants to work must be in accordance with the individual's beliefs. This belief is presented, for example, by the impact on the social and environmental environment and on the ethical nature of the company, which according to Deloitte (2018) is important for 77% ot the Gen Z. Moreover, activities in these areas must be real and should be developed through the entire stakeholder system (Francis & Hoefel, 2018). According to Kleinschmit (2019) 60%, and according to EY (2016) 38% of the Gen Z wants to act by changing the world for the better and the profession could be one of the tools.

Regarding *career opportunities* and *career development*, unlike their predecessors, the Gen Z does not place much emphasis on job titles and does not recognize the traditional career ladder system (Baldonado, 2018; Monych, 2017). According to Kubátová (2016), Kirchmayer and Fratričová (2018b) and Baldonado (2018), expectations of career growth and opportunities are among the main motivators. However, career opportunities are not only related to advancements, but also to alternative career changes, such as rotating at different positions, participating in multiple projects (their own), performing multiple roles or diverse workloads regardless of individual specialization (Deloitte, 2018). KPMG, 2018). It is estimated that the youngest generation should also become the most educated generation (Adecco, 2019; Deloitte, 2015). Long-term education also has an impact on the need for further education in the workplace.

As mentioned above, the *work environment/culture* and *flexibility* are other factors of motivation. As both the Millennials and the Gen Z are looking for a job that provides them the possibility of flexible schedule, more and more organizations will be offering workplace flexibility to attract and retain these

talents in the long term (ManpowerGroup, 2018). According to KPMG (2018), 47% of the Gen Z consider the entertainment environment to be important and 44% wanted flexibility in their work schedule. However, can be found the studies in which flexibility and work-life-balance factors do not feature prominently (eg Meret et. Al., 2018; Kirchmayer and Fratričová, 2018b). Because of their positive relationship to technology, they are willing (if the nature of work permits) to work anytime and anywhere (Henley, 2019). It follows that the Gen Z is more focused on completing tasks than on the time spent at work.

Finally, it is necessary to mention the *diversity* in the workplace, which is a matter of course for the Gen Z rather than a factor influencing them in the choice of their employer (Deloitte, 2018; Hppy, 2018). Companies with high homogeneity (age, race, gender, etc.) may thus be unattractive for Gen Z representatives (Deloitte, 2018; Monych, 2017).

Research Methodology

The research was carried out using the Delphi method, which is characterized as a qualitative method with the form of controlled group communication, the aim of which is to converge to the same opinion or view of the examined issue. The communication process is represented by several-round questioning of respondents with controlled feedback. The use of this method in research is recommended for areas that do not work with historical data and therefore is a very little explored area (Wright & Grime, 2016; Ferreira et al., 2015; Habibi et al., 2014). Experts are guaranteed anonymity and are not under pressure from their surroundings, social norms or working position when expressing their opinions, views and feelings. (Ferreira et al., 2015). Thanks to individual answers, the respondent cannot succumb to the majority influence or interests of a strong personality. Strengths of this method are low cost, no time limitation and no need for collective meetings (Habibi et al., 2014).

The group of respondents, called as experts, consists of competent experts who have sufficient knowledge and experience with the subject matter. It is possible to define a group of experts using conditions that all or part of the experts must match. According to Wright & Grime, (2016) the optimal number of heterogeneous group is between 5-20 experts. Laurie & Mortimer (2019) report a number of 10-15 experts. It is also necessary to think about the return rate of questionnaires, which ranges between 40-77% (Egerová & Mužík, 2010).

The reason for terminating the questioning is stated to reach a consensus among the interviewees, but Green (2014) states that the reason may also be the fact that the data show a big mismatch and no consensus among the interviewees can be expected. However, it is stated that two rounds are considered to be the absolute minimum and three rounds of questioning are considered sufficient (Wright & Grime, 2016; Green, 2014).

Delphi Survey

The Delphi research is focused on the expectations of the Generation Z from the perspective of employers. However, as can be seen in the theoretical framework of the article, expectations are often obtained only from Gen Z views, but the perspective from employers and the subsequent comparison are equally important.On this basis, the following research question has been evaluated:

The research question*: Which factors and areas, according to employers, will be expected from the Gen Z in relation to their employer?*

It is the view of the employers themselves that, on the basis of comparison with data from the representatives of the Gen Z, tells about the readiness of companies. It is also possible to identify possible areas where there is no consensus between the two parties of the psychological contract. Ruchika & Prasad (2019) define the Anticipatory Psychological Contract (APC) as a term that indicates a set of mutual expectations and responsibilities between employees of an organization and an organization. This, of course, undermines the performance of the organization.

The research itself took place between November 2019 and January 2020. Before the research, the questionnaire was piloted on a smaller group of experts. The panel of experts selected for this research is composed solely of persons with sufficient knowledge of the issue of the Gen Z expectations. This assumption was fulfilled as a result of setting out the following criteria for the selection of panelists.

- The research participant (expert) is a person who represents an organization that employs or will employ a representative of Generation Z in the near future.
- The research participant (expert) is a person who has at least 3 years of practical experience in the field of human resources.

Based on the above criteria, 29 persons satisfying the given conditions (both together) were approached. Out of the addressed respondents, a total of 24 experts representing national and multinational companies operating in the Czech Republic promised to participate in the interview.

Procedure and evaluation of first round of Delphi method

The first round of research was carried out between November and December 2019. The addressed experts were asked for opinions or views on the issue of working expectations of the Z generation representatives from their future employers. The form of the answer was open to ensure the widest range of different opinions and views on the issue. In total, 21 experts took part in the first round with a response rate of around 88%. The form of distribution of questionnaires was using Google forms.

During the evaluation of the first round, individual answers were processed. Synthesis was used to unify the opinions and views of individual experts. Based on the answers, a total of 29 unique factors were obtained, which occurred several times in the expert's answers. These factors were further divided into 4 areas. The theory of the anticipatory psychological contract was based on the creation of areas. This theory according to Lub et. al (2016) mentions five dimensions of the APC fulfilment, which have been adjusted to the following 4 areas due to the opinions and views of the researched issue and because of the saturation of individual areas: *Benefits and Rewards; Content of Work; Social and Corporate Atmosphere; Learning and Career Development*. Experts are more focused on narrower issues in their rating and the factors are more easily compared to each other - especially in the third round of the Delphi method. All areas and their factors are shown in Tab. 1-4, which are part of the evaluation of the second round.

Procedure and evaluation of second round of Delphi method

The second round was carried out immediately after the evaluation of the results of the first round and took place from 10 to 24 December 2019. The aim of the second round was to evaluate the factors that were the output of the first round of the Delphi method. The experts were asked to evaluate the individual factors, which were divided into the mentioned areas. Likert's 5-grade rating scale was used for the assessment, where the lowest grade 1 presents a low-impact opinion (the factor will not be crucial for the expectations of individuals of the Z generation from future employers). On the other hand, the highest level 5 means the fundamental influence of the factor and thus the fact that individuals will expect this factor from their employers. A total of 20 questionnaires were completed in the second round, indicating a high rate of participation / return.

For the evaluation of the second round were used descriptive statistical methods – *the mean, median and the sample standard deviation*, which is the characteristic variability of a statistical sample (Laurie & Mortimer, 2019). Using the values of the mean, the importance of the individual factors and thus their order for the third round of the Delphi method is determined. At the same time, given the 5-degree scale, it can be argued that the factor becomes important at an mean value of 3 and above. Mean values that are equal to or greater than 4 can be considered very important. Factors with a value less than 3 can be described as unimportant and these factors were eliminated for the third round.

In the first area, the highest rated factors were „Flexible hours“ and „Regular growth of salary“ with an average value higher than 4. This value was also approached by the Generous salary factor. On the contrary, the factor "Financial contribution for non-work benefits according to the individual's interests (books, cinemas, etc.)" reached a below average rating of 2.75 and is not taken into account for the third round of the questioning. At the same time, when compared to other areas, the sample standard deviation values are higher for most factors, indicating greater variability in individual responses.

Tab. 1: Importance of factors - Area of Benefits and Rewards

Benefits and Rewards	Mean	Median	Std. dev
Flexible hours	**4.25**	4.5	0.91
Regular growth of salary	**4.15**	4	0.88
Generous salary	3.95	4	0.94
Home-office	3.9	4	0.97
Sick days	3.65	4	0.81
Individualization of benefits according to individual needs	3.2	3	1.01
Shortening of working time	3.05	3	0.89
Financial contribution for non-work benefits according to the individual's interests (books, cinemas, etc.)	*2.75*	3	1.07
Total Mean	**3.61**		

The second area is "Content of Work", where three factors have a value greater than 4 and can be considered as important. Conversely factor "Shorter work Concentration (No need to work continuously and focused)" reached average value lower than 3, and for the third round was eliminated. The sample standard also indicates greater variability of the research sample. Moreover, the overall average for this area is the lowest ever, specifically 3.59. If, however, the overall average were calculated only from factors that are also used for the third round, then its value would be higher - 3.74.

Tab. 2: Importance of factors - Area of Content of Work

Content of Work	Mean	Median	Std. dev
Meaningful work	**4.15**	4	0.88
Work-life-balance	**4.1**	4	0.85
Focus on tasks than on time at work	**4**	4	0.73
Diverse and creative work	3.7	4	0.92
Use of flexible types of working time (part-time etc.)	3.3	3	0.86
Slow work pace	3	3	1.12
Shorter work concentration (no need to work continuously and focused)	*2.85*	3	1.04
Total Mean	**3.59**		

The "Social and Corporate Atmosphere" area contains two factors with a value greater than 4. Even the "Attractive workplace culture and friendly atmosphere" factor is the best rated factor across all areas and is the only one reaching a median of 5. No factor has an average value of less than 3, which is also the cause of a higher overall average of 3.68.

Tab. 3: Importance of factors - Area of Social and Corporate Atmosphere

Social and Corporate Atmosphere	Mean	Median	Std. dev
Attractive workplace culture and friendly atmosphere	**4.45**	5	0.76
Open communication	**4.2**	4	0.77
Workplace trust	3.75	4	0.72

Modern elements of relaxation and fun at workplace	3.55	4	0.76
Emphasis on environmental and social responsibility of the company	3.45	4	1
More frequent teambuilding events	3.4	3	0.75
Less bureaucracy and administration	3.35	3.5	1.18
More personal space (against open workplaces)	3.25	4	1.12
Total Mean	**3.68**		

In the fourth area of study "Learning and Career Development", there was only one factor rating of 4. However, the first five factors, as can be seen in Tab. 4 below, reached a very above-average value of 3.9. This implies that an overall average of 3.88 makes this area the highest rated and therefore most important. The sample standard deviation reachs lower values for most factors, indicating low variability in the examined values.

Tab. 4: Importance of factors - Area of Learning and Career Development

Learning and Career Development	Mean	Median	Std. dev
Skill/capability development and learning needs	**4**	4	0.79
Fast career advancement	3.95	4	0.76
Traveling is part of job (eg internships abroad)	3.95	4	0.76
Using and improvement in foreign languages	3.95	4	0.83
Engaging digitization in work and development	3.9	4	0.97
Development outside scope of job position	3.5	3.5	0.69
Total Mean	**3.88**		

It is clear from the results of the second round that "Learning and Career Development" is the area that the Gen Z will place the greatest emphasis in its expectations. The second area according to the overall average is the "Social and Corporate Atmosphere". A total of 7 factors with an average values of more than 4 have been identified across all areas (bold highlighted), making them very crucial already after the second round. In other words, employers identify them as important and expected from the Gen Z.

Procedure and evaluation of third round of Delphi method

The third round of Delphi research was carried out immediately after the evaluation of the results of the second round from December 2019 to January 2020. The aim of the third round was to evaluate the factors in the selected areas. In the questionnaire, factors were presented in order from most important to least important, based on the results from the previous round. However, unlike the second round, the evaluation of experts consisted of considering the order (importance) of the factors within each of the 4 areas. All three rounds of the Delphi method were actively attended by 18 experts, which means a return of 75% (according to Egerová & Mužík (2010) it is the upper limit of the expected return).

Similar to the second round, statistical methods were used to evaluate the third round, namely *the non-parametric Kendall's coefficient of concordance (Kendall's W)* (Habibi et al., 2014). Using this coefficient it is possible to determine the tightness (compliance) of evaluation of individual experts. The calculation is performed using the following formula:

$$W = \frac{\Sigma X^2 - \frac{(\Sigma X)^2}{n}}{\frac{1}{12}k^2.(n^3 - n)} \quad (1)$$

where:

W… value of Kendall's coefficient of concordance;
X… total ranks of factor;
n… number of ranked factors;

k… number of judges (Chráska, 2016).

The coefficient can be a value of 0 - +1, while a value of +1 indicates a complete match of the order of factors between the experts. According to Habibi et al. (2014) there is strong agreement for W values> 0.7; slight agreement for W≈0.5 and poor agreement for W <0.3. In the Tab. 5-8 below, the factors, that were identified as key areas in the second round, are indicated in bold.

In the "Benefits and Rewards" area, there were only two shifts in the third round, between 2nd and 3rd and between 5th and 6th. As in the second round, the experts rated the factor "Flexbile hours" as the most important. On the contrary, the „Shortest of working time“ was again chosen by experts as the least important. The coefficient of agreement is 0.53, which indicates a slight agreement among the experts.

Tab. 5: Factors ranking - Area of Benefits and Rewards

Benefits and Rewards	Primary rank	Sum of ranks	Final rank
Flexible hours	1.	40	**1.**
Regular growth of salary	2.	49	**3.**
Generous salary	3.	46	**2.**
Home-office	4.	68	**4.**
Sick days	5.	104	**6.**
Individualization of benefits according to individual needs	6.	92	**5.**
Shortening of working time	7.	105	**7.**
Kendall's *W* = 0,53			

In the "Content of Work" area, only the "Diverse and creative work" factor was shifted to the 3rd place (at the expense of "Focus on tasks rather than time at work" factor). As the least important factors for the Gen Z, HR experts expect the factors "Use of flexible types of working time (part-time etc.)" and "Slow work pace". The Kendall's *W* value is 0.46, which is less than in the "Benefits and Rewards" area, but the data still shows a weak concordance in the experts' answers.

Tab. 6: Factors ranking - Area of Content of Work

Content of Work	Primary rank	Sum of ranks	Final rank
Meaningful work	1.	35	**1.**
Work-life-balance	2.	46	**2.**
Focus on tasks than on time at work	3.	69	**4.**
Diverse and creative work	4.	52	**3.**
Use of flexible types of working time (part-time etc.)	5.	80	**5.**
Slow work pace	6.	96	**6.**
Kendall's *W* = 0,46			

In the third area of study "Social and Corporate Atmosphere", where most factors occurred (8), the ranking changed only to the 2nd and 3rd position and to the 6th and 7th position. However, it should be noted that the 2nd and 3rd place factors have very similar value to the sum of ranks. The total Kendall's W for this area is the same as the previous area, 0.46 (weak concordance).

Tab. 7: Factors ranking - Area of Social and Corporate Atmosphere

Social and Corporate Atmosphere	Primary rank	Sum of ranks	Final rank
Attractive workplace culture and friendly atmosphere	1.	25	**1.**
Open communication	2.	62	**3.**
Workplace trust	3.	58	**2.**
Modern elements of relaxation and fun at workplace	4.	92	**4.**
Emphasis on environmental and social responsibility of the company	5.	95	**5.**
More frequent teambuilding events	6.	107	**7.**
Less bureaucracy and administration	7.	96	**6.**
More personal space (against open workplaces)	8.	113	**8.**
Kendall's *W* = 0,46			

The fourth area focused on "Learning and Career Development" shows the lowest concordance (*W* = 0.4), even though the area contains only six factors. The change occurred in the first position (Fast career advancement). As can be seen in Tab. 8 below, based on the results of the second round, where the first five factors oscillated around a value of 3.95 (+ -0.05), it was possible to expect different shifts in order due to the significant importance of all factors.

Tab. 8: Factors ranking - Area of Learning and Career Development

Learning and Career Development	Primary rank	Sum of ranks	Final rank
Skill/capability development and learning needs	1.	44	**2.**
Fast career advancement	2.-4.	35	**1.**
Traveling is part of job (eg internships abroad)	2.-4.	64	**4.**
Using and improvement in foreign languages	2.-4.	62	**3.**
Engaging digitization in work and development	5.	83	**5.**
Development outside scope of job position	6.	90	**6.**
Kendall's *W* = 0,40			

Discussion and Conclussion

The aim of the research was to identify factors that will be important for the youngest economically active generation, ie for the Gen Z, based on the opinions and views of the HR experts. The research was conducted by using the three-round Delphi method, which resulted in the following findings. The experts identified a total of 29 factors that have been divided into 4 areas (see tables above). These factors were evaluated by experts using the 5-degree Likert scale in the second round of the Delphi questioning. According to the results, the most important factors for experts are (these factors have rating of 4 and above):

- Flexible hours;
- Regular growth of salary;
- Meaningful work;
- Work-life-balance;
- Focus on tasks than on time at work;
- Attractive workplace culture and friendly atmosphere;
- Open communication;

- Skill/capability development and learning needs.

Conversely, on the basis of below-average evaluation, the following factors were considered by experts as an unimportant (values below 3):

- Financial contribution for non-work benefits according to the individual's interests (books, cinemas, etc.)
- Shorter work concentration (no need to work continuously and focused)

When comparing the different areas, experts rated the Gen Z as the "Learning and Career Development" area (total mean 3.88), followed by the "Social and Corporate Atmosphere" area (total mean 3.68). The other two areas reached the same rating of the total mean of approx. 3.6. According to the outputs from the last round, the preferences of the factors within individual areas were adjusted by changing the order. According to Kendall's W values, there is only a slight consensus among the participating experts across areas of research.

The following conclusions can be drawn when comparing the research results with the theoretical framework of the paper. L&D (Learining and Development) is a highly valued area for both the Gen Z and experts. In addition, Gen Z representatives also report the involvement of digitization in this field. In the "Social and Corporate Atmosphere", businesses have identified attractive corporate culture and open communication as important factors, which does not contradict the views of the Gen Z. On the contrary, they identified as unimportant the factor „More personal space (against open workplaces)", which, however, is gaining importance in the youngest the Gen Z (unlike the Millennials). Estimates of businesses may be distorted by the previous generation of the Millenials, for which an open workplace was in high demand. Also the factor concerning "Emphasis on environmental and social responsibility of the company" was not identified by experts as very important, but representatives of the Gen Z place great emphasis on this issue. The agreement of experts with the Gen Z can be found in the area of the „Work content", where both sides identify „Meaningful work" and „Work-life-balance" as very important factors. A similar consensus can also be observed in the area of the „Rewards and Benefits", where high pay and flexibility in the choice of working time are important for both the Gen Z and HR experts.

Among the areas that are important for the Gen Z, but experts have not been mentioned in the Delphi survey, are the focus on diversity and entrepreneurial spirit of this generation. The application of these areas, together with the other factors mentioned above, may lead to greater business readiness, which may ultimately result in easier recruitment or retention of Gen Z workers.

Trademarks in Company Resources at The Background of Their Valuation

Iwetta BUDZIK-NOWODZINSKA

Czestochowa University of Technology, Poland
iwetta.budzik-nowodzinska@wz.pcz.pl

Abstract

The paper addresses the issue of the place of trademarks in the company's resources and the use of such resources in business activity. The concepts of trademark and brand were distinguished, specifying their definitions. The considerations were also focused on the concept of their legal protection. The objectives of trademark valuation were described, and income methods were indicated as being among those that best estimate their value, based on generating future economic benefits. Particular emphasis was focused on the definition of discounting itself and the discount rate as the cost of the company capital.

Keywords: Trademark, Trademark Valuation, Discounting, Discount Rate.

Introduction

In the times of market economy, competition between different entities makes each of them strive to be recognisable among customers. Such recognisability is very often achieved through the identification of the seller with certain positive (or negative) characteristics of the products or services sold. It can be achieved by marking one offer with a specific trademark, which is to be associated with the brand and its quality. A trademark that is known on the market and well associated is part of the company's assets, the value of which is often difficult to estimate.

The issue of trademarks and their valuation is also particularly important when an entrepreneur wishes to use another's trademark against payment, or to let his own trademark be used by another entity.

The purpose of this paper is to present the methods of financial mathematics used in trademark valuation, and more specifically the process of discounting future benefits generated by the valuated trademark. The paper also points out the most common practical objectives of the valuation of such intangible assets.

Objectives of trademark valuation

A very important part of the company's activity is its development, ensured, among other things, by its internal resources. Subject literature usually distinguishes three types of company resources: material, human and intangible. This paper focuses on intangible resources, which include: know-how, technology, patents, licenses and the brand, as well as the trademark characterised below.

According to the definition of a trademark provided in the Industrial Property Law Act [The Act 2000] “a trademark is any sign that can be used to discern the goods of one entrepreneur from those of another and can be presented in the trademark register in a manner that allows for the identification of the unequivocal and accurate subject matter of the protection granted. A trademark may be, in particular, a word, a drawing, an ornament, a colour composition, a spatial form, including the form of the goods

or their packagng, as well as a melody or another sound signal. Commonly, trademarks are referred to as: trade name, company marking, company name or logo."

In turn, European Union regulations [Council Regulation 2009] indicate that EU trade mark may consist of any signs (words, including names) or drawings, letters, numbers, colors, the shape of goods or their packaging or sounds, provided that that such signs enable the goods or services of one company to be distinguished from the goods or services of other company, and that they can be presented in the register in a way that makes it possible to establish the unambiguous object of protection.

In view of the high competitiveness of companies operating on the market, it is essential to distinguish their products or services from others, of the same kind but offered by other entities. They allow to distinguish between products of the same type offered by different entrepreneurs, thus constituting the basis for building the image and reputation of the brand [Zieliński, Kubacki 2014]. An important aspect of the use of a given trademark is to provide it with legal protection by registering it with the relevant office. The duration of a trademark's protection right is 10 years from the date of its registration with the Patent Office. It is possible, however, to renew it for further ten-year periods upon the fulfilment of certain conditions.

It indicates that a trademark may be granted a protection right which, according to the balance sheet law, may constitute an intangible asset upon the fulfilment of certain conditions.

Providing trademarks with adequate legal protection not only prevents infringement by other companies but can also contribute to the material benefits arising from their use. The trademark's protection right brings its owner various benefits, including the fact that the right to the trademark may be traded, i.e. it may be transferable and inherited. The establishment of a trade mark licence agreement is also permissible [Furman 2015]. Such a case constitutes an example of a situation where a need arises for the valuation of a trademark, allowing the entrepreneur to grant other entrepreneurs the right to use its trademark in exchange for payment, based on a license or a franchise. Another motive for trademark valuation can be e.g. its sale or a contribution-in-kind to the company, which will increase the value of the entire company. The trademark therefore increases the company's market value and reputation. It makes a given brand not only popular but also credible. The registration of a trademark allows to build bonds with customers and leads to the association of the products of a given company (entrepreneur) with a certain standard and quality, while the customers know that this is where they can find them [Falkowski and Słupicka 2019].

A trademark may have legal protection throughout the country or may be protected throughout the European Union. In the second case, the trademark is registered in the European Union Intellectual Property Office (EUIPO) based in Alicante, Spain. EUIPO is the European Union Intellectual Property Office responsible for managing the EU trade mark and the registered Community design. We also work with the IP offices of the EU Member States and international partners to offer a similar registration experience for trademarks and designs across Europe and the world.

Trademark valuation is associated with yet another objective. Unfortunately, the legislation does not allow companies to register the trademarks they have developed. In order for a trademark to become an intangible asset entered into the company's accounting ledgers, certain conditions must be met under both balance sheet and tax law. The conditions that must be met by the entity in this respect are set out in the Accounting Act. The trademark must be acquired by the entity, it must be suitable for economic use, and its expected period of economic utility must be longer than one year; moreover, it must be intended for the needs of a given entity [The Act 1994]. This implies that only trademarks that have been purchased can become part of intangible and legal assets included in the balance sheet. In such a case, it is necessary to estimate the value of the purchased trademark, which includes its purchase price (excluding VAT and excise duties) increased by the costs directly related to the purchase. The initial value calculated in such a way is subject to depreciation or amortisation write-offs in accordance with the general principles set out in the Accounting Act [Pach 2019]. Tax depreciation consists in spreading over time the costs associated with the introduction of certain assets into the company, in this case

those of a trademark. It affects the amount of the company's income, which constitutes the basis for income tax. The subject of depreciation, however, is not the trademark itself, but rather the right of protection assigned to it, which means that only a trademark for which a protection right has already been granted within the meaning of the Act on Industrial Property Rights may be subject to tax depreciation. Depreciation of an unregistered trademark is possible, however, in such cases the trademark is regarded as a work subject to copyright law and may be subject to depreciation on the basis [Falkowski and Słupicka 2019].

There is one more need for trademark valuation, pointed out by G. Urbanek, namely the need to estimate the value of collateral in order to raise external capital and for the purposes of legal disputes concerning the infringement of intellectual property rights [Urbanek 2011].

The problem of trademark valuation

Intellectual property (IP) and intangible asset (IA) issues abound throughout the business world, touching nearly all aspects of a company, from product development to human capital, and staff functions such as legal, accounting, finance to line operations such as R&D, marketing and general management [Flignor, Orozco 2006]

The valuation of a company's intangible assets may be related to their overall value or the value of individual factors, which include trademarks. In the valuation of trademarks, the same approaches are used as in the valuation of tangible assets or entire companies, namely the cost, market and income approach. This three generally accepted valuation approaches are employed by valuation analysts to estimate the value intangible property, including trademarks [Marcinkowska 2011; Smith,, Richey 2013].

The cost approach assumes that the value of a trademark is the result of the updated value of outlays that would have to be incurred to reproduce a given mark [Czerwiński, Wiszowata 2013]. These may be, e.g. costs related to the creation of the image of the mark or the costs of its registration at the Patent Office. [Thoma, 2017] This method leads to the lowest value of the mark being valued. The problem with this method is the estimation of costs for trademarks that have been on the market for a long time due to the frequent lack of data for calculations. [Niklewicz-Pijaczyńska 2017]

The advantage of the cost method is the ability to simplifying the estimation of the value of the trademark. On the other hand, the disadvantage of this method is the fact that the estimated value of the trademark does not take into account its market nature or ability to generate profits, which the company can generate due to the given trademark. It only indicates the expenditure that has been incurred in connection with the creation of the trademark, its registration or marketing activities. The valuation of a trademark using the cost method is also associated with the risk of making an quite significant error resulting from underestimation of the value of trademark. A trademark can be created at a low cost, while its recognition can be very high and can generate considerable revenues.

The second approach to trademark valuation is the market approach. The point is to compare transaction prices for analogous trademarks [Damodaran 2009]. In this method, the value of a trademark is determined on the basis of the market value of the sale transactions of similar trademarks. However, this method is difficult to apply because there is no market for this type of transaction. In addition, transactions are mostly confidential, which means that external entities are not able to obtain accurate information on the terms of the transaction and the price set by the parties in the agreement [Stronka, Kołata 2018].

The next approach mentioned to trademark valuation is the income approach. In this approach, the value of the trademark is in line with the current value of the expected economic benefits arising from its ownership. This method takes into account projected future revenues and costs associated with the trademark and can be used to a much broader extent than the two approaches described earlier. This

method is consistent with the Discounted Cash Flow (DCF) [Götze, Northcott, Schuster 2015] used in determining the value of an enterprise as a whole [Flisiuk, Gołąbek 2017].Summing up the characteristics of valuation methods used for trademarks, I conclude that they are identical to the methods used to value companies. In addition, the income method has an advantage over the others.

Nevertheless, the valuation of the company's intangible assets, which include trademarks, constitutes a more difficult task for an analyst in comparison with the valuation of tangible assets or entire companies [Urbanek 2011]. This is related to certain limitations, such as the unique character of the trademark, but also its absence of the market on which the sale of trademarks would take place. Another obstacle pointed out by G. Urbanek is the problem with estimating the economic benefits brought by the trademark. [Urbanek 2008].

As indicated by P. Szczepankowski, the trademark's value depends on how it affects the company's financial results, including the value of sales revenues, the value of net profit or that of the cash flows. In view of the above, he argues that the best method for estimating a trademark's value would be the income or market (comparative) method, and not the property method which presumes that the trademark's value is its expressed replacement or reproduction cost [Szczepankowski 2007, Borkowski 2009].

The income methods of trademark valuation are based on predictions of the future in terms of revenues generated by the owned trademarks. According to the income approach, the value of the intangible asset that is a trademark is as high as the current value of the expected future economic benefits generated by the trademark [Borkowski 2009, Urbanek 2001, Polański 2006]. The income approach indicates the key factors that need to be estimated while taking this path of trademark valuation. Such factors include [Urbanek 2011] the volume of expected future economic benefits that will be generated in subsequent periods by the trademark, time of their generation and the risk associated with obtaining them.

The general model of trademark valuation based on the income approach may be shown mathematically by means of the following formula [Michna 2003]:

$$\text{BRV} = \frac{p_1}{(1+k)^1} + \frac{p_2}{(1+k)^2} + \cdots + \frac{p_n}{(1+k)^n} + RV \times \frac{1}{(1+k)^n},$$

where: BRV – value of the trademark subject to valuation, p – future net cash flows generated by branded products, RV – residual value, K – rate of return required for the trademark (discount rate, cost of capital), n – income generation period.

When pointing out the problems that may be encountered by the analyst during trademark valuation, the estimation of the economic benefits generated by the trademark was indicated, as such benefits should be separated from the overall benefits generated by the company's business activity. One of the methods of estimating a trademark's benefits is to calculate them using hypothetical licence fees that would arise in the case of using someone else's trademark and bearing the resulting lease (license) fees. The amount of the license fee is typically based on market fees charged for similar factors, whereas license rates are most commonly set as a percentage of sales revenues [Urbanek 2011].

The second problem encountered in trademark valuation is the determination of the time of future income generation by the trademark. It could be assumed that the lifespan of a trademark is the duration of legal protection that is granted for a period of ten years by both the Patent Office and the European Union Intellectual Property Office. However, upon expiry of this period, it is possible to renew the protection for further periods of ten years. It would therefore be unjust to limit the time taken into account during trademark valuation to only ten economically beneficial years. It is therefore reasonable to set the financial projection period for an infinite number of years, which is reflected in the residual value (RV).

Another parameter used in income methods is the discount rate recognised as the cost of capital and the discount factor. These issues will be discussed in the following section of the paper.

Discount rate in trade mark valuation as an element of financial mathematics

When using the income approach in trademark valuation, it is necessary to forecast the future economic benefits that will be generated by the valued trademark. Given that they are distant in time, their value must be converted into their present value, i.e. their value as of the date of trademark value estimation. For this purpose, the accounts require the use and application of the change in the value of money over time [Mączyńska 2005].

The determination of the discount rate is of great importance for trademark valuation valuation [Krüger, Landier, Thesmar 2015], as with the same level of economic benefits generated by the trademark being valued over the following years, but with different discount rate levels, the value of the trademark will also differ. The discount rate allows for the estimation of future income as of today and thus allows for the estimation of the value of the trademark [Gollier, Hammitt 2014].. Its assumption is the changing value of money over time. The value of the amount that we may receive in a year or two is, from our perspective, fundamentally different from the same amount received today, as we may invest the present amount in a different manner, thus obtaining greater (or lesser) amounts in a period of one or two years. To calculate the value of money over time, the compound interest account is used, along with its inverse, discounting [Węgrzyn 2018].

According to M. Podgórska and J. Klimkowska, discounting consists in calculating the value of the initial capital PV on the basis of the known value of the final capital FV for a fixed time n [Podgórska, Klimkowska 2005]. Discounting consists in determining the present value of future cash flows generated by the trademark. It answers the question what the present value of the future benefits is, thus allowing for their comparison with the present benefits [Marcinek 2002].

The following formula is used to calculate the future value of capital FV [Bojańczyk 2011; Davidson, Song, Tippett 2015]:

$FVn = PV \times (1+r)^n$,

where: FV – future value of capital; PV – present value; n – number of years; r – interest rate per annum.

The above indicator allows for the calculation of the future value of a given amount of money invested today. However, from the point of view of income-based methods of trademark valuation, the amount required is not the future value of the trademark, but its present value. It is therefore necessary to transform this formula in order to calculate the present value PV [Sobczyk 2011].

$$PV = \frac{FV_n}{(1+k)^n},$$

where: k – discount rate (cost of capital).

The discount rate r and the so-called discount factor dn are used in economic calculation. The discount factor is distinguished from the percentage rate [Towarnicka 2004]. If the cost of capital is determined, then the discount factor dn is calculated using the formula [Walica 1999; Rogowski 2004]:

$$d_n = \frac{1}{(1+k)^n},$$

where: n – period of generation of economic benefits by the trademark.

When shown this way, the discount factor is the inverse of the percentage rate, whereas the main element of the discount factor is the discount rate that expresses the change in the value of money over a given period (usually per year).

The value of a trademark depends not only on the value of future economic benefits, but also on the time they can be made available to the company, as over time their present value decreases, despite setting the same discount rate for each year. Current, present value PV of individual future economic benefits is lower than their future value FV [Mączyńska 2005].

The application of the discount rate in trademark valuation has for its purpose not only to provide comparability of individual economic benefits obtained at different moments in the future, but also to express the limit rate of return on capital employed expected by the investors [Rogowski 2004]. The reason for this is that the capital invested by the investor in a given trademark or company could be used in other ways, possibly generating higher benefits. This alternative use of capital is expressed precisely by the discount rate. The existing discount rate estimation methods typically use two factors that influence its level, namely the cost of capital and the risk premium [Bojańczyk 2011]. Typically, in the case of trademark valuation, it is assumed that the cost of capital and the risk of obtaining benefits in the future are equivalent to the cost of capital and the operational risk of the entire company. The cost of capital is related to financing the company and investing the capital in this particular company, which means that its estimation will depend on whether the company is financed solely with own capital, or with foreign capital as well. Subject literature places particular emphasis on hybrid, or mixed, financing. In this case, a weighted average cost of capital is calculated, which is the cost of engaging all forms of capital in the company's operations. And it is precisely the weighted average cost of capital (WACC) that constitutes the discount rate used in income-based trademark valuation, converting future economic benefits to their current value as at the time of trademark valuation. [Zarzecki 2016].

In order to calculate the WACC [Magni 2015],, it is necessary to determine the share of individual capital involved in financing the company operations and, separately, determine the cost for own capital and foreign capital. These issues, however, will be subject to theoretical and empirical research in a separate study.

Conclusion

Intangible resources, including trademarks, represent a significant proportion of the company's total value and are therefore increasingly subject to corporate finance studies. Their role in a competitive environment is continuously expanding. More and more often, the trademark is perceived separately from the concept of the brand, which is only a marketing concept. This entails the need for trademark valuation. According to the literature of the subject, the best methods of trademark valuation are income-based methods that use financial mathematics processes, namely discounting, that is bringing future economic benefits generated by trademarks to the valuation date. A key element of this process is the estimation of the discount rate that will correspond to the financing structure and, at the same time, reflect the cost of capital involved in the company's operations.

The Aspect of Fair Value in the Valuation of the Enterprise

Iwetta BUDZIK-NOWODZINSKA

Czestochowa University of Technology, Poland
iwetta.budzik-nowodzinska@wz.pcz.pl

Abstract

The purpose of this article is to present fair value and its impact on the valuation of the enterprise from the appraiser's/analyst's perspective. Asset-based and income-based methods in a theoretical aspect have been presented as well as a case study of the valuation of the enterprise with these methods with the use of the fair value. Adjusted values of the assets on the basis of the balance sheet of the analyzed entity have been defined and correlated with their fair value.

Keywords: Fair Value, Book Value, Asset-Based Valuation, Income-Based Valuation, Valuation Of The Enterprise

Introduction

The valuation of the enterprise comprises many activities carried out in accordance with the rules of science and evaluation, the aim of which is to define its value as at a given moment of business operation [Maćkowiak 2009, p. 149]. The valuation of business or its assets is necessary for various reasons [Matschke, et al., 2010]. Most often they include situations connected with the change of the owner, e.g. as a result of a purchase-sale, or lease transactions, merger or division of companies. Other reasons include situations connected with compensation, transfer of ownership of a leased object to users, balance sheet revaluation of assets and liabilities of the enterprise, assessment of creditworthiness, or property or financial restructuring of the enterprise [Mączyńska 2005, p. 11; Zadora 2010, p. 89-91; Tabara 2010, p. 96-104;].

The literature presents various ways of comprehending the value of the enterprise, which is caused by the fact that depending on the adopted valuation method the same business entity may have a different value [Zarzecki 1999, p. 21-38; Sulik-Górecka et al. 2017, p. 356-364].

The purpose of this article is to present valuation methods of the enterprise, appraised for the purpose of sale taking into account the fair value.

The concept of fair value

The value is a basic economic category; however, it has no concrete definition. Following the market definition, the value of an enterprise is a price that the market is ready to pay for the enterprise at a given moment. A classic definition says that the value of the enterprise is a sum of values of tangible and intangible assets [Siempińska, Leśniewski 2009, p. 13;]. In economics money being a measure of the value determines a few concepts of the value. It is a real, market, investment, fundamental, fair value [Barlev, Haddad 2003, pp. 383-415].

In accountancy the concept of value is defined otherwise, used within the meaning of being precious and expressed by a measurement formula relevant for the object. Most often it consists in giving the price or cost with reference to which a given object is presented in the accounting books of the entity. The source literature provides a few types of value used in the accountancy [Zadora 2010, p. 19-22]. It is the so-called good will, residual value and fair value [Fargher, Zhang 2014, pp. 184-199].

The problem of valuation of fixed assets exists in every enterprise, and one of the possible methods of estimation is valuation at fair value. Estimated values are disclosed in the financial statements. Fair value is a type of value used in accounting. In Poland, according to the Accounting Act, it is "the amount for which a given asset could be exchanged and the liability settled on the terms of a market transaction between interested and well-informed, unrelated parties" [Accounting Act].

Different definition is given in the International Financial Reporting Standards No. 13 - Fair value measurement. According to the IFRS cited, "this is the price that one would receive for the sale of an asset or would be paid to transfer the liability in a transaction carried out on normal terms between market participants at the measurement date" [IFRS 13 Commission Regulation (EU) 2018/1595 of 23 October 2018 amending Regulation (EC) No 1126/2008 adopting certain international accounting standards in accordance with Regulation (EC) No 1606/2002 of the European Parliament and of the Council with regard to Interpretation 23 of the International Financial Reporting Interpretations Committee]. IFRS 13 is used in many parts of the world, including the European Union, Hong Kong, Australia, Malaysia, Pakistan, the Gulf Cooperation Council countries, Russia, South Africa, Singapore and Turkey. All listed companies of the European Union have been obliged to use IFRS since 2005. According to IFRS and other national legislations, fair value is the result of a measurement based on market data. According to the standard, the determination of fair value consists in estimating the price of a given asset in a transaction carried out on ordinary terms. Depending on the type of asset, access to market information may be limited, which can significantly impede valuation [Walkiewicz, 2018]. As indicated by A. Mazur - fair value is a reflection of the likely price to be obtained on the market for an identical component to the one being measured [Mazur, 2011, p. 59; Gierusz 2017, pp. 207–219]. It should be noted that both of the above definitions relate fair value to the current market value of individual components of the balance sheet. The form of the verbs 'received by' and 'paid by' indicates that no real transaction is required to make a valuation. Such events do not occur, and the object being valued does not change ownership. It is still owned by an economic entity [Gierusz, Stepnowska 2018, pp. 143-163].

Fair value refers to the value used in accountancy which, according to the Accountancy Act and International Financial Reporting Standards, serves to evaluate, among other things, elements of assets. It is a reflection of the amount at which a given asset could be exchanged and the obligation settled in a market transaction, between interested and well informed, unrelated parties [Szczepankowski 2007, pp. 43-44]. The fair value constitutes:

- in case of financial instruments traded in an active market – the market price reduced by the costs connected with the transaction, if their amount was significant;

- the market price of financial assets held by the entity and financial obligations to be incurred by the entity – the current bid price in the market;

- the market price of financial assets to be purchased by the entity and financial liabilities incurred – the current selling price in the market [Szczepankowski 2007, p. 40].

In the Accountancy Act the historical cost principle is provided for the majority of the assets. The historical cost consists in the purchase price or the cost of manufacture, in compliance with the prudence principle. The reduced use value of the assets is taken into account, including also in form of depreciation and amortization write-offs [Mączyńska 2005, p. 40].

The cost of manufacture of a product includes costs directly related to a given product and a justified part of the costs indirectly connected with manufacture of such product. Direct costs include the value of direct materials used, the costs of acquiring and processing directly connected with manufacture and other costs incurred as a result of bringing the product to the form and place it can be found on the valuation date. The net selling price (value) of an asset shall be the potential selling price of such asset to be obtained as on the balance sheet day, less value added tax and excise duty, reduced by discounts, rebates and other similar reductions and costs connected with adjusting the

asset to sale and effecting such sale, and increased by a specific subsidy due [Ustawa o rachunkowości, 2019].

Apart from the historical cost, i.e. the purchase price or the cost of manufacture, the fair value of the assets listed below can also be used in their evaluation:

- real property and intangible assets,
- shares in other entities,
- shares in subsidiaries,
- short-term investments,
- liabilities.

In the Accountancy Act there is a concept of both market value and fair value. The market value is the possible price to be obtained in the active market, which means that the market value of a given asset can be determined if such asset is traded in the active market [Molenda 2008, p. 16-17]. Fair value is a wider concept than the market value, as it is determined by the market price formed in the active market, on which an authoritative evaluation of goods takes place, and in a hypothetical market when there is no active market for a given asset, i.e. in fact such market does not exist. The fair value is then a hypothetical value of the asset that would be obtained in the effective market provided that such market existed [Hasik 2007, p. 48-51]. The fair value is a value that would be obtained by a given enterprise in the conditions of market-based evaluation [Duliniec 2007, p. 72], and more generally, it is a value determined during casual negotiations between the parties to the transaction holding a full range of information.

According to A. Bieda, [Bieda 2009, p. 71] the fair value does not have to be comparable to the market value. As far as the majority of measures used in production is concerned, they even cannot be said to be equal since specialist devices are not the object of a purchase-sale transaction in a free market [Ronen 2008, pp. 181-208; Barth, Landsman 2018, pp. 49-58].

The challenge of fair value is the lack of an exact algorithm for its determination by the Accounting Act. However, the methods of its determination, possible valuation techniques and methods for determining its levels are presented in the International Financial Reporting Standards No. 13 - fair value measurement [International Accounting Standards IAS No. 13; Ball 2006, pp. 5-27; Iatridis 2010, pp. 193-204; Schneider et al. 2017, pp. 378-403].

The value of the enterprise versus asset-based valuation

As far as the enterprise is concerned, its multi-aspect value can be quoted, of diversified nature, depending on the way it is perceived. At the same time, it results from the fact that the process of valuation of the enterprise is presented as set of calculations, based on an individual nature of the assets of a given enterprise and on its financial results [Jaki 2000, p. 53; Sayed 2015, pp. 832-844].

As far as valuation methods of the enterprise are concerned, asset-based methods prevail. They help both in the valuation of individual assets and in the assessment of the value of the enterprise being a sum of their values. Asset-based methods need to be used as it is necessary to assess the value of individual assets or its organized part at purchase, sale, rental or lease transactions. Therefore, it is justified for the asset-based valuation method to be the first stage in the valuation of the value of the enterprise. Their essence consists in the assumption that the value of the enterprise equals the sum of

the values of tangible assets, i.e. the difference between the value of foreign assets and liabilities of the enterprise [Borowiecki 1997, p. 55; Farooq, Thyagarajan 2014, pp. 7-14].

Valuation of the assets in the enterprise

Valuation of the enterprise may comprise different scopes and areas. They are connected with different elements making up the value of the enterprise but also with corresponding determinants of such value. Additionally, factor that have a material impact on the scope and course of the valuation include its purpose, likewise its functions which are directly related to the nature of the parties making the valuation and the circumstances of such valuation [Jaki 2008, p. 40]. These elements enable to differentiate two attitudes to the assets and to the value of the enterprise [Borowiecki 1997, p. 25; Jaki 2000, p. 41]:

- as a material substance of the enterprise, i.e. elements reflected in the assets of the enterprise;
- as non-material elements, resulting from the level of organization of production measures and inputs in the enterprise which enable to use them, deciding thereby on the ability of the entity to multiply the capital invested.

In case of such apprehension of the assets of the enterprise the valuation may refer to its material elements, i.e. most often fixed assets or the enterprise as a whole, which comprises tangible and intangible assets. It seems that the assets of the enterprise can be evaluated independently, since it can be the object of a barter transactions in the market. On the other hand, in case of the other meaning the assets cannot be evaluated independently as it only exists in combination with tangible assets of the enterprise. Determining the value of a business is critical to many important managerial decisions. Because the future of any enterprise is uncertain, business valuations are rarely identical across analysts [Schill 2017].

The easiest valuation method of the enterprise is to use the information included in the balance sheet. The result of such valuation consists in the asset value of the enterprise which defines the current value of the capital to be spent in order to restore the assets of the enterprise indispensable in further operation [Biela 2000, p. 16; Khurana, Kim 2003, p. 19-42; Jenkins 2006, pp. 48-50]. Such attitude to the valuation is called the asset-based attitude. It is the oldest historical attitude, which not long ago was used in Poland as the only attitude. It combines the value of the enterprise only with its material substance.

The advantage of the asset-based valuation consists in relative simplicity, easy interpretation and comparison of the results of the valuation. It also includes disadvantages, among which failure to take into account development opportunities of the enterprise shall be the basic disadvantage [Zarzecki 1999, p. 54; Laughton et al. 2008, pp. 46-65]. The attitude does not distinguish good profitable enterprises and failing and loss-making enterprises. The results of the asset-based valuation do not depend on the surroundings of the enterprise, which has a significant impact on economic results. Asset-based methods consist in the valuation of fixed and current assets of the enterprise, irrespective of the level and effectiveness of use of such assets. The valuation is based on the reporting data concerning the assets of the enterprise and its sources i.e. the balance sheet. It is, among other things, the structure of assets and liabilities that decides on the value of the enterprise [Zadora 2010, p. 70; Pomykalski, Pomykalska 2007, pp. 283-284].

Income-based methods of valuation of the enterprise

Income-based methods of valuation of the enterprise are built on a theoretical background of efficiency calculus of the investment. The enterprise is the object of investments in accordance with the efficiency calculus despite should provide the investor with specific income in the future which

are defined as profits, dividends or cash flows [Mączyńska 2005, p. 93; Barth et al. 2014, pp. 297-327].

Income-based methods are based on the ability of the enterprise to create future income irrespective of the assets. The enterprise is worth as much income as it is able to generate in the future, no as much as it results from the said assets. The company can dispose of small property but many elements not presented in the financial statements may cause that the ability to generate income would be very significant [Panfil, Szablewski 2006, p. 40]. The most important financial measure used in the valuation of the enterprise with income-based methods consists in specification of free cash flows (FCF) [Gołębiowski Szczepankowski 2007, p. 133]. Cash flows consist in juxtaposition of receipts and expenditures of the enterprise connected with its operation within successive years of the settlement period and determination on their basis of a financial surplus that will be the basis of the valuation [Jaki 2008, p. 93-94; d'Amato 2015, pp. 207-219].

The literature distinguishes two fundamental types of cash flows [Gołębiowski, Szczepankowski 2007, p. 134; Szablewski, Tuzimek 2007, p. 149; Panfil 2009, p. 18; Piekkola 2016, pp. 28-51]. The first one is marked as ECF and consists in income generated by the company and coming from the operating activities, being the ownership of the company's owners, discounted by the cost of equity. The other type marked as FCF consist in income generated by the company and coming from the operating activities, being the ownership of both the company' owners, and lenders. They are discounted by weighted average cost of capital (WACC) [Szablewski, Tuzimek 2007, p. 149; Frank, Shen 2016, pp. 300-315; Ortiz-Molina, Phillips 2014, pp. 1-32].

Case study

The valuation of the enterprise started with the appraisal, which involve reporting data concerning property of the enterprise and its sources, i.e. the structure of assets and liabilities. The first valuation method applied referred to the net book value method which serves as a basis for the valuation using other asset-based methods. The net book value refers to the value of equity, in other words, it is a difference between the sum of assets and current and long-term liabilities [Maćkowiak 2009, p. 155]. The results of valuation using this method are presented in Table 1.

Table 1: Book value of the enterprise in years 2014-2018 [thousands PLN]

Specification	**Years**				
Years	**2014**	**2015**	**2016**	**2017**	**2018**
Fixed assets	12 937	12 740	17 321	60 611	199 506
Current assets	20 457	33 348	39 407	56 826	17 942
Fixed assets available for sale	-	-	-	-	19 040
Total assets	33 394	46 088	56 728	117 437	236 488
Equity	16 790	19 261	26 957	54 618	154 600
Foreign capital	16 604	26 827	29 771	62 819	81 888
Total liabilities	33 394	46 088	56 728	117 437	236 488
Book value	**16 790**	**19 261**	**26 957**	**54 618**	**154 600**

Source: own survey on the basis of data of enterprise X

Book value of enterprise X in years 2014-2018 was dynamically growing. In 2015 it increased by 15% in comparison to 2014, in 2016 by 25% in comparison to the previous years, in 2017 by 63% with reference to 2016, and in 2018 by 80%. Increase in the book value was caused by the increase in the book value of assets and significantly lower dynamics of increase in foreign capitals.

In the analyzed years, the sum of total assets increased, resulting from growth of fixed assets, while the value of current assets was growing until 2017, and then dropped. Decrease in 2018 was caused

by decrease in inventory, receivable and cash and separation of assets held for sale. The amount of equity was growing as well as the amount of foreign capital, however, not as dynamically as the amount of equity.

Net book value indicated the value of the enterprise specified on the basis of data included in the balance sheet, presented in the purchase price or cost of manufacture, taking into account depreciation in case of fixed assets. However, depreciation is not a market deduction which means that balance sheet values are not market values. In all valuations of the enterprises using asset-based method, always value corrected by market value of main assets and liabilities is taken into account.

In case of the enterprise being analysed, the value of corrected assets in the amount of 224,000 zloty was obtained after applying comparative attitude for the elements of fixed assets. The paper contains no calculations concerning market values as it is too extensive concept to be analyzed herein. For the purposes of this article, only fixed assets were corrected, current assets and liabilities were not corrected which results from a very good financial situation of the analyzed entity.

Following the definition, specific corrected values of the assets are correlated with their fair value. International Accounting Standards (IFRS 13) indicate three commonly used methods of measuring fair value. These are market, cost and income methods. To determine fair value, an entity uses measurement techniques that are consistent with one or more of these approaches.

Cost methods reflect the amount for which a given asset could be reproduced (often referred to as the current cost of replacement). This is the price that takes into account the cost incurred to acquire or construct a replacement asset with similar utility. In addition, this amount is corrected for loss of usefulness, physical consumption. [Bareja, Giedroyć 2016, pp. 9-18]. Very often the cost method is used to determine the fair value of tangible assets that are used in conjunction with other assets or liabilities.

It should be underlined that fair values obtained may have different impact on the recommended final value of the enterprise, depending on its financial situation. The obtained fair values may affect the recommended final value of the enterprise in various ways depending on its financial situation. Due to the fact that the net book value method, as well as other cost asset methods, value the company's fixed and current assets without directly taking into account the degree and effectiveness of using the assets, it is necessary to value income methods that take into account the effectiveness of the use of the assets.

As IFRS 13 indicates, the income approach is based on converting future amounts (e.g. cash flows or income and expenses) into one current (i.e. discounted) amount. When an income approach is used, the fair value measurement reflects current market expectations for these future amounts.

As the method of net book value of the assets as well as the other asset-based methods evaluate fixed and current assets of the enterprise without taking into account the level and efficiency of use of these assets, income-based method of valuation is required which take into account effective use of the assets. To this effect, free net cash flow method is used most in case of the enterprise.

Free cash flows refer to cash flow coming from the operating activity, adjusted by income tax paid (operating profit subject to income tax), increased by depreciation and increased or decreased by growth or decline in working capital and expenditures on new fixed capital. The advantage of such estimated cash flows is that they can be used freely by the owners of the enterprise to finance growth or (i) to reduce debt of the company, pay dividend or purchase own shares for redemption.

Cash flows for the analyzed enterprise have been calculated in table 2, using the following assumptions to the valuation using discounted cash flows method (FCF):

- tax rate shall be 19%,
- FCF shall be discounted by weighted average cost of capital,
- Fixed growth rate of 1% has been adopted.

FCF method is connected with financing of operating activities of the enterprise, its development and growth of value through equity and foreign capital. Specific group of entities, likewise the owners, is interested in forming the value of the enterprise X. Evaluating this value, free cash flow account was taken into consideration for all parties financing the activity of the enterprise, i.e. owners and creditors.

Table 2: Free cash flows FCF in 2018 [thousands PLN]

Year	**2018**
EBIT (Operating profit)	74 910
Depreciation and amortisation	296
EBITDA (Operating profit incl. depreciation and amortisation)	75 206
EBITDAAT (Taxed operating profit incl. depreciation and amortisation)	60 917
NOPAT (Taxed operating profit)	60 677
Current assets	17 942
Current liabilities	12 710
Change in net working capital	5 232
FCF (Free cash flows for the enterprise)	55 685

Source: own survey on the basis of data of enterprise

Free cash flows FCF in 2018 amounted to 55 685 thousand PLN. Using the value of free cash flows for the analyzed enterprise, in table 3 the valuation of enterprise X using discounted cash flow method.

Table 3: Valuation using FCF method [thousands PLN]

Years	**2019**	**2020**	**2021**	**2022**	**2023**	**>2023**
FCF	50 066	69 091	87 746	11 1 4378	141 526	
Fixed growth rate						1%
Cost of debt	5,8%	5,8%	5,8%	5,9%	6,0%	6,1%
Cost of capital	11,0%	11,1 %	11,1%	11,2%	11,3%	11,4%

Discounted FCF (PV)	45 556	57 100	66 105	76 391	87 876	
Residual value						1 415 255
Discounted residual value						341 275
Value of the enterprise	674 304					

Source: own survey on the basis of data of enterprise

According to the valuation using discounted cash flows method (FCF), the value of the enterprise X has been estimated at the level of 674,304 thousand zloty, provided that the existing development strategy shall be continued.

As a result of the valuation of the enterprise X with the use of various methods, different value of the enterprise has been obtained. The results obtained have been presented in table 4.

Table 4: Statement of the results of valuation of the enterprise X

Valuation method	Value of the enterprise [thousand PLN]
Net book value	154 600
Adjusted book value (fair value)	224 000
Discounted cash flows FCF	674 304

Source: own survey

The results in the evaluation using different methods included in table 4 present a very significant difference in the value of the very enterprise. The evaluated object X holds a very low property value (154,600 thousand zloty), a little bit higher value adjusted by fair values (224,000 thousand zloty), while a very high-income value (674,304 thousand zloty).

On the basis of practical calculation of the value of enterprises, in the event that the property value and income-based value significantly differ, most often the arithmetic average of those two values is calculated (mixed German method) or the average value of the property value and two income-based values (Swiss method). Table 5 presents calculations of the analyzed enterprise in German method.

Table 5: Final recommended value of the enterprise X [thousand PLN]

Valuation method	Value of the enterprise
German method	414 452
German method taking into account fair value	449 152

Source: own survey

If the asset-based valuation method used assets in the fair value, then, as far as the analysed enterprise is concerned, it would have a slight impact on recommended value for sale.

The purpose of calculation was to provide valuation of the enterprise X in case of negotiations in purchase-sale transactions. On the basis of the results obtained, it may be concluded that the limit price to be accepted by the buyer could be the value of the enterprise specified in a mixed attitude using German method.

Summary

Using the aforementioned valuation methods, the current value of the enterprise was calculated for the purpose of sale. The goal was achieved and precise results of valuation of the entity for sale were obtained, taking into account its asset value, which is much lower than the income-based value calculated on the basis of free cash flows.

However, consideration should be given how assets and liabilities calculated at the fair value, adopted for the purpose of valuation of the enterprise X, change the entire result of the valuation. The use of assets and liabilities at the fair value in the valuation may cause significant changes in the value presented in the financial statement on account of its variability. Followers of those using the

fair value state that such variability of valuation is the advantage since changes in the fair value reflect changes in prices and risk connected with a given asset, which could mean that they are better in presenting the real image of this entity [Molenda, 2008, p. 17].

Presentation of assets at the fair value provides the information on how much the entity would earn if it sold its net assets, although it still uses it in the operation activity. According to T. Gabrusewicz [Gabrusewicz 2009, p. 29], investors hoping to earn profits from dividends can ignore valuation at the fair value, presuming that the amount of dividend in a longer perspective would anyway depend on the final result upon sale of assets and settlement of liabilities. The result on sale of assets shall be finally dependant on its selling price compared to the price of purchase, i.e. the historical cost.

The aforementioned research shows that the fair value in the valuation of the enterprise has no significant role if the entity is in a good financial condition and obtains high income on sale and high profits. Then income-based value decides on its final value. However, it is not the case when the enterprise has no profits and its income-based value is negative or equal to zero. Then it is reasonably to estimate the property value with the use of the fair value in order to obtain the most probable value of such entity that is held for sale. Likewise, when the adjusted value of assets at fair values is significantly higher than income-based value. In such case the adjusted value of assets has a great impact on the final recommended value of the enterprise.

Safety Management in Quality Management Approach - The Context of Safe Working Conditions in Micro-, Small and Medium-Sized and Large Enterprises

Dorota KLIMECKA-TATAR

Czestochowa University of Technology,Faculty of Management, Czestochowa, Poland
d.klimecka-tatar@pcz.pl

Abstract

The purpose of this paper is to compare the assessment of occupational health and safety (OHS) management effectiveness in various size enterprises (micro, small and medium-sized, large enterprises). In the paper the results of research conducted among employees of enterprises from the manufacturing sector have been presented. The survey form were developed based on the interpretation of the safety management principles in analogy to the principles of quality management. It has been stated that the safety management in large enterprises usually work properly. Whereas in micro, small and medium-sized enterprises the safety management are completely unapplied and occupational safety issues (regulation, principles e.t.c.) are not treated properly. In micro-enterprises is often lack of health and safety policies, and employee knowledge in this area are negligible.

Keywords: Safety Management, Quality Approach, Quality Principles, OHS

Introduction

According to world statistics, the manufacturing sector is still the sector where accidents at work occur most frequently. Regardless of the industry of the enterprise, the risk of hazardous events occurring in manufacturing enterprises is the highest. The results of the number of accidents (also with fatal outcomes) are shocking (Chi et al., 2005; Yang and Jeong, 2019; Huizinga et al., 2019). However, these data result from the fact that in the production sector there is a continuous interaction between human and technical resources, processes are implemented by people using machines and devices of varying degrees of complexity (Hwang and Yoon, 2020; Kolbachev and Salnikova, 2018). Despite the applicable laws regarding the development of technical and commissioning documentation for all devices placed on the market, it is still assumed that the most common cause of accidents is improper (or inattentive) use of machinery by employees (Furci and Sunindijo, 2020; Cowing et al., 2004; Sanni-Anibire et al., 2020). One of the concepts of eliminating (or reducing the occurrence) of accidents is full automation and monitoring of processes, which is in line with the main assumptions of the Industry 4.0 revolution (Taylor et al., 2020; Hirsch-Kreinsen, 2016; Kagermann, 2015; Nelles et al, 2016; Haque and Oino, 2019; Ingaldi and Ulewicz, 2020). Interestingly, accidents at work occur for both more manual and automated processes. National and even international strategy for managing employee safety is to indicate the so-called 'national priorities', the observance of which is aimed at achieving short-term and long-term improvements in the field of safety management. The priorities are to (Burt, 2015): provide safe working conditions, effectively manage work safety, reduce high incidence and high severity risks, improve the capacity of business operators and workers to manage OHS effectively, prevent occupational disease more effectively, eliminate hazards at the design stage, strengthen the capacity of government to influence OHS (occupational health and safety) outcomes (Oswald et al., 2020; Lee et al., 2020; Hale, 2003; Burt, 2015; Lobanova and Tulenkov, 2019). Many production companies, despite a very strong emphasis on safety issues, still prefer the economic effect, effectiveness, efficiency and quality over the safe and hygienic working conditions of their employees. What's more, entrepreneurs, who know the main assumptions of multilevel enterprise management, put a lot of emphasis on ensuring quality as the

primary advantage - turning a blind eye to the safety issues of their employees. Occupational safety is as important as professionalism, resource availability, quality, costs and work organization (Hale et al., 1997; Aburumman et al., 2019). And since entrepreneurs are familiar with the principles of quality management, their can be tempted to interpret safety management in the context of the basic principles of quality management.

Methodology

This paper attempts to identify the level of safety management in various size companies. The level of safety management has been determined based on the opinions of employees of enterprises from the manufacturing sector. As research tool an anonymous survey (filled in electronically) has been used. Employees from enterprises in the manufacturing industry were invited to the study. Based on the completed metric, the employees have been divided into three groups, to unify the number of groups for analysis, 100 questionnaires from each group have been randomly selected:

Group 1 – 100 employees of large enterprises from the production sector,

Group 2 – 100 employees of small and medium-sized enterprises (SMEs) from the production sector (enterprises employing employees),

Group 3 – 100 employees/owners of micro enterprises from the production sector (enterprises employing only employees with family relationships).

All employees answered a series of questions. The questions contained in the form were developed based on the interpretation of the safety management principles in analogy to the principles of quality management (Table 1). Respondents were asked a number of questions (40 questions) about safe working conditions maintanance and safety management in the enterprise, but for the purposes of that study only 7 statements have been considered – statement that that best correlate with safety management in the quality management approach. The respondents rated the situation in their company by assessing factors on a scale of 0 to 5, where 0 meant: I totally disagree (this is not true), and 5 meant: I completely agree (it is true).

The general assumptions of quality management in an enterprise are based on eight principles. Table 1 presents the basic principles of quality management and their interpretation from the safety management point of view. As it can be seen, the interpretation of quality management principles in the context of safety management is relatively easy, because all areas of management are based on the same doctrines (Aziz et al., 2019; Ulewicz and Nový, 2019) . Therefore, the focus on employee safety in the context of the achievements of management sciences is to manage and supervise the organization in relation to employee safety, which is the most important element in the enterprise. Due to this approach, the principles that relate to the identification of employee requirements in the context of occupational safety should be constantly verified in terms of their compliance (Mullen et al., 2017).

The employees, absolutely, are the most important element of every enterprise, and their sense of safety as well as the awareness of safe and hygienic working conditions should be constantly strengthened (Mullen et al., 2017). Considering the aspect of occupational health and safety when planning resources means that infrastructure, environment, employees, information and other resources must be checked for their ability to meet OHS requirements – principle 1.

Regarding the best leaders - people do not notice their presence. Good leaders are respected and praised. Leadership is the ability to influence people by unleashing their strength and potential to enable them to strive for increased safety – principle 2. Furthermore, leadership is the art of motivating employees to achieve amazing goals. A good leader is a co-creator of vision and mission, but in their actions they do not avoid transferring responsibility and giving voice to employees. The main responsibilities of the leader are: creating a mission and vision, setting goals, planning resources, assigning responsibility,

controlling activities in goals achivement (Costa-Font and Ljunge, 2018). Leadership, therefore, is a process of planning, organizing, leading and controlling the activities of members of an organization and the use of all its other resources to achieve the objectives of OHS management. The leader ensures good relations and strengthens employee relations with the organization. They give them a sense of participation in something important and good. The leader allows employees to see in the organization something more than just a workplace, builds trust between the supervisor and the employee. Provides employees with safety and support in crisis situations (Cooper and Phillips, 2004; Guldenmund, 2000).

Employee involvement is based and is identified by: motivation, communication, organizational culture and teamwork (Cooper, 2000; Guldenmund, 2000). In the aspect of safety, it is nothing but respect for the rules in force in the company, cooperation and mutual care for health and safety at work and in the whole enterprise – principle 3. An employee is the most important value of any organization. And every employee should take part in creating safe working conditions. Involvement and commitment are the basic conditions for achieving a high level of safety in an enterprise.

The process approach focuses on the company presentation by a set of interrelated processes - the dependences of processes are determined by the need to achieve the organization goals. With regard to safety, it is primarily a model of information flow and the ability to apply safety procedures and instructions (Aziz et al., 2019). Documentation of the processes interdependencies should be based on: the impact of the process on the safety level, the reluctance of employees adaptation to the principles and culture of safety, general safety regulations, economic risk, and above all, the effectiveness and efficiency of operations – principle 4.

The system approach to OHS management consists in understanding and managing interrelated processes as a whole system - i.e. combining all activities into one working system – principle 5. This helps to increase the efficiency and effectiveness of the organization in achieving their goals. The system approach in safety management is particularly important in relation to physical and intangible flows. In this aspect, it is advisable to constantly monitor variables that have an impact on employee safety. And taking care of an appropriate level of communication between departments - in particular in the field of occurring dangerous and conducive events. To safety management in a system approach, one must: create a clear process structure, understand correlations between processes, integrate processes, eliminate organizational constraints, constantly improve the system by regularly measuring, monitoring and auditing (Li et al., 2020; Duijm, 2009).

Table 1: The basic principles of quality management and their interpretation from the safety management point of view

	Principles of quality management	**Principles in the context of occupational health and safety management**
PRINCIPLE 1		
	Customer orientation	Focus on employee safety - putting employee needs above economic, efficiency and productivity conditions
PRINCIPLE 2		
	Leadership	Leadership - being a role model in the aspect of care for work safety
PRINCIPLE 3		
	Employee involvement	Employee involvement in the implementation of the mission, vision and goals of safe working conditions
PRINCIPLE 4		
	Process approach	Process approach - documenting the interrelationships of processes aimed at

		maintaining safety
PRINCIPLE 5		
	System approach to quality management	System approach to safety management
PRINCIPLE 6		
	Continuous improvement	Continuous improvement - introducing additional safety systems, conducting regular trainings etc.
PRINCIPLE 7		
	Making decisions based on facts	Making decisions based on facts - legal documents, statistics and results of monitoring security parameters
PRINCIPLE 8		
	Mutual beneficial relationships with suppliers	*Not applicable*

Source: Own study

Continuous improvement in the field of health and safety provides not only efficient operation, but also the ability to cope with crisis situations (Bhuiyan and Baghel, 2005). Continuous improvement is based on the Deming cycle (PDCA) and consists in constantly raising the level of safety, often before the actual need arises – principle 6 (Jagusiak-Kocik, 2017). The elements on which the continuous improvement process is based are, first and foremost: safety policy, general and specific objectives of enterprises in the field of safety, corrective and preventive actions in the field of occupational health and safety management in the enterprise.

Decisions making based on facts requires constant monitoring of safety parameters, systematic collection of information, analysis of obtained data by use of reliable methods and forwarding the results to the right addressees, responsibility transfer to a person with an appropriate level of safety competence – principle 7. The process of data collection should extend to the both internal and external information. Internal information primarily are: the results of the processes and products safety measurement, effectiveness indicators, results of employee evaluation e.t.c. As external information, helpful can be: national and global statistical data, research results on the expectations of safety levels e.t.c.. An organization that wants to implement the philosophy of effective OHS management must remember about the proper way of collecting data and presenting safety data. Despite the fact that many management specialists are skeptical about the necessity of conducting measurements, considering them to be time-consuming and bureaucratic, they mainly give the opportunity to check goals with achieved results, constituting a challenge and motivation to improve.

The principles of health and safety management are based primarily on legal regulations, but it should be remembered that the specificity of company management directly determines the safety of the employee. Therefore, it is very difficult to generalize the way of management in enterprises, e.g. in the manufacturing or service sector. It is also very difficult to generalize the management assessment method in enterprises of various size with different levels of process automatization. The purpose of this paper is to compare the assessment of OHS management methods by employees of various size manufacturing enterprises (micro, small and medium-sized, large enterprises).

Results and Discussion

Tables 2-4 present the structure of rates awarded by employees of micro, small and medium-sized enterprises (SMEs) and large enterprises. Based on experience and opinions, employees assessed the statements that best correlate with safety management in a quality management approach:

1. My safety (as an employee) is the most important thing at work.

2. My supervisor is a role model in respect of compliance with the OHS principles.
3. Together with other employees, we care about ourselves and others' safety.
4. I pay special attention to the relationship between safety and efficiency of work.
5. All OHS recommendations at positions are documented and easy to interpret.
6. The company is constantly introducing new safeguards to guarantee safe working conditions.
7. Changes in OHS management are made on the basis of data and statistics.

Table 2: Assessment structure for OHS management principles - according to employees of micro enterprises

For comparison the employees of micro, small and medium-sized enterprises and large enterprises ratings and perceptions, based on the results presented in Tables 2-4, the charts have been constructed (Fig. 1-7). Regarding the principle 1 (Focus on employee safety), regardless of the size of the enterprise, employees have doubts about the priority of their safety. At the same time, employees of large enterprises gave the highest scores at level 4. Employees of micro enterprises gave the most answers 2, this is due to the fact that very often the employee is the owner and manager of the company (Fig. 1).

Source: Own study

Fig. 1: Comparison of the assessment structure for the principles of health and safety management - according to employees, micro, small and medium-sized enterprises and large enterprises. Statement 1 (regarding principle 1): My safety (as an employee) is the most important thing at work

A similar uncertainty and lack of unanimity is observed in the case of principle 2 (Leadership). Employees, regardless of the type of enterprise, are not convinced that their supervisor is an example to follow in terms of compliance with health and safety rules. The worst were assessed supervisors by employees of small and medium-sized enterprises, as many as 36 votes at level 0. In the case of large enterprises, the votes are evenly distributed between rates 3, 4 and 5 - so it can be said that supervisors make every effort (although not always effectively) to be a role model for their subordinates (Fig.2).

Fig. 2: Comparison of the assessment structure for the principles of health and safety management - according to employees, micro, small and medium-sized enterprises and large enterprises. Statement 2 (regarding principle 2): My supervisor is a role model in respect of compliance with the OHS principles

With regard to principle 3, it can be seen that employees of large enterprises are most aware of the safety behavior, care of themselves and other colleagues safety. In this case, the highest 5 rate has been given by as many as 57 employees, while the lowest has not been awarded at all. An interesting tendency is observed for the next principles (Figs. 4 - 7) of those related to system and process safety management (the domain of well-organized enterprises). It is observed that the responses of employees from large enterprises tend to take on higher values, while in micro enterprises, principles 4, 5, 6 and 7 have been rated low. This demonstrates the extensive safety management system in large enterprises. Whereas low ratings from employees of micro, small and medium enterprises show that the OHS management system is not working properly. Critically low grades awarded by employees of micro-enterprises are proof that occupational safety issues are not treated properly in these enterprises. In micro-enterprises is often lack of health and safety policies, and employee knowledge in this area are negligible.

Fig. 7: Comparison of the assessment structure for the principles of health and safety management - according to employees, micro, small and medium-sized enterprises and large enterprises. Statement 7 (regarding principle 7): Changes in OHS management are made on the basis of data and statistics

The summary of the results presented in the tables and figures is a radar chart for average ratings of all discussed principles, for three sizes of manufacturing enterprises (Fig. 8). In general, it can be seen that the approach to health and safety management looks the worst in the case of micro enterprises - average ratings range from 0.7 to 2.6, none of the averages exceeded 3, which could indicate compliance with the minimum health and safety requirements. On the other hand, employees of large enterprises received significantly higher grades and average values for individual principles range from about 3 to over 4 - which indicates the fulfillment of OHS requirements. For SMEs, the average grades are strongly differentiated, to clearly state whether these enterprises meet the requirements of OHS, it is necessary to conduct in-depth research, which are carried out by other authors (Niciejewska and Klimecka-Tatar, 2018).

Source: Own study

Fig. 8: Comparison of average ratings for the principles of health and safety management - according to employees, micro, small and medium-sized enterprises and large enterprises

The limitation in this study was, that despite the fact, the respondents are employees of enterprises from the production sector, the survey did not examine the degree of automation of production processes and the strength of the impact of human labor on the production process. The further development of research work, research can be expanded to include a technological factor, i.e. determination of the technological level based on known management tools in relation to the literature (Ingaldi and Zhuravskaya, 2018).

Conclusions

Based on the analysis, it can be clearly stated that it is possible (and relatively simple) to interpret OHS management principles in relation to the principles of quality management, however, this requires a horizontal transfer of customer needs to the employee's needs. On the other hand, on the basis of presented results, the employees' perception of OHS management in enterprises from the manufacturing sector has been assessed - the perception of micro, small and medium-sized enterprises and large enterprises employees'. It has been noted that with respect to the general principles of safety, all employees, regardless of the size of enterprise, have mixed feelings about the importance of their safety, and supervisors are not always a role model in safety issue. Immediate differences have been noticed in relation to the principles of safety management, which are mainly based on management in process and system approach. In this case, high rates awarded by employees of large enterprises clearly indicate, that in large enterprises the occupational health and safety management system works best. In large enterprises processes are properly planned and documented, and all safety parameters are constantly monitored and form the basis for changes implementation. While, the low rates awarded by employees of micro enterprises indicate that this is far from the minimum fulfillment of the requirements in the scope of proper OHS management.

Based on the presented results, it is generally recommended to: increase knowledge on occupational safety at all levels, introduce of trainings enabling hatching leaders in the field of health and safety, build pleasant trust between employees and inform about mutual responsibility for safety. Whereas, in particular form micro and small and medium-sized enterprises are recommended to: build a culture of safety based on legal regulations and plan processes in relation to the principles of systemic management in the field of occupational health and safety.

How to Study Complex Social Phenomena in The Organization?

Agnieszka KOWALSKA-STYCZEN

Faculty of Organization and Management, Silesian University of Technology,
41-800 Zabrze, Poland,
E-mail: agnieszka.kowalska@polsl.pl

Abstract

In this article, the way of conducting research on complex social phenomena in an organization is shown. The basic assumption in the proposed concept is that the organization is a social system, and consequently a complex adaptive system (CAS). In such systems, understanding the local dynamics of the system is important because it allows insight into the behavior of the entire system and identifies key reasons for changes. The whole concept is based on inductive reasoning ("bottom up" approach). As a research method, simulations using agent-based model (ABM), were proposed, because firstly ABMs show a lot of similarities to the social systems, secondly they allow to study systems dynamics based on local interactions of their elementary units (individual agents or networks of agents)

Keywords: Organization, Social System, Agent-Based Model, Complex Adaptive System, Simulation

Introduction

Complexity concerns both physical, biological and social systems. Each of these fields of study develops tools for studying complexity, and many of these tools can be universally applicable. An example is the recently intensively developed econophysics, where for the needs of economics the latest concepts and methods of physics are used, such as: critical phenomena, scaling, fractals, multifractals, deterministic chaos (chaos theory), turbulence theory, complex networks, agent models. It is also quite popular to transfer to the field of social and economic research models from synthetic biology, which aims to design and create artificial biological systems modeled on natural ones. As a result, we are witnessing the integration of knowledge from many disciplines: physical sciences, social sciences and humanities.

Studies of complex systems at the border of various fields can be summarized in the following main areas:

1) **complex adaptive systems** studied at the Santa Fe Institute (SFI) in the USA mainly by Kauffman (1993, 1995, 2000), Holland (1995, 1998), Langton (Waldrop 1992), Gell-Mann (1994), and in Europe by Goodwin (1995); Axelrod (1990, 1997; Axelrod & Cohen 2000); Bonabeau et al (1999), Axtel and Epstein & (1996);
2) **far-from-equilibrium** and **dissipative structures** developed by Prigogine and Stengers (1984), Prigogine (1990, 1997), Maturana and Varela (1992) and Luhmann (1990);
3) **autopoiesis theory** studied by Maturana in biology and transferred to social systems by Luhmann (1995);
4) **systems theory, cybernetics, social network theory** and other work in social systems and management (Maguire and McKelvey, 1999a, 1999b; Parker & Stacey (1994) and Stacey (1995, 1996, 2000, 2001).

All these areas relate to the complex systems attributes, but present different approaches to defining them. This article uses theories of complex adaptive systems (CAS) because this approach is consistent with the proposed way to study social phenomena in an organization based on computer modeling. The basis for researching organizations in the context of CAS is the perception of

organizations as a complex social system. Numerous studies in the field of social sciences indicate that individuals are embedded in the networks of social relations and interactions (Borgatti, et al., 2009). Such a situation also occurs in organizations perceived as social systems. The organization as a social system is a group of people who cooperate on the one hand in an orderly and coordinated (institutional) way to achieve a certain set of goals but on the other hand participate in informal mutual interactions resulting from individual characteristics and rules of behavior. Such social systems also show features of complex adaptive systems (CAS).

According to Plsek and Greenhalgh (2001), CAS is a collection of individual agents with freedom of action, which is not always entirely predictable. In addition, agents are so connected to each other that the behavior of one agent changes the context for other agents. As emphasized by Mille and Page (2007) in CAS there are therefore units at the micro level that, through mutual interactions, form global system properties, which then, by feedback, affect the interaction at the micro level. In addition, CAS through interaction with the environment modifies its behavior, adapting to changes in the environment (Rammela et al., 2007; Rotmans and Loorbach, 2009). This behavior of the system is a manifestation of its adaptability. Complex adaptive systems are also characterized by co-evolution, self-organization and emergence (Mitleton-Kelly, 2003). Kauffman (1995) defines co-evolution as a process of coupled, deforming landscapes, where the adaptive movements of each individual change the landscapes of the neighbors. These landscapes are states of factors determining the behavior of individuals at the micro level. Adaptive movements of individuals, on the other hand, are the effects of agents' interaction (e.g. changes in attitudes, views, etc.) referred to as co-evolution. The effect of these changes at the level of the entire adaptive system is co-evolution with its environment, i.e. responding to changing external requirements. The characteristic feature of CAS is also self-organization, a phenomenon in which elements of the complex system undergo spontaneous order. This arrangement is the result of independent interactions between individual agents within the system and iterations of agents with the environment (Mainzer, 1994). It is a process in which the internal organization of a complex system increases complexity without being managed by an external source (Rotmans and Loorbach, 2009). The phenomenon characterizing the CAS is also emergence. The system has emergent properties if its presence is new at the evolutionary level or at the physical level of the complexity of the system in which it occurs (Newman, 1996). It is the emergence of new and consistent structures, patterns and properties in the processes of self-organization occurring in complex systems (Goldstein, 1999).

Bearing in mind the above features of CAS, it can be concluded that most organizations are characterized by a set of attributes and special behaviors typical for such systems. First of all, the organization is a relatively large group of related elements (agents) that enter into various interactions with each other. They are rather intense and non-linear (with multiple feedbacks), which means that each organization member affects many others and vice versa. Furthermore, the influence of even one person or small group can cause significant changes in the entire spheres of the organization's activity. In addition to basic interactions (mainly with members of the same substantive teams, informal groups) members of the organization also react to information flowing directly or indirectly from the environment. The organization is therefore an open system. Organization members are autonomous units that can themselves initiate activities without external management and control. Between these units, there is interaction through various forms of communication. They also have the ability to learn, through which they are able to adapt by modifying their individual capabilities and changing their operating principles to improve their performance. These characteristics and behaviors of agents (organizational members) affect adaptability, self-organization and co-evolution of the social system that is the organization. Because it is difficult to predict the effects of interaction at the micro level for the organization as a whole, even if the behavior patterns of individual organization members are known, then the behavior of the organization as a whole is emergent.

It should also be noted that in such systems rules at the local level, i.e. at the level of individual units or networks of units, as well as the way they interact, are often more important than global directives. In addition, as Sanders and McCabe (2003) show, understanding of the local dynamics of the system can allow insight into the behavior of the entire system and help identify key reasons for changes and transformations.

The purpose of this article is to build tutorial: how to study complex social phenomena in an organization?. The following paragraphs of this article therefore show:

- adequate reasoning in the case of CAS study
- computer modeling (agent-based modeling) as a CAS research tool
- the way to build, verify and validate the agent model
- steps of agent-based model creating
- example of the use of the proposed approach

Type of reasoning used to study complex social system

The basis of the CAS analysis and the study of social processes occurring in complex systems is an attempt to explain the behavior of the entire system (at the 'macro' level) based on the recognition of the rules of behavior of its constituent elements (the 'micro' level). Therefore, it is necessary to think about an appropriate way of inference that realizes such a research perspective. The most popular types of inference used in social sciences, and in particular in management sciences is deduction and induction. Both these types of reasoning, as shown in the work of Trochim (2010), have their terms used informally. Deductive reasoning is sometimes called “top-down” approach, and it works from the more general to the more specific. Inductive reasoning moves from specific observations to broader generalizations and theories and informally is called "bottom up" approach. The ideas of both types of inference in this sense are shown in Figure 1and 2.

In the study of the organization in the context of CAS, the 'induction' perspective is particularly interesting (Fig. 2), because on the basis of knowledge about system elements on the micro level it allows to explain the behavior of the entire system on a macro level, as opposed to the deductive reasoning where, on the basis of knowledge about the system (and its operation) at the macro level, conclusions are drawn about relations and factors explaining behavior, usually without referring too deeply to its basic elements (Fig. 1).

Fig. 1: The idea of deductive reasoning (Trochim, 2010)

Fig. 2: The idea of inductive reasoning (Trochim, 2010)

Computer modeling as a tool for studying a complex social system

Choosing the right way to research and analyze complex social systems, attention should be paid to limitations that the nature of such systems causes. These limitations are as follows:

- a large number of basic elements of such systems (agents), hence also a large number of interactions
- the high complexity of real organizations/institutions (study too many aspects at the same time is actually not possible)
- the need to take into account changes in time, limits the ability to analyze the dynamics of real-world behavior in the long-term
- in real conditions, it is not possible to carry out factor experiments (properly designed) that allow to check the hypothesis of the investigator or search for causal relationships that combine behavior at the micro level with the behavior of the organization as a whole.

The answer to these restrictions can be computer modeling which is a practical implementation of the computational paradigm (Hoekstra et al. 2010). The appearance of this concept is associated with the development of IT technologies and concepts after the Second World War. The origins of the computational paradigm date back to the analysis of Alan Turing (1950) and concern artificial intelligence. Turing's research leads to the assumption that artificial cognitive systems with discontinuous states have cognitive abilities qualitatively identical to those of natural entities.

The computational paradigm plays a fundamental role in situations when precise, analytical descriptions of the observed phenomenon are unavailable or are beyond the scope of direct experimentation. Such a situation refers complex systems - especially social ones. For example, many real characteristics of relationships between people (agents) can be identified, but it is practically impossible to conduct a factor experiment that examines the course of the effects of such relationships in real time in real communities.

Computer modeling mentioned earlier is also called computer simulation, which is understood as the process of building a model of a specific, real object (system) and conducting experiments based on this model (Anderson, 1999). It is an abstract model implemented into a computer program.

The importance of the simulation approach in the organization's research was emphasized by Burton (2003), who describes it as a computational laboratory. In his opinion, it is a way by which it is possible to:

- asking questions about the behavior of individual agents or teams, including for information processing and communication in the organization, the results of various organizational processes, the influence of the organizational context and environment

- building a computational model that relates to the question
- design and conduct an experiments, the results of which can be used to solve the problem (answers to the questions asked)
- answer the questions asked, or at least refer to them

As it was emphasized earlier, the social system is described by individuals who react to each other and the environment (agents act according to established rules, cooperate with each other and learn). The answer to such a system can be a computational laboratory based on agent-based modeling (ABM). Agents (actors) in such models (as in real social systems) interact and influence each other, learn from their experiences and adapt their behavior to the environment (Macal and North, 2010). They can represent people, but also companies, organizations or states. In addition, what is important, ABM is a simulation, which involves the study of system dynamics based on local interactions of their elementary components (Gotts et al., 2003). It is assumed that the behavior of the system can be explained bottom-up, through a dynamic analysis of local behaviors, i.e. the interaction between elementary components of the system (Miller and Page, 2007). These are therefore analyzes based on an inductive (bottom-up) way of reasoning.

The method of building an agent model to study social system

A typical agent-based model consists of three elements (Macal and North, 2010):

1) a set of agents, their attributes and behaviors;
2) a set of relationships and methods of interaction of agents (i.e. how and with whom agents interact);
3) spatial environment of agents (agents interact with their environment in combination with other agents).

In ABM, agents have states that varies over time. An agent's behaviors are conditioned on its state. The richer the set of an agent's possible states, the richer the set of behaviors that an agent can have. Agents have rules for interaction with other agents. These rules apply to communication, movement, the capability to respond to the environment, and others. Agents are autonomous because there is no central behavior control, and agents can act independently in their environment and interact with other agents. Depending on the context of the research, they may be homogeneous, that is, they react according to the same behavioral patterns or heterogeneous, i.e. they can be distinguished from other agents and they are also recognizable by other agents. Agents interact in a certain social environment consisting of a network of interactions with other agents on which they influence and are at the same time under their influence (cooperate and compete with each other). Information exchange between agents can be direct or indirect. Although the agent-based models do not have a central authority that sends information to individual units, this does not exclude the possibility of receiving information from a management authority and responding to it. Agents obtain mainly information from their neighbors, whose set may change, e.g. as a result of spatial movement of agents. It is a neighborhood in a physical, geographical or defined by the social network of the agent. These features of the ABM indicate similarity with the social system. They can be summarized in the following way in Table 1.

Table 1: Similarities between agent-based model (ABM) and social system

	ABM	Social system
Basic units	Agents/cells	Individuals/ people
Environment	Spatial environment of agents, most often a two-dimensional network/lattice	Groups of people, families, teams, workers' groups, etc.
Possible states	The agents are in states taken from a certain set of possible states	People make certain choices, take certain attitudes and emotional states

Interdependence	Agents affect other agents and are at the same time influenced by them	Individuals affect each other mutually
Level of impact	The level of impact is determined by the rules of interaction. Agents interact mainly with their neighbors, but they can also receive information from the system or some central authority	People interact and influence each other directly locally in a certain environment, but they also undergo external influences, authorities
Applications/Possibilities/Tasks	Agents adaptation. Patterns, structures, and behaviors emerge that were not explicitly programmed into the models, but arise through the agent interactions. The emergence of self-organization, macro effects explained by rules at the micro level	To understand the phenomena occurring in social systems, it is important to: understand emergences, adaptations, understand micro and macro-trends, understand social dynamics

As shown in Table 1, ABM show many similarities to social systems, which is why social phenomena can be modeled in an artificial agent environment, which is also underlined by Macal and North (2010), Fioretti (2012), Smaldinoa et al. (2012), Sajjada et al. (2016), Li and Xiao (2017). The importance of agent-based model is growing due to the dynamic development of computational techniques. However, despite the growing availability of software, the agent-based models in organizational and management sciences are rarely used. Therefore, to facilitate the use of agent-based model (ABM), the exact steps of model creating are proposed in Table 2. The table, in addition to the steps of agent's model creating , contains questions that should be asked in each phase of the model construction. The proposed classification uses the Macal and North (2010) and Johnston et al. (2012) approach, but also simulation research Kowalska-Styczeń et al. (2018a), Kowalska-Styczeń et al. (2018b), Kowalska-Styczeń, A. Owczarek, T. (2017), Paradowski et al.(2018).

Table 2: Steps of agent-based model (ABM) creating

Steps **The following elements must be defined:**	**Questions to ask when ABM is formulating**
Goal	What is the research problem (research hypothesis)? Why was this type of modeling chosen? What specific questions should the model answer to? What will we consider a satisfactory end result?
Agents	How will the agents be represented on the network? What types of agents will be used in the model (one type or several types)? Who or what will be represented by individual agents?
Properties, attributes for agents	What states will the agents be assigned in the next steps of simulation? With which agents (cells), individual agents will interact? Is agents movement on the network possible? What will the agent's environment be defined?
Rules for agents	What will be the possible actions of each agent? What or who will influence agents' decision making? What sources of information will be used by agents

	in the decision-making process? How do the agents interact with each other? How do the agents interact with the environment?
Simulation steps and duration of the simulation	What will the time interval of each next step of the simulation be? What will the duration of the simulation be? Will the results be averaged after a certain number of simulations?
Model verification and validation	How will it be possible to check the correctness of the model, especially the behavior of agents and mechanisms of interaction between them? Will empirical data or knowledge about the modeled phenomenon be used for verification and validation?

As you can see in table 2, the construction of the ABM requires a thorough understanding of the modeled phenomenon and consists of many stages. However, such a thorough analysis of the examined problem allows to create a theoretical model, which is then implemented as a computer program. The results obtained during simulation using a computer program must be verified and validated. Verification is checking the adequacy between conceptual models and a computer model, while validation is ensuring that both conceptual and computer models are an appropriate representation of the theory or phenomenon being studied (David, 2009). In the case of social simulation, the verification methods include (David, 2013):

- **dynamic methods** that rely on checking the computer program through various ranges of input parameters (obtained in this way results allow to determine whether the model is appropriately programmed)
- **static methods** that focus on the analysis of the static representation of system elements (mainly on the detection of program code errors) and are aimed at showing that the computer model adequately performs its tasks without software flaws.

In the case of validation, it is important whether the goal of the model is prediction or explanation. In the context of social simulations, prediction is quite a difficult task, because social systems are characterized by complexity, non-linearity and high sensitivity to initial conditions. Therefore, the purpose of social simulations is mainly to explain modeled phenomena. In this case, the validation consists in showing that the mechanisms created in the model by simulation are able to reproduce real-like behaviors. The aim of validation is first of all to assess whether the structure of mechanisms at the micro level allows the creation of macro-level effects consistent with known theories or qualitatively and quantitatively convergent with real data (David, 2013).

The proposed simulation approach was used in the works Kowalska-Styczeń et al. (2018a), Kowalska-Styczeń et al. (2018b), Kowalska-Styczeń, A. Owczarek, T. (2017), Paradowski et al.(2018).

Below, in table 3, an exemplary ABM describing the transfer of knowledge was shown in the form of the proposed in table 3 approach. Details of the simulations carried out using this model can be found in the works: Kowalska-Styczeń et al. (2018a), Kowalska-Styczeń et al. (2018b), Paradowski et al.(2018). These articles use the special case of ABM - cellular automata. The concept of a cellular automaton was introduced in the 1940s by John von Neumann, while the practical application of AK is associated with the development of computers in the 1980s and with the popularization of this tool by Wolfram (2002).

Table 3: Steps of knowledge transfer model creating

Steps The following elements must be defined:	Answers for the created ABM model
Goal	What factors influence the efficiency and effectiveness of knowledge transfer in the organization?
Agents	Members of the organization (employees) who are represented by cells of the square lattice of cellular automaton. Each agent can be a leader of knowledge or a follower. In a single interaction, an agent who has more knowledge (more chunks) is the leader of knowledge. Each agent has the ability to have each K portion of knowledge with the probability q
Properties, attributes for agents	Each agent can be a leader of knowledge or a follower. The transferred knowledge is divided into a number of knowledge chunks. In a single interaction, an agent who has more knowledge (more chunks) is the leader of knowledge. Each agent has the ability to have each K chunks of knowledge with the probability q.
Rules for agents	Each agent in each step of the simulation t can receive one chunk of knowledge from one of his neighbors. Transfer in time t is possible, if in time t - 1 neighbor of the selected agent has exactly one chunk of knowledge more than himself. Initially, the missing chunk of knowledge is drawn randomly, and then a neighbor with a knowledge distance equaling one is sought. If such an agent exists in the neighborhood, then knowledge transfer takes place.
Simulation steps and duration of the simulation	A single simulation is carried out until the stable state of the system is obtained (i.e. the state in which agents do not change anything in the system). The results were averaged usually after 100 such simulations
Model verification and validation	Model verification consisted in checking various ranges of input parameters and observing the behavior of the system. The validation of the model consisted in assessing its compatibility with knowledge in the field of psychology, management and research on knowledge transfer. Simulation results were also compared with the results of empirical studies by Fleming et al. (2007) and Coleman (1988).

Summary and conclusions

An organization is a multidimensional, multi-faceted and complex system, especially an organization considered in the context of the social system.

Undoubtedly, this state of affairs is the impulse to look for specific tools that allow analyzing and describing processes taking place in organization. A new direction is attempts to combine the presented perspectives of analysis within the complex systems theory. The theory of complex systems, developed initially in the spheres of physical and biological sciences, in its essence is aimed at modeling and explaining the behavior of systems of interrelated objects based on the knowledge of

the rules of individual elements (on the local level) and structures (networks) of their connections. Understanding the behavior of a complex system therefore requires understanding not only the behavior of its part, but also understanding how they work together and how they create the behavior of the whole. Therefore, it seems interesting to use computer tools developed on the basis of complexity theory, especially agent-based models.

The importance of simulation, and in particular agent models is growing due to the dynamic development of computational techniques. However, despite the increasing availability of software, attempts to use agent models in organizational and management sciences are scarce. In order to fill this gap and identify new possibilities of analyzing social phenomena in the organization, in this article the methodology of conducting simulation studies of complex social processes was developed.

Approaches for The Russian Competitiveness Improvement in The World Through Sustainable Development of Human Capital

Ekaterina Sergeevna NOVIKOVA

Plekhanov Russian University of Economics, Moscow, Russian Federation
eknov1981@gmail.com

Abstract

The aim of this research paper is the identification of human capital role in the sustainable economic development of any country in the changing world. This paper includes the overview of general current trends in the world, influencing on further development of countries and its competitiveness level to each other. Based on the literature review the role of human capital has been outlined and its involvement in different rankings has been studied. The target of this paper is the understanding of development track for the Russian economy through reforms in human capital area with attraction of investments, efficient cooperation with trade partners and sustainable policy of a government. As a result, several rankings have been analyzed and required proposals for the Russian economy have been revealed.

Keywords: Higher Education, Social and Economic Indicators, Competitiveness, Digitalization, Innovativeness, Economic Growth, Human Capital Development.

Introduction

Recently the world has changed dramatically influenced by global financial crisis initiated in USA and covered almost all countries around the world through international trade and international division of labor. The world society meets the issue of further capital accumulation or sustainable economic development of any country with scarcity of resources and markets in the world scale (Akhmadeev et al, 2019).

Such problem has its influence on the trade interaction among countries through sanction policy, trading wars by whole regions as USA and China, USA and EU, USA and Russia, etc. The allocation process of numerous financial flows among strategic companies in key world economies with a target to develop and launch new technologies and cover more markets is a consequence of aggressive policy by leading countries. As a result, government debts to the annual GDP indicator of many countries have grown exponentially. For example, Japanese debt to GDP is 238%, Italian – 134%, American – 106%, French – 98%, etc. (Table 1).

At the same time, this is important to analyze the debt of these countries to the whole world debt both in percent and in absolute numbers. Thus, the first ten countries are USA (31% of the whole world debt), Japan (17%), China (9, 8%), Italy (4%), France (3,9%), UK (3,5%), Germany (3,5%), India (2,7%), Brazil (2,4%), Canada (2.2%).

Table 1: World debt by countries, %

Place in the ranking	Country	Government debt to GDP of a country, %	Government debt in absolute numbers, US dollars	% of the world debt
1	USA	104,3%	21,465	31%
2	Japan	237,1%	11,788	17%
3	China	50,6%	6,764	9,8%
4	Italy	132,2%	2,744	4%
5	France	98,4%	2,736	3,9%
6	UK	86,8%	2,455	3,5%
7	Germany	61,7%	2,438	3,5%
8	India	68,1%	1,851	2,7%
9	Brazil	87,9%	1,642	2,4%
10	Canada	89,9%	1,540	2,2%
11	Spain	97,1%	1,386	2,0%
12	Mexico	53,6%	655	0,9%
13	South Korea	37,9%	652	0,9%
14	Australia	41,4%	588	0,8%
15	Belgium	102%	543	0,8%

Source: https://www.visualcapitalist.com/69-trillion-of-world-debt-in-one-infographic/

At the same time, China is increasing its influence in the world GDP based on purchasing power parity: the share of Chinese economy was 25,4 trillion US dollars or 18,6% and American economy – 20,5 trillion US dollars or 15% accordingly (Table 2).

Table 2: Position of a country in the ranking by GDP based on PPP, trillion US dollars

Place in the ranking	Country	GDP based on PPP, trillion US dollars	Share in the world GDP, %
1	China	25,4	18,6
2	USA	20,5	15,0
3	India	10,5	7,7
4	Japan	5,5	4,0
5	Germany	4,5	3,3
6	Russia	4,0	2,9
7	Indonesia	3,5	2,6
8	Brazil	3,4	2,5
9	US	3,1	2,3
10	France	3,1	2,3

In conjunction with the growing debt of leading economies, fundamental changes in the structure of global value chains have occurred. There was a shift in the export of goods and services from industry to services. During last 10 years the share of services has increased in 0,4% in the whole world volume of export, then the share of industrial goods has decreased in 1,2% and natural resources – in 0,6% accordingly (Lehoux et al, 2019). At the same time, the sector of services includes IT and telecommunication (7,8% of world GDP), business services (5,3%), patenting (5,2%), financial and insurance services (3,2%), and transport (1,7%) (Morozova et al, 2019).

Due to some changes in the structure of world economy based on GDP and trade turnover between countries, and additionally global trends in the field of digitalization and automation in majority of production processes in goods and services, there is an issue on competitiveness level of key world economies based on the development of human capital (Dorofeev et al, 2018). In accordance with last

data of Word bank the structure of common wealth in Russia in 2017 includes the human capital (46%), production capital (33%), natural resources (20%) and net foreign assets (1%). The share of human capital in average in OECD countries is 70%, and this indicator is higher in 24% than in the Russian economy. Such difference in the development of human capital is the main indicator in further analysis of competitiveness level of Russian in comparison with leading world economies (Yukhimov et al, 2002).

Thus, the target of this research paper is to reveal weak points in further development of human capital development for competitiveness level improvement of Russia within the world economy.

Literature Review

Research papers on the development of human capital and its influence on the economic growth of a country have been appeared several decades ago, but only today, the role of a human being has been raised due to digitalization and automation trends. Researchers have revealed main 5 stages of economic development and human capital: pre-industrial, mass education, late industrial, first and second post-industrial stages (Anikin, 2017).

The pre-industrial stage (up to the end of 18th century) can be described by the development of agricultural sector without additional investments in the educational process of a society. During the second stage or mass education of population (first decade of 20th century), there is a new concept formation of a human capital by creation of qualified human resources. And during post-industrial stage (end of 20th century) intangible assets have a crucial role in the economic development of a country. This is a reason why skills and abilities of human beings are the factor of competitiveness for some countries in comparison with others (Becker et al, 1962). The special attention pays to the professional education for adults, but the main investor in the human capital level growth is the government (Schults, 1961).

Within development of first and second post-industrial stages from the end of 20th century to date there was seen the importance of development and influence of additional factors besides educational level on a person progress, including a family quality, preschool education, communication, etc. (Heckman et al, 2010). Moreover, some researchers are considered such resources as social capital (Augusto et al, 2014), cultural capital (Bourdieu, 1986), and internal qualities of people and their preferences to the special line of work, which can be described as a talent for a person. Consequently, researchers take into account rankings of satisfaction for human beings by their job and rankings of happiness at the level of countries, etc. (Deaton et al, 2013).

Methodology

Further comparative analysis assumes the implementation of different indicators describing the attraction of human resources with the highest economic value (the labor efficiency) within leading world economies. Such indicators include labor efficiency, innovativeness of economies, complexity of economies, ease of doing business ranking, etc. The list of countries is defined in accordance with the following principles:

- The biggest economies in accordance with GDP volume per PPP: China, USA, India, Japan, Germany, Russia, Italy, Brazil, UK, France
- Economies with the highest growth in the field of trade turnover with Russia after year 2014: Finland, Austria, the Netherlands, Saudi Arabia, South Korea

Findings

First, there is a need to pay attention on innovativeness index of different economies worldwide. This ranking includes leading position of South Korea, Germany, Finland, Switzerland, Israel, Singapore, Sweden, USA, Japan and France. Russia has 27th place before Brazil, India and Saudi Arabia but behind China (Table 3).

Table 3: Innovativeness index of different economies, 2019

Position in the ranking	Country	Position in the ranking	Country
1	South Korea	16	China
2	Germany	18	UK
3	Finland	21	Italy
8	USA	27	Russia
9	Japan	45	Brazil
10	France	54	India
12	Austria	56	Saudi Arabia
15	The Netherlands		

Source: Bloomberg Innovation Index, 2019

This index includes key points, which define the level of innovativeness for any country: (1) R&D investments by country, (2) number of patents per person, (3) number of graduates in universities, (4) export volume, (5) labor efficiency, (6) share of human capital in key fields, (7) number of researchers.

As a next step, consider positions of Russia in indicators mentioned above, which have its impact on the qualitative level of human activity in the economy of a country nowadays.

Taking into account government investments in R&D of a country, Russia has invested 40330 mln US dollars for year 2018. At the same time China and USA have invested approximately 370605 and 476452 mln US dollars accordingly or ten times more than in Russia. Additionally, India and Brazil have more investments annually in comparison with Russia based on Figure 1.

Source: http://uis.unesco.org/apps/visualisations/research-and-development-spending/

Figure 1: Government investments in R&D, mln US dollars, 2018

Russia is on the last positions in accordance with investments in R&D to GDP of a country in percent or 1,1% in comparison with indicators of South Korea (4,3%), Japan (3,4%), Finland (3,2%). Only India is located behind Russia with 0,8% of investments (Figure 2).

Figure 2: Government investments in R&D to GDP of a country, %

The number of patents worldwide has achieved 3,3 mln issues for the year 2018, and China has 46,4% of all patents. Russia has the 7th position with 37957 patents after China, USA, Japan, South Korea, Germany and India (Figure 3). Such result is the consequence of insufficient investments in R&D during a long period.

Figure 3: Number of patents by countries, 2018

Nowadays, Russia has one of a leading position in graduates by universities in comparison with other countries (Figure 4) but these results do not take into account the qualitative valuation by the level of human capital by countries in different fields (Table 4). Additionally, Russia has around 3094 researchers by one mln of population, and it proves the average research potential of a country worldwide (Figure 5).

Figure 4: Number of graduates by countries, %

As a consequence of a lack both in the qualification of workers and the technological modernization of enterprises, there is a low level of labor efficiency in the Russian economy, which is revealed in low volumes of production in goods and services in comparison with other countries, and accordingly, the decrease of economic potential of a country (Figure 6).

Figure 6: Labor efficiency by country, 2018

Source: OECD report on Labor efficiency

The role of a country at the international cooperation is supported nowadays by its place in the international division of labor and trade relationships with main partners. Any country can get additional profit and increase its economic growth in comparison with other countries through export

of goods and services. Thus, leading positions of China, USA, and Germany by its export volume are obvious taking into account key positions in global value chains (Table 5). Russia has 14th position in this ranking before India, Saudi Arabia, Brazil, Austria and Finland.

Table 5: Export volume by country, 2019

Position in the ranking	Country	Export volume, US dollars
1	China	2, 494, 230, 195,000
2	USA	1,665,992,032,000
3	Germany	1,557,176,334,000
4	Japan	738,188,768,000
5	South Korea	605,169,190,000
6	The Netherlands	585,622,815,000
8	France	568,448,540,000
9	Italy	543,466,795,000
10	UK	487,069,299,000

Conclusion

Thus, nowadays the Russian sustainable economic development depends not only on the technological progress in companies but also on the influence of a government on the human capital development within a country. The following list of issues could be considered for this reason taking into account indicators mentioned above:

- the direct investment in R&D of a country based on advantages of every region. Partly this initiative can be launched though financing of national projects;

- the close cooperation with the main trade partners in the field of investments with mutual development of R&D;

- the improvement of legal regulations in the country for business transparency and attraction of SMEs in regional technoparks and its interaction with large companies;

- the development of all educational stages taking into account latest trends worldwide taking into account best practices of other countries (Finland, Japan, etc.) but with historical and cultural aspects of home country;

- the analysis and increase of labor efficiency level in the national economy through the professional education enlargement among the whole population;

- the development and improvement of regional infrastructure in the country taking into account the latest trends;

All listed above measures are essential for the Russian economy for its further development and position in the world. Nowadays this is important to understand that the level of human capital in a country is the key point in the interaction with each other.

Presumerism – Trend, Fashion or New Face of Emotional Marketing?

Paweł NOWODZINSKI, Associate Professor

Czestochowa University of Technology
Poland, pawel.nowodzinski@wz.pcz.pl

Abstract

The paper presents the concept of a presumer and the factors which determine this particular type of consumer activity on contemporary markets in the context of the development of emotional marketing. The first part of the paper presents significant changes in the contemporary form of company-consumer communication, which are based on the use of new forms of customer involvement. Traditional methods of communication between an organisation and its market environment evolve towards individual experiences. This is inevitable due to both the new communication possibilities (technological aspect) and the evolving needs of target groups (emotional aspect). The following part of the study outlines the concept of a prosumer and a presumer and attempts to provide a synthesis of the factors that determine the emergence of new consumer attitudes.

Keywords: Presumerism, Marketing, Consumer.

Introduction

Contemporary changes in the social environment impose a change in the approach towards a company's operating philosophy and focusing the attention of those in charge on changing the profile of the contemporary consumer. In business markets, collaborating with customers and users has become increasingly important to get knowledge about consumer needs and to develop new products [Laage-Hellman, et. al. 2014, pp. 257-276]. The contemporary consumer has become more demanding and active, he expects specific solutions and offers "tailored" to his sublime expectations [Dusi, 2018, pp. 663-681]. From a hitherto passive recipient, he has transformed into a prosumer - a consumer who is both conscious and involved. For this reason, special attention is to be paid to three facets of a marketing strategy: product differentiation, competitor orientation and brand profiling emphasis. [Kaulio 1998, pp. 141-149; Svendsen, et. al., 2011, pp. 513-530]. The customer has a broad understanding of products and services available on the market, makes conscious purchasing decisions and willingly shares his knowledge with others, primarily via the Internet (Trentmann, 2009, p. 107; Miles 2017, pp. 16-19). The next stage in the development of the concept of an involved customer is the presumer, or a prosumer who engages in active interaction with companies before the products or services enter the market and thus participates in the concept phase [Alderete 2017, pp. 1-12; Pauwels 2015, pp. 66-84; This raises the question of whether contemporary consumers do indeed feel the need to establish such relationships, or whether presumerism (preceded by prosumerism) is a fashion created by companies that use the potential of emotional marketing. The author's intention is that the findings of the literature review conducted for the purposes of this study contribute to the attempt at finding the answer to this question.

A new understanding of contemporary times

Companies base their operations on rational and effective activities. Similar trends are observed in the contemporary society, where “a shift has been made from seeking the truth to seeking effectiveness and efficiency. The boundaries between ideology and science, opinion and knowledge are being blurred. Knowledge is the sum of commercialised information operating in the pragmatics of the free market. Commercialisation promotes a constant change in fashion, a search for novelty, the rejection of permanent values and norms, the denial of authorities, in reality promoting consumerism,

individualism, commercialism, extreme liberalism, hedonism [Hoffmann, et al, 2018, pp. 167-178.]. The commercialisation of social structures is the source of the spread and deepening of the consumption lifestyle [Drożdż, 2012, p. 18]."

The observation of current global trends in subject literature indicates that research directions tend to be related to strategies of the period of transition and crisis, the development of the resource theory and building strategies supporting key business processes. They concern mainly the proper implementation of marketing policy, "in particular the creation of a brand and engaging the customer in manufacturing and customisation processes, networking and supply chains, logistic strategies and new manufacturing methods, information strategies [...], they enable better adjustment of forecasts and the related methodologies to the requirements of modern business, based to an increasing extent on information and knowledge [Gospodarek, 2012, p. 24]."

The awareness of company managers is on the increase in terms of the role of innovation in the management process (and thus in the development of the company). Management is becoming "innovation-sensitive" [D'Olivio et. al., 2018, pp. 392-406]. Demand-based approach to innovations presumes that they are not only formed within the organisation, but primarily acquired from the environment [Crespi 2008, pp. 655-672; Fabrizio 2012, pp. 42-64; Edler 2016, pp. 414-426]. The source of knowledge and innovative solutions are no longer just employees, but mainly entities operating in its environment (the so-called external stakeholders) – trade partners, customers, end users. The managers acknowledge the possibility of involving the customers in the process of creating new, innovative products. From final recipients, customers are turning into active co-participants involved in the innovation process by searching for new product concepts, testing prototypes, adapting products to individual consumer needs [Żelichowska and Furman, 2013; Koren et. al., 2013, pp. 719-729]. What is significant in this context is the emotions – the emotional model assumes that "it is the emotions associated with the product that are the basis for shaping customer satisfaction. The factor mediating the development of satisfaction is the analysis of the results of product use in terms of success or failure. A purchaser experiencing satisfaction manifests it, whereas dissatisfaction is expressed more discreetly [Desmet 2002, pp. 60-68; Desmet 2008, pp. 379-397; Czerw, 2008, p. 22;]."

Table 1: Values and features of post-modern consumption culture

No.	Values	Culture Features
1	Pluralism	Negation of universal ideology or norms, scepticism, disappointment, plurality of beliefs
2	Diversity	Searching for individual identity, lifestyle diversity, growing diversification of demand
3	Globalisation	Consumers' drive for a modern, more attractive lifestyle in which global products play a major role
4	Tribal community	Growing importance of social bonds – searching for goods and services that facilitate social interaction
5	Symbolism	Creation of a hyper reality and virtual reality
6	Fragmentation	Fragmentation of experiences, detaching them from the context
7	Lack of hierarchy	Disorderly sequences of consumption stimuli
8	Multiculturalism	Drawing upon the heritage of different cultures
9	Popularisation	Omnipresent influence of the mass media

Source: Mazurek-Łopacińska [2011, p. 47]

Along with the development of the concept of marketing and the emergence of relationship marketing, the approach towards the customer has changed. The communication addressed to the consumer ceases to be collective and anonymous. A new era of individual communication begins, primarily due to the customer's individualised approach to the purchase of products, the context of individual taste and specific preferences [Quinton, 2013, pp. 912-932; Chrąchol, 2013, p. 149; Cao et. al., 2016, pp. 1303-1321; Habicht 2017, pp. 114-131]. Emotional marketing [Consoli 2010, pp. 52-59; Deshwal 2015, pp. 254-265], in turn, is based on the understanding that the advertising and promotional tools used should have a strong, emotional impact on the consumers. When faced with huge information (media) noise, it is indeed difficult to communicate with the potential consumer. It is also unlikely that he will receive the message, understand it and, on top of that, will act upon it when making individual purchasing decisions. Consequently, marketing activities in context should appeal to the emotional realm so that the message can reach its target audience and prove successful. In view of these considerations, however, a certain doubt arises which was aptly defined by K. Wójcik in the form of a question about the ethical context of marketing activities (in this case public relations) [Wójcik, 2014, p. 25]: "Is there a chance […] not to manipulate the marketing audience in the era of searching for ever new sources of influence on consumers, such as marketing of emotions and feelings, guerrilla, olfactory, whisper or value marketing, and more recently neuromarketing, […] when all rules of rhetorical expression are used with full awareness, also those that lead to the manipulation of the advertising audience?"

The prosumer and the prosumer on the contemporary market

The role and importance of the consumer is not limited solely to a passive acceptance of the company's market offer. Consumers are becoming active market participants, providers of specific services and co-creators of the offer – the prosumers. The consumer, hitherto passive, submissive towards product and service offers of companies, has transformed into an active consumer – the prosumer [Planells 2017, pp. 620-638]. Targeting strategies should distinguish carefully between truly innovative consumers and other early adopters. The costs of identifying them in a particular market need to be weighed against the potential benefits. [McDonald 2007, pp. 421-435; Fursov et. al. 2017, pp. 153-160]. A cognitively interesting definition has been proposed by A. Niezgoda. She defines the presumer as a "consumer whose activity exceeds the average, who is aware of his personal needs, who has knowledge about products and passes it on to other consumers, takes part in designing (creating) the product, is involved in the process of developing and selling the product by passing information to other consumers. Thus, he can also be considered as an opinion leader, as he often anticipates the consumer's general behaviour [Niezgoda, 2013, p. 205]." This thesis is confirmed by I. Zdonek who also defines a prosumer as a local public opinion leader. According to the author quoted above, one of the characteristics of the prosumer is his active involvement in publishing information about his product experiences in electronic media (on the Internet), as such information has a great influence on other consumers' purchasing decisions [Zdonek, 2010, pp. 399-406].

In conclusion, a prosumer is more than a consumer [Ritzer, 2019, pp. 75-95]. He is defined by his extensive knowledge of products and services related to given brands and is eager to share this knowledge with others. We can therefore describe prosumers as active consumers who are more than just passive recipients of marketing messages and media content. Such people often become good ambassadors for a given brand or product. However, should they lose confidence in the brand, they are quick to become their ardent adversaries [Bobola, 2013, p. 58]. In turn, when trying to identify the characteristics of a presumer, one could be tempted to say that it is a prosumer who wants to take part in active creation of products and services (and even brands) before they enter the market. In this context, some interesting research results have been presented by W. Wolny, who states that "active participation in designing an individualised service can be considered to be the highest form of the prosumer phenomenon." According to research, however, such participation in the development of e-services still has little popularity, but continues to develop, particularly in the area of the Internet [Wolny, 2013, p. 161; Roberts 2019, p. 213-230;].

Determinants of Presumer Attitudes

Is it possible to determine, in the context of the development of society, such phenomena which favour consumer attitudes?

Mass individualisation of the offer, which according to the managers influences customer loyalty, will probably have a significant impact in this case. The objective of mass individualisation is to adapt the offer in such a way that each (individual) consumer may find precisely what he wants in the value communicated by a given company. What is important in this case is the pre-defined (and not random) potential for individualisation.

An interesting division of the bonds enabling individualisation has been presented by P. Stach [Stach 2009, p. 46-55] The conducted literature review allowed the Author to draw a number of interesting conclusions on the quality and durability of the relationship between the organisation and the customer. He concludes that the factor responsible for the durability and quality of the relationship are the bonds. The first level encompasses financial bonds. These are relatively easy to establish; however, they do not last and can be easily copied by competitors. The second level is social bonds that are responsible for the durability of the relationship. They are based on the personalisation of the relationship between organisation and the customer. Another level is the relationship based on the individualisation of the offer and adapting it to the specific (concrete) needs of the consumer, as well as shaping proximity in the relationship between the buyer and the supplier. In the case of consumption services, the service provider's partnership approach to the customer is a process consisting in building and strengthening the bonds with selected customers at the aforementioned levels, particularly the third one. Based on the Author's observations, a presumer approach emerges in such cases, consisting in engaging the customer in the process of perfecting the service offer (e.g. surveys of needs and satisfaction, consultations during design of new products) or treating the customer as a partner or friend, which makes him feel unique in comparison with other consumers [Stach, 2009, pp. 47-48]. In conclusion, economic development, increased consumption and prosperity are the factors that contribute to a decrease of interest in the standard offer (even in the case of mass consumption) [Van Tonder 2016, pp. 289-302; Sureshchandar et. al, 2002, pp. 363-379; Aburoub et al, 2011, pp. 107-118; Taylor 1994, pp. 163-178].

As confirmed by other research, if a specific product is available to an increasingly wider group of customers, its attractiveness decreases. Consumers expect products that are tailored to their individual needs and available at attractive prices comparable to those of standard products. Managers strive to adapt to these requirements while maintaining relatively low costs of such adaptation. The measures aimed at meeting these challenges are referred to as mass customisation. Thanks to the mass customisation strategy, it is possible to gain a competitive advantage by offering the customer something more than a standard product by offering additional attributes related to that product [Tiihonen 2017, pp. 1-7; Bednarz, 2010, p. 102]. “The strategy of mass customisation seeks to achieve something that has so far only been achieved in certain types of production: the customisation of products to the individual requirements of a specific customer, typical of traditional artisanal production and its modern form, known as engineering to order, with low prices and short delivery cycles typical of mass production. It allows to simultaneously meet both of these opposing requirements. [Deradjat 2017, pp. 95-121; Bednarz, 2010, p. 105; Noguchi et al, 2016, pp. 95-119; Cannas et al, 2018, pp. 495-517].”

Contemporary economic and social changes result in multidirectional transformations of many areas of life and of the social structure, as well as changes in customs and mentality, in value systems, lifestyles and consumer behaviour. Consumption has become a driving force behind the behaviour of Polish consumers as well, determining the shape of their life aspirations, dreams and desires. In the capitalist world, consumption has become one of the basic values, especially in the context of the previous consumption asceticism, regarded as a relic from the previous era. The accumulation of goods became, and in some periods of actual regulation of consumption, the possession and accumulation of goods ceased to be a shameful relic of small bourgeois attitudes. Being in possession of attractive goods became a symbol of social status and an indicator of personal success. The spread of materialistic systems of values and consumption attitudes is favoured by the accelerating processes of globalisation

and integration, which enable the free flow of civilisation patterns, lifestyles and consumption. Highly developed consumerism is a certain *signum temporis* of contemporary societies in economically developed countries [Bylok 2017, pp. 61-74; Drapińska 2017, pp. 103-110; Delieva 2019, pp. 59-67 Mróz 2015, pp. 25-36].

In the decision-making process concerning his consumption needs, the consumer follows his own needs and their hierarchy which depends on the values he confesses. A consumption need is a tendency to use or own a given product. A desire is a need that has not been satisfied, while a requirement is a request or demand for a good or service. Every consumer has his own hierarchy of consumption needs and, on that basis, he makes choices based on specific needs which, if not satisfied, result in a feeling of dissatisfaction. Making the final purchasing decision is the process of identifying the market, obtaining useful information and planning the purchase. The described actions have for their purpose the elimination of the undesirable state of dissatisfaction. [Włodarczyk-Śpiewak 2011, pp. 64-65; Antioco 2018, pp. 301-310; Poushneh 2017, pp. 97-118].

With respect to the psychological dimension of the consequences of consumption, a distinction can be made between the micro-social context (related to the consumer's role, his interactions and interpersonal relations in a broader aspect) and the macro-social context (related to structural changes that the society is undergoing). In turn, the main functions of consumption in the context of these considerations include primarily: ensuring the individual's expected quality of life (health and wellbeing), enabling the identification of individual identity and belonging to a particular social group, achieving and maintaining a social status and a place in the structure of society, assigning a symbolic meaning to the purchased goods and services and acting as a means of expression and communication with other consumers and social groups [Bylok, 2006, p. 212; Shen et al. 2016, pp. 2265-2270; Duffett 2017, pp. 19-39; Black 2017, pp. 416-429].

Consumption redefines the sense of belonging; according to a concept by M. Maffesoli [Maffesoli 2016, pp. 739-747] individualisation does no longer constitute a guiding principle for individuals. Rather, it constitutes an volutionary step towards new forms of community. In the Author's opinion, the individual needs to be re-embedded and to share a certain territory with others. The phenomenon of disembedding (*disembeddment*) is accompanied by the phenomenon of re-embedding (*re-embeddment*), i.e. the process of deindividualization – the transition from individualism to new forms of socialisation and social bonds [Skorodumova 2019, pp. 947-953; Nemesh 2017, pp. 151-159]. Identity is not constituted individually, but rather through participation in certain different emotional communities, defined as tribes. These are new forms of community which the consumer joins of his own free will, through an individual decision. Such communities provide the individual with a sense of belonging, a meaning, they offer an attractive lifestyle and facilitate identification with other consumers. This allows for the creation of an identity as if “from scratch”. Thus, individualism gives way to a redefined sense of community, defined by consumption [Olcoń-Kubicka, 2006, p. 147].

Certain companies make excellent use of this phenomenon by provoking their customers to behave in a way that has more to do with religion than with consumption. In a way, the consumers become "faithful followers" of their brands. This kind of "cult", however, has no rational justification; it is the companies that create a quasi-religious bond with their consumers. They often achieve this effect using the principles of sensual *branding*, offering their consumers a unique sense of belonging that stimulates and strengthens the bonds between the participants, a clear vision associated with a sense of purpose, authenticity, consistency, perfection, influence on the senses, established rituals, symbols and a sense of mystery. The brand's role is that of creating a social bond that connects individuals, creates a platform for understanding and action and gives a strong sense of belonging [Lindström 2009, p. 218-220; Koch 2019, pp. 1-25; Humayun 2017, p. 677; Mathras et al. 2016, pp. 298-311]. What helps in the creation of the said platform is the Internet. In the communities of fans, for example, it plays a significant role. Without virtual fan communities operating in the Internet, people with similar interests would not have the opportunity to interact at all. Such communities can be considered as legitimate human communities. “The full-fledgedness that encourages participation and various activities results from the fact that these communities become a source of social life, support, information, sense of belonging and social identity [Orgad 2018, pp. 251-260; Siuda 2008, p. 248].”

Conclusion

Upon analysis of the determinants of both the prosumer and presumer attitudes, the question posed in the introduction to this paper cannot be answered unambiguously. Consumer attitudes are indeed evolving towards an increased activity, treating presumerism as a form of individual self-fulfilment. On the other hand, however, marketing is undergoing a change of the existing paradigms, there is a growing need to integrate communication, marketing is defined by a strong influence on emotions. Market goals are achieved through the perception of the brand, its association with strong and positive features by means of comprehensive and multi-level strategies, using unconventional promotion methods [Datko, 2012, p. 13-14]. As a result, consumers feel the need to interact more closely with the brands operating on the market, while on the other hand, companies position their brands (and make available the potential for interaction) in a way that ideally allows for the creation of closer bonds.

Abstract

The article presents a common method of external financing of assets in the real property market, i.e. a mortgage secured bank credit facility. The purpose of the study was to assess the mortgage value of a commercial property. An attempt was made to assess the value of the commercial property for the purpose of securing repayment of the bank credit facility. Commercial property referred to in the article being subject to external financing is a hypothetical shopping centre in the area of a housing estate. The investor has no sufficient funds and decided to finance the construction of the aforementioned property with the use of a bank credit, secured by mortgage. One of the existing real estate valuation methods - the income method - was used to calculate the value of the analysed property. In this method, the value of the property depends on the income it generates in the future.

Keywords: Bank Credit Facility, Mortgage, Income-Based Approach, The Value Of The Commercial Property, Valuation Of The Real Property.

Introduction

In the article, the income of the owner from the analysed property is in the form of rent obtained from renting the property. The value of the property is the basis in the investment loan process, so assessing this value is crucial (Baum 2008). The commercial real estate appraisal presented in the article is an important aspect in the process of crediting the purchase of real estate. The estimated value affects the amount of credit granted depending on the adopted LTV ratio by the bank (Lin 2014; Ambrose 1993).

The authors used the case study methodology – as case study is expected to capture the complexity of a single case, and the methodology which enables this has developed within the social sciences. Such methodology is applied not only in the social sciences, such as psychology, sociology, anthropology, and economics, but also in practice-oriented fields such as environmental studies, social work, education, and business studies (Johansson 2007).

When buying the real property which will or should bring profits in the future, investors make decisions what kind of (whose) capital to choose to finance the purchase. Most often investment outlays are so high that the investor's own funds are insufficient. Therefore, the bank credit facility helps in many cases, most often repaid for a period of several dozen years (Kucharska-Stasiak 2011). One of the most important elements analysed by the financing bank consists in the collateral of repayment of credit. The subject of the loan is commercial real estate. In this case, the bank may protect itself against the owner defaulting on the loan by establishing a mortgage. The purpose of the

article is to describe the most common source of external financing in the real property market, i.e., bank credit and attempted estimation of the value of a commercial property for the purpose of the bank credit when the property is encumbered with a limited property right constituting collateral of the debt.

In the survey, income-based approach and investment method were applied as one of possible methods to be selected in order to establish the value of the commercial property. This is the most commonly used method for real estate that can generate income.

Bank credit in financing of the commercial property

An investor financing the undertaking connected with the purchase of commercial property takes into account different sources of financing, classified by corporate finance literature as own and external sources. In the event of an individual investor, own capital comes most often from personal savings. In case of enterprises, own financing of investments in commercial properties most often comes from the part of profit allocated for development. Usually own share in financing of an investment in the market of commercial properties is minor (Hellwig 2001; Jonak 2015a; Clementi 2006). The financial market offers many different instruments of financing investments, however, the most popular include bank credit offered by commercial banks. In case of financing investments in the market of commercial properties, bank credit secured by mortgage is the most popular source of financing (Calem 2004; Wielgórka 2009; Boleat, 2012). Mortgage established on the real property is one of many ways of securing repayment of credit. Mortgage is considered the most effective form of collateral. Such credit shall be granted provided that the borrower is creditworthy, i.e. that they are able to repay the credit granted including interest on the agreed dates. The assessment of creditworthiness concerns not only current but also future financial situation of the borrower (Bednarz, Gostomski 2008). Moreover, credits for financing of commercial properties are most often long-term credits, therefore, stable security is required, i.e. the value of a real property. The collateral enables the bank to get its funds back, including interest and commissions if the client defaults on credit under the terms of the credit agreement (Kucharska-Stasiak 2006; Jonak 2015b). Thanks to financing from external sources, the investor can undertake investments without engaging its own capital. However, financing with the bank credit is subject to certain risk since future income from the property can be insufficient to repay credit instalments or even interest (Jonak 2015a; Ranyard 2012).

LTV (Loan-to-Value) ratio applied by banks plays a significant role in case of such type of credits; it combines the amount of credit with the value of collateral, i.e. with the market value of the real property. The majority of banks adopts LTV ratio at the level of 60-80%, and on account of safety of the bank the level of LTV shall not exceed 100%. The ratio is used to establish the amount of interest rate, and more precisely, the bank's margin. The lower LTV ratio, the lower interest rate can be proposed by the bank (Epley 1996, pp. 71-86; Marcinek 2009, p. 76-77; Lin 2014; Ranisavljević 2016). Banks establish their own maximum level of LTV ratio they are able to accept. The higher value of the ratio, the greater risk for the bank. It used to happen in the previous years that LTV ratio could be at the level of 100%, which meant that one could take credit without own contribution. Some banks even offered credits for 110-120% of the value of the real property. On the basis of an analysis concerning offers of commercial banks it was noticed that the higher LTV ratio was usually accompanied by additional security of own contribution – usually when it exceeded 80%. Due to the economic crisis (2007) banks became more careful in granting credits and moreover, the Polish Financial Supervision Authority (KNF) which monitors the situation in the banking market on a regular basis issued recommendations concerning, among other things, recommended level of LTV ratio. The maximum LTV ration in 2014 was 95% according to the recommendations provided by KNF and it is reduced every year. Starting in the 1st January 2017, banks have to apply LTV ratio at the level of 80% or 90%. In the other case it is necessary to apply insurance or additional collateral of credit (Bester 1987; Wójcik-Mazur; Bilan 2019).

Commercial property as Collateral of a Bank Credit

The source literature divides real properties into land, buildings and premises (Źróbek, Bełej 2000). However, on account of the fact that the real property may generate income for the owner, commercial properties have been separated, i.e. properties purchased for the investment purposes, bringing periodical income on account of rent, when rented for use to third parties (Nalepka 2006; Breuer 2019; Roberts 2007). They are non-residential properties but purchase or built for the purpose of obtaining profit.

Commercial properties include, for instance, office buildings, shopping malls, hotels, sport centres, tourist centres etc. Owners of such properties can obtain financial benefits in many ways. They may include revenues resulting from rental or shares in the user's (tenant's) profits –or capital benefits resulting from the increase in the value of a given property in time (Kietliński and Woźniak 2009; Clapp 1992; Geltner 1995). J. Lipiński defines commercial property as a real property generating systematic revenues resulting from its use or ownership (Lipiński 2000). M. Prystupa points out that the basic source of income from real property comes from rent generated by rent or lease, and additional source may include income from rental of parking space, from advertisements situated on the property, as well as different types of slot-machines (Prystupa 2016, p. 89-90), e.g. with drinks, sweets, coffee, or ATM machines. Investors in the commercial property market are often interested in shopping centres. The source of income for the investor are rents paid by tenants of commercial space for the rented space. Additionally, tenants participate in financing of costs of maintenance of common areas, e.g. parking space, elevators, promenades (Marcinek 2009).

Therefore, the value of real property depends on whether it is rented or leased in a given period. There is a relation between income generated by the property and its market value, thanks to which such property can be evaluated for the purpose of securing credit with the use of an income-based method (Dydenko 2015).

If the investment of purchase/building a shopping centre (commercial property) is financed with funds coming from the bank credit, the bank shall establish mortgage on the property credited. „Mortgage consist in a limited tangible right that can be established on the property or on selected rights such as perpetual usufruct, ownership right to premises, debt secured by mortgage, wholly or partly (fraction), constituting share of a co-owner. Mortgage constitute security of the debt, pursuant to which creditors can claim compensation against real property, with a priority before personal creditors of the owner of the real property (Feldman 2004; Lendo-Siwicka 2016; Wang 2006; Holland 2000; Lieser 2014).

Case Study

Commercial property referred to in the article being subject to external financing is a hypothetical shopping centre in the area of a housing estate. The investor has no sufficient funds and decided to finance the construction of the aforementioned property with the use of a bank credit, secured by mortgage. One of key documents based on which such credit is granted is the opinion concerning the value of pledged property. A hypothetical value of LTV ratio adopted for the purposes of this article amount to 85%, which means that 85% of the value of real property can be financed by credit and the remaining 15% by the investor's funds. In table 1 the area of the shopping centre and the rate of rent have been presented, since the basic element of income related to the said commercial property consists in rent paid by tenants for the use of individual commercial premises.

Table 1: Data of real property

Specification	Area m2	Rent for m2
Usable service area	745	35.00

Source: own survey

The total usable service area amounts to 745m2. A monthly net rent resulting from rental agreements amounts to 26 075 zloty, i.e. annually almost 312 900 zloty.

The object of the valuation concern real property and the source of value consists in business activity connected with rental of the said property, while the carrier of the value used in the valuation shall be rent from the analysed property (Konowalczuk 2009).

For the purpose of evaluation of a hypothetical value of commercial property being the object of the analysis in this article, an income-based approach was used as well as the investment method and a technique of discounting future income (Trojanek 2012; Gollier 2010). In the aforementioned approach, the value of real property is defined assuming that the selling price will depend on the expected potential future income from the real property, possible to be obtained by a potential buyer. This approach is used in relations to real properties which bring or may bring income (the Act dated 21 August 1997). Other definition points out that „…the income-based approach is used in case of establishing the value of real properties generating income or offering an opportunity of obtaining income, assuming that income is the basic factor having impact on the value of such properties" (Zabielski 2011; Adebimpe 2018).

In the process of estimating the hypothetical value of commercial property, the investment method was used (Mączyńska 2005; Gane 1995; Lefley 1996) due to the fact that income obtained from such property is defined in the rates of rent. In this technique the value of real property was estimated as a sum of discounted streams of variable income to be obtained in the future. The value was increased by a discounted residual value of the commercial property (Cymerman, Hopfer 2009):

$$DCF = CF1 / (1+r) + CF2 / (1+r)2 + CFn / (1+r)n + RV / (1+r)n \quad (1)$$

where:

CF – cash flows in subsequent years of forecast
r – discount rate
n – the last year of forecast
RV – residual value

According to J. Dydenko, most often the residual value of real property is established assuming fixed income after the period of forecast that is adopted as the amount of income from the last year of forecast (Dydenko 2015):

$$RV = CFn / r \quad (2)$$

The number of years of forecast depends on the expected period for which income from the evaluated property will be generated. As far as the said property is concerned, a 10-year period of forecast has been adopted. The source of income from the analysed property shall be rent generated for the owner by real property (Prystupa 2016). Calculation of income generated by the real property has been organised and three stages of estimation have been distinguished (Dydenko 2015; Edelstain 2006; D'Amato 2015).

The first stage consists in calculation of potential gross income (PGI) which includes all possible income from real property, established with the assumption that all the areas are rented and all rents are collected. On the basis of data included in table 1 the potential gross income (table 2) has been calculated, i.e. possible income to be obtained annually with reference to the real property under analysis.

Table 2: Potential gross income PGI

Specification	Area m2	Rent for m2 PLN/m2	Net rent PLN/m-c	Potential gross income PLN/ year
Usable service area	**745**	**35**	**26 075**	**312 900**

Source: own survey

In the process of valuation of the market value of real property, even if the property is rented in 100%, certain reserve is taken into account for vacant areas. In the second stage of estimation of income generated by the analysed property, the potential gross income specified above has been verified taking into account vacant areas. These are losses in income connected with periods during the year when not all areas are rented or losses are caused by arrears in payment of rent. The average vacant areas in the market of similar properties amount approx. to 10% and such value was adopted herein. The potential gross income verified by loss in income enables to determine the effective gross income (EGI) which is the value actually obtained by the investor. Therefore, the effective gross income for the analysed property has been calculated in table 3.

Table 3: Effective gross income EGI

Income and its elements	[PLN]
Potential gross income	312 900
Effective gross income	281 610

Source: own survey

The third stage consist in calculation of net operating income NOI, being a difference between the effective gross income and operating expenses incurred continuously on account of current use of the real property. Operating income for the hypothetical property includes property tax, insurance, costs of keeping books as well as repairs and regular maintenance. Amortisation, depreciation and the cost of credit have no impact on the difference between the effective gross income and the net operating income in the process of valuation (Dydenko 2015). Operating costs of the analysed property have been adopted at the level of 50 699 zloty per year.

After estimation of the potential and effective income generated by the real property and after estimation of the running costs of the said property, the expected income to be obtained by the investor has been established. It is a value which determines potential of the real property to obtain the net income by the investor. Net operating income calculated for the analysed commercial property has been presented in table 4.

Table 4: Net Operating Income

Specification	Value [PLN/year]
Effective gross income	281 610
Operating expenses	50 699
Net operating income	230 911

Source: own survey

Another stage of valuation consists in the estimation of a discount rate, used subsequently to calculate the value of the real property (Dydenko 2015, p. 498-500). The discount rate of 6% was adopted on the basis of research and analyses of the real property market for 2018 conducted by CUSHMAN&WAKEFIELD. (Cushman and Wakefield 2016). Another step in the valuation of the commercial property in asset-based approach consist in the definition of future income from the analysed real property within next 10 years of the period of forecast, and then discounting. Growth of

income was adopted at the level of the average inflation rate of 1.5%. Table 5 contains calculation of the value of land developed by a commercial building.

Table 5: Calculation of the value of real property

Specification	1	2	3	4	5	6	7	8	9	10
Expected income [PLN]	234 375	237 890	241 459	245 080	248 757	252 488	256 275	260 119	264 021	267 982
Discount rate	0.050									
Discount coefficient	0.952 4	0.907 0	0.863 8	0.822 7	0.783 5	0.746 2	0.710 7	0.676 8	0.644 6	0.613 9
Residual value [PLN]	5 359 631									
Discounted expected income [PLN]	223 214	215 773	208 581	201 628	194 907	188 410	182 130	176 059	170 190	164 517
Discounted residual value [PLN]	3 290 349									
Market value [PLN]	5 215 760									

Source: own survey

Research methodology used, enabled to estimate the hypothetical market value of the commercial property in the amount of 5 215 760 zloty, which can be the basis for security of debt. Financing of this investment with the use of external capital coming from the bank credit could be realised in the amount calculated according to LTV ratio used by commercial banks. As mentioned before, its value in the amount of 85% means that the investor could apply for financing of the investment in the analysed commercial property with the use of external capital in the amount of 4 433 396 zloty. The investor should provide own funds in the amount of 786 364 zloty.

Summary

The purchase of the commercial property involves considerable financial outlays. Most often investors use external sources of financing, especially bank credits. The value of a given property serves as a basis in the process of crediting investment, therefore its valuation is essential. The attempt to evaluate the commercial property presented herein shows that the bank credit can be used in the amount of 4 433 million zloty depending on the value of LTV ratio, to finance the investment, which will generate income in the future coming from rental.

The income-based approach is not the only way to “reach” the value of the commercial property. There is also a cost-based and a comparative approach, however, income-based approach used herein is deemed to be the most appropriate in case of commercial properties since their value depends on income generated by a given property. It means that the higher forecasted income, the higher the value of the estimated real property.

Abstract

This study examined the impact of pension assets on economic growth in Nigeria from 2007 to 2017. The study adopted secondary data which were sourced from the annual reports of Pension fund administrators (PFA) and Central Bank of Nigeria (CBN) Statistical Bulletin. Thirteen investment outlets were extracted but made use of seven of them because they were commonly employed throughout the 11-year period (2007 – 2017). Descriptive statistics, test of stationarity using Augmented Dickey-Fuller (ADF), Co-integration test using Engle-granger and Ordinary least square (OLS) were employed to ascertain the impact of pension assets investment on economic growth in Nigeria. The results revealed that there is positive and significant relationship between investment of pension fund and economic growth in Nigeria. The study recommended that more pension assets should be made available by the pension operators as financial capital to industries for development and improve Gross domestic product (GDP) in Nigeria. It also recommended that there should be efficient control of the funds by pension fund managers and the returns from the investments giving to pension contributors, into their Retirement savings accounts for enhanced funding at retirement.

Keywords: Pension assets, Gross Domestic Product, Pension investment, Retirement saving accounts.

Introduction

The development of any economy is premised on the gross domestic products generated by the residents of that country at a given period of time. Every industry within the economy requires huge capital outlay and funding to remain in business and pension fund is a major source needed to propel the economy. One of the reasons for investing pension fund in pension assets is to keep the fund active till when the contributors will be retiring. The main thrust of Pension Reform Act 2004 include making sure that their employees receive their retirement benefits as and when due; assist low income earners save so as to handle their livelihood at old age; and to provide a uniform set of guidelines and standards that will ensure prompt payment of retirement benefits to workers (Akpan and Ukpong, 2014).

The funded nature of the contributory pension scheme in operation in Nigeria make for provision of source of finance for both capital and money markets. This is the reason why pension assets are invested in portfolios stipulated in the investment guidelines issued by the National Pension Commission

(PenCom). However, as plausible as the provisions and implementation of the Pension Reform Acts 2014 (as amended) are, operation of the funded pension scheme in Nigeria might have been made difficult by weak institutions, corruption, social injustice and insecurity and leading to lot of challenges which threatens its objectives. It is therefore important to consider operation of pension assets as source of funding has contributed to the growth and development of the Nigerian economy; and whether its continuity has prospects, (Farayibi, 2017).

Section 86 of Pension Reform Act (PRA) (2014) provides various portfolios where pension assets should be invested. The investment instruments were graded as contained in PenCom's Investment Guidelines which guide pension fund investments (Sule and Ikechukwu, 2009). Pension assets can be traded in bonds, bills and other securities issued and guaranteed by the Federal Government of Nigeria (FGN); in equity stocks of public limited companies, money market securities among other stipulated windows.

Despite the provisions of the Act mentioned above, studies have not been updated to look at how investment of pension fund has impacted the growth or decline in the Nigerian economy. Pension Fund Administrators (PFAs) have as major challenge, dearth of investment outlets where pension funds could be invested, coupled with the directives in the PenCom guidelines which streamlined the quantity of Pension assets that should be invested in a given instrument (Akowe, Ocheni and Daniel, 2015). Akpan and Ukpong, (2014) in their study on Challenges of pension administration and capital formation in Nigeria concluded that efficient pension administration and capital formation is a solution to industrializing the Nigerian economy. Akowe, *et.al* (2015) in their study, while evaluating the contribution portfolios of new Contributory Pension Scheme on Nigerian economy have concluded that investing in domestic equity shares, FGN securities and Real Estate Properties have positive contributions to Nigerian GDP and investing pension funds in Domestic Money market securities have negative contributions to the GDP. Other studies have looked at effect of new pension scheme on Nigerian retirees (Anazodo, *et al*, 2014); comparison of pension investment analysis using a variance-comparison tests of non-contributory and contributory schemes in Nigeria (Okoro and Okoye, (2017).

Literature Review

Empirical Framework

Nwawolo and Nwogwugwu (2019), looked at pension contributors' involvement in decision making on pension fund investment and their living standards using University of Lagos, Nigeria as case study. The study made use of a sample size of 100 respondents from population of 5,098 non-academic staff through Taro Yamane (1967) formula. Data were analysed using descriptive and inferential statistics (linear regression). The research employed convergent parallel research design and revealed that contributors' decision making on pension fund investment resulted in positive significant effects on retirees' living standard. However, Andonov and Rauh (2018) while looking at the expected expectations of institutional investors revealed that the investors depend on past performance in setting future return expectations. The study used statistical testing on real return versus expected return on pension investments to analyse its data. The study found that asset class around 22% weight of variation in portfolio expected returns, leaving a large role for difference in beliefs concerning returns in the different asset classes. The study also discovered that unfunded liabilities are positively correlated to the portfolio expected returns. This is in line with the hypothesis that 'fiscally entangled' government face pressure in maintaining higher expected rates of return (Andonov, Bauer and Cremers (2017); Novy-Marx and Rauh (2011); Brown and Wilcox (2009). The study also found that the expected returns in risky asset classes (public equity, real assets, private equity and hedge funds) are significantly and positively correlated to the past return. Osondo (2016) appraised the adoption of the pension reform act 2004 to explore the possibility of the scheme influencing the payment of pension to retired employees.

Uzoh and Anekwe (2018) examined contributory pension scheme vis-a-vis fate of retired and retiring Nigerian workers used conceptual and observations in the pension industry in Nigeria. They found that administration of pension funds in Nigeria was fraught with lots of challenges since the advent of

pension payments to pensioners. The study asserted that the provisions of amended Pension Reform Acts (2014) made good the challenge embedded in the old pension scheme especially as it affects regular payment of pension benefits to pensioners. It also believed that the new contributory pension scheme is a source of new hope to retired Nigerian workers. The study did not highlight how this hope can be brightened by investing the pension fund during periods before retirement. Ishola, Sanusi and Abayomi (2016) looked at the effects of contributory pension scheme (CPS) on productivity of employees in Lagos state civil service. The study revealed that significant relationship exists between employees' productivity and retirement package resulting in positive effect on organisation's efficiency. The study advised organisations to key in to the new CPS as a means to reduce overall cost and wasteful expenditure.

Zubair (2016) examined how pension funds investment has impacted capital market performance in Nigeria. The study concluded that there is a significant positive relationship between pension fund investments and capital market performance in Nigeria after 2004 major industrial reform. In specific term, the study revealed that total pension investments in Nigeria enhances the performance of the Nigerian capital market significantly. It further concluded that the interaction of macroeconomic indicators vis-a-vis pension investments affect the market performance significantly. Eke and Onafalujo (2015), in their own work examined capital market, interest rate and pension management in Nigeria between 1981 and 2013. The study made use of ordinary least square to test elasticity of impact of Treasury bill, stock market index, with GDP as control variable on growth of pension assets. The study saw pension assets to be directly related to stock market index but inversely related to short term interest regime leading to impairment of 'wholesome' presence of pension assets in the capital market.

Njeru, Njeru and Kasomi (2015) evaluated financial performance in relation to portfolio investments by pension funds in Kenya. A survey of 1,262 pension funds as population was carried out of which 35 of them were sampled. Data relating to pension fund portfolio, the price schedules, the investment reports and audited accounts of sampled pension funds were used. The study employed inferential statistics to ascertain the difference in asset classes. Comparisons were made between compositions of the various portfolios, the weighting of the asset classes and the returns from on each portfolio. The study concluded that performance of the pension fund was influenced by both discretionary and non-discretionary mandates entrusted to pension managers. Nwanne (2015) investigated the impact contributory pension scheme has on Nigeria's economic growth between 2004 and 2012. The study made use of two parameters which include pension funds traded in specified investment outlets and pension savings contributed by both private and public sectors in Nigeria vis-a-vis economic growth variables. The study found out that pension funds have significantly influenced economic growth in Nigeria.

Ezugwu and Itodo (2014) analysed the portfolio where pension funds managers invested pension funds in Nigeria using secondary data obtained from PenCom during 2007 – 2012. Using ordinary least square (OLS) estimation techniques, the study found out that ordinary shares recorded the highest percentage in portfolio of pension fund management. Essien and Akuma (2014) descriptively made comparison between the present contributory pension scheme and the old defined benefit plan based on core values. The study revealed that the old pension scheme was fraught with overwhelming financial misappropriations and embezzlement. Edame and Okoro (2013) using neoclassical growth model examined the impact of capital market on the economic growth of Nigeria. Ordinary least square (OLS) technique was employed to analyse the data collected from Central Bank of Nigeria (CBN) annual reports and statistical bulletin using time series covering 1970 -2010. The study revealed that capital market has a significant and positive effect on the economic growth in Nigeria. Odo, Igbeka and Ani (2011) ascertained the root causes that made pension reform inevitable. Their study evaluated the strengths, weaknesses and measures that will correct the weaknesses in the pension reform in Nigeria. In their theoretical analysis, they observed that employers and employees were forced by law to provide fund anticipated to pay pension claims at retirement compared with the old order when no financial provisions were made.

Bikker, Broeders and Dreu (2010) examined 'Stock market performance and pension fund investment policy: Rebalancing, free float, or market timing?' The study made use of a detailed set of data containing quarterly information on entire Dutch pension funds for 1999: Q1 to 2006:Q4 derived from De Nederlandsche Bank. The researchers employed self-reported returns and MSCI World total return index dominated in Euro in assessing the effect of equity returns on actual and fundamental equity allocation. The sample used was unbalanced panel because some of the pension funds did not provide data for the whole period as a result of mergers, terminations and failures in reporting and new entrants. The study revealed that stock market operation has influence pension assets allocation in the short run, and the out-performance of equities over bonds and other investment categories and this resulted automatically in higher equity allocation (and vice versa). This is because pension funds do not continuously rebalance their asset allocation. In the medium term, out-performance of equities motivates pension funds to maximise their strategic allocation (and vice versa). Conclusively, the estimates showed that the investment policy of pension funds is slightly driven by cyclical performance of the stock market.

However, as plausible the earlier studies were, none of the studies have taken holistic view on the contribution of Contributory pension fund to the capital development of the Nigerian economy by looking at the contribution of the pension assets to the gross domestic products in recent time. Few studies have been carried out on pension fund and capital development and on capital formation in Nigeria especially, capturing the most recent happenings in the use of pension funds for capital development. Earlier study by Eke and Onafalujo (2015) made use of ordinary least square (OLS) alone to analyse data. This has been proven not to be reliable enough to address the consequences of auto-correlation which this study addressed by using ADF unit-root test to address such short-coming.

This study improved on the existing works on the use of pension funds to provide capital in Nigeria. Reliable data were gathered from PenCom annual reports for eleven-year period (2007 – 2017) and also from the reliable Central Bank of Nigeria Statistical Bulletin (2017). Seven portfolios from those specified in the Pension Reform Act (2014) were used against gross domestic product (GDP) to arrive at robust results. In order to obtain the results, descriptive statistics, unit root test, co-integration test, ordinary least square (OLS), Engle-granger test and parsimonious ECM tests were carried out to surpass the results in previous studies. It was found out from the earlier studies above that capital development through pension funds were not examined up to date thereby distorting the actual contribution the funds has made to capital development in Nigeria. Akpan and Ukpong (2014) only examined capital formation through pension fund in Nigeria up to 2013. Zubair (2016) looked at just few macroeconomic variables (interest rate, inflation and GNP per capita) The gap discovered from literatures included increasing the size of the macroeconomic variables and expanding the years of consideration of the effects of the variables on the pension fund investments and Nigeria's economic growth from 2007 to 2017. This study delved into how contributory pension scheme has provided reliable funding to financial and money markets with a view to examine how such funds availability have created an impact in the Nigeria Gross domestic products (GDP). As at the time of writing this paper, no study has been carried out to look at the contributory effect of employing pension assets to provide capital and impact on the GDP up to 2017.

Theoretical Framework

The theory of pooling as discussed in the work of Matheson, Jorge, Ramana and Anna, (2004), the theory of intermediation applied by Allen and Santomero, (1998), and the theory of life cycle used in Bailliu and Reisen, (1997) are relevant to this study. These theories follow Tijani (2002) because most of the studies conducted were on developed economies. It is therefore believed that using the theories on the study of Nigeria is quite relevant. Adoption of the theories help the study to determine how the investment management processes of the magnitude volume of pension fund contribution and the indivisibility assets such as property which are not within the reach of small investors contribute to capital development in Nigeria. Adoption of pooling theory is to confirm whether or not pension funds could compensate for the rising risk by pooling at a minimal cost across assets whose income are imperfectly correlated.

Intermediation theory was adopted to help the study establish whether the operation of pension funds is to be seen as agents of economic development and growth by rekindling the functions of financial systems more efficiently than banks and individual investors. Pension fund managers are considered growth oriented when they are able to cover all their costs of operation from the revenue generated for themselves, which they derive from pension contributions. Life cycle theory was adopted to discover the development of pension fund as coming from three stages consisting of start-up and growth and maturity stages. This theory explains the three stages of development of pension fund managers and their financing needs. Life-cycle theory also proposes that the sources of pension fund manager‘s funding has linkage with their stages of development and economic development and growth (Lapenu and Zeller, 2001 and Farington and Abrahams, 2002)

Materials and Methods

The methodology adopted for the study involved the use of time series data obtained from PenCom Annual Reports, annual reports of Pension fund administrators (PFA) operating in Nigeria (2007-2017) and Central Bank of Nigeria (CBN) Statistical Bulletin (2017). Data on Gross domestic product (GDP) were sourced from Central Bank of Nigeria (CBN) Statistical Bulletin (2017), and data on Cash and other assets (COA), Corporate debt instruments (CDI), Federal Government of Nigeria securities (FGNS), Domestic ordinary shares (DOS), Local money market instruments (LMMI), Mutual funds (MUF) and Real Estate properties (REP) sourced from Annual reports of PenCom and Pension Fund Administrators for the years under study. Data were analysed using descriptive statistics, test of stationarity using Augmented Dickey-Fuller (ADF), unit root test, co-integration test, ordinary least square (OLS), Engle-Granger Test for co-integration and parsimonious ECM. Stationarity test was adopted on a priori that most times series data have unit root. However, to study the long run relationship of micro economic variables to economic growth, the series must be tested for unit root where if found that such exists, we apply integration approach to stationarity for such model to be efficient. Engle granger cointegration approach was adopted due to the smaller number of observations used for the analysis. This was because adoption of the Pension scheme started in year 2007.

Model Specification

The model specification for the study is as given is as given below:

$$GDP = f(COA+DOS+LMMI+MUF+REP+FGNS+CDI) \quad (1)$$

$$GDP_t=\beta o+\beta_1 COA_t +\beta_2 DOS_t+\beta_3 LMMI_t+\beta_4 MUF_t+\beta_5 REP_t+\beta_6 FGNS_t+ \beta_7 CDIt+\mu_t \quad (2)$$

Where,

GDP = an indicator representing Gross Domestic Product (Dependent variable);

βo = a constant;

$\beta_1, \beta_2, \beta_3, \beta_4, \beta_5. \beta_6,$ and β_7 = Coefficients of the Independent variables

COA_t = a predicator representing independent variable (Cash and Other Assets of Pension Administrators);

DOS_t = a predicator representing independent variable (Domestic Ordinary Shares);

$LMMI_t$ = a predicator representing independent variable (Local Money Market Instruments);

MUF_t = a predicator representing independent variable (Mutual Funds);

REP_t = a predicator representing independent variable (Real Estate Properties);

$FGNS_t$ = a predicator representing independent variable (Federal Government of Nigeria securities);

CDIt = a predicator representing independent variable (Corporate debt instruments);

and

μ = Stochastic error term.

Results and Discussion

Descriptive Statistics

Table 1 contains summary statistics for the variables drawn for this study. The results revealed that the average for GDP was 75681.59t with a maximum of 113711.6t and minimum of 32995.38t, CDI has an average of 118.4070 with maximum of 285.82 and minimum of 0.24, COA over the period was about 26.5585b, with a maximum of 38.22b and minimum 14.19b respectively. The average DOS over the period was about 447.1740b, with a maximum of 672b and minimum 220.71b respectively. The FGNS has an average of 2322.798b with maximum and minimum of 5292b and 279.69 respectively. The LMMS averaged 478.6095b over the study period with a maximum of 681.35b and minimum of 186.01b. The MUF was at the average of 14.077b and it fluctuated between the upper limit of 24.99 and the lower limit of 4.46b. Also, the average REP during the period stood at 188.5510b, with a maximum of 233.89b and minimum of 79.08b.

Unit Root Test Results

Before the estimation of the empirical models, the unique characteristics of the data were examined. Testing the stationarity of economic time series is vital since stationarity in time series data is assumed in standard econometric methodologies. In actual sense, there might be violation of the assumption of stationarity. This may render statistical tests inappropriate and the inferences drawn may result in misleading conclusions. The study employed augmented Dickey-Fuller (ADF). The unit root tests results for stationarity for the ADF of the variables is as presented below. The ADF results in Tables 2 shows that all the variables are non-stationary at their levels.

Table 2: Unit Root Tests Results for Stationarity of the original data

Variable	Augmented Dickey Fuller Test (ADF)					
	Level	Critical value at level	First Differencing	Critical value at First Differencing	Second Differencing	Critical value at Second Differencing
COA	-2.006637	0.2796	-3.028536	0.0615	-3.298547	0.0215*
DOS	-0.633083	0.8203	-4.1372608	0.5443	-4.179698	0.0041*
GDP	0.985921	0.9916	-3.197897	0.0752	-3.397297	0.0193*
LMMS	-2.908967	0.0787	-3.114373	0.1096	-3.444363	0.0108*
MUF	-1.384397	0.5463	-4.336687	0.2036	-4.475997	0.0208*
REP	-2.875221	0.0861	-5.678336	0.2082	-6.678446	0.0010*
FGNS	2.250499	0.9993	-2.291552	0.0654	-3.123342	0.0072*
CDI	0.227563	0.9587	-2.614221	0.1248	-3.467156	0.0413*

Source: Authors' Computation, 2019

The unit root test in Table 1 shows that COA, DOS, GDP, LMMS, MUF, REP, FGNS and CDI are not stationary at levels and I(1). However, they are all stationary at second difference I(2), since the p-values of each of the variables at second difference are less than 5% significance level. Hence, the variables are stationary at second differencing. As a result of the stationarity of the series at I(2), we go ahead to test the variables for cointegration using Engle granger approach as evidenced from table 3.

Co-integration Test Results

Table 3: Engle-Granger Test for co-integration

Dependent	tau-statistic	Prob.*	z-statistic	Prob.*
GDP	-7.214869	0.0200	-28.32143	0.0064
CDI	-5.500782	0.1718	-73.70584	0.0000
COA	-4.600604	0.4069	-45.30706	0.0000
DOS	-4.990113	0.2878	-54.13693	0.0000
FGNS	-6.585175	0.0447	-26.65745	0.0288
LMMI	-5.785776	0.1334	84.19101	1.0000
MUF	-5.167406	0.2342	-23.49360	0.1580
REP	-6.946105	0.0282	-27.65509	0.0124

Source: *Authors' Computation, 2019*

From table 3, it can be evidenced that virtually all the variables have long run relationship with economic growth (p-value <5% level of significance) except LMMI and MUF since there associated p-values were relatively higher than 5% level of significance.

Parsimonious ECM Results

Table 4: Summary of Parsimonious ECM

Variable	Coint. Eq	Standard Error	t-Statistic	p-value
ECT_{t-2}	0.227394	1.028522	0.221088	0.8295
D(CDI)	167.0588	145.1526	1.150918	0.2765
D(COA)	418.3159	33.00462	12.67447	0.0000*
D(DOS)	66.55813	9.563181	6.959832	0.0010*
D(FGNS)	66.27734	16.77638	3.950634	0.0000*
D(MUF)	949.9702	191.2802	4.966380	0.0000*
D(REP)	119.3713	19.12682	6.241042	0.6984
C	71989.22	6898.328	10.43575	0.0009

Source: Author's computation

The long run coefficients form which allows for the determination of the short run adjustment process towards the long run equilibrium state in the system known as error correction modelling as written in equation 3. The result of the error correction term in table 4 suggests that the previous year's deviation from long run equilibrium is corrected at a speed of 22.7%. This indicates that economic growth as a measure of capital development and pension assets has inertia of adjusting back to a state when acted upon by external forces.

It can also be evidenced from the table that after adjusting for long run equilibrium, coefficients of the predictor variables were statistically significant as it explains the behaviour of economic growth in Nigeria particularly during the period under consideration. This is an indication that the economic growth in Nigeria was influenced by the current state of Cash and other assets (COA), Domestic ordinary shares (DOS), Real estate property (REP) for the year under study.

Table 5: OLS Regression Result

Variable	Coefficient	Standard Error	t-Statistic	p-value
COA	105.6209	43.63133	2.420759	0.0297*
DOS	48.75018	4.057147	12.01588	0.0000*
LMMS	5.63E-04	0.000360	0.308664	0.9229
MUF	-0.006312	0.006856	-0.747427	0.6469
REP	134.7533	10.31946	13.05818	0.0000*

CDI	-5.522705	13.96173	-0.395560	0.6984
C	6991.714	1666.645	4.195083	0.0009

R =0.9992; R-square=0.99843;Adj. R-square=0.99787;
F-stat = 1780.637 (P-value 0.000); DW = 2.1265
Source: Authors' Computation, 2019

Table 5 shows that the overall significance of the OLS regression results for the model implies that it was statistically significant at 5 percent level, indicating that the model was sufficient and adequate in relating the dependent and the independent variables together. In addition, about 99.8% of the total variation in gross domestic product (GDP) is explained by the joint effect of COA, DOS, LMMS, MUF, REP, FGNS and CDI. The model result tells us that GDP has a positive and significant relationship with COA, DOS, REP and FGNS as indicated in table 4. Thus a unit increase in COA results in 105.6 unit increase in GDP (provided other independent variables were held constant); a unit increase in DOS will cause 48.75 unit increase in GDP (provided other independent variables are held constant). Also, a unit increase in REP results in 134.75 unit increase in GDP. Lastly, every unit increase in FGNS results in 8.322 unit increase in GDP. This implies that for the years under consideration, increase in Cash and other assets (COA), Domestic ordinary shares (DOS), Real estate property (REP) and Federal Government of Nigeria securities (FGNS) lead to increase in Gross domestic product (GDP). However, out of these variables, Real estate property (REP) contributes more to GDP followed by Cash and other assets (COA). The least contributing variable is Federal Government of Nigeria securities (FGNS).

Conclusion and Recommendations

This study has provided evidence on the effect of the pension scheme on economic growth of Nigeria using error correction mechanism (ECM) and Ordinary Least Square (OLS) methodology. It was observed from the analysis that increase in pension fund has positive effect on the economic growth. The cash and other assets, domestic ordinary shares, real estate property and federal government of Nigeria securities have positive and significant effects on GDP. However, the original data for the variables under consideration were not stationary at their levels. Hence, they were made stationary at second order differencing, which leads to their integration at order two for long run effect to be measured. The co-integration test was conducted using Engle-granger produced and developed by Robert Engle in 1987. It was established that co-integration exists among Cash and Other Assets (COA), Domestic ordinary shares (DOS), real Estate Property (REP), Federal Government of Nigeria Securities (FGNS) and Gross Domestic product (GDP).

The ordinary least square (OLS) result shows that increase in cash and other assets (COA), domestic ordinary shares (DOS), Real Estate Property (REP), Federal Government of Nigeria Securities (FGNS) lead to increase in GDP, meaning that increase in these variables will cause increase in the amount of pension assets invested, hence an increase in GDP. Result of parsimonious error correction model (ECM) reveals that these variables are significant at their levels and past level of federal government of Nigeria securities. However, while cash and other assets, domestic ordinary shares and real estate property have effect at their present levels, the federal government of Nigeria securities have significant effect at past level. This indicates that the past value of Federal Government of Nigeria securities is having effect on GDP of Nigeria. The results have correlation with the study carried out by Zubair (2016) but for the fact that the study made use of fewer macroeconomic variables.

From the foregoing, it was found out that investment of pension funds improves the size of financial and capital employed in business positively. This will also bring a positive influence on the Nigeria gross domestic product (GDP). Further use of pension assets as source of capital for industries is highly recommended so as to aid the supply of needed capital in the industries. It is, however, recommended that there should be adequate monitoring and control of the movement of the pension assets to the users of the funds by the regulators of pension funds in Nigeria, in this case, the National Pension Commission (PenCom). The commission should carry out its oversight functions over Pension Fund Administrators (PFAs) and Pension Fund Custodians (PFCs) with utmost efficiency. There is the need to expand the investment windows of pension funds to give room for optimum investments in order to further boost the GDP.

Finally, since the investment of pension funds in capital and money markets is meant to generate returns on investment (ROI), it is expected that such returns should translate to further income to the pension fund contributors and pensioners, which means increase in the amount credited to their Retirement savings account and as a soft-pad for eroded value of money due to inflation. The study had beamed a searchlight on investment of pension fund and the outcome of such investments in different portfolios. There will also be caution to pension managers to invest the funds in better income-yielding portfolios with minimal risks. The result of this is better living standard for potential retirees and existing retired persons in Nigeria.

Abstract

The article discusses the information and communication sector of the Russian economy. His condition is assessed by various indicators reflecting his role in the country's economy. Since the digital Russian sector is still quite young and not all the institutions that regulate and promote its development are fully operational, it has not high indicators compared to the leading countries of the industry. This conclusion is confirmed by the data on the digital competitiveness rating of the countries of the world where Russia occupies only 40th place out of 63. The article identifies the reasons for the low development of the ICT sector and suggests measures to improve its situation.

Keywords: Digital Technologies, Russian Federation, IKT Sector, Digital Competition.

Introduction

Digital technologies play a key role in improving the competitiveness of the economy and in stimulating the economic growth of many countries. The use of digital technologies launches the modernization of traditional sectors of the economy and creates new industries, which becomes the basis for economic growth. The introduction of new digital technologies increases labor productivity, reduces business costs, increases the availability of information and reduces barriers to entry into new markets, which has a multiplier effect on the development of the economy.

Recognizing the importance of digital technology, many countries are taking steps to accelerate digital development. According to OECD data, 32 of the 36 member countries of the organization, as well as 6 partner countries, have national digital strategies (OECD, 2017). Large-scale programs for the development of the digital economy operate in the USA, China and the countries of the European Union, and exists in Russia.

The high penetration of digital technologies in economic activity allows us to use these competitive advantages to strengthen our position in the world. Countries that fail to fully realize the digital transformation and realize their potential risk falling behind more successful partners and fail to provide the population with a high standard of living, guarantee their economic sovereignty. All this confirms the relevance of this work (Plotnikov, V., Kuznetsova, V., 2018).

The purpose of the work is to assess the level of development of the digital sector of the Russian economy based on several indicators characterizing the degree of development of the industry and propose measures conducive to its development.

The objectives of the study are:

- Consider the main features of the IT sector of the Russian economy;
- Determine the place of the ICT sector in the country's economy based on indicators;
- Analyze Russia's place in the global ranking of digital competitiveness;
- Identify the obstacles to the development of the digital sector of the Russian economy;
- Propose measures conducive to its development.

To achieve the stated goal, theoretical methods and a systematic approach are used, allowing to consider the ICT sector as a system. The method of comparative analysis of statistical data comparing individual economic phenomena in order to identify their similarities and differences made it possible to identify the characteristic features and problems of the Russian information and communication technology sector. The method of formal logic allowed us to consider the processes taking place in the digital sector of the Russian economy.

Results and its Discussion

The information and communication technology sector (ICT sector) are a collection of organizations engaged in economic activities that are related to the production, distribution and application of information and communication technologies.

The structure of the Russian ICT sector includes the following sectors:

• Telecommunications;
• IT and other information services;
• Production of ICT equipment;
• Wholesale trade in ICT goods;
• Publishing activities;
• Activities in the field of production, rental and screening of films, broadcasting and television.

The largest share in the overall structure of the ICT sector belongs to telecommunications, their share in 2010 was 50%, and in 2017 already 38%. The second place is taken by IT and other information services, their share in 2010 was 16%, and in 2017 increased to 33% due to the growth of data processing services. In connection with the development of projects in the field of state information systems, a high share has grown in the production of equipment (16%). The share of other elements of the sector has not changed dramatically and amounts to an average of 5-7%.

The contribution of the digital sector to the Russian economy is relatively small in comparison with the economies of developed countries. So, in 2018, its share in the economy amounted to 3% of GDP. At that time, in most developed countries, the size of the digital sector averaged 6-7% of GDP. In France - 5.7%, in Germany - 6.3%, in the UK - 7.1%, in the USA - 7.4%, Sweden - 8.6% (Fig. 1).

In absolute terms, Russia's digital sector is also relatively small - in 2018, its size amounted to 2.5 trillion. rub. (PPP 103 billion US dollars). At the same time, in Japan, with a comparable population, the digital sector is almost 3.5 times larger (355 billion US dollars in PPP), and in the United States with a twice as large population - 13 times (1348 billion US dollars) (Abdrakhmanova G. et. al. 2018).

Fig. 1: Share of the digital sector in GDP by country, %.

Compiled by authors from the Digital Economy Indicators in the Russian Federation: 2018.

The Russian IT sector is characterized by a small number of companies working in it. As of 2018, only 0.8 enterprises of the IT sector accounted for 1 thousand people. In developed countries, the number of enterprises per 1,000 people averages 2.7 (Fig. 2). For example, Germany, which has 1.3 enterprises per thousand people, is making serious efforts to rectify the situation: in recent years the number of enterprises has decreased by more than 40%.

Since technological and innovative enterprises are the driver of the development of the digital economy, their small number in Russia poses serious risks for the digital development of the country.

Fig. 2: Number of enterprises in the IT sector and per 1 thousand people, units.

Compiled by authors from the Digital Economy Indicators in the Russian Federation: 2018.

In 2018, the number of people employed in the ICT sector in Russia amounted to 1.7% of the total number of people employed in the economy (1.2 million people). This value is significantly lower than in most developed countries, where it averages about 3%. For comparison, 2.7% of people employed in France in the IT sector, 2.9% in Germany, 3.1% in the USA, and 3.5% in the UK (Fig. 3). The low share of employees in this sector only confirms that the digital sector in Russia is relatively small.

Compiled by authors from the Digital Economy Indicators in the Russian Federation: 2018.

Fig. 3: Percentage of employees in the ICT sector of the total number of employees, %.

In 2018, the value added per 1 employee in the ICT sector in Russia amounted to 1.8 million rubles, or 75 thousand dollars. USA (PPP). Which is significantly lower than in European countries such as

Finland, France, Germany, Sweden, Great Britain and Norway (Fig. 4). In these countries, there is a closer relationship between digital technologies and applied software products - primarily in the field of finance, new equipment is being developed, and modern technologies are being introduced. Leading countries are Norway, the UK and Belgium.

Compiled by authors from the Digital Economy Indicators in the Russian Federation: 2018.

Fig. 4: Value added per 1 employee in the ICT sector, thousand dollars. US (PPP).

Over the past 8 years, the growth dynamics of the digital sector of the Russian economy has changed significantly (Fig. 5). It can be noted that on average from 2010 to 2013 the growth was 4.8%. Since 2014, there has been a decrease in the growth of the ICT sector, and in 2016 it showed a negative value. In subsequent years, there was an increase, which in 2018 amounted to 5%.

Compiled by authors from the Digital Economy Indicators in the Russian Federation: 2018.

Fig. 5: Growth rates of the digital sector in Russia, %.

The peculiarity of the digital sector in Russia is that it has a high state share. The share of state ownership in the authorized capital of companies in the IT sector was 35.2% in 2018. The campaigns that occupy a large share in the digital sector are the state corporation Rostec and the company Rostelecom. At the same time, the share of small and medium-sized businesses in the communications sector was only 13.1%, while the share of Rostelecom accounted for 16.4% (Selishcheva T.A. et al. 2018).

In this case, the state is one of the main participants in the ICT sector and one of the main consumers of information products and services. The growth of the digital sector of the Russian economy is largely due to the expansion of the public sector, which is reflected in the creation of new public accounting systems in the fiscal sphere and the creation of new state and municipal systems (e-government,

digitalization of transportation). Examples of government investments in the development of the country's digital sector can be seen in table 1.

Table 1: State investments in the digitalization of the Russian economy

	Project	Number of devices	Investment
1	Online ticket offices	2 million	30 billion rubles
2	System PLATON	1 million	6.8 billion rubles
3	Tachographs	1 million	30 billion rubles
4	EGAIS ALCOHOL	69 000 companies	284 million rubles

Compiled by N. Sopina

From the foregoing, it can be concluded that the digital sector of the Russian economy is still underdeveloped and requires significant investment not only from the state, but also from private business. Let us consider what factors influence the competitiveness of Russia in the field of digital technologies in the world based on the rating of the World Competitiveness Center.

Digital competitiveness shows the degree to which a country implements and explores digital technologies that contribute to the transformation of the state, business and society itself.

The main countries ranking first in the global digital competitiveness ranking are presented in table 2.

Table 2: The leading countries in the global ranking of the digital competitiveness in 2017-2018.

2017			2018		
Number in the rating	**%**	**Country**	**Number in the rating**	**%**	**Country**
1	100	Singapore	1	100	USA

9	91,671	Canada	9	93,886	Netherlands
10	90,790	Norway	10	93,239	United Kingdom
42	62,854	Russian Federation	40	65,207	Russian Federation

Compiled by authors from the World digital competitiveness ranking 2018.

According to the rating, in 2018, most of the countries that participated in the study increased their digital competitiveness, while about 40% of countries showed a decrease in level and only eight countries continued to remain at the same level. It should be noted that the change in the level of digital competitiveness is not directly related to the geographical position of the country but is directly determined by the conditions that allow improving the level of digitalization of the state (Tab. 1).

As for Russia, in 2018 the country improved its position in the ranking and moved from 42 to 40 places, which is determined by an increase in the level of factors such as technology (from 44 positions to 43) and readiness for the future (from 52 positions to 51) (Borkova E., Kochkin T et al.).

The “knowledge” factor did not change its values in 2018, as in 2017 it is equal to 24 points. At the same time, the situation on sub-factors was as follows: “talent” decreased from 35 to 40 positions, it should be noted that Russia’s weakness is the low involvement of international experience (59 points), “training”, on the contrary, the indicator improved its position from 14 to 12 , this is due to the fact that Russia has high indicators in such areas as the level of higher education (8), the ratio of students and teachers (12), the number of graduate students (13), and the number of women with an academic degree

(3). sub-factor "development of scientific potential" moved from 25th to 23rd place, , which is related to such indicators as an increase in the efficiency of R&D (6), but the weaknesses were a small number of patents (35) and low R&D expenses (OECD, 2017).

The “technology” factor in 2018 increased its value from 44 to 43 points. Let us consider in detail what change in subfactors led to this. The sub-factor “regulatory framework” here should state a deterioration, as the indicator has shifted from 36th to 38th place. This can be explained by the low level of protection of intellectual rights (52), the legislation on scientific research (50) and technology development (51) is not well developed, however, a positive trend in the implementation of contracts should be noted (17). The technological base sub-factor weakened its position by 1 point, falling to 38. Here, the weakness should be noted: insufficient number of Internet users (45), wireless broadband (44), Russia's dependence on high-tech exports and low Internet speed (36), but as a plus, many mobile users can be called (28). The sub-factor “capital”, it also decreased, moved to 58 position, adding 1 point.

Here, the minuses for attracting capital to the development of technologies in the ranking are indicated first of all - these are high investment risks (57), low attraction of venture capital (55), insufficient level of banking and financial services (53), the highest indicator is investment in telecommunications sector (37).

The factor of “readiness for the future” in 2018 rose to 51 lines, which is associated with a positive trend in some sub-factors. So, the sub-factor “adaptive attitudes” increased its value by 5 points. This positive direction is associated with participation in the development of digital technologies (28), the level of smartphone ownership (31), the weakness of the rating highlights the attitude towards globalization (61). The “business flexibility” sub-factor, on the contrary, worsened its importance and increased from 59 to 62 places. Here, weaknesses of companies about digitalization (61), insufficient use of big data (58) and knowledge transfer (54) are indicated as weaknesses, but the increase in the number of innovative companies (46) can be called a plus. The sub-factor "IT integration" takes 38th place, worsening it by one position. According to the rating, Russia has low security against computer piracy (54), insufficiently well-developed public-private partnerships in the field of digital technology development (50), insufficient cyber security (37), but a high rate of electronic government development (30).

Compiled by authors from the World digital competitiveness ranking 2018.

Fig. 6: Comparison of the level of competitiveness and the level of digital competitiveness of Russia.

If we compare the level of world competitiveness of Russia and the level of its digital competitiveness, we see that in the second rating Russia occupies better positions than in general world competitiveness (Fig.6). This can be explained by the fact that the overall global competitiveness rating considers not only the level of development of (digital) technologies, but also other areas of the country's economy.

Conclusion

The sector of information and communication technologies in Russia began to emerge quite recently, therefore, in terms of its indicators, it lags the digital sector of foreign countries. This is evidenced by the low level of digital competitiveness of the country. The main reasons are:

Poorly developed legislation for the protection of intellectual property rights;

• The development of the Internet network is insufficient due to the large territory of the state;
• Underdevelopment of a venture capital institution;
• High investment risks;
• Cybersecurity issues.

To solve these problems, a comprehensive interaction of business and the state is necessary. The state should pay attention to the following issues, the solution of which can contribute to the development of the ICT sector:

• Attraction of investments;
• Creation of conditions for the development of small and medium-sized businesses in the IT sphere;
• Training of qualified personnel;
• Creation and development of new technologies considering world experience;
• Development of the institution of public-private partnerships in the field of digitalization;
• Improving legislation.

Abstract

The integration of Romania into the European Union has led to the development of the vegetable agricultural sector by increasing the agricultural surfaces destined for cereal cultivation. Using new technologies, financial programs to support farmers and quick access to the international market, Romania ranks among the top producers and exporters of cereals in the European Union. The study compares the evolution of wheat and maize productions during 2007-2018 and the trade in the same period.

Keywords: Wheat, Corn, Export, Import

Introduction

Grain cultivation is a long and important tradition in Romania. The production of wheat and maize has grown significantly in recent years due to the measures taken by the government to support farmers both in setting up crops, stimulating the use of high-performance technologies, storing them and marketing them.

Wheat (Triticum aestivum L.) is one of the most important crops, providing over 20% of the calories consumed by the world population. Global wheat production in 2017/18 was 757.92 million tons, increasing with 5.92 million tons compared to the previous year (STATISTA, 2019). In the year 2050, the world population is estimated to be 9 billion, while the demand for wheat is estimated to reach more than 900 million t (Dixon et al., 2009). In many countries, wheat (Triticum aestivum L.) is a widely grown and major field crop, and as such it is of great economic importance. (Har-Gil et al., 2011).

The European Union reported that its wheat production in the year 2017/18 raised at 151.58 million tons, being the main wheat producer and exporter, alongside China, India and Russia. Egypt, Indonesia and Brazil being the largest importers (Statista, 2019). Within these trade exchanges, special attention is paid to the quality of wheat that plays an important role in price justification.

The European Union (EU) harvested 129.0 million tonnes of common wheat and spelt in 2018, representing 43.7 % of all cereal grains harvested. This was 13.6 million tonnes less than in 2017, a decline of -9.5 %. The main reason for this decline was the drought in central and northern Europe, although the cultivated area of common wheat and spelt was also slightly lower (-1.6 %) than in 2017. In contrast, the harvested production of grain maize and corn-cob-mix (CCM) in the EU was

4.4 million tonnes higher in 2018 at 69.1 million tonnes, with much of that increase coming from much higher production levels in Romania (+30.3 %) and Hungary (+18.4 %). (Eurostat, 2020).
The harvested production of cereals (including rice) in the EU was 295.1 million tonnes in 2018, about 11.3 % of global production. This was 14.9 million tonnes less than in 2017, representing a sharp fall of -4.8 %. This decline reflects the drought conditions that prevailed in many areas of central and northern Europe, the cultivated areas of cereals being broadly unchanged (-0.3 %). To put this in some further context, the EU's harvested production of cereals in 2018 was 37.5 million tonnes lower than the record harvest of 332.6 million tonnes in 2014.

France harvested 62.6 million tonnes of cereals in 2018, a little more than one fifth (21.2 %) of the EU's total production. Germany harvested 38.0 million tonnes (12.9 % of the EU total), Romania a further 31.5 million tonnes of cereals (10.7 % of the EU total) and Poland harvested 26.8 million tonnes (9.1 % of the EU total). (https://ec.europa.eu/eurostat, 2020).

According to the data published by STATISTA, the wheat production estimated at EU level in 2020 will be approx. 136.7 million tonnes, with an annual increase of approximately 1.2-1,3 million tonnes per year, following that in 2028 the estimated production will reach 144.2 million tonnes, being still below the production obtained in 2015, respectively 144, 4 thousand tons.

Materials And Methods

The article follows the evolution of wheat and maize productions in Romania between 2007-2018, as well as the evolution of imports and exports during this period. The data come from the reports of the Ministry of Agriculture and Rural Development, the National Institute of Statistics and the European Commission. The analyzed period represents the first 11 years since Romania's integration into the EU and the effect of investments in agriculture.

Results and Discussions

Romania has the 6th largest agricultural area used between EU countries and is among the top 10 exporters of wheat and maize. According to the data published by National Institute of Statistics of Romania (INS), the wheat production in Romania in 2018 was 10.14 million tonnes compared to 2007, when the production was 3.04 million tonnes. The growth of 330% in 2018 compared to 2007 was influenced during the period analyzed by the economic measures to stimulate the agriculture, the support programs for farmers, the development of irrigation networks, access to European funds. Table 1 shows the wheat production from 2007-2018, noting that 2018 was the year with the highest production.

Table 1: Evolution of wheat productions in Romania between 2007-2018

Year	Surface (thousands of hectares)	Average production Kg/ha	Total production mii to
2007	1.975,0	1.541	3.044,5
2008	2.110,3	3.403	7.181,0
2009	2.148,8	2.421	5.202,5
2010	2.162,4	2.688	5.811,8
2011	1.947,0	3.663	7.131,6
2012	1.997,6	2.652	5.297,7
2013	2.104,0	3.468	7.296,4
2014	2.112,9	3.59	7.584,8
2015	2.106,6	3.78	7.962.4
2016	2.137,7	3.944	8.431,0
2017	2.052,9	4.888	10.035,0
2018	2.109,0	4.803	10.130,0

Source: Ministry of Agriculture and Rural Development

The use of new technologies and varieties and hybrids adapted to the pedoclimatic and drought-resistant conditions, diseases and pests have led to an increase in average yields per hectare. The arable agricultural areas used in the cultivation of wheat did not suffer any diminution or significant increases, the differences coming mainly from crop rotation. Of the agricultural area used in Romania, respectively 14.6 million hectares, the arable area represents 64%, respectively 9.4 million hectares. For wheat cultivation, a percentage of 20-22% of the total arable land is constantly used, and the share of arable land intended for corn cultivation is on average between 26-28% of the total agricultural area of the country.

Wheat production in the EU at 2019 level stood at 135.324 million tonnes, compared to 124,892 million tonnes in 2018 and 137,707 million tonnes in 2017. Based on the centralized data in Table 1, we can see the weighted growth of Romanian wheat production in production at EU level, reaching in 2018 at 8.1%.

From the comparative analysis presented in the Table 2, it results that the corn production per hectare has increased significantly, and at the national level the corn production reached 18,353 million tonnes reported in 2018, compared to 3,853 million tonnes in 2007.

From the two tables there is a record increase of wheat and maize production in 2011 and a decrease in 2012, these fluctuations of production are motivated by the environmental factors of the respective agricultural year.
Another factor that has influenced the yields per hectare is the association in producer groups and the purchase or lease of land by natural persons by farmers, thus obtaining large and compact areas.

Table 2: Evolution of maize productions in Romania between 2007-2018

Year	Surface (thousands of hectares)	Average production	Total production
		Kg/ha	mii to
2007	2524,7	1526	3853,9
2008	2441,5	3215	7849,1
2009	2338,8	3409	7973,3
2010	2098,4	4309	9042,0
2011	2589,7	4525	11717,6
2012	2730,2	2180	5953,4
2013	2518,3	4488	11305,1
2014	2512,8	4770	11988,6
2015	2605,2	3462	9021,4
2016	2581,0	4159	10746,4
2017	2402,1	5959	14326,1
2018	2371,0	7740	18.353,0

Source: Ministry of Agriculture and Rural Development

The ability of a country to face challenges in the international market depends upon the export competitiveness of the country. (Kedar et al., 2003)

At EU level, Romania is one of the top wheat exporters in Europe, and since 2008 the quantity of wheat exported has been constantly higher compared to the imported quantity. In 2016, the largest quantity of wheat exported and the largest quantity of important wheat, as shown in Table 3.

Table 3: Evolution of imports and exports of wheat in the period 2007-2018

Year	Imported quantity (tons)	Imported value (thousands of euros)	Exported quantity (tons)	Exported value (thousands of euros)
2007	587.525,7	108.968,9	206.633,7	45.936,9
2008	441.636,9	93.295,2	1.988.757,9	381.635,1
2009	628.843,0	77.874,2	2.340.673,1	302.947,4
2010	719.954,0	112.444,4	2.480.143,0	379.446,1
2011	559.138,5	124.235,5	1.568.734,0	309.768,9
2012	531.827,0	118.663,4	2.314.888,2	544.095,9
2013	679.827,7	122.897,1	4.773.293,8	977.679,5
2014	670.919,4	116.079,9	4.965.442,7	959.356,8
2015	652.266,9	115.459,3	3.555.280,7	692.534,9
2016	2.155.962,6	330.860,5	6.993.999,2	1.141.908,4
2017	1.249.972,1	203.869,0	5.837.479,8	1.003.815,9
2018	695.173,2	115.544,7	5.886.755,9	1.037.727,8

Source: Ministry of Agriculture and Rural Development

Analyzing the wheat production from 2011 and 2012 and the quantity exported in the respective years, we also observe an increase of the price per ton in 2012 by the ratio between the value and the quantity exported.

The export of maize during the period analyzed as shown in Table 4, registered a constant growth from 2008 to 2015, year that is evidenced as having a record production. The imported quantity of maize was greater than the quantity exported only in 2007. As in the case of wheat, there is an increase in the price of maize when purchased on the domestic market in 2011 and 2012.

Table 4: Evolution of imports and exports of maize in the period 2007-2018

Year	Imported quantity (tons)	Imported value (thousands of euros)	Exported quantity (tons)	Exported value (thousands of euros)
2007	667.005,7	126.369,6	312.288,5	74.693,7
2008	521.411,9	127.179,7	695.100,7	134.275,4
2009	813.356,1	130.754,1	1.698.139,9	252.018,1
2010	430.548,7	89.426,9	2.054.488,2	388.317,9
2011	373.881,2	113.221,6	2.310.665,1	578.710,3
2012	698.581,3	191.133,1	2.272.649,4	596.517,6
2013	284.155,7	121.343,3	3.233.350,7	730.995,2
2014	471.204,1	123.510,5	3.708.953,0	755.147,2
2015	1.621.458,1	293.968,4	5.125.274,3	959.907,5
2016	583.451,4	141.228,0	3.439.250,7	702.405,89
2017	463.117,3	130.107,18	3.773.159,53	729.885,51
2018	416.964,6	120.903,5	4.680.005,9	869.347,3

Source: Ministry of Agriculture and Rural Development

At EU level, in 2019, 75.8% of all wheat production was obtained due to the high yields of seven Member States, respectively: France, Germany, United Kingdom, Romania, Poland, Spain, and last

but not least, Italy . Romania, ranked fourth in wheat production, held 7.3% of total wheat production.

In terms of maize production, Romania ranked first at European level, becoming the largest corn grower in the EU. This was followed in the ranking by France, Hungary, Italy, Poland, Spain and Bulgaria.

In the external trade balance of cereals and "cereal preparations" the value of exports was over € 2.17 billion in 2018, and imports amounted to over € 905 million.

In 2017, EU-28 harvested production of cereals was 310.6 million tonnes. The highest levels of production, at least 3.5 million tonnes, were principally located in:

- nine French regions, mainly in the west and the north, including the French region of Centre — Val de Loire which harvested more cereals (8.9 million tonnes) in 2017 than any other region in the EU, producing mainly common wheat and spelt;
- nine German;
- three Romanian regions and two Polish regions. (Agriculture statistics, Eurostat 2020)

Conclusions

The quantitative variations are due to the lack of climate sensitivity or the lack of precipitation in the critical moments of development or harvest.

By implementing a set of measures, Romania could increase its total cereal production and implicitly the quantity of cereals it can export.

Among the necessary measures would be to reduce tax evasion, increase the degree of capitalization of agricultural holdings, the adoption of new technologies, the digitization and use of robots in agriculture.

Considering the vast agricultural area and the reasonable utilization rate in Romania, it is clear that the yield of production is the main limiting factor of the agricultural sector

Abstract

The article explores the scientific and theoretical provisions on managing the cadres' potential of trade enterprises: the nature and methods of evaluating the efficiency of its use. The cadres' potential of trade enterprises is an aggregate of qualified full-time employees whose professional training and work experience enable them to perform the functions and their competences assigned to them within the framework of the trade enterprise's activities. The components of cadres' potential, of which professional and physiological qualities are obligatory, are considered. As a result of the researches the existing methods of the analysis of the level of cadres' potential with improvement of costly, profitable, comparative approaches and personnel audit have been improved. An algorithm is proposed and an assessment of the constituent groups of competencies of cadres' potential of trade enterprises (personal, professional, instrumental, interpersonal and systemic) is made. The indicators of cadres' potential diagnostics are analyzed, as well as a number of reasons that hinder the qualitative organization and carrying out of the cadres' potential diagnostics according to the results of the conducted survey. The conclusions were drawn on the basis of which the outstanding problems in the personnel policy related to: the transformation processes of economic formation and adaptation to the European standards in the personnel sphere were established at the enterprises of Ukraine; preparation of personnel for the needs of the enterprise, type of economic activity, society; mismatch of the system of training and advanced training to the needs of the market; imperfection of the personnel selection system, etc.

Keywords: Cadres, Personnel, Cadres' Potential, Competencies, Diagnostics, Trade Enterprises.

Introduction

Whatever technical capabilities, organizational and managerial advantages are not opened before the enterprise, it will not start to work effectively without the appropriate cadres' potential. The quality of cadres' potential directly affects the competitiveness of the enterprise and is one of the most important conditions for maintaining competitive advantage. Ensuring the efficient use and maintenance of an adequate level of cadres' potential in the enterprise management system is one of the promising ways to minimize the impact of the crisis on the activity of trade enterprises and their competitiveness.

Formation of cadres' potential is a priority of each enterprise. The main task of cadres' potential management is to identify and make the most effective use of the abilities of each employee in accordance with the goals of the company, as well as to establish good relationships between members of the workforce. Today, there is a need to improve the cadres' potential management system of the enterprise, whose main functions will be to perform diagnostics of cadres' potential, and will allow to identify and evaluate the problems of personnel management and plan the directions of its development in the future. Modern Ukrainian enterprises, for the most part, have problems in the area of personnel management, namely: lack of innovative orientation of personnel policy and use of good experience of foreign enterprises; non-accounting by departments of personal characteristics of each individual employee; lack of a clear system of development of cadres' potential of employees, etc. The result of such personnel policy is a high turnover of personnel at enterprises and a low level of interest in achieving organizational goals.

Great contribution to the study of theories of social development and personnel management, including formation of basic principles of modern personnel policy of enterprises, made by both foreign and domestic scientists: M. Amstrong, S. Bandura, D. Bogin, V. Gurne, V. Kibanova, A. Kolot, E. Libanova, M. Magura, J. Roberts, G. Shchekin and others. Scientific views on the criteria and methods of personnel assessment, methodical approaches to the personnel diagnostics at the trade company outlined in the works of T. Bazarov, V. Vasilchenko, A. Grinenko, A. Grishnova, G. Dessler, G. Zavinovskaya, E. Vilka, L. Kerb, A. Krushelnitskaya, V. Moskalenko, A. Oleksiuk, A. Fedonina, A. Shakhno, etc. Various aspects related to the personnel potential of trade enterprises and its evaluation were investigated in the works of V. Apopy, S. Bai, L. Garmider, V. Zhukovskaya, Y. Karpenko, V. Kravchuk, M. Menshikov, G. Pisarevskaya, I. Savchenko, P. Smirnova, A.Hodakevych and others. However, an analysis of scientific publications and practical experience shows that today there is practically no scientifically-based holistic system of staffing for the activities of enterprises that meets the requirements that are changing dynamically. A particularly current problem is the creation of a scientifically based system for an integrated assessment of the cadres' potential of a trade enterprise, which determines the relevance of the topic of the article.

The Main Part

In the modern economic literature, the concept of "cadres' potential" is viewed differently. For example: as a set of qualitative and quantitative characteristics of the personnel of the enterprise, including the number, composition and structure, physical and psychological abilities of employees, their intellectual and creative abilities, professional knowledge and qualification skills, communication skills and ability to cooperate, attitude to work and other qualitative characteristics [Belorus, 2007, p.8]. In a narrower sense, cadres' potential can be considered as temporary vacancies or reserve jobs that can be occupied by professionals as a result of their development and training. According to the results of the analysis of publications in which scientists offered their vision of the essence of the concept of "cadres' potential", it was concluded that there were disagreements in its interpretation. Therefore, in order to clarify and clearly define what it is expedient to understand by the cadres' potential of the enterprise, a systematization of the currently available theoretical approaches to the interpretation of the concept of "cadres' potential" was carried out (Table 1).

Table 1: systematization of definitions of the concept of "cadres' potential" in publications of domestic and foreign scientists

Author (s) / Source	Cadres' potential is:
Resource approach	
G. Boldyreva, F. Mosin [2011]	general (quantitative and qualitative) characteristics of personnel as one of the types of resources, related to the performance of the functions assigned to it and the achievement of the goals of future development of the enterprise;
N. Geber [2013, p.104]	one of the important resource elements of the enterprise potential, the effective formation and use of which allows to achieve the main strategic goals;
Systems approach	
L. Garmider [2011, p.96]	1) a socio-economic phenomenon that reflects the totality of relations (economic, social, organizational, personal, etc.) associated with the enterprise and obtaining the desired result, as well as dependent on the conditions of the production process, distribution, exchange and consumption of labor; 2) what makes the human factor a driving force, that is, its internal basis, a latent opportunity with dynamism;
V. Moskalenko [2010]	a generalized characteristic of the system of formation, distribution and use of personnel, which includes both those employed in social production and the unemployed, but able to work depending on their capabilities;
Continuation of the table 1	
Factor approach	
I. Tsvetkova, A. Sivolap [2007]	skills of employees of the enterprise, which can be used to increase its effectiveness in various fields of production, with the aim of generating income (profit) or achieving a social effect;
T. Bilorus [2007]	the capabilities of workers, the quality of their vocational training, labor, personality, psychological and physiological qualities, as well as the most important creative abilities;
Attributive-synthesizing or integration approach	
N. Kasyanova [2013]	a set of staff abilities and capabilities to ensure the achievement of the goals of long-term (perspective) development of the enterprise;
I. Pletnikova [2007, p.78]	the set of abilities of the production personnel of the enterprise to ensure the production of consumer values that meet the needs of the market in specific economic, scientific and technical conditions of production;
Indicative Resulting Approach	
V. Grineva, G. Pisarevska [2012]	the magnitude of the possible participation of highly skilled workers in production, their ability to innovate, their educational, qualification level, psychophysiological characteristics that can be used to achieve the strategic goals of the enterprise and ensure competitiveness in the market;
V. Dovbenko, V. Melnik [2010]	temporary free or reserve workplaces that may be occupied by specialists as a result of their development and training.

Along with this, on the basis of the analysis of the above definitions, it was concluded that some of them are controversial in their semantic content. For example, the position of V. Grineva, G. Pisarevska [2012] , which associates the cadres' potential only with the possible participation of employees in the enterprise's activity, ignores their existing participation, during which the cadres' potential also manifests itself, is ambiguous. In our opinion, the binding of I. Pletnikova [2007, p.78] on cadres' potential to the capabilities of only production personnel is also incorrect. The cadres' potential of I. Tsvetkova and A. Sivolap [2007] is very narrowly defined, which reduces it to the abilities and skills of workers, neglecting their physical and psychological qualities, professional knowledge and abilities.We cannot agree with the interpretation of N. Kasyanova [2013] and other scientists who associate cadres' potential with those abilities and capabilities of

personnel that ensure the achievement of the goals of only the long-term development of the enterprise. We believe that the cadres' potential at enterprises is used both to achieve long-term and medium- and short-term goals. A fuzzy and one that can come to the definition of other types of activities of the enterprise is the definition proposed by N. Geber [2013, p.104]. We do not support the position of L. Garmider [2011, p.96], where she considers cadres' potential as a socio-economic phenomenon, since the essence always manifests itself in specific objects or actions (in our case, one way or another connected with cadres' potential), and the phenomenon expresses only some side of the essence. Too primitive and one-sided is the proposal of V. Dovbenko and V. Melnik [2010] to determine the cadres' potential of the enterprise through free and reserve jobs and the like. Due to the presence of disagreements in the interpretations of the essence of cadres' potential, there is no single scientific opinion on the definition of its components. It has been established that the vast majority of scientists (90.9% of the sample studied) are of the opinion that professional and physiological qualities are mandatory components of cadres' potential. 81.8% still add psychological qualities to these two components, 72.7% - qualification, 63.6% - social, 54.5% - educational, 45.5% - intellectual, 27.3% - cultural, moral and organizational, 18.2% - humanistic, motivational, communicative, personal, structural and creative, 9.1% - adaptive, innovative, creative, leadership, technical and technological, labor qualities and characteristics, as well as a component of development potential. Based on all of the above, as well as using a competency-based approach, we offer the cadres' potential of an enterprise to understand the totality of personnel and their competencies that determine the personnel capabilities of the enterprise. Thus, by the cadres' potential of a trade enterprise, we consider it appropriate to understand the totality of qualified full-time employees whose professional training and work experience allow them to fulfill the functions and their competencies assigned to them within the framework of the activities of a trade enterprise [Peniuk, 2015, p.243].

As a result of the analysis, a number of methods and approaches for diagnostics of cadres' potential were identified, and a number of their advantages and disadvantages were also highlighted (Table 2).

Table 2: advantages and disadvantages of methods and approaches to the diagnostics of cadres' potential of trade enterprises

Name of method / approach	Advantage (s)	Disadvantage (s)
Methods		
Expert methods	- savings when attracting experts from their own staff; - speed of obtaining results; - objectivity of the assessment of external experts; - adaptation to the values of reference indicators; - coverage of a large volume of qualitative values;	- the need to form an independent / disinterested group of experts; - lack of independent / «fresh» vision; - the cost of attracting external experts; - the risk of obtaining an incorrect assessment by an incompetent expert; - high level of subjectivism;
Pointed methods	- ease of use; - convenience and speed of interpretation of results;	- lack of a unified methodological base; - considerable level of subjectivism;
Methods of economic-mathematical modeling	- possibility of repeated (periodic) calculations of values; - full evaluation / diagnostics; - convenience and speed of interpretation of results;	- the need for special equipment and specialists; - the cost of buying software, updating or modifying it; - moral aging;

Benchmarking method	- systematic eradication of differences from the best representatives of this class; - borrowing the best methods; - achievement of a leading position in competition; - recognition of technological «breakthroughs»;	- a small number of specialists with sufficient experience to implement benchmarking; - restriction in access to information;
Rating methods	- ease of use; - convenience and speed of interpretation of results;	- lack of a unified methodological base; - high dependence on benchmarks; - ack of consideration of the specifics of an enterprise;
Approaches		
Comparative	- reliable factual information improves the accuracy of calculations and reflects the specifics of the object of assessment, taking into account the actual results achieved;	- ignoring the prospects of enterprise development in the future; - the complexity of collecting a large array of information; - the need for complex adjustments; - inability to evaluate unique or specific objects for lack of analogs for comparison;
Profitable	- the image of real benefit; - permission to evaluate the future profitability of cadres' potential; - accounting for economic use;	- complexity of calculations; - subjective risk assessment; - the difficulty or inability to determine the contribution of an individual employee;
Costly	- the ability to accurately estimate the cost of creating the object; - the possibility of elemental assessment of the components of	- limited use of market information in valuation; - difficulties in selecting the most informative quantitative characteristics of the potential;

Ending of the table 2

	cadres' potential; - presence of clearly formalized dependencies between the value of the cadres' potential and the values of the input parameters; - slow adaptation of cumulative costs to changes in their cost over time.	- lack of a single information base of incoming information; - fragmentation of methods of calculation of the same parameters by the methods of different scientists and practitioners; - the difficulty or inability to determine the contribution of an individual employee.

With a large number of diagnostic methods, mainly related to the nature of the functions performed by employees, most of them are based on indicators and standards. Such diversity of methods leads to the idea that the methodology of cadres' potential diagnostics should be based on a system of indicators that would reflect the full utilization of the potential of each of the components of the cadres' potential of the enterprise. As the competitive advantages of the enterprises in the market depend on the level of qualification, professionalism and other qualitative characteristics of the personnel, it is also worth paying attention to studying the methods of assessing the competitiveness of the cadres' potential of the enterprises. Modern economic literature identifies expert, matrix, graphic, mathematical, criterion methods and other methods. For example, indicator methods provide for the comparison of personnel evaluated with personnel from only one competing enterprise, as

well as the determination of the quantitative gap in the values achieved. Matrix methods are to determine the quantitative value of an integral rating indicator of the competitiveness of an individual frame or to graphically determine its competitive position in the competitive matrix by certain parameters.

Since the realization of an enterprise's ability to use or create conditions for the development of cadres' potential is directly related to the personnel policy, which it implements, it is necessary to determine the indicators of its evaluation. Any personnel policy is formed with the purpose of effective use of personnel resources, timely provision of the company's divisions by qualified employees, creation of conditions for effective use and development of the potential of the company's personnel, satisfaction of socio-economic hopes and interests of employees and the like. Under the most favorable working conditions, the staff will be able to provide the highest possible results of the enterprise. Therefore, in our opinion, the evaluation of the effectiveness of the personnel policy will depend, first of all, on the overall results of the enterprise. The process of diagnostics of cadres' potential should be carried out in stages, which simplifies its carrying out. The data of the conducted researches and the analysis of the methodological base for carrying out diagnostics of the cadres' potential of the enterprise indicated their versatility. It is determined that diagnostics can be performed both on its own and by involving external participants, using mathematical calculations or solutions of working situations.

It is established that diagnostics of cadres' potential, when using one or another method, can be accompanied by imperfection in calculations, problems in obtaining information base or attraction of funds, subjectivism or gravity in obtaining quick results, etc. As the results of diagnostics of cadres' potential can allow to form priority areas for investing in human capital, assessing the effectiveness of personnel policy and / or giving impetus to its reconfiguration, and under such conditions such results you can be false, it is worth refining the methodology of cadres' potential diagnostics and adapting it for trade enterprises. Thus, an important component of the development of cadres' potential is its monitoring with the help of specific indicators and analysis of the efficiency of the personnel of the enterprise. Carrying out an assessment of the level of cadres' potential will allow to realize one of the main functions of management - control, and will also provide information on perspective ways of building up. In this context, there is a need to develop approaches to the formation of a system of performance indicators of cadres' potential development that would meet the expectations of stakeholders, allowed to evaluate and analyze the cadres' potential.

Taking into account previous studies [Peniuk, 2016, p.200] let us try to assess the state of development of the cadres' potential of five trade enterprises. We will evaluate the cadres' potential according to their competences, which are its components. Among them: personal (provide the employee with such qualities as responsibility, ability and willingness to self-development, etc.); professional (determined by the ability to act successfully on the basis of practical work experience, skills and knowledge when solving professional tasks) instrumental (include cognitive ability, linguistic and technological skills and abilities); interpersonal (assuming that the employee has such traits as the ability to express feelings, the ability to self-criticize, as well as social skills related to the processes of social interaction and cooperation) systemic (combining understanding, knowledge and abilities that allow to perceive the relationship between parts of the whole and evaluate the location of each component). Within the framework of interpersonal competences, intercultural ones, which are connected with the ability of employees of the enterprise to successfully communicate with representatives of other cultures in the process of fulfilling their duties, can also be distinguished. Let's diagnose the cadres' potential of the enterprise on the example of some trade enterprises. The estimation of the components of cadres' potential of trade enterprises is given in Table 3.

Table 3: constituents of cadres' potential of trade enterprises

Components of cadres' potential	Calculation algorithm	*Optimal value*	Eurobud LLC	Universam LLC	Maxam PE	Zdoroviy son LLC	Val-Yan LLC
Personal							
Responsibility (R)	$R = \frac{N_{ct}}{N_{st}}$, N_{ct} - the number of completed tasks of the employee; N_{st} - number of scheduled tasks of the employee.	1	1,00	0,95	1,05	0,97	1,15
Stability (S)	$S = \frac{N_{ee}}{\overline{E}}$, N_{ee} - number of employees with experience in the organization for more than one year ; $\overline{E}$ – average number of employees of a certain period.	1	0,83	0,88	0,75	0,29	0,45
Determination (D_t)	$D_t = \frac{N_{qe} - N_{ilo}}{\overline{E}}$, N_{qe} - number of employees quitting during the period; N_{ilo} - number of inevitably laid-off workers of a certain period; $\overline{E}$ – average number of employees of a certain period.	1	0,01	0,04	0,13	0,20	0,01
Discipline (D_s)	$D_s = \frac{N_{ae}}{N_{tot}}$, N_{ae}- number of absenteeism of employees during a certain period; N_{tot} - total number of man-hours worked for a certain period.	1	0,02	0,07	0,05	0,13	0,05

Continuation of the table 3

Professional							
Education (E_d)	$E_d = \frac{N_{eh}}{N_{ev} + N_{ebs} + N_{ewe} + N_{we}}$, N_{eh} - number of employees with higher education; N_{ebs} - number of employees with vocational education; N_{ewe} - number of workers with basic secondary education; N_{we}- number of employees without education.	1	0,83	0,82	1	0,61	0,81
Experience (E_x)	$E_x = \frac{N_{ech}}{\overline{E}}$, N_{ech} - the number of employees who have changed jobs within the organization during a certain period; $\overline{E}$ – average number of employees of a certain period.	1	0,01	0,03	0,01	0,05	0,06
Competence (C_p)	$C_p = \frac{In}{\overline{E}}$, In - income from the activities of the unit; $\overline{E}$ – average number of employees of a certain period in unit	Increase	2146	1028	265	545	491
Qualification (Q)	$Q = \frac{N_{hq}}{N_{hq} + N_q + N_{fq} + N_{nq}}$, N_{hq} - number of highly skilled workers ; N_q - number of skilled workers; N_{fq} - number of few-skilled workers ; N_{nq}- number of unskilled workers.	1	0,16	0,75	0,5	0,27	0,30
Instrumental							
Entrepreneurial abilities (A_e)	$A_e = N_{re}$, N_{re} - the number of risky cases performed by the employee during a certain period.	Increase	15	17	14	18	12
The ability to organize activities (A_{oa})	$A_{oa} = \frac{N_{ot}}{N_{pt}}$, N_{ot} - number of organized tasks of the employee; N_{pt} - number of planned employee organized tasks.	1	1	1	1	1	1
Ability to generate ideas (A_{gi})	$A_{gi} = N_{gi}$, N_{gi} - the number of ideas generated by the employee during a certain period.	Increase	9	8	18	16	13

Ending of the table 3

Decision making ability(A_{md})	$A_{md} = N_{md}$, N_{md} - the number of decisions made by the employee during a certain period.	Increase	13	8	18	16	10
Interpersonal (including intercultural)							
Ability to work in a group (A_{gw})	$A_{gw} = N_{zgw}$, N_{zgw} - the number of realized group work involving an employee during a certain period.	Increase	9	11	15	17	9
Conflict (C_f)	$C_f = N_{cf}$, N_{cf} - the number of conflicts involving the employee during a certain period.	Increase	12	9	1	7	11
Mood for interaction (Int)	$Int = N_{cd}$, N_{cd} - the number of collective decisions, actions or issues involving the employee during a certain period .	Increase	15	10	9	12	9
Communication predisposition (CP)	$CP = N_{cc}$, N_{cc} - the number of colleagues, comrades, partners of the employee during a certain period.	Increase	3	5	4	7	5
Kindness (K)	$K = N_{iw}$, N_{iw} - the number of cases done, identified wishes, tips by the employee during a certain period in relation to the colleagues of the enterprise.	Increase	9	6	16	12	14
Systemic							
Ability to innovate (A_{inn})	$A_{inn} = N_{pi}$, N_{pi} - the number of proposed, implemented, forecasted innovations by an employee during a certain period.	Increase	5	5	11	12	9
Research skills (A_{rs})	$A_{rs} = N_{sc}$, N_{sc} - the number of studies carried out by the employee during a certain period.	Increase	3	4	9	2	4
The ability to put theoretical knowledge into practice (A_{tp})	$A_{tp} = N_{cpt}$, N_{cpt} - the total number of completed (completed) practical tasks by the employee during a certain period.	Increase	21	16	30	21	16

The data of the table 3 indicate the following the components of personal competencies at these enterprises do not correspond to their optimal value, excluding competencies «purposefulness» at Universam LLC. Among the professional components, the significant difference between the actual and the optimal values are the values of competence «experience», which indicates that the employees have insufficient level of experience in three enterprises, possibly due to their young age or unwillingness to improve. An exception is the level of

education at the enterprise of Eurobud LLC. In terms of instrumental, interpersonal (including intercultural) and system competencies, all their values at these enterprises are positive. The positive would be an increase in their values, except for the «conflict» component, the optimal value of which should decrease or equal to 0. The dynamics of these indicators indicate the need for stable work on the diagnostics of the level of cadres' potential in three enterprises. Priority directions of work at the studied trade enterprises are: reduction of staff turnover; increasing the level of employee experience; reducing conflict; increase in teamwork, communication development and the like.

At the studied enterprises only some indicators (staffing) is the indicator whose value corresponds to the optimal value at the studied enterprises. The values of such indicators as labor productivity, the coefficient of constancy of the staff, the coefficient of staff turnover and the level of conformity of education of the position occupied are only approximate to their optimal values. The exception is Eurobud LLC, where the turnover rate and the level of conformity of the education of the position still correspond to their optimal value.

Diagnostics of cadres' potential of a single personnel unit in the process of the enterprise (including the trade enterprise) is a measurement of the individual contribution of each employee to the overall result of the whole enterprise. In other words, such diagnostics make it possible to determine the value of an employee for an enterprise. If we consider personnel management activities as a set of specific functions, then as a result of diagnostics of cadres' potential, we can achieve a better result in the implementation of all these functions. For example, the executives and managers of trading companies who were interviewed in the course of our research noted the following:

- diagnostics of cadres' potential is necessary in the process of selection of personnel, as it allows to fill the enterprise with the necessary amount of qualified personnel, to select the best applicant for a vacant position and to minimize the costs of selection;
- diagnostics of cadres' potential of the existing employees allows to determine the needs of the enterprise in their development, rotation, replacement; provides the most effective decision making related to the personnel (change of motivation, increase / decrease in the career ladder, etc.), optimizes the budget for personnel development and allows to determine the expected profit from investments in the staff (due to projected production, labor productivity);
- diagnostics of cadres' potential helps to more carefully and reasonably approach the selection / adjustment of personnel policy, including: in terms of solving the problem of staff turnover, identifying and analyzing the positive and negative sides of a set of specialists from the outside and in the process of promoting or moving their employees within the enterprise.

According to the heads of trade enterprises, the following were highlighted among the main reasons that hinder the qualitative organization and diagnostics of cadres' potential at enterprises today:

- at the enterprises there was no need to form an HR department (for personnel);
- the number of employees does not allow to form the responsible person / department for diagnostics;
- diagnostics of cadres' potential is carried out only in the course of promotion of the employee on the career ladder or in the process of problems with the personnel;
- assessment of cadres' potential is mainly carried out at the stage of selection of employees, according to the established scheme of the producer of products (brands of a specific department);
- ignorance of management about features of work;
- measures for the employment of workers are carried out by reducing non-productive costs, reducing the amount of time lost, primary vocational training, training and the like.

For example, at Val-Yan LLC trade company, there is a clear procedure for evaluating the promotion on the «career ladder» of supervisors / heads of trade departments of different brands. This procedure is carried out periodically (once every 3 months) solely for the purpose of checking the relevance of knowledge about the specifics of brands of goods. Workers of sales departments of different brands - sales representatives, according to a similar scheme, take a daily assessment at the same enterprise, taking into account the peculiarities of their functional responsibilities (work in the fields, daily communications, work with «problem clients» / clients-debtors).

Conclusion

So, it is worth noting that not all trade enterprises pay attention to the assessment of cadres' and diagnostics of cadres' potential. It is established that in large and medium-sized enterprises of trade, as a rule, personnel are evaluated at the selection stage (i.e, to make a hiring decision) and periodically in the work process (for example, to make a decision on career growth, preparation of the reserve, identification reasons for unsatisfactory results, etc.). However, at large networked trade enterprises (especially when it comes to enterprises that have «foreign roots»), the assessment is carried out according to certain criteria, at certain times by clearly written procedures with a clear definition of possible variants of the end result of diagnostics and consequences, which this result stipulates.

At the enterprises of Ukraine there are unresolved problematic issues in personnel policy related to: transformation processes of economic formation and adaptation to European standards in the sphere of personnel; preparation of personnel for the needs of the enterprise, type of economic activity, society; mismatch of the system of training and advanced training to the needs of the market; imperfection of the personnel selection system and the like. The main thing in an enterprise (in an organization, company, firm) is not the potential of individual workers, but their only cadres' potential, as in the system the main interaction between the elements that form it. Cadres' potential characterizes the level of employees' capabilities and their ability to interact with employees and interact with other components of the enterprise's potential. The higher the cadres' potential of the enterprise, the higher the potential of the employed workforce, the more complex problems can be solved by the team (regarding the production, its quality, the rate of development of its new types, the efficiency of production and economic activity, etc.).

Abstract

The study of interpersonal relations in the supervisor-subordinate system is one of the most important areas in the modern social psychology of organizations. Consideration of this issue is essential in solving such applied problems as improving the adaptability, motivation, trustworthiness, and loyalty of employees, effective leadership, developing an organizational culture and introducing innovations. Almost no problem of organizational psychology can be solved without an analysis of the interaction of the supervisor and subordinates. A special issue of organizational psychology of interpersonal relations is the subordinate's perception of the personality and actions of the supervisor. In the process of implementation, the manifestation of leadership is recognized and interpreted by employees in one way or another, and the results of this social perception make a significant contribution (positive or negative) to the functioning and development of the organization. The perception of the personality of the supervisor is the most important factor in the formation of professional self-awareness and professional identity. As a result of perception, the characteristics of the perceived object are usually structured, and the object of perception belongs to a certain category by the subject of perception. Thus, the main issue in the scientific analysis of the perceptual process is the definition and study of the determinants of structured perception. The article discusses the specifics of the psychology of relations in the context of "supervisor-subordinate." In the course of a multi-stage socio-psychological study conducted in mixed teams of manufacturing enterprises, the structure of the manager's image was revealed, including two parts: the core and the peripheral part. In the male and female parts of the respondents of mixed groups, the perception of the core of the perceptive image of the supervisor was identical, while differences were revealed in the structure of the elements of the peripheral part of the image of the supervisor. The peripheral part of the manager's image has a variable dynamic structure that is sensitive to external changes (transformation of the socio-economic situation, change of ownership of a manufacturing enterprise, etc.). The data obtained are of interest for further study of the socio-perceptual process in management and can be used as part of a course to increase the psychological competence of managers of mixed production teams.

Keywords: Socio-perceptual process in management, image structure, supervisor, subordinate.

Introduction

In order to successfully and long-term maintain their advantages, companies are constantly forced to adapt to the changing market realities and look for innovative approaches to solving their problems (Brimhall 2019). In these conditions, managers need to increase their competence in the field of psychology of personnel management. The success of interaction in the social-production team is achieved through the joint efforts of all its members. Accordingly, the importance of scientific data on the individual personality characteristics of each employee is growing.

One of the socio-psychological reasons for the decline in labor productivity is a psychological distortion or loss of objectivity of the information of the team members about each other in the process of communication. This is especially pronounced in the interaction of "supervisor-subordinate." The increase in the share of mixed teams in various industries has had a significant impact on the psychology of interpersonal relationships between employees. At the same time, the psychological characteristics of the interpersonal relationships of employees in the labor process are not well understood (Suazo, Turnley and Mai-Dalton 2008).

The work of domestic and foreign authors is devoted to the study of the specific psychophysical qualities of employees of mixed teams (Obozov 2001; Hewlett, Sherbin, Dieudonne, Fargnoli and Fredman 2014; Stoet and Geary 2018). Scientists have identified the peculiarities of psychophysical qualities in women employees of teams (fine motor skills, sound, and verbal memory, the speed of perception of digital information, speech communication skills, etc.), allowing them to perform certain labor operations more successfully than men, as well as be more successful in some areas of business (Markova 2003). If we talk about digital competencies, which are currently becoming particularly relevant due to changes in all production and management processes in all areas of activity (Masyuk and Pankova 2019, then the leader must make every effort to master them, thereby demonstrating compliance with the requirements of the time and gaining additional authority among subordinates.

Method and Methodology

The development of methodological foundations of socio-psychological practices for constructing new harmonious types of relationships in groups is impossible without taking into account both priority values, attitudes, norms, role-based behavior of employees, and psychological characteristics of interpersonal relationships. In the course of the study, a set of methods was used: questionnaires (the “Business Portrait” methodology), testing, sociometry, observation, standardized interviews, as well as economic and statistical methods.

For three decades, Ivanovo State University (Russia) conducted research on socio-perceptual processes in management on the basis of collectives of enterprises of various forms of ownership. At the first stage (1988–2010), the ways of increasing labor efficiency in mixed groups were studied, the psychological resources of managerial interaction were analyzed (Gitelmacher 1992; Ptitsyna and Nikiforova 2001; Nazarov 2006; Nazarov and Nikiforova 2006: Nikiforova 2008). At the second stage (2011–2018), the specifics of the psychology of relations between employees of mixed teams were revealed. During this period, there was an increase in the interest of the organizers of production activities in studying the characteristics of interpersonal relations and leadership (Pantyushina, Nazarov 2016).

It was found that recently, the formation of a team aimed at the effective implementation of production tasks has become increasingly important for managers. The social life of any individual begins with its formation as part of a collective subject, while remaining an individual carrier of the relations of this subject. If a person, for various reasons, is opposed to his social environment, then he remains alone. A similar conditioning of psychological processes is also characteristic of production teams (Sushkov 2008; Ulich 2001; Mattan, Kubota and Cloutier 2017). When studying the structure

of leadership images, we proceeded from the metacognitive orientation of the perception process (Jussim 2014; Bach and Schenke 2017; Nazarov et ol 2019; Karpov 2018).

Results

The socially perceptual process in management is a multifactorial, hierarchically organized process, determined by objective and subjective determinants. An important parameter is the attitude to the immediate supervisor, which is formed as a result of the influence of various information flows on the perception of a subordinate. In the course of the study, a number of the most significant qualities of managers for respondents were identified (Table 1).

Table 1: Significant personality traits of supervisors in subordinate's assessments (generalized indicators, samples of the 80s, 90s, 2000s)

Parameter (max=10 points) M±m по годам	80s N_1=323	90s N_2=372	2014-2016s N_3=212
P n_1	6,8±0,40	7,6±0,34	8,8±0,07
M n_2	6,7±0,30	6,4±0,32	6,71±0,13
B n_3	5,1±0,12	5,6±0,23	7,9±0,06
Significance of Differences p≤0,05	P_{1-3}<0,019 P_{2-3}<0,06	P_{1-3}<0,013 P_{2-3}<0,04	P_{1-3}<0,08 P_{2-3}<0,018

where - N is the number of respondents in the sample;

- p - significance of differences;
- 80s , 90s; 2014-2016 - observation time intervals;
- P - an integral indicator of the performance of the supervisor in the interests of the organization;
- M - an integral indicator of the performance of the supervisor in the direction of supporting the interests of employees;

B - other characteristics of the personality of the supervisor.

A study of the structure of perceptual images of the supervisors of product segments and the recreation of the image of supervisors among respondents (both men and women) revealed two functional parts: the core of the image (stable) and the peripheral (variable part). According to the data obtained, the identity of perception in the male and female parts of the core sample of the perceptual image of the leader is established. At the same time, discrepancies in the structure of the elements of the peripheral part of the image of the leader were revealed. The peripheral part of the manager's image has a variable dynamic structure that is sensitive to external changes (transformation of the socio-economic situation, change of ownership of a manufacturing enterprise, etc.). The ambiguous interpretation of the problems of gender socialization is the subject of discussion by researchers of the socio-perceptual process in management (Pantyushina 2016; Ptitsina, Nikiforova 2001).

Discussion

Most researchers come to the conclusion that the image of a leader is constructed by employees on the basis of his perception as a representative of a certain social group, and the psychological characteristics of the leader's personality are less important. Nevertheless, for many employees, an important quality of a leader is the ability to make informed management decisions and resolve conflict situations. In the case when an optimal solution does not exist or cannot be accepted for one reason or another, we propose the use of a conflict-compromise methodology described in detail in a number of works (Macyuk 2016, 2018), the main element of which is a local compromise that allows

us to accept a quasi-optimal solution and reduce the tension of the situation. This methodology works especially well in resolving financial conflicts (Bushueva, Korovin and Masyuk 2013).

Conclusion

Social perception as a process has a dynamic nature of development, the variability of the structure of the main result (employee's attitude to the leader). A study of the social practice of the functioning of production teams indicates the presence of identity perception of the core of the image of the leader of both male employees and female employees. Differences are revealed in the perception of the peripheral part of the image of the leader. To a greater extent, these features were manifested in the changing forms of ownership of enterprises (for example, state to private). The dynamics of socio-economic transformations have a significant impact on the psychology of interpersonal relationships of participants in production activities. According to the data obtained, one of the conditions for increasing the effectiveness of the leader is to take into account information about the psychological characteristics of the relationship of the subordinate to the leader. Long-term observations show that during the formation of an effective team in the management process, more attention should be paid to studying the characteristics of the perception of functional-business and individual-personality characteristics of both the manager and employees. The discrepancies in the structure of the elements of the peripheral part of the manager's image in men and women made it possible to assume that the individual-personal picture of the subordinate's perception of the leader's image requires further in-depth analysis. In this regard, the attention of researchers should be focused on the further study of the characteristics of the psychological response of employees of mixed teams to changes in industrial relations.

Abstract

Microcredit has become a significant element in development strategies (Islam 2015), but microcredit has not always had a positive impact on the welfare of the borrowers. In many cases the recipients do not use the loans in accordance with the designation. One example of inappropriate use of microcredit loans is in the form of consumption of temptation goods. Using data from Indonesia Family Live Surveys 5 (IFLS 5) in 2014, this study aims to analyze the impact of microcredit loans on households' temptation goods expenditure. Using linear regressions and propensity score matching (PSM), our empirical results show that there were differences in expenditure on temptation goods between recipients and non-recipients of microcredit. Microcredit recipients' weekly real expenditure on temptation goods is around 39,000 rupiahs (3 US dollar) higher compared to non-recipients, or equivalent to around 2 million rupiahs (146 US dollar) a year. Despite the impact on real expenditure, we found no evidence that microcredit affects the proportion of expenditure on temptation goods with respect to total household expenditure. In addition, the proportion of expenditure on temptation goods is decreasing with a higher degree of risk aversion.

Keywords*:* Microcredit, Temptation Goods, Risk Preference

JEL classification: G21, O12, D01

Introduction

Microfinance has become a significant element of development strategies in various developing countries (Islam 2015). The assumption used is very simple, providing the community with access to credit will increase their income, open an entrepreneurial spirit, strengthen development through business improvement and ultimately reduce poverty (Ledgerwood and White 2006). However, several studies show that microcredit has not always had a positive impact on the welfare of the borrowers (Bylander 2015; Jahiruddin et al. 2011; Wickramasinghe and Fernando 2017; Zeballos, Cassar and Wydick 2014). One of the causes is due to the occurrence of what is called *moral hazard*, a situation in which the microcredit obtained is not used in accordance with its designation (Presbitero and Rabellotti 2014).

People often think of microcredit as an instant income and use it as a tool for consumption smoothing instead of using them for productive activities that can generate income (Bylander 2015; Zeller 1999). Karlan and Zinman (2008) found that 50% of borrowers lied about their credit usage activities. Microcredit customers do report their business investment activities, but they do not report the use of credit loans (Karlan and Zinman 2011).

In addition to basic needs, households also spend a lot of their money on temptation goods. The term temptation goods refer to goods that only provide satisfaction when consumed but make the consumer regret purchasing them in the future (Banerjee and Mullainathan 2010). Items included in the category of temptation goods include alcohol, cigarettes, betel, candies, chocolate, soft drinks, processed food both consumed inside and outside the house, sweepstakes, entertainment, and festival (Banerjee et al. 2015; Banerjee and Duflo 2007; Dasso and Fernandez 2013).

Banerjee and Mullainathan (2010) stated that consumption of temptation goods could cause poverty trap. In microcredit borrowing households, consuming temptation goods can cause a debt trap. Increased expenditure on temptation goods means sacrificing the expenditure allocations for more productive goods, or durable goods, which will have an impact on businesses owned by the households (Banerjee et al. 2015). In addition, overborrowing and overconsuming behaviour can also cause borrowers to experience a debt trap (Nakajima 2012).

Several studies have been conducted previously to investigate the impact of microcredit or cash transfers on the consumption of temptation goods. Banerjee et al (2015) found that when household received microcredit loans, they would divert temptation goods expenditure to durable goods. This means that consumption of temptation goods will decrease as the size of credit increases. Meanwhile, Dasso and Fernandez (2013) found that households receiving cash transfers increase their food consumption by 10% to 20%. The increase is driven by the consumption of candy, chocolate, soft drinks, and going to meals at restaurants.

Other factors that may influence credit usage and consumption behaviour are time and risk preferences (Ferecatu and Önçüler, 2016; Start, 2013). (Stiglitz and Weiss 1981) implies that risky borrowers invest more on risky investment which reduces consumptions. Also, many people are impatient in spending the money, so they ignore their long-term consumption plans. As a result, they are tempted to spend money on goods that satisfy them now but not in the future (Laibson 2011; O'Donoghue and Rabin 1999), or what are referred to as temptation goods.

This study was conducted to analyze the effect of microcredit on household temptation goods expenditure. In addition to the previous studies, we also explored whether the effect was influenced by risk and time preferences of the head of the households. Using survey data from Indonesia, we found that households who received loans spent round 39,000 rupiahs higher in real temptation goods expenditure compared to non-recipients, indicating *moral hazard* problem in the provision of microcredit. However, there is no statistically significant differences in the proportion of household expenditures on temptation goods between microcredit recipients and non-recipients. It implies that while receiving loans leads to higher household expenditures in temptation goods; the change is not more than proportional to the change in total household expenditures. We also found that the proportion of temptation goods expenditures is 2.3% lower for households with more risk-averse household head.

Our paper proceeds as follows. Section 2 contains a literature review. Section 3 describes our data and model and discusses the expected effects of microcredit on temptation goods expenditure. Section 4 presents the estimation results. The final section provides a conclusion.

Literature Review

Microcredit and Consumption of Temptation Goods

Zeller (1999) explains that the presence of microfinance institutions influences household consumption through two components. The first component is income that is expected to be obtained by the households using human, physical and social capital (ex-ante or permanent income). Access to financial institutions can be used to increase the capital owned by the households, which in fact can increase the value of household income. The second component is income that is generated from ex-post income by households, namely the existing income after the results of agricultural and non-agricultural businesses and from labour costs, are realized. If the ex-ante income turns out to be lower

than the minimum level of disposable income needed to meet food and other basic needs, then the household will conduct ex-post activities to generate additional income.

Figure 1: Microcredit and Consumption Smoothing

Source: (Zeller 1999) and (AIMS 2001)

Figure 1 shows alternative strategies that can be done by households when getting microcredit loans. With the available resources (human capital, physical capital and financial capital) and the ability to overcome risks, households can use credit loans for production, investment, and consumption activities. Production is income-generating activities, such as buying business raw materials and paying employee salaries. Investment activities are activities carried out to increase household resources and assets. This includes buying production machinery, investing in shares and buying properties such as land and buildings.

Unlike the two previous activities, consumption is an activity that does not directly generate income. Consumption matters include food, entertainment, clothing, health expenses and education. If the household spends microcredit loans for consumption activities, the household has committed moral hazard, where the credit loans they receive is not used according to its purpose. However, if households use it for education and health type of consumption, in the long run this will support their productive activities, especially in increasing productivity in human capital.

This study referred to the model developed by Banerjee et al. (2015) which assumed that the borrower's household consumption consists of temptation goods (c_t) and durable goods (c_d). Borrowers decide how much households will consume each of the goods in the current period and in the future period. Their model shows that when a household borrower is patient enough, then it is assumed that the household places fewer utilities in the t period than in the t + 1 period. In this case, households tend to delay consumption of temptation goods and invest in durable goods.

In other case, households might sacrifice their consumption of temptation goods and engage in investment activity. Thus, the increase in the welfare of households that get microcredit loans comes

from the utility of increasing durable goods as the return of the investment; in the long run, this increase can be seen from the rapid investment in household businesses so that business profits increase which lead to an increase in overall consumption.

One of the main results of this model is that households with access to microcredit may sacrifice short or even medium-term consumption to get durable goods or to invest in businesses. The available investment opportunities through loans require them to reduce their consumption of temptation goods. Various empirical studies with various methods have been conducted to analyze the impact of microcredit on household consumption. One of them is Karlan et al. (2016) which tested the consumption and investment response to liquidity shock that occurs in households. The results show three findings: first, respondents reported that they used very little of the bank loans for non-business, but they reported higher amounts when asked directly by an independent surveyor. However, when given a list of questions by independent surveyors without having to disclose what they are doing with a bank loan directly, the results will be more significant. Second, even when borrowers tend to report what they think is truth, their answers were counterfactuals, as there is additional expenditure spent. Third, they estimated that the full business credit loan is allocated to business investment, specifically inventory.

Risk Preference, Time Preference, and Consumption of Temptation Goods

The expected impact of risk preference on consumption in general and consumption of temptation goods in particular is not clear. Neave (1971) proposed that risk preference does not affect how much and individual consumes or invests, the investment (and consumption) decisions is only affected by the person's preference over current and future consumption. Meanwhile, Stiglitz and Weiss (1981) theorized that an increase in interest rate encouraged risky borrowers to invest too much on risky business that leads to default and credit rationing. Zeballos et al. (2014) conducted an experimental test of a concept introduced by Stiglitz and Weiss (1981) regarding borrowers' behaviour. The results they found was surprising. They found that defaulted borrowers are more risk-averse than non-defaulted ones. They invest too little and spent the loans on for non-risky expenditures, including consumption of temptation goods.

Contrary to Zeballos et al. (2014), Ferecatu and Önçüler (2016) studied the relationship between risk preference and time preference. They found that risk-averse individuals tend to be more patient and more willing to defer consumption for other purposes, such as investment. Conversely, risk-seeking individuals are less patient and less willing to defer consumption. In addition, risk aversion is also negatively associated with cigarette smoking, heavy drinking, and the probability of being obese (Anderson and Mellor 2008).

Microcredit Provision in Indonesia

In 2013, the Government of Indonesia launched a financial institution whose mission was to empower micro-businesses in Indonesia. The institution provided microcredits and funding for small businesses as well as consultation. Since then, the government and banking sectors have provided a massive number of microcredits for micro and small business development. In June 2019, the amount of credit provided for micro and small businesses reached over 1,000 trillion rupiahs. The amount of fund provided by microcredit is around 50 million rupiahs per applicant.

Methodology

The empirical study in this research used data from Indonesia Family Live Surveys 5 (IFLS 5/Sakerti) for the 2014 period. IFLS is a longitudinal survey in the socio-economic and health sectors. The survey was conducted on a sample representing 83 percent of Indonesia's population in 13 provinces. The survey was conducted by collecting data on individuals, including families, households, the smallest communities where they live and the health and education facilities they use. We limit our study to households who own non-farm businesses.

This study used one data period and aims to capture the short-term effect of microcredit on households' expenditure on temptation goods. The model used in this study refers to the research conducted by Banerjee et al. (2015):

$$\mathrm{TG_{ij}} = \beta_0 + \beta_1 \mathrm{Credit_{ij}} + \beta_2 \mathrm{Risk_{ij}} + \beta_3 \mathrm{Time_{ij}} + \beta_4 \mathrm{Kredit_{ij}} * \mathrm{Risk_{ij}} + \beta_5 \mathrm{Kredit_{ij}} * \mathrm{Time_{ij}} + \delta \mathrm{X_{ij}} + \gamma Z_j + \varepsilon_{ij}$$

where:

$\mathrm{TG_{ij}}$	: household weekly real temptation goods expenditures; the proportion of temptation goods expenditure to total household expenditures
$\mathrm{Credit_{ij}}$	: dummy microcredit (households that have non-farm businesses and get credit loans from formal financial institutions = 1)
$\mathrm{Risk_{ij}}$	: dummy risk preference (more risk averse=1)
$\mathrm{Time_{ij}}$	: dummy time preference (more impatient=1)
$\mathrm{X_{ij}}$	: vector of household-specific controls
Z_j	: vector of regional controls
ε_{ij}	: error term

We use two measures of temptation goods consumption. The first one is the household's weekly real expenditure on temptation goods. We divided nominal expenditures on temptation goods with regional (provincial level) CPI because the price level in the regional level varies, and this might affect the money households spent on temptation goods. The second measurement is the proportion of temptation goods expenditure to total expenditure. If the proportion of expenditure on temptation goods increases, it means the proportion of expenditure on other goods such as durable decreases, which will then affect the sustainability of household businesses.

We define temptation goods consumption as consumption of alcohol, cigarette, betel, chocolate, soft drinks, prepared foods consumed outside or inside the house, lottery, and entertainment. The data is collected at the household level.

Microcredit variable is a dummy which is equal to 1 if the household had a non-farming business and got a micro-credit facility from the formal sector and 0 otherwise. We controlled for total yearly wages received by all household members, micro-profit earned by the household from their business activity, age of the household head, education of the household head, number of household members (household size), the gender of the household head, the residence area of the household, and the value of total assets owned by the household. We also include provincial-level minimum wage and island dummy to control for regional heterogeneity.

In addition, this study also included time preference and risk preference variables which may affect how microcredit affects temptation goods expenditure. Risk preference was measured using the approach used by Ng (2012). In the survey conducted by IFLS, respondents were given lotteries using five questions. In each question, the respondent was presented with two financial choices, a certain proceed and another alternative based on probability. Based on their answers, respondents were grouped into four levels of risk preference. Respondents who did not like risks most (most risk-averse) would be in the terminal box in the lower-left corner of Figure 3, which was in category 4. Conversely, the respondents who liked risk most (least risk-averse) would come out in the lower right terminal box, which was category 1. After obtaining four risk aversion respondent categories, we formed a dummy variable following Zeballos et al. (2014). Respondents who scored 4 is categorized as more risk-averse while the rests are categorized as less risk-averse.

Figure 2: IFLS 5 Risk Preference Measurement Flow Chart

Source: (Ng 2012)

The time preference measurement techniques were the same as those used in risk preference measurement where after four preference categories were obtained, a dummy was then formed from that category. The time preference variable would be equal to 1 for category 4 (the more impatient) and 0 for the rest.

Econometrics Issue

The model is estimated using linear regression (OLS). However, OLS estimates might be biased since we are not able to ensure the causal effect of microcredit due to selection bias. Households who received credits might fundamentally different from the ones who did not. As a consequence, the difference in consumption of temptation goods cannot be attributed solely to receiving microcredit (Caliendo and Kopeinig 2008).

To overcome this problem, we also employ propensity score matching (PSM) technique. PSM allows us to construct an artificial control group by matching each treated household with non-treated counterparts which share similar observable pre-treatment characteristics. Taking into accounts of those characteristics, then it is assumed that the difference in outcome between the treatment group and control group is due to treatment or intervention (Gertler et al. 2010). We use nearest neighbour matching with caliper to match the observations. We chose this type of matching because we have a large number of non-treated units in the study.

Results and Analysis

By using wave 5 of the Indonesia Family Life Survey (IFLS), which was conducted in 2014, this study aims to capture the short-term effect of microcredit on household temptation goods expenditure. We limit the sample to households who own non-farm business. Table 1 contains a statistical summary of the variables used in this study.

Table 1: Summary of Household Statistics

Variable	Statistics				
	Obs.	**Mean**	**Std. Dev**	**Min**	**Max**
Dependent Variables					
weekly real temptation goods expenditure (in rupiah)	2468	148,392	197,182.1	0	2,304,415
the proportion of temptation goods expenditure (%)	2468	15.665	12.295	0	75.218
Explanatory Variables					
microcredit (1= recipients)	2468	.136	.343	0	1
risk preference (1= more risk-averse)	2468	.046	.210	0	1
time preference (1= more impatient)	2468	.697	.460	0	1
yearly business profit (in ten million rupiahs)	2468	1.717	2.324	0	30
yearly household wage income (in ten million rupiahs)	2468	5.322	8.276	0	211.04
household head age	2468	43.722	12.162	17	101
household head gender (1=female)	2468	.139	.346	0	1
university (1=university education or higher)	2468	.208	.406	0	1
urban (1=urban area)	2468	.660	.474	0	1
household size	2468	5.446	2.621	1	18
total asset (in ten million rupiahs)	2468	20.620	31.261	.014	295.05

The number of samples included in the study was 2,468 households. On average, households spent 148,392 rupiahs (10.8 US dollar) per week for temptation goods. This amounted to 15.67% of the total household expenditure. There is a considerable variation in the expenditure of the temptation goods. Around 14% of the sample received microcredit. Only around 5% of them are most risk-averse, the rests are less risk-averse. Meanwhile, 70% of them are more impatient.

Table 2 presents the estimation results of the effect of microcredit on temptation goods spending. The first two columns use weekly real temptation goods expenditure as dependent variable, whereas the last two columns use the proportion of temptation goods as the dependent variable. The OLS results are shown on the first and the thir column whereas the regression after applying PSM are shown on the second and the fourth column. The results show consistent results in terms of sign and statistical significance between OLS and PSM results.

Table 2:Estimation Results of the Effects Microcredit on Temptation Goods Spending

	Dependent variable: Weekly Real Temptation Goods Expenditure (in rupiah)		**Dependent variable: Proportion of *Temptation Goods* Expenditure to Total Expenditure (%)**

The results show that microcredit recipients' weekly real expenditure on temptation goods is around 39,000 rupiahs (3 US dollar) higher compared to non-recipients, or equivalent to around 2 million rupiahs (146 US dollar) a year. The results are contradictory to the research by Banerjee et al. (2015) who found that temptation goods expenditure in households receiving credit loans would decrease in line with the increase in durable goods expenditure. However, it is in line with the results of Dasso and Fernandez (2013) study which found that when having cash, households tended to consume temptation goods such as chocolate, soft drinks and food purchased at restaurants. If this happens, then there is a *moral hazard*, a situation where the household does not use microcredit they got for business purposes but for household consumption activities, or in this case temptation goods.

One possible explanation which drives the difference in our results might be because the findings of Banerjee et al. (2015) were obtained from household respondents who borrowed a large size of loans for a relatively long period of time, while the results of this study were obtained from data with shorter time periods. The results of this study indicate that in the short-term households are suspected of using microcredit loans as consumption smoothing, especially consumption on temptation goods.

Another possible explanation, the goods included as temptation goods are different in a number of studies, which might drive different results. Evans and Popova (2014) investigated the effect of cash transfer on alcohol and cigarette consumption, type of consumption goods that not only our future self has no care for but also detrimental and might lower utility in the future. They found a negative association in most cases and no association in other cases of cash transfer and expenditures on alcohol and cigarette. Banerjee et al. (2015) directly asked respondents of the type of goods they considered as temptation goods pre-treatment, whereas we used secondary survey data and had no information on the goods respondents consider as temptation goods. Consequently, some goods we use for construction might derive positive utility to respondents' future self and are not considered inferior after they receive credit.

However, when we instead used the proportion of temptation goods expenditure to total expenditure as the dependent variable, we found no significant impact of microcredit on the proportion of temptation goods expenditure to total expenditure irrespective of econometrics method being used. Thus, although microcredit encourages loan recipients to spend more on temptation goods, the increase in spending is still lower than the increase in total expenditure.

Based on the results time preference has no impact on temptation goods expenditures. Nevertheless, households with more risk-averse head tend to have a lower proportion of expenditures in temptation goods. The proportion of temptation goods expenditure is around 2.3% smaller for risk-averse households. OLS estimates on column three suggest that risk aversion affects how microcredit is impacting proportion of expenditures in temptation goods, however the effect is not significant once we use PSM to overcome selection bias. This is in line with research by Anderson and Mellor (2008) and Ferecatu and Öençüler (2016) which found that risk-averse borrowers tend to defer consumption and are negatively associated with cigarette smoking and alcohol drinking which are some examples of temptation goods.

In addition, we found that profit, wage income, university education and total asset are positively associated with household real temptation goods expenditure. However, the household's business profit does not affect the proportion of temptation goods expenditure. Total asset is negatively associated with the proportion of temptation goods expenditure.

Female and older household heads spent less on temptation goods, not only that, but they also tend to have a smaller proportion of expenditure dedicated to temptation goods. Households that have more household members also tend to have lower proportion of temptation goods expenditure.

Conclusions

Giving microcredit has become a major element of development strategies in various developing countries (Islam 2015). However, there is evidence that microcredit obtained is not always used in

accordance with its designation (Presbitero and Rabellotti 2014), creating a *moral hazard* in microcredit provision. One of those unintended use of microcredit is for temptation goods consumption, goods that only provide satisfaction when consumed but make the consumer regret purchasing them in the future such as alcohol, cigarettes, betel, candies, chocolate, soft drinks, processed food both consumed inside and outside the house, sweepstakes, entertainment, and festival (Banerjee and Mullainathan 2010).

Previous theoretical and empirical studies suggest that microcredit provision will decrease consumption of temptation goods since the goods become inferior and households shifted their consumption to durable goods (Banerjee et al. 2015; Evans and Popova 2014). However, Dasso and Fernandez (2013) found that chocolate, soft drinks and food purchased at restaurants increase with cash transfer.

Using data from Indonesia, we found that microcredit recipients' weekly real expenditure on temptation goods is around 39,000 rupiahs (3 US dollar) higher compared to non-recipients, or equivalent to around 2 million rupiahs (146 US dollar) a year. However, when we instead used the proportion of temptation goods expenditure to total expenditure as the dependent variable, we found no significant impact of microcredit on the proportion of temptation goods expenditure to total expenditure irrespective of econometrics method being used. Thus, although microcredit encourages loan recipients to spend more on temptation goods, the increase in spending is still lower than the increase in total expenditure. Also, households with more risk-averse head tend to have a lower proportion of expenditures in temptation goods.

Abstract

Today the most important part of the nations' strategy for innovative development is the elaboration of financing mechanisms for innovative activities. The research tests the hypothesis on the impact of financial performance of innovative companies and the spatial distribution of innovation capital across Russian regions on the effective innovative activity development and presents some elements of the authors' methodology for assessing the amount of innovation capital invested by innovative companies as well as the rate of regions' spatial development. The financial indicators influencing the income of Russian innovative companies are studied based on their financial status analysis; the determinants conditioning the growth of innovative activity within the framework of regional innovation systems, the identification of barriers to innovative capital spillover and the measures for overcoming them in order to develop innovative activities are analyzed. Using the methods of correlation-regression, comparative and graphical analysis, it is analyzed to what extent the individual financial indicators of financing innovative companies influence the final results of the innovative companies' activities. The study reveals a high degree of differentiation in the financial indicators of regional innovative companies and the uneven distribution of innovation capital across the regions of Russia, which inhibits the effective spillover of innovation capital, transfer, diffusion and implementation of innovations. In conclusion, the potential regional centers for innovation capital concentration and areas of developing sources of innovative activity financing are identified.

Keywords: financing of innovative activity, structure of sources of financing, innovative enterprises, regional economy, spillover of innovation capital.

Introduction

At the current stage of the advanced economies development, innovations are the most important factor in maintaining the competitive advantages of companies and countries; which is why in public policy of all countries of the world the attention is focused on the development of sources of innovative activities financing (OECD, 2000). The success of innovation, as one of the main requirements for the growth of economic efficiency, is largely determined by the forms of its organization, by the ways of financial support (Davidson, Mariev & Pushkarev, 2018).

International studies demonstrate that the contribution of innovation to GDP growth can reach 50-75% (Rodríguez-Pose, Crescenzi, 2008; García-Manjón, Romero-Merino, 2012). Today the most important part of the nations' strategy of innovative development is the elaboration of financing

mechanisms for innovative activities (Coad, Rao, 2008), (Broekel, Brenner, 2011). In economically developed countries, the public share in these expenditures is on average 25-35% (Firsova, Novoselova & Vavilina, 2018). The remaining funds are provided by the private sector.

In Russia, the opposite trend in the structure of innovation financing sources is observed; the share of budgetary funds continues to increase from 60% in 1995 to 67% in 2017, demonstrating a structural imbalance between innovation financing sources, a high share of the public sector, insufficient development of the venture capital market, and angel and private investments, lack of owner's equity of enterprises to be invested in innovation, poor development of long-term investment instruments in the stock market as a source of financing innovative projects, and most importantly, the lack of incentives to invest private capital in innovation due to high internal innovation risks and the presence of other areas for more favorable capital allocation (Firsova, 2017).

Quantitative indicators of innovation financing reflect the level of country's economic development. One of the relevant research in this area is the problem of finding the determinants of innovative and economic growth, analyzing the structure of innovations financing in the Russian regions, the search for a correlation between the amount of funds and the effectiveness of the innovative development in the region.

The study tested the hypothesis about the impact of financial performance of innovative companies and the spatial distribution of innovation capital across Russian regions on the effective innovative development.

The research objective is to examine financial indicators influencing the income of Russian innovative companies based on their financial status analysis, to analyze the determinants conditioning the growth of innovative activity within the framework of regional innovation systems, to identify the barriers to innovative capital spillover and to find method of overcoming them.
The article also presents elements of the author's methodology for assessing the amount of innovation capital invested by innovative companies as well as the rate of spatial development of regions.

To solve these problems, the following research steps were taken:

- defining the research object, which is innovative companies and organizations, determining indicators of financing sources for innovative companies, aggregating their financial statements by regions, and analyzing the development indicators of innovative companies by region;
- cleaning the set of regions from abnormal entities, grouping by key indicators and clustering entities for research into the groups of regions;
- analyzing a set of financial indicators-factors that affect the results of the studied companies determination, correlation coefficients within the groups and assessing the parameters of intra-group regressions;
- modeling and forecasting analysis results for maximum and minimum values of indicators;
- identifying Russian regions with a high potential for concentration of capital and innovations financing in terms of innovation capital amount based on a center-peripheral approach;
- making conclusions on the development trends of innovation financing processes and developing recommendations for overcoming capital spillover restrictions and for the development of innovative activity financing factors in the regional context based on the analysis.

Methods and data

Every country has its own macroeconomic statistical indicators for assessing the effectiveness of the innovation system resources. However, at the micro level, assessing the status and structure of innovative companies financing is difficult due to the lack of primary data in the statistics registers. The awareness of this problem leads us to the idea to analyze the information on the financial and economic activities of innovative enterprises, which are in the accounting statements.

Of all the actors in the national and regional innovation systems, of the many independent entities of the innovation process that implement their individual stages we selected for analysis the most basic level, where the success in innovation process depends on its activity and which reacts most flexibly to changes in the market environment - to innovative companies.

The research object is the financial indicators of the capital structure for innovative companies that carry out research and development, which include innovatively active enterprises engaged in the development and implementation of new products, technological processes or other types of innovative activities. To assess the current state of innovation financing and analyze the sources and structure of financing innovative enterprises by Russian regions, we used a database in which we collected official financial statements of 4,032 innovative organizations and enterprises for 2016 (the latest available data at the time of the study) in 85 regions of Russia (Firsova, 2019), (Federal Taxation Service, 2019).

We analyzed accounting financial statements (balance sheet and statement of financial performance) of each individual enterprise, then they were aggregated by region, calculated; then we evaluated the main financial indicators of innovative companies — the structure of assets and liabilities as sources of companies financing. Based on this data, we carried out a comparative analysis of the financing sources structure of innovative enterprises in the Russian regions.

To develop a statistical model for analyzing the outcomes of innovation at the regional level, the following base of indicators was formed. The indicator of gross proceeds from the goods sale of innovative companies was chosen as the dependent variable: the key indicator of the volume and scale of the company's activity and the result of its innovative activity, by analogy with the region's gross regional product or the country's GDP. The main indicators of composition and structure of assets and liabilities, without taking into account the interdependence of indicators, were chosen as the independent variables (Table 1).

Table 1: Indicators of innovative companies financing

Variable	Indicators, mln rubles
Y	Sales proceeds (goods, operations, services)
X1	Non-current assets
X2	Fixed assets
X3	Current assets
X4	Equity
X5	Long-term liabilities
X6	Short-term liabilities

The dynamics of the number of innovative companies over 22 years is presented in fig. 1-2. The rate of innovative development in the Russian Federation varies across regions depending on the level of productive forces development, natural and geographical conditions, historical and socio-economic development and territorial distribution of industries and science; therefore, there is a high differentiation and polarization in their number across Russian regions, which is reflected in the regional specifics of innovative enterprises financing (Rosstat, 2019; Ministry of Education and Science, 2019). These factors inhibit the spillover of innovation capital and innovative evolution.

Fig. 1: Dynamics of the number of innovative companies, 2005-2017

Fig. 2: The number of innovative companies in Russia in comparison with GRP per 10,000 people by Russian regions, 2017

In the set of regions under examination there are some companies that are obviously in better conditions, which means that they receive a larger (relative to other regions) number of innovative products. Such entities are considered “abnormal outliers”; they were excluded from the analyzed sample.

Bringing the original set to a homogeneous form is a separate statistical task. As part of the study, the entities with the largest and smallest values were “cut off”; for this, the lower and upper percentiles were calculated using the effective variable. Thus, the lower 5% percentile equals 13,521 million rubles, and the upper 95% percentile - 49,588,241 million rubles.

Out of 85 regions, 72 regions were selected for further analysis; indicators of innovative companies in Moscow, St. Petersburg, the Moscow regions, Samara regions, and small-sized regions such as

Mari El, Khakassia and others were excluded from the analysis due to incomparably polarized indicators of these regions or lack of statistical data.

Then, to highlight the most homogeneous groups, a cluster analysis was carried out using the Ward's method, the result of which is a structural diagram - a dendrogram shown in fig. 3.

The grouping of regions of the Russian Federation by indicators of the innovative companies' financial status allowed us to distinguish two groups of regions - underdeveloped and leading regions:

- the regions included in the first group have lower values of financing indicators of innovative companies (54 regions): Altai, Amur, Arkhangelsk, Astrakhan, Adygea, Altai Republic, Belgorod, Bryansk, Buryatia, Volgograd, Vologda, Dagestan, Zabaykalsky, Ivanovo, Irkutsk, Kabardino-Balkaria, Kaliningrad, Karachay-Cherkessia, Kemerovo, Kirov, Kostroma, Kurgan, Kursk, Lipetsk, Magadan, Mari El, Murmansk, Novgorod, Omsk, Orenburg, Oryol, Primorsky Krai, Pskov, Kalmyk, Karelia, Komi, Crimea, Mordovia, Sakha (Yakutia), North Ossetia-Alania, Ryazan, Saratov, Sakhalin, Sevastopol, Smolensk, Stavropol, Tambov, Tver, Tyumen, Udmurtia, Khabarovsk, Chechnya, Chuvash, Yaroslavl regions.

- regions leading in innovative development, which are included in the second group, have the maximum values of the indicators (18 regions): Vladimir, Voronezh, Kaluga, Krasnodar, Krasnoyarsk, Leningrad, Nizhny Novgorod, Novosibirsk, Penza, Perm, Bashkortostan, Tatarstan, Rostov, Sverdlovsk, Tomsk, Tula, Ulyanovsk, Chelyabinsk regions.

Fig. 4 presents a map of regions demonstrating the spatial distribution of two groups of regions according to the level of financing progress of innovative companies.

Fig.3: Diagrammatic map: two types of regions

Fig. 4: Dendrogram is a tree-like hierarchical clustering of Russian regions by indicators characterizing the financial status of regional innovative companies

To assess the quality of regions grouping and the differentiation in intra-group mean values, the Student t-test was analyzed (Table 2).

Table 2: The actual values of t-student's test

Indicators	Mean values		Student's t-statistics	Significance level of p-values
	Underdeveloped regions	Leading regions		
Y	1468715	16858627	-12.15	0.00
X1	579122	12786212	-9.73	0.00
X2	394058	8012852	-8.43	0.00
X3	1222327	26271354	-6.94	0.00
X4	858221	14923235	-11.25	0.00
X5	119384	2788114	-7.51	0.00
X6	824215	21337383	-5.81	0.00

The criterion values presented in Table 2 indicate that the whole complex of indicators differ (the p-value exceeds 0.05) therefore, the division of the original set regions into two groups can be considered acceptable.

Results

Further on, during testing the impact of various factors - indicators of innovative companies financing using the methods of correlation and regression analysis, we analyzed the influence of individual financial indicators on the final performance of the innovative companies. The values of the correlation coefficients obtained in the course of the modeling for each group are presented in Table 3.

Table 3: The results of the correlation coefficients assessment for two groups of regions

Groups of regions	Indicators	Y	X1	X2	X3	X4	X5	X6
Underdeveloped regions	Y	1.00						
	X1	0.64	1.00					
	X2	0.58	0.92	1.00				
	X3	0.92	0.64	0.58	1.00			
	X4	0.77	0.86	0.77	0.81	1.00		
	X5	0.38	0.37	0.34	0.54	0.48	1.00	
	X6	0.84	0.60	0.56	0.87	0.57	0.30	1.00
Leading regions	Y	1.00						
	X1	0.53	1.00					
	X2	0.44	0.77	1.00				
	X3	0.46	0.70	0.20	1.00			
	X4	0.61	0.93	0.73	0.73	1.00		
	X5	0.44	0.47	0.25	0.23	0.32	1.00	
	X6	0.40	0.70	0.20	0.99	0.69	0.19	1.00

In each of the two groups of regions, there are a different set of factors-determinants that affect the sale proceeds generated by innovative products:

- in the first group of underdeveloped regions, the determining factors are X1 (non-current assets), X3 (current assets), X4 (equity), X6 (short-term liabilities);
- in the second group of leading regions, the decisive factors are X1 (non-current assets), X4 (equity).

But the joint application of the selected factors in the models is excluded due to the presence of multicollenarity, therefore, two pairs of linear models were compiled, while the variable having the highest effect on the resulting revenues was included in the regression equation (table 4).

Table 4: The results of the assessing regression equations for two groups of regions of Russia

Group	Model	Fisher's F-statistics	R^2
Underdeveloped regions	Y' = 171147.78 + 1.06X3	274.64	0.84
Leading regions	Y' = 7894228.43 + 0.06X4	9.69	0.38
Note: calculated by the authors in the STATISTICA package; model parameters are statistically significant at 5% level			

The results were interpreted and transferred into percentage using the following formula:

$$\theta_j = a_j \frac{\bar{x}_j}{\bar{y}} \quad (1)$$

a_j – parameters (coefficients) of the regression equation.

$\bar{x}_j$ average value of the j-factor (independent variable).

$\bar{y}$ –average value of the j-factor (dependent variable).

The coefficients in the first model of underdeveloped regions allow us to conclude (1), that with an increase in current assets (X3) by 1 million rubles sale proceeds from innovative enterprises increase by 1.06 million rubles:

θ_1 – 1.06*(1222327/1468715) = 0.88

Thus, an increase in X3 (current assets) by 1% in the first model leads to an increase in product sales by 0.88%.
According to the second model, in the leading regions, the increase in X4 equity by 1 million rubles leads to an increase in product sale proceeds by 0.6 million rubles (1):

θ_2 = 0.60*(14923235/16858627) = 0.53

Thus, with an increase by 1% in the variable X4 (equity) in the second group of leading regions, it will lead to an increase in the dependent variable by 0.53%.
Since the obtained models are statistically significant, situational modeling was carried out on their basis.
As the expected values of factor variables we use the actual values for the city of Moscow, where the highest values were registered, and the Republic of Tuva with the smallest value of the variable X3 (current assets) = 8 million rubles, and the Republic of Ingushetia with the minimum value of the variable X4 (equity) = -1082 million rubles.
Thus, the capabilities of the Russian regions of each selected groups were modeled and evaluated, provided that the values of the dominant factors were brought to extreme values (table 5).

Table 5: The results of situational modeling based on regression equations for two groups of the Russian territorial entity

Indicators	Underdeveloped regions		Leading regions	
	maximum	minimum	maximum	minimum
Factor score	1 089 270 621	8	592 675 387	-1 082

Lower confidence bound	1 016 637 099	-90 580	127 572 663	813 551
Upper confidence bound	1 296 346 713	432 892	600 256 879	14 973 606
Note: calculated by the authors in the STATISTICA package				

According to the modeling results shown in Table 5, the greatest success in innovative development could be achieved in the first group of regions, bringing current assets to the level of the flagship Moscow region. In general, the growth of current assets in underdeveloped regions can be achieved by using and expanding lending tools and increasing innovative companies financing. The growth of equity in the leading regions can be increased through direct and indirect support for innovation.

Discussion

The results can be interpreted in two aspects. Firstly, one of the most important outcomes of our research should be emphasized: the structure of the liabilities of innovative companies has insufficient long-term sources of financing for innovative enterprises while in some regions they do not have them at all. Long-term loans are one of the sources of long-term investment projects; their absence implies the lack of investment for innovative projects, the damping of innovative activity and a decrease in all indicators of innovative development.

The problems of underfunding are also exacerbated by the spatial uneven distribution of innovation capital in the regions of the country.

The effectiveness of national innovation systems in any country is evaluated from the position of its ability to form and maintain the favorable environment for innovation for the full application of all available resources, create innovations and diffuse them on a large scale, providing a new quality of the country's economic growth (Firsova, Makarova, 2017; Pittaway, Robertson, Munir, Denyer & Neely, 2003).

For Russia, as well as for many large countries, the problem of analyzing the uneven distribution of resources and the quality of innovative growth in the effectiveness of innovation in the regions and developing a policy for its development is of great urgency.

The spatial features of Russia explained by its vast territories and existing distribution of industries and science, accordingly, innovation generation centers, determine the specifics of the innovations diffusion processes and innovative spillover effects.

The uneven spatial distribution of fixed assets, production resources, and human capital leads to spatial heterogeneity of regional development negatively affecting innovation processes (Krugman, 1991; Spielkamp, Vopel, 1998; Audretsch, 1998).
The financial resources of innovative companies (along with the resources of other scientific and academic organizations) are the predominantly important (i.e. the largest) part of the country's innovative capital, which significantly affects the intensity of innovative processes in the regions. The uneven distribution and the efficiency of spillover between regional innovation systems are an important determinant of effective innovation processes and significantly affect the transfer, diffusion and implementation of innovations.

The spatial remoteness of the leading regions and the “disconnection” of the channels for innovations and capital spillover hinder the innovations diffusion and the progress of the innovation spillover across the regions of Russia.

The capital is concentrated in a small number of leading regions of economic and innovative development, and the distances between existing centers of capital concentration are so great that innovation diffusion and spillover effects are disrupted.

Sources of financing and development of new innovative projects - long-term liabilities of innovative companies - are extremely “disconnected” and differentiated by region (Fig. 5).

Fig. 5: Differentiation of inequality of innovative capital by regions in Russia, 2016, the average value is 0,93 million rubles (Rosstat, 2019)

The differentiation of the Russian regions selected for analysis based on indicators of innovative enterprises is presented in Figs. 6 and 7. The regions are ranked in descending order of considered indicators values. In line with the identified determinants during the analysis, the leading regions are ranked by the share of their own funds in the liabilities of innovative companies. Underdeveloped regions are ranked by the share of current assets in the assets of innovative companies.

Fig. 6: Asset structure of innovative enterprises in underdeveloped regions of Russia, 2016 (Rosstat, 2019)

Fig. 7: The structure of earnings and liabilities of innovative enterprises in leading regions of Russia, 2016 (Firsova, 2019)

The rate of concentration and unevenness of the Russian regions in terms of equity and current assets of innovative companies is presented in Figs. 8 and 9.

Fig. 8: The concentration of current assets in underdeveloped regions, the share of current assets in GRP, the size of the balls - the volume of current assets

Fig. 9: Concentration of earning and liabilities of innovative capital in leading regions, share of equity in GRP, size of balls - the amount of equity of innovative companies

Such a spatial uneven structure of financing sources cannot provide macro-assumptions for financing the change of technological structures that require a significant structural upgrade of the fixed assets and equipment. However, it is possible to single out a number of regions, in which indicators of financing innovative companies point to potential development capacities for innovative activities with an increase in the volume of funding sources.

Based on the results of a graphical analysis using the "center – periphery" model, it is possible to distinguish the following centers – the cores of financing innovation in the territorial structure of Russian regions, semi-periphery and periphery zones.

The regions of quadrant I are potential centers for the development of innovative activity due to the availability of investment opportunities for investing innovation capital, while the remaining regions belong to the semi-periphery (quadrant II) and periphery (quadrants III and IV). The most innovative and effective regions in terms of their own funds capacity to finance innovation are Tatarstan, Nizhny Novgorod, Samara, Perm, Tomsk regions, etc. (as well as Moscow, St. Petersburg); these regions claim to be centers of innovative development. Similarly, in quadrant II, we can identify regions with a high opportunity and potential to become centers, provided that funds are invested and sources of financing are developed at the public and private levels.

Conclusion

Thus, the results of the study demonstrate a very high level of differentiation in indicators of financing innovation in Russian regions. The existing capital structure of innovative companies complicates innovation and inhibits the effective sustainable development of innovative enterprises as well as impedes the effective flow of innovation capital.

The problem of insufficient financing of innovative activity is one of the most serious constraining forces in the development of the innovation system in Russia. It is the insufficiency of region's own financial resources and the inaccessibility of external sources of financing that in most cases explain the low level of innovative activity of economic entities.

It is necessary to reduce the polarization and transform semi-peripheral regions into sources and "points" of innovative growth, as well as to develop sources of financing in peripheral regions.
The measures necessary for the effective development of innovative companies and the diversification of their financing sources are:

- to form a national balanced financing system for fundamental and applied research and development, direct support for financing those areas that are not in demand for financing by private investors and the creation of attractive indirect steps to support the "capital building-up strategy" for private investors in R&D;
- to develop innovative infrastructure, taking into account the territorial specifics and regional differentiation of Russian regions, the features and competitive advantages of the regions, promote fundamental science, and the corresponding education system;
- to establish the regulatory framework and practice of applying new forms of financing innovation in the context of new information technologies and fintech;
- to form sectoral, intersectoral and regional innovation clusters, combining scientific, educational institutions, production and markets that attract syndicated forms of financial resources;
- to stimulate demand for innovations by the government (for example, removing administrative barriers, public contracts and procurement, indirect measures and targeted support of strategic directions of R&D development);
- to provide point targeted funding for the creation of innovative products that can be commercialized, and not the creation of ideas that cannot be realized in the future;
- to ensure the interaction of public and private capital in order to develop science, engineering and technology;
- to develop indicators, procedures and mechanisms for the functioning of the national innovation financing system, monitor and adjust the system according to the current state of public policy measures in the field of R&D;
- to work out regional strategies of economic development, aimed at creating so-called "growth points" by improving the investment climate and infrastructure in the regions.

The role of the government in this process should consist in the effective use of the financial capacities and public instruments to support the financing of innovative activities, in measures of indirect stimulation and attraction of private resources in the field of innovation and the creation of a common stable institutional environment that ensures effective regulation of the relationships of all participants of the innovation process.

Administration and coordination of financing sources for innovative activities by the state as a regulator of financial and innovation processes should provide the participants of the investment resources market with an effective legislative framework, mechanisms and tools for accumulating "long" investments, guarantees of investments, improving the institutional environment, developing innovative financial infrastructure to increase accessibility of private sources and stimulation of private investors and commercial banks to finance innovative activity. The implementation of these measures will contribute to the development of innovation and the creation of an effective innovative economy in Russia.

Work Values and Turnover Intention in Chinese New Generation Employees Based on Multiple Intermediaries

Kai Liu[1], She Maoyan [1+], and Na Wang[2]

[1 2] Business School, Sichuan University, 610064, China

Abstract

In this study the aim was to ascertain the effects of work values on job satisfaction, organizational commitment, and turnover intention in a Chinese context. Job satisfaction and work values were employed as determinants of organizational commitment and turnover intention. The mediating effect of job satisfaction andorganization commitment on work values and turnover intention was also examined，using EQS 6.3 computer program.Atotal of 463 questionnaires were distributed to employees of different corporations in China. The results indicated that job satisfaction led to greater organizational commitment and lower turnover intention. Participants also indicated that their work values significantly affect normative commitment and turnover intention through job satisfaction.

Keywords: Work Values;Job Satisfaction;Organizational Commitment;Turnover Intention.

Introduction

At present, the situation at home and abroad has undergone numerous changes. The trade war between China and the United States has been on the verge of explosion and China is facing a critical period of economic transformation and upgrading. New technologies, new formats, and new models such as "Internet Plus," shared economy, and supply-side reforms have had an impact on the old labor relations management model. Faced with the gradual disappearance of the "demographic dividend" and the urgent need for economic restructuring, the conflict between labor and capital has intensified. In the past, extensive labor relations management methods have been unable to meet the requirements of the times. By establishing a good atmosphere of labor relations, the management of labor relations has been standardized. It has become the focus of current management work to improve employees' job satisfaction and promote their better initiative and enthusiasm in a good atmosphere.

In China, new generation employees are who were born after 1st January 1980, including the post-80s, the post-85s, and the post-90s. Nowadays, new generation employees have been the major driving force in companies. From managers' point of view, they are unstable, having independence of thought, poor self-discipline, and blind confidence. High turnover rate and blurred value orientation of new generation employees are the biggest blocks of companies' strategic development, which brings huge challenge to managers. Therefore, this research focused on the explicit and implicit work value, their

difference, and the relationship between work value, job satisfaction, organizational commitment, and turnover intention.

Fig. 1: Proposed model for work value and turnover intention

Literature Review and Hypothesis

The New Generation of Employees

The new generation of employees in this study pointed out that employees born after January 1, 1980 were subdivided into post-80s, post-85s, and post-90s. At present, although more and more scholars are beginning to pay attention to the turnover intention of specific types of employees .Today, many view job choice and turnover intent as distinct aspects of work and are aware that these are directly related o their job. However, since this was not always the case this new attitude of workers has created problems in the current labor market in China. Younger generations of Chinese workers have become individualistic and materialistic and also tend to seek more challenges and changes, thus causing them to pursue better employment opportunities and seek higher wages (Ralston, Egri, Stewart, Terpstra, & Kaicheng, 1999).

Work Values

Values are regarded as the essential concepts that are possessed by individuals and a society.The operational definition of work values is defined as the value judgment of the work itself, work and environment, and work and self-relationship formed by employees in their careers. It belongs to the individual's internal and stable personality tendency or personality dynamic system, which affects the employees' external Work behavior and performance. Studying the structure of work values helps us better understand work values.

Turnover Intention

The time always comes when an individual considers the possibility of terminating his or her employment with an organization (Mobley, 1982). Turnover intention has been defined as a conscious psychological willingness to leave an organization (Tett & Meyer, 1993).

Job Satisfaction

Job satisfaction, usually refers to a person's work in the organization, the work itself and related aspects (including work environment, work status, work style, work pressure, challenge, interpersonal relationships at work, etc.) Mental state with benign feelings. An individual's emotional response, emotional experience, and attitude to their work. It is an important employee attitude variable derived from the evaluation of their work or work experience. Studies have shown that job satisfaction includes satisfaction in five areas: job itself, compensation, promotion opportunities, supervisors and colleagues. Based on whether work can help to achieve individual values, and whether it can meet individual needs and interests, it is reflected in different levels of high and low. High levels of job satisfaction occur when work matches personal needs, interests, and working conditions and interpersonal cooperation are satisfactory.

Organization Commitment

There are a number of definitions of organizational commitment.Organizational commitment has been described as an antecedent of turnover intention(Poznanski & Bline, 1997). Other researchers have demonstrated the importance of organizational commitment in explaining turnover intention (Bluedorn, 1982).OReilly and Chatman combined empirical research to point out that the support path presented by individuals in enterprises and organizations includes three parts: obedience, belonging and consistency(O'Reilly Iii & Chatman, 1986). Obedience reflects the purposeful measures of individual enterprises to obtain rewards; belonging is due to the goals and attitudes of the organization. Allen and Meyer based on the results of empirical research, sorted out, analyzed, and defined the content of three factors, improved the content of organizational commitment, and has become a widely accepted concept of organizational commitment by researchers.Organizational commitment has also been recognized as having a significantly negative association with turnover intention(Allen & Meyer, 1996).

Influence of the work value on the turnover intention

Values can steadily influence a person's behavior and way of doing things. Because of this stable influence, the research on values has become a research hotspot in recent years. During the work, employees will show their likes or dislikes about their work, and they will also show their love or dissatisfaction with the organization. The stable development of such emotions is the work values and the embodiment of values in people's work.

There are many factors affect the turnover intention. Amongst these factors, the function of work values to the turnover intention can't be ignored. Schwartz suggested that the pursuit of intrinsic work values (e.g., personal growth or opportunities for creativity) was likely to be seen as desirable and justified when the value of autonomy is emphasized(Schwartz, 1999). Hofstede suggested that in patriarchal societies motivation may be based more on the acquisition of money and possessions than on quality of life because money is associated with security and stability. Jaw and colleagues believed that, in this respect, Western culture has had an effect on Chinese Confucian dynamism(Jaw, Ling, Wang, & Chang, 2007). Apossible explanation for this is that people in management positions in Chinese industries/businesses who have been exposed to Western cultures are thought to work more diligently so they can obtain more rewards that are related to performance, and this is a major feature of management practices in the Western work environment . We therefore form the following hypothesis on the impact of work value on turnover intention:

H1: Work value is negatively related to turnover intention.

The mediating effect of the job satisfaction and organization commitment on the relationship between work values and turnover intention

In previous studies, it has been found that the relationship between job satisfaction and organizational commitment is variable and at times results are contradictory. Bateman and Strasser determined that organizational commitment was the initial affective factor and was an antecedent to job satisfaction(Bateman & Strasser, 1984). Porter et al. (1974) held the opposite view, arguing that satisfaction represents one specific component of organizational commitment. Williams and Hazer were of the view that satisfaction does causally affect organizational commitment(Williams & Hazer, 1986), while Steers found that as an employee's needs are satisfied by the organization, they develop more commitment to the organization. Chen and Francesco adopted the view that job satisfaction has a causal influence on organizational commitment(Chen & Francesco, 2000).

The expression of work attitude is job satisfaction. Stable values can guide a person's behavior. In work, it is shown that work values affect employees' work attitude, that is, they will affect job satisfaction. This has been confirmed in previous studies.Organizational commitment is the emotional dependence of employees on the existing organization, loyalty to the organization and strong emotional dependence on the organization, and the ability to dedicate themselves to the emotional development of the organization.

Most scholars' research on organizational commitment and job satisfaction is a combination, because the two are interconnected and very similar in some aspects, except that emotional commitment is a more stable job satisfaction. Attitude performance. The simple point is that job satisfaction is temporary, and it is a current emotion. Organizational commitment is something deep in the heart. It is an identification with the organization. If a person does not agree with his organization in attitude, then the performance The job satisfaction that comes out will definitely have a certain impact, which in turn will affect the emotions of the organization.

Based on the above analyzation, we can form the following hypothesis on the function of job satisfaction and organization commitment on the relationship between work value and turnover intention.

H2a: The job satisfaction plays the mediating effect on the relationship between work values and turnover intention

H2b: The commitment plays the mediating effect on the relationship between work values and turnover intention

Research Methodology

With the objective to contrast the research hypotheses presented, market research was carried out by combining the qualitative and quantitative methodologies that are detailed hereafter.

Context of the research

During the last decade, China has been trying to stimulate economic growth through implementation of innovation. The Chinese government and relevant organizations have issued a number of policies to promote business development by focusing on work value and turnover culture in Chinese universities. China's increasing focus on work value provides a favourable environment for human resource management research, which can measure the new initiatives' effect on employee turnover intention.

Setting and participants

In order to empirically contrast the proposed research hypotheses, a quantitative investigation was carried out using surveys of the new generation of employees. To ensure the variability and representativeness of respondents, we selected employees from different cities. we conducted a questionnaire survey on them, covering basic information, work values, job satisfaction, organization commitment turnover intention.

Of the 463 questionnaires distributed, 405 were were determined to be valid, of which 58 were subsequently discarded because of incomplete information. The 463 fully completed questionnaires (response rate of 87.5%) were from 196 males (48.4%) and 206 females (51.6%).

Design and Measure

The questionnaire was developed and pretested on a small sample of students for validation purposes. The study's constructs were work values, job satisfaction, organization commitment, and turnover intention. The information that was collected was brought together using a questionnaire in which the variable in the theoretical model was measured with a multi-item scale. This makes it possible to

obtain evaluations of psychological variables that cannot be quantified directly(Churchill, 1995). The evaluations were found using the Likert scale of five positions (1 = strongly disagree with the affirmation made and 5 = strongly agree).

Work values

Refer to the measurement scale of the The 21 items that were used for measurement of work values were taken from the Work Values Scale (Meyer & Alien, 1991).Three dimensions of work values were defined in this study: Suitability,stability,career development and employee status. People-related factors included relationships with colleagues and supervisors, personal growth, recognition, the use of expertise, knowledge, and competence. Job outcome represented the desire for respect, economic rewards, secure and stable lifestyle, benefits, prestige, and social status. Finally, the job itself focused on working conditions, hours worked, degree of autonomy, ideal pursuance, and meaningfulness of job content. All statements were measured on a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

The job satisfaction

Following Hochwarter、kacmar、Perrewe(2003), the job satisfaction was measured through four statements on a five-point Likert scale ranging, which assessed the degree of attraction of starting a new job for participants.

The commitment

Meyer andAllen developed a 3-component conceptualization that we adapted to measure organizational commitment in this study(Meyer & Alien, 1991). The questionnaire contained 3 items classified as affective commitment , continuance commitment , and normative commitment . Participants rated their responses using a 5-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree.

Turnover Intention

In order to investigate how often respondents seriously considered quitting their job, whether or not they wanted to quit, and/or were actually planning to quit, six items were extracted from a scale developed by Konovsky and Cropanzano (Konovsky & Cropanzano, 1991). Responses followed a 5-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree.

Assessment of measures and common method bias

In order to test the research model, a Structural Equations Model (SEM) approach is used. This statistical method allows the estimation of causal interrelations between

latent factors measured with multi-item scales. Therefore, it is especially appropriate to study psychological variables that are not directly observable, as is the case in this research. In particular, SEM approach requires the development of two levels of analysis: first, Confirmatory Factor Analysis (CFA) is carried out to confirm the psychometric properties (reliability, convergent validity and discriminant validity) of the measurement scales (measurement model), and then, structural model is estimated to test the causal interrelations established in the theoretical model. In this research, the measurement model and the structural model are estimated through the Maximum Likelihood Robust method, using EQS 6.3 computer program.The results of the CFA summarized in Table 2 confirm the convergent validity of all the measurement scales.

Table 2: CFA for model variables

latent variable	measured variable	Stand.Lambda	R^2	CR	AVE	Goodness of fit
work value	VAL1	0.83	0.69	0.86	0.56	BBNNFI=.916 RMSEA=.059 IFI=.972 CFI= .972
	VAL2	0.77	0.59			
	VAL3	0.74	0.54			
	VAL4	0.63	0.40			
	VAL5	0.76	0.53			
Job satisfaction	SAT1	0.92	0.92	0.94	0.77	
	SAT2	0.89	0.89			
	SAT3	0.88	0.88			
	SAT4	0.93	0.93			
Commitment	COM1	0.92	0.85	0.73	0.48	
	COM2	0.86	0.74			
	COM3	0.89	0.80			
Turnover intention	INT1	0.92	0.68	0.88	0.66	
	INT2	0.89	0.76			
	INT3	0.88	0.60			
	INT4	0.93	0.67			

Test the convergence and discriminant validity according to the procedures proposed by Steenkamp and Trijp (1991) and Anderson and Gerbing (1988). The method proposed by Murtagh and Heck is used to test the validity of aggregation, that is, the degree of correlation between tools used to measure potential factors(Anderson & Gerbing, 1988). According to the annotations proposed by Steenkamp and Trijp , if the reliability of all items reaches a significance level of 95% and the standardized lambda coefficient is higher than 0.5, the convergence validity of the metric can be confirmed. The CFA results summarized in Table 3 confirm the consistent validity of all measurement scales(Steenkamp & van Trijp, 1991).

In addition, the calculation results of the goodness-of-fit index indicate the correctness of the model. We use the statistical data given by EQS6.3. According to the parameter indicators proposed in the

literature widely used in SEM(Byrne, 1994), Table 3 confirms that the BBNNFI, IFI, and CFI statistics exceed the recommended minimum of 0.9, while RMSEA It is below the maximum limit of 0.08, so the model has a good fit.

Discriminant validity refers to the degree to which there is a correlation but a difference between two potential factors. Anderson and Gerbing (1988) argued that if the confidence interval of the correlation between potential factors does not include 1 (the maximum correlation), then the discriminant validity can be determined. The results summarized in Table 4 confirm the discriminant validity of all measurement scales.

In addition, the reliability of the scale was evaluated by calculating the combined effect of Cronbach`s a, Composite reliability and AVE(Bagozzi & Yi, 1988). The values of these statistics (summarised in Table 3) are in each case above the required minimum values of 0.7 and 0.5. Therefore, the internal reliability of the assumed structure is supported.

Table 3: Confidence intervals for the correlations between pairs of latent variables

Latent variable	work value	Job satisfaction	Commitment	Turnover intention
work value	1.000			
Job satisfaction	.705**	1.000		
	(.633;.781)			
Commitment	.658**	.695**	1.000	
	(.578;.732)	(.620;.755)		
Turnover intention	-.581**	-.692**	-.585**	1.000
	(-.679;-.484)	(-.758;-.614)	(-.676;-.479)	

It can be seen from Table 3 that work values significantly affect turnover intentions, and work values are negatively correlated with turnover intentions, hypothesis H1 is supported.

Mediation Analysis

Work values are negatively related to turnover intentions. In order to test the proposed mediation effect, we use the two predictors of job turnover and organization commitment as the predictors for regression analysis. Next, we conducted a regression analysis on the main effect and the mediation effect of turnover intentions, and found that for each model, work values significantly predicted job satisfaction and organization commitment, providing support for further mediation tests on each model. Subsequently, we loaded two variables, job satisfaction and organization commitment, and

verified them according to the mediation effect test model shown in Figure 2 and Figure 3.

Fig. 2: Test diagram of the mediating effect of Job satisfaction between Work value and Turnover Intention

Table 4: Fitting index of the job satisfaction mediation model

□²	df	□²/df	RMSEA	CFI	NNFI	GFI	IFI
175.885	62	2.837	0.067	0.969	0.957	0.940	0.969

The validation parameters in Table 4 indicate that the model has a good fit, so the model studied is acceptable. Figure 2 shows that the mediating effect of job satisfaction between work value and turnover intention is significant.H2a mediation effect hypothesis holds that the job satisfaction plays the mediating effect on the relationship between work values and turnover intention.

Fig 3: Organization Commitment test chart of the mediating effect between work values and turnover intention

Table 5: Fitting index of the organization commitment mediation model

□²	df	□²/df	RMSEA	CFI	NNFI	GFI	IFI
156.252	51	3.064	0.071	0.965	0.89	0.942	0.965

The validation parameters in Table 5 indicate that the model has a good fit, so the model studied is acceptable. Figure 3 shows that the mediating effect of organization commitment between work value and turnover intention is significant.H2b mediation effect hypothesis holds that the organization commitment plays the mediating effect on the relationship between work values and turnover intention.

Discussion and implications

Conclusions and Discussion

In this study, work values, job satisfaction, and organizational commitment were found jointly and individually to have a significant influence on turnover intention.We found that when a company's management supports its employees' value systems, the employees tended to have a higher commitment to the organization.Based on the analysis of the mediation effect, this paper explores the impact mechanism of the new generation of employees' work values on turnover intentions, constructs an optimized multiple intermediary model(Mitchell, 1999), and discusses the impact mechanism of the work values of the new generation of employees on turnover intentions. The study lays the foundation.

Based on the perspective of multiple intermediary roles, this article studies the turnover intention from a new perspective through argumentation, design, induction of job satisfaction, and organizational commitment, and looks at the problem of turnover intention in the perspective of intergenerational differences, deepening the discussion of the new generation of employees. Of the various variables. Combined with the literature, Western scholars' research on the work values of employees in organizations has a deep characteristic that reflects the western cultural background. In the Chinese context, its applicability and the degree of differences are explored and compared(Mobley, Horner, & Hollingsworth, 1978).

The results of this study may provide some guidelines for managers in understanding the work vales of the younger generation of Chinese employees, and this could lead to implementation of more effective policies for improving employee retention. Some companies in China have not tried to find ways to reduce turnover because the labor supply has been plentiful. This situation has changed and it has become increasingly difficult for Chinese firms to recruit new employees. Our results confirming that job satisfaction and organizational commitment were strong predictors of turnover intention, indicate that companies should conduct periodic surveys of employees on their job satisfaction and organizational commitment. This could lead to a better understanding of employee reactions and feelings about, and opinions of, the company's current operations or policies; it could also help management to take precautions against unexpected developments.

Limitations and Future Studies

There are some potential limitations in the present study that inform possibilities for future research. Attempts to explain an increase or decrease in the level of organizational commitment and turnover intention can involve many factors. Work values and job satisfaction are just two factors that were

used in this study; however, there are many other factors that could be considered or examined. This study might also have been limited by the quantification methods that were used. Future researchers could include qualitative measures for obtaining additional information from the participants. Generalizing the opinion of individuals could provide a more complete picture of the relationships between organizational commitment and turnover intention. Additionally, the questionnaires were distributed in the Chengdu area; hence, their representation might not be generalizable to other areas in China(Mitchell, 1999; Palich & Ray Bagby, 1995).

First, the target of the investigation was a single industry. The respondents possessed a high level of education and other specializations, so they are not necessarily representative of the general workforce in China (e.g., people working in the service and manufacturing industries might possess different work values relating to organizational commitment and turnover intention). Future researchers should test the reliability of the findings with other sectors of business and industry, as well as taking demographics into account as control variables in the analysis. Additionally, there is a possibility that the structure of this research might have been too simplistic, and the survey may also suffer from common method variance. Consequently, our findings may not be generalisable to developed economies in individualistic cultures like those of the USA or Europe(Hofstede, 1993). It is possibilie to replicate this theoretical model in other countries with different economic, cultural and legal characteristics, which could affect the effects of the risk dimensions associated with work value, as a future line of research. Finally, longitudinal studies for turnover intention are required. Future studies should also include other related variables, such as the personal characteristic variables and situational variables to clarify how turnover intention will be transmitted over a longtime.

Abstract

The aim of the paper is to identify the principles (dimensions, areas) of sustainability development. The paper is based on information gathered through extensive literature review (research publications, research studies, documents about the principles of sustainability) using internet and research databases. It should be emphasized that the principles of sustainability are interrelated, interacting with each other and all areas need to be addressed, and it is not enough to choose just one area that will be given increased attention and neglect the other.

Keywords: Sustainability, Sustainable Development, Principles of Sustainability.

Introduction

The present time places particular emphasis on sustainability. This is also confirmed by the 2030 Agenda for Sustainable Development (United Nations, 2015). The increasing pressure to achieve and maintain competitiveness on the domestic and international market in recent years signed by the sharp increase in the need to implement the concept of sustainability into business strategy.

The concepts of *sustainability* and *sustainable development* began to be used in the early seventies, mainly in the context of the knowledge that any uncontrolled growth, whether population, production, consumption or pollution, etc. is unsustainable in an environment of limited resources. (National Sustainable Development Strategy, 2001)

The term *sustainability* covers environmental issues, wider corporate social responsibility (CSR), the long-term continuity, and economic survival of business (Scottish Enterprise, 2011). According to R. B. Pojasek (2012), sustainability is only one of several terms now being used to denote the same concept; other terms include corporate social responsibility (CSR), social responsibility (which drops the "corporate" modifier in an attempt to make the term more universal), corporate citizenship, corporate responsibility, environmental sustainability, sustainable development, and each of these terms in turn can be defined in scores of different ways.

One of the best known and used definition of sustainable development was first introduced in 1987 in the Report of the World Commission on Environment and Development: Our Common Future (World Commission on Environment and Development, 1987): *Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs*.

It contains within it two key concepts (World Commission on Environment and Development, 1987):

- the concept of “needs”, in particular the essential needs of the world's poor, to which overriding priority should be given,

- the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs.

Sustainability and sustainable development comes in many different shapes and sizes which is demonstrated by many authors (Blašková et al., 2019; Soviar et al., 2019; Jankalová & Jankal, 2018; Varmus et al., 2018; Jankalová, 2016; Figurska, 2014; Craddock, 2013; Cerin & Dobers, 2008; Kotler & Lee, 2005; Elkington, 1994)

Sustainable development in the Slovak Republic is defined in § 6 of Act No. 17/1992 Coll. on the environment (Law on the environment, 2007): *Sustainable development of society is a development that preserves the ability of current and future generations to satisfy their basic living needs, while not reducing the diversity of nature and preserving the natural functions of ecosystems*.

The aim of the paper is to identify the principles (dimensions, areas) of sustainability development. The paper is based on information gathered through extensive literature review (research publications, research studies, documents about the principles of sustainability) using internet and research databases (Scopus, WoS, Google Scholar).

Main findings - Principles (dimensions, areas) of Sustainability and Sustainability Development

The principles of sustainability are the foundations of what this concept represents. The most widespread view is that sustainability is made up of three pillars: *economic, social and environment*. These principles are also informally used as *profit, people and planet*. John Elkington, from a sustainability consultancy firm, was one of the first people to integrate these 3 principles. He argued companies needed to start considering this triple bottom line so that they could the world thrive in the long run. (Elkington, 1994; Jankalová & Jankal, 2017; Youmatter, 2019)

Archie B. Caroll (1979) stated four areas – the economic, legal, ethical and discretionary. The economic component represents the fundamental social responsibility of business. The legal component recognizes the obligation of the enterprise to obey laws. The ethical responsibilities have been considerably more difficult to define and interpret. Referred to as the "grey area", this component "involves behaviors and activities that are not embodied in law but still entail performance expected of business by society´s members". The fourth area of responsibilities is called discretionary or voluntary. This category is totally dictated by the "discretion" of the organization as there are no laws or codified expectations guiding the corporations’ activities. Later Carroll (1991) defined this component as philanthropic because this term provides a more specific description of how this component is typically implemented in organizational practice.

Alexander Dahlsrud (2008) specified five primary areas, namely: environmental, social, economic, stakeholder and voluntariness (Table 1). The reason for this choice is also the fact that companies are forced to engage all key partners (*stakeholder*), including item of providing quality products and services, transparent company management (*economic*), care of employees (*social*), environmental protection (*environmental*) and cooperation with the local community (*voluntariness*). (Jankal & Jankalová, 2016) In the table 2 are another views on areas of sustainability.

Table 1: The five dimensions, how the coding scheme was applied and example phrases

Areas of sustainability	The definition is coded to the item if it refers to	Example phrases
Environmental	the natural environment	"a cleaner environment" "environmental stewardship" "environmental concerns in business operations"
Social	the relationship between business and society	"contribute to a better society" "integrate social concerns in their business operations" "consider the full scope of their impact on communities"
Economic	socio-economic or financial aspects, including describing CSR in terms of a business operation	"contribute to economic development" "preserving the profitability" "business operations"
Stakeholder	stakeholders or stakeholder groups	"interaction with their stakeholders" "how organizations interact with their employees, suppliers, customers and communities" "treating the stakeholders of the firm"
Voluntariness	actions not prescribed by law	"based on ethical values" "beyond legal obligations" "voluntary"

*Marc J. Epstein and Marie-Joseé Roy (2003) in their paper "*Improving Sustainability Performance: Specifying, Implementing and Measuring Key Principles*" in order to identify the key principles of sustainability, reviewed corporate standards and a wide variety of governmental and NGO guidelines. The guidelines were rigorously analyzed, synthesized and organized into nine principles of sustainability (Epstein & Roy, 2003):*

- *Principle 1 - Ethics* - The company establishes, promotes, monitors, and maintains ethical standards and practices in dealings with all of the company stakeholders.

- *Principle 2 - Governance* - The company manages all of its resources conscientiously and effectively, recognizing the fiduciary duty of corporate boards and managers to focus on the interests of all company stakeholders.

- *Principle 3 - Transparency* - The company provides timely disclosure of information about its products, services, and activities, thus permitting stakeholders to make informed decisions.

- *Principle 4 - Business relationships* - The company engages in fair-trading practices with suppliers, distributors, and partners.

- *Principle 5 - Financial return* - The company compensates providers of capital with a competitive return on investment and the protection of company assets.

- *Principle 6 - Community involvement/economic development* - The company fosters a mutually beneficial relationship between the corporation and community in which it is sensitive to the culture, context, and needs of the community.

- *Principle 7 - Value of products and services* - The company respects the needs, desires, and rights of its customers and strives to provide the highest levels of product and service values.

- *Principle 8 - Employment practices* - The company engages in human-resource management practices that promote personal and professional employee development, diversity, and empowerment.

- *Principle 9 - Protection of the environment* - The company strives to protect and restore the environment and promote sustainable development with products, processes, services, and other activities.

The International Sustainability Council developed, from a culmination of discussions and thought processes by the ISC Council, 7 principles of sustainability. These principles are further divided in 75 subprinciples (ISC, 2009):

- *Principle 1 - Interdependence, participation, providing information, and improving science* - We all need to recognize our economic, ecological and social interdependence on a global scale and understand and respect differing economic and social views, values, traditions and aspirations. We are all caretakers of the economy, the environment, and social well-being for the benefit of present and future generations. Today's decisions must be balanced with tomorrow's effects. A participatory process on all scales of decision making is vital to community sustainability. Such a process engages all the people who have a stake in the outcome of the decision being contemplated. It encourages the identification of concerns and issues, promotes the wide generation of ideas for dealing with those concerns, and helps those involved find a way to reach agreement about solutions.

- *Principle 2 - Provide intergenerational equity and durability* - The economy, environment, and social well-being should be managed for the equal benefit of present and future generations. A sustainable community does not deplete its resources, destroy natural systems, or pass along unnecessary hazards to future generations. We should incorporate disaster resilience and mitigation into our decisions and actions. A community is resilient in the face of inevitable natural disasters like tornadoes, hurricanes, earthquakes, floods, and drought if it takes steps to ensure that such events cause as little damage as possible, that productivity is only minimally interrupted, and that quality of life remains at (or quickly returns to) high levels. A disaster-resilient community further takes responsibility for the risks it faces and, to the extent possible, is self-reliant. That is, it does not anticipate that outside entities (such as federal or state government) can or will mitigate its hazards or pay for its disasters.

- *Principle 3 - Support and improve the rules of governance* - Growth management planning, community design, green building practices and environmental mitigation all play a role in maintaining the quality of life while accommodating growth through sustainable development strategies. It is imperative that our societies develop an informed democracy. The practice of publishing reports on the state of the environment, and of indicators of environment and social quality, used effectively by the proponents of sustainability should allow citizens to view the risks and threats to their lifestyle and to demand political honesty and accountability. Good decision making by government is imperative on all four scales: global, national, regional, and local.

- *Principle 4 - Maintain and, if possible, enhance the quality of society through community building* - A sustainable society is one that persists and thrives. It provides a high quality of life for all of its inhabitants without harming the integrity and productivity of the natural systems and resources upon which all life depends. Humans' needs and desires are met within the limits of what nature can provide. Choices on design, particularly at medium and high density, greatly affect energy use and natural materials consumption. Public transport and road investment, and decisions that affect an individual's car ownership choices are important when talking about improving the quality of society through community building.

- *Principle 5 - Maintain and, if possible, enhance the quality of human life* - Quality of life - or "livability" - differs from community to community. It has many components: income, education, health care, housing, employment, legal rights on the one hand; exposure to crime, pollution, disease, disaster, and other risks on the other. One town may be proud of its safe streets, high quality schools, and rural atmosphere, while another thinks that job opportunities and its historical heritage is what makes it an attractive place to live. Each locality must define and plan for the quality of life it wants and believes it can achieve, for now and for future generations. A sustainable community's resources and opportunities are available to everyone, regardless of ethnicity, age, gender, cultural background, religion, or other characteristics.

- *Principle 6 - Maintain and, if possible, enhance economic vitality* - A viable local economy is essential to sustainability. This includes job opportunities, sufficient tax base and revenue

to support government and the provision of infrastructure and services, and a suitable business climate. A sustainable economy is also diversified, so that it is not easily disrupted by internal or external events or disasters, and such an economy does not simply shift the costs of maintaining its good health onto other regions or onto the oceans or atmosphere. Nor is a sustainable local economy reliant on unlimited population growth, high consumption, or non-renewable resources.

- *Principle 7 - Maintain and, if possible, enhance the quality of the environment* - A sustainable community sees itself as existing within a physical environment and natural ecosystem and tries to find ways to co-exist with that environment. It does its part by avoiding unnecessary degradation of the air, oceans, fresh water, and other natural systems. It tries to replace detrimental practices with those that allow ecosystems to continuously renew themselves. In some cases, this means simply protecting what is already there by finding ways to redirect human activities and development into less sensitive areas. But a community may need to take action to reclaim, restore, or rehabilitate an already-damaged ecosystem such as a nearby wetland.

Michael Ben-Eli (2015) in his publication "*Sustainability: Definition and Five Core Principles. A New Framework*", inspired (in particular) by the work of R. Buckminster Fuller, describe five sustainability principles. These principles are expressed in relation to five fundamental domains (Ben-Eli, 2015):

- *The Material Domain* - Constitutes the basis for regulating the flow of materials and energy that underlie existence. *The First Principle* - Contain entropy and ensure that the flow of resources, through and within the economy, is as nearly non-declining as is permitted by physical laws.

- *The Economic Domain* - Provides a guiding framework for defining, creating and managing wealth. *The Second Principle* - Adopt an appropriate accounting system to guide the economy, fully aligned with the planet's ecological processes and reflecting true, comprehensive biospheric pricing.

- *The Domain of Life* - Provides the basis for appropriate behavior in the biosphere with respect to other forms of life. *The Third Principle* - Ensure that the essential diversity of all forms of life in the biosphere is maintained.

- *The Social Domain* - Provides the basis for social interactions. *The Fourth Principle* - Maximize degrees of freedom and potential self-realization of all humans without any individual or group adversely affecting others.

- *The Spiritual Domain* - Identifies the necessary attitudinal orientation and provides the basis for a universal code of ethics. *The Fifth Principle* - Recognize the seamless, dynamic continuum of mystery wisdom, love, energy and matter that links the outer reaches of the cosmos with our solar system, our planet and its biosphere including all humans, with our internal metabolic systems and their externalized extensions — Embody this recognition in a universal ethics for guiding human actions.

The set of five domains and five primary principles is fundamentally systemic in nature, meaning that each domain affects all the others and is affected by each in return. By anchoring the essence of human motivation and intention, the spiritual principle acts as the causal root, which sets the tone for the whole. It drives the integration of the other four principles, those related to the material, economic, life, and social domains. If integrated in a balanced way, it can infuse a common purpose, provide a common foundation, and stimulate common resolve. Lacking the ethical commitment implied by the spiritual principle, considerations of questions related to the four other domains, no matter how elaborately expressed, are reduced to mere technicalities. When the principles are thus

integrated and seamlessly inform choices and actions, a state of sustainability, which otherwise appears as a difficult, distant goal, can be realized spontaneously and completely. (Ben-Eli, 2015)

One of the standards directed at helping businesses and organizations contribute to sustainable development is ISO 26000, Guidance on social responsibility. This International Standard describes seven principles for social responsibility, which every organization should respect and apply (ISO, 2017):

- *Accountability* - an organization should be accountable for its impacts on society, the economy and the environment.
- *Transparency* - an organization should be transparent in its decisions and activities that impact on society and the environment.
- *Ethical behavior* - an organization should behave ethically.
- *Respect for stakeholder interests* - an organization should respect, consider and respond to the interests of its stakeholders.
- *Respect for the rule of law* - an organization should accept that respect for the rule of law is mandatory.
- *Respect for international norms of behavior* - an organization should respect international norms of behavior, while adhering to the principle of respect for the rule of law.
- *Respect for human right* - an organization should respect human rights and recognize both their importance and their universality.

As Kozlovska et al. stated (2014), in Slovakia, the first set of sustainable development indicators was approved by the Government Resolution in 1997 and the National Strategy for Sustainable Development of the Slovak Republic was adopted in 2001. The assessment of sustainability is based on the following fundamental principles (National Strategy for Sustainable Development, 2001; Kozlovska et al., 2014):

- *the principle of supporting the human resource development,*
- *the ecological principle,*
- *the principle of efficiency,*
- *the principle of self – regulation and self-supporting development,*
- *the principle of reasonable sufficiency,*
- *the principle of preventive care and predictability,*
- *the principle of respecting the needs and rights of future generations,*
- *the principle of intra-generational, inter-generational and global equality of Earth inhabitants' rights,*
- *the principle of cultural and social integrity,*
- *the principle of non-violence,*

- *the principle of emancipation and participation,*
- *the principle of solidarity,*
- *the principle of subsidiarity,*
- *the principle of acceptable errors,*
- *the principle of optimization,*
- *the principle of socially, ethically and environmentally friendly economy, decision making, management and behavior.*

Conclusion

Organizations on the road to sustainability can benefit from the help of different organizations and can also benefit from the recommendations of authors dealing with sustainability. Authors look at the principles of sustainability differently and their number varies from 3 to 16. Regardless of the approach taken by organizations, it should be emphasized that the principles of sustainability are interrelated, interacting with each other and all areas need to be addressed, and it is not enough to choose just one area that will be given increased attention and neglect the other. The same opinion is also expressed by Ben-Eli, who claims (Ben-Eli, 2015): *It implies that in seeking a transition to sustainability as the organizing principle in a new world order, a piecemeal approach—emphasizing some aspects, while neglecting others—is unlikely to yield effective, lasting results*.

Abstract

Advances in communication technology that is so dynamic in the all-digital era now also penetrated the television media. Many platforms use the internet to reach a wider audience. No exception on-campus community television such as Suska TV using the Youtube account "Suska TV Official" took part in providing information to the campus community. The purpose of this study was to determine the extent of internet-based live streaming video into alternative communication media at Suska TV. The research method uses an interpretive paradigm with a case study approach. Data collection techniques using observation, in-depth interviews, and online search. The results found 3 factors utilizing live streaming video using virtual mixer technology and internet networks in Suska TV. First, it can generate live shows anywhere. Production of news broadcasts, campus programs, and events does not have to be done in Suska TV studios. Second, Following communication technology trends. Through a YouTube account, it gives freedom for the campus community to choose to watch the programs they want from their respective gadgets. Third, this alternative communication media makes it easy for Suska TV as a community television to continue to be productive through broadcast digitalization.

Keywords: Live Streaming Video, Television, Alternative Media Communication

Introduction

In the digital era nowadays, communication technology advances are increasingly massive. Broadcasting activities through various media platforms have become commonplace. This was triggered by the spread of media digitalization. The users' behavior changes overtime, frequently we meet individuals who get to the Internet without knowing the time limit. This activity is carried out wherever and whenever. Furthermore, there are many platforms with various options and interesting features available so that they reach a wider audience.

Television is one example of technological development and has a great influence on people's lives. The industry has experienced technological and structural changes in the past decade. [1] Advances in communication technology that is so dynamic in the all-digital era now also penetrated the television media. Many television stations in Indonesia are also utilizing digital services and are starting to abandon conventional broadcasting methods. To reach a wider audience, it's undoubtedly television shows are now also reaching content that can be accessed through internet-based live streaming broadcasts.

As far as television innovation, there is a term called Smart TV or Hybrid TV that is connected to the Internet or convergence technology that connects computers, television sets and set-top boxes, for

[1] ("Y.Shim and D.H. Shin, "Analyzing the Development of 4th Generation Mobile Network in China : Actor Network Theory Perspektive, " Info Vol. 17. No. 1, pp 22-38, Jan. 2015," n.d.)

example, Google TV and Apple TV. [2] At present, many television shows are competing to use various platforms to stay alive. The high mobility of everyday audiences requires television shows to be enjoyed not only in the home but also anywhere. One of them, many television programs that broadcast shows via new media. Call it through streaming websites or with a touch of other new media or more familiar with the term social media, like Youtube, Instagram TV and so forth.

Internet-based television shows that utilizing the social media have recently begun to increase their audience. This has certainly become a special interest especially for information providers and business operators. Internet-based shows on social media are considered effective for promoting the products and services offered. Moreover, if the target audience is young people like Gen Y (Millennial) and Gen Z.

Referring to some recent communications research, young generation, for example Gen Z, tends to prefer watching television through social media platforms compared to conventional television at home. There are some interesting motives for them to always use social media, first, as a place of self-existence, second to follow the style in relationships and third, namely to want to earn income from social media. [3]

The high use of the Internet in Indonesia is progressively gigantic from year to year. The survey results from the Polling Indonesia in collaboration with the Association of Indonesian Internet Service Providers (APJII), the number of Internet users in Indonesia grew by 10.12 percent. This field data was taken during the period from March to 14 April 2019. According to the Secretary General of APJII, Henri Kasyfi, from a total population of 264 million people in Indonesia, there were 171.17 million people or around 64.8 percent who have been connected to the Internet. [4]

As shown by the phenomenon as above, it isn't astounding that numerous TV media in Indonesia are contending to communicate their shows through media convergence on the web. The community television is no exemption. Community television is a media established by a particular group in a region with the aim of being a forum for information for that group.

Up to this point, the quantity of community TV in Indonesia can be said to have not grown too fundamentally. This happens in light of the fact that there are genuinely severe limitations and rules given by the Ministry of Communication and Information Technology (Kemkominfo) for authorization to air the community TV. In addition to the establishment permit, the broadcast radius is just restricted to 2.5 kilometers with a maximum transmit power of 50 watts. Likewise, the TV channel must utilize recurrence stations dependent on specialized investigations that do not interfere with local or national private TV. Concerning the authorizing procedure, it isn't entirely different from how the private area presents a grant through the Local Indonesian Broadcasting Commission (KPID). To date, there have been 13 network TV channels that have acquired authority-broadcasting licenses in Indonesia. [5] One of the community television stations within the Sultan Syarif Kasim State Islamic University (UIN Suska) Riau is SUSKA TV.

This campus television has obtained an establishment permit since November 10, 2017. Since its establishment, SUSKA TV has had several programs and collaborations with various parties, which are certainly very helpful to the campus academic community to get information. However, to date, SUSKA TV does not have a broadcast license in analogue because of a moratorium from the Minister of Communication and Information.

The Minister of Communication and Information of the Republic of Indonesia issues Circular Letter Number 1 of 2017 concerning the Moratorium on New Applications for Analogous Television

---

[2] ("A. Boztas, A.R. J. Riethoven, and M. Roeloff, "Smart TV Forensics ; Digital Traces on Television, " Digit. Investig., Vol. 12, pp. S72-S80, Mar. 2015," n.d.)
[3] (Anwar, 2019)
[4] (Media, n.d.)
[5] (KOMINFO, n.d.)

Broadcasting Services Licenses through Terrestrial since February 6, 2017 until an undetermined deadline. However, this moratorium does not apply to applications for new licenses and expansion of broadcast coverage in the Disadvantaged, Frontier and Outermost (3T) areas as long as the service area is still available by following the radio frequency master plan for analog TV broadcasting purposes. [6]

With the existence of this Ministry of Communication and Information moratorium, SUSKA TV could not broadcast analog shows from the beginning. However, SUSKA TV tries to take advantage of the opportunity of digitization by showing internet-based production through the YouTube channel "SUSKA TV Official" and the SUSKA TV Instagram Account. This step is considered as an alternative solution so that SUSKA TV information shows can continue to be enjoyed by the campus academic community. Currently, there are 5 SUSKA TV programs that can be watched, including, Suska News, Cahaya Hati, *Young Inspiration*, *Let's Find Out* and *Top List*. The program was welcomed by the academics on campus and off campus. This is evident from the number of active followers on SUSKA TV's Instagram account, which has reached 6112 followers. In addition, the number of subscribers on the YouTube channel "SUSKA TV Official" has exceeded 1034 subscribers.

Some Suska TV programs are broadcast live streaming through the Youtube channel. Usually live streaming is done at official events such as the Flag Ceremony in commemoration of state holidays, graduation processions, seminars, and other official events. Live streaming broadcasts utilize virtual mixer (VMix) Pro 17 so that the audience of Suska TV viewers can enjoy multi-camera shows like watching television on a television screen. The purpose of this study was to determine the extent of Internet network-based live streaming video by utilizing virtual mixer technology to become an alternative communication media in Suska TV. This live streaming video based on Internet network is a form of application of new media theory.

Picture 1: (Right) Suska TV' Instagram Account and

(Left) Suska TV Official' Youtube Channel

[6] (KOMINFO, n.d.)

As quoted by Mark Poster in Littlejohn, new media theory is about a new period in which interactive technology and network communication, especially cyberspace, will affect society. In this article we will explain how to use new media in the development of campus community television broadcasts. [7]

The utilization of new media and old mainstream media has become a kind of media convergence. This is happening more and more around us. Many televisions incorporate new and old media in the production process, as well as in terms of promotion. New media is a variety of communication technology devices that share the same characteristics, which apart from being new, is possible with its wide digitalization and availability for personal use as a communication tool. [8]

Lia Kurniawati from Kridatama Polytechnic conducted previous studies according to the theme of this study in March 2019. Lia raised the title on Utilization of Video Streaming Technology at LPP TVRI West Java. This research focuses on the integration of information technology, information technology and mass communication where it is related to all the activities of processing, manipulating, managing, transferring information between media. The results of Lia's research, namely video streaming technology that is utilized in LPP TVRI West Java, greatly affects both TV stations and the public. With LPP TVRI West Java can compete with regional and national TV stations in the use of video streaming technology, especially LPP TVRI is the first TV station to utilize video streaming technology and LPP TVRI West Java is in it, whereas for video streaming technology community is very helpful in the needs the public will be information and entertainment, the public can easily and practically watch TVRI West Java LPP programs through gadgets wherever and whenever. [9]

Advantages of video streaming technology that is utilized in LPP TVRI West Java is that the network chooses separately, especially in video streaming so that there are no network constraints, missed programs can be watched again by selecting TV catchup contained in the live streaming TVRI application. The drawbacks of LPP TVRI West Java's live streaming: LPP TVRI West Java's live streaming programs can be watched starting at 15.00 on the Kalawarta program until 21.00 on the music program. For YouTube when selecting LPP TVRI West Java programs that appear is the National TVRI live program, because LPP TVRI West Java's live streaming starts at 3:00 PM LPRI TVRI West Java program titles available on youtube when selected are still empty, so users must type the program desirable in the search engine. The obstacle faced by LPP TVRI West Java in video streaming is the Internet network used by users. [10]

Furthermore, Irfan has carried out the other research in 2017, with the headline "Analysis of the Application of Internet Television as a Digital Information Dissemination Media for Regional Development (Case Study of the Communication, Information, Archive and Regional Code of Kotabaru District)". This study discusses the readiness of the application of Internet television to optimize the dissemination of regional development information. In terms of the Regional Government especially those, which have a fairly large area and consist of islands, the existence of Internet television provides an opportunity to be able to disseminate information on regional development effectively and efficiently. This is related to the increasingly widespread use of gadgets that can access the Internet quickly, in addition to the support of the BTS (Base Transceiver Station) infrastructure that has entered into remote villages. Therefore in this study, it will be seen the readiness of the Regional Government (Kotabaru Regency) in implementing internet television technology using a quantitative approach through the distribution of questionnaires to Employees of the Kotabaru district's communications, information, archives, and regional code. In this study, an index of readiness for the communication, information, archives and Kotabaru regency was produced in terms of readiness to apply Internet television technology to optimize the dissemination of regional

[7] (*Littlejohn, S. W. (2009). Teori komunikasi, theories of human communication, edisi 9. Terjemahan Mohammad Yusuf Hamdan. Jakarta: Salemba Humanika*, n.d.)
[8] (*McQuail, D. (2011). Teori komunikasi massa, Edisi 6. Terjemahan Putri Iva Izzati. Jakarta: Salemba Humanika*, n.d.)
[9] (Kurniawati, 2019)
[10] (Kurniawati, 2019)

development information. [11]

In other references, as stated by Elhussein (2016), Tagging systems design is often neglected despite the fact that most system designers agree on the importance of tagging. They are viewed as part of a larger system which receives most of the attention. There is no agreed method when it comes to either analyzing existing tagging systems or designing new ones. There is a need to establish a well-structured design process that can be followed to create tagging systems with a purpose. This chapter uses practical inquiry methodology to generate a general framework that can be applied to analyze tagging systems and proceeds to suggest a design process that can be followed to create new tagging systems. Existing user behavior while tagging is the main guide for the methodology. User-centric approach in information system tries to discover how users' behavior is affected by the design of the system. With users in mind, user-centric design tailors how the information system is constructed according to the user group that is expected to interact with the system. This chapter introduces the concept with social tagging by following a methodology that is focused on providing solutions to specific problems. After a solution is found, the methodology suggest ways to expand it to similar problems within the domain. The conclusion of this research is Better understanding of the effect tagging components have over tagging behavior was achieved through FATS. Although this is useful, it is sometimes hard to explain tagging behavior coming from multiple tagging interface e.g Flickr taggers provide tags from the web-based system and/or the mobile based system. [12]

Research and Metodology

The research method in this article uses an interpretive paradigm with a case study approach. Data collection techniques using observation, in-depth interviews, and online search. Sources of data in this study are from various sides. Among them are the Chairperson of Suska TV Crew, Suska TV Master Control Room (MCR) Coordinator, Suska TV Users / viewers, and Community Television Observers. In selecting this informant the researcher used a purposive technique in which the researcher chose people who were considered to know clearly the problem under study. Sources of data in this study are from various sides. Among them are the Chairperson of Suska TV Crew, Suska TV Master Control Room (MCR) Coordinator, Suska TV Users / viewers, and Community Television Observers. In this study, researchers also used the method of triangulation with data sources.

Case study research is generally a study that has been produced from many sources. This research uses data collection techniques such as in-depth interviews, observation and document study. Stake in Creswell states that case studies are research that will explain an inquiry strategy where researchers explore in depth a program, event, activity, process or one or more individuals. [13] Creswell suggests several characteristics of a case study, namely: (1) identifying the "case" for a study; (2) The case is a "system bound" by time and place; (3) Case studies use various sources of information in gathering data to provide a detailed and in-depth description of the response of an event and (4) Using a case study approach, researchers will "spend time" in describing the context or setting for a case. [14]

Meanwhile, according to Patton in Pawito see that the case study is an attempt to collect and then organize and analyze data about certain cases regarding issues of concern to researchers and then the data is compared or linked with one another while still holding on to holistic and contextual

[11] (Irfan, 2017)

[12] (Saeed, S., Bamarouf, Y.A. and Ramayah, T. eds., 2017. Design solutions for user-centric information systems. Hershey: IGI Global., n.d.)

[13] (*Julianna Davidson, "John W. Creswell Research Design Qualitative, Quantitative, and Mixed Methods Approaches SAGE Publications, Inc (2009),"* n.d.)

[14] (*John W.Creswell, Qualitative Inquiry and Research Design: Choosing Among Five Tradition. (London: SAGE Publications, 1998),hlm.61-62*, n.d.)

principles. [15]

Asmussen and Creswell displays data collection through a matrix of information resources for the for its reader. This matrix contains four types data; interviews, observations, document and audio-visual material for the column and specific form of information such as students, administration for classifields. submission of data through this matrix is intended to see the depth and many forms of data collection, so it shows complexity form the case. The use of a matrix will be usefull if ap[lied in an information rich case study. Cresswell further revealed that interviews and observation are data collections tools which is widely used by various studies. This shows that both tools are central to all the traditions of qualitative research so requires additional attention from researchers. [16]

Results and Discussion

In the case study perspective approach, the use of internet-based live streaming video as an alternative communication medium of Suska TV is often referred to as having many integrated factors. There are factors that can be supporting and there are factors that might hamper production. Suska TV programs that are broadcast to community viewers, especially the UIN Suska Riau academic community at the same time as the original event, through internet-based Virtual mixer (Vmix) media make communication data connected.

The digitalization opportunity utilized by Suska TV is broadcasting its shows through the "Suska TV Official" Youtube account has been carried out for more than a year. From an online search and researcher interview with the chairman of the Suska TV crew for the 2017-2018 period, Ibnu said that SUSKA TV conducted the first live streaming broadcast on January 10, 2019, at the Judicial event organized by the Da'wah and Communication Faculty of UIN Suska Riau at the Premiere Hotel in Pekanbaru. Since then, almost every time there is a big event held on campus, for example, flag ceremonies, seminars, commemorative holidays, etc., SUSKA TV broadcasts live streaming on Suska TV Official's Youtube account and also through the Instagram platform.

> "Suska TV has a virtual video mixer around the end of 2018 if I'm not mistaken. We order through the custom procurement team from Solo and fix the first live streaming broadcast on the official Suska TV on January 10, 2019 to coincide with the Faculty Judicial event at the Premiere hotel. "(Interview on 29 Jan 2020)

Picture 2: Virtual Mixer Pro 17 Suska TV

[15] (Vebrynda et al., 2017)

[16] (*John W.Creswell, Qualitative Inquiry and Research Design: Choosing Among Five Tradition. (London: SAGE Publications, 1998),hlm.61-62*, n.d.)

In the production process of SUSKA TV's live streaming broadcast via YouTube channel, it is not much different from the satellite system on analog TV, both go through the process of selecting images that will air on the control room or better known as the Master Control Room (MCR). SUSKA TV also has a crew (MCR) working in the broadcast control room. SUSKA TV's MCR Coordinator will be responsible for controlling all live streaming programs. SUSKA TV's MCR coordinator, Fikrul Irsyad, said that the virtual mixer used was indeed intended for live streaming anywhere. It doesn't have to be in SUSKA TV's studio, because the shape is portable so it's practically taken anywhere to help the production process.

> "So indeed, since Suska TV, which is a campus TV, has a virtual mixer, our production process has been greatly helped, especially if we are having an important event outside of campus. So, this Vmix is portable so you can carry it anywhere. Practical. "(Interview on 4 Feb 2020)

Picture 3: The crew personnel while using The Virtual Mixer Outside The Studio

Meanwhile, how to work a virtual mixer (Vmix) can be said to be simple. Fikrul said that the principle works through the transfer of images directly from the camera to Vmix using certain software. Fikrul Irsyad, MCR Coordinator Suska TV said;

> "The way Vmix works is quite simple. The captured image is transferred via SDI cable to Vmix. Then, Vmix software will display a real-time Multicam of what is captured by the camera, there are several views in the Vmix software, including, 1 preview view, 1 program view or image which is on air, and some camera angle display all connected to Vmix and audio which enter Vmix through the audio port. "(Interview on 4 Feb 2020).

Meanwhile, from the viewer / user / users of Suska TV, one of the student informants, Aisyah expressed her appreciation to the research team. He said that since Suska TV has live streaming technology, many campus academicians have benefited greatly. For instance, during the graduation occasion on grounds. Suska TV broadcasts helped her family to watch the procession when Ayesha joined the graduation ceremony.

> "So yeah, this is another trend everywhere, live streaming broadcasts, moreover I'm proud that my campus can also participate in live streaming of graduation processions, so it benefits large families of students who are going to graduation because, no need to bother coming to the PKM building, it's full and crowded. You can just watch Suska TV on the graduation program. "(Interview on 5 Feb 2020)

Picture 4: Live Streaming Scenes on The Graduation Event

On the other hand, Hisam Setiawan, deputy chairman of the Riau Regional Indonesian Broadcasting Commission (KPID) as a community television observer stated that until the beginning of 2020 there was still a moratorium on Broadcasting Operations Licenses by the Ministry of Communication and Information Technology (Kominfo). Hisam said that at this time in Pekanbaru, in particular, there was not a single community TV that could broadcast analogs via terrestrial.

> "Since its establishment, SUSKA TV should have been running a broadcast trial for 1 (one) year, and after that, it would obtain permanent permission for analog broadcasts. However, due to constraints on the moratorium from the Minister of Communication and Information of the Republic of Indonesia which issued Circular Letter Number 1 of 2017 concerning the Moratorium on New Applications for Analogous Television Broadcasting Services for Terrestrial Broadcasting Services since February 6, 2017. This is valid for an undetermined deadline. However, this does not apply to applications for new licenses and expansion of broadcast coverage in Disadvantaged, Frontier and Outermost (3T) areas. Well, for borders, you can, but, for TV campus communities like SUSKA TV, you have to be patient. "(Interview on 3 Feb 2020).

However, the enactment of the community TV broadcasting moratorium until now has not broken SUSKA TV's enthusiasm as a campus TV to continue producing through digitizing broadcasting. This is in line with what was written by Putri Adenia, regarding "Campus Television: Enlighteners Without Regulation". Campus media, including campus television, are identified as part of community media with limited reach. But the development of technology and the world of the Internet, it is appropriate that the understanding and regulation of community media be reviewed. Because of the Internet platform, making the campus media reach broad and has the same opportunities as the mainstream mass media. Even campus television has the opportunity to become an alternative TV for the community when the condition of the mainstream-broadcasting world is currently controlled by a handful of people. Seeing this opportunity, AJI Indonesia supported the implementation of TELEVISIONAIR organized by UMN TV, television campus of the Multimedia Nusantara University. [17]

[17] ("Televisi Kampus," n.d.)

According to Euis, Technician of Suka TV at UIN Sunan Kalijaga, they have been using live streaming technology using an analog system since 2015, and then in 2019 began using Internet-based Black Magic technology. According to him the use of internet-based live streaming technology has advantages and disadvantages.

"The advantages related to an unlimited target audience, internet-based live streaming systems could also be recorded and watched multiple times after live broadcasting. But, the drawback is that the network must be stable, then for off-campus production, we must always refill Internet data packages. "(Interview on 5 Feb 2020)

Besides, concerning the use of Youtube and Instagram platforms in broadcasting Suska TV, this has its advantages. In the article it is mentioned that the use of various platforms to support broadcast programs is very useful, in addition to free, good management will make the target to be achieved will be easier. From various media platforms used, such as conventional television, TV streaming, netcj.co.id website, Net CJ applications, Twitter, Facebook, Path, Instagram, Google Hangout and YouTube have different functions. The merging of various media platforms is known as convergence. [18]

Conclusion

It can be concluded based on observations and in-depth interviews, then found 2 factors supporting and inhibiting the use of live streaming video using the internet network at Suska TV. Supporting factors include, first, can produce live shows anywhere. Production of news broadcasts, campus programs, and events does not have to be done in Suska TV studios. Second, Following communication technology trends. Through a Youtube account, it gives freedom for the campus community to choose to watch the shows they want from their respective gadgets and then freely watch Suska TV shows again. While the inhibiting factors include, Bandwidth in the campus of UIN Suska Riau, which still needs to be increased. This is needed so that the quality of the broadcast is maintained and is not constrained by delay. Second, the qualification of live streaming technology that is used must always follow existing developments. This requires a lot of costs and Human Resources (HR) so that Suska TV can still be active in producing through digitizing broadcasting. This research is expected to be one of the references in the next research regarding the same theme of broadcasting digitalization, new internet-based media, campus community television, and so on.

Abstract

The building sector is featured by significant influence on the environment. Both buildings and non-building structures require natural resources to be constructed and maintained. There are many unsolved problems in the construction industry. One of the most important is the extensive usage of resources for construction projects. In the absence of proper education, even the most excellent ideas may be insufficient in eliminating emissions and other negative externalities. Due to the complexity of the organizations, both in a project and in corporations, that is among individual stakeholders, it is worth indicating leaders of change. In the article, based on the literature review, it was pointed out that knowledge management in a construction company should primarily be based on the corporate culture that shows a preference for the idea of Circular Economy. The path to CE maturity has been shown as a continual pursuit. The consistency enables for effective promotion of the concept of CE in the construction company. The research allowed to draw three explicit phases: disharmony, euphoria, harmony in becoming CE-matured by the enterprise.

Keywords: leadership, construction company, Circular Economy, organizational behaviour.

Introduction

Waste collected during construction and demolition phases is a priority for many policies at a local, regional and global level (López Ruiz, Roca Ramón and Gassó Domingo, 2020) at the moment. Whereas in the building sector many issues connected with energy efficiency are being widely studied, the ways to get rid of the pollution problem is still in its embryonic stage (Leising, Quist and Bocken, 2018). The concept that is gaining increasing recognition, especially among legislative decision-makers in the European Union, is Circular Economy (CE). Its applicability in different sectors is an evident advantage. In the construction industry, its implementation consists mainly of new design philosophy where different disciplines are integrated in advance to check their applicability and constructability.

The organization is the basic assumption on which the methodology of a system theory of organization is based. In a system approach, instead of dealing with individual segments of the organization separately, it is treated as a whole and a purposeful system, composed of interrelated parts. Similarly, in the case of construction companies which, apart from the main processes, there have also several side processes (managerial or supporting). A model of the construction company system is presented in Figure 1.

Fig. 1: Business process map in construction companies – specification of managerial processes including CE management

One of the key challenges of the construction industry is the transition from an extensive development model based on the concept of linear production, which treats the used product at the end of its life as waste (Bassi and Dias, 2019), to a sustainable development model involving production in a closed circulation of resources. Various issues threaten the sustainability and many of them are coming from human behaviour (Abusafieh and Razem, 2017). Due to a limited number of studies which take into consideration the human behaviour, the organizational behaviour, or the leadership models and their influences on the sustainable built environment (Soares *et al.*, 2017; Wang, Pan and Luo, 2019), this article addresses the issue of leadership as a prerequisite for the diffusion of knowledge about Circular Economy in construction companies. The roles of individual stakeholders in construction projects in shaping corporate culture based on CE principles are detailed in the manuscript. Showing a changeable leadership ecosystem based on an evolutionary approach, and situational leadership theory developed by Hersey and Blanchard, was the main concern of the research. All considerations were based on the desk research method.

Circular Economy in the building sector

Circular Economy usually means the philosophy of breaking with the current thinking about products based on a linear model and promoting a new production system created on the basis of a perpetual circulation of resources. Due to the multitude of manufacturing processes within construction projects, there are many types of waste that are generated in large quantities. When considering supply chain models in the construction industry, it should be borne in mind that they reflect the mutual relationship between stakeholders in construction projects in the field of material flow. When it comes to adding value to customers, one can consider a model that shapes the form of a closed-loop (Figure 2).

Fig. 2: Closed-loop project value chain for value management of construction projects (Górecki *et al.*, 2019)

Each working package related to the implementation of a new production effect is characterized by the standard material usage. It determines their quantity necessary to perform a unit of process or an element of the structure, in accordance with all applicable technical and rational, i.e. economical, material management standards. The standard of material usage includes not only the amount of material built into the building/non-building structure (basic consumption) but also the amount of waste and losses. Even the most restrictive set of procedures will not limit the amount of waste and losses to an absolute minimum. In addition, demolition processes provide waste, which is treated as worthless matter.

Circular Economy, as an idea on the one hand, and as a real action on the other, supports the construction industry by reducing its negative impact on the environment. The degree of involvement of main stakeholders of the construction projects in Circular Economy was shown in Table 1, depending on the project's phase. At the same time, the risks that should be considered at each stage were shown.

Table 1: Possibilities of using CE by various stakeholders of construction projects, based on (Bennett, 2003; Nuñez-Cacho *et al.*, 2018; Górecki *et al.*, 2019; Górecki, 2020a)

Stakeholder's name	First phase of the involvement	Last phase of the involvement	Potential activities	Dominant risks
Investor	Pre-project phase – initiation	Closure – end of project closeout and termination phase	- setting CE requirements for an architect, - setting CE-related requirements for a contractor, - selection of investment location enabling materials recovery,	- the unprofitability of investments in CE (financial risk), - extension of construction time (schedule risk), - lack of suitable architects, contractors and managers,

Stakeholder's name	First phase of the involvement	Last phase of the involvement	Potential activities	Dominant risks
Contractor	Execution – the start of contractor mobilisation phase	Handover – end of contractor mobilisation phase	- selecting ambassadors of Circular Economy (ACE), - setting ACE in the organizational structure of the enterprise, - establishment of the CE training program, - promoting CE as a part of corporate culture, - carrying out the reorganization/reengineering processes, - search for new technologies for the recovery of building materials,	- resistance to changes among employees, - incorrect and inefficient training, - wrong organizational changes, - lack of appropriate technologies at the time of operation
Architect	Start of planning and design phase	Execution – end of architectural supervision	- proposing CE-friendly design solutions, - design in accordance with CE, - analysing the possibilities of reusing materials after their end-of-life,	- lack of appropriate competences, - lack of appropriate tools for analysis,
Project manager	Pre-project phase – definition of project	Closure – fulfilment of project goals	- selecting Circular Economy managers (CEM), - setting CEM in the organizational structure of the project, - using measures of the degree of involvement to the idea of CE, - preparing response plans for CE-related risks, - selecting project partners according to their levels of CE maturity	- inappropriate project assumptions, - bad diagnosis of project status, - inefficient planning and risk management, - lack of knowledge about all project activities

The table above shows that CE can be considered on many levels, including both a construction company and a project. It has been noted that there is a number of risks that give rise to uncertainty about future CE-related states.

Finally, it can be seen that a lack of knowledge and tools hampers Circular Economy in the building sector, which in turn is treated as a macro-level transformation to a sustainable economy (Anastasiades *et al.*, 2020; Foster, 2020). Therefore, in order to promote closing loops of supply chains in construction projects, it seems inevitable to put stress on a controlled leadership. The specificity of the building sector implies a need for considering the attributes of business activity in the whole life-cycle perspective.

Building CE-based corporate culture

General Background

Environmental issues have recently become the focus of considerations on the modern paradigm of management of construction companies (Górecki and Bizon-Górecka, 2019). Noticing the significant impact of these organizations, participating in various construction projects, on the natural environment has become the beginning of changes in thinking about their resources. It has become necessary to review the needs of enterprises, reduce the degree of consumption, as well as to develop new technologies or methods of process management in accordance with the principles of sustainable development (Górecki, Swoiński and Bizon-Górecka, 2018).

A large number of investments around the world, as well as the multitude of construction project stakeholders, who are mainly construction companies responsible for erecting building or constructing infrastructure, having various impacts on the course of these processes (Bizon-Górecka and Górecki, 2017), raises concerns about the effectiveness of measures to reduce the negative externalities of this business activity.

The risk of construction projects is of great importance, which determines the concern of enterprises for effective methods of planning their activities. This term is generally understood as the likelihood of diverging between plans and reality (Górecki and Bizon-Górecka, 2017). It may relate to various aspects, but particularly concerns issues of cost, time, scope and quality.

Basic Attributes of Models

The risk manager, responsible for preparing response strategies (including planning and decision making process) for possible deviations of the actual course of the project from the initial plans, may become a creator of the project maturity in a construction company (Górecki and Bizon-Górecka, 2018). This concept understood as the pursuit of a high level of perfection in mastering the management of the basic attributes of construction projects becomes rudiments of the new leadership model. To ensure appropriate dissemination of knowledge about Circular Economy, it is necessary to create a specific ecosystem based on the CE maturity (Górecki, 2018), achieved through the appropriate strategy and corporate culture.

Figure 3 shows a situation where there is a lack of harmony in the values represented by the employees of a given enterprise. A change leader is emerging - the so-called leader of the Circular Economy in a construction company, also known as Circular Economy manager (CEM) (Górecki, 2020b). His/her competences are indisputable, he/she can be a graduate of post-graduate studies in the field of Circular Economy in construction or a participant of training/workshops on such topics. At this time, only he/she and the top management (because they hired him) are aware of the advantages of managing construction projects under CE requirements. The beliefs and values of the leader are usually divergent with the beliefs and values of other employees. The CEM's effort should be directed towards sharing these qualities with others and educating them. This stage is characterized by the evolution of CE maturity, and when it comes to the period it can be called adolescence of Circular Economy culture in a company. The success of this phase depends on the level of commitment of the leader, the belief in the correctness of matters, as well as the consistent pursuit of change.

Fig. 3: The pursuit of high perfection in meeting CE requirements in construction companies - stage one: disharmony

The next stage is the euphoria (Figure 4). After a monotonous period of internal organizational changes, employee training, discussions, consultations, reorganization, and sometimes reengineering in a construction company, the phase is reached where all beliefs and values of the leader and other employees become shared. This is not a state given once and for all; turnovers, periodic failures, as well as the routine can lead to these qualities being diverged again. The CEM's effort should be directed towards maintaining a state of euphoria. This moment $M(t_0)$ can be called CE-maturity-equilibrium. Further actions must lead to the perfection of actions and, associated with it, the harmony.

Fig. 4: The pursuit of high perfection in meeting CE requirements in construction companies - stage two: euphoria

The harmony (Figure 5) that can be observed in construction companies, related to achieving perfection in mastering procedures in accordance with CE principles by all employees, is the final

stage of the pursuit. It crowns the efforts of CEM, as well as all employees who have gained the conviction that their beliefs and values are common to all. The newly created corporate culture can be a condition for the success of a construction company that uses the advantages of the CE approach.

Fig. 5: The pursuit of high perfection in meeting CE requirements in construction companies - stage three: harmony

However, for the transformation described above to be realistic, it must be conditioned by appropriate leadership models.

Modelling leadership

Effective business activities depend on the quality of individual employee behaviour (Gilstrap and Hart, 2020). To effectively implement construction tasks, it is necessary to use appropriate tools to use power and influence the subordinates in a clever way. Acting as a leader, who should be equipped with the sensitivity and diagnostic ability, is not easy (House, 1997). There are many leadership theories also covering various leadership styles (autocratic, democratic, laissez-faire). When choosing the right strategy, one can be guided by the achievements of modern science, including situational leadership theory (Hersey and Blanchard, 1988). The style, developed by Paul Hersey and Ken Blanchard, is based on the following assumption: a good superior should provide his subordinates with what they need to effectively carry out the tasks set. The leadership is conditioned by the fact the boss should base his/her influence on subordinates not only on the professional hierarchy but also on the authority he/she builds around him/her (Al-Najjar, 2001).

Therefore, at the beginning of activities aimed at transforming a construction company into an organization based on procedures in accordance with CE principles, some resistance from employees should be expected. A situational leadership model in a construction company is shown in Figure 6. It can be noted that an appropriate approach at the beginning is to use high discipline (manager - drill sergeant). One should gradually strengthen the instructions and transform the approach (manager - athletic coach).

Fig. 6: Situational leadership model for effective knowledge diffusion about Circular Economy in a construction company

Once all the rules are understood by most employees, one can begin to limit the discipline by replacing it with greater concern for the wellbeing of subordinates (manager - teacher-counsellor). As work is not a military training ground, it is necessary to balance management styles with the effects observed. When everybody starts to understand what CE is about, what the rules are and why it is beneficial to keep it, the guidance can be limited and a relaxed attitude towards employees begins (manager - buddy).

This model emerged on the basis of parent-child relationships described in the literature (Eloff and Ebersöhn, 2004).

Summary

Transforming a construction company into an organization that cares about ecology, sustainable development and promotes behaviours based on Circular Economy principles is not easy. It requires time, experience and persistence in pursuing the goal. It is not only about conducting a series of training sessions with certificates. It is not just about drawing up and enforcing new procedures. This transformation is a constant pursuit of harmony in which the beliefs and values of the corporation are the same as what the employee feels. Of the many leadership models, the situational one presented in this article seems to be the most rational.

It is obvious that the leadership may be a subject of criticism. Leaders may commit some mistakes too. They can resign from the values they praised before. People are just people but in the end, one should trust them to achieve some goals.

The basic concept of situational leadership including four original steps: delegating, participating, selling and telling was adapted to new circumstances of effective knowledge diffusion of Circular Economy in a construction company.

Abstract

Construction is a sector of the economy being under a significant influence of developing technology. Buildings and non-building structures shape the environment and "consume" natural resources throughout their life cycle. They "live" many years what makes that management of a construction project (taking into account the entire life cycle) is the goal of many generations of supporting technologies. The technologies may be used in the phase of design, construction, maintenance and demolition of buildings and non-building structures. They refer to manufacturing processes, construction production or management. They include the use of computers, automated tools and machines or other intelligent devices. Therefore, contractors of construction projects have to be sensitive to these issues. In the article, based on literature studies, it was revealed that knowledge management in a construction company should primarily be based on the corporate culture that shows a preference for computer-aided methods. The path to technological maturity of the construction company has been shown as a continual process. The consistency enables for effective promotion of innovative technologies in the construction company. The research allowed to draw three explicit phases: lack of experience, euphoria, experience in becoming technologically-matured by the enterprise.

Keywords: knowledge, technology, skills, construction company, IT.

Introduction

Construction as a significant sector of the economy has been a subject of the continuous impact of the technology. After the Second World War, development of the technology was concentrated on the methods of constructing prefabricated buildings and non-building structures. A straight advantage of the approach was a rapid construction process which resulted in a quick supply of the ecosystem needed by and convenient for societies in many European countries after years of destructive military activities. After some decades, technology development was focused on other issues, e.g. manufacturability (Fastenau, 1984), energy savings (Opitz *et al.*, 1997), quality (Neelamkavil, 2009), cost and time efficiency (Blake, 1990; Salam and Jose, 1995), diversification of solutions etc. – it means a further improvement of the construction methods. Nowadays, development in this area is still observed (e.g. graphic or transparent concrete (Goss, 2016), new and improved precast accessories, including seismic-resistant joinery techniques (Kurama *et al.*, 2018) etc.), but the effects are no longer as spectacular. On the other hand, brand new materials are expected to replace the currently used, and not always environmentally friendly material technologies.

A final phase of the 20th century was connected with other technological revolution – implementation of IT to construction projects. It was noticed that methods of construction were developed sufficiently but there were still other undiscovered challenges connected with an efficient way of raising buildings and creating infrastructure. Digitalization of the construction sector is not a rapid process.

Unlike in other sectors of the economy (manufacturing or services), market players of the construction are still quite sceptical about the innovations of the IT origin. Many construction companies are featured by comparably low level of use of computer-aided methods. Due to this fact, there is still a small percentage of enterprises using Building Information Modelling (BIM) (EUBIM Taskgroup, 2017) or accompanying technologies Virtual Reality (VR) (Kim *et al.*, 2013), Augmented Reality (AR) (Shanbari, Blinn and Issa, 2016) or Mixed Reality (MR).

Lately, it has been discussed that sustainable ways of conducting construction processes are inevitable. Therefore, more and more theoreticians and professionals concentrate on new concepts like environment-focused certifications of buildings including the Building Research Establishment Environmental Assessment Method (BREEAM) (Cheng, Behzadsodagar and Feifeisun, 2017) or the Leadership in Energy and Environmental Design (LEED) (Azhar *et al.*, 2011), the ISO 14000 and its relevance to the construction industry, the Life Cycle Assessment (LCA) (Bribián, Capilla and Usón, 2011; Wang, Zhang and Wang, 2018), Life Cycle Costing Analysis (LCCA) (Cabeza *et al.*, 2014), cradle-to-cradle (C2C) approach (Silvestre, De Brito and Pinheiro, 2014; Van Dijk, Tenpierik and Van Den Dobbelsteen, 2014), design for deconstruction (DfD) (Cai and Waldmann, 2019; Basta, Serror and Marzouk, 2020), green labels (Chegut, Eichholtz and Kok, 2019) or Circular Economy (CE) (Nuñez-Cacho *et al.*, 2018; Górecki *et al.*, 2019; Górecki, 2020). All these ideas seem quite complicated, but they all have something in common - are connected with mechanisms that are favourable, not harmful to the environment, and related to construction projects. Despite the apparent environmental connotation, these activities are possible mainly due to the use of product or process innovations - whether in the field of heating, ventilation, and air conditioning (HVAC) technologies, whether in the field of new recovery, reuse and recycling technologies, or finally due to the use of new, yet even uncovered or untested building materials.

The development of construction-related technology has not been limited by the aforementioned actions. The Industry 4.0 (or its related term of Construction 4.0) (Hossain and Nadeem, 2019; Spisakova and Kozlovska, 2020) concept brings even more challenges. It requires changes on many levels: technological, organizational or mental both in construction companies and construction projects. It seems that despite the unimaginable development of the entire construction ecosystem including all elements of business activity in construction, upcoming years may be a moment of a critical juncture in which it will be possible to combine seemingly disjoint and incoherent elements into one idea sustainable and circular construction. Remodelling the entire traditional construction process into a chain of interrelated activities carried out by automated production systems (like 3D printing (Khorramshahi and Mokhtari, 2017)) based on Big Data (Batty, 2016; Górecki, 2018; Burak Gunay, Shen and Newsham, 2019), processed in data mining supervised by artificial intelligence (AI) (Cheng, Chang and Korir, 2019; Xu, Chong and Liao, 2019), in accordance with the spirit of sustainable development, with a closed-loop of resources conditioned by product and process innovations is becoming the industry's most important challenge in 21st century.

All in all, the subject of trends in the construction sector should be broadly perceived. This article focuses on the issue of technological conditions for the development of construction companies. It has been assumed that the technological process is one of many processes present in the company's production system (Figure 1).

Fig. 1: Business process map in construction companies – specification of supporting processes including technical support

However, it requires constant technical support. Preferring a development model based on technology treated seriously as an advantage and an implementation of innovative technologies as an opportunity both for companies and projects has become the starting point of the study.

Technological challenges in the construction sector

Building means erecting buildings and other constructions, infrastructure etc. From the executive point of view, the erection process can be categorized according to where most construction production takes place. Therefore, it is possible to erect the building and non-building structures from delivered building materials directly on the construction site (e.g. monolithic construction). Another option is prefabrication (pre-construction) of elements that, after being transported to the construction site, are built into the place, i.e. jointed using various joinery techniques. The further division consists in taking into account the dominant material used to manufacture a given building element (concrete - precast, reinforced concrete, ceramic, wooden, metal structures - although the latter are only prefabricated). Today, it is believed that it is easier to implement innovations with regard to the quality criterion in a prefabrication mode.

Mechanization of the production of building materials is a part of the economy that drives the development of technology basically around the construction sector, but which has a significant impact on this sector. It turns out that innovations derived from manufacturing materials create pressure to seek new solutions at the stage of construction works. Prefabrication factories are a place of robotization of production processes. To meet expectations of the customers and not to squander a high quality obtained at an earlier stage, contractors are somewhat forced to demonstrate continuous improvement of processes at the further step – on a construction site. What's more, innovations from the design stage also reinforce the need for implementing innovations on the construction site. The best example of this is the use of BIM. Software, based on such attitude, is a great tool for simulating the best solutions and creating the so-called Digital Twin (Kaewunruen and Xu, 2018; Lu *et al.*, 2020) of a future facility. However, the potential of BIM is unused as long as technologies based on this idea are not used in subsequent life cycle stages of a building or a non-building structure, i.e. at the stage of construction, maintenance or end-of-life. All in all, the conceptual package related to the development of technologies used in construction is very capacious and contains a lot of concepts. A set of these ideas are presented in the form of a word cloud in Figure 2.

Fig. 2: Word cloud based on concepts connected with new technologies connected with the construction sector

Historically, technology has always been the driving force of the industry. Today, thanks to the universal availability of technology, as well as remodelling business concepts of various industries, it is a competitive advantage mainly in the sphere of services. The development of innovations, not only in the construction industry, is based on three pillars: technology, law and administration and social acceptance. Today, this first foundation is easily solvable thanks to advanced computational techniques or modern production systems that are able to provide a product whose specification is unimaginably complicated. And we can do it. The law is a little harder to manage. Legal regulations take place at various levels and in various forms. However, the most difficult is to convince users and system participants to accept, adopt and use innovations. People and their perception are becoming the industry's most difficult challenge.

Construction works the same way. Perhaps the conditions in which construction projects are carried out remain unchanged. Still, the building must ultimately be erected (whether built or assembled) in the target area, in certain variable soil and water conditions, with the participation of many entities, not always agreeing with each other, etc. But the methods and means of achieving the same goal as before have been and are being improved. To sum up, technological innovations in construction are present in various areas, from the production of building materials, design processes, through logistics processes, methods of erecting construction objects, including technologies of construction works - junctures and constructing, techniques of project management (in costing, scheduling, quality control, inspections or project settlement), up to the stage of managing the existing building or non-building structure, and finally the moment of its demolition.

Technology-oriented leadership models

General Background

It has to be noted that, on the one hand, technology is an opportunity that leads to increasing the efficiency of processes. On the other hand, however, it is a threat, it will be a surveillance tool or a

technique used for unfair competition, etc. Therefore, how to deal with this dilemma? First of all, one should focus on education as a dimension of implementing strategies to deal with the threats arising from the development of technology. This article is devoted to searching for a way to shape the technological maturity of a construction company expressed by the harmonized state of competence of all employees in the field of technology used in the enterprise.

Basic Attributes of Models

Figure 3 presents a case where there is a lack of harmony in the values represented by the employees of a given enterprise. A change leader is emerging - the so-called leader of the technology development in a construction company, who can be called construction technology manager (CTM). His/her competences are indisputable, he/she can be a graduate of post-graduate studies in the field of IT for construction, construction technology or a participant of training/workshops on such topics. At this time, only he/she and the top management (because they hired him) are aware of the advantages of managing computer-aided construction projects. The skills and knowledge of the leader are usually divergent with the skills and knowledge of other employees. The construction technology manager's effort should be directed towards sharing these qualities with others and educating them. This stage is characterized by the evolution of technological maturity, and when it comes to the period it can be called technological adolescence of a company. The success of this phase depends on the level of commitment of the leader, the belief in the correctness of matters, as well as the consistent pursuit of change.

Fig. 3: The pursuit of high perfection in meeting technological requirements in construction companies - stage one: lack of experience

The next stage is the euphoria (Figure 4). After a monotonous period of internal organizational changes, employee training, discussions, consultations, reorganization, and sometimes reengineering in a construction company, the phase is reached where all skills and knowledge of the leader and other employees become shared. The construction technology manager's effort should be directed towards maintaining a state of euphoria. This moment $M(t_0)$ can be called technological-maturity-equilibrium. Further actions must lead to the perfection of actions and, associated with it, the full experience level.

Fig. 4: The pursuit of high perfection in meeting technological requirements in construction companies - stage two: euphoria

The full experience level (Figure 5) that can be observed in construction companies, related to achieving perfection in mastering competence in terms of technology by all employees, is the final stage of the process. It crowns the efforts of CTM, as well as all employees who have gained the conviction that their skills and knowledge are common to all. The newly created corporate culture can be a condition for the success of a construction company that uses the advantages of competence perfection in technology connected with construction.

Fig. 5: The pursuit of high perfection in meeting technological requirements in construction companies - stage three: full experience

However, for the progress described above to be realistic, it must be conditioned by appropriate leadership models.

Modelling Leadership

Effective business activities depend on the quality of individual employee behaviour (Gilstrap and Hart, 2020). To effectively manage construction processes, it is necessary to apply appropriate means to use power and impact the subordinates in an efficient way. Being a leader is not an easy task (House, 1997). There are many leadership theories with various leadership styles (autocratic, democratic, laissez-faire).

A choice of the right strategy should be guided by the achievements of modern science, including evolutionary leadership theory (van Vugt and Ahuja, 2010). The attitude, developed by Van Vugt & Ahuja, is based on the following assumption: both leadership and followership are important for the reproductive success of ancestors. However, modern organizational structures of companies of all industries are sometimes inconsistent with innate psychological mechanisms of two processes: leading and following. This explains some problems in the relationship between managers and subordinates. The leadership is conditioned by the fact that turning subordinates (employees) into followers of the leader is a key success factor for organizations.

An evolutionary leadership model, configured for technology knowledge management in a construction company, is shown in Figure 6. It can be noted that an appropriate approach at the beginning is to use open communication model for superior-subordinate. Then a feedback quality increases and the behaviour of the employee switches into a distant observer.

Fig. 6: Evolutionary leadership model for effective knowledge diffusion about technology in a construction company

Once all the communication model converts into a closer one, once again a feedback quality decreases as the subordinates become more suspicious again. When everybody in the organization starts to understand how to use all advantages of the technology in a construction company, the feedback quality can increase one more time and an employee becomes a loyal companion as he/she trusts in the leader and his/her position.

This model emerged on the basis of student-master relationships described in the literature**.**

Summary

Transforming a construction company into an organization that cares about technology development and diffusion of the related competences is not easy. It requires time, experience and persistence in reaching established targets. Going towards technological adulthood is not only about conducting a series of training sessions about BIM, Big Data, drones etc. with certificates. It is not just about creating new procedures. This transformation is a process of getting experience in which the skills and knowledge of the whole corporation are the same as what the employee can and knows. The evolutionary leadership model seems to be the most rational of all. It is obvious that the leadership may be a subject of criticism. Leaders may be the wrong example. They can trick and lie. But in the end, one should trust them to achieve some measurable benefits. The basic concept of evolutionary leadership including four original states: suspicious subversive, distant observer, trustful sloth and loyal companion was adapted to new circumstances of effective knowledge diffusion of technology development in a construction company.

Abstract

To pay Zakat (alms) is an obligation for a Muslim. However, this religious obligation cannot encourage Muslims in Indonesia to pay Zakat. In fact, in several cities, some Zakat organizations are established to collect the zakat. Some of them is the BAZNAS which is spread in most cities in Indonesia. In fact, this organization is a semi-government because there are some collaborations between the BAZNAS and local government in most regions. This collaboration indicates also that it tries to get benefit from the modern and established government structure. This article aims to know the BAZNAS negoitation with modernity, specifically it wants to deal with the BAZNAS zakat socialization. Using a case study, this article finds that the zakat organization like the BAZNAS Kepulauan Meranti Indonesia deals with a complicated negoitation with modernity through its zakat socialization. In fact, there is a religious understanding among Muslims there that to pay zakat is an obligation but it cannot deal with their religious awareness to pay zakat. This article identifies that disseminating the zakat payment obligation is a never ending project. The BAZNAS improves Muslim understanding about Zakat through socialization. Some socialization activities done are using modern instruments but some are not.

Keywords : Zakat, BAZNAS (National Zakat Collection Agency), Socialization.

Introduction

Zakat, undeniable, is a major issue in Islam. A number of studies discuss the urgency of zakat in seizing the potential of economic resources left behind in Muslim societies, for example Farida (2016: 1-76), Marpuah (2016: 313-412) and Ismail (2016: 629-680). The issue of zakat and the problem of underdevelopment of Muslim communities in economic aspects is a logical impact of the development of globalization and modernization which often places Muslim communities in marginal positions (Hadiz, 2018). The marginalization of Muslim communities from national economic competition becomes a force on the one hand in 'sharia mobilization', one of which is through the issue of zakat and the potential economic strength of the ummah and political mobilization on the other. This is shown by one interesting research conducted by Salim (2015). Through zakat regulation issued by the local government, he explained how zakat is used as an economic and political mobilization tool in West Sumatra.

Nevertheless, the aspect of zakat and economic empowerment remains a favorite in research related to zakat. The focus of related research that has not been touched is the efforts made by zakat institutions that flourished in the post-New Order era to encourage preaching for alms in the Muslim community. These institutions continue to try to encourage awareness of the zakat Muslim

community, because paying zakat is a major symbol of piety in Muslim societies (Hassan, 2006: 59-60). The symbol of piety that will be shown in this article is a discourse that continues to be contested in Muslim societies in the context of paying zakat. Then, the research related to zakat needs to focus on the efforts of zakat institutions to understand the complex and complicated negotiations they undertake regarding religious awareness and modern instruments. These institutions as in other regions in Indonesia often face technological stuttering and modern management amid a strong spirit of religiosity .

This article would like to explain the ways taken by the Meranti Islands National Zakat Agency in spreading the obligation of paying alms among communities in the Meranti Islands. The findings of this article are useful to see how to spread the understanding of the obligation of zakat as an unfinished project because the values of religiosity often require modern instruments. The empty space needed by these religious institutions is, instead of increasing their established religious understanding, strengthening the basis of understanding and implementation of instruments of modernity such as management and use of modern media .

The method used in this article is a case study since this article focuses on one institution. This article is based on a sociological approach that negates doctrinal-based research models. Thus the descriptive qualitative method is a method that is considered appropriate to explain the facts 'as is' in the process of preaching the obligation of tithe carried out by the Meranti Islands BAZNAS. Data collected through observation, interviews, and documentation. Because it is based sociological approach, the findings produced do not promise to be directly proportional to religious texts that are considered authoritative in Muslim societies.

The informants in this article are 8 people selected based on *purposive sampling techniques.* Mechanical *purposive sampling* is sampling or informants based on certain considerations. Consideration is meant for example the person who is considered most knowledgeable about what we expect or maybe he as a ruler so that it will be easier for researchers to find the facts expected (Sugiyono: 2015). Five informants were selected from the management of the Meranti Islands National Amil Zakat Board (BAZNAS), namely the Chairman of the Meranti Islands BAZNAS, the Deputy Chair I of the Collection and Development Division of the Meranti Islands BAZNAS, the Chair of the Meranti Islands Collection and Development Division in the Meranti Islands, the UPZ (Zakat Collection Unit) of West Rangsang District, The Secretary of UPZ, West Rangsang District and 3 informants were taken from the Rice Plant Farmers in the West Rangsang District of Meranti Islands.

This article argues that zakat is both a religious and secular phenomenon. It is considered a religious phenomenon because a number of doctrines in Islam mention the obligation to pay alms. The Qur'an at least mentions 82 times which is often associated with the obligation to pray (Ali, 1988: 9 & Salim, 2015: 79). It is considered a secular phenomenon because in order to succeed these obligations require modern instruments that are worldly in nature. Thus the discussion of this article will look at the process of negotiation of these two phenomena in the local context in the Meranti Islands.

The BAZNAS in Muslim Communities in the Meranti Islands

Most Muslim communities in the Meranti Islands, as in other regions in Indonesia, work as traditional farmers. The basis of community income is natural resources. No wonder Indonesia is known as an agricultural country. This country has great potential from the agricultural sector. Supported by climate, soil fertility, forests, and water sources, the majority of Indonesia's population is dependent on its main profession as a farmer. In terms of revenue sources, the Meranti Islands have diverse natural resource potentials in the oil and gas and non-oil and gas sectors. The oil and gas sector comes from petroleum and natural gas, while the income from the non-oil sector comes from sago, rice, coffee, rubber, areca, and others. One of the districts in Meranti Island that has an abundant source of rice income is the West Rangsang District. Not surprisingly, the government of the Meranti Islands Regency set West Rangsang District as a rice granary

area. Statistical data shows that the area of rice plants in the West Rangsang District is 1872 hectares and produces 3.7 tons of dry grain per hectare.

BAZNAS of the Meranti Islands focuses the propagation of rice zakat in the West Rangsang District as the main program. West Rangsang Subdistrict is one of the sub-districts in the Meranti Islands Regency, consisting of 12 villages namely, Segomeng Village, Bantar Village, Anak Setatah Village, Lemang Village, Bokor Village, Sungai China Village, Melai Village, Telaga Baru Village, Bina Village, Sialang Pasung Village, Permai Village, and Mekar Baru Village. However, there are only six villages that have paddy fields, namely, Mekar Baru Village, Bina Maju Village, Segomeng Village, Melai Village, Anak Setatah Village, and Sungai Cina Village.

Because the large income of Meranti Island communities is from the paddy farming sector, BAZNAS Kepulauan Meranti then arranged a program related to efforts to spread understanding about the importance of paying rice zakat for Muslims. The efforts made by BAZNAS cannot be separated from the early history of the establishment of the Meranti Islands BAZNAS through the Decree of the Meranti Islands Regent No. 76 A in 2011 aimed at raising zakat funds for the economic development of the people.

The formal goal of the Meranti Islands Regency's BAZNAS is to achieve efficiency, effectiveness and accountability in the management of Zakat, Infaq and Alms (ZIS) funds. This is certainly related to efforts to increase the participation of Muslims in the Meranti Islands district in the context of full human development through ZIS fund management.

Before the Meranti Islands BAZNAS was established, the collection and management of Zakat funds was managed by the Amil Zakat Agency (BAZ) of Tebing Tinggi District, which at that time was led by HA Karim, Z, SH. Tebing Tinggi District BAZ is a unit of Bengkalis Regency BAZ which was formed before the division of the Meranti Islands Regency.

Juridically, the establishment of the National Amil Zakat Board in the Meranti Islands Regency refers to the Law of the Government of the Republic of Indonesia, namely; Law Number 38 of 1999 concerning Management of Zakat (State Gazette of the Republic of Indonesia of 1999 Number 164, Supplement to the State Gazette of the Republic of Indonesia Number 3885), Decree of the Minister of Religion of the Republic of Indonesia Number 373 of 2003 concerning Implementation of Law Number 38 of 1999 dated 18 July 2003, Decree of the Director General of Islamic Community Guidance and Hajj Affairs Number D / 291 of 2000 concerning Technical Guidelines for Management of Zakat, Regional Regulation of Riau Province Number 2 of 2009 Regarding Management of Zakat, Law Number 23 of 2011 concerning Management of Zakat, which was passed by the DPR RI on October 27, 2011 which was the result of an amendment to substitute Law Number 38 of 1999 because it was not in accordance with developments and legal needs in the community, the Decree of the Meranti Islands Regent Number: 76 of 2011 dated March 21, 2011 concerning the Establishment of the National Amil Zakat Board Management (BAZNAS) Kepulauan Meranti Regency, Decree of the Regent of the Meranti Islands District anti Number: 299 Year 2015 June 23, 2015 concerning the Appointment of the Implementation of the Management Task of the National Amil Zakat Board (BAZNAS) of the Kepulauan Meranti Regency, the Regional Regulation of the Kepulauan Meranti District No 05 of 2015 concerning zakat.

The various regulations related to zakat above indicate the management of zakat in Indonesia, especially in the Meranti Islands, which is not cohesive and solid. The various regulations also show the dimension of the attraction of permits that allows every social actor in related aspects to make a profit, and zakat is essentially not free from that aspect.

Socialization of Rice Alms

In modern terms, the socialization of rice zakat means efforts to spread or socialize the urgency of paying zakat from rice income for Muslim farmers. In an effort to maximize the collection of zakat, based on the Amil Zakat Agency Regulation No. 2 of 2016 concerning the Formation and Work

Procedures of Zakat Collecting Units, Zakat Collecting Unit was formed or abbreviated as UPZ in each district in the Meranti Islands Regency, including in the West Rangsang District.

The potential of rice zakat in the West Rangsang Subdistrict of the Meranti Islands is large enough to encourage the Meranti Islands BAZNAS to try to spread the understanding of rice farmers to pay zakat. The method adopted by BAZNAS, first, is to form an extension organization from BAZNAS in the form of UPZ at the District level in the Kepulauan Meranti Regency.

The distribution of authority through the formation of the UPZ is possible to facilitate the implementation and management of zakat as a manifestation of the modern management system. The manifestation of modern management is in line with that delivered by Sodikin UPZ Rangsang Barat's Secretary that "We (UPZ Rangsang Barat Management) always coordinate with the management of BAZNAS in the Meranti Islands Regency in carrying out the socialization of zakat, both the socialization of zakat in general and the socialization of rice zakat in particular" .

The religious approach model is also carried out by BAZNAS of the Meranti Islands Regency in socializing or preaching paddy alms. The lecture, for example, was carried out by BAZNAS to encourage the understanding of the Muslim community about zakat on the one hand while distributing BAZNAS institutional authority to preachers.

Based on interviews with Abdul Rauf, Chairman of UPZ Rangsang Barat, said :

> "The lecture method is one of the methods we use in this rice zakat socialization. Its nature is like a recitation or majelis taklim, the lecturer is myself and does not rule out the possibility of also lecturer from outside, like from the management of BAZNAS Kepulauan Meranti Regency. "

Sodikin, Secretary of UPZ Rangsang Barat said :

> "UPZ Rangsang Barat currently has indeed carried out the socialization of rice zakat through the lecture method, the lecturer himself is the chairperson of UPZ Barat Rangsang sub-district namely Ustaz Rauf, but it can also be lecturers from outside according to the UPZ management agreement, the important thing is that the lecturers understand this rice zakat material." .

Sunarto, Chair of BAZNAS of Meranti Islands Regency, said that: "UPZ Rangsang Barat in the implementation of rice zakat socialization has implemented this lecture method, the lecturer was directly delivered by Ustadz Rauf who is also the Chairperson of UPZ Rangsang Barat, he is very understanding about this rice zakat material ".

Using a religious approach model such as lecture is considered effective if it combines modern instruments and management. This is done for example through planning the timing of the implementation, where the socialization is and how the process in the lecture method is carried out. This is done in the hope that the objectives of the da'wah or socialization of zakat will run well. This was stated by Abdul Rauf, Chairperson of UPZ Rangsang Barat that: "This lecture method was effectively carried out in the fasting month during the Ramadan Safari activity, so we visited the mosques of every village that had paddy fields."

In addition to the momentum of the month of Ramadan, lectures are also held during the commemoration of Islamic religious holidays.

The model of utilizing certain religious activities is an implementation of modern management aimed at effectiveness and efficiency. This is because an approach like this does not require energy to gather people in one place. Furthermore, Abdul Rauf, Chairman of UPZ Rangsang Barat explained that:

> "We conducted this lecture method like majelis taklim or recitation in general, lecturers have about 30-40 minutes to deliver material during the month of Ramadan, the duration of time is not very long, because we also consider the condition of the community when the fasting month, of course already tired, during the day fast, and at night certainly need adequate rest. But if the socialization is during the celebration of the Islamic holidays only about 20 minutes, because it is only a distraction in the event ".

The term 'distraction' in the above statement is assumed to be like 'advertising'. It adopts ' *marketing* ' in modern management. The *marketing* product offered is the socialization of rice zakat which is packaged in such a way. The contents of preaching or outreach is also adjusted to the needs of rice farmers. Therefore, as stated by Abdul Rauf, Chairman of UPZ Rangsang Barat, "The material that we convey is in accordance with the needs of rice farmers, such as explaining the mandatory size of rice zakat, then when rice zakat is issued, how much rice zakat must be issued, as well as threats for people who do not want to pay zakat, the importance of zakat through UPZ and so on. ".

In terms of intensity, the lecture method like this is often done by UPZ Rangsang Barat in socializing this rice zakat, as stated by Sodikin, the secretary of UPZ Rangsang Barat that "The method that we always carry out in the socialization of rice zakat is the lecture method because this method is very easy to implement ".

Abdul Aziz Wahab (2012: 88) says that the lecture method is an easy method to do, in the sense that it does not require complicated preparation. Besides being uncomplicated, this method can be done in a short time with a large audience (Maryatin, 2014). Nevertheless, this method still has shortcomings as revealed by Wahab (2012) and Fathurrahman & Sutikno (2017).

In addition to lectures, BAZNAS of Meranti Islands through UPZ Rangsang Barat also uses the method or method of discussion in giving alms. The discussion method is done in the socialization of rice zakat, because this method supports rice farmers to understand about the implementation of this rice zakat. The use of this discussion method is related to the flexibility of this method in responding to things that may not be known by participants. In its implementation, Sodikin Secretary of UPZ Rangsang Barat explained that: "The discussion method is carried out based on mutual agreement between UPZ officials and rice farmers, usually carried out after the Asar Prayer at the nearest mosque, but also this discussion method is carried out when women are married every week, if in Segomeng Village, wirid Yasin ibuk-ibuk were held on Friday at 14.00. "

This method seems to be a modernization of the lecture method that has flaws. Sunarto Chair of BAZNAS Kepulauan Meranti Regency explained that:

> "This method is led by presenters who have extensive knowledge about rice zakat, because the discussion method requires presenters to be able to answer all questions from rice farmers. In this case, the method of discussion was led by Ustadz Rauf who is also the Chairperson of UPZ Rangsang Barat and did not rule out other religious teachers who have extensive knowledge about the implementation of rice zakat ".

However, the hybridity of the method is also possible according to the circumstances and conditions that allow the method needed. Abdul Rauf Chairperson of UPZ Rangsang Barat added:

> "Before this discussion method was held, we first gave a few lectures related to the material delivered in about 10 minutes, then continued with questions and answers, whereas if it was carried out when Yasin Ibn Ibuk-ibuk, the discussion method was carried out after reading Yasin together and the lecture submission by the cleric then continued the question and answer session ".

In addition to the lecture and discussion method, the *door to door* method is also used to increase the understanding of Muslim communities in paying rice zakat. Based on an interview with Abdul

Rauf, Chairperson of UPZ Rangsang Barat said, " We also carry out this *door- to-door* method in the socialization of rice zakat, if it is termed like picking up the ball, where we visit rice farmers who have paddy fields".

UPZ Rangsang Barat conducted this *door-to-door* method by visiting local community leaders. This method is deemed effective for some BAZNAS administrators because traditionally this approach model increases relations and social engagement of both parties. Face to face communication such as *door to door* above is used in order to get the effect of *behavior change* from the communicant. This is possible because in this communication model direct feedback will occur (Wardani : 2018). According to him, as quoted by Dedy Mulyana, by interacting and meeting face to face, the communicator can find out the response and response of the communicant to the message conveyed. Furthermore, by meeting in person, a communicator can build emotional connections with the communicant. This is useful to invite the sympathy and desire of the communicant to give alms (Effendy: 2017).

Integration of Modern Instruments

In this section, we will explain how the da'wah project never separates from the elements of modernity. Responding to the guidance of modernity, the socialization or propaganda of alms is carried out using modern media. Sunarto, Head of BAZNAS, Kepulauan Meranti Regency said,

> "In addition to conducting traditional socialization methods such as lectures and the like, BAZNAS Kepulauan Meranti Regency also utilizes electronic media such as radio. The radio that we are cooperating with in the socialization of zakat is the 88.4 FM Selat Panjang Vocational School radio ”

This is also in line with what was conveyed by Mustafa Deputy Chairman I of the Collection and Development of BAZNAS Kepulauan Meranti Regency, "BAZNAS Kepulauan Meranti Regency has long used the radio as a media for socializing zakat, which is in collaboration with 88.4 FM Selat Panjang Vocational School Radio".

The main reason for the use of radio as a means or medium for propagation of zakat as said by Muslims, Chairman of the Collection and Development Staff of BAZNAS, "The use of radio as a socialization of zakat in BAZNAS Kepulauan Meranti Regency in collaboration with 88.4 FM Selat Panjang Vocational School Radio, we select this radio because it has a very broad reach, up to 6 villages that have paddy fields ".

Zakat promotion through radio is considered to have advantages in aspects of the system, procedures, facilities, and procedures. It is not surprising if the Meranti Islands BAZNAS then collaborates with related radios. Sunarto, Chair of BAZNAS, Kepulauan Meranti Regency said, "The collaboration system conducted by BAZNAS Kepulauan Meranti District with 88.4 FM Selat Panjang Vocational School is in the form of lectures and questions and answers and the screening of public service announcements about zakat socialization ".

Muslim, Chair of the Collection and Development Division of BAZNAS, Kepulauan Meranti Regency explained that:

> "This lecture and question and answer session is held once a month, usually the first week of Thursday or on another day, according to the agreement with the speaker. The time for implementation is at 16.30-17.30 WIB. The 15 minutes are for lectures and the remaining 45 minutes are questions and answers with listeners via telephone, the theme of lectures changes each month, while for questions and answers may come out of a specified theme, while the public service advertisement contains an explanation of the BAZNAS program, types types of zakat, procedures for tithe and appeals to tithe to BAZNAS, Kepulauan Meranti Regency, this ad is about 1 minute in duration, and is rotated every day ".

The implementation of zakat socialization on this radio was also justified by one of the rice farmers in Anak Setatah Village, Abdul Hamid, who said, "We found out about the rice zakat ratio from advertisements on the Selat Panjang Vocational School radio, which explains that our rice income reaches 55 The TEAM is obliged to pay alms ".

For more details, the following is a table of rice zakat implementation through an interactive dialogue on the 88.4 FM Selat Panjang radio SMKArt:

Table 1: Socialization of Rice Zakat through SMKArt Radio

No	Date and time	Hour	The place	Theory	Presenters
1	Thursday / March 8, 2018	4:30	SMKArt radio studio	Implementation of rice zakat	Khozin, MA (Secretary of BAZNAS Meranti)
2	Friday / April 6, 2018	4:30	SMKArt radio studio	Pay zakat to BAZNAS	Sunarto, S.Ag (Chair of BAZNAS Meranti)
3	Wednesday / May 2, 2018	4:30	SMKArt radio studio	Alms for Prosperity of the People	Mustafa, S.Ag, MM (Deputy chairman of BAZNAS I Meranti)

The use of radio media in the propagation of rice alms enables the effectiveness of these activities. Some dakwah organizations, like IKMI (Indonesian Mosque Association) also uses radio as a medium to gain its objectives (Rosidi and Yusuf, 2018). This is because of this modern media, according to Samsul Munir Amin (2009: 270-271) as a communication medium, it has direct power, has a penetrating power, and has appeal. In addition, radio can provide information refreshment and public entertainment. This media is also easily accessible to the wider community because the price is relatively cheap and the easy way to use it (Ma'arif, 2010: 163).

Besides radio, BAZNAS Kepulauan Meranti also uses other modern media such as print media. Muslim, Chair of the Division of Collection and Development of BAZNAS, Kepulauan Meranti Regency explained,

> "We carry out the socialization of zakat through banners by installing banners in strategic places, such as at crossroads, mosques, and on paddy fields. This banner contains an explanation of Nisab, haul, and the level of rice alms and an appeal for alms to the BAZNAS of the Meranti Islands Regency. "

Banners and brochures are used as a medium for propagation of rice alms which allows each farmer to easily find information about rice alms. One of the rice farmers in Segomeng Village, Farida, said that: "Banners containing procedures for implementing rice zakat are installed in our village, usually at the crossroads and also in our paddy fields ." Brochures are distributed to farmers to read and understand. Sodikin, Secretary of UPZ Rangsang Barat added, "We increase the brochure and distribute it to rice farmers and place it in strategic places such as mosques, daily shops and rice mills."

Conclusion

After the New Order, zakat institutions flourished as a result of the widespread awareness of Muslim communities in the context of marginalization of the people in the arena or competition for economic resources. During this time, as stated by Hadiz (2018), the issue of marginalization of the ummah is so strong so that strengthening Islamic symbols in the public sphere (read: Islamic populism). However, the facts as found in this article, the issue of backwardness of the ummah is still not perfect in strengthening the awareness of Muslim communities in paying paddy zakat. This can be seen from how BAZNAS efforts to integrate management and modern instruments in socializing rice zakat in the Muslim community. Constrained by the lack of modern management, BAZNAS as a charity institution continues to strengthen and encourage the awareness of the zakat Muslim community as a symbol of piety. This article also shows that semi-modern zakat institutions, such as the Meranti Islands BAZNAS carry out complex and complicated negotiations related to religious awareness and the problem of modernity. These institutions as in other regions in Indonesia often face technological stuttering and modern management amid a strong spirit of religiosity.

The findings of this article show how to spread the understanding of the obligation of zakat as a never-ending project because the values of religiosity often require modern instruments. The empty space needed by these religious institutions is to strengthen modern instruments and the implementation of modern management in these institutions. The problem is thus not to increase their established religious understanding through religious lectures or other religious activities.

In this article it was found that BAZNAS of the Meranti Islands integrated modern methods in the propagation of rice alms activities. This can be seen from the methods they use through discussion methods, the use of radio media, as well as the use of print media such as brochures and banners. The success of this method depends on the extent of their success in using modern management and instruments in the future, not their success in raising awareness of their religiosity.

Abstract

The urgency of the research stems from studying the processes taking place in cross-border regions of the Russian Federation and ever-increasing impact of their neighbourhood with near and far abroad countries. Studies in the field of structural changes in economic sectors of Russian cross-border territories are assuming particular importance due to increasing geopolitical influence and economic cooperation. Thus, the paper considers the peculiarities of structural changes taking place in sectoral structure of cross-border territories economy during 10 years. The purpose of the study is the assessment of tendencies connected with changing the sectoral production structure of border territories of the Russian Federation from 2006 to 2016. The study was based on the following methodology: 1) defining the production specialization of 50 cross-border subjects of the Russian Federation by means of calculating the coefficient of production specialization and the criteria of mono-specialization and poly-specialization of these regions; 2) analysing the changes in the sectoral production structure of cross-border regions with the help of the system for indicators of sectoral and cross-sectoral shifts; 3) defining the tendencies of changing sectoral production structure in cross-border territories of the Russian Federation. The study revealed the following results: a) the structure of cross-border regions according to their specialization (mono-specialization, poly-specialization); b) sectors of production specialization which are in the focus of mono-specialized regions' production (agriculture, hunting and forestry as well as mining operations); c) more dynamic sectoral structure of mono-specialized regions targeted at mining operations; d) more intensive period of structural changes in relation to mono-specialized regions (2006–2011); e) a complex of structural policy measures should be aimed at the diversification of sectoral structure of border regions.

Keywords: Cross-Border Regions, Sectoral Production Structure, Structural Shifts.

Introduction

In current circumstances cross-border regions of the Russian Federation have a particularly important role in providing sustainable social and economic growth and national security of the country. It can be demonstrated by the fact that according to the end of 2016 border regions occupied 86.0% of the total territory of the Russian Federation, with 52.1% of the country's population and more than 51.3% of the total gross domestic product of the Russian Federation (Source: Calculated by the authors on the basis of official data of the FSSS *(Gks.ru, 2018)*.

Obviously, the past 25 years have seen significant changes in the sectoral production structure of Russian border territories with the collapse of the USSR, the building of a market economy as well as due to the changes in the new geopolitical and economic interaction.

Thus, the purpose of the study is to assess the tendencies of changing sectoral production structure of the RF cross-border territories during 2006–2016. To this end, the following objectives have to be carried out:

- to study the theoretical grounds for sectoral production structure in cross-border regions;
- to propose the methodology of sectoral production structure analysis;
- to assess modern tendencies of changing sectoral structure of mono-specialized cross-border territories of the Russian Federation.

Theoretical grounds for studying the sectoral structure of Russian cross-border territories

The peculiarities of developing structural changes in economics were first studied by J. B. Clark (1891), who proposed a theory of structural changes in his research on economic dynamics. Later, the basics of structural changes were analysed by V. V. Leontief in 1941 (Leontief, V., 1941, 1953) by means of applying an input-output model. The dynamics of structural shifts in economics was also studied by J. M. Esteban-Marquillas (1972), P. Krugman (1991), V. J. Matlaba, M. Holmes, P. McCann, J. Poot (2014) and others.

The peculiarities of structural changes in regional development were analysed by C. Clark (1940), B. Hansen (2001), Sh. Fan, X. Zhang, Sh. Robinson (2003), A. Urraca-Ruiz, N. E. Laguna-Molina (2016), O.P. Ivanova (2018), E. Cutrini (2019) and others.

The structural changes theory was also proposed by Soviet scholars L. V. Kantorovich (1960) and V. S. Nemchinov (1960) who used quantitative analysis methods while solving planned economy issues in order to better use the resources in the national economy with simultaneous complication of internal economic links in the Russian Federation.

Russian economists of the Soviet period made a special contribution to the development of the theory of cross-sectoral structural shifts. Among them we should mention O. Yu. Krasilnikov (2017) who revealed the theoretical grounds of interconnection and development of structural shifts in the economy of modern Russia. V. Danilov-Danilian (2015) assessed the effect of macro-economic tendencies on structural shifts in Russian economy. Transformational structural changes in Russian industrial production were studied by V. A. Bessonov (2000), O. V. Daneev (2004), V. S. Antonyuk, E. R. Vansovich (2012), A. N. Lyakin (2013), O. S. Sukharev (2014), V. S. Bilchak (2014), V.A. Kolosov, A.P. Klemeshev, M.V. Zotova, A.B. Sebentsov (2015), L.A. Strizhkova, G.O. Kuranov, G.YU. Kuznetsova, A.A. Blokhin (2019), O. A. Romanova, A. O. Ponomareva (2019), S. Yu. Glaziev (2019) and others.

The problems of assessing cross-border specialization of cross-regional interactions of border territories were the subject of studies performed by N. M. Mezhevich, N. P. Zhuk (2013).

According to the Federal Law "On the basics of cross-border cooperation" dated July, 26, 2017, No 179-FZ *(On the basics of cross-border cooperation, 2017)*, Russian cross-border territories are defined as "the subjects of the Russian Federation whose territories are adjacent to the State border of the Russian Federation".

Production specialization of a cross-border territory is understood as orientation of its production site towards the creation of certain products which meets the needs of the region as well as other subjects of the country and foreign partners and has a considerable share in the output of this territory. As this definition illustrates, the orientation towards the production of a product exported in foreign countries is a peculiarity of production specialization of a cross-border region. Production specialization of a region is defined on the basis of analysing its sectoral structure of production (GRP) which presents a set of proportions between different types of economic activities using various indicators.

We should also mention a system of factors defining the sectoral structure of the region's production: its geographical position, natural and climatic conditions, resource endowment, the level of development and access to technologies, economic and social factors. The channels which have a strong impact on the sectoral structure of a region's production also include the following: a banking system, law and regulation system as well as an international system. International cooperation of these territories with other countries, export-import operations are of particular relevance to cross-border regions.

In the course of time the factors determining the sectoral structure of a region can be transformed which can lead to shifts in the role of certain sectors or types of economic activities, that is to sectoral structural changes and later, it can lead to the changes in a production specialization of this territory. These changes are called sectoral structural shifts.

Methodology of sectoral structure analysis of production in cross-border territories

The sectoral structure analysis of production in territories adjacent to the border is carried out according to the following algorithm.

At the first stage we identify the production specialization of cross-border regions of the Russian Federation. After calculating the coefficient of production specialization and criteria of regional mono-specialization and poly-specialization *(Antonyuk and Vansovich, 2013)* cross-border territories of Russia will be divided into mono-specialized and poly-specialized ones.

$$K_l = \frac{O_p / P_p \times 100}{O_c / P_c \times 100}, \quad (1)$$

where Op is the output of the given sector in the region in terms of gross amounts;
Oc is the output of the same sector in the country on the whole in terms of gross amounts;
Pp – the whole output in the given region in terms of gross amounts;
Pc – the whole output in the country in terms of gross amounts.

At the second stage we analyse the changes in sectoral structure of production in cross-border regions of the Russian Federation using the system of indicators of sectoral proper and cross-sectoral shifts (Fig. 1). The sectoral structural shifts proper are presented by the following indicators: "absolute increase", growth rate and progression rates of the sector. The cross-sectoral structural shifts are presented by linear and quadratic coefficients of "absolute" structural shifts, linear and quadratic coefficients of relative structural shifts.

Indicators of sectoral structural shifts

Sectoral proper	Cross-sectoral	
1. "Absolute" increase in the sector's share 2. Growth rate of the sector's share 3. Rate of increase in the sector's share	1. Linear coefficient of "absolute" structural shifts	$\delta_{F_2-F_1} = \frac{\sum_{i=1}^{n}\lvert F_{i2} - F_{i1}\rvert}{n}$
	2. Quadratic coefficient of "absolute" structural shifts	$\sigma_{F_2-F_1} = \sqrt{\frac{\sum_{i=1}^{n}(F_{i2} - F_{i1})^2}{n}}$
	3. Linear coefficient of relative structural shifts	$\bar{\delta}_{\frac{F_2}{F_1}} = \sum_{i=1}^{n}\left\lvert\frac{F_{i2}}{F_{i1}} - 1\right\rvert F_{i1}$
	4. Quadratic coefficient of relative structural shifts	$\sigma_{\frac{F_2}{F_1}} = \sqrt{\sum_{i=1}^{n}\frac{(F_{i2} - F_{i1})^2}{F_{i1}} \cdot 100}$

Fig 1: Indicators of sectoral structural shifts
(Source: Kazinets, 1981)

where F_{i1} and F_{i2} are specific values of Sector i in the first and second period of time.

At the third stage it is appropriate to present the tendencies of changes in the sectoral production structure in cross-border territories of the Russian Federation.

Results of the study

Among 48 cross-border regions we identified mono-specialized (16) and poly-specialized (23) regions (2016) based on the calculation of localization coefficient and application of mono- and poly-specialization criteria (Fig 2). The rest 9 regions are those subjects of the Russian Federation which are not characterized by production specialization.

The majority of mono-specialized regions are oriented at agriculture, hunting, forestry and mining industry. Over half of the poly-specialized regions are oriented at agriculture, hunting, forestry as well as transportation and communication (14 regions amount to 61% of all the regions); nearly half of the regions – at processing and manufacturing, wholesale and retail trade (11 regions – 49%); less than half of the regions (9 regions – 39%) – at building and construction; and nearly a quarter of the regions (5 regions – 22%) – at mining industry.

Fig. 2: Distribution of regions according to their production specialization
(Source: compiled by the authors)

In all the cross-border regions the most important, in our opinion, is the analysis of changes in the sectoral production structure concerning border territories of a mono-specialized type, since they are more at risk due to their narrow specialization in case of global market shocks. For that reason Table 1 presents the indicators of sectoral proper and cross-sectoral structural shifts in mono-specialized regions in the short-term (2006–2011, 2011–2016) and long-term periods (2006–2016).

Table 1: indicators of sectoral proper and cross-sectoral structural shifts in mono-specialized regions

No	Regions	"Absolute" increase			Rate of increase, %		
		2011/ 2006	2016/ 2011	2016/ 2006	2011/2006	2016/2011	2016/2006
		Agriculture, hunting and forestry					
1	Kursk Oblast	-0.30	5.00	4.70	-2.19	37.31	34.31
2	Karachay-Cherkess Republic	-1.00	2.00	1.00	-4.29	8.97	4.29

(Source: Calculated by the authors on the basis of official data of the FSSS (Gks.ru, 2018)

According to Table 1, the dynamics of structural changes in sectors of production specialization is sufficiently high which is characteristic for the regions specializing in mining. The top regions according to the positive indicators of both "absolute" increase and rate of increase are Sakhalin Oblast, Chukotka Autonomous Okrug (2006–2011) and Magadan Oblast (2011–2016). On the other hand, Krasnoyarsk Krai during 2006–2016 shows a downward trend.

The most illustrative among all indicators of cross-sectoral structural shifts, in our opinion, is a linear coefficient of "absolute" structural shifts which characterizes the mean value of the variation of sectors' weight as well as a quadratic coefficient of relative structural shifts characterizing the intensity of changes in the sectoral structure of the region on the whole.

Table 2 and Figure 3 present some analysis of indicators of cross-sectoral structural shifts in mono-specialized regions.

Table 2: indicators of cross-sectoral structural shifts in mono-specialized regions

Number of region	Linear coefficient of "absolute" structural shifts			Quadratic coefficient of relative structural shifts		
	2011/2006	2016/2011	2016/2006	2011/2006	2016/2011	2016/2006
	Agriculture, hunting and forestry					
1	1.08	1.76	2.53	22.66	29.99	42.36
2	1.05	0.99	1.35	21.61	19.10	27.64
3	1.60	**2.47**	2.40	30.43	**91.56**	54.99
4	0.71	1.04	1.43	20.38	19.41	30.49
5	1.41	1.76	1.69	35.09	41.86	32.21
	Fishery and fish-farming					
6	1.17	1.15	1.25	23.91	26.46	32.52
	Processing and manufacturing					
7	0.75	0.47	1.07	13.73	12.67	22.63
8	2.53	0.75	3.00	73.22	12.90	86.09

	Mining industry					
10	1.45	0.69	1.81	27.10	13.61	32.81
11	1.15	0.72	1.43	19.15	14.71	29.09
12	1.61	0.72	1.56	47.45	16.15	35.30
13	1.44	1.21	2.07	27.07	19.88	35.13
14	1.36	2.11	3.20	28.96	36.21	55.30
15	**4.71**	1.37	4.48	83.33	33.86	75.95
16	4.61	1.33	**5.69**	**130.66**	24.79	**162.40**

(Source: Calculated by the authors on the basis of official data of the FSSS (Gks.ru, 2018)

According to Table 2 the greatest changes in the sectoral structure are observed in two regions – Chukotka Autonomous Okrug and Sakhalin Oblast, whose specialization is directed at mining industry. Besides, the most significant changes characterize both the sector of production specialization and the time period 2006–2011. During the period under review (2006–2016) the proportion of mining operations in Chukotka Autonomous Okrug increased almost 7 times (from 7.5% in 2006 to 50.1% in 2016). Moreover, there have been significant changes in other sectors – production and distribution of gas, electric energy and water, building and construction, transport and communication, real estate operations, renting and provision of services, public administration – since their shares decreased approximately two times.

The share of mining industry in Sakhalin Oblast increased more than two times during 2006–2016 (from 25.4% in 2006 to 60.6% in 2011 and 54% in 2016). Significant changes have also taken place in building and construction (31.5% in 2006, 6.3% in 2016).

The share of the main sector of production specialization in the sectoral structure of Krasnoyarsk Krai – processing and manufacturing – have dropped since the "absolute" rate of increase was (– 20.6%) (52.4% in 2006, 31.8% in 2016), but at the same time the share of mining industry increased 5 times (from 3.7 % in 2006 to 19% in 2016). Thus, we can observe here a tendency towards the change of the region's production specialization.

a) Linear coefficient of "absolute" structural shifts 2011/2006

d) Quadratic coefficient of relative structural shifts 2011/2006

b) Linear coefficient of "absolute" structural shifts 2016/2011

e) Quadratic coefficient of relative structural shifts 2016/2011

c) Linear coefficient of "absolute" structural shifts 2016/2006

f) Quadratic coefficient of relative structural shifts 2016/2006

Fig. 3: Indicators of cross-sectoral structural shifts in mono-specialized regions
(Source: compiled by the authors)

The mean values of the quadratic coefficient of relative structural shifts were 38.89% and 26.75% during 2006–2011 and 2011-2016 respectively. Meanwhile, the most significant value of the quadratic coefficient of relative structural shifts during 2011–2016 characterizes the Republic of Kalmykia which specializes in agriculture, hunting and forestry.

The mean values of the linear coefficient of "absolute" structural shifts among all the mono-specialized regions were 1.71% and 1.20% during 2006–2011 and 2011–2016 respectively.

Thus, the most intensive changes of the sectoral structure in mono-specialized regions were observed during 2006–2011, which can be connected with significant changes in the sectoral production structure due to the world financial crisis in 2008 and adaptation of regional economies to the new conditions.

In the long-term period (2006–2016) the mean values of the linear coefficient of the "absolute" structural shifts and the quadratic coefficient of relative structural shifts were 2.24% and 48.44% respectively.

Conclusion

The analysis leads to the following conclusions.

1. The absolute majority of all cross-border regions of the Russian Federation (80%) have a distinct specialization: they are either mono-specialized or poly-specialized. Mono-specialized regions are

more at risk since their functioning and development is limited by one sector of specialization which results, in its turn, in their strong dependence from external and internal markets.

2. Most mono-specialized regions are oriented at such types of economic activities as agriculture, hunting and forestry as well as mining industry.

3. The most intensive dynamics of structural changes in mono-specialized regions is observed in the sectors of production specialization especially in those oriented at mining operations.

4. The most intensive period of structural changes in mono-specialized regions was during 2006–2011, which can be proved by quadratic coefficients of relative structural shifts.

Thus, during 10-year period taken for our analysis the sectoral structure of cross-border regions suffered significant changes, especially in mono-specialized regions. The main tendencies here included an increase in the share of mining operations and a decrease in the share of processing and manufacturing in the sectoral structure of the gross regional product, which means an increase in commodity-based economy of cross-border subjects of the Russian Federation. All this indicates that there is a strong need to develop a complex of structural policy measures directed at the diversification of the sectoral structure in cross-border regions, which would provide economy's movement from a mono-specialized to a poly-specialized type.

Possibility to Apply Selected Decision-Making Models in Designing and Implementing Cost Strategy in an Insurance Company

Magdalena CHMIELOWIEC-LEWCZUK

Wroclaw University of Economics and Business, Wroclaw, Poland,
magdalena.chmielowiec-lewczuk@ue.wroc.pl

Abstract

The purpose of this paper is to analyse the possibility of applying selected decision-making models in the design and implementation of a cost strategy in an insurance company undertaking subject to the achievement of financial management objectives. In the area related to decision analysis two groups of decision-making models have developed. These are the groups that include prescriptive (normative) models, and descriptive models. The presented models are analysed in the context of the possibility of their application by insurance companies when implementing the cost strategy. This analysis is carried out using the deduction method. As a result, seven areas were identified which are related to factors determining the selection and design of cost strategy in an insurance company. In addition, the paper is supplemented by the presentation and description of the organizational and behavioural aspect of the implementation of a cost strategy in an insurance company.

Keywords: Insurance Company, Cost Strategy, Financial Management, Decision-Making Models

Introduction

Insurance companies belong to this group of financial institutions which offer their clients financial products. These institutions operate on a robustly developing market. Accordingly, all the operations regarding their management require constant modifications and adjustment to the current market needs. One such activity is designing a cost strategy. Designing a cost strategy as an element of financial management in an insurance company includes planning activities related to the implementation of the strategy, the implementation of which is to guarantee the achievement of the set objectives.

The purpose of this paper is to analyse the possibility of applying selected decision-making models in the design and implementation of a cost strategy in an insurance company undertaking subject to the achievement of financial management objectives [more: Chmielowiec-Lewczuk, 2019]. In addition, the paper is supplemented by the presentation and description of the organizational and behavioural aspect of the implementation of a cost strategy in an insurance company. These aspects are extremely important in practice.

Literature Review

The design of a cost strategy is a decision-making-based activity, therefore the assumptions of the decision-making analysis should be taken into account. In the book by Goodwin and Wright (2016, p. 19), primary objective of the decision-making analysis is to spread the decision-making problem into a set of smaller problems. As a result of the development of decision-making theory there has been a change in the perception of the role of decision analysis.

Currently, it is believed that decision analysis is not a method of obtaining optimal solutions to decision-making problems, but that its aim is to gain knowledge and stimulate the creativity of managers. Such a view is represented by, among others, R.L. Keeney and L.D. Phillips in the book by Goodwin, Wright (2016, p. 21-23). In the contemporary application of decision analysis, attention is drawn to the fact that the decision making of a manager is conditioned by two factors. These are: a rational factor related to the fact that the decision maker takes into account the results obtained through

the analysis, and an intuitive factor related to his feelings - the decisions are influenced by behavioural aspects.

The issues related to modelling cost strategy in an insurance company are little known and rare in the world literature. On the other hand, one can find publications presenting issues related to the development of strategies in insurance companies, or topics related to cost management problems.

In 2005 an article was published in which the effects of work on the project of the team consisting of twelve people led by R. Massey were presented. The subject of this project was to develop the application of theoretical strategy models for non-life insurance companies. Seven strategy models were used for this purpose, such as: competitive advantage, Porter's five strengths, value chain, PESTL, SWOT, product life cycle and the Blue Ocean theory and innovation value. The application of these strategy models was analysed in two hypothetical insurance companies (one of medium size, which operates only in the UK, and the other, larger, which has international coverage).

An interesting publication on this issue has also appeared in 2014. Its author, S. McGregor, presented the process of implementation of modification of the existing cost accounting system used by the life insurance company AXE in the United States. It describes the analysis of problems connected with costs, managers' opinions, actuaries' expectations and organizational solutions, as well as presents the whole process of changes in the scope of cost management.

There is one more article among the publications related to the subject matter discussed. It was published in 2010 and its authors are P. Francis and S. Butler. They focus in their study on the reduction of costs related to compensation and benefits of insurance companies. They point to a very important role of this cost item, which in their opinion is crucial in the management of costs of an insurance company. The authors propose the use of one of the four models of claims and benefits management as a solution giving the possibility to control activities in this area and the use of a matrix based on the segmentation of claims and benefits, which allows for the reduction of costs in an insurance company.

Methodology

In the area related to decision analysis two groups of decision-making models have developed. These are the groups that include:

- prescriptive (normative) models,
- descriptive models.

The first group is represented by models which are applicable to structured decision-making problems and which primarily use analytical methods using mathematical methods, from the area of operational research. This group includes such models as: Altman, Valenzi and Hodgetts' monocriteria model, Robbins and Coulter's multi-criteria model, Sutherland's model, Holt's model, praxeological model, operational research model, cybernetic model and fuzzy decision-making rules model. These models are based on the assumption that following the adopted algorithm gives the possibility to obtain an unambiguous solution to the decision problem, and they also assume the possibility of fully quantifying all decision options.

The second group consists of descriptive models, which are descriptive in nature. They are based on the fact that in the practice of business entities, decisions are not only made as a result of rational analysis but are also shaped by human behaviour. Therefore, Teale et al (2003, p. 17) mentioned that during solving decision-making problems, psychological and sociological factors should be additionally taken into account. In the book by Holska (2016, p. 240) is written that descriptive models are of different nature, some of them are similar to normative models, and some propose a completely different approach, completely different from prescriptive models.

Descriptive models include Simon's suboptimization model, in which he proposes to assume that decision making is shaped by limited rationality (managers have limited knowledge, want to achieve

different goals, often at the same time or are satisfied with the first good solution). This model does not, admittedly, assume fully irrational human behaviour when making decisions, but it does change the view on the possibility of applying normative models in practice.

Among the descriptive models, there are also those that propose a complete abandonment of rational analysis of decision-making problems, e.g. the "trashcan" model or Brunsson's irrational model. These models aim at directing the decision-making process towards generating creativity among managers and assume that human behavioural factors such as lack of motivation, doubt or unwillingness to engage should be taken into account in the process.

The presented models will be further analysed in the context of the possibility of their application by insurance companies when implementing the cost strategy. This analysis will be carried out using the deduction method.

Cost Strategies Possible to Implement in Insurance Company

If an insurance company makes a decision to implement a cost management strategy, it should work it out on the basis of one of the adopted cost strategies. The choice of a strategy enables a precise definition what is objective achievement index of cost management whether a defined cost level, profitability or some other parameter whose achievement should guarantee achievement of the aims set by the insurer.

Table 1 presents the objectives of financial management in the insurance company, the cost strategies assigned to them which may support the achievement of those objectives, as well as the most important areas which are related to them. These areas determine the limits of the analysis to assess the current conditions and capabilities of insurance companies.

Table 1: Financial management objectives, cost strategies to support their implementation and the most important areas subject to analysis of current conditions and possibilities in an insurance company

No.	Financial management objective	Cost strategy	Areas to analysis
1	Profit maximization, Realization of a definite profit level	Strategy subordinated to cost reduction	Financial condition Human Resources Organisation
2	Sales maximization, Market share increase	Strategy subordinated to profitability Strategy subordinated to price policy	Insurance risk portfolio Financial condition Human Resources Organisation
3	Financial Stabilization	Strategy subordinated to price policy Strategy subordinated to financial liquidity	Insurance risk portfolio Human Resources Relationships with others
4	Efficiency of action	Strategy subordinated to cost reduction Strategy subordinated to profitability Strategy subordinated to capital cost minimization Strategy subordinated to value creation of the insurance company	Insurance risk portfolio Financial condition Reinsurance
5	Financial liquidity maintenance	Strategy subordinated to financial liquidity Strategy subordinated to insurance risk	Investments Insurance risk portfolio

6	Solvency maintenance	Strategy subordinated to insurance risk Strategy subordinated to cost reduction Strategy subordinated to price policy Strategy subordinated to financial liquidity	Insurance risk portfolio Financial condition Reinsurance Investments Human Resources Organisation
7	Value maximization	Strategy subordinated value creation of the insurance company Strategy subordinated to capital cost minimization	Financial condition Relationships with others

source: own study

Cost management process in the insurance company can be designed in various ways in accordance with the chief objective the process is to serve. Here are three most common situations:

1. cost management is subordinated to finance management,
2. cost management is correlated with implementation of kaizen (continuous improvement process) based on activity management,
3. cost management is part of value-based management process.

This paper is based on the first concept when cost management is subordinated to financial management in an insurance company. In cost management concept based on finance management indicated areas refer to typical notions, which are important for the financial economy of the insurer.

Results

The problem of designing a cost strategy in an insurance company as well as its implementation is complex. It is influenced by various factors. Therefore, let us consider whether prescriptive or descriptive models should be used when making decisions concerning the design and implementation of a cost strategy that is to support the financial management of an insurance company. To this purpose we will analyse the areas that are related to the factors presented in Table 2 that influence the cost decisions of an insurance company.

Table 2: Factors influencing cost decisions of an insurance company, cost strategies in which they are most important, and determinants of the modern insurance market related to these factors

Group of factors	Factors	Cost strategy	Determinants of the modern insurance market
Financial factors	Financial result (profit/loss) and profitability	Strategy subordinated to cost reduction Strategy subordinated to profitability	Independent factor
	Revenue	Strategy subordinated to profitability Strategy subordinated to price policy	New insurance risks
	Costs	Strategy subordinated to cost reduction Strategy subordinated to profitability	All determinants
	Capitals	Strategy subordinated to capital cost minimization	New systems of insurance supervision, financial groups

	Investments	Strategy subordinated to financial liquidity	Financial markets and financial instruments
	Reinsurance	Strategy subordinated to profitability	Independent factor
Non-financial factors	Market position	Strategy subordinated to cost reduction Strategy subordinated to price policy	Financial groups
	Sales policy	Strategy subordinated to price policy	New insurance risks
	Distribution policy	Strategy subordinated to cost reduction,	New distribution channels
	Insurance portfolio policy	Strategy subordinated to insurance risk	New insurance risks
	Loss adjustment policy	Strategy subordinated to cost reduction	Services of indemnity chancellery
	Territorial network	Strategy subordinated to cost reduction	Independent factor
	Relationships in the financial group	Strategy subordinated to value creation of the insurance company Strategy subordinated to capital cost minimization Strategy subordinated to insurance risk	Financial groups
	Human resources	All strategies	Independent factor

source: own study

On the basis of the factors presented in Table 2, seven areas can be identified for which we will consider the application of individual decision-making models.

The first area concerns the objectives to be pursued by the application of the cost strategy in the insurance company. These are objectives that are quantified. They relate to financial figures and are fully measurable. Their achievement is assessed by clearly verifying whether a given financial volume has been achieved or not (level of costs, profitability, level of income, insurance risk, insurance price, etc.). The financial nature of the objectives related to the cost strategy, especially when it is subordinate to financial management, indicates that normative models seem to be the best solution when making decisions.

The second area relating to the factors that shape an insurance company's cost decisions is that of the actions and activities that need to be carried out in order to achieve the intended strategy objectives. These activities and actions in practice mean changes in the reorganisation or reduction of human resources. Therefore, in order to achieve financial, clearly measurable objectives, it is necessary to plan and implement activities that are related to people. This means that in practice this can prove difficult and requires taking into account human behaviour (their reaction to change, acceptance, commitment, etc.), which affects both managers and employees of different departments. The impact of the human factor on the achievement of objectives related to the implementation of the cost strategy indicates the validity of using descriptive models in the insurance company.

Another of the analysed areas is insurance risk, and in particular its impact on costs. The amount of insurance risk is measurable, but not fully. First of all, it is not always possible to clearly determine the probability of loss occurrence (e.g. in relation to new risks). Secondly, the probability of occurrence of a given loss is also influenced by human behaviour (of the insured, current and potential customers). Therefore, the assumptions made about the planned costs of compensation and benefits may turn out

to be partly wrong. The level of the insured risk determines most of the financial objectives and conditions to be met by the insurance company, and therefore this level is very important in the implementation of the cost strategy. The nature of the area related to insurance risk indicates the use of both prescriptive and descriptive methods in the analysis of insurance company costs.

Another area is related to the product, which is insurance. Insurance risk is also important in its construction. However, this product, its sale (form, amount of premium) or acquisition costs are also influenced by the human factor, resulting from the expectations of customers of the insurance company and their inclination to purchase insurance. The specificity of the product, which is insurance, makes the application of solutions tested in other entities conducting e.g. production activity impossible. This is indicated by H.C. Kunreuther, M.V., Paulty, S. McMorrow [2013, p. 146], who believe that normative models do not work in an insurance company due to the nature of the product. Therefore, the area of the insurance product indicates the use of descriptive models in an insurance company.

The next area discussed is that of differences relating to the legal form of an insurance company and the sector in which it operates. While insurance companies operating in the form of joint stock companies can be treated as entities whose general objective is to achieve good financial results, this is not the case for mutual companies. As these entities operate on different principles, the choice and development of a cost strategy for them must be subject to different, modified objectives. Mutual companies operate on the basis of self-insurance. For this reason, social aspects, which are not always fully measurable and not always capable of improving financial results, are more important for them. Therefore, in those entities, descriptive models are more applicable than in insurance companies operating as joint stock companies.

Differences also apply to the insurance sector offered by the insurance company. The sellers of life insurance are more dependent on human factors and their claims valuation is more ambiguous and subjective than that of non-life insurance. Therefore, the descriptive models are more applicable to life insurance sector than to non-life insurance sector, where the use of prescriptive models is more justified.

Another area determining the possibility of using decision making models is the area related to investors. Behaviour, reactions and decisions of investors influence the results of investment activity and the cost of capital of an insurance company. Behavioural finances, whose problems include the issue of investment decisions in financial markets, highlight the role of the human factor and the influence of human behaviour on the economic situation in financial markets. As the relationship of an insurance company with financial markets is very close and its performance depends in part on the situation in financial markets, it is justified to take into account the impact of the human factor on the achievement of the objectives set for the cost strategy. However, an approach based on the rationalisation of investment decisions cannot be completely disregarded, and therefore this area indicates the use of both prescriptive and descriptive models.

The last area that is relevant for the choice of models to be used in an insurance company's cost decision-making is the relationship within the financial group. The problem of these relations is very important for designing cost strategy in an insurance company. The links between the different entities that are relevant for cost decision-making also determine the nature of the models that can be used in an insurance company. Relationships in a financial group affect the setting of objectives, in particular strategic objectives, and may also give rise to disparities between objectives in different entities. Therefore, the existence of financial groups should be regarded as a factor which makes it difficult to apply prescriptive models in an insurance company. It therefore seems more appropriate to use descriptive models in this case.

Table 3 summarises the possibility of using cost decision-making models in insurance companies in relation to the areas that relate to them.

Table 3: Application of models of decision making according to the area that shapes decisions on insurance company costs

No.	Area	Models
1	Defining and achievement of objectives of the cost strategy	Prescriptive model
2	Operations and activities related to implementation of the cost strategy	Descriptive model
3	Insurance risk	Prescriptive model Descriptive model
4	Insurance products	Descriptive model
5	Legal form of the insurance company and insurance sector in which it operates	Prescriptive model – insurance company in the form of a joint-stock company, nonlife insurance sector Descriptive model – mutual insurance company, life insurance sector
6	Investors	Prescriptive model Descriptive model
7	Relationships in the financial group	Prescriptive model Descriptive model

source: own study.

Having analysed the impact of factors in the various areas that are related to an insurance company's cost decisions, it can be concluded that there is no clear solution as to the type of model that should be used in the design and implementation of a cost strategy under the financial management of the insurance company. In that situation, a normative-descriptive model or a descriptive model that assumes a partial rationality of the decision-makers' behaviour should be used.

The organisational aspect of implementing cost strategies in an insurance company

After selecting the cost strategy in the insurance company and designing it according to the adopted decision-making model, it is necessary to proceed to its implementation. The performance of this activity should be analysed taking into account two aspects: organizational and behavioural.

The organizational aspect of cost strategy implementation, which is an element supporting financial management in an insurance company, is connected with the following problems:

- appointment of a person or persons responsible for the cost strategy,
- to define the responsibilities of these persons,
- the qualifications and desired characteristics that these persons should possess,
- indicating the area covered by the implementation of the cost strategy,
- identification of persons involved in activities related to the implementation of the cost strategy.

In designating the person or persons to be responsible for the cost strategy, attention should be paid to the distinction between activities related to the selection and design and implementation of the cost strategy, as well as to the nature of the cost strategy, which, as part of financial management, requires that close cooperation between the persons responsible for it and the persons who take decisions in the area of the financial management of the insurance company be included.

Deciding on the choice of the cost strategy to be subordinate to the achievement of the financial management objectives is an activity which should involve both the decision-makers of the financial management of the insurance company (primarily the CFO) and the person who is directly responsible for the cost strategy. The decision to choose a cost strategy, which would be taken without cooperation

between those persons, may result in a lack of coordination between the objectives of the cost strategy and the financial management.

On the other hand, when designing and implementing a cost strategy, the scope of cooperation between these persons is smaller. At this stage, the task of the person responsible for the cost strategy will be to plan activities resulting from the adopted assumptions in the strategy, as well as to monitor and supervise their implementation. While designing and implementing the cost strategy, the cooperation of the person responsible for it with other managers should also be taken into account (depending on the type of strategy that has been chosen, these may be persons making decisions in the area of sales, investment activity, reinsurance, etc.).

The responsibilities and tasks of the person who has been appointed to carry out the activities related to the cost strategy should include:

- cooperation with the CFO in selecting the cost strategy,
- planning activities related to the implementation of the cost strategy using the selected decision-making model,
- to define the scope of these actions and the areas in which the strategy will be implemented,
- monitoring progress in the implementation of the strategy and supervising the effects of its implementation (drawing up reports and statements showing the degree of achievement of the financial objectives set).

The person who is responsible for the cost strategy in the insurance company should have certain qualifications and characteristics which will allow him/her to carry out the activities assigned to him/her efficiently and properly. Such a person should in particular:

- be familiar with the financial reporting rules of insurance companies,
- have knowledge of financial management,
- know the specificity of activities of insurance companies and financial institutions,
- have the ability to think analytically and make decisions.

The range of activities carried out by the person responsible for cost strategy in an insurance company includes activities of a different nature, and that person should therefore have interdisciplinary skills and be able to solve problems in terms of both calculation and compilation of financial data and human relations (e.g. including the need to explain the justification for cost reductions). However, the person responsible for cost strategy should primarily be the 'link' between financial reporting and accounting and financial management.

Behavioural aspect of implementing cost strategies in an insurance company

The second aspect to be considered when discussing these issues is the behavioural aspect of implementing a cost strategy in an insurance company. Its inclusion is dictated by the fact that the presented topic concerns the area of decision making, which is directly related to human behaviour.

Behavioural finance, which includes, among others, research on the influence of human behaviour on the decisions made in the area of finance of companies or institutions, has become very popular for several years, which has contributed to the development of this area of science. One of the most important representatives of behavioural finance is D. Kahneman and A. Tversky, who created the so-called theory of perspective. Currently, as a result of very dynamic development, behavioural finance is represented by many scientists, and the issues covered by them concern a very wide range of problems from the borderline of economics and psychology. Behavioural finances can be divided into two streams of research that concern [Czerwonka 2016, p. 15]:

- analysis of individual behaviour (perspective theory, predisposition effect, heuristics),
- market behaviour analysis (seasonal anomalies, fundamental anomalies, market over reactivity anomalies).

In the case of modelling cost strategy for the purpose of supporting financial management in an insurance company, the first trend that concerns the behaviour of individuals, i.e. individual people, deserves attention. When implementing a cost strategy in an insurance company, problems related to human behaviour in two groups of people should be considered. These groups include:

- managers (making decisions),
- employees (carrying out activities) of the insurance company.

Influence of managers' behaviours on the decisions that are made in relation to the activities aimed at implementing the cost strategy manifests itself in their subjective approach to solving problems. In order to understand the complexity of this issue, it is possible to consider the possibility of applying in an insurance company one of the methods of the theory of individual differences psychology. It is the Big Five personality traits (also known as the five-factor model), developed by P.T. Costa and R.R. McCrae (1980), which assumes that decisions made by people are shaped by five features of his personality, such as:

- neuroticism (tendency to experience negative emotions and susceptibility to psychological stress),
- extraversion (determining the quality and quantity of social interactions and the tendency to experience positive emotions),
- amicability (attitude towards other people),
- conscientiousness (degree of organisation, perseverance and motivation in pursuing a goal),
- openness to experience (degree of tolerance to novelty, cognitive curiosity).

The five-factor model provides an opportunity to observe how managers' decisions can vary depending on their individual characteristics. It is worth noting that research has shown that there is geographical variation in personality traits, which is reflected in the fact that managers in different countries may behave differently (more: Rentfrow P.J., Jokela M, 2016).

The application of this model does not relate directly to cost decisions in the insurance company, but to the decision making of managers in general. Therefore, there is no need to indicate to what extent individual personality traits shape decisions on how to implement a cost strategy in an insurance company, but it should be noted and taken into account in the application of the model in practice that differences in those traits influence decisions, including on the costs of the insurance company.

The second group of people whose behaviour is important for the implementation of the cost strategy are employees of the insurance company who are not decision-makers but perform activities that shape costs. Taking into account the employees' behaviour is a very important element of the implementation of the cost strategy, which to a large extent determines the success and achievement of objectives. The analysis of such employees' behaviours deserves special attention:

- reaction to changes,
- willingness and ability to cooperate,
- the degree of motivation,
- commitment.

The implementation of a cost strategy very often requires changes that relate to the scope of activities allocated to individual employees, reorganization of their work and reduction of their activities. That is why the willingness of employees to accept and accept changes is so important.

The same applies to the willingness and ability of employees to cooperate, as this is also a key factor in implementing the cost strategy. On the other hand, the degree of employees' motivation and involvement in activities related to the implementation of the cost strategy are the features which, although they also determine the effectiveness of the cost decisions taken, the behaviour of employees shaped by them is a result of the generally conducted personnel policy in the insurance company.

Discussions and Conclusions

The aim of the article was to analyse the possibility of applying selected models of decision making while designing and implementing cost strategy in an insurance company subordinated to the realization of financial management objectives. This goal has been achieved and the results of the analysis are presented in Table 3. As can be seen from these results it is not possible to determine one decision making model which would be applicable in the insurance company. A normative-descriptive model or such a descriptive model should be used, which assumes partial rationality of decision-makers' behaviour. That model is also closely related to the areas that shape the cost decisions of insurance companies.

It is also possible to adjust the decision-making model to the conditions of designing and implementing the strategy and to the type of strategy that has been chosen. If an insurance company adopts a cost strategy with a range of activities that focus on activities that are closely related to the finances of the insurance company (e.g. a strategy that is subordinated to financial liquidity, profitability), then a prescriptive model should be chosen. If, on the other hand, the chosen strategy includes activities whose effects are determined by people's behaviour (e.g. a strategy that is subordinated to insurance risk), a descriptive model is better. However, it is not so explicit, and one cost strategy cannot be assigned to one decision making model, as there are such strategies as e.g. a strategy subordinated to cost reduction, which may involve the implementation of actions of very different nature. Therefore, those considerations should only guide those responsible for designing and implementing a cost strategy, as the final decision on this issue depends on the individual circumstances of the insurance company.

Further research in this field should focus on trying to propose a decision-making model designed for insurance companies. That model should take into account the specificities of the activities of those financial institutions as well as changing market conditions. An important factor which should be taken into account in this proposal is the behavioural factor.

"The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN".

Abstract

At the present stage, a significant pool of financial instruments can stimulate the growth of energy efficiency indicators by industry. In the process of the research, solutions and measures of optimal conditions that can contribute to improving the energy efficiency of buildings were studied. A residential building located in Almaty for research was chosen, for which the costs of energy efficiency projects were calculated. Based on the modeling of the measures, we can conclude that the proposed system can objectively evaluate not only the available data for specific objects, but also offer specific recommendations for improving the energy efficiency class of buildings according modern standards. For economic and financial evaluation of energy efficiency projects in buildings, several methods and indicators were used: simple payback period; net present value and internal rate of return, cost of energy savings. Key elements of the methodology are: selection of a reference building; determination of measures to ensure target levels of energy efficiency and thermal protection parameters and assessment of cost; conducting financial and economic analysis of projects. An important conclusion on the use of financial instruments is that government bodies need to rethink the concept of energy efficiency, that must are used as independent energy source, the value of which is equal to the cost of energy resources saved.

Keywords: Energy Efficiency, Rating, Energy Savings, Environmental Management.

Introduction

In conditions of fierce competition in the world market, any country aimed at economic growth and development should take thoughtful and consistent steps to create optimal conditions for the development of the industrial sector. As the experience of developed countries shows, for the harmonious development of industry it is necessary to take into account energy efficiency indicators. Today, the energy intensity of industry in Kazakhstan is 4-5 times higher than in European countries. The energy intensity index of Kazakhstan's GDP in the world ranking is 1.9, while the indicator of Japan, for example, is 0.1, and that of Germany is 0.16.

The average data on heat consumption in the residential sector in Central Asia countries (230-270 kW * h / m2) exceed this indicator in Europe (100-120 kW * h / m2) and are comparable with Russia (210 kW * h / m2). Per square meter in Kazakhstan, an average of 13.8 kg OE (162 kWh per m2), while in Germany and France 3.24-3.76 for apartments (38-43.7 kWh) and 7.2-8.2 for individual houses (83.7-95 kWh).

It is worth noting that the level of requirements for thermal resistance of structures in Kazakhstan is significantly lower than the requirements imposed in EU countries with similar climatic conditions. In general, the level of our lag in the degree of thermal protection of newly constructed buildings is 15-20 years.

The European Union is a leader in environmental standards applicable in Kazakhstan. In the practice of technical regulation of energy efficiency in the EU, two main methods are used - labeling energy efficiency and establishing requirements for eco-design of products (environmentally-friendly design).

At the moment, in the field of energy saving and energy efficiency in buildings, the republican building standards "Energy Consumption and Thermal Protection of Civil Buildings" are in force SN RK 2.04-21-2004, SN RK 2.04-04-2011 "Thermal Protection of Buildings".

The classification and standard values of the specific characteristics of the consumption of thermal energy for heating for residential and public buildings, the form of the energy passport of the building in SN RK 2.04-04-2011 are identical to Russian standards.

The role of standards is undeniable in the transition to more sustainable, but at the same time economically viable energy solutions that can develop a green economy. Most technologies, including renewable energy, must be cost-effective and cost-effective due to the large volumes of implementation and the gradual increase in productivity as knowledge of them increases. They also require the implementation and standardization of relevant technical specifications in order to expedite their widespread use. It is also important to clearly understand the relationship between various energy efficiency standards in the development of a green economy, which can be represented as follows (Figure 1)

Fig. 1: The relationship of standards in the development of the green economy

It is necessary to study the reasons that impede the implementation of standards, as well as to work on the coordination of existing and newly implemented. Harmonization of energy efficiency standards helps:

- minimize the cost of testing and verification of energy efficiency of products;

- make it possible to compare energy efficiency on a common basis;

- simplify the introduction of more efficient production;

- Accelerate the translation of best practices into policy measures.

On the basis of financial, technical, environmental and social indicators, methodologies for environmental assessment of building construction have been developed in various countries, of which the following are best known: LEED - a guide to energy and environmental design (USA); BREEAM - environmental impact assessment method (United Kingdom); DGNB - certificate of sustainable construction (Germany), Standard STO NOSTROY 2.35.4-2011 - Residential and public buildings. Rating system for assessing the sustainability of the environment (Russia) and others. The financial indicators for assessing the construction of a building are described in the cost-optimal methodology concept, which became widely used after the adoption of Directive 2010/31 / EC on the energy performance of buildings. This methodology is discussed in various studies: Araujo et al. (2016), Ascione et al. (2016), Atanasiu et al. (2013), Ballarini et al. (2017), Bashmakov et al. (2015), Becchio et al. (2015), Hamdy et al. (2017), Hamilton B. A (2010), Enseling and Loga (2013), Gurgun A.P. and Arditi D. (2018), Leutgöb and Rammerstorfer (2013), Miller (2014), Ortiz et al. (2016), Pikas et al. (2015), Tadeu et al. (2016), Tabunshchikov et al.(2013), Tleppayev (2019). Based on previous standards and studies, a rating metodology for Kazakhstan's practice was developed to assess the attractiveness of energy efficiency projects.

Results

As a study of the best practices in the field of improving energy efficiency shows, the investment attractiveness of energy efficiency projects depends on the use of various assessment tools that contribute to the formation of objective and relevant forecasts for investors. The current practice of development of the economy of Kazakhstan indicates the need to develop this issue and apply project evaluation methods that take into account the particular development.

The life cycle cost of a building is the total discounted cost of owning, operating, repairing and disposing of a building or complex of buildings over a period of time. The concept of life cycle costs has been known for a long time. However, in relation to buildings, it has become actively used relatively recently - after the adoption of the EU Directive 2010/31 / EC on the energy performance of buildings, which requires EU members to set energy efficiency requirements not lower than economically optimal levels. To determine such levels, states are obliged to use a framework methodology that is fully based on the concept of the costs of the building's life cycle [6]. In addition to assessing the initial costs of building the building, all future costs associated with its operation, repair and subsequent demolition are taken into account. The sum of all costs associated with the construction and operation of buildings is "the cost of the building's life cycle". Optimization is carried out according to the criterion of minimizing the total life cycle costs of the building for the builder, owner and society, including the requirements to reduce environmental damage and reduce greenhouse gas emissions. Analysis of the life cycle cost of a building can be carried out for buildings of any type - existing and new, residential and public, individual and multi-unit.

The discount factor significantly affects the indicators of economic efficiency of projects. Its high value leads to a rapid depreciation of future income and underestimates the positive cash flow, and hence the economic effect of the project. A package of measures is cost effective if the net present value of the revenue stream calculated with a given discount factor is greater than zero, or the discounted income is greater than the discounted cost. In substantiating investment projects, two approaches are used: calculating cash flow at current prices and at comparable prices. In the first case, the refinancing rate is often used as a discount coefficient in economic analysis, and in the financial analysis, the market interest rate on long-term loans. In comparable prices - the interest rate taking into account the level of inflation.

For comparison and obtaining comparative data for analysis, the proposed and modified approach with a reduction in indicators was applied to the building, which is located in Almaty. For the building selected for examination in the project, it is known that it was built in the 70s. The readings

of the heat meter installed in the heat point of the building were analyzed for the period from February 1, 2016 to April 15, 2019.

In 2016/17, the actual heat consumption for the heating season amounted to Qот = 364.69 Gcal, i.e. exceeding 68.09 Gcal or 29%, while the actual specific heat consumption of the building, taking into account the energy efficiency class, q_s =204,3kWh/м^2. In 2017/18г Qот =332,0 Gcal, i.e. excess 35,4Gcal or 12, the actual specific heat consumption of the building, taking into account the energy efficiency class, q_s =186,0kWh/м^2. In 2018/19г Qот =330,0 Gcal, i.e. excess 33,4 Gcal or 11, the actual specific heat consumption of the building, taking into account the energy efficiency class, q_s =184,0kWh/м^2.

The cost of heat consumption by a building can be reduced only through the introduction of an automated heat point and measures for thermal modernization of the building.

Electricity costs for lighting the common areas of use of the building were also calculated. In a year they amounted to 3710 kWh or 1.79 kWh/m2. Lighting costs can be reduced to 700-800 kWh or 0.34-0.4 kWh/m2 through the introduction of energy-saving LED lamps.

Average data on heat consumption in the residential sector in Kazakhstan q_s =270 kW * h / m2. In the EU, a building with low heat consumption for heating is considered at qs from 50 to 80 kWh / m2.

For the considered residential building, the total score was 37 points, which corresponds to class E. This rating corresponds to the class of construction and operation of the building 40 years ago.

The heat consumption rate for such a building according to the standards of the Republic of Kazakhstan is about 222 Gcal. To ensure efficient heat supply to the building, a system of automatic recording of the outdoor temperature during the heating period and regulation of the regulation of the supply of thermal energy for heating are required. According to calculations, the heat consumption will be 204 Gcal against the standard in 222 or actual in 330 Gcal.

A business plan for the energy efficiency of the building was calculated with various options to calculate the economic efficiency of the proposed measures, such as installing an automated heat point, building insulation to reduce energy consumption to class B.

According to calculations, the simple payback period of an automated heating substation, together with installation without borrowing due to energy saving measures, is 4 years, building insulation - 13 years. Calculations were also made taking into account borrowing for the purchase of an automated heat substation for 10 years and heat modernization for a period of 20 years at an interest rate of 4.5% (state program rate) and 15% in commercial bank. According to calculations, the installation of district heating substation pays off at any interest rate, since energy savings cover all interest payments with debt repayment. Insulation of the building without and with substations is paid back only at a rate of 4.5% for the next year after closing the loan (21 years) and for 31 years, respectively. Calculations show that lengthening the terms of borrowing makes it possible to cover annual payments of the main debt and interest due to savings in energy consumption, while increasing the interest rate lengthens the payback periods of the proposed major energy efficiency measures. Thus, measures to stimulate energy efficiency in buildings are impossible without government support for subsidizing interest rates and lengthening the term of borrowed funds.

Among the recommendations for upgrading the building class in Almaty, the following measures should be proposed:

- automation of heat energy consumption by apartment buildings (automation of heating units, facade control): the installation of an automated heat station will reduce specific energy consumption in the winter from 180 kWh / m2 to 115, which will correspond to class C;

- thermal insulation of pipelines and increase of energy efficiency of the equipment of heat points, distributing pipelines of heating and hot water supply;

- restoration / implementation of circulating hot water supply systems, hydraulic adjustment, automatic / manual balancing of distribution heating systems and risers;

- installation of frequency regulation of pump drives in hot water supply systems;

- insulation of the building, basement and attic with overhaul of the roofing and replacement of the outer windows of public spaces, which will reduce energy consumption by another 20-25% to class B;

- installation of automated lighting control;

- Relocation of electric networks to reduce losses of electric energy;

- Development, together with municipal authorities, of separate waste collection tools.

It should be noted that if the automatic control of the heating temperature is limited by the central heating system (central heating unit), the system corresponds to an ineffective class D, since the heat carrier of the same temperature is supplied to different rooms of the building with different heating needs. In order to comply with at least the standard class C, it is necessary to provide room temperature control with at least one of the following methods: radiator valves, thermostats, room controllers, etc. For class B, it is necessary to organize room temperature control with communication between the controllers and the central station. Feedback communication allows you to extract additional savings potential in the heating system. And finally, in order to comply with class A, it is necessary to provide room temperature control with communication between the controllers and the central station, plus control of the presence of a person in the room. Thus, the higher the level of automation, the more opportunities there are to extract the potential for savings in engineering systems.

Conclusions

The above examples indicate the need to use an integrated approach in determining the sustainability parameters of buildings with the allocation of energy efficiency and energy saving indicators.

An integrated approach allows you to:

1) Include in the assessment the maximum number of indicators that relate to the energy efficiency of the building;

2) Allow, based on the data obtained, to plan measures to eliminate the most inefficient indicators;

3) Allows you to comparatively evaluate indicators for various objects;

4) With a lack of data allows you to vary the data for evaluation;

5) Reflects the multidimensionality of the measurement of the project energy efficiency indicator

Also, the use of an integrated approach is based on the following provisions:

- At the present stage, there is a large list of energy efficiency indicators for buildings, which includes 5 main groups, within which indicators are distributed into subgroups.

- Using an integrated approach to assessing energy efficiency allows you to get significant returns in accordance with a variety of parameters and criteria. What is especially important in conditions when obtaining some data may be difficult or distorted as a result of various phenomena and circumstances.

- Based on international and Russian experience, a building in Kazakhstan was evaluated, on the basis of which the main obstacles were identified.

- Based on the data obtained, it can be concluded that the proposed approach allows us to understand how different standards and approaches can be harmonized to obtain generally accepted and comparable data.

- In Kazakhstan, the relevance of the proposed approach is especially felt when working with residential facilities. This is due to the fact that usually such buildings have a large number of owners, and decisions are taken for a sufficiently long period.

- objective factors affecting obstacles to reducing incentives in energy efficiency projects are high bank interest rates, rising costs of materials and equipment. Calculations for European countries show that energy efficiency packages are applicable if one or more of the following conditions is met: a lower discount rate (i.e., from 3% to 1%), an increase in energy prices (i.e., from 2.8% up to 4%), reducing investment costs between options.

- the economic return on projects in existing and new buildings, in our opinion, depends on the creation of energy efficiency programs for overhaul and subsidies from the budget for the overhaul of energy-efficient projects; creation of revolving funds for energy conservation and business development of energy service companies; developing standardized banking products to finance energy efficiency programs.

Abstract

There are many approaches to measure systemic risk (Hansen 2013), but the main distinction entails financial soundness indicators and advanced systemic risk models. The advanced models are based on the statistical multivariate distributions or on the stochastic processes. In the paper the Conditional Value-at-Risk (CoVaR) proposed by Adrian and Brunnermeier (2011, 2016) will be used to assess systemic risk. Two methods, i.e. the conditional (DCC-GARCH) and unconditional (quantile regression) will be applied for these estimations. As a proxy of a financial system a construction of an index, free from disadvantages as opposed to the stock market index, will be proposed by the author. The empirical analysis for the Polish financial system will contain: a model risk analysis, comparison of results for selected measure of systemic risk and estimation methods, an evaluation of results (back testing and a financial condition assessment of financial institutions). In the study existence of the strong and positive relationship between results of the delta CoVaR gained while applying the DCC-GARCH and quantile regression confirmed complementarity of both approaches. The relationship between the systemic risk measure for an individual bank and measure of its financial condition was confirmed, but the results were not consistent. The *delta CoVaR* was more influenced by the size of a bank rather than its financial condition. This study indicated that the *delta CoVaR* and a composite indicator contained different sets of information.

Keywords: Systemic risk, banking industry, CoVaR, model risk

Introduction

In this paper systemic risk will be meant in a very narrow sense as a risk of breakdown or major dysfunction in a banking system. The term is used by some researchers to include the potential insolvency of a major player or a component of the financial system. The development of these models is observed after the financial crisis of 2007-2008 and significantly after 2010. There is a large group of systemic risk measures in the literature e.g. Acharya et al (2010); Hansen (2013); Benoit et al (2013). The main representation of different approaches in systemic risk measurement includes the following measures:

- ***CoVaR*** (the Conditional-VaR) - Adrian and Brunnermeier (2011, 2016),
- ***MCoVaR*** (the Multi-Conditional-VaR) - Cao (2012),
- ***MES*** - Acharya et al. (2010); Brownlees, Engle (2012),
- ***SV*** (the Shapley value) approach - Tarashev et al. (2010),
- ***CES*** (the Component Expected Shortfall) – Banulescu, Dumitrescu (2012),

- ***SRISK*** (the Systemic RISK) measure - Acharya et al. (2012) and Brownlees and Engle (2012),
- ***DIP*** (Distress Insurance Premium) – Huang, Zhou, Zhu (2009, 2010, 2011),
- ***JPoD*** (Joint Probability of Distress) – Segoviano, Googhart (2009).

Risk models play a fundamental role in the regulatory process and are directly embedded within the Basel Committee regulations. Therefore, the risk models are used to determine bank capital. While their use for macroprudential purposes is not clear, there are a number of proposals from the academic and public sectors to apply these models setting bank capital and surcharges to meet systemic risk. Thus the output of these models has a real economic impact (Danielsson et al. 2011).

The goal of this paper is to identify model risk and its sources for a selected systemic risk measure, namely delta CoVaR. The following research hypotheses were formulated by the authors of this paper:

Hypothesis 1. The main source of the model risk of delta CoVaR is an estimation procedure.

Hypothesis 2. There is a relationship between the systemic risk measure for an individual bank and measure of its financial condition.

In the empirical study delta CoVaR (measured with the DCC and the quantile regression approach) will be selected to measure the systemic risk and the composite indicator – a classical measure of development proposed by Hellwig will be the measure of bank's financial performance.

Such an empirical study concerns the Polish banking system and covers the lack of studies with the aim to investigate a relationship between the systemic risk and a financial condition of a bank. This study enhances the literature by verifying results in a less developed market.

The structure of the paper contained literature review, research methodology, empirical results, conclusions and finally references.

Literature Review

Model risk is the risk of economic or reputation loss due to errors in data, errors in the development, implementation or use of models. The use of models invariably poses model risk which may potentially account for adverse consequences while reaching decisions based on outputs and reports derived from an incorrect or an inappropriately employed model (McCarthy, Ananthapadmanaban, Warner, Cryezu, 2017). A model consists of three main components:

- an information input component which delivers assumptions and data to the model;
- a processing component which transforms inputs into estimates; and
- a reporting component which translates the estimates into useful business information.

All these components are exposed to model risk. Model risk occurs primarily for two reasons:

- The model may have fundamental errors and may produce inaccurate outputs when viewed against the design objective and intended business uses.
- The model may be used incorrectly or inappropriately. Even a fundamentally sound model which provides accurate outputs and is consistent with the design objective of the model may exhibit high model risk if misapplied or misused.

Therefore, model risk is a regular risk and must be managed accordingly by applying a process of risk identification and an analysis followed by an assessment, monitoring and mitigation. In the empirical study the first step in risk management process – namely, risk identification was analyzed by the authors.

In practice, the existence of the model risk is often ignored. Only in the banking sector, because there are recommendations of Basel Committee and regulators about the model risk steering, cannot be

underestimated. Therefore banks have procedure to manage model risk. In case of the systemic risk there is to our best knowledge a few papers focused on the model risk. But there is a large literature on model risk in related areas. Colletaz et al (2013) present a method, called the Risk Map, for validating risk models. This method jointly accounts for the number and the magnitude of extreme losses and graphically summarizes all information about the performance of a risk model. Authors indicate that the Risk Map can be used to validate market, credit, operational, or systemic risk estimates (VaR, stressed VaR, expected shortfall, and CoVaR) or to assess the performance of the margin system of a clearing house. Danielsson et. al (2011) evaluate the model risk of models used for forecasting systemic and market risk. Model risk, is shown to be increasing with market uncertainty.

There are several contributions which analyze CoVaR and other systemic risk measures from the model risk point of view (e.g. Boucher et al. 2013, Danielsson et al. 2011 and Löffler, Raupach 2011). Boucher et al. (2013) conclude that riskiness of systemic risk measures is crucial for the sake of the fairness and the global system stability.

Research Methodology

CoVaR is a systemic risk measure proposed by Brunnermeier and Adrian (2011, 2016). *CoVaR* represents conditional Value at Risk, i.e. it indicates the *VaR* for a financial institution conditional on a certain scenario in a particular bank or a set of banks (a system). *CoVaR* measures the contribution of a given financial institution to the systemic risk and other financial institutions. Some institutions can have a low *VaR* but a high *CoVaR*. Therefore, the simple *VaR* is not a sufficient measure to evaluate the systemic riskiness of financial institutions. It should be taken into consideration by a policy maker while forming policy regarding risk of an institution. *CoVa*R has a complement in another risk measure i.e. Marginal Expected Shortfall. *CoVar* is defined as follows (Brunnermeier, Adrian 20011, 2016):

$$P\left(X^{j} \leq CoVaR_{q}^{j|i} \middle| X^{i} = VaR_{q}^{i}\right) = q$$

In this paper the *CoVaR* measure was not directly applied by the authors. However, a related measure such as the delta *CoVaR* was employed. The delta *CoVaR* of institution *i* is defined as a difference between the *VaR* of the system conditional on this particular institution being in financial distress and the *VaR* of the system conditional on institution *i* being in its median state ($q = 0.5$):

$$\Delta CoVaR_{q}^{j|i} = CoVaR_{q}^{j\left|X^{i}=VaR_{q}^{i}\right.} - CoVaR_{q}^{j\left|X^{i}=VaR_{0.5}^{i}\right.}$$

CoVaR provides an answer for the question: what is the *VaR* of the financial system if a particular institution is under financial stress? While the delta CoVaR responds to the following issue, namely – what is the *VaR* of the system change like when a particular institution becomes financially stressed?

CoVaR estimation methods include: the Quantile regression approach, the Multivariate GARCH approach, the Copula Function approach, the Extreme Value Theory approach and, finally, the Bootstrap approach. In this paper the focus is directed towards the quantile regression (Koenker, Basset 1978, Koenker 2005) and the DCC GARCH procedure. In both methods the delta CoVaR can be defined in a similar way i.e. it takes into account a multiplier and a difference between VaR calculated for different *q*:

$$\Delta CoVaR_{q,t}^{j|i} = \hat{\beta}_{q}^{j|i}\left(VaR_{q,t}^{i} - VaR_{0.5,t}^{i}\right)$$

where beta is a parameter estimated by the quantile regression, and

$$\Delta CoVaR_{q,t}^{j|i} = \hat{\gamma}_{ji,t}\left(VaR_{q,t}^{i} - VaR_{0.5,t}^{i}\right)$$

where gamma is a parameter estimated by the DCC GARCH approach (Engle, 2002).

The concept of the **pattern of development** and the **measure of development (composite indicator)**in English was presented in English by Professor Zdzisław Hellwig at the UNESCO conference in Warsaw in 1967 (eg. Hellwig 1968, Walesiak 2016). The following terms were introduced in this study:

• stimulants and destimulants,

• pattern of development,

• measure of development (distance from the pattern of development).

There is a taxonomy of the pattern objects: a pattern object (an upper pattern object, an ideal object, an upper pole) and an anti-pattern object (a lower pattern object, an anti-ideal object, a lower pole). The coordinates of a pattern object cover the most desired values of preference variables (stimulants, destimulants, and nominates). The coordinates of an anti-pattern object comprise the least preferred preference variable values. The pattern of development is defined as follows:

$$m_i = 1 - \frac{d_{i0}}{d_0},$$

where: m_i – measure of development for i-th bank, d_{i0} – distance between a pattern of development and i-th bank, d_0 – distance between a pattern object and an anti-pattern object.

The measure of development is constructed so that it fulfills the following properties:

1. the higher the level of the complex phenomenon, the higher the value of the development;

2. values of the measure of development are included in the range [0,1], while the measure of development calculated for the pattern of development equals one, whereas the value for the anti-pattern comes to- zero.

Research on financial performance indicators was conducted mainly by the International Monetary Fund (IMF). The IMF uses the term Financial Soundness Indicators (FSI) as referring to statistical measures used for monitoring the condition and financial soundness of the financial sector as well as enterprises and households (IMF 2006, 2009, 2013). In this paper financial ratios which cover different areas to evaluate a bank's activity, e.g. risk, quality of debt were selected by the authors. Presented in Table no. 1 ratios are the compromise between availability of data and diversity within groups of ratios used in empirical study.

Additionally, the classical Euclidean distance was utilized as the distance measure:

$$d_{i0} = \left(\sum_{j=1}^{m} w_j \left(z_{ij} - z_{0j}^{+} \right)^2 \right)^{\frac{1}{2}},$$

$$d_0 = \left(\sum_{j=1}^{m} w_j \left(z_{0j}^{+} - z_{0j}^{-} \right)^2 \right)^{\frac{1}{2}},$$

where: z_{ij} – value of the j-th transformed into stimulant and normalized ratio X_{ij} (idicator) for i-th object (bank), z_{0j}^{+}, z_{0j}^{-} - pattern and anti-pattern co-ordinates, w_j – weight of the j-th variable, m – number of variables.

The system of 10 variables and equal weights has been used.

Table 1: Variables to describe a bank's financial condition

	Ratio	Variable	Type
X_1	return on assets	stimulant	profitability
X_2	return on equity	stimulant	profitability
X_3	net interest margin	stimulant	Risk
X_4	TIER 1	stimulant	Risk
X_5	cost to income ratio	destimulant	efficiency
X_6	noninterest expenses/total income (noninterest +interest)	destimulant	efiiciency
X_7	loans to deposit ratio	destimulant	liquidity
X_8	liquid assets to deposit ratio	destimulant	liquidity
X_9	impaired loans to gross loans	destimulant	quality of debt
X_{10}	reserves for impaired loans/impaired loans	stimulant	quality of debt

Source: own elaboration

Empirical Results

Sample periods range from 5 Jan 2015 to 28 Dec 2015, from 4 Jan 2016 to 27 Dec 2016 and from 5 Jan 2017 to 28 Dec 2017. A sample of weekly rates of return for the 9 largest banks in Poland, i.e. a banking index (WIGBanks) and a WIG index (WIG index comprises all companies listed at WSE) were employed by the authors for delta CoVaR. For the above mentioned 9 banks ten financial ratios were calculated (for each bank separately) in the years 2015-2017 and total assets values in PLN were collected. The assumptions concerning the delta CoVaR estimation are as follows:

1) Due to prudential reasons 1% of tolerance level for VaR and delta CoVaR was assumed.
2) Two estimation methods of delta CoVaR: the Quantile regression approach and the Multivariate GARCH approach were applied, for the VaR estimation a method of filtered GARCH historical simulation was utilized by the authors.

By definition, while employing delta CoVaR, the results of the systemic risk contribution measurement for a bank are related to the size of a given bank. Therefore, the pure results of the delta CoVaR as well as the results additionally weighted by asset values were scrutinized by the authors.

Such a construction of the *delta CoVaR* implemented by the authors allows it to use market prices instead of the net asset value. However, a problematic issue appears while defining a system. Instead of taking into consideration solely 100% of banking index, the financial system was extended by the authors. While measuring the *delta CoVaR,* the system with the banking index and banking index plus stock index were approximated by the authors. Such an approximation was performed in order to search for a more convenient solution rather than applying accounting data. Finally, the financial system is composed of a banking index and a banking index plus WIG index (three different weights of WIG – namely, 0.1, 0.2 and 0.3 were considered):

- 0.9 of banking index + 0.1 of stock index;
- 0.8 of banking index + 0.2 of stock index;
- 0.7 of banking index + 0.3 of stock index.

The influence of this solution is illustrated in Figure 1 which presents results of the *delta CoVaR* for a selected bank (for illustrative purposes only one bank was randomly selected, namely mBank) and different weights of stock index WIG (0.1, 0.2, 0.3 and 0). Such a comparison of results indicates that the following phenomena were included. Firstly, the higher weight of stock index, secondly, the higher

value of the *delta CoVaR* calculated by using both approaches, and finally, considerably higher difference in results obtained by both approaches were detected.

Figure 1: Results of the delta CoVaR for a selected bank with different weight of stock market index (WIG index)

Source: Own calculation.

To verify both research hypotheses, relationships between the results of *delta CoVaR* (calculated by two methods) and a composite indicator, together with relationships between the results of the *delta CoVaR* weighted and not weighted by size of a bank were investigated in this paper by the authors. Therefore, Spearmen's rank correlation coefficients were calculated. The results of Spearman's rank correlation coefficients between the *delta CoVaR* and a composite indicator are collected in Table no. 2, whereas Table no. 3 provides the results from an analysis of the *delta CoVaR* weighted and unweighted by the size of a bank.

Source: own elaboration.

The analysis of results proved that the correlation coefficients between results of delta CoVaR obtained in both methods were positive, high and statistically significant. The results based on the unconditional (quantile regression) and conditional (DCC) approach consistently indicated changes in the systemic risk level of the banking system. However, the correlation coefficients between results of delta CoVaR and a composite indicator were positive, low and statistically insignificant. It did not confirm the relationship between measures of systemic risk based on market information (market prices/returns) and a measure of a financial condition based on published financial information (available in financial reports).

Source: own elaboration.

The correlation coefficients were partially statistically significant. The significantly negative and strong relationship existed between results of delta CoVaR weighted and unweighted by the size of a bank which were estimated with the DCC GARCH approach, while the system comprised banking index plus WIG index. For the delta CoVaR estimated by the quantile regression, the relationship was statistically insignificant.

Conclusions

CoVaR and *ΔCoVaR* extend the *VaR* framework to measure the systemic risk rather than the individual institution risk. *ΔCoVaR* is higher for the quantile regression in comparison with the DCC approach. The results bear resemblance to the ones obtained by Girardi, Ergün (2013), Benoit et al. (2013).

Without the size adjustment (a restricted sample) it was observed that ranking banks in accordance with their size was consistent for the DCC approach in 2016, only on the condition that the share of banking index in the 'system' was higher. With the size adjustment (a restricted sample) rankings gathered by using both methods were similar and stable in time (correlation coefficients were positive, high and statistically significant).

Existence of the strong and positive relationship between results of the *delta CoVaR* gained while applying both methods confirmed complementarity of the approaches. The first hypothesis was verified negatively.

The results of the delta CoVaR and a composite indicator were not consistent (correlation coefficients were positive, low and statistically insignificant). The *delta CoVaR* was more influenced by the size of a bank rather than its financial condition. Lower values of financial condition measure (a composite indicator) were not reflected in higher values of the *delta CoVaR*. This study indicated that the *delta CoVaR* and a composite indicator contained different sets of information. It did not allow for the second hypothesis to be verified positively.

According to the literature and the previous studies conducted by authors, the proper systemic risk measure, *delta CoVaR* was chosen. Therefore, the model appropriateness was not considered as a source of model risk in this case. The following should be considered as sources of model risk:

1) Data structure: stock rates of return or net asset value;
2) Frequency of data: weekly, monthly or daily data;
3) Definition of the system: banking index or other stock market index;
4) Estimation method: the Quantile regression approach or the Multivariate GARCH approach;
5) Measure a bank size: total assets or market capitalization value;
6) Results: pure result of the *delta CoVaR* or adjustment with size of a bank.

On the basis of the results elaborated by the authors it is highly recommended to identify and use corrections while applying various methods to assess the systematic risk so that it does not depend on a size of a bank.

Analysis of sources of model risk is very important element in the model risk management process because model risk cannot be removed, only mitigated through such critical analysis. Danielson stated the broader context of this issue: "Policymakers should be wary of relying solely on models. Formal model-risk analysis should be a part of the regulatory design process." (https://voxeu.org/article/model-risk-risk-measures-when-models-may-be-wrong).

Measurement of Expenditure Efficiency of Polish Cities with County Rights in The Context of Quality of Life

Alicja SEKULA

Gdansk University of Technology, Gdansk, Poland
Alicja.Sekula@zie.pg,gda.pl

Abstract

The article is devoted to the measurement of efficiency of overall expenditures. The purpose of the study is to evaluate the efficiency of use of budget resources by local government units in the context of fostering quality of life. The subject of the study is 65 Polish cities with county rights (county status). Calculations were carried out using Data Envelopment Analysis (DEA). The results of analysis confirm the two research hypotheses: the efficiency of budget expenditures is higher in larger cities with county rights (status), and the efficiency of budget expenditures is higher in cities with county rights (status) with lower overall per capita expenditures.

Keywords: Efficiency, Budget Expenditures, Data Envelopment Analysis, DEA, Cities With County Rights, Cities With County Status.

Introduction

The subject of local government finances encompasses issues related to the rationality of public fund management that include processes of collection and expenditure of these funds by local government bodies. An expenditure policy should be governed by the criteria of rationality and efficiency of public and social task performance. One of these criteria – efficiency – is examined in this article.

Cities with County Rights (status) in the Structure of Polish Local Government

Polish local government has been functioning on three levels since 1999: commune (gmina), county (powiat) and region (voivodeship). A commune is the fundamental local government unit, while a county has the status of a local unit performing tasks that exceed the competences of communes. With respect to the nature of the localities that make up a commune, they are divided into three types: urban, rural and urban-rural. Some urban communes, i.e. of the first type, have a specific status: one administrative centre performs both commune and county tasks. Formally, they are referred to as cities with county rights. Their overall revenue consists of revenues derived from performing both commune tasks and county tasks. Cities with county rights do not form a separate level of local government or a fourth type of commune. However, because of their distinctive functional, demographic, urban, administrative and economic features, they are often considered a separate category in statistics. Cities with county rights are also known as county-free cities (Kuhlmann 2010). They exist in a number of European countries, such as France, Norway, Spain and Hungary (Pickvance 2002). Examples of cities with county rights include Dresden, Schwerin and Munich in Germany (*kreisfreie Städte*), Innsbruck and Graz in Austria (*Statutarstädte*), Oslo in Norway, and Paris in France (Sekuła 2015).

The concept of efficiency and Urban Quality of Life

The concept of efficiency can be differently defined. For the purpose of further considerations, Farrell's concept of technical efficiency is adopted as a measure describing the ratio of the output produced from the input to the maximum output possible to achieve in the specific circumstances and using a particular technology (Farrell 1957). On this basis, we can say that technical inefficiency describes a situation where more input is used than necessary to achieve a particular output level or the output produced is below the output capabilities for a particular input level.

With respect to economic and research practice, the concept of efficiency is treated strictly quantitatively. However, in view of the emphasis placed on the rationalisation of public spending, it is reasonable to give particular attention to the qualitative aspects of actions undertaken using public funds. This aspect directly relates to the concept of quality of urban life as strictly connected with the perception and subjective experiences of people.

Quality of urban life is defined as the relationship between the perceptions and feelings of residents and their own experiences relating to the space they inhabit (Senlier et al. 2008). A comprehensive explanation of this term is connected with such concepts as "satisfaction", "personal growth" and "well-being". Because it often refers to a specific place, in the case of cities it is referred to as the urban quality of life (Marans 2015). The quality of life in a particular area can be analysed in the context of its two main dimensions – objective and subjective. Studies focusing on the objective dimension are chiefly based on socio-economic indicators that can be used to present the achievements and shortcomings in certain component areas of quality of life (Liao 2009).

There are many publications devoted to the problem of selection of areas for analysis to evaluate quality of life. In the most general sense, it is thought that quality of life is affected by cultural, social, economic, environmental and even personal factors. The choice of factors taken into account depends on the type of quality of life to be measured (urban, rural, general) and the relevant geographical area. There are sets of factors relating to urban life in general, i.e. without geographical constraints (Marans 2015), considering the specific character of European cities (Senlier et al. 2008) or European functional regions (Cheshire and Magrini 2006) or US metropolitan areas (Shapiro 2006). The areas selected for this study are the seven areas proposed by P. Liao (2009).

The determination of the areas for analysis is as important as the selection of appropriate methods of efficiency evaluation. The literature devoted to this subject identifies the following methods, as required: classical, parametric and non-parametric. Non-parametric methods use mathematical programming, and, unlike the previous category, they do not make it necessary to consider the effect of random factors or measurement errors or to make assumptions as to the functional relationship between inputs and outputs. The original non-parametric method of efficiency evaluation is DEA.

Data Envelopment Analysis

Data Envelopment Analysis (DEA) is a non-parametric method for evaluating relative efficiency, based on linear programming and referring to the construction of production function as empirical data envelopment (Charnes et al. 1978), drawing on Farrell's concept (Farell 1957).

The determination of efficiency involves solving a mathematical decision-making problem. It consists of identifying reference observations among the set of objects analysed and comparing the other objects to them. Thus, DEA is said to evaluate the relative efficiency of decision-making units (DMUs). The units are "decision-making" because they have an impact on the level of resources incurred (inputs) and results obtained (outputs). The efficiency of DMUs that, from the point of view of the production process, are best at transforming inputs into outputs and therefore are situated at the best practice frontier, is given the value 1, whereas the efficiency of other, less efficient units is less than one.

DEA makes it possible to find the causes of inefficiency and determine the directions of input or output changes enabling inefficient units to achieve maximum efficiency. The distinguishing feature of DEA is the capability of examining objects that transform multiple inputs into multiple outputs. The application of DEA does not require attaching weights to the individual inputs and outputs as measures of significance or making assumptions as to the functional relationship between the variables (Cooper et al. 2007). Unfortunately, DEA is highly sensitive to outliers (atypical data) describing efficient units, which may lower the efficiency results for the remaining objects. When using the most basic DEA models, redundancy of efficient objects may sometimes be observed. To ensure reliability of analyses conducted using DEA, it is necessary to adhere to specific assumptions and limitations, which will be described in the methodological section.

Application of DEA in Evaluation of The Efficiency of Local Government Expenditures – a Literature Review of The Results of Previous Research

There are many studies examining local government expenditures all over the world. Analyses conducted by Kalb et al. are regarded as being among the first studies devoted to the efficiency of German local government units. The study covered more than 1000 municipalities of the German state of Baden-Württemberg. The data for 2004 were used, and the inputs were the total current expenditures, net, i.e. excluding the capital expenditures. The study employed four areas: the social, educational, recreational and infrastructural spheres (Kalb et al. 2012).

Geys and Moesen measured the efficiency of local government units using the non-parametric methods DEA and FDH (Free Disposal Hull), as well as econometric techniques (stochastic approach). The study was carried out based on data for 2000 collected from 304 Flemish municipalities and was intended to compare different measurement methods. The authors pointed out that many analyses concerning the efficiency of local governments focus on a single area, and therefore cannot be used as a basis for comprehensive evaluation. Total current expenditures were selected as the input variable. The outputs were measures in five areas, i.e. the social, educational, recreational, infrastructural and environmental spheres (Geys and Moesen 2009).

Another study assessed the efficiency of local government units in Brazil. The analysis used data for 2001 obtained from nearly 4,800 Brazilian municipalities. Calculations were made using the FDH approach and different variants of DEA. The study employed 4 inputs representing 3 categories: total costs, personnel and public services, and 11 outputs from the communal service areas relating to administration, education and health and housing conditions. The results obtained indicated a link between the municipality size and its efficiency rating. The analyses suggest that smaller municipalities are less efficient than larger ones. There could be different reasons why the efficiency increases with municipality size. The authors point out that the economies of scale could explain this effect in large units (Sousa and Stošić 2005).

The efficiency of the municipal sector was also investigated in Spanish region Murcia. Data for 2000–2002 were collected from 31 units. The following spheres were analysed: green spaces, water supply, waste collection, police, culture and sport. The results revealed a positive correlation between efficiency and the following determinants: economic level, size of the municipality, decentralisation, political sign and financial situation (Benito et al. 2010).

Study conducted in Finland, focused on the cost efficiency of basic service provision by municipalities. The data were collected from 353 Finnish municipalities and covered the period 1994–2002. A two-stage approach was employed in the study. The first stage involved calculation of efficiency, and in the second stage regression models were applied to explain the obtained efficiency scores. While only a single input was used throughout the study – aggregate net cost of provision – the outputs included between 6 and 10 constituent basic municipal services. The cost efficiency median was 87.2%, with a minimum value of 62% (Loikkanen and Susiluoto 2005).

A combination of the DEA method and parametric analysis was also used in the evaluation of efficiency of Portugal municipalities. The study included estimation and analysis of expenditure efficiency for 278 clustered continental municipalities. The study was based on data for 2001. The input was per capita expenditure, whereas the output was a composite indicator referred to as the Local Government Output Indicator (LGOI). It consisted of sub-indicators referring to municipal service provision in the following areas: social services, education, cultural services, sanitary services, territory organisation and road infrastructure. The results obtained led to the conclusion that most municipalities can improve their efficiency without increasing budget expenditures. The second stage of the research was intended to explain the distribution of efficiency results. The following factors contributing to efficiency improvement were identified: education, municipal per capita purchasing power and the distance from the district capital (Afonso and Fernandes 2008).

Analyses carried out for Turkish municipalities employed a combination of DEA and Grey Relation Analysis (GRA). The analysis covered 14 metropolitan municipalities. The data collected applied to the year 2011. In the first stage carried out using the DEA model, a set of 3 inputs (current expenditures, investment expenditures and transfer expenditures) and 3 outputs (tax revenues, non-tax revenues and the revenues obtained from aid and funds) was used. Then the municipalities identified as efficient were sequenced by the GRA method (Kaygisiz Ertuğ and Girginer 2015).

An article concerned with the efficiency of Italian local government presents the results of research evaluating the expenditure efficiency of the 103 largest Italian cities on the basis of data for 2011. The inputs consisted of annual expenditures in 9 areas, including municipal waste management, public transport or cleaning services. The outputs covered 5 areas: urban infrastructure development, urban ecosystem quality, kindergartens, municipality area extension, and the number of residents. The results obtained indicate a probable impact of economies of scale on efficiency. It was additionally noted that uncontrollable environmental variables, the decision-making process complexity and managerial skills may have a stronger effect on the efficiency of large cities than their size alone (lo Storto 2013).

Efficiency of local government expenditures was also investigated in a group of 37 large cities (with a population exceeding 100,000) in Poland. The time frame of analysis was the period between 2009 and 2013. The input consisted of total expenditures per resident, whereas the outputs included values representing the areas of health care, household finances, labour market, education, leisure and recreation, public safety and environmental protection. The analysis proved that an increase in efficiency is promoted by the proximity of other units which offer cooperation possibilities, but also exert competitive pressure. It was demonstrated that budget expenditure efficiency in the large city category is greater in cities that have smaller populations and lower per capita expenditures (Sekuła and Julkowski 2015).

In Poland, the research was carried out on the subject of the efficiency of local governments' expenditures on public and merit goods at the communes' level. The analysis using DEA and Tobit regression covered the years 2002-2006 and three fields: education, environmental protection and public administration. The results prove that communes with higher population and revenues tend to be more efficient, whereas small rural ones are generally less efficient (Karbownik and Kula 2009).

Other research on the area of Poland evaluated the efficiency of investment activity in the communes in Poland on rural areas. The inputs and the effects of investment activity of rural and urban-rural communes in the years 2007-2013 were compared. The studies showed that the amount of expenditure incurred on the studied spheres of investment activity does not translate into their efficiency. This was connected with the possibility of obtaining additional funds from EU, which were not included in the study (Kobiałka and Kubik 2017).

In other studies devoted to efficiency of capital expenditures of Polish municipalities in the Westpomeranian Region it was shown a link between the size and specificity of the entity, and the level of efficiency of its spending for investment. The lowest level of efficiency ratio carried small territorial units - rural profile generally. The article evaluated the efficiency between 2004–2009 using the DEA method (Zioło 2012).

Research Methodology

Selection of units (sample)

This study examines 65 cities with county rights, which constitute the DMUs. This category includes all province capitals as well as cities that have a relatively large impact on the surrounding area. Hence, they are often referred to as "local capitals" even if they are not administrative capitals of regions. From the statistical viewpoint they are classified at both NUTS-5 and NUTS-4 levels. When investigating the expenditure efficiency of such units, it is therefore possible to take into account both commune and county tasks.

One of the fundamental assumptions of DEA is that the set of units to be analysed should be a homogeneous group (Domagała 2007), to avoid comparing inherently different objects. Therefore, Warsaw was excluded from the study, since it performs the tasks of the state capital in addition to commune and county responsibilities. Taking into account the basic homogeneity criteria concerning the similar nature of activities and tasks performed, equal access to resources and functioning in comparable environments (Dyson 2001), the cities with county rights included in the study are a homogeneous group.

Selection of variables

Keeping in mind the purpose of this study the total expenditures [PLN] per resident were selected as the input (I). To identify the measures enabling evaluation of the efficiency of public funds spending by local government units, quality of life indicators can be employed and these were used to determine the results. For this purpose, indicators (Tab. 1) were selected within the areas suggested by P. Liao (2009) to reflect the characteristics of these areas.

The figures used in the study were sourced from the Local Data Bank. Mean values for the 2010–2014 period were applied to ensure an objective character of the measures used. Two exceptions are the O5 and O6 indicators, available at NUTS-4 level only for the 2012–2014 period.

Table 1: Output indicators representing quality of life areas

Symbol	Area	Indicator
O1	Medical services	Number of beds in general hospitals [per 10,000 residents]
O2	Domestic finances	Mean gross monthly salary [per resident]
O3	Work	Proportion of employed people in the working age population [%]
O4	Education	Number of students awarded the secondary school leaving certificate out of the total number of exam takers [%]
O5	Leisure	The area of sport and leisure areas out of the total survey area [%]
O6	Public safety	Crimes confirmed in completed pre-trial criminal proceedings [%]
O7	Environmental quality	Purified sewage [dam^3/100 km^2]

Source: Own calculations

The set of variables selected meets the uniform preference trend condition, i.e. an increase of output will be considered favourable, whereas an increase of input with constant output will be regarded as undesirable. The results of the analysis indicating a low correlation between the variables confirm the possibility of using the selected indicator set in further investigations.

Model Selection

There are numerous DEA models available, meeting different analysis needs (see Cook and Seiford 2009). The most common, basic models include CCR (short for the names Charnes, Cooper and Rhodes), assuming constant returns to scale (Charnes et al. 1978), and BCC (short for the names Banker, Charnes and Cooper) with variable returns to scale (Banker et al. 1984). When these models are used, the maximum efficiency (equal to 1) is usually achieved by more than one DMU, which limits the possibility of comparing efficient units. To remedy this shortcoming, P. Andersen and N. Petersen developed the super-efficiency model, where a ranking of efficient DMUs can be created by assigning to them efficiency scores greater than 1 (Andersen and Petersen 1993). The aforementioned models are of the radial type, assuming a proportional change of inputs and outputs. Because of this, they do not take into account deficiencies in the form of slacks, while allowing zero weights (measures of significance) within inputs and outputs, which in turn may lead to a situation where some variables are not included in the determination of the efficiency score of a particular DMU.

For the purpose of this study, to enable full comparison, including between efficient DMUs, while taking into account the significance of all inputs and outputs, the authors decided to use the Super Slacks Based Measure (Super SBM) proposed by K. Tone (2002), which, assuming constant returns to scale and an input-oriented approach, is expressed as follows:

$$\min \delta = \frac{1}{\frac{1}{s}\sum_{r=1}^{s} \bar{y}_r / y_{r0}}$$

subject to:

$$\bar{x} \geq \sum_{j=1,\neq 0}^{n} \lambda_j x_j$$

$$\bar{y} \leq \sum_{j=1,\neq 0}^{n} \lambda_j y_j$$

$$\bar{x} = x_0, \qquad \bar{y} \leq y_0, \qquad y_0 \geq 0, \qquad \lambda \geq 0$$

The model orientation is an important feature relating to inputs and outputs. An input-oriented model aims to minimise the inputs incurred while assuming constant outputs, whereas an output-oriented model maximises the outputs given a constant level of inputs (Cooper et al. 2007). In view of the fact that local government units, by appropriate adjustment of their policies, have a greater potential to maximise the results of their activities than to directly influence the resources they have at their disposal, an output-oriented model was adopted. Therefore, further considerations are based on the assumption of constant budget expenditures per resident and the objective of maximising performance results that enhance the living conditions and quality of life.

Fig. 1: Distribution of efficiency scores

Source: Own calculations

Calculation and Results

Calculations were made using MaxDEA Ultra 6.11 software. Calculation results suggest that the efficiency scores of the units investigated range between 0.103 and 1.119, and the mean score is 0.557. Fourteen cities out of 65 DMUs were rated as efficient. As regards the remaining (inefficient) ones, a remarkable fact is that only 4 cities achieved a score between 0.7 and 1, as shown in Fig. 1. Thus, there is a clear division between the efficient and inefficient units. Most of the inefficient units attained a score between 0.289 and 0.685.

All the 14 efficient cities with county rights and the same number of least efficient units with their efficiency scores are presented in Tab. 2. Eight out of the 14 efficient units, i.e. more than half, are situated in the Upper Silesian metropolitan area. One of them is Katowice – the capital of the Silesian Province, where the aforementioned metropolitan area is located and winner of a national quality of life ranking created by the Polish edition of Newsweek magazine. It could be proposed that the proximity of urban centres that cooperate and compete with each other contributes to the higher efficiency. This concept, known as the cluster theory, is widely known and well-grounded in theory and practice, although mainly with respect to businesses (e.g. Engel 2015).

Table 2: Efficiency scores of the budget expenditures of Polish cities with county rights – the most and least efficient units

Rank	DMU	City	Efficiency	Rank	DMU	City	Efficiency
1	DMU17	Chorzów	1.119	52	DMU3	Skierniewice	0.298
2	DMU3	Kraków	1.074	53	DMU5	Radom	0.296
3	DMU13	Piekary Śląskie	1.049	54	DMU48	Koszalin	0.296
4	DMU23	Jastrzębie-Zdrój	1.049	55	DMU4	Ostrołęka	0.289
5	DMU18	Katowice	1.046	56	DMU53	Wałbrzych	0.250
6	DMU22	Świętochłowice	1.043	57	DMU39	Łomża	0.237
7	DMU56	Bydgoszcz	1.037	58	DMU63	Sopot	0.227
8	DMU28	Sosnowiec	1.020	59	DMU2	Piotrków Trybunalski	0.203
9	DMU11	Bielsko-Biała	1.014	60	DMU26	Dąbrowa Górnicza	0.190
10	DMU34	Krosno	1.012	61	DMU25	Żory	0.190
11	DMU47	Poznań	1.011	62	DMU40	Suwałki	0.168
12	DMU30	Biała Podlaska	1.005	63	DMU62	Gdynia	0.166
13	DMU54	Wrocław	1.004	64	DMU50	Świnoujście	0.128
14	DMU21	Siemianowice Śląskie	1.002	65	DMU37	Tarnobrzeg	0.103

Source: Own calculations

The capitals of provinces in the south and west of Poland are also efficient units. This suggests a potential link between the unit's location in the European area and its efficiency level, which was also noted in the Finnish study (Moisio and Uusitalo 2013). Meanwhile, inefficient units are characterised by relatively small populations, as presented in Fig. 2. It could be concluded from the graph that efficiency increases with increasing population, which confirms hypothesis 1. High efficiency is a feature of the largest Polish cities, such as Cracow, Wrocław, Poznań or Katowice, as mentioned above. B□□d o□ □□mpl□ of 65 ob□rv□tio□, □po□itiv□, mod□r□t□ li□□r r□l□tio□hip w□□obt□i□□d; th□ correlation coefficient of 0.3820 proved to be of high statistical significance (p<0.01). The studies quoted earlier also pointed to a similar relationship, which confirms the existence of economies of scale (lo□torto 2013; □ou□□□d □tošić 2005).

The second hypothesis is verified by demonstrating a relationship between efficiency and public expenditures per resident. It is of significance because the model analysed used total expenditure per resident as the input and assumed it to be constant while aiming to maximise the outputs, being the effects of activities resulting from local governments' expenditure policies, which was the basis for efficiency measurement. Based on the sample of 65 observations, a negative, moderate linear r□l□tio□hip w□□obt□i□□d; th□ □orr□l□tio□ □o□ffi□i□□t of -0.3525 proved to be of high statistical significance (p<0.01). These results are consistent with the findings of earlier studies examining a sample of large Polish cities (Sekuła and Julkowski 2015) and confirm hypothesis 2. This situation can be explained by more rational spending of resources where they are in shorter supply.

Fig. 1: Scatter plot – Population (in thousands) : Efficiency

Source: Own calculations

Conclusions

An efficiency ranking of cities does not answer the question how inefficient cities could improve their situation. For management purposes, the position relative to other cities is of less importance, but it is useful to know in which areas and to what degree efforts should be concentrated to improve efficiency and manage the city's policy with a view to improving the quality of life. This information is provided by variable projection, which is obtained by solving the DEA model. The first obvious conclusion is that there is considerable diversity in the mean values of the desired magnitude of changes as well as in the maximum values in the individual areas. This indicates that the recommended magnitude of changes aimed at improving efficiency and the significance of the individual factors/areas show large differences.

The greatest mean deviation between the initial and projected values (magnitude of change), equal to 931%, was observed with respect to variable O5: *The area of sport and leisure areas out of the total survey area*. According to the DEA model calculations, the share of recreational areas relative to the total survey area for inefficient cities should range between 3.1% and 27.1% (given the present actual share in the range 0.49–8.58%). A far smaller mean magnitude of change (229%) was observed with respect to variable O6. *Crimes confirmed in completed pre-trial criminal proceedings*. The greatest projected percentage increase applies to the city of Sopot, struggling with the problem of multitudes of tourists in the holiday season. An average magnitude of change exceeding 100% (equal to 136%) is also observed in the case of variable O7: *Purified sewage*. It applies to the natural environment area, which plays a major role in the improvement of the quality of life. Improvement of sewage treatment plant capacity is the responsibility of the commune authorities. In the remaining cases (O1, O2, O3,

O4) the projected changes do not exceed 50% on average, and the values of standard deviations are not so significant

Summary, Limitations and Further Research

The most important conclusions drawn from the research are as follows:

- an increase in efficiency is promoted by the vicinity of other units which offer cooperation possibilities, but also exert competitive pressure;
- the majority of the efficient cities with county rights are situated in the south-western part of Poland;
- the efficiency of budget expenditures is higher in larger cities with county rights (confirming the first hypothesis);
- the efficiency of budget expenditures is higher in cities with county rights where per capita expenditures are lower (confirming the second hypothesis);
- three out of seven result indicators (outputs) characterising the individual aspects of the quality of life – leisure, public safety and environmental quality – show a far higher mean magnitude of change, i.e. difference between the initial and projected values, than the remaining four indicators.

The conclusions drawn from the study focused on the investigation of the population of cities with county rights, and as such they are certainly of significance for the characterisation of such units as a group. Analysis focused on individual cities was not the purpose of this article.

It is necessary to bear in mind the relative character of DEA results, which entirely depend on the selected set of objects to be analysed and the defined set of variables. In this study, inefficiencies due to measurement errors, the presence of outliers, and other statistical discrepancies were not taken into account.

Further research into the area under discussion here should focus on the evaluation of changes in efficiency over time and identifying the factors determining such changes. Additionally, to enhance the objective character of the data representing the quality of life areas used as outputs, it is possible to use composite indicators, enabling a larger number of variables to be included in the analysis.

Acknowledgment

I would like to express my gratitude to Dr Andrzej Szuwarzyński, M.Sc. Bartosz Julkowski, for statistical advice.

Abstract

The main objectives of this paper are: to identify factors influencing safety culture and to discover and analyse the interaction among these factors using ISM. This research utilizes interpretive structural modelling as the methodology and framework to develop the relationships between the selected safety culture factors in two large companies operating in Poland. The proposed model provides a useful tool for enterprises to focus on those determinants of decision-making process that are most important for effective safety culture improvement. The authors used MICMAC analysis to classified variables involved in the study into five clusters: input variables, intermediate variables, resultant variables, excluded variables and clustered variables. This study highlights the benefits of an interpretive approach where interrelationships between safety culture factors can be modelled to demonstrate potential influence on other connected factors thereby, increasing the chances of safety improvements success.

Keywords: Safety Culture Management, Interpretive Structural Modelling (ISM), MICMAC

Introduction

Safety is one aspect among others that needs to be managed by organizations. Study on safety culture requires multidimensional approach and safety culture issues may vary based on country, geographic location within the country and organizational culture of the company. Lot of research has been carried out in the field of safety culture modelling. Some researchers did empirical studies and presented conceptual or theoretical models (Cooper et al., 2019; Waszkowski, 2019; Rubin et al., 2020).

In the literature, researchers indicate many techniques to use for modelling and multi criteria decision-making. Main of them, which allow for taking into consideration multiple decision criteria simultaneously, are Interpretive Structural Modelling (ISM), Analytic Network Process (ANP) and Analytic Hierarchy Process (AHP). ISM is a methodology for identifying and summarizing the

relationships among specific elements, which define a problem or an issue (Warfield, 1973). To the best of authors 'knowledge, this is the first study to examine the interrelationships between safety culture factors utilizing the ISM methodology.

The main objectives of this paper are: (1) to identify the key interrelationships between safety cultural factors based on empirical data via expert participant opinion; (2) to develop a model of the causal links between safety cultural factors to identify interdependencies in the context of driving and dependent factors; (3) to present a relationship driven architecture that can clearly identify how certain individual factors can affect and be affected by other factors in the model.

The rest of the paper is organized as follows. The next two sections deal with literature review for identifying the safety culture factors and ISM methodology. Section "Methodology" deals with the research methodology used to analyse the factors. MICMAC analysis of developed ISM model is carried out in this section. Finally, last section includes general conclusions with research findings, limitations and suggestions for future research.

Literature Review

Safety culture is just one of many within an overall organizational culture. Therefore, before continuing with review of a safety culture literature, it is necessary to understand what organizational culture is. Organizational culture comes from the external environment and the integration of an internal framework (Schein, 1990). According to Hopkins (2018) culture is a characteristic of a group, not an individual, and talk of culture must always specify the relevant group.

There are varying definitions of organizational culture (Sun, 2008). Frazier et al (2013) according to Kotter and Haskett (1992) indicate that stronger cultures that involve employees can affect the organization in three ways. "When goals of management and employees are united, each understands the necessity of their work to the organization. Thus, strong communication between management and employees is vital. Secondly, the motivation and "engagement" of employees can favourably affect business outcomes. Lastly, strong cultures enhance performance by supplying structure and control without the need of an overbearing establishment of rules and other formalities. All of these components can contribute to a positive safety culture as well".

Safety culture, like organizational culture, does not have a universal definition. Table 1 shows examples of safety culture definitions based on literature analysis.

Table 1: Safety culture definition

Author/s	Definition
International Atomic Energy Agency (1991)	"assembly of characteristics and attitudes in organizations and individuals which establishes that, as an overriding priority, [nuclear power] safety issues receive attention warranted by their significance"
Pidgeon (1991)	"set of roles, norms, technical, social, attitudes, and belief practices intended to minimize the exposure of the public, managers, employees, and customers to injurious or dangerous conditions"
NSAG (1996)	"an organizational atmosphere where safety and health is understood to be, and is accepted as, the number one priority"
Clarke (1999)	"values and beliefs of an organization that is specific to health and safety".
Cooper (2000)	"shared organizational beliefs, attitudes, values, and norms including attitudes associated with the proper conduct, danger, and risk of hazardous operations"
Guldenmund (2010)	an aspect that influences behaviour and attitudes related to decreasing or increasing risk
Antonsen (2017)	The safety culture term is a construct used to explain how internal organizational social environments directly influence organizational risk practices that could lead to personal injuries or catastrophic process safety disasters
Cooper (2018)	"social construct used by industry and academe to describe the way that safety is being managed in organizations to avoid catastrophes and personal injuries"

The above definition implies that safety culture is not a standalone concept and it is the reflection of shared values, beliefs, attitudes, and perceptions manifested in the employee perception of environmental safety and organizational characteristics that influence safety behaviours.

According to Cooper et al., (2019) the purpose of the safety culture construct is to reduce organizational and occupational accidents. Rubin et al., (2020) suggests that safety culture and climate variables operate as important predictors of risk-taking. According to Boughaba et al., (2014) the manager's commitment, the employees' involvement, and the safety management system are the key indicators of the safety culture concept. Cooper (2018) suggest that top management can positively influence an organizations safety culture by paying attention to the effectiveness of the development, execution, and performance of the safety management system, routine meetings with employees, and visiting various business units to discuss safety issues. An overview of the factors influencing safety culture by different authors is presented in Table 2.

Table 2: The factors influencing safety culture

Author/s	Factors
Flin et al., (2000)	management/supervisors, safety systems, procedures and rules, risk, work pressure, and competence
Studenski (2000)	attitude towards health and safety regulations and trust in their preventive role; superiors attitude towards subordinates taking risks; the attitude of employees towards risk-taking colleagues; attitude of superiors to employees who require meeting safety standards; attitude towards OHS training; prestige of services and rank of the OHS position; employers' involvement in the organization of safe working conditions
Mielczarek (2002)	management commitment; open and honest communication; employees participation; OHS education; accident analysis; motivating and strengthening of safe behaviour; cooperation between employees
Ejdys (2010)	an appropriate employee training system shaping their awareness; compliance with health and safety regulations by both employers and employees; visible signage system - communication routes, emergency exits, danger zones, rooms; safe working conditions; general order in the enterprise; OHS procedures and instructions valid in the company; personal protective equipment used by employees; preventive measures taken (medical examinations); ensuring technical safety of machines and devices; liability of the employer and employees for health and safety matters; low accident rate; control system existent in the organization
Frazier et al., (2013)	supervisor concern, senior management concern, work pressure, supervisor/management blame, risky behaviour, incident reporting, caution others, respectful feedback, communication, training, discipline, rewards and recognition
Boughaba et al., (2014)	safety communication; safety incentives; safety manager's attitude; safety manager's behaviour; safety compliance; safety policy; safety participation; safety rules and procedures; safety training; safety worker's involvement
Cooper (2018)	management/supervision; safety systems; risk; work pressure; competence; procedures and rules

A good/poor safety culture affects all managerial aspects of Occupational Safety and Health. It has been stated elsewhere in the literature that organizations with good safety culture have lower accident rates than those with weak safety culture (Stemn et al., 2019).

Interpretive Structural Modelling (ISM)

The concept of Interpretive Structural Modelling (ISM) was primary introduced by J. Warfield in 1973. According to Malone (1975) ISM "is used to refer to the systematic application of some elementary notions of graph theory in such a way that theoretical, conceptual, and computational leverage is exploited to efficiently construct a directed graph, or network representation, of the complex pattern of a contextual relationship among a set of elements". ISM process transforms unclear, poorly

articulated mental models of systems into visible, well-defined models useful for many purposes (e.g. Vinodh et al. (2016; Attri et al., (2017); Li et al., 2019).

To get the model, there are several steps in adopting the ISM technique (Kannan et al. 2009):

Step 1: Variables affecting the system under consideration are listed.
Step 2: From the variables identified in step 1, a contextual relationship is established among variables with respect to which pairs of variables would be examined.
Step 3: *3*Astructural self-interaction matrix (SSIM) is developed for factors, which indicates pair-wise relationships among factors of the system under consideration.
Step 4: A reachability matrix is developed from the SSIM and the matrix is checked for transitivity. The transitivity of the contextual relation is a basic assumption made in ISM.
Step 5: The reachability matrix obtained in Step 4 is partitioned into different levels.
Step 6: Based on the relationships given above in the reachability matrix, a directed graph is drawn and the transitive links are removed.
Step 7: The resultant digraph is converted into an ISM, by replacing variable nodes with statements.
Step 8: The ISM model developed in Step 7 is reviewed to check for conceptual inconsistency and necessary modifications are made.

Although not a formal element in the ISM process, many studies develop an additional step to derive the Matrics d'Impacts Croises-Multiplication Applique a Classment (MICMAC) analysis after the canonical form step. The MICMAC step is included in this study.

Methodology

Introduction of the Object of the Research

The current study tackles an assessment of relationship among selected factors of safety culture by applying an Interpretive Structural Modelling (ISM). The research was conducted in two large companies (Company A and Company B) operating in Poland. Company A belongs to the automotive industry. Its customers are world leaders in the automotive industry such as Volvo, Ford and Mercedes. The company works on the basis of lean manufacturing principles, uses such improvement tools as e.g. 5S, SMED. Improvement activities (Kaizen events) concern all areas of the company's operation, including the area of occupational health and safety. In 2016, the company received the Best Global Performance Award. The second company (Company B) products furniture. For more than 10 years, the company has been implementing the IWAY Standard, concerning minimum requirements for working conditions, social conditions and environmental protection. IWAY Standard is based on eight main conventions defined in the Basic Principles of Labor Law, the ILO Declaration of June 1998 and the Ten Principles of the UN Global Compact of 2000. In addition, the company has introduced ISO 9001 and ISO 14001.

Selection of Factors

The authors of the paper and eight industry professionals of SHE department were consulted to confirm the factors influenced on safety culture. Based on the analysis of the literature (section "Literature review" and taking into consideration the opinions of experts, 10 factors were selected (Table 3).

Table 3: The list of important factors identified by experts and influencing safety culture

No.	Factor	Description
F1.	Management commitment	The management is personally involved in employee safety issues, shows interest in the state of OSH in the company. Defines and allocates financial resources as required. Investing in security measures ensuring, among others, employee comfort.
F2.	Employee engagement	Employees provide information on existing threats and cooperate with management, suggest improvement actions and actively participate in their implementation.
F3.	Trust between managers and employees	Managers treat employees with respect, keep their promises and encourage mutual trust and support. Employees respect the orders of their superiors and follow their recommendations.
F4.	Attitudes towards OHS regulations	A sense of personal responsibility for the safety of each employee, attitude to health and safety regulations and compliance with them.
F5.	Communication	Free and open communication in the enterprise. Informing clearly about safety aspects such as occurring threats, occupational risk, and safety prevention. Using various forms of communication, e.g. information meetings, materials in the form of brochures, posters and instructions.
F6.	Education on OHS	Health and safety training, which are adapted to the specifics of the work (on-the-job training) and hazards occurring at the workplace. In addition, promoting safe behaviour through educational campaigns, posters and practical exercises
F7.	Rewards and Recognition	Encouraging employees to perform work safely, by rewarding (approving, praising) correct behaviour.
F8.	Analysis of accidents	Reporting accidents and near misses and their analysis, taking into account the causes and effects of accidents, initiating corrective and preventive actions.
F9.	Monitoring employees behaviour	Monitoring the state of safety and supervision over the way work is performed (e.g. the use of protection measures and detection of potential problems).
F10.	Employees' competences	Assigning tasks to employees with appropriate knowledge, skills and education. Training in given positions must be carried out by persons who have properly documented competences.

Development of structural self-interaction matrix (SSIM)

The next step is to analyse the interrelationship between these factors using ISM. ISM methodology suggests the use of the expert opinions. The expert participants from company A and company B were tasked with identifying all pairwise relationships between the factors.

''Leads to'' or ''influences'' type of contextual relationship was chosen for analysing factors of safety culture. Considering this as a basis, the contextual relationship amongst factors is developed. Four symbols were used to denote direction of relationship between the factors (i and j): V: factor i influences factor j; A: factor i is influenced by factor j; X: factor i and j influence each other; O: factor i and j do not influence each other, since they are unrelated. Using experts' expertise, in each of two enterprises the SSIM was developed (Table 4).

Table 4: Structured Self Interaction Matrix (SSIM) – Company A and Company B

Company A

Factors Fi →	Factors Fj→									
		2	3	4	5	6	7	8	9	10
1	X	X	A	X	A	A	X	A	A

3			X	X	O	O	X	A	V	

Company B

Factors Fi →	Factors Fj→									
		2	3	4	5	6	7	8	9	10
1	X	X	A	X	A	A	O	A	A	
2		X	A	X	V	X	X	O	X	
3			A	X	O	V	X	A	V	

4				A	X	X	A	A	O		**4**				V	A	V	O	V	A
5					X	V	X	O	V		**5**					X	X	X	X	X
6						X	A	O	A		**6**						X	X	O	X
7							A	V	O		**7**							A	X	O
8								X	O		**8**								X	O
9									V		**9**									V

The initial reachability matrix is obtained from SSIM by transforming information of each cell of SSIM into binary digits (i.e., 1 or 0). The substitution of 1s and 0s are as per the following rules: (1) If the (i, j) entry in the SSIM is V, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry becomes 0; (2) If the (i, j) entry in the SSIM is A, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry becomes 1; (3) If the (i, j) entry in the SSIM is X, the (i, j) entry in the reachability matrix becomes 1 and the (j, i) entry also becomes 1; (4) If the (i, j) entry in the SSIM is O, the (i, j) entry in the reachability matrix becomes 0 and the (j, i) entry also becomes 0. Following the above rules, the initial reachability matrix was prepared (Table 5).

Table 5: Initial Reachability Matrix (IRM)

Company A

Factors Fi →	Factors Fj→ 1	2	3	4	5	6	7	8	9	10
1	1	1	1	0	1	0	0	1	0	0
2	1	1	1	1	1	1	1	1	1	1
3	1	1	1	1	1	0	0	1	0	1
4	1	0	1	1	0	1	1	0	0	0

7	1	0	0	1	0	1	1	0	1	0
8	1	1	1	1	1	1	1	1	1	0
9	1	0	1	1	0	0	0	1	1	1
10	1	1	0	0	0	1	0	0	0	1

Company B

Factors Fi →	Factors Fj→ 1	2	3	4	5	6	7	8	9	10
1	1	1	1	0	1	0	0	0	0	0
2	1	1	1	0	1	1	1	1	0	1
3	1	1	1	0	1	0	1	1	0	1
4	1	1	1	1	1	0	1	0	1	0
5	1	1	1	0	1	1	1	1	1	1
6	1	0	0	1	1	1	1	1	0	1
7	1	1	0	0	1	1	1	0	1	0
8	0	1	1	0	1	1	1	1	1	0
9	1	0	1	0	1	0	1	1	1	1
10	1	1	0	1	1	1	0	0	0	1

To get final reachability matrix (FRM), the concept of transitivity was introduced, and some of the cells of initial reachability matrix were filled by inference. If a factor 'i' is related to 'j' and 'j' is related to 'k', then transitivity implies that factor 'i' is necessarily related to 'k'. The final reachability matrix is developed after incorporating transitivity concept (Table 6). The completed FRM was assessed based on the reachability and antecedent sets for each of the variables in the matrix (Warfield, 1974). The reachability set R(Pi) consists of the element itself together with other elements which it may help to achieve. The antecedent set A(Pi) consists of the element itself and other elements which may help in achieving it. Table 7 shows the canonical form of the FRM matrix.

Table 6: Final Reachability Matrix (FRM)

Company B	**Factors**	**Reachability set R(Pi)**	**Antecedent set A(Pi)**	**Intersection set**	**Level**
	F1	1,2,3,5	1,2,3,4,5,6,7,8,9,10	1,2,3,5	I
	F2	1,2,3,5,6,7,8,10	1,2,3,4,5,6,7,8,9,10	1,2,3,5,6,7,8,10	I
	F3	1,2,3,4,7,8,10	1,2,3,4,5,8,9	1,2,3,4,8	IV
	F4	1,2,3,4,5,7,9	4,6,10	4	VI
	F5	1,2,3,5,6,7,8,9,10	1,2,3,4,5,6,7,8,9,10	1,2,3,5,6,7,8,9,10	II
	F6	1,2,4,5,6,7,8,10	2,5,6,7,8,10	2,5,6,7,8,10	IV
	F7	1,2,5,6,7,9	2,3,4,5,6,7,8,9	2,5,6,7,9	II
	F8	2,3,5,6,7,8,9	2,3,5,6,8,9,	2,3,5,6,8,9	III
	F9	1,2,3,5,7,8,9,10	4,5,7,8,9	5,7,8,9	V
	F10	1,2,4,5,6,10	2,3,5,6,9,10	2,5,6,10	IV

The canonical form is a restructured version of the FRM where the factors are grouped to align with the level partition stage. The *Level* column in the table highlights the implicit ordering that will be represented in the final ISM diagram denoting the dependent and driving attributes of each of the factors.

MICMAC Analysis

The MICMAC system is a specialized computer program developed by M. Godet (2011), serving as a tool for structural analysis. The use of the MICMAC program allows the analysis of complex systems with many driving forces, enabling the transition from a comprehensive mapping of the system to its simplified form. The major highlight of the ISM–MICMAC approach is that, it helps to analyse the problem situation through graphical representation and structured model (Singh 2015). In MICMAC analysis, variables involved in the study are classified usually into four clusters: (1) autonomous factors; (2) dependent factors; (3) linkage factors and (4) independent factors. However, in this study, the authors used five clusters according to Godet and Durance (2011): (1) input variables; (2) intermediate variables; (3) resultant variables; (4) excluded variables and (5) clustered variables.

The MICMAC program determines the strength of direct and indirect interactions between factors based on a previously defined matrix of direct influences. The direct influence matrix is transformed into a graph whose vertices correspond to individual factors. The direct influence / dependence map and direct influence graph for Company A and Company B is drawn as shown in Fig. 1. This figures was prepared with MICMAC software (http://en.laprospective.fr).

Fig. 1: MICMAC graph for Company A and Company B

The MICMAC diagram presented in Fig.2 highlights the driving and dependence attributes of the safety culture factors respectively for Company A and Company B.

Fig. 2: MICMAC diagram

More details about clusters and its characteristics for both companies are provided in Table 8.

Table 8: Clusters and its characteristics

No	Clusters	Characteristics (Godet and Durance, 2011)	Safety culture factors
1	Input variables	These variables are highly influential and also independent. They tend to describe the system under study and condition the system's dynamics. When at all possible, these variables should be a priority when considering strategic plans of action	**Company A** F5 Communication F8 Analysis of accidents
			Company B F6 Education on OHS F8 Analysis of accidents F9 Monitoring employees behaviour
2	Intermediate variables	These variables are both highly influential and highly dependent. Thus, they are, by their nature, unstable. Any action taken on these variables will cascade throughout the rest of the system, profoundly affecting the system's dynamic.	**Company A** F2 Employee engagement
			Company B F2 Employee engagement F5 Communication
3	Resultant variables	These variables are not influential but very dependent. Their behaviour explains the impacts coming from other variables, principally input and intermediate variables.	**Company A** F1 Management commitment F4 Attitudes towards OHS regulations
			Company B F1 Management commitment F7 Reward and recognition
4	Excluded variables	These variables are neither influential nor dependent. They have little impact on the system under study. Often these variables simply describe inertial or prevailing trends, which change little over time. Sometimes, these variables are simply autonomous, and therefore have little impact on the system.	**Company A** F7Reward and recognition F10 Employees' competences
			Company B **------**

		Excluding these variables will therefore have few consequences for analysis.	
5	Clustered variables	These variables tend to congregate together. They are not sufficiently influential or dependent to be included among the previous classifications. We cannot draw any definitive conclusions about these variables and their impact on the system	**Company A** F3 Trust between managers and employees F6 Education on OHS F9 Monitoring employees behaviour
			Company B F3 Trust between managers and employees F4 Attitudes towards OHS regulations F10 Employees' competences

The presented studies were treated as preliminary, and their result was to determine further directions of analyses. The conclusions drawn should be treated with some caution. Nevertheless, some regularities are worth noting.

In both companies, the factor F10 "*Employees' competences*" is underestimated as development indicators. In Company A, this factor is clearly classified as "Excluded", in Company B it is part of the "Clustered" set. This may mean that competences are treated as so-called "Must have", which is something that must be met for legal reasons, but their usefulness or potential for the development of a culture of security in the enterprise is not further considered. In both companies in the "Resultant variables" cluster, F1 "Management Commitment" found the result variables as an indicator of the OHS policy measure. Nevertheless, depending on the company, the second indicator of measure was factor F4 "*Attitudes towards OHS regulations*" (Company A) or factor F7 "*Reward and recognition*" (Company B). This may indicate two trends in treating health and safety matters: as a "punishment or reward" - that is, forcing certain actions by rewarding employees (Company B) or shaping employee awareness and engaging them in actions based on understanding the needs and acceptance of a given policy (Company A). The set of influence variables in both companies includes factor F8 "*Analysis of accidents*". This seems a natural situation - both companies are production companies and despite the fact that they operate in different industries and different conditions, this indicator is associated with the technical conditions and causes of accidents. Next, there is the difference in the "Input variables" cluster: factor F5 "*Communication*" (Company A) and factor F6 "*Education on OHS*" and F9 "*Monitoring employees behaviour*" (Company B). These sets of tools shaping health and safety policy in these companies harmonize with the measures of the result, reinforcing the thesis about the strategy adopted in the companies. In this case, it is natural to place in both companies the F2 variable "*Employee engagement*" in the group of "Intermediate" variables, i.e. those that are a policy implementation tool - they are influenced by input variables and shape other groups of variables. The "location" of factor F5 is also right: in Company A, factor F5 "*Communication*" is an input tool for policy implementation, in Company B an indirect tool - through the motivation system, employees are encouraged to communicate, hoping that this will shape the culture of security.

Conclusions

Research Findings and Implications

This study indicates that adopting an ISM-based approach can help in deeper understanding of the correlations between the factors of security culture in an enterprise, and thus support managers in the decision-making process and the implementation of the basic goal of reducing organizational and occupational accidents.

The construction of a positive safety culture is not easy, and it is not universal. Something that works well in one organization may not work in another. Adjustments will need to be made depending on the resources available and the goals of the different organizations.

Limitation and Suggestions for Future Research

First, study on safety culture is a multidimensional concept. The safety culture issues may vary based on country, geographic location within the country and organizational culture of the company. In addition, as the research focuses on two large companies operated in Poland, the findings are not universally applicable across different sectors or in different countries. In this study are investigated only selected factors of safety culture in enterprises experts' opinion. There are many other areas of challenges in this area and future research should investigate the relationships between other dimensions of this concept. Second, the ISM model was developed using the experience and judgements of the expert team, which represents an element of bias. Finally, the model has not been statistically validated.

Nevertheless, the findings suggest that the safety culture survey is an interesting theme for future research. A number of research propositions may be proposed that would be appropriate for further study and research concerning the modelling the safety culture factors using various modelling techniques like AHP, ANP, etc.. Research work in this area may act as a roadmap for safety culture improvement in enterprises.

Abstract

The article provides an overview of key national model of socially responsible behaviour of businesses, defined the role of government and the degree of regulation of corporate social responsibility in different countries. The features of the formation of the Russian model of corporate social responsibility. The different types of models that combine national models of countries and their comparative analysis on the following criteria: the main factor in the development of social responsibility of business entities, the basic stakeholders, financial reporting, cooperation with non-profit organizations, the legal framework of corporate social responsibility.

Keywords: socially responsible behaviour of businesses; the model of socially responsible business conduct.

Introduction

Current changes in Russia are tending to strengthen a social orientation of the market economy. The government priority programmes and the strengthening of social partnership gaining resonance among the public bear witness to the mainstreaming of the problem concerning the development of civil society and socially responsible corporate behaviour in the first place. Meanwhile, one of the primary factors determining the prospects of the Russian society and nationhood is the culture of the relationships between the state, business and society, rather than politics or even economy *(Yakimets, 2005)*.

In many countries across the world, these relationships represent a powerful tool for developing economic systems and solving social problems. A lengthy and continuous capitalist development process in the Western countries created a sophisticated and well-balanced regulation system for the relationships of private business, government agencies and society in the area of socio-economic development of the countries and individual territories *(Yakimets, 2005)*.

Corporate Social Responsibility: The Background

The problem of social responsibility as it concerns different agents has been addressed by a variety of academic disciplines: philosophy, sociology, management, law and economics. Said disciplines provide a multifaceted and ambivalent interpretation of the "social responsibility" concept as a derivative of the "responsibility" concept.

Social philosophy normally approaches social responsibility from the perspective of "social justice", "social inequality", "freedom", "power" or "social power", "tolerance", "violence", "harmony", "justice and equality". According to the approach practised in philosophy, the concept of "social responsibility" is treated as the flip side of "freedom" and is subordinated to such categories as freedom and necessity whose status is more generic. According to philosophers, the more freedom a person enjoys, the greater the responsibility vested therein. Social responsibility is a necessary condition for social and personal freedom. The agents of responsibility may be the society as whole or specific social institutions including teams, families, groups and individuals constituting the elementary units of responsibility *(Ladykina, 2015)*.

From the standpoint of sociological analysis, the concept of "corporate social responsibility" is a sub-type of "social responsibility" defined by the peculiarities of the social responsibility agent, i.e. business, and its proactive and transformative role in the society. Social responsibility arises as an indispensable condition for interaction between individuals or groups and the other social groups. For instance, the sociological dictionary *(Kravchenko, 2004)* defines social responsibility in a broader sense, specifically as 'certain expectations of the immediate social environment from the individuals and public organisations on the one hand, and their awareness of their obligations to the society, team and individuals on the other' (p. 268). Therefore, sociologists deem social responsibility to be defined by internal awareness and internal motivation manifested through assumption of certain ethical obligations. Furthermore, as contrasted with the other types of responsibility, social responsibility is not necessarily characterised by a vertical hierarchy associated with performance of certain obligations. It also includes horizontal ties integrating the components of public life with closer and more informal links. As noted in the Russian Sociological Encyclopaedia *(Osipov, 1998)*, social responsibility arises from social norms and fulfils itself both through the forms of social control (public opinion, charter, law), and through social agents' awareness of their social role. Social responsibility in the narrow sense refers to the realm of social welfare, the immediate living environment of the people and satisfaction of their diverse social needs *(Osipov, 1998)*.

Economists appropriated "social responsibility" as a research subject much later and normally addressed it at the intersection of ethics, morality and economics. It is believed that the traditions of social responsibility originate from England and date back to the 17th-19th centuries depicted as a period of cardinal changes in the economic paradigm. The idea of socially responsible corporate behaviour was shaped by A. Smith and his followers. As he analysed ethical standards, A. Smith largely framed the future study of the problem. According to A. Smith (1993), the society functions in accordance with certain unobserved but natural process binding private and public interests together. It is notable that the nature of the factors underlying this process was not been clearly identified.

D. Ricardo's (1955) approach to the issue of whether the business or the public interests should be prioritised was free of the mysticism so typical of A. Smith's approach. D. Ricardo declared his ethical position when he came up with a criterion for distributing profits. In D. Ricardo's view (Ricardo, 1955), this criterion is social justice: "... Independently of the consideration of the discovery and use of machinery, ... the labouring class have no small interest in the manner in which the net income of the country is expended, although it should, in all cases, be expended for the gratification and enjoyments of those who are fairly entitled to it" (p.186). This quote illustrates D. Ricardo's idea according to which an equitable distribution of profits does not go well with the utilitarian principles of classical political economy and is just indirect evidence confirming the relevance of the ethical factor for the economy. During D. Ricardo's times, the methods of implementing social justice in practice did not go beyond speculation.

Contemporary researchers note that despite the incorporation of the ethical factor in A. Smith's and D. Ricardo's works, it is hard to identify any evidence of a detailed and well-balanced analysis. Meanwhile, we should highlight that even the fathers of the bourgeois political economy incorporate the prerequisites for the development of the socially responsible corporate behaviour concept in their works.

Throughout the entire 19th and in the early 20th century, the problem of balance between the interests of the society as a whole and of its specific members – social groups and individuals – was the prime focus of such prominent thinkers as R. Owen, A. Carnegie, H. de Saint-Simon, A. Comte, M. Weber, W. Sombart, T. Veblen, V. Pareto, J. Galbraith, H. Gantt, O. Tead, etc.

Many researchers name A. Carnegie's *The Gospel of Wealth* published in 1889 as the landmark work spearheading a serious debate about the phenomenon of socially responsible corporate behaviour. A. Carnegie *(Carnegia, 1995)* views a properly shaped philanthropic policy intended to make up for the true unfairness of wealth distribution in the society and ease the tensions between the rich and the poor as a real alternative to revolutionary programmes. The business community did not give a particularly warm welcome to A. Carnegie's ideas. Nonetheless, a combination of public pressure, resounding exposures of fraud and instances of tax evasion forced the business elite to reconsider their approach to social responsibility in the future.

In the first third of the 20th century, a number of works were published in the United States that created the foundations for the concept of socially responsible corporate behaviour. Publication of these works was due to the aggravation of antagonisms between various social groups in the form of protests, strikes, racial and student unrest during this period, in a word – growing instability, which raised the problem of respect for the public interest once more. Thus, in the 1930s, *The Modern Corporation and Private Property* by economists A. Berle and G. Means *(Berle and Means, 1991)* generated widespread interest and played an important part in the development of the present-day concept of socially responsible corporate behaviour. This study defines the key idea concerning the prerequisites for the survival of a business corporation.

A. Berle and G. Means' ideas were developed further by German researcher A. Müller-Armack *(Kozlowski, 1999).* He insisted on a compromise between the requirements of private ownership, competition and free pricing on the one hand and social justice on the other to be secured through government and public regulation. The political will to accept the concept of socially responsible corporate behaviour was expressed by the prominent German post-war reformer L. Erhard stated: "I am addressing the major responsible businesses controlling the production tools and national wealth distribution machinery and I am raising the strongest possible demand to take the highest toll and to be most conscious of their responsibility" *(Erhard, 1991, p.131).*

One of the first fundamental works on corporate social responsibility (hereinafter referred to as CSR) was H. Bowen's *Social Responsibilities of the Businessman* published in 1953. According to H. Bowen *(Bowen, 1953)* often referred to as the father of this concept, the social responsibility of the businessman is to implement such a policy, make such decisions or to follow such a course that would be desirable from the standpoint of social values and public objectives. H. Bowen's works largely determined the ensuing debate on CSR, but they lacked the arguments to defend the concept of socially responsible corporate behaviour.

M. Friedman and T. Levitt are most often mentioned as the main opponents of this concept in the literature. Specifically, in *The Dangers of Social Responsibility* (*Levitt, 1958*), T. Levitt treats the increasing focus of business on local community development as a "new orthodoxy", "new feudalism" and even "fascism" that will inevitably lead to the death of capitalism. In his study *Capitalism and Freedom*, M. Friedman (1962) claims that "a few trends could so thoroughly undermine the very foundations of our free society as the acceptance by corporate officials of a social responsibility other than to make as much money for their stockholders as possible" (p.133). In a later study *The Social Responsibility of Business is to Increase its Profits,* M. Friedman came up with

more sophisticated arguments (*Friedman, 2007*). Specifically, he referred to the managers advocating and applying the concept of social responsibility as to "thieves of their owners' money".

Corporate Social Responsibility: Basic Theories

As for the concept of corporate social responsibility, the toolkit of present-day economics includes multiple theoretical concepts reflecting various aspects of the problem under consideration. A major contribution to the analysis and systematisation of knowledge on the genesis of the concept of socially responsible corporate behaviour in the Russian academic literature has been made by Yu.E. Blagov *(Blagov, 2014)*. The basic theories are depicted in Table 1.

Table 1: basic theories of socially responsible corporate behaviour

Basic theories of socially responsible corporate behaviour	Key ideologues	Definition of socially responsible corporate behaviour under a given theory	Essence of the approach
Corporate social responsibility concept	H. Bowen (1953) K. Davis (1960) J. McGuire (1963) S. Sethi (1975) A. Caroll (1979)	H. Bowen is the author of the definition most typical of this concept - The social responsibility of the businessman is "to implement such a policy, make such decisions or to follow such a course that would be desirable from the standpoint of social values and public objectives.	The normative and declarative nature of the approach provided an excessively wide interpretation of CSR definition. Further development of the concept in A. Caroll's pyramids made it possible to systematise the normative approach by identifying economic, legal, ethical and discretionary responsibility (Fig. 1)
Corporate social sensitivity concept	R. Ackerman (1976) W. Frederick (1978) J. Pos (1978)	Social responsibility is treated as the first stage in the development of the social sensitivity concept that "describes a corporation's capacity to be sensitive to the public influence" (Frederick, p.6)	Logical development of the social responsibility concept addressing the use of CSR at the level of a single firm. Positive approach
Stakeholder theory, stakeholder concept	E. Freeman (2004) T. Donaldson D. Preston (1995) M. Clarkson (1995)	Socially responsible behaviour is treated as a leverage to influence the stakeholders.	This theory envisages certain cooperation with all the stakeholders. Companies' objectives should recognise the diverse interests of various parties that will represent a certain type of an informal coalition
Corporate social activity concept	E. Epstein (1987) W. Frederick S. Sethi (1975) S. Wartick& F. Cochran (1985) W. Wood	Social responsibility is defined as "related primarily to such outcomes of organisational decisions that under certain normative standards produce more of a	According to S. Sethi (1975), the essence of "corporate social activity" is corporate behaviour segregated into performance of "social obligations" assumed as a response to the action of "market forces and legal restrictions", fulfilment of "social

	(1991)	positive rather than negative effect on the stakeholders"	responsibility" in excess of stringent economic and legal obligations, as well as "social sensitivity" construed as the corporation's capacity to adapt its behaviour to public needs" (p.62).
Sustainable development concept	M. Van Marrwijk (2003) R. Steurer (2005)	Socially responsible corporate behaviour is construed as behaviour recognising the environmental, economic, social and moral aspects of business	The concept of sustainable development is based on the understanding of the main task of development as "meeting the needs of the current generation without compromising the prospects of the future generations" (Steurer et al, 2005, p.263)
Corporate citizenship concept	D. Logsdon& D. Wood (2002)	Under the model of corporate citizenship, socially responsible areas of activities are treated as resources for improving economic efficiency and competitiveness	In order to implement the corporate citizenship model, a corporation will develop and implement socially responsible initiatives intended for specific parties involved. This kind of activities are defined as corporate social responsibility Corporate citizenship models prioritise the value orientation in the motivation of a company as a morally responsible community, a vehicle of a certain value system

(Source: compiled by the authors)

After systematising the basic concepts of socially responsible business, we were able to identify a number of scholars (including H. Bowen, C. Davis, P. French, R. Blomstrom, J. McGuire, S. Sethi) whose works would consistently add something new to the concept of corporate social responsibility. Without downplaying the importance of their works, a majority of contemporary researchers give most attention to A. Caroll's works. It was A. Caroll's approach that generated widespread interest due to the fact that it gives certain shape and coherence to the concepts of the authors mentioned above. Caroll's famous pyramid reflects the poly-agency of the interpretation applied to the corporate social responsibility of the business community. Interestingly, as A. Caroll *(Carroll, 1979)* consistently defined the levels of corporate social responsibility, he named discretionary responsibility quite relevant construing it as complementary will of the business manifested in the performance of social obligations beyond the legal requirements concurrently with the obligations prescribed by law (Fig 1).

Fig. 1: Multi-level responsibility
(Source: compiled on the basis Carroll, 1979)

Consequently, A. Caroll's and M. Schwartz offered a modified pyramid. In essence, we are talking about the inclusion of philanthropic responsibility in the categories of ethical and/or economic responsibility. According to A. Caroll's and M. Schwartz *(Schwartz& Carroll, 2003)*, such reclassification is due to the fact that first, philanthropic responsibility and ethical responsibility are oftentimes hardly discernible both in theory and in practice and second, philanthropy oftentimes relies on business interest directly. In other words, as they engage in "strategic philanthropy", businesses are often motivated by economic reasons based on their economic responsibility.

The above definitions of corporate social responsibility, even though they reflect the overall development logic of the corporate social responsibility concept, do not obviously cover the entire range of diverse approaches to the interpretation of corporate social responsibility. We believe that by comparing these different conceptual perspectives, it can be concluded that all of them are legitimate and reflect different aspects of the complex interconnections between the society, the state, politics and business.

The concept of socially responsible business and all subsequent modifications thereof as they currently exist were imported to Russia from Western economies in the late 1990s. But it would be a misstatement to say that they were borrowed completely. At the time, Russia has already accumulated its own experience in the area of interaction between business and society. This experience can definitely include traditional charity and patronage so common in Tsarist Russia and the social function of the core enterprises that is a true "relic of the Soviet era". It should also be noted that Russia, as opposed to the Western countries where all initiative in the area of socially responsible behaviour was virtually fully concentrated in the hands of the society, was characterised by state initiative.

Essence of Social Responsibility: The Russian Interpretation

Over the past 15 years, corporate social responsibility has been studied and analysed by such Russian scholars as Liborakina et al (2003), Turkin (2003), Kostin (2004), Yakimets (2005), Katyrin (2004) etc.

According to many researchers, the lack of a uniform terminology is among the most pressing problems in the field of corporate social responsibility. In a situation when there is no clear understanding of CSR, companies interpret both the components of corporate social responsibility and the phenomenon of sustainable corporate development differently. The other members of the society also diverge in their understanding of the terminology, as evidenced by the surveys of the population, managers and state figures conducted by the Russian Managers Association *(Litovchenko&Korsakova, 2003)*.

The peculiarity of CSR interpretation in Russia in the present-day context is that the definition of socially responsible business goes as far as to include the companies' capacity to pay salary to their employees and taxes in a timely manner. According to certain experts *(Litovchenko&Korsakova, 2003)*, this approach is typical for "the young, developing, emerging (about 10 years old) markets".

However, it should be noted that a growing number of companies treat social responsibility as ability and willingness of the business to address the issues directly associated both with the production and sale of goods and services and with the welfare of the country where the company operates.

According to S.A. Strizhov *(Strizhov, 2005)*, "the difference in the understanding of corporate social responsibility between the Russian and Western business communities is that in Russia, businesses normally make one-time projects (as a reputation management tool) the cornerstone of social responsibility and social accountability, while in the West, companies view social responsibility and accountability as a long-lasting continuing process of productive, mutually beneficial and sustainable interaction between the employer and all stakeholders: employees, customers, public organisations and regional government authorities" (p. 117).

According to The Concept of the Social State of the Russian Federation (2003), corporate social responsibility is defined as business' proactive involvement in the funding of social welfare in addition to the social welfare spending by the government. In our view, this definition reflects just one aspect of socially responsible corporate behaviour.

We fully agree with the opinion expressed in The Concept of the Social State of the Russian Federation according to which corporate social responsibility is manifested in the following areas:

- the market – fair pricing, high quality of goods and services, consumer safety and fair competition;
- the employee and the workplace – decent remuneration, occupational safety and health, equal employment opportunities, professional and career development, involvement in the company's operations;
- the environment – green production, lean consumption of natural resources and waste management;
- partnership with the society, state and territories;
- human rights understood as employee and citizen rights.

Meanwhile, it is hard to identify the specific objects of socially responsible corporate behaviour within this approach. There are other approaches to the definition of social responsibility. Thus, for instance, according to S.V. Bratyushchenko *(Bratyushchenko, 2005)*, social responsibility includes the following types:

1. Legal responsibility. This approach assumes that any steps that are legally legitimate can be considered socially responsible: "there is no place for ethics in business".
2. Professional responsibility. This approach is dictated by the rules of engagement between a professional and an employer: "the only responsibility of business is to make maximum profit".
3. Economic responsibility. This approach recognises corporate social responsibility only if there is a specific benefit or utility for business.
4. Moral and ethical responsibility. This approach assumes that corporate responsibility is governed by moral and ethical standards and prioritises the problem of securing and reconciling the interests of all parties involved in the "life" of a company.

The existing diversity of CSR definitions is largely reflected in the approaches referred to above. In the Russian context, the most typical interpretation of CSR is the one under the theory of altruistic corporate social responsibility.
In our view, it is through the lens of this theory that CSR is understood by the Russian Managers Association as a voluntary contribution of business to social development in the social, economic and environmental realms directly related to the core business of the company and going beyond a certain minimum required by law.

By contrast with responsibility under law (labour law, taxes, etc.), CSR implies a free choice, goodwill, a sui generis social contract between the state, population and business.
Interestingly, this definition does not address such components of CSR as responsibility for the quality of goods and services, environmental protection, bona fide conscientious partnership, job creation and welfare of the employees.

Yet another definition of corporate social responsibility suggested by N.A. Krichevsky and S.F. Goncharov *(Krichevsky & Goncharov, 2007)* treats corporate social responsibility as a system of voluntary relations between the employee, the employer and the society aimed at improving social and labour relations, maintenance of social stability within the work team and the community, development of environmental activities at the national and international levels. However, this definition lacks such basic criteria of corporate social responsibility as compliance with the standards codified by law, i.e. formal obligations.

Thus, the overview of conceptual approaches and interpretations of corporate social responsibility provided by the authors demonstrates that there is no generally accepted definition of corporate social responsibility and corporate social responsibility management to date. Meanwhile, all approaches have a common feature: corporate social responsibility is treated as responsibility of a company with respect to all the people and organisations that it comes across while conducting its operations and with respect to the society at large. This broadest interpretation considers socially responsible corporate behaviour through the lens of roles and responsibility areas.

Identification of the responsibility area makes it possible to set the benchmarks and attributes of a socially responsible company that essentially constitute its obligations. Meanwhile, these obligations can conventionally be divided into formal (must) and informal obligations (does not have to, but does) on their face.

The limits of formal obligations of socially responsible business are determined by law, regulations and other regulatory instruments. The authors concur with the view expressed by Russian and foreign scholars claiming that socially responsible behaviour should be based on the principles of totally voluntary assumption and performance of social obligations that go beyond the minimum prescribed by law. This explains why informal obligations lack a framework codified by law.

Models of Social Responsibility

Most researchers worldwide identify two models of social responsibility or socially responsible behaviour in business: the open and the closed models. According to V.S. Poluhina (2011), "the models of corporate social responsibility are primarily examined through the lens of a dilemma: whether it is the business that determines the extent of its contribution to social development at its own discretion or these are formal and informal institutions that reconcile the public interests ultimately transformed into mandatory requirements to business" (p.12). Most often, scholars explain such differences by the socio-historical and socio-economic contexts in the country in which the relations between public institutions were developed where the main role belongs to state regulation. The open model provides for the minimum possible government interference with CSR development policy typical for the American model. By contrast, the closed model provides for the predominance of the state in promoting corporate social responsibility (Fig 2).

The report on social investments in Russia reads, "Due to the nature of business in the U.S. that is based on the maximum freedom of its agents, many social realms still remain self-regulating up to the present day... minimum interference with the private sector is typical for the United States. And yet, the U.S. is famous for its traditions of business' and/or its representatives' systematic involvement in the funding of a wide variety of goodwill projects" *(Litovchenko, (Ed.), 2004, p.18)*. Therefore, when we mention the open model of socially responsible corporate behaviour, we primarily refer to the American model as the social policy implemented by corporations is initiated by the businesses themselves rather than by the government. State regulation is indirect and catalytic in nature such as rewarding socially responsible companies with tax benefits. Yet another distinct feature of the American model is the social image of a company and its reputation that are largely dependent on social policy activities. They are implemented through the funding of social programmes tailored to the interests of internal stakeholders (creating jobs, ensuring safe working conditions, vocational training, etc.), as well as of external stakeholders (sponsoring cultural and sports activities, engaging in charity work through corporate funds).

The main difference between the European model and the American model is state influence and regulation of companies' activities manifested through development of relevant rules, standards and laws with a focus on the social labour realm. According to V. Ivanova (2009), "The main effort within the realm of corporate social responsibility is aimed at combating unemployment by reducing staff turnover, creating jobs and implementing regional social business projects" (p. 47). For instance, minimum wage, 35-hour working week or regulation of overtime work, etc. Furthermore, there are multiple documents that regulate the business' external social policy. These include the European

social policy directive The Green Book. If we take a look at the European system of corporate social responsibility, etc., we can argue that on the one hand, all the areas of responsibility in the European model are very articulate and well-elaborated, but on the other, despite the state's dominant positions in the promotion of CSR, the authors note a shift towards indirect regulation measures that are increasingly replacing direct regulation in recent years.

Fig. 2: Basic models of corporate social responsibility
(Source: Poluhina, 2011)

Even inside the European Union, there are distinct models of corporate social responsibility that can be identified and examined separately. Many scholars *(Mantaev et al.,2012; Ostroukhova, 2009)* name the British model as a distinct model. The British model combines the essential features of both the American and European models and is characterised by a greater involvement of the government and civil institutions in the consideration and reconciliation of social interests. Collaboration between the government and business entities in the British model finds expression in public-private partnership involving co-funding of educational, social and cultural projects, etc. Indirect state regulation is manifested in the form of tax benefits and support of initiatives aimed at bringing national CSR standards in conformity with international standards. Nowadays, the British model of corporate social responsibility tends to shift towards a more open model to a certain extent, which brings it closer to the American model *(Perekrestovet al., 2011)*.

A comparative analysis of the European and American models by A. Crane and D. Matten *(Crane & Matten, 2004)* is based on A. Carroll and M. Schwartz's *(Schwartz & Carroll, 2003)* approach who were the first to construe CSR as public expectations in four different realms: economic, legal, ethical and philanthropic (traditional charity). Economic responsibility in the European model includes employees and the local community, while the American model is limited to responsibility to owners and shareholders. The American model does not include any legal rules of CSR regulation as inadmissible, while the British model abounds in such legal rules. Philanthropic responsibility in the American model is very widespread, which represents a major difference from the European model. This is largely due to a significant social load of European companies that can be considered compulsory.

In addition to the American, European and British models, researchers name the Canadian, Japanese and Chinese models that have a number of peculiar features.

The Canadian model stands out for the corporate social responsibility standard developed by the National Quality Institute of Canada that regulates labour activities using the so-called "quality and healthy workplace excellence model" and Canada's national excellence award. In order to secure the award, a company must demonstrate improvements in the basic criteria of quality and healthy workplace excellence developed by Canadian specialists over the course of 3-5 years.

The Japanese model is quite young. The first corporate social reports in Japan did not appear until the early 2000s as a mandatory condition for entering international markets and bringing the documentation in conformity with the requirements set out in the international standards including social responsibility standards. Nonetheless, this does not mean that CSR principles did not priory exist in Japan's business practices. Thus, according to Bobrova *(Bobrova, 2013)*, the genesis of the Japanese CSR model was influenced by the Japanese economic system in general and major business associations in particular (such as Keidanren and Doyukai). The Japanese CSR model is based on the national cultural traditions envisaging solidarity at the company level and business solidarity at the industrial group level. The Japanese model is characterised by a proactive role of the government in corporate strategic planning. Business people focus on profit generation and responsibility for the company's successful development to the society.

Thus, after analysing a relatively broad range of international CSR models, the authors have reached the conclusion that the main issue or dilemma is whether it is the business that determines the extent of its contribution to social development at its own discretion or these are formal and informal institutions that reconcile the public interests ultimately transformed into mandatory requirements to business.

Due to historical, social, economic and political peculiarities, the Russian model of corporate social responsibility has major differences from its Western peers in terms of forms, drivers and roles of the business itself, the state, civil society and non-profit organisations. Russian scholars and business practitioners have diverging opinions regarding the existence of a distinct "Russian model" characterised by a number of specific features that make it different from the other models. Such opinions may be classified in three groups. According to the first, corporate social responsibility in Russia is a "hybrid" of the British and European CSR models. As the proceedings of an international conference on corporate social responsibility state, the Russian version of social responsibility is a blend of the British model (voluntary initiation by business) and the continental (European) model (companies' interest in obtaining a clear legislative framework for social responsibility from the state) *(Poluhina, 2011)*.

In general, this view reiterates the reasoning of those researchers who advocate the "convergence" theory of governance models that has gained popularity in the West over recent years. According to this theory, current development trends (globalisation of commodity and financial markets, improvements in telecommunications) will inevitably make national governance models converge *(Chirikovaet al., 2005)*. According to the second group, Russia has currently chosen the British model of social responsibility that prioritises social investments in local communities and "human capital" *(Ivchenkoet al.,2003)*. Specifically, this opinion is advocated by S. Peregudov *(Peregudov, 2005)*. According to the third group, the Russian model of social responsibility does exist and stands out for combining new social practices with Soviet and even pre-revolutionary traditions.

Conclusion

This study has examined the genesis of social responsibility as it is presented in the works of the economists, identified the basic theories of corporate social responsibility that currently exist alongside with their followers and ideologues. A review of the models presented in Chapter 4 of this paper suggests that the Russian model of socially responsible corporate behaviour is currently at its initial development stage, as due to historical reasons and peculiarities associated with the

development of the market economy in the country, there are certain factors that constrain the development of corporate social responsibility in Russia. Despite the fundamental similarities of the Russian and European models, where the state is the primary initiator of socially responsible corporate behaviour, there are significant differences, including absence of stimulation for CSR initiatives by the government, weakness of formal institutions, corruption, etc. We will just note that the interest of the state in the implementation of socially responsible practices in the form of relevant measures intended to support and encourage such practices both reduces the political risks and eases social tensions on the one hand, and creates the prerequisites for a strong performance of business and ultimately improves the Russian companies' investment potential ratings on the other.

Causal Dependencies between the WIG and Other Stock Market Indices

Joanna GORKA

Nicolaus Copernicus University, Torun, Poland
E-mail: joanna.gorka@umk.pl.

Abstract

The purpose of the paper is to investigate the linkages between the Warsaw Stock Exchange Index (WIG) and selected stock indices, such as BUX, DAX, FTSE100, S&P500, HIS and NIKKEI in the period 2009–2016. There are many studies examining different aspects of the interdependencies between the WIG and selected indices but usually they use only two out of four following methods: causality in mean, causality in volatility, nonlinear relationships, tail dependencies. In this study, we apply all four methods to detect these linkages taking into account many aspects of potential interdependencies. We show that causal relationships between stock markets observed in earlier studies have incompletely be confirmed and have not been stable in all cases.

Keywords: Granger Causality, Diks-Panchenko test, crisis, copula, tail dependence, stock index.

Introduction

Contemporarily the interdependence between financial markets and stock markets is being more and more strong observed. Movements in stock market in a given country are linked not only to the internal factors reflecting financial, economic and political state, but also to the events on other foreign financial markets. Especially, the impact of subprime crisis on the relationship of returns of financial instruments is considered (Misiuk and Zajkowska 2010; Righi and Ceretta 2012; Buszkowska and Płuciennik 2013; Doman and Doman 2013; Buszkowska 2014; Syczewska 2014; Jiang *et al.* 2017). However, these relationships before and after the onset of subprime crisis are expected to differ (Syczewska 2014). There are many different economic and political events that occurred in the last decade which potentially might have influenced the interdependencies of financial and stock markets (Righi and Ceretta 2012; Su 2013).

Causal linkages among stock markets have important implications for security pricing, hedging and trading strategies, and financial market regulations. Also, the presence of linear and nonlinear relationships may be used to achieve financial gains from international portfolio diversification and to reduce systematic local risks. Consequently, there exists a large body of literature on examining the presence of causal linkages between markets, especially developed (less risky) markets. There existing various estimation techniques and testing methodologies are applied to investigate the interdependencies of stock markets. The VAR model and impulse response functions (IRF) are often used (Geweke *et al.* 1983; Lütkepohl 1991; Hiemstra and Jones 1994; Fiszeder 2001, 2009; Osińska 2004; Égert and Kocenda 2006; Misiuk and Zajkowska 2010; Madrak-Grochowska and Żurek 2011; Su 2013; Syczewska 2014). Many authors use the family of GARCH models, specifically bivariate GARCH (Ghysels and Jasiak 1998; Chuang *et al.* 2012), generalized VAR-GARCH (Kim *et al.* 2005; De Gooijer and Sivarajasingham 2008; Su 2013) and multivariate GARCH-BEKK or DCC-GARCH model (Cheung and Ng 1996; Kim *et al.* 2005; Hafner and Herwartz 2006; De Gooijer and Sivarajasingham 2008; Fiszeder 2009; Madrak-Grochowska and Żurek 2011; Balcerzak *et al.* 2016) or copula-based multivariate GARCH models (Righi and Ceretta 2012; Doman and Doman 2013; Su 2013).

This study relates to the studies considering the changes in interdependencies of index returns in the presence of crisis events, i.e. in the period from 2009 to 2016 when the Greek debt crisis (2010) and the Fukushima disaster (March 2011) occurred. The purpose of the paper is to investigate the linkages between the Warsaw Stock Exchange Index (WIG – Poland) and selected stock indices, such as BUX (Hungary), DAX (Germany), FTSE100 (UK), S&P500 (U.S.), HSI (China), NIKKEI (Japan). The causal relationships between stock indices were found in earlier mentioned studies; i) in mean for the WIG and BUX, DAX, FTSE100, S&P500, ii) in variance the WIG, BUX, FTSE100, S&P500. Besides, Doman, Doman (2013) showed that dynamics of the WIG20 is strongly linked to the dynamics of the BUX. Due to the growing trade links between Poland and China and the disaster in Fukushima (Japan), the HSI and NIKKEI indices were also taken into account.

There is the vast literature on examining different aspects of the interdependencies between the WIG and selected indices: causality in mean (Fiszeder 2001, 2008, 2009; Osińska 2004; Égert and Kocenda 2006; Misiuk and Zajkowska 2010; Madrak-Grochowska and Żurek 2011; Syczewska 2014); causality in volatility (Fiszeder 2001, 2008, 2009; Osińska 2004; Égert and Kocenda 2006; Madrak-Grochowska and Żurek 2011; Buszkowska 2014; Balcerzak *et al.* 2016), nonlinear relationships (Orzeszko and Osińska 2007; Syczewska 2014; Orzeszko 2016; Burzała 2017) or tail dependencies (Doman and Doman 2011, 2013; Trzpiot and Majewska 2014).

The current study, in contrast to others, focuses simultaneously on examining causality in mean and variance, tail dependencies and nonlinear relationships. To detect potential nonlinear relationships the Diks-Panchenko test will be applied. The existence of causality in mean will be verified by the means of the Granger test based on the VAR model. Also, the impulse response functions will be applied. In order to examine the causality in variance the DCC-GARCH model and Hafner and Haerwart test will be used. To investigate changes in dynamics of interdependencies the dynamic correlation will be applied. Moreover, the copula-based GARCH model will be used to study the relationships in variance and tail dependencies.

The contribution of this paper lies in applying different approaches to detect causality between the WIG and selected stock indices taking into account many aspects of potential interdependencies. The previous studies are usually limited only to two different approaches (ie. causality in mean or causality in volatility or nonlinear relationships or tail dependencies). In addition, it was examined whether previously observed dependencies occurred in 2009–2016.

The structure of the paper is as follows. Section 2 describes the methodology and data. The empirical results are discussed in Section 3. Summary of results and general conclusions are stated in the last section.

Methodology and Data

This section presents a brief description of the methodologies and data used in this study.

A Linear Granger Causality

Let us consider two time series, X_t and Y_t. The Granger causality holds if (X_t) helps predict (Y_t) at some stage in the future what can be written as follows (Granger 1969), if

$$\sigma^2(Y_t|\Omega_t') < \sigma^2(Y_t|\,\Omega_t'\backslash X_t'), \tag{1}$$

then X_t Granger-cause Y_t,

where:

σ^2 – prediction error variance,

Ω_t' – a set of all information from the past available in time t,

$\Omega_t'\backslash X_t'$ – a set of all information from the past available in time t except information from the past about X_t.

Bi-directional causality exists if Granger causality runs in both directions.

In practice, the Granger causality is modelled via vector autoregression (VAR) models:

$$\mathbf{r}_t = \boldsymbol{\phi}_0 + \boldsymbol{\phi}_1 \mathbf{r}_{t-1} + \cdots + \boldsymbol{\phi}_p \mathbf{r}_{t-p} + \boldsymbol{\varepsilon}_t, \tag{2}$$

where:

$\mathbf{r}_t$ – a k-dimensional vector of the returns at period t,
$\boldsymbol{\phi}_0$ – a k-dimensional vector of constants,
$\boldsymbol{\phi}_i, i = 1, \dots, p - k \times k$ matrixes of parameters,
$\{\boldsymbol{\varepsilon}_t\}$ – a sequence of serially uncorrelated random vectors with mean zero and covariance matrix $\boldsymbol{\Sigma}$.

The VAR models are estimated by the Maximum Likelihood (ML) method, the optimal lag lengths are determined using the Bayesian information criterion (BIC), and the Wald variant of the Granger causality test is used.

Granger Causality in Volatility – Bi-variate-GARCH

Hiemstra and Jones (1994), among others, provide evidence that the nonlinear structure characterizing univariate daily stock return series is related to ARCH errors.

To test nonlinear Granger causality in variance we use the Hafner and Herwart test (HH; 2006) based on the dynamic conditional correlation model (DCC-GARCH; Engle 2002) in which the null hypothesis of non-causality in conditional variance is tested. DCC-GARCH model is defined by the following equations:

$$\begin{aligned} \mathbf{r}_t &= \boldsymbol{\mu}_\mathbf{t} + \boldsymbol{\varepsilon}_t, \qquad \boldsymbol{\mu}_\mathbf{t} = E(\mathbf{r}_t | \Omega_{t-1}), \qquad \boldsymbol{\varepsilon}_t = \sqrt{\mathbf{H}_t}\mathbf{z}_t, \\ \mathbf{H}_t &= \mathbf{D}_t \mathbf{R}_t \mathbf{D}_t \\ \mathbf{R}_t &= (\mathbf{Q}_t^*)^{-1/2} \mathbf{Q}_t (\mathbf{Q}_t^*)^{-1/2} \\ \mathbf{Q}_t &= \left(1 - \textstyle\sum_{i=1}^q \alpha_i - \sum_{j=1}^p \beta_j\right)\mathbf{S} + \sum_{i=1}^q \alpha_i (\boldsymbol{\varepsilon}_{t-i} \boldsymbol{\varepsilon}'_{t-i}) + \sum_{j=1}^p \beta_j \mathbf{Q}_{t-j}, \end{aligned} \tag{3}$$

where:

$\mathbf{D}_t$ – a diagonal matrix of time varying standard deviations from univariate GARCH models,
$\mathbf{z}_t$ – a vector of the standardized residuals ε_{it},
$\mathbf{R}_t$ – a time varying conditional correlation matrix of the $\mathbf{z}_t$,
$\mathbf{S}$ – an unconditional correlation matrix of the $\mathbf{z}_t$,
$\mathbf{Q}_t^*$ – a diagonal matrix composed of the square roots of the diagonal elements of $\mathbf{Q}_t$.

The model is estimated using the Quasi Maximum Likelihood (QML) in two stages. In the first stage univariate GARCH models are estimated for each asset series. In the second stage, residuals, transformed by their standard deviation estimated during the first stage, are used to estimate the parameters of the dynamic correlation.

Nonlinear Granger causality – A Nonparametric Test

In this paper, the nonlinear Granger test proposed by Diks and Panchenko (2006) was used. This test draws on the following causality definition: the series X_t is said to Granger cause Y_t if the past and the present of X_t have additional power in forecasting Y_t after controlling for the past of Y_t (Diks and Panchenko 2006), i.e. X_t Granger-causes Y_t, if

$$Y_{t+1} | (\Omega_{X,t}, \Omega_{Y,t}) \nsim Y_{t+1} | \Omega_{Y,t}, \tag{4}$$

where:

$\Omega_{Y,t} = \left\{Y_{t-l_y+1}, \dots, Y_t\right\}$ – a set of all information of Y_t,

$\Omega_{X,t} = \{X_{t-l_x+1}, \dots, X_t\}$ – a set of all information of X_t,
$l_y, l_x \geq 1$ – time lags.

The Diks-Parchenko test focuses on examining the impact of X_t on Y_{t+1}.The null hypothesis implies that X_t is not a cause of Y_t.

Tail Dependence – Copulas

Empirical studies have pointed out that stock returns display also an asymmetric dependence in bearish and bullish markets, i.e. this dependence may be stronger in bearish markets than in bullish markets and tends to increase in the periods of violent fluctuations of prices (Longin and Solnik 2001; Ang and Bekaert 2002; Jondeau 2014). Because, the asymptotic dependence of random variables in tails is a property dependent only on the copula (Patton 2006), we apply the copula-based model (Definitions, examples and properties of copulas can be found amongst others: Doman (2011), Joe (1997)). This approach allows investigating the dependence in variance and in tails which provides absolute control of the marginal latent trait distributions and accommodates several dependence structures what is not possible using standard dependence measures.

In this paper, we used functions from VineCopula library in R (Stoeber *et al.* 2018). First, for each pair, the Kendall's τ is estimated and the p-values of the independence test based on the Kendall's τ were determined. Second, from the catalogue of pair-copula family are fitted copulas using maximum likelihood estimation.

To measure the discrepancy between a hypothesized model and the empirical model we use the Goodness-of-Fit (GoF) statistics based on the Kendall's process as proposed by Wang and Wells (2000). For computation of p-values, the parametric bootstrap described by Genest et al. (2006) is used.

Data

The data used in this study cover the period from January 7th, 2009 to September 30th, 2016. They consist of daily closing values of indices (WIG, S&P500, BUX, DAX, FTSE100, HSI, NIKKEI). We analyse logarithmic returns (we assume further in the paper that 'returns' stand for 'logarithmic returns'), i.e.

$$r_t = 100(lnP_t - lnP_{t-1}),$$

where P_t is a stock index closing quote.
Stock indices and returns are displayed in Figure 1 and 2. It can be easily found that increases and decreases of stock indices (Fig. 1) occur in similar time periods, but their returns (Fig. 2) display diversified volatility at the same time periods. This can indicate a potential relation between markets.

Fig. 1: Time plots of stock indices

Fig. 2: Time plots of stock indices returns

Empirical Analysis

Results of the Diks-Panchenko Test

To conduct tests for nonlinear causality among stock indices, we use the nonlinear Granger causality test of Diks and Panchenko (2006). We perform the test for different embedding dimension (d =2 and 3) in order to be robust against the lag order used in the test. Results are presented in Table 1.

Table 1: Results of the Diks-Panchenko test for the pairs of returns

X↛Y	d=2		d=3	
	Test statistic	p-value	Test statistic	p-value
BUX↛WIG	1.393	0.0819	0.818	0.2067
WIG↛BUX	5.159	0.0000	3.521	0.0002
DAX↛WIG	5.327	0.0000	3.345	0.0004
WIG↛DAX	1.133	0.1286	0.063	0.4750
FTSE100↛>WIG	2.417	0.0078	1.783	0.0373
WIG↛FTSE100	2.368	0.0089	0.75	0.2267
HSI↛WIG	2.74	0.0031	1.814	0.0348
WIG↛HSI	2.748	0.0030	1.785	0.0371
NIKKEI↛WIG	0.904	0.1829	1.150	0.1250
WIG↛NIKKEI	3.456	0.0003	1.282	0.0999
S&P500↛WIG	3.033	0.0012	2.556	0.0053
WIG↛S&P500	1.685	0.0460	1.491	0.068

Note: X↛Y means that X is not a cause of Y; Calculations were done with the use of program available at the website of V. Panchenko: http://research.economics.unsw.edu.au/vpanchenko.

The results of the test are depending on the number of lags (d). For d=2 the null hypothesis of non-causality is rejected for almost all pairs of returns, i.e. returns of selected indices and the WIG returns are interrelated (except NIKKEI and BUX). Moreover, there is bidirectional causality between the WIG returns and returns of selected indices (except DAX). For d=3, there is a unidirectional causality running from returns of DAX, FTSE100, HSI, S&P500 to returns of WIG, and returns of WIG cause only returns of BUX and HSI. There is no causality for the pair (WIG, NIKKEI) when d=3. Because the test results are depending on the number of lags, the decision about causality between returns of selected indices, in the analyzed period, cannot be unambiguous. Additionally, the influence of small Polish market on the economy of the US, China or Japan seems to be unlikely. This is the reason why other methods of causal analysis are needed.

Testing Causality in Mean

To examine causality in mean the bivariate VAR models are applied for the pairs of returns of stock indices. The following models: VAR(2) for pairs: (WIG, DAX) and (WIG, S&P500), and for the rest of pairs – VAR(1), are fitted. Then, we carry out the Granger causality test (see – Table 2) and compute impulse response functions (Table 3) which measure the response of one return of rate to unit shock of another return of rate.

Table 2: Results of Granger causality test

Null hypothesis	F-Wald Statistic	p-value
S&P500↛WIG	33.7513	<0.01
WIG↛S&P500	1.6078	0.1544
DAX↛WIG	279.1007	<0.01
WIG↛DAX	1.1885	0.3048
FTSE100↛WIG	4.0674	0.0437
WIG↛FTSE100	0.2485	0.6182
BUX↛WIG	0.0000	0.997
WIG↛BUX	410.5159	<0.01
HSI↛WIG	2.0443	0.1529
WIG↛HSI	129.5722	<0.01
NIKKEI↛WIG	0.3073	0.5794
WIG↛NIKKEI	196.9251	<0.01

Results displayed in Table 4 indicate the causal relationship running from returns of major world economy (S&P500) and the most influential European markets (DAX, FTSE100) to returns of WIG. In each case the response of WIG returns is immediate and persists several periods, and then starts dying (see Table 3). The returns of WIG do cause the returns of BUX, HSI and NIKKEI, but there is no reverse causality. While the impact of the WIG returns on the BUX returns is reliable, the unidirectional influence of returns of WIG on returns of NIKKEI and HSI is a surprising result. This is rather an indirect impact carried through other returns which influence the WIG returns and is an effect of local time zone differences. This is in line with the results obtained by Madrak-Grochowska and Żurek (2011) who studied causal relationship between WIG20 and NIKKEI returns.

Table 3: Characteristics of the response of returns to unit shock

Shocks→Responses	Period of strongest response	Dying periond
S&P500→WIG	1	5
DAX→WIG	2	6
FTSE100→WIG	1	4
WIG→BUX	1	2
WIG→NIKKEI	Indirect impact due to time zone difference	
WIG→HSI	Indirect impact due to time zone difference	

Causality in Variance

The distributions of all returns turn out to be leptokurtic and fat-tailed hence the GARCH models for each return innovations are estimated. We consider different specifications of GARCH(p,q) model, i.e. q=1,2 and p=1, 2, with Gaussian, Student t and skewed t distributions. As a result, the GARCH(1,1) is chosen for each returns, in most cases with t-Student distribution, except the WIG, DAX and FTSE100 returns for which skewed t-Student is taken.

Then, for given pairs of return innovations: (WIG, BUX), (WIG, DAX), (WIG, FTSE100), (WIG, HSI), (WIG, NIKKE) and (WIG, S&P500) the DCC-GARCH(1,1) are estimated. The multivariate t-Student distribution is applied as the null hypothesis of multivariate normal distribution (using Shapiro-Wilk test) is rejected.

The estimated DCC-GARCH models satisfy the restrictions imposed on conditional variance and conditional correlation in the case of the pairs of returns: (WIG, S&P500), (WIG, DAX), (WIG, FTSE100) and (WIG, BUX). For pairs of returns (WIG, HSI) and (WIG, NIKKEI) conditional correlation parameters are insignificant at the 5% significance level, hence the models for these pairs are excluded from further considerations.

Using innovations from the models with significant conditional correlation, we apply the Hafner-Herwartz (HH) test. The test results indicate the causal relationship in variance for pairs of return innovations (Table 4). However, it should be remembered that it is not possible to determine the direction of causality using this test.

Table 4: The HH test results for the pairs of (WIG, …)

HH test	BUX	DAX	FTSE100	S&P500
Statistic	370.488	14.934	30.960	55.710
p-value	0.000	0.005	0.000	0.000

The conditional correlation analysis for the pairs of stock indices returns unable to determine the power and direction of indices retruns' interdependencies. The strongest relationships are seen between the WIG returns and FTSE100 returns (see Fig. 3), however, we can observe a highly volatile time path of conditional correlation, meaning the co-movement (correlation) between Polish and British stock markets returns is time-varying. The co-movements between Polish and US stock markets returns are less volatile and more stable (conditional correlation in the studied period ranges from 0.35 to 0.6) indicating the constant influence of S&P500 returns on WIG returns.

Fig. 3: Conditional correlation for pairs (WIG, …) – DCC-GARCH model

Interdependencies between Polish and German (DAX) stock markets are not stable during the observed period what is manifested by both negative and positive conditional correlations. It is possible that this relationship is affected by the subprime crisis and later the Greek debt crisis. The Greek debt crisis "broke out" at the beginning of 2010, and with 7th May, 2010 Angela Merker presented the plan of bail-out package demanding new austerity and major reforms and informed the Germany's participation in this package will be EUR 22,4 mld (Koszel 2015).

Changes in the conditional correlation between Polish and Hungarian stock markets with regard to volatility are similar to that between Polish (WIG) and British (FTSE100) stock markets till the beginning of 2010. Since then the trend of conditional correlation between Polish and Hungarian stock markets is falling, indicating that these stock markets have become less interdependent, and the time path of this correlation is approaching that for correlation between returns of WIG and DAX. Changes of this interdependence coincide with taking power in 2010 by Orban who introduced the bank tax and nationalized the pension system.

Fig. 4: Conditional correlation for pairs (WIG, …) – Copula-DCC-GARCH model

To eliminate the potential influence of returns volatility on the conditional correlation between these returns we applied Copula-DCC-GARCH models with t-Student distribution. It is seen in Fig. 4 that conditional correlations based on Copula DCC-GARCH model are less volatile than those received on the basis of DCC-GARCH model (Fig. 3). However, general conclusions concerning the interdependencies between pairs of returns remained the same (including the HH test).

Tail Dependence

To quantify the degree of tail dependence in each pair the Kendall's τ is estimated and the p-values of the independence test based on the Kendall's τ are determined (see Table 5). The results indicate the existence of positive dependence for 5 pairs at the 5% significance level. Only for the pair (WIG, DAX) we cannot reject null hypothesis what is rather surprising result whereas in previous studies this (tail) dependence was revealed (Doman and Doman (2013) found that since 2007 the tail dependence between WIG20 returns and DAX returns was not observed. However, they applied different models than in current paper). The strongest dependencies have the pair (WIG, FTSE100) what can be explained by the strong connection of the Polish and British economy. Then, for the pairs of returns revealing the significant tail dependence, the appropriate Copulas are fitted. The chosen copulas parameters are presented in Table 5.

Table 5: Tail Dependence for pairs (WIG, …)

Index	Copula	$\hat{\tau}$	Indep. (p-value)	GoF test (p-value)	λ_L	λ_U
BUX	t	0.101	0.000	0.830	0.013	0.013
DAX	–	0.030	0.293	–	–	–
FTSE100	t	0.396	0.000	0.550	0.148	0.148
HSI	BB1	0.239	0.000	0.320	0.090	0.191
NIKKEI	BB1	0.140	0.000	0.540	0.042	0.069
S&P500	BB1	0.272	0.000	0.220	0.117	0.228

Note: $\hat{\tau}$ – empirical Kendall's τ; Indep. – testing for independence for pairs of variables (H_0: $\tau = 0$); λ_L – coefficient of lower tail dependence; coefficient of λ_U – upper tail dependence

The results indicate that for chosen copulas we cannot reject null hypothesis, i.e. our copulas are the true copulas. For pairs (WIG, BUX) and (WIG, FTSE100) the symmetric copula is selected, and for the rest of pairs of returns – asymmetric copula allowing to depict the lower- and upper-tail dependencies. The obtained results indicate that the tail dependence between WIG and BUX returns is very weak

and symmetric, while between WIG and FTSE100 returns – slightly stronger. For the rest pairs of returns the upper-tail dependence is stronger than lower-tail one, but still rather weak. The occurrence of simultaneous extreme events (increases) is most likely for the Polish (WIG) and US (SP500) stock markets.

Conclusions

The aim of this study was to examine causal relationships between WIG returns and selected indices returns in the period 2009–2016, but in contrast to previous studies, we focused simultaneously on different aspects of these interdependencies. The summary of the results is tabulated in Table 6.

In most cases, the results of Diks-Panchenko test correspond to those obtained from the Granger-causality test, except the pairs (WIG, HSI) and (WIG, NIKEI). It is found that the S&P500, FTSE100 and DAX returns cause in mean WIG returns what is in line with findings revealed before the sub-prime crisis (see Fiszeder, 2008; study period: 3.10.1994–3101.2008). However, there is one exception in comparison to study by Fiszeder (2008), i.e. BUX returns do not cause in mean WIG returns any longer. On the other hand, WIG returns turn out to cause in mean BUX, NIKKEI and HSI returns, but no reverse causality is observed. While the impact of WIG returns on BUX returns might have been expected, the lack of its feedback is rather surprising.

Causality in volatility is found between WIG returns and BUX, DAX, S&P500 and FTSE100 returns. Additionally, the time paths of conditional correlations indicate that interdependencies between (WIG, S&P500) and (WIG, FTSE100) returns are constant and stable, whereby interdependencies between (WIG, S&P500) returns are more stable and weaker, and between (WIG, FTSE100) returns – less stable and stronger. However, the correlation between Polish (WIG) and German (DAX) stock markets, and Polish (WIG) and Hungarian (BUX) stock markets are time-varying since the beginning of 2009 and 2010 respectively. Applying Copula-DCC-GARCH models with t-Student distribution to obtain the conditional correlation between indices returns did not change the general conclusions.

Table 6: Causality between WIG returns and selected stock indices returns – summary of results

WIG and …	Methods for testing causality				
	Diks-Panchenko test (d=3)	VAR model	DCC-GARCH model	Tail dependence	
				λ_L	λ_U
BUX	WIG→BUX	WIG→BUX	yes	0.013	0.013
DAX	DAX→WIG	DAX→WIG	yes	–	–
FTSE100	FTSE100→WIG	FTSE100→WIG	yes	0.148	0.148
HSI	HSI↔WIG	WIG→HSI	–	0.090	0.191
NIKKEI	–	WIG→NIKKEI	–	0.042	0.069
S&P500	S&P500→WIG	S&P500→WIG	yes	0.117	0.228

Interdependence between pairs (WIG, FTSE10) and (WIG, S&P500) identified in earlier methods are also observed in the tails distributions. The strongest symmetric dependence has the pair (WIG, FTSE100) whiles for the pair (WIG, FTSE100) weaker and asymmetric dependence (stronger in the upper tail) is found.

Summing up, the situation on world stock markets does influence the WIG returns in the observed period, 2009–2016, however not all earlier observed interdependencies are validated. It is likely that the change of interdependence pattern results from different country-specific events like changes in fiscal policy in Hungary, Greek debt crisis and German bailout). Changes in interdependence between WIG and FTSE10 returns are rather not affected by the Greek debt crisis because it refers mainly to countries in the Euro zone (and both Poland and the UK do not belong to it and were not involved into preparing the bailout package for Greece), but it might have been expected that the Fukushima catastrophe did influence co-movements (conditional correlation) between WIG returns and others selected stock indices returns.

Abstract

There are modern sources, business financing instruments and investment projects galore. Not only direct investment attraction through a share or debt issue, collective financing (mutual funds, etc), project financing via an SPV, banking investment crediting and other classic forms are popular now. The methods, which were unknown in Russia until recently are gaining popularity -- crowdfunding, crowdinvesting, digital currency issues (ICO), etc. The article will consider one of these modern financing and business project instruments, which is especially important for startups, -- crowdfunding, in detail. Crowdfunding in Russia is a relatively new type of business financing, while abroad it has been popular for more than 15 years. However, growing popularity of this type of financing triggers growth of related problems. That is why the research underlines the importance of crowdfunding in financing of startups, offers the key directors of its improvement to minimize risks and losses of potential investors.

Keywords: Crowdfunding, Financing, A Crowdfunding Platform, A Startup, A Project, Investment, Crowdinvesting

Introduction

More and more companies with new startups appear each year in Russia and in the world causing financing problems as investors often avoid projects with the high risk inherent to many startups. Crowdfunding, or collective financing of charity or business projects, has been gaining popularity in the last few years (Andre, K. 2010). The method unites many groups of people, including businessmen, investors, inventors, small business owners, people involved in charity (Petrov, A. 2019). Crowdfunding helps them attract the capital needed to start a business, creation and sales of goods and services, in project financing (Attanasio, O. 2003). The key goal of crowdfunding is financing, while different business projects are aimed at satisfying demands of a person or a group of people. Consequently, according to Akhmadeev (2018), Bade (2020) success of crowdfunding depends on effectiveness of marketing. Interest to alternative financing ways of company operations is in the

development of modern payment technologies, which facilitate payments significantly and help its users make use of the money almost immediately.

Theoretical Background

There are many definitions of crowdfunding. According to Petrov and Kosolapova (2019), crowdfunding is accumulation of money from a lot of people (thus, the word 'crowd' – a crowd as a collection of individuals and 'funding' as financing) done for the promotion of goods or services, organization of different events. The very notion of crowdfunding appeared in 2006 thanks to Jeff Howe. The textbooks or the Internet define crowdfunding as follows – cooperation of people, who give away their money or other resources voluntarily to support efforts of other people or commercial enterprises. At that, a project can be both charitable and socially important, which, as a rule, is not meant to bring profit. In fact, crowdfunding can be considered an example of Internet effectiveness as a functional floor, which bring people together (Kosov, 2018). There are three types of crowdfunding:

1. Reward crowdfunding – most popular among investors, which receive different bonuses and gifts, for example, an invention, which they financed (Sotnikova, 2019).

2. Equity crowdfunding – when the initiator of fund raising offers a stake in the project to the investor. Equity crowdfunding is popular with small and medium-sized business, when significant financial resources are needed for intensive development (Calic, 2016), but their attraction is very difficult because of various reasons: low business transparency in Russia, high interest rates (Korableva, 2019). Crowdfunding helps solve the problem, attract sufficient investment in the shortest time possible and at a low cost (Zimakova, 2016).

3. Debt crowdfunding includes debt repayment, a share in the future project or repayment of some investment from profits. Here the debt nonrepayment risk can be very high, if the project fails, but if it is successful, the return on such investment can be very high (Colombo, 2015).

There are also three key crowdfunding models:

1. Without reward, gifts. As a rule, this model is used in social business projects, political, ecological, medical projects (for instance, fund raising to pay for medical treatment, for charity organizations). This model led crowdfunding seven years ago (Ustyuzhanina, 2017).

2. The Kickstarter Model (nonfinancial reward). This crowdfunding system is at the moment the most popular by the number of internet platforms. An example of nonfinancial reward can be a mention in the captions, etc. The Kickstarter floor collected U.S. $4,666,193,837 and had 173,509 successful projects in 2019.

3. Crowdinvesting (financial reward). The key features of crowdinvesting is in the financial reward received by the sponsor in exchange for his support.

Another form of crowdfinancing is crowdlending -- P2P, P2B and B2B collective crediting (Turishcheva, 2019). This form of financing is not very popular in Russia now. The advantage of crowdlending is a higher margin of the investor compared with banking rates, while for the borrower, on the contrary, the cost of credit is lower. However, the non-return risk is also very high here because of the absence of any collateral. This kind of financing can be very promising, if the non-return problem is solved by new laws. Another type of collective financing is crowdsale, whose key goal is to pool money or other resources to develop an idea, a project. Its key different from crowdfunding, when the investor gets different kinds of rewards for his investment, is his getting tokens (the crypto currencies) in exchange for investment. Russia now has many different crowdplatforms (Boomstarter, Planeta, Kroogi, etc.).

These projects copy the western floors, like Kickstarter and Indiegogo. The Russian crowdfunding history started in 2010 from platform Smipon.ru, where the public was attracted to fund raising to build a monument to Apple's founder Steve Jobs. The largest Russian crowdfunding floors, Planeta.ru and Boomstarter, started operations only in 2012. Planeta.ru has so far raised 1.5 bln rbl for over 5,000 projects. In 2016, the platform launched the country's first offline course The Crowdfunding School. The following sections topped the floor by popularity – public projects, music, cinema, video and animation. The key difference of the first local crowdfunding platforms was in the mechanism of operations – the funds raised through Boomstarter can be used only on condition of raising the whole sum, "all or nothing." A change in people's mentality that crowdfunding is not charity but chance is the goal of the floor. Now Boomstarter is Europe's top crowdfunding platform by the number of active users, which has collected over 380 mln rbl. The projects implemented by Boomstarter vary, the same is the case with the floor described above (Fassin, 2017). These include the Young Moscow project implemented together with the Moscow city's culture department, which raised about 15 mln rbl. This is a good illustration of local crowdfunding – state involvement in the projects (Morozova, 2019). There should be several prerequisites to launch crowdfunding – you should choose a floor depending on the project and resident status, etc; check the project for compliance with the rules of the platform; register on the website, register the project in the chosen category and mention the sum to be raised; choose the type of the award for sponsorship; pass moderation and launch the campaign. You should also not forget to assess the risk of underfinancing, termination of the platform's operations and consider additional costs for the use of crowdfunding platforms (the fees for the placement, different fees of the platform and the payment system, taxes.) Together with the promotion costs and bonuses in the form of souvenirs, etc., total costs usually amount to 30–40% of the raised amount. One should also keep in mind that the Platform is only needed to raise money, while promotion, advertising of his idea is to be done by the businessman in any way he deems reasonable. He will not succeed in fund raising on the Platform without promotion.

Results

The key advantages of crowdfunding are minimization of intermediary services, accountability of the funds' recipients, transparency of fundraising, identical, voluntary and understandable rules of operations. However, crowdfunding also has its downsides:

1) intended swindling or failure to fulfill their obligations by the borrowers. Although the crowd platform moderators check the crowd projects, this is no guarantee of their reliability. For instance, according to Satis Group, about 80% of ICO is scam. Willful misrepresentation, false information about the projects and their results are also frequent. Con work is often performed on the project, different reports are provided to the investors, while the money is spent on personal needs of the unscrupulous borrowers;
2) poor business plans (although some platforms allow borrowers to change the end sum as the plan is fulfilled);
3) the risk of plagiarism in case of full disclosure of technical and financial information about the project;
4) insufficient financing (there is no guarantee that the necessary sum will be raised, while the fees for registration on the platform are obligatory).

According to the central bank of the Russian Federation, the crowdfunding market slumped by 42 % to 5.2 bln rbl in the first nine months of 2019 compared to 8.9 bln rbl in the same year-ago period and to 7.7 bln rbl in 2017 (fig. 1).

Fig. 1: Russian crowdfunding in the last 5 years, bln rbl

Compiled by the author with the use of research http://icopartners.com/2019/01/games-and-crowdfunding-in-2018.

The central bank says a large unscrupulous player leaving the market is behind the slump. At the same time, crowdfunding market players say that the reason is affordable credits – allegedly getting money from a bank is now easier than convincing many small investors. However, the negative trends are not seen in the charitable unrewarded crowdfunding, when people donate money in exchange for a non-financial reward. The international crowdfunding market exceeded $10 bln in 2018 with the two thirds of the money collected in China and the USA (Mollick, 2018). Experts say the figure may triple in the next five years. Of course, the character and development rates of the international and local crowdfunding markets are different. First, this is because of the users' mistrust to the modern technologies of the world wide web. Second, insufficient knowledge about crowdfunding and its risks prevent the volumes of the Russian platforms from becoming comparable with their foreign peers. However, popularity of crowdfunding has been growing steadily in our country in the last few years, the number of participants increased. In 2018, the Association of Investment Platforms' Operators was founded primarily with the aim of establishing dialogue between the authorities and market participants. The association also aims at spreading and development of crowdfunding in Russia. At the moment its key goal is formation of initiatives to support stable market development and advertising new digital services and financial products.

Hypothesis

The aforementioned risks of crowdfunding, its market's rapid growth as well as the increasing number of funders disappointed by their investment predetermined the problem of legal regulation of this activity in Russia and introduction of strict legal measures for unscrupulous recipients to ensure due protection of investors (donors). This is why the State Duma passed a bill on crowdfunding regulation № 259-FZ "On Investment Attraction with the Use of Investment Platforms and Adjustments to Some Legal Acts of the Russian Federation." The document outlines the rules of fundraising by companies or individual entrepreneurs via investment platforms as well as the legal basis of such platforms' operations (Bykanova, 2018). Now only the companies from a special central bank register can raise money to develop their projects. This bill should aid the development of crowdfunding in Russia. However, the document has lots of loopholes and problems. The bill does not provide for investment in the form of a cryptocurrency or the use of utilitarian digital rights outside the Russian digital venues.

The bill lacks the notion of a cryptocurrency, but allows an ICO (attraction of investment via an issue of tokens on a block chain). This makes stipulations of a law on ICO and tokens pointless. You can only invest Russian rubles under the new type of ICO. The tokens you receive in exchange can only circulate on the Russian Federation's local market, which undermines their liquidity and consequently, investor interest. Investment for individuals is limited by 600,000 rbl within one year – very low, if we consider the possibility of investment return (Thaler, 2018). There are gaps in regulation of platform operations. For instance, according to the new bill, a platform operator can only be a company from the central bank's register of investment platforms operators. However, there is no order of keeping this register. Besides, some obligations of the operators are formal. For example, the bill orders the operators to establish the people with whom they sign deals, but there are no criteria of such establishment.

A formal approach to investor protection. For example, the operator must check the volume of individuals' investment on other platforms basing on the statements of the individual, which is impossible. If the statement is false, the losses are born by the investor (Ekimova, 2016; Prodanova, 2018). The absence of investor funds' blocking. Unjustified restrictions on the persons able to raise funds to only Russian companies and individual entrepreneurs, although individuals are the key participants of crowdfunding projects. This creates problems during fundraising for non-commercial projects in social and other good causes (Zhang, 2001). Prohibition on advertising of utilitarian digital rights, which may hurt marketing campaigns to attract attention, including for socially important projects.

Conclusion

Although crowdfinancing and crowdfunding is perceived very skeptically in Russia, we can say that this type of financing is developing quite rapidly and counts about 20 platforms for this type of activity. Businessmen have been waiting for long for legal regulation of this sphere, that is why adoption of the new law should influence further development of crowdfunding, which is yet to happen. The document has numerous arguable points, which can make the investment platforms unsuitable for work, because, for instance, they cannot be advertised, while ordinary users will have no access to it. Unfortunately, the bulk of the documents, which regulate crowdfunding are still under government consideration. The consideration and approval should be spurred up. Besides, further improvement of the crowdfunding bill is necessary – adding the possibility to convert investment into stakes, investment freeze, a cryptocurrency notion, regulation of relations between the funders and the crowdfunding venue. It was the cryptocurrencies, which allowed the investment floors to carry out international projects, cut transaction costs and time of implementation. The bill deprives crowdfunding of its potential without regulation of cryptocurrencies.

The Wasta – Is it an Ethical Problem for Muslim Auditors and Accountants?

Malgorzata CZERNY

Poznan University of Economics and Business, Poznań, Poland

malgorzata.czerny@ue.poznan.pl

Abstract

Progressive globalization means that business entities conduct business in various parts of the world and in different cultural circles, often using the local services. A knowledge of certain cultural differences and the resulting phenomena that create mechanisms and style of doing business becomes indispensable today. The article aims to present a phenomenon of the wasta, relatively little known in other cultures but widespread in Muslim society. This paper shows what a wasta is from a sociological point of view and investigates some consequences of it (political and economic), but mostly tries (by analyzing principles of Islamic ethics – qualitative research) to answer the question whether the wasta can pose an ethical challenge for Muslim accountants and auditors, whose threats their clients should be aware of.

Keywords: Wasta, Islam, Ethics, Accountants, Auditors

Introduction

The earliest research of wasta's phenomenon was conducted by Cunnigham and Sarayrah (1993), who identified two types of it: intermediary and intercessory. Intermediary wasta is used to facilitate the resolution of inter-group or interpersonal conflicts. In this system, wasta improves interpersonal relationships and strengthens social norms. On the other hand, intercessory wasta includes those who intervene on behalf of the client to gain benefits (obtain an advantage) or overcome an obstacle on the part of the authority. It is this type of wasta that affects i.e. employment decisions.

Although the use of wasta is firmly rooted in the Arab culture, it is inconsistent with Muslim teachings regarding e.g. hiring practices. Islam is stressing the importance of hiring based on qualification and merit in several places (Abbas 2005). There is a phrase in the Quran: "the best that you can hire employee is one who is competent and trustworthy" (Holy Quran, 2011, 28:26). Quoting Prophet Mohamed: "He who is in a leadership position and appoints knowingly a person who is not qualified to manage, than he violates the command of God and His messenger" and "when a person assumes an authority over people and promotes one of them because of personal preferences, God will curse him forever" (Mohamed and Handy 2008).

In spite of its violation of Islamic teachings, using wasta is quite rampant in the Islamic world. A number of factors may have led to the spread of wasta. First, to maintain their grip on authority, Arab political regimes tend often to place close confidants in key positions even if they are not the most qualified (top governmental positions are reserved for members of the ruling families or members of their supporting tribes). Being connected to the right people becomes critical when seeking a position. The fear of being disadvantaged by the lack of a proper connection motivates people to seek and use wasta (Mohamed and Handy 2008). Also, many Muslim economies suffer from very high levels of unemployment, so job, especially "good one", is scarce, what motivates applicants to use every possible way to improve their chances of being hired. The wasta works, because human resource departments in the Muslim world depend heavily on subjective assessment tools (unstructured interviews). There is a question, if informal relationships like wasta can affect some way behaviors of professionals, like accountants and auditors, and harm the public confidence that society places usually in these professions. It is also very important question from point of view their clients, especially foreign ones.

The wasta as the social relationship

The wasta means "intercession" or "mediation". This concept covers a wide range of social activities and it is quite difficult to translate into Western conceptual categories. Górak-Sosnowska (2010) rightly points out that the wasta in its concept resembles clientelism, because it assumes the existence of an informal relationship between the patron and the client and concerns the economic or political sphere. Clientelism, however, corresponds only to one type of wasta – intercessory. The wasta is a broader concept than nepotism. It applies usually to one's own group - tribe, clan, family, ethnical or religious group. However, this relationship may also apply to people who are not relatives – f.e. the politician and potential voter (offering vote in exchange for benefits). It indicates the corruptogenic nature of wasta, however, it is also not synonymous with corruption (Górak-Sosnowska 2010). If the relationship is not maintained "today", at the expense of a third party (state, nation, other person), there is not "corruption space". For this reason a distinction is made between "good" and "bad" wasta (Loewe et al, 2007) - therefore a wasta may be seen as relation which brings benefits, and does not affect the social system (benefiting the individual). In "good" meaning, intercessory wasta can be f.e. a particular commitment of the employee to the company and the superior - because of their kinship; in "bad" meaning - if it is a state-owned company, and someone's admission to work was determined by family ties, not professional qualifications. A good intermediary wasta's example can be mediation in a dispute between two people to resolve it in a mutually beneficial and just way; but if the dispute involves personal connections and the mediator only forces a favorable solution on one side, it is an example of wrong wasta's use. It shows the different contexts of wasta functioning. The wasta in terms of conciliation may alleviate or resolve an inter-conflicts, so maintain positive relationships between groups or individuals. The wasta as an intercessory - if its purpose is intervention of the patron/agent on third party customer benefit, may be about avoiding negative sanctions or to gain benefits (Mohamed and Handy 2008).

Initially, the wasta was primarily of an amicable nature and was associated with the management of the Muslim community. It was therefore positively connotated and testified to the fact that the leader the community is able to effectively and responsibly care for (Hooker 2009). It creates a social capital (Putnam 2000), because a social bond between the members of the community (belonging to various social categories) is established. This traditional wasta still exists in local communities and helps to regulate social relations. However, in parallel with the processes of modernization and urbanization, wasta has evolved in intercessory one. It is based on similar norms and values and is grounded in informal networks, however, it assumes actions whose purpose is to obtain benefits only through one of the parties. The external environment is also different; this is not local authority, but a state institution or corporation. It aims to maintain order in one's own group, but to obtain benefits for a member of their own group at the expense of others (Mohamed and Handy 2008)

The relationship within wasta is between two or three parties (Loewe 2006):

• a person (the client) trying to get the benefit,

• an agent/patron who can provide him with this benefit,

• a mediator helping the client contact the agent (unless they know each other directly).

The wasta is a social relationship, because it fulfills all its features (Sztompka 2002). It assumes the existence of a multitude of interactions that are multi-thematic. They can be specialized (e.g. obtaining a driving license by a customer) or relate to various spheres of life (e.g. activities aimed at raising the standard of the client's life - from facilitating access to basic goods or services after providing work) (Górak-Sosnowska 2010). The wasta is a permanent relationship, which results in its character and client and agent expectations of each other. Its feature is also a normative on adjustment; it is regulated by certain patterns. They are not formalized, but create a framework for mutual expectations and powers. The client has the right to beckoning from his patron to find him employment (a good job, well-paid, etc.) In turn, the patron (or agent) has the right to client's loyalty. The relationships arising from the wasta are imposed on the partners of the relationship because of their social positions. As a social relationship, wasta is unbalanced - the client usually has more responsibilities than the agent, and the benefits under the patron-customer relationship are unevenly distributed. The patron

accumulates benefits from many customers, so the sum of the benefits he receives is greater than what he redistributes to his clients (Amundsen and Ezbidi 2002). Still, the wasta cannot be seen as a claim or exploitation, because both parties enter it for instrumental reasons, focused on obtaining specific benefits. As about creating a social capital, it is positive for those remaining in the discussed relationship, but for people excluded or losing it on its existence – negative (Górak-Sosnowska 2010).

It's important to notice, that the wasta practices, sometimes referred to as a feature of Muslim culture, exist around the world in various forms and intensities. Susceptible to clientelism are especially countries undergoing systemic transformation, because of changes in the functioning of the economy that cause, among others, unemployment and the deterioration of the material situation of society. Radical changes force the search for adaptation strategies; one of them is the development of informal networks and so-called the gray area. Also in undemocratic countries, the patron-client relationship is new foundation of social order in which a particular segment of society (ethnic group, family, tribe) has a privileged position (Güneş-Ayata 1994). But there is also a culture as a factor creating informal bonds, like guanxi in China. The wasta is sometimes compared to the Chinese concept of guanxi. Both use social networks to influence the distribution of advantages and resources. However, while guanxi is based on Confucian ethics which focus on strengthening collective ties (Hutchings and Weir 2006a; Hutchings and Weir 2006b) and therefore widely accepted in a society, as may benefit organizational competitiveness and performance, the wasta violates generally Muslim ethics.

The wasta's role in economy and politics

The wasta's role in the economy is not clear and mainly concerns the labor market. If a patron employs a client in its own enterprise, becomes directly interested in his work as his employee. It creates a loyalty relationship and builds social capital; if the client has been recommended by a mediator, it is in the client's interest to perform as well as possible. Otherwise he will "lose face"; more, his mediator can lose face as well. In the public sector, however, giving the client employment the patron is less interested in his efficiency and effectiveness as an employee. Working in the public sector means to obtain benefits like a fixed salary and/or social prestige. Having a wasta is an important factor in increasing probability of getting a job in the public sector or promotion (Tlaiss and Kauser 2010). The mediator is obliged to find employment for the client (often many clients) because of social expectations. His high position is seen as a sufficient condition to find a job for clients. There is no excuse (reluctance to find employment, lack of appropriate opportunities, lack of positions in the public sector, insufficient client's qualifications). These expectations are maintained by the nature of Middle Eastern societies in which the individual is seen as part of the group and committed to loyalty to it. A mediator is therefore under pressure, which he transfers to the patron - asking him for employment. The mediator may be in independent wasta relationship with the patron (the mediator is the patron here, and the patron is the client), which causes an additional pressure on the patron (Górak-Sosnowska 2010). Such contact with the patron (or indirectly - with the mediator) is not only for the benefit of individual, but as well for collective benefits, like the implementation of infrastructure projects can be an advantage - construction or renovation of school, roads, sewage system etc. Their implementation requires significant financial outlays that are obtained from ministries or non-governmental organizations. The patron mediates in acquiring these funds (Makhoul and Harrison 2002) and in such terms his role is perceived rather as something positive. It must be taken into consideration that economic reforms, in particular liberalization and privatization, have hit primarily in the lowest segments of the social structure, which caused a return to proven mechanisms such as clientelism (King 2003). The restructuring of the labor market may cause in some circumstances perception of wasta as the only effective method to find a job (Al-Ali 2008). The wasta's role is then complementary to institutional solutions, if state system is proved to be inefficient - not able to meet the needs specific social groups. For this reason, groups at risk of marginalization seek support in informal networks. Still, the wasta as a concept is rather publicly condemned, blamed for Arab world's poor economic performance and brain drain (Cunnigham and Sarayrah 1994). Kilani and Sakijha (2002) stress that wasta is becoming a burden on its seeker, its granter and the government, while Makhoul and Harrison (2004) warns that it may lead to economic decline, and practicing the wasta may feed feelings of injustice and frustration among those who are qualified for the job but do not have proper connections.

As about politics, the power is without doubt one of the most important socially valued goods. In countries with a high level of hierarchy, having power can guarantee access to other desirable goods, like material resources or prestige. An authority guarantees access to resources, and exercising it enables their redistribution. This gives rise to the creation and strengthening the patron-client network, and thus to maintain influence through ruling (Górak-Sosnowska 2010). At the state level, this illustrates the degree of state intervention in the economy. Guaranteeing access of specific social categories to socially valued goods for many years constituted the basis for state power and social order (Bowker 2010). For this reason, state authorities are often not interested in taking action aimed at eliminating or limiting the wasta - it would harm the whole power system (Loewe et al. 2007).

At the local community level, political influence of wasta is still grounded in networks of informal relationships. It is a dynamic system in which positions are negotiated and agreed on an ongoing basis. Due to the collectivist nature of Muslim society, more often it is based on whole families or communities than individuals. Contact with the patron is an important symbol of status, which gives credibility. The inflows of individual parties are dynamic and they often clash. If a given patron does not meet the expectations of the local population, citizens may begin to support another (Makhoul and Harrison 2004). In a way, therefore, wasta enables marginalized individuals and groups to articulate their needs and interests in public space. The patron-client relationship works also during the elections. In exchange for a small fee clients may offer a politician their votes. The transaction, however, is one-off and the amount of payment depends on external factors - distribution of votes in constituency. A participation in the election is for them only the source of income; the political orientation of the candidate is unimportant (Blaydes and El Tarouty 2009).

Due to its informal nature and wide scope, it is difficult to define measurable significance of wasta in economy and politics. An indirect measure can be international rankings on corruption. Positions of Arab countries in the corruption rankings point to the varying effectiveness of measures taken against and at the same time indicate their level of governance. However, international corruption indicators do not reflect specifics of wasta well, because they often focus on financial advantages/benefits (e.g. bribes). For this reason, the position in the corruption rankings does not seem to be correlated with the prevalence of wasta, one can therefore suppose that an effective state management system does not exclude the existence of informal networks within wasta (Górak-Sosnowska 2010).

Muslim accountants and auditors: between Islamic ethics and the wasta

The Islam provides guidance for Muslims in every situation (Al-Ghazali 2001). Islamic ethics covers all aspects of life, physically, morally, spiritually, intellectually, emotionally, individually, and collectively (Al-Qaradawi 1996; Yaken 2006). Islam represents moral values derived from transcendental source - a fundamental concept is based on the Quran (Amin et al. 2013). Islamic ethical system is based generally on equal, justified, benevolent, and accountable principles. Islamic ethical behaviors have much more spiritual dimension, what is understandable, considering that a background is here a religion. More emphasis is placed on individual's conscience and observance of religious teaching, while the pressure is much stronger than in case of other religions, because breaking the rules excludes individual from the circle of believers and thus from the whole community (umma). Because a whole social and economic life in Muslim countries is based on umma, this threat is particularly onerous. There is also an element of fear of punishment in not only mortal life, but also in the afterlife. The wasta seems to be then hard to reconcile with Muslim ethics, but otherwise some features of this ethics (rooting from collectiveness of these societies) cause that the attitude towards wasta is ambivalent. As a phenomenon, it seems to be contrary to the Muslim model of social justice, and therefore not fitting in Muslim society. Still many Muslims admit that the wasta is an effective facilitator of daily life.

Considering a specific position of professionals like accountants and auditors, their independence, honesty and accountability are the key virtues, necessary to practice. Auditors and accountants by definition should be objective in their work and free from conflicts of interest in discharging their professional responsibilities. The study of Muslim ethical principles can help to find an answer, if the wasta can negatively affect their professional behaviors (like to succumb to patron's pressure for employment, desired opinion etc.).

The concept of Amaanah (trust) in Islam is the fundamental ethical principle greatly emphasized in Quran. Muslims must be truthful in their dealings in all aspects of activities (Ahmad et al. 2019). Honoring the public trust means that individuals should accept the obligation to serve the public interest and demonstrate commitment to professionalism (Al-Aidaros et al. 2011). Muslims consider the principle of public interest as more important than an individual interest (Al-Qaradawi 1994). According to this concept, auditors and accountants are trustee of the company resources and they should keep high degree of honesty and respect of information confidentiality. Amaanah comes with the concept of stewardship and responsibility. Auditors and accountants' duty is to be trustworthy in their practices. A responsibility towards God and the umma demands on them to refrain from engaging in activities that may jeopardise their integrity, objectivity and independence (Abdul Rahman, 2003). This principle goes against the assumptions of an intercessory wasta.

The principle of integrity (and righteousness) encompasses a moral integrity based on religiosity and supreme accountability to Allah and requires Muslims to be competent in their professional work (Naqvi 2003), so for Muslim auditors and accountants it will mean to work diligently and provide professional duty with the best service they could. Acting with integrity is to maintain and broaden public confidence, by holding Iman (faith), as the key that protects and increases personal integrity (Al-Qaradawi 1994). Again, this rule contradicts with the wasta and should restrain from practices of hiring incompetent ones.

Khalifah principle implies that the interactions and relationships of human being are based on justice, accountability and trust (Parvez 2000). So accountants and auditors – like other Muslims – following this rule should be honest and truthful in their practice, performing their professional duties by following Allah commandments and avoiding prohibitions (and the wasta is clearly banned in Quran, like it has been mentioned above). With this principle comes along A'del, meaning to treat everyone equally regardless of race, religion, wealth and occupation (Al-Gazali 2001), so from A'del comes at least partially obligation to maintain objectivity and independence, without any bias (Al-Aidaros et al. 2011). Justice is the shortest way to achieve Iman. An order to behave fairly with every Muslim or non-Muslim is connected with acting just, so also acting faithfully.

The same way, an accountability and piety principles encompass Muslim professionals a priority of accountability to Allah over accountability to others (like clients), as well as accountability to society over client's wishes and expectations. In literature of subject it is clearly stated: an auditor (accountant) is accountable to Allah first and foremost, then the umma, then profession and client (Ahmad et al. 2019).

Clear ethical guidelines concerning the day-to-day activities and their transparency come from the sincerity principle, which requires auditors and accountants to perform duties sincerely for Allah and without subject to external influences such as to gain certain rewards or pressures due to their obedience to God. The sincerity in performing duties can benefit the profession by contributing to high productivity and efficiency in professional work, and discourages manipulations as well as enhances cooperation and trust (Ahmad et al. 2019). There is no room for the wasta practices, at least these negative intercessory bonds.

Finally Sabr, which means endurance or more accurately perseverance and persistence, is one of the parts of Muslim faith. The Sabr teaches to remain spiritually steadfast and to keep doing good actions in the personal and collective domain, specifically when facing opposition or encountering problems, setbacks, or unexpected and unwanted results. It is then a patience in face of all unexpected and unwanted outcomes. With respect to the Sabr, there is expected f.e. that professional auditor (accountant) will perform even when has not yet received the fees for previous work done; but more important is, that professionals according to Sabr should not care of possible, unwanted consequences, like client's displeasure and loss (Al-Aidaros et al. 2011).

According to Islam then, auditors and accountants must have professional competency and sufficient knowledge related to financial transactions. Both must be sincere in performing their duties be able to make right decision in seeking Allah's satisfaction (Abdul Rahman 2003). They refrain from agreeing to perform professional duties if they have no sufficient knowledge or competency to perform. Moreover, professional competences in Islam are especially important due to desire to gain Allah's

satisfaction. It is actually very strong motivation to exercise sensitive professional and moral judgments in all their activities (Al-Aidaros et al. 2011). They should observe the profession's technical and ethical principles, develop competence and the quality of services, and discharge professional responsibility to the best. More, they should perform their duty beyond the expectation of clients, because their life should be as perfect as possible (Al-Qaradawi 1994). Also, the reward in the next life is much more important than the reward in this life (such as fees or salary), thus professional auditors and accountants are expected to carry out their work as best as possible in this society, not for the sake of money (Al-Aidaros et al. 2011).

The possible source of wasta's acceptance are then perhaps some specific principles like e.g. Ihsan, representing values that Islam stresses to be incorporated in the daily Muslim life. With respect to Ihsan (kindness), auditor (or accountant) is encouraged to provide perfect services beyond the expectations of the clients (Al-Qaradawi 1994). But kindness in some circumstances means also to be helpful (e.g. to relatives) and lenient (forgiving about their deficiencies), so it may be a background of wasta as well.

Conclusions

Despite the professional ethical codes, we can still witness some unwelcomed practices in business, considering also professional behaviors. The informal, but non-illegal relationship of wasta may be one of them. It is difficult to assess the wasta, though, because – like Chinese guanxi with which it is sometimes compared - it has some advantages and disadvantages. The wasta, deeply rooted in Islamic culture, has become a keyword explaining the failures of economic and political reforms in Muslim countries. However, it should be remembered that the concept of wasta definitely goes beyond the negative practices that are associated with it – like nepotism, mobbing and corruption. It can also mean mediation, lobbying and social solidarity (and here it stays in line with Islamic ethics, emphasizing the solidarity). The wasta in the whole range and variety exists also in other cultures and its universal character allows Muslims to excuse its existence. If it goes beyond the Islamic world and exists actually everywhere, but under different names and in other forms, therefore it may be seen as an immanent element of social order. Another explanation is practical in nature and associated with extensive bureaucracy (Górak-Sosnowska 2010), while the wasta can significantly reduce the time needed to settle matters. It is also really difficult to assess to what extent wasta actually limits the possibility of employment of competent and highly qualified persons; this practice seems to concern primarily the public sector.

This article attempted to find the answer to the question whether representatives of financial services, professionals such as accountant or auditor, may be under the negative influence of the wasta. The paper focused on Islamic religious ethics as a source of moral values, because the religion is considered to be a very strong factor shaping law, manner of conducting business and social bonds in Muslim countries. However, it is some limitation of this paper, which does not analyze f.e. the recommendations of the formal ethical code developed by The Accounting and Auditing Organization for Islamic Financial Institutions and their impact of the subject of matter and does not contain quantitative research. This is a possible field for complementary studies, as well as surveys of Muslim accountants and auditors in order to check their moral judgment regarding wasta and its possible impact on their professional situation, frequency of the phenomenon, etc. Further studies may also be heading towards a deeper comparison of wasta with guanxi, in terms of moral assessment and the risks these phenomena may pose in the environment of financial professionals.

In this paper, an analysis of ethical principles of Islam shows clearly that most of them exclude the wasta as admissible way to professional conduct. Only value of solidarity and principle of Ihsan may be some background to justify its existence. Considering that unethical behavior in Muslim countries carries risk not only bearing legal consequences, but a threat of exclusion from the umma and condemnation in Allah's eyes, beyond the temporal after-effects, it seems that one can venture to say that accountants and auditors' independence, qualifications and objectiveness are not more threatened in Islamic countries than anywhere else, or maybe even less. The existing of the wasta doesn't make their virtues more questionable, as well as it does not seem like these professions may be particularly susceptible to its negative impact.

Abstract

This study aims to determine the effect of the number of members, business volume, capital and assets on cooperative business profits in Indonesia Indonesia. The data used are secondary data taken by the Central Java Cooperative and UMKM Office, the data were analyzed by multiple linear regression. The results showed that partially the number of members did not affect business profits, business volume affected business profits, capital did not affect business profits and assets affected business profits.

Keywords*:* business profits, number of members, business volume, capital, assets, cooperatives

Introduction

Economic development is a very important sector and is one of the focus of the government in making various policies to achieve prosperity. So important is this economic sector that in every policy making must consider all aspects that may affect both positive and negative.

The Indonesian Nation has three economic power sectors that carry out various business activities in the economic order of life, the three sectors are the State-Owned Enterprises (BUMN), private and cooperative sectors. To achieve a strong economic position and achieve a just and prosperous society, the three sectors of economic power must be interconnected and collaborate well. Of the three economic sectors, cooperatives are considered the most suitable to be developed in Indonesia because of their family-friendly nature in the interests of members in particular and society in general. Cooperatives are formed by members and the results are used for the welfare of members.

One indicator of the success of cooperatives can be seen from the size of the business profits that are cooperative income obtained during the fiscal year after deducting depreciation costs and other obligations including taxes in the fiscal year concerned. The greater the business profits obtained by a cooperative, the more it shows progress from year to year.

In the managerial efficiency theory of profit, it is stated that a company can achieve above-normal profit if it succeeds in managing efficiency in various fields and can meet the desires of its consumers. Under the concept of cooperatives, cooperatives will benefit from the results of managerial efficiency, because the business orientation is more emphasis on business services that can provide benefits and

joint decisions of its members. In a cooperative the benefits of the business carried out are called business profits (SHU). So it can be said that to get maximum business profit (SHU), cooperatives must certainly maximize or streamline all components both financial and non-financial. The financial component of cooperatives can be seen from the capital and the volume of business carried out, while for non-finance can be seen from the number of cooperative members (Wiyono, 2016: 612).

Related to this problem, several studies have been conducted, including; Dewik, et al. (2016), who state that the number of members, the number of deposits, the number of loans and working capital has a significant effect on business profits. But partially, the number of deposits has a negative and significant effect on business profits. Cahyani's research (2015) states that there is a direct influence between the number of members on the acquisition of business profits, and there is an indirect effect between the number of members on the acquisition of business profits through member participation. Research Rianto, et al. (2012) concluded that; Capital, Number of Members, and Business Volume together have a significant effect on business profits. But the variable Number of Members harms business profits. In research Lilis (2011) states that the number of members and the number of deposits does not affect the acquisition of business profits, the variable that has a dominant effect on business profits is the variable amount of loans. In Ghazali Syamni's (2016) research on Determinant Cooperatives of Business Profit in Indonesia: A Partial Least Square Approach states that business profits are influenced by employees and business profits are not influenced by members, managers, internal capital, external capital, and business volume. research Carlo Russo et al's (2001)on Effects of Managers 'Power on Capital Structure: A Study of Italian Agricultural Cooperatives states that business profits are influenced by managers' power and capital structure.

The renewal of this study compared to previous research is on the independent variables, the independent variables studied include: number of members, business volume, capital, and assets. As for previous studies, no one has examined the four variables together. Also, the researchers looked at how the overall condition of cooperatives in Central Java. That way we can see the condition of cooperatives in Central Java as a whole.

Literature Review

Business Advantages

Business profits represent the difference between cooperative income in one year after deducting costs and taxes incurred by the cooperative. (Susanti, 2013: 9). Based on Law No. 25 of 1992 business profit (SHU) is the income of cooperatives obtained in one financial year reduced by costs, depreciation, and other obligations including taxes in the fiscal year concerned (Kuznetsov & Kuznetsova, 2008). Wigati and Cornelio (2003) state that business profits are cooperative income obtained from activities or businesses during one accounting period after deducting costs (Putu Trisna Ganitri, 2014: 3).

In general, cooperative business profits are divided as follows: (1) cooperative reserves are part of the allowance for business profits that are not shared and can be used to accumulate their capital and to foster their capital and to cover cooperative losses if needed, (2) member services within the cooperative has a dual function, namely as the owner (owner) and at the same time as a customer (customer), (3) management funds are SHU that is set aside for management or service fees in managing organizations and cooperative businesses, (4) employee funds are allowance for business profits used to pay salaries for employees who work in cooperatives, (5) education funds are allowance for business profits used to finance the education of management, managers, and cooperative employees as an effort to improve the ability and expertise of human resources in managing cooperatives, (6) Social funds are allowance business profits that are used to help ang members of the community and surrounding communities affected by the disaster, (7) the funds for the development of the working area are the allowance for business profits that are used to develop the working area (Tamba, 2001: 78).

The Number of Cooperative Members

The number of cooperative members according to Karta Saputra is the number of cooperative persons or legal entities that have the same interests, namely as the owner and at the same time the cooperative service users themselves (Saputra, 1991: 25). Based on the opinion above, it can be explained that the number of members is a group of cooperative persons or legal entities that have the same interests in carrying out their duties as owners and users of the cooperative's services, so members are required to be active in every cooperative business activity.

The number of members according to Tiktik Sartika Partomo is the owner and at the same time a cooperative service user. (Partomo, 2009: 56). whereas according to Hendar, members are the owners of the cooperative so they will participate in making important decisions for the progress of the cooperative. Members who do not have the ability and willingness to take part in important decisions in their implementation will have an unfavorable impact on the development of cooperatives. Also, Hendar reiterated that members are the main investors who expect benefits for their membership as well as the main customers of cooperative companies. (Hendar, 2010: 148). Members as the main customers are also under Ropke's opinion that the number of cooperative members is the final consumer and entrepreneurs who use the cooperative in its socio-economic activities. (Ropke 2003: 83). Based on this theory, it can be explained that members are investors and cooperative owners who participate in decision-making and as well as the main customers who take advantage of cooperatives in their socio-economic activities.

Cooperative members according to Baswir are individuals who are part of the cooperative following specified requirements (Baswir 2012: 67). It can be explained that the members of the cooperative are a group of individuals who have fulfilled the requirements specified by the cooperative, the same thing was also stated by Wibowo, according to Wibowo cooperative members are people who have been able to take legal actions and meet the requirements set by the cooperative concerned and function as the owner and user of savings and loan services by the cooperative (Wibowo 2017: 13). It can be explained that besides fulfilling the requirements set by the cooperative, cooperative members are also people who have been able to take legal action because there are several rights and obligations of cooperative members that must be obeyed.

Based on the theories above, it can be synthesized that the number of members is a group of individuals who have the same interests and have fulfilled the specified requirements. Besides, members are owners and users of cooperative services, so members are required to be active in every cooperative business activity.

Indicators of members, if we see from the above definitions, are members joining certain requirements determined by cooperatives, members provide benefits as the main customers of cooperatives and members are cooperative investors

Business Volume

The economic activities of cooperatives can be seen from the large volume of cooperative businesses. Activities towards the volume of business carried out by cooperatives can provide maximum benefits, especially for cooperative members and cooperative benefits in general. Business volume is the total value of sales or receipts of goods and services in a given period or financial year. Thus the volume of cooperative businesses is the accumulation of the value of goods and services receipts from the beginning of the fiscal year (January) to the end of the financial year (Hendar, 2010: 159). Based on the above definition, it can be explained that from the total sales of goods or services income will be obtained, so that the business can be seen from the large volume of business so that later it will have an impact on the income received by cooperatives.

The volume of business according to Tamba is the amount of gross circulation of the business or also referred to as operating income (Tamba, 2001: 141), thus the business volume is income from the cooperative business unit. A similar opinion was stated by Siegel that, sales (business volume) are the overall turnover of goods and services sales which are the main operations of all cooperative business units (Siegel, 1999: 123). It can be explained that the volume of business is the sale of goods and services from cooperative business units. Some of the above understanding can be concluded that the volume of business is the amount of gross circulation or can be called operating income for the overall turnover of sales of goods and services which is the main operation of all cooperative business units in a year.

According to Alamiyah and Padji in Fridayana, the volume of business is successfully achieved or wants to be achieved by a company in a certain period (Fridayana 2016: 4). Meanwhile, according to John Down and Jordan Elliot Goodman, translated by Susanto Budidharmo in Astari, business volume is the total sales obtained from commodities traded in a certain period (Astari 2016: 3). So it can be explained that the volume of business is the total sales that a company wants to achieve.

Chaniago in Agustin, business volume is the overall amount of income derived from the sale of goods or services within a certain period (Agustin 2014: 3). It can be explained that the volume of business is the overall results obtained from the sale of goods and services in a certain period. Assegaf Abdullah in Beni Susanti's business volume is the number of units sold from the production unit of a transfer from the producer to the consumer and remains in a certain period. (Susanti 2014: 5). Based on this theory, it can be explained that the total volume of total income from consumer sales in a given period.

The volume of cooperative businesses can consist of various types of businesses depending on the type of cooperative. In a multi-business cooperative, its business activities are not only in the savings and loan business but also in the trade or service business managed by the cooperative. The volume of business or income from a cooperative consists of several characteristics as follows: 1). Revenues arising from product sales transactions or delivery of services to members and non-members, 2). Revenue of certain income is still dependent on the terms/conditions applied. According to PSAK No. 27 concerning Cooperative Accounting, it is stated that income derived from product sales transactions or service delivery to members is reported separately in the calculation of the results of operations as sales to members or income from members. (IAI, 2009: 12) can be interpreted that the business volume is obtained from product sales transactions and service delivery, which in reporting is separated between member transactions and non-member transactions.

Indicators of the volume of business according to Kotler in Sudaryono include:

a. Price. Price is an exchange rate that can be equated with money or other goods for the benefits derived from an item or service for a person or group at a certain time and place. Price interacts with all elements and all elements of.
b. Product Quality Product. quality is the ability of products to carry out tasks that include durability, reliability, progress, strength, ease of packaging and product repairs.
c. Distribution Channels. Products that have been made need to be distributed to reach the hands of consumers, either through distribution channels, intermediaries or sent directly to users of
d. Product. Products are anything that can be offered into the market to reach consumers, up through distribution channels, intermediaries or sent directly to the user
e. Promotional Costs Promotional. costs are the activities of a company that are designed to provide information to persuade other parties about the company concerned and the goods and services offered.

The above theories can be explained that the volume of business is the result of sales of goods and services that are influenced by several indicators of price, product quality, distribution channels, products and production costs. These indicators will affect business units in cooperatives so that cooperatives need to pay attention in determining the price of products and services, determine the distribution channel distribution and create product innovations, and regulate promotional costs so that

they are not too excessive but can attract the market, the way above is done so that business income or business volume is increasing.

Based on the study of the experts above, it can be concluded that the volume of business is the total operating income from the sale of goods or services in a certain period which is recorded separately between member transactions and non-member transactions. The indicators that influence business profits are price, product quality, distribution channels, product and promotion costs.

Capital

Adam Smith in a book entitled "The Wealth of Nations" defines capital as part of the value of wealth that can bring income (Firdaus and Susanto, 2004). the cooperative capital consists of own capital and external capital. As Lukman noted, Mmdal cooperatives comprise and are fostered from the principal, mandatory and voluntary savings of their members (which in this case are also voluntary deposits from non-members), loans and allowances for business results and other sources (Article 32 (1), (2), and (3) Law No. 12 of 1967). Therefore, in a cooperative capital consists or constitutes internal capital and external capital which are equally potential to finance businesses that are specialized as reserves, while external capital comes from loans and deposits (deposits) from outside membership whose amount will depend on the trust that can be fostered by the cooperative itself (Lukman, 2010: 4).

Own capital is capital that comes from the founding funds or members of cooperatives that were first deposited, in the technical language of a company organization commonly referred to as the basic capital for establishing cooperatives (Pachta 2005: 8) based on the above understanding it can be explained that own capital funds from cooperative members who must be deposited at the beginning when joining a cooperative. Meanwhile, according to Hadhikusuma his capital in cooperatives comes from several deposits as follows (1) Principal Deposits (2) Mandatory Deposits, (3) Reserve Funds (4) Grants (Rahardja, 2000: 17). It can be explained that own capital is the accumulation of principal savings, mandatory savings, reserve funds, and grants.

Own capital is capital that comes from several sources, namely the founding funds or cooperative members in the form of principal savings, mandatory deposits that are first deposited, reserve funds, as well as non-binding external funds in the form of grant funds. According to Agustin Lusiana Dewi, loan capital or outside capital is capital that comes from outside as a loan. Loans can be obtained from various parties, including private entities, individuals or government loans and so forth. (Susanti, 2013: 3) can be explained that external capital is capital obtained from loans from individuals or entities.

Arifin Sitio and Halomon Tamba stated that cooperative loan capital can be sourced from the following, (1) Members, (2) Other cooperatives and / or members, (3) Banks and other institutions, (4) Issuance of bonds and other debt securities, (5)) Other legal sources (Tamba, 2001: 67). It can be explained that external capital is loan funds obtained from members, other cooperatives or their members, banks and other institutions as well as from the issuance of bonds and other debt securities and other legal sources.

Both opinions above can be concluded that external capital is capital sourced from outside, namely members, other cooperatives and or their members, banks and other institutions, issuance of bonds and other debt securities, other sources that are legitimate and considered as loans, and based on debt service between the cooperative and the parties concerned..

Aset

Munawir (2007: 30) states that assets are facilities or resources that have economic value that can support a company in its acquisition price or fair value must be measured objectively. Meanwhile, according to Hidayat (2011: 4) that the definition of an asset is the goods in a legal sense is referred to as an object, which consists of movable and also immovable, both tangible (tangible or intangible (intangible). The entirety of this includes assets or assets or assets of an agency, organization, business

and individual or individual

An asset is an object, consisting of movable and immovable objects, both tangible and intangible and the means or resources having an economic value that can support the company in its cost or fair value should be measured objectively. Siregar (2004: 178) states that the assets, in general, is a good (thing) or for something (anything) that has a use-value or economic (economic value), commercial value (commercial value) or exchange value (exchange value) owned by a bad business, agency or individual. So it can be explained that assets are goods that have a use or economic value, commercial value, or exchange value owned by individuals or entities.

Financial Accounting Standard 16 of the 2011 Revision which states that the definition of assets is all assets owned by individuals or groups that are tangible or intangible, which has benefits for each person or company.Based on the understanding it can be concluded that the assets are all assets owned by the business entity or individual who has a use-value or economic (economic value), its commercial value (commercial value) or exchange (exchange value) which is owned by a business entity, institution or individual.

Under ETAP Financial Accounting Standards (2009) Assets are resources that are controlled by an entity as a result of past events and from which future economic benefits are expected to be obtained by the entity. The future economic benefits that are manifested in assets are the potential of these assets to contribute, directly or indirectly, to cash flows and cash equivalents to the entity. Some assets, for example, fixed assets have a physical form. However, the physical form is not essential to determine the existence of assets. Definition of assets according to International Financial Reporting Standards (2008) that the definition of an asset is defined: "an asset is a resource controlled by the enterprise as a result of past events and from the which future economic benefits are expected of flow to the enterprise"

From notions in It can be concluded that the assets are all assets owned by the business entity or individual who has a use-value or economic (economic value), its commercial value (commercial value) or exchange (exchange value) which is owned by a business entity, institution or individual form an object, consisting of movable and immovable objects, both tangible and intangible as well as facilities or resources that have economic value that can support the company in its acquisition price or fair value must be measured objectively.

Method

This study is a causal study to analyze the relationship between one variable and another. This research will discuss the number of members, business volume, capital and assets that can affect business profits. Data obtained through data collection in the field which is done by using the documentation method, through the collection of reports records and financial reports relating to the cooperative situation. This method is used to collect data on the number of members, business volume, capital assets and business profits from 2008 to 2017. The

subjects in this study are Central Java which has a full report during the observation year, while the object of this report is the number of members, business volume, capital and assets, and business profits in Central Java for the period 2008-2017. This type of research data using quantitative data used is cooperative performance data in Central Java in 2008-2017. The data source used in this study is secondary data. Secondary data is data obtained from a second source or secondary source of the required data. Data processed with program e-views 8. In more detail, the formulation model is explained in Figure 1.

Figure 1: The Proposed Model

$\acute{Y} = \alpha + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + e$ .....(1)

Description:

$\acute{Y}$ = business profit
α = constants
β = regression coefficient
X_1 = Number of Members
X_2 = Business Volume
X_3 = Capital
X_4 = Assets

Results and Discussions

Based on the results of the descriptive statistical analysis test, the following distribution of variable data in this study were obtained with the help of Eviews 8.

Table 1: Values of Each Variable Data Statistics

	Business Profit	Number of Members	Business Volume	Capital	Assets
Mean	447636.8	6046888.	27474303	29203463	10250512

Detection of symptoms of classic assumptions is done to find out whether the model used meets the criteria BLUE (Best Linear Unmark Estimator). If the estimation model used has met these criteria, then this model is feasible to be used as a estimation model of the remaining operating results variable. Detection of symptoms of the classic assumptions made in this study include normality, heteroscedasticity, multicollinearity, and autocorrelation. The following are the results of detecting symptoms of these assumptions: At this stage the data under study must pass through hetrokedastisitas, multicollinearity and normality tests. Data can be said to be good if it passes the normality test.

Table 2: Detection Result of Kasik Assumption

Detection Result of Kasik Assumption	Result				
	Nilai Jarque-Bera			P-value	
Normality (Jarque-Bera Test)	4.89			0.08	
	Chi Sqaure-Table			Significant	
	9.49			0.050

Detected normality results shown in table 4.4, it can be seen that the value of Jarqueresults of detection of normality shown by table 4.4, it can be seen that the value of Jarque Wath -Bera is 4.89, while the Chi-Square table is 9.49, with a significance level of 0.05 d an degree of freedom (4-1). With so H0 accepted for Jarque-Bera value smaller than the Chi-quare tabel. In addition, the probability value of the Jarque-Bera is at 0:08 slightly larger than the significance level (0.05), so that H0 is received. Then it can be concluded that the residual value of the estimation model used is normally distributed. Heteroscedasticity detection results shown by table 4.4, which is done using white, the t-statistic probability value of all X variables is greater than the significance level of 0.05. So that H0 is received, which means thatstructure of the variance-covariancethe residuals are homoskedastik. Coefficient value of the correlation between the independent variables shown in table 4.4 on thevalue centered VIF below 10 means that there is no multicollinearity. Thetest Durbin-Watson will produce a Durbin-Watson (DW) value and from the Durbin-Watson value it can be determine the decision whether there is autocorrelation or not. In table 4.4 it is known that if the probability value is greater than the significant level, it can be concluded that this study did not occur autokoleration. If seen from the DW value, then du ≤ DW ≤ 4-du and the meaning of the study there is no autokoleration.

Discussion and Conclusion

Effect of the Total Number of Members on Business profits

The maximum value on the variable number of members is 8221627.which is the total number of Central Java cooperative members in 2017 fourth quarter. While the minimum value of the variable data on the number of members is 4408888.which is the total number of Central Java cooperative members in the first quarter of 2008. To see the dynamics of the variable data movement of the number of Central Java cooperative members during 2008-2017 can be seen through Figure below

Graph. 1: Data Movement Dynamics Number of Members in Central Java in 2008-2017

Based on partial testing (t-test) intended to find out if there is any effect of the number of members on business profits with a significant level of 0.05. From these tests the value of $_{arithmetic}$ = 0.005148 <t_{table} = 0.05 means that the number of members does not affect business profits.

The first hypothesis does not support the hypothesis that is formulated, as well as following the theory, where the number of members always influences the profitability of the business. From the research results obtained probability values indicate that this variable does not significantly influence business profits, with a probability value of 0.9959 thus it can be said that the number of members does not significantly influence business profits. this is following a similar study studied by Sudaryanti, et al (2017) finding the same results that partially the number of members has no significant effect on the effect of the number of members. In addition to Sudaryanti, Ghazali Syamni in his research entitled *Determining Cooperative Business Profit in Indonesia* stated that business profits are not influenced by cooperative members.

This is consistent with the opinion expressed by Hendar that members of the cooperative are the owners

of cooperatives so that they will participate in making important decisions in their implementation, and will have an unfavorable impact on the development of cooperatives. (Hendar, 2010). The number of cooperative members does not have a significant effect on business profits because of the possibility of members who are members of cooperatives less actively participating in businesses conducted by cooperatives. Many members who are members of a cooperative do not influence business profits if the members do not participate in cooperative business activities.

Effect of Business Volume on Business Profits

The average value of the business volume variable is 27474303. the standard deviation of the business volume variable is 14538727, this shows that the sample value is far below the average value. The maximum value of the business volume variable is 61879534, which is the total business volume of Central Java cooperatives in 2017 fourth quarter. While the minimum value of the variable business volume is 10878303, which is the total assets of Central Java cooperatives in the first quarter of 2008. To see the dynamics of the variable volume of cooperative business data movement in Central Java in 2008-2017, can be seen through the picture below.

Graph. 2: Dynamics of Business Volume Data Movement in Central Java in 2008-2017

Based on partial testing (t-test) intended to find out whether there is an influence of business volume on business profits with a significant level of 0.05. From this test, the value of $_{arithmetic}$ = 3.971789> t_{able} = 0.05 means that the volume of business affects business profits.

The second hypothesis supports the hypothesis that was formulated, as well as following the theory. Where the number of members always influences the business profits. From the research results obtained, the probability value indicates that this variable has a significant effect on business profits, with a probability value of 0.0003. under previous research studied by Putu Indira Widiartin, I Wayan Suwendra, Fridayana Yudiatmaja who examined the effect of the loan capital and business volume on business profits, where one result was that business volume affected business profits. The results of this study prove that the opinion expressed by Sitio and Tamba (2011) which states that the volume of business will affect the acquisition of business profits.

Effect of capital on business profits

The capital variable data movement in Central Java in 2008-2017, can be seen through the figure below:

Capital

Based on partial testing (t-test) intended to find out whether there is an influence of capital on business profits with a significant level of 0.05. From the test, the value of $_{arithmetic}$ = -0.745713 <t_{table} = 0.05 means that capital does not affect business profits.

The third hypothesis does not support the hypothesis that was formulated and is not under the theory. Where capital always influences business profitability. From the research results obtained, the probability value indicates that this variable has no significant effect on business profits, with a probability value of 0.4608. this is under a similar study studied by Sudaryanti, et al (2017) finding the same results that partially capital does not have a significant effect on the effect of the number of members. Besides Sudaryanti, Ghazali Syamni in his research entitled *Determining Cooperative Business Profit in Indonesia* stated that business profits are not influenced by capital.

This is consistent with what was stated by Andjar Pachta W, et al (2005), the factors that influence business profits consist of two factors, namely internal and external factors. The internal factors consist of the participation of members, the amount of their capital, the management's performance, the number of business units owned, the manager's performance and the employee's performance. External factors consist of loan capital from outside, the behavior of outside consumers in addition to members and the government. So much or less capital does not affect business profits because the development of capital must also be followed by the performance of employees in managing the business unit.

Effect of Assets on Business Profits

The average value of asset variable data is 10250512. The standard deviation of the variableis baget7343403. This shows that the data shows that the sample values gathered or clustered around the average value of the calculation. The maximum value of variable asset data is 26249000 which is the total assets of Central Java cooperatives in 2017 fourth quarter. While the minimum value of variable

data assets is 3260187.which is the total assets of Central Java cooperatives in the first quarter of 2010. Asset movement can be seen in the dynamic movement of data variable assets for the period 2008-2017 in each uarter, can be seen through the picture below.

Graph. 4: Asset Variable Data Movement in Central Java in 2008-2017

Based on the picture above, it can be seen that assets tend to experience a steady increase from 2008 to 2017 the decline occurred in 2010 the second quarter, but another increase in the next quarter. Based on partial testing (t-test) intended to find out whether there is an effect of assets on business profits with a significant level of 0.05. From this test, the value of $_{arithmetic}$ = 2.650036 <t_{table} = 0.05 means that the assets affect business profits.

The fourth hypothesis supports the hypothesis that was formulated, as well as under the theory. Where capital always influences business profitability. this is under previous studies examined by Dedeh Sri Sudaryanti, Nana Sahroni, who examined the effect of the number of members, external capital and total assets on business profits, where one result is the total effect on business profits.

Simultaneously the independent variable (number of members, business volume, capital, and assets) has a significant effect on the dependent variable (business profit). *under the(managerial efficiency theory of profit*), it is stated that a company can achieve above normal profit if it succeeds in managing efficiency in various fields and can meet the desires of its consumers. Under the concept of cooperatives, cooperatives will benefit from the results of managerial efficiency, because the business orientation is more emphasis on business services that can provide benefits and joint decisions of its members. In a cooperative the benefits of the business carried out are called business profits (SHU). So it can be said that to get maximum business profit (SHU), cooperatives must certainly maximize or streamline all components both financial and non-financial. The financial component of cooperatives can be seen from the capital and the volume of business carried out, while for non-finance can be seen from the number of cooperative members (Wiyono, 2016: 612). The results of output *e-views 8* after the significance test are seen that $F_{arithmetic} > F_{table}$ or 18.60369> 2.63 which means that there is a joint influence between the number of members, business volume, capital and assets on business profits.

Conclusions and Suggestions

Based on the results of research and discussion can be concluded as follows. (1) The number of members does not affect business profits, (2) business volume influences business profits, (3) capital does not affect business profits (4) assets affect business profits (5) number of members, business volume, capital, and assets jointly affect business profits.

In subsequent studies, it is recommended that researchers use more diverse cooperatives with more variables so that the research to be carried out can be more optimal and comprehensive. with diverse cooperatives, it is hoped that further research can be used for all types of cooperatives not just one type of cooperative.

The Effect of Renewable and Nuclear Energy on CO2 Emissions and Economic Growth in Selected EU Countries

Mariola PIŁATOWSKA

Nicolaus Copernicus University, Toruń, Poland
mariola.pilatowska@umk.pl

Abstract

In the paper we examine how renewable and nuclear energy consumption impact the economic growth and CO2 emissions using a four variables Vector Autoregression methodology (VAR) together with causality analysis, forecast error variance decomposition and impulse response function. We use a sample of three countries (France, Spain and Sweden) with different level of economic development and social structure but with a high level of nuclear or/and renewable energy consumption over the period 1970-2018). Our main finding is that renewable and nuclear energy decouples the economic growth from carbon emissions in France and Sweden (in contrast to Spain) what may suggest the policy aimed at reducing carbon emissions is effective, and that introduction of green energy sources contributes to it considerably. Additionally, we have found that renewables in Spain have the negative impact on nuclear energy consumption suggesting that renewable energy tends to squeeze out nuclear energy instead of fossil energy source. Hence, to mitigate climate changes in Spain, the RES support needs to be more markedly completed with changes to political-economic structures that effect fossil fuel use.

Keywords: Renewable and Nuclear Energy, CO2 Emissions, Economic Growth, Decoupling, VAR Model.

Introduction

Global climate change is most of all driven by anthropogenic greenhouse gas emissions, especially CO2 coming mainly from the combustion of fossil fuels. Since the Paris Agreement has been entered into force in 2016, many countries have quantified their contributions more formally known as nationally determined contributions (NDCs) to the United Nations Framework Convention on Climate Change (UNFCCC), in terms of greenhouse gas (GHG) emission reductions. For example, the European Union pledged to reduce GHG emissions by at least 40% below 1990 levels by 2030. Many researchers and policymakers tend to agree that to curtail the effects of climate change, nations must substantially reduce the use of fossil fuels and replace them with "green" technology. Hence, dealing with global warming and emission reductions it is crucial to find sources of energy alternatives to fossil fuels. Many believe that both renewable (hydro, wind, solar, biomass and geothermal) and nuclear energy sources as virtually carbon free energy sources can provide some solutions to the problems of energy security and climate change (Elliott 2007; Ferguson 2007; Adamantiades and Kessides 2009). However, a debate still persists whether the development of renewable and nuclear energy can allow to effectively address environmental problems without harming the economic growth (Apergis *et al.* 2010; Menyah and Wolde-Rufael 2010; Jorgenson and Clark 2012; York 2012; York and McGee 2017).

It is assumed in environmental science and policy analyses that the development of green energy sources, especially the renewable energy, could take the place of fossil fuels and thereby allow for a reduction in carbon emissions and be the contributor to the decoupling of economic growth from CO2 emissions where economies grow but emissions do not (OECD 2011; Weizsäcker *et al.* 2014). However, some empirical analyses have shown that the development of "green" technologies often does not lead to the expected environmental benefits due to complex interactions in political and

economic systems (York 2012; McGee 2015; York and McGee 2017). For example, the common assumption that renewables primarily compete with fossil fuels is not necessarily valid as in affluent nations with high levels of renewables, fossil fuels and renewables may tend to squeeze out nuclear power (York and McGee 2017). Then, high levels of renewables make the economic growth dependent on fossil fuels in place of nuclear power, and conversely, in affluent nations with high levels of nuclear power, growth in renewables tends to substitute more for nuclear power than for fossil fuels (York and McGee 2017).

While there have been numerous studies examining the causal relationship between pollutant emissions, energy consumption and economic growth (e.g. Chontanawat et al. 2008; Dinda 2004; McGee 2015; Ozturk 2010; Payne 2009; Tiba and Omri 2017; Waheed et al. 2019), there is much less empirical research that has attempted to test the causal relationship between emissions, nuclear energy consumption, renewable energy and economic growth (e.g. Apergis et al. 2010; Menyah and Wolde-Rufael 2010). The most important distinction between these studies is the approach they use with regard to multiply- or single country analysis and hence the use of pane data or time series techniques. The majority of these works performed the analysis in a panel data framework. Although, there have been some criticisms of panel data techniques pointing that the main assumption behind pooling the data of different countries in one panel is not satisfied, i.e. the assumption that economic development trajectory is the same for all countries in a panel (Dinda 2004). Moreover, even the countries in seemingly a homogenous group like developed countries differ in the level of economic growth and social structures what seems to speak rather in favour of focussing on individual country analysis in a time series framework. Therefore, we follow the time series approach.

The purpose of this study is to investigate the causal link between nuclear and renewable energy consumption, CO2 emissions and economic growth and the effects of these two energy sources (as potential sources of mitigating greenhouse gases emission) both on emissions and economic growth with the use of modern advances in time series econometrics of integration and causality. This study contributes in the literature by three ways. First, it tests the effects of renewable energy and nuclear energy on CO2 emissions and economic growth using time series approach (VAR model incorporating causality analysis as well impulse response function and forecast error variance decomposition) for three countries (France, Spain, Sweden) with different level of economic development and social structure but with a high level of nuclear or/and renewable energy consumption, while most of the studies focus on group of countries using cross-national time-series (panel model) assuming homogeneity of all countries with regard to the same trajectory of economic development (Fosten *et al.* 2012). Second, we examine whether renewable and nuclear energy development decouples economic growth from carbon emissions based on a relatively longer period of time (annual data from 1970 to 2018) when the renewable energy consumption has already reached a level allowing it to significantly contribute to emissions reduction unlike in previous studies (e.g. Menyah and Wolde-Rufael 2010); then it is more likely to reflect general tendencies than in the shorter period of time. Third, we inspect to what extent the development of renewables may affect the use of nuclear power, which may in turn influence dependence on fossil fuels, and thereby CO2 emissions (York and McGee 2017).

Methodology and Data

To investigate the effect of renewable energy consumption on carbon emissions and economic growth we use the VAR(p) methodology (Juselius 2006):

$$X_t = c + \pi_1 X_{t-1} + \pi_2 X_{t-2} + \ldots + \pi_p X_{t-p} + \varepsilon_t$$

where X_t is (n x 1) vector of endogenous variables, c is constant, π_i – (n x n) coefficient matrices; i=1, 2,…,p, where p is the autoregression order of VAR model and ε_t is an (n x 1) vector of error terms with zero mean and the variance-covariance matrix Ω. This VAR model is estimated to evaluate the impacts of renewable energy (RES) on economic growth and carbon emissions in four countries (France, Spain, Sweden) with different level of economic development and social structures but with a high level of renewable energy consumption (wind, solar, hydro, geothermal or wave power, biofuels). Except renewable energy, we include also the nuclear energy consumption to check the hypothesis that high

levels of renewables tend to squeeze out the nuclear power. Therefore the vector of endogenous variables includes: X_t'=[ΔCO_2, ΔGDP, ΔNUC, ΔRES]), where CO_2 – CO_2 emissions in metric tons per capita), GDP – real gross domestic product in constant 2015 US dollars per capita and NUC – nuclear energy consumption in kg of oil equivalent per capita, RES – renewable energy consumption in kg of oil equivalent per capita. The data with regard to emissions, nuclear and renewable power is taken from the BP databank (www.bp.com) and GDP from OECD database (www.oecd.org). Our sample covers the period from 1970 to 2018 (annual data).

Fig. 1: Renewable and nuclear energy consumption, CO2 emissions and GDP per capita in the selected countries

Fig. 1 shows that since the end of seventies the considerable increase in nuclear energy consumption and since 2000 – in renewable energy consumption has occurred in all countries which is also illustrated by very high rates of growth (Fig. 2). At the same time, it is seen that the GDP has been growing but carbon emissions have been decreasing (Fig. 1). This is an evidence that more energy-efficient technologies and energy policy aimed to reduce carbon emissions have been started to be implemented. However, still the changes in emissions are in general procyclical, i.e. they increase during expansions and decrease during recessions.

Fig. 2: Growth rates of nuclear and renewable energy consumption, carbon emissions and GDP in the selected countries

Note: the prefix 'dl' stands for differences of the natural log of a given variable.

Fig. 1-2 are also the reflection of different economic development trajectories and more importantly – different energy policy in the countries under review. Let us outline some of these differences.

France has a low-carbon electricity mis due to its large nuclear fleet, yet many reactors are reaching the end of their lifetime (IEA.org). Since 2019 the country has started an ambitious energy transition under the Energy and Climate Change Law by designing a national low-carbon strategy, carbon budgets, a carbon price trajectory and a planning framework for energy investment. France plans to reduce the share of nuclear from current 75% to 50% in the electricity mix by 2035 (IEA) as the support for nuclear technology is fading, both politically and socially (due to the cost of post-Fukushima security improvements, delays and over costs in the construction of the new Flamanville 3 reactor in Normandy, in addition to the high cost of replacing plants that will soon reach their useful life). However, reducing nuclear energy will require investments in renewable energy (e.g. planned growth of the share of electric vehicles and variable renewable electricity will demand enhanced power system operation and flexibility, including demand-side response, smart grids and metering and more interconnections.

Spain is a world leader in integration and renewable energy and has built a robust electricity system with high shares of wind and solar PV. In 2016, Spain generated a significant amount of power from renewable sources, with 39% of gross electricity generation (18% of Spain's gross electricity generation came from wind energy, 14% from hydropower, 5% from solar, and 2% from other renewable sources in 2016). The quick growth of renewable generation was possible due to government subsides. However, the government reformed its renewable energy subsidy program in 2014 to cap renewable energy producers' rate of return due to the rising costs of the subsidies. As a result, a drop in renewable generation occurred in 2015, most likely because of these reforms and the low-price environment of coal and natural gas. As a consequence, non-renewable sources (including fossil fuels, 40% and nuclear energy, 22% of country's electricity generation in 2016 respectively) still held the largest share of generation at 62% (IEA, Red Eléctrica de España).

Spain's Kyoto target (GHG emissions increase below 15%) was not reached as emissions were 24% above their 1990 level in 2012. After a 25% fall due to the economic downturn between 2007 and 2016, GHG emissions rose by 4.4% in 2017, as coal-fired power generation had to offset lower hydro resources (due to Europe's massive heat wave in the summer of 2017) and as road transport emissions continued to rise. Therefore, Spain needs to implement clear long-term energy and climate policies to encourage the transition to a low-carbon energy system, and also develop an energy strategy that integrates security of supply, sustainability and internal market dimensions (IEA).

Sweden is a global leader in building a low-carbon economy, with the lowest share of fossil fuels in its primary energy supply among all IEA member countries. Swedish success in its energy transformation has been achieved through market-based policies that focus on energy efficiency and renewable energy, notably CO_2 taxation which helped drive decarbonisation across several sectors (IEA News, 2019). The reason why Sweden has a low emission rate is that about 80% of electricity production comes from nuclear and hydroelectric power; about 11% of the electricity comes from wind power; the share of renewable energy used in Sweden already in 2012 reached the government's 2020 target of 50% (Swedish Energy Agency). Sweden is a good example that ambitious energy transition policies which are well integrated with climate objectives can be accompanied by strong economic growth.

Empirical Results

All variables expressed in natural logarithms are tested for the unit roots using the ADF-GLS (Elliott *et al.* 1996) and KPSS (Kwiatkowski *et al.* 1992) tests. The results tabulated in Table A1 on zenodo.org indicate that all variables are integrated of first order. Therefore, we use the logarithmical differences; this guarantees that all variables are stationary. Then, the order of the VAR model is chosen basing on the lag length test. The detail estimation results are available on request; in this paper we display only the residual diagnostics of VAR models (Table A2 on zenodo.org). The VAR models satisfy the stability condition (no root lies outside the unit circle) and pass all of the multivariate diagnostic tests, including the Breusch-Godfrey LM test for serial correlation, the White test for heteroscedasticity, the Jarque-Bera normality test (reported in Table A2).

Results of Granger Causality Tests

It is seen in Table 1 that in the short run, there is unidirectional Granger causality running from renewable consumption to carbon emissions in the case of France and Spain, while in Sweden the renewables have a neutral effect on CO2 emissions; although, the results for the renewables equation suggest that CO2 emissions Granger-cause the renewable energy consumption. The results in carbon emissions equation show that the nuclear energy consumption significantly affects the emissions in the case of France and Sweden which have a high share of nuclear power in the electricity mix. The findings for Spain and Sweden indicate that the renewable energy consumption has an effect on nuclear energy consumption. It can be seen from the economic growth equation that in the case of France only the renewable energy consumption influences the economic growth. For the other two countries none of the variables have a significant impact on economic growth, implying that the neutrality between renewables and nuclear energy consumption, carbon emissions and economic growth is observed in the short run. However, the economic growth significantly affects carbon emissions and nuclear energy consumption in Spain. In turn, carbon emissions Granger-cause the nuclear energy consumption in Spain and renewable energy consumption in Sweden.

Table 1: Granger causality results of the Wald test for France, Spain and Sweden

Country dependent variable	Causes (short-run effects)

Note: ***, **, * stand for the significance at the 1%, 5% and 10% level respectively.

Forecast Error Variance Decomposition

In this study we focus on the forecast error variance of changes in CO2 and GDP (Table 2). Spain has the largest share of CO2 variation explained by changes in GDP, reaching about 38% after the 6th period. The other countries show lower values, ranging from 27% in France and 11% in Sweden after the 6th period (in line with Granger causality results indicating insignificant impact of GDP on CO2). The contribution of changes in nuclear and renewable (RES) energy consumption to the variation of CO2 is relatively small all countries except France where it reaches about 16% (nuclear) and 24% (RES) after the 6th period. Variations in GDP are explained the most by RES (33%) in France, while in other countries the contribution of RES and NUCLEAR to the explanation of GDP variations is rather small, i.e. 9% and 2% in Spain and 6% and 7% in Sweden respectively. The same occurs to the contribution of CO2 to variations in GDP.

Table 2: Forecast error variance decomposition results

Impulse Response Functions

Figures 3-6 show the results of generalised impulse response functions of each variable to shocks in all variables in the system. We employ the generalized impulse response which is not sensitive to the ordering of variables in the VAR system (unlike the standard approach). Impulse responses show how a given variable responds to a shock in the other variable initially and whether the effect of the shock persists or dies quickly. We combine the interpretation of impulse responses with the results of Granger causality indicating the significant relationship between given variables.

It is clear from an examination of Fig. 3 that carbon emissions respond to changes in GDP only in case of Spain, i.e. shocks in GDP have positive and significant (Table about causality) initial impact on CO2 emissions which appears to die since the 3rd year after the shock. This increase of emissions due to growing economic growth indicates that the decoupling of economic growth from emissions is not observed in Spain so far. Whereas, results for Sweden and France show that carbon emissions respond also positively but insignificantly to one standard deviation innovation in GDP changes (see Table 1), and reversely, the effect of shocks in CO2 emissions on GDP shocks is also positive but again insignificant (Fig. 4, Table 1). This performance of impulse responses together with causality pattern may mean the lower sensitivity of carbon emissions to variations in GDP due to widespread use of low-carbon technologies (Lanne and Liski 2004). Then, these findings provide some evidence for decoupling of economic growth from carbon emissions in the case of Sweden and France. This also means that the conservation policy aimed at the reduction of carbon emissions will not hinder the economic growth in these countries.

Fig. 3: Responses of carbon emissions to shocks in all variable in the system

Carbon emission responses to nuclear shocks in the case of France and Sweden (Fig. 5) are significantly negative and this initial impact of nuclear power shocks on emissions reduction lasts longer in the case of France than Sweden. This indicates that nuclear energy contributes significantly to the abatement of emissions and improvement of environmental quality in both countries. Our result that nuclear energy plays an important role in reducing CO2 emissions is similar to previous research by Iwata et al. 2010 for France and Menyah and Wolde-Rufael 2010 for the US.

Due to the shocks in RES the response of CO2 emissions in France is initially negative reaching its minimum in the 2nd year and then it is persisting several years before dying. While in the case of Spain the initial positive response of emissions to shocks in RES is observed, and then there is a dip in the second year dying quickly in the consecutive years. This means that renewable energy consumption does contribute to reduction of carbon emissions in all countries under study. Our result is in contrast to that obtained by Menyah and Wolde-Rufael (2010) and Apergis et al. (2010) who have not found a significant impact of renewable energy on CO2 emissions. However, it is possible that France and Spain have already reached the threshold pint where renewable energy starts to mitigate CO2 emissions.

Fig. 4: Responses of GDP to shocks in carbon emissions, nuclear and renewable energy consumption

From an examination of Fig. 4 it is seen that GDP does not respond at all to changes in CO2 emissions, nuclear and renewable energy, except the case of France where shocks to RES have initially tiny positive and significant impact on changes in GDP, which switches to negative one since the second year and after reaching its minimum at the third year dies out slowly. This surprising decrease in GDP may be explained by additional generation costs imposed by RES. Another possible explanation is the vulnerability of renewable energy to positive oil prices shocks as renewable energy is considered as a substitute for oil; and it is believed that increased oil price will reduce economic growth (Sadorsky 2009; Lahiani *et al.* 2018).

To examine the possibility that renewable energy may squeeze out nuclear energy we consider the responses of nuclear energy consumption to shocks in RES (Fig. 5). These responses are significant in case of Spain and Sweden, however there are differences in their pattern. Namely, the shock in RES in Spain has an immediate negative impact on nuclear energy consumption which is persisting during several years after shock. This result may suggest that high level of renewables tends to squeeze out nuclear energy rather than fossil fuels (York and McGee 2017). This seems to occur in case of Spain where the rise in fossil fuel consumption has been observed, i.e. coal consumption recorded its highest surge at 28.5% in 2017, boosting CO2 emission by 6.9% (BP 2018). This is surprising that there are barely any improvements in the energy mix over the last 20 years (coal consumption which accounted for 38% in 2017 is the same as in 1998) despite long-lasting political efforts to promote the replacement of coal with cleaner fuels and lower CO2 emissions.

While the shock in RES in Sweden has a positive effect on nuclear energy which is slowly decreasing in consecutive years but still remains positive, unlike the case of Spain. This result is a confirmation of coherent energy policies focused on energy efficiency and 'green' energy sources which in turn helped drive decarbonisation.

Fig. 5: Responses of NUCLEAR to shocks in carbon emissions, GDP and renewable energy consumption

Fig. 6: Responses of RES to shocks in carbon emissions, GDP and NUCLEAR energy consumption

Conclusions

The growing concerns about climate change, reduction of emissions and energy security have brought the importance of both nuclear and renewable energy to the forefront of the energy usage debate. This paper explores the causal link between renewable and nuclear energy consumption, CO2 emissions and economic growth for three countries (France, Spain, Sweden) over the period 1970-2018 using the VAR approach.

The empirical evidence indicates that nuclear energy consumption (France, Sweden) and renewable energy consumption (France and Spain) significantly reduce CO2 emissions. The forecast error variance decomposition also shows the pronounced contribution of nuclear and renewable energy consumption in explaining variations in carbon emissions (it ranges from 8% to 16% for nuclear energy, and from 14% to 24% for renewable energy after the 6th period). These findings indicate that both nuclear and renewable energy plays an important role in reducing carbon emissions.

The finding of no causality between carbon emissions and GDP for France and Sweden suggests both that emissions are less sensitive to variations in GDP and conservation policy aimed at reducing emissions does not hinder economic growth. This can be interpreted as an evidence of decoupling economic growth from carbon emissions mainly due to widespread use of low-carbon technologies combined with effective energy transition policy which is well integrated with climate objectives. Therefore, France and Sweden can be thought to be on leading-edge trend because of their small CO2 emissions despite their relatively high economic growth. The results for Spain, in contrast to those for France and Sweden, do not provide evidence for decoupling of economic growth and CO2 emissions as the variations in GDP significantly contribute to the increase in emissions. Despite the significant impact of renewables on emission reduction, growing economic growth in Spain seems to offset the reduction in emissions due to the expansion of renewables. It also means that the potential reduction of carbon emissions will be at the cost of economic growth. Moreover, the negative impact of renewables on nuclear energy consumption suggests that the production of electricity from renewable sources is prone to suppress the production of nuclear power instead of fossil fuel use. This is surprising that despite long-lasting political efforts to promote green energy sources and lower carbon emissions, there are barely improvements in Spanish energy mix with regard to coal consumption (in 2017 it accounts for 38% as in 1998). Hence, to mitigate climate changes and reduce carbon emissions in Spain, the development of non-fossil energy sources should be more markedly completed with parallel changes to political-economic structures that affect fossil fuel use.

Patenting Activities in The Context of Innovative Capacities of Public and Private Sectors in Poland

Krzysztof KLINCEWICZ

Faculty of Management, University of Warsaw, Warsaw, Poland
kklincewicz@wz.uw.edu.pl

Abstract

The paper analyses the origins of innovative capacities in various industries in Poland. The analyzed data covered years of 2006-2015, decomposed into patent applications filed by public and private sectors, as well as high and low technology industries. More patenting activities were registered in low technology industries, which also tend to be dominated by private sector applicants, while majority of high technology patents were granted to public sector organizations. Public sector applicants have higher patent success rates, while more applications originating in private sector tend to be rejected by patent examiners, and many patents granted to public sector owners expire because universities and research institutes refrain from paying the maintenance fees. This comparative analysis reveals diversified approaches to patenting and their respective effectiveness. It also supports the quest for relevant innovation indicators, highlighting the limitations of aggregate measures of patenting, commonly used to characterize innovation systems.

Keywords: Patents, High Technology, Innovation Indicators, Public Sector, Industry

Introduction

The paper investigates the origins of innovative capacities spread across various industries in Poland. For each industry, patenting activities were analyzed for years of 2006-2015. Counts of patent applications and granted patents were decomposed into subsets representing individual industries, as well as divided into patent documents filed by public and private entities. This enabled cross-sectoral comparisons, revealing diversified approaches to generating inventions, protecting them and collaborating in R&D in specific industries, public and private organizations.

Analyses of patents can offer interesting insights into practices of public and private sectors across multiple industries. The paper looks at this important dimension of sectoral innovation systems, contrasting the performance of industries in Poland, 2006-2015. Decomposition of patent applications and granted patents helps analyze the activities of public and private sectors, revealing their differentiated effectiveness and collaboration patterns. Patent analysis offers only limited insights into innovation systems, owing to its focus on inventive results that could be protected by patents, and disregarding diffusion of innovations or creative processes that are not patentable. Nevertheless, the study offers a systematic comparison of important aspects of the innovation system and management practices.

Literature Review

Knowledge gaps exist in relation to the differences in patenting of public and private sectors, and there is a notable lack of relevant studies for Poland. Acs et al. (2002) discussed the merits of using patent data as proxies for innovations, offering an overview of literature and a comparison between patent statistics and other indicators such as R&D expenditures and literature-based innovation measures (bibliometric indicators referring to scientific or technological publications).

The US universities became sources of commercialized inventions through regulations that facilitated the protection and transfer of academic inventions (Mowery et al., 2001; Grimaldi et al., 2011). Czarnicki et al. (2016) analyzed the role of scientific inventors commercializing academic patents through the establishment of spin-offs or start-ups. Geuna and Nesta (2006) analyzed university patenting in Western Europe, with mostly reputational uses of patents by universities. Scientific inventions at European universities are rarely licensed and when they are, licenses tend to generate revenues not covering the costs of their development and protection. In the past, many European universities refrained from patenting and allowed scientists to individually pursue protection (Lissoni, 2013: 380). The European public science displays heterogeneity of approaches to patent protection (Czarnitzki et al., 2009: 28). These challenges have not played a significant role in Poland, as even prior to the change of economic system of the 1990s, universities and research institutes retained the ownership of inventions and were actively patenting, albeit usually with limited commercial interests, using the patents as indicators of research excellence. Inventions generated by Polish scientists are owned by the employing scientific institution, which differs from some countries (Geuna, Rossi, 2011: 1069).

Patents are used either to protect inventions, or for other, "strategic" uses. Goktepe-Hulten and Mahagaonkar (2010: 401) indicated that scientists tend to patent for reasons other than financial benefits, focusing on reputational gains. Many patents in public sector serve as quality signals, building up the recognition and academic reputation of scientists (Goktepe-Hulten, Mahagaonkar, 2010: 407). For academic entrepreneurs, founders of start-ups or spin-offs, patenting remains relevant and instrumental for their success, and the filing of a patent application increases their willingness to initiate entrepreneurial activities (Goel, Goktepe-Hulten, 2013: 472). Patents signal the competence and managerial sophistication of start-ups (Lai, 2017: 826), so reputation is prioritized over commercial gains. Similarly, in a survey of patent holders at the European Patent Office, individuals (including founders of small companies) were found to use the signaling function of patents rather than expecting their inventions to be monetized (Veer, Jell, 2012: 514).

Patents have different uses depending on industry. Cohen et. al (2002) surveyed R&D managers to analyze R&D performance of companies in the US and Japan. Their results reveal differing propensity to patent, including cross-sectoral diversity in the uses of patents, which might either be transformed into marketable products, or maintained for strategic reasons, e.g. to block competitors from entering into a specific field, demonstrate technological strengths, support negotiations or prevent infringement suits (Cohen et al., 2002: 1358).

For private sector, including individual inventors and newly established companies, patenting costs can become prohibitive (Goel, Goktepe-Hulten, 2013: 474), resulting in decisions to cease patent protection. Inventions protected by individuals tend to be less valuable than outcomes of corporate R&D (Laplume et al., 2015: 40). Individual patent owners play important roles in Poland, in a manner different from many other countries. For example, majority of South-Korean patents are held by organizations, while in Taiwan, far bigger share of patents were filed by individuals (Wang, Tsai, 2010: 1413), and in the US, individual applicants retain visible roles (Agiakloglou et al., 2016: 147).

Cross-sectoral cooperation in patenting, involving joint patent applications filed by representatives of public and private sectors, is still relatively rare. The suggestion to look into linkages between public and private R&D was formulated by Narin et al. (1997). Joint patenting, licensing or transfer of patented inventions remain only some of possible collaborative mechanisms, and not the most widely used ones (Perkmann, Walsh, 2007: 262-263). Interactions between scientists and companies take multiple forms, with many approaches not formally registered or not relying on transfer of patents (Boardman, Ponomariov, 2009: 142). Comparable results are also provided by the analysis of US industrial patents held by multiple co-owners (Mahnken, Moehrle, 2018).

Following the literature review, the following research gaps were identified, and will be filled in by the present study:

- differences between patenting of public and private sectors, depending on the specific industry and high or low technology,
- cooperation patterns that result in joint patenting, including multiple co-owners of an application, and cross-sectoral applications filed together by public and private sectors,
- differences in the rates of success (patent grant), failure (rejection of patent application) and discarding the already awarded patents (no payment of maintenance fees), which indicate differing approaches to patenting, varying degrees of professionalism and commitments to pursue patented results as commercially relevant.

These research gaps lead to the formulation of the research theme, which consists in the analysis of the origins of innovative capacities in sectoral innovation systems in Poland, decomposed into activities of applicants representing public and private sectors, and patent applications belonging to various specific industries/fields of technology.

Research Methods

The research presents quantitative analysis of patent applications, using bibliometric techniques (Porter and Cunningham, 2005). The dataset was downloaded in 2018 from the database of the Polish Patent Office. The queries identified all priority applications matching the selected patent sub-classes filed between 2006 and 2015. The document subset consisted both of applications with granted patents, as well as applications that have received negative decisions or were still awaiting a grant. Based on the adopted methodology and selected data sources, the research maps technological activities from a period of tremendous changes in Poland's innovation system due to the increased availability of public funding for R&D, and accompanied by proportional increases in the levels of private R&D expenditures.

Patent applications were identified from the International Patent Classification (IPC), corresponding to the specific types of technologies or industrial activities from NACE classification of industries and services, as proposed by van Looy et al. (2014) (Table 1).

Table 1: The concordance table between NACE and IPC classes used to match specific industries to subsets of patent documents. Source: van Looy et al. (2014)

NACE class	Industry	IPC classes
10	Manufacture of food products	A01H, A01J, A21D , A23B, A23C, A23D, A23F, A23G, A23J, A23K, A23L 1/*, A23L 3/*, A23P, C12J, C13B, C13F, C13J, C13K
11	Manufacture of beverages	A23L 2/*, C12C, C12F, C12G, C12H
12	Manufacture of tobacco products	A24B, A24D, A24F
13	Manufacture of textiles	D04D, D04G, D04H, D06C, D06J, D06M, D06P, D06Q, D06N
14	Manufacture of wearing apparel	A41B, A41C, A41D, A41F
15	Manufacture of leather and related products	A43B, A43C, B68B, B68C
16	Manufacture of wood and of products of wood and cork, except furniture; Manufacture of articles of straw and plaiting materials	B27D, B27H, B27M, B27N
17	Manufacture of paper and paper products	B42F, D21C, D21H, D21J
18	Printing and reproduction of recorded media	B41M, B42D, B44F

NACE class	Industry	IPC classes
19	Manufacture of coke and refined petroleum products	C10G, C10L
20.2	Manufacture of pesticides and other agrochemical products	A01N, A01P
20.3	Manufacture of paints, varnishes and similar coatings, printing ink and mastics	B27K, C09D
20.4	Manufacture of soap and detergents, cleaning and polishing preparations, perfumes and toilet preparations	A61K 8/*, A61Q, C09F, C11D, D06L
21	Manufacture of basic pharmaceuticals products and pharmaceutical preparations	A61K (except A61K 8/*), A61P, C07D, C07H, C07J, C07K, C12N, C12P, C12Q
22	Manufacture of rubber and plastic products	B29B, B29C, B29D, B60C, B67D, C08C
23.3	Manufacture of clay building materials	B28B, B28C
23.4	Manufacture of other porcelain and ceramic products	E03D
23.5	Manufacture of cement, lime and plaster	C04B
25.7	Manufacture of cutlery, tools and general hardware	E05B, E05D, E05F, E06B
27.1	Manufacture of electric motors, generators, transformers and electricity distribution and control apparatus	H02B, H02J, H02K, H02N, H02P
27.2	Manufacture of batteries and accumulators	H01M
27.3	Manufacture of wiring and wiring devices	H01B, H01H, H01R, H02G
27.5	Manufacture of domestic appliances	A21B, A45D, A47G, A47J, A47L, B01B, D06F, E06C, F24B, F24C, F24D, F25C, F25D, H05B
28.3	Manufacture of agricultural and forestry machinery	A01B, A01C, A01D, A01F, A01G, A01K, A01M, B27L
29	Manufacture of motor vehicles, trailers and semi-trailers	B60B, B60D, B60G, B60H, B60J, B60K, B60L, B60N, B60P, B60Q, B60R, B60T, B60W, B62D, F01L, F02B, F02D, F02F, F02M, F02N, F02P, F16J, G01P
30.1	Building of ships and boats	B63
30.2	Manufacture of railway locomotives and rolling stock	B61
30.3	Manufacture of air and spacecraft and related machinery class	B54
31	Manufacture of furniture	A47B, A47C, A47D, A47F
32.4	Manufacture of games and toys	A63
32.5	Manufacture of medical and dental instruments and supplies	A61B, A61C, A61D, A61F, A61G, A61H, A61J, A61L, A61M, A62B, B01L, B04B,

NACE class	Industry	IPC classes
		C12M (not A61K except A61K 8/*), G01T, G21G
42	Civil engineering	E02B, E03B, E03C
43	Specialised construction activities	E03F, E04B, E04C, E04D, E04F, E04G, E04H

The data were divided into submitted by public sector entities (public universities and research institutes, public hospitals and governmental agencies) and private sector applicants (companies and individuals). Applications submitted by two or more applicants, representing both sectors, were assigned to two sector at the same time (shares of applications filed by public and private entities may add up to more than 100%).

The delineation of documents was based on applications not granted patents, owing to limited certainty of receiving the patent rights, time lags between submission and award, and limited opportunities to track actual R&D merely on the basis of granted patents. The results may thus include applications that were negatively evaluated by patent examiners, and were not innovative, lacked inventive steps, referred to known or prematurely disclosed solutions, or described ideas that could not be subject to patent protection.

Research Hypotheses

The study will verify 8 research hypotheses, related to the origins of innovative capacities revealed by patent applications filed by representatives of public and private sectors in Poland.

H1. More patent applications are filed in high technology or medium-high technology sectors than low or medium-low technology sectors of the Polish economy.

Various industries differ in their patenting propensities. Proportionally more patent applications can be expected in high technology or medium-high technology sectors than in more traditional, low technology or medium-low technology industries, which had limited experiences in using the intellectual property protection. The distinction between levels of technology is possible thanks to a standardized classification. Eurostat (2016) divided industries into:

- high and medium-high technology: NACE 20, 21, 26, 27, 28, 29 and 30
- low and medium-low technology: NACE 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 22, 23, 24, 25, 31, 32 and 33

For the present study, 14 sub-groups of patents were considered to represent high technology or medium-high technology (including also NACE 32.5, medical technologies), while the remaining patents were considered to be low technology or low-medium technology.

H2. High and medium-high technology patent applications in Poland are dominated by public sector organizations, while low and medium-low technology patents are primarily filed by private sector applicants.

The scale of patenting activities of public and private organizations might be notably different depending on the type of technologies or NACE classes. Public sector entities are hypothesized to excel in patenting of inventions in the fields that are scientifically advanced and linked to the high-technology. Private sector organizations and individual inventors-owners might be more active in low-tech NACE classes, which in turn do not correspond to research interests of scientists working for universities or public research institutes.

H3. High and medium-high technology patents in Poland are granted primarily by public sector organizations, while low and medium-low technology patents are granted mostly to private sector applicants.

In a manner similar to the analysis of patent applications, counts of granted patents can be divided into grants awarded to public and private sector representatives. Shares of granted patents awarded to public and private entities reveal the differing activities of actors in each sectoral innovation system, with some NACE classes dominated by either public or private actors. Similarly to patent applications, it could be hypothesized that public sector tends to concentrate its patenting activities in high-technology NACE classes, while private sector leads the patent grants in other types of technologies.

H4. High and medium-high technology sectors in Poland are characterized by higher propensity to interorganizational cooperation that results in joint patenting when compared with low and medium-low technology sectors.

Innovation processes are increasingly collective, involving multiple collaborations in accordance with the open innovation model. Polish organizations have been catching up with the trends, but many R&D and innovation still remain restricted to inhouse activities. This can be measured by shares of patent applications submitted by more than one applicant. High and medium-high technology industries are expected to be more active in inter-organizational collaboration.

H5. High and medium-high technology sectors in Poland are characterized by higher propensity to science-industry cooperation that results in patenting applications submitted jointly by representatives of public and private sectors when compared with low and medium-low technology sectors.

Cross-sectoral ownership of patent applications between public and private sector corresponds to results of science-industry R&D projects, carried out as partnerships of equals rather than contract R&D. Occurrence of such joint patenting might be limited, because transfer of intellectual property to the commissioning party is more popular for science-industry cooperation.

H6. Success rates of patent applications filed by public sector organizations are higher than for applications submitted by private sector applicants.

Success rates can be interpreted as shares of applications that lead to a grant. Comparison of success rates reveals cross-sectoral differences related to abilities to screen for viable inventions, prepare patent applications and deal with patenting procedures. Some public sector applicants might not have sufficient experience in patenting, and file imperfect applications. Even within the same university, applications from one field might have rates significantly lower than other fields due to diversified skills of attorneys and research teams.

In private sector, individual inventors often draft applications by themselves, disregarding procedural requirements or not following the common standards. Less experienced companies might also make mistakes that restrict patenting probability (e.g. premature invention disclosure).

H7. Failure rates of patent applications filed by public sector organizations are lower than for applications submitted by private sector applicants.

Failure rates indicate shares of applications with negative decisions. Patenting failures may result from characteristics of technologies (e.g. lack of novelty; solutions not protected in the Polish system such as software). Other reasons relate to procedural mistakes (e.g. premature disclosure; inadequate contents; failure to respond to patent examiners requests). Failure rates are expected to reveal diversity among NACE classes and between the public and private sector. Public organizations are hypothesized

to be more professional in patenting, when compared with private entities that also include individual inventors.

H8. Shares of patents that are no longer maintained by their owners and loose exclusive protection due to unpaid patent maintenance fees are higher for patents owned by public sector organizations than by private sector applicants.

Counts of applications or grants illustrate the scale of R&D activities in industrial sectors, but might not be viable indicators of commercial outputs. Some NACE classes appear dominated by patenting of public sector, with limited interests of private applicants. This leads to misleading conclusions about their innovativeness. Applications filed by scientific institutions might be indicators of excellence of research, but not necessarily filed to introduce new products, or to transfer the technologies to companies that would commercialize them.

This could be analyzed by patterns of patent maintenance. After a patent is awarded, its owner is obliged to pay maintenance fees in order to retain exclusive rights to the invention. Some owners stop paying the maintenance fees and their invention loses the patent protection.

This might be linked to multiple scenarios:

- use of patents as signals of research quality not commercial instruments,
- patent is no longer commercially attractive (failed attempts to transfer the technology),
- lack of funding to pay maintenance fees,
- mistakes of patent owners.

Patent application fees are low in Poland, amounting to ~120€ for short applications, but the costs of maintenance fees need to be paid. "No maintenance rates" were calculated by comparing counts of granted patents discarded by owners with the counts of granted patents. They did not include applications still under examination. Public organizations are hypothesized to discard more patents than private owners, who tend to apply for protection of inventions considered commercially important.

Research Results

The analysis of patent data enabled stepwise verification of the eight research hypotheses, which are discussed in this section of the paper.

High and medium-high technology industries yielded more applications (10,538) than low and medium-low technology industries (7,051), thus confirming **H1**, see: Table 2.

Table 2: Patent applications submitted by applicants representing public and private sector in Poland. Source: own elaboration, based on data from the database of the Polish Patent Office.

NACE class	Applications (all)	Applications (public)	Applications (private)
Low and medium-low technology			
10	894	395	531
11	169	66	106
12	139	4	135
13	220	104	130
14	137	40	101
15	33	6	27
16	112	17	99

NACE class	Applications (all)	Applications (public)	Applications (private)
17	84	24	65
18	110	4	106
19	476	167	340
22	733	246	492
23.3	134	21	114
23.4	40	2	38
23.5	530	272	285
25.7	689	16	674
31	418	28	393
32.4	329	64	266
42	253	81	179
43	1,551	196	1,369
Total	**7,051**	**1,753**	**5,450**
High and medium-high technology			
20.02	385	123	271
20.03	208	99	119
20.04	330	156	176
21	2,747	2,146	675
27.1	666	332	343
27.2	162	122	48
27.3	467	160	316
27.5	916	123	801
28.3	700	252	458
29	1,473	543	947
30.1	233	57	178
30.2	289	111	188
30.3	166	68	103
32.5	1,796	860	1,000
Total	**10,538**	**5,152**	**5,623**

H2 was not supported by empirical data (Table 2). For high and medium-high technology, 53.4% of applications were filed by private applicants, and 48.9% by public sector. The only distinctive differences concern NACE classes: 21 (pharmaceuticals), with 78.1% applications filed by public sector, and 27.2 (batteries and accumulators; 75.3% from public sector).

Fig. 1: Shares of patent applications filed by representatives of public and private sectors in specific industries. (L) indicates low and medium-low technology sectors, (H): high and medium-high technology sectors. Source: own elaboration, based on data from the database of the Polish Patent Office.

In low and medium-low technology industries, private sector dominated (77.3% of applications) over the public sector (24.9%). In some of the NACE classes, public entities were hardly active (12, 18, 23.4, 25.7, 31), see: Figure 1. Private sector accounts for majority of patenting in low and medium-low technology, while in high and medium-high technology, the situation is more diversified, with some fields dominated by public entities while others displaying also strong activities of private sector.

Results of analyses confirm **H3**, as illustrated by Figure 2. For high and medium-high technology, 63.4% of granted patents are owned by public sector, while only 38.9% by private sector; for low and medium-low technology, the distribution of granted patents is reversed, as 68.8% of patents belong to private owners and 34.1% to public entities.

Fig. 2: Shares of granted patent owned by representatives of public and private sectors in specific industries. (L) indicates low and medium-low technology sectors, (H): high and medium-high technology sectors. Source: own elaboration, based on data from the database of the Polish Patent Office.

Shares of patent applications filed jointly by two or more applicants were not distinctively different for high/medium-high technology (11.5%) and low/medium-low technology (12.1%), so **H4** was not confirmed (see: Table 3).

Table 3: Shares of patent applications filed by more than 1 owner and filed jointly by representatives of public and private sectors. Source: own elaboration, based on data from the database of the Polish Patent Office.

NACE class	Shares of applications with more than 1 owner	Shares of applications jointly filed by public and private applicants
Low and medium-low technology		
10	15.0%	3.8%
11	8.3%	1.8%
12	0.0%	0.0%
13	22.3%	6.4%
14	19.7%	2.9%
15	18.2%	0.0%

22	10.2%	1.9%
23.3	11.2%	0.7%
23.4	5.0%	0.0%
23.5	12.5%	5.1%
25.7	9.0%	0.1%
31	8.9%	1.0%
32.4	9.4%	0.3%
42	12.6%	2.8%
43	10.6%	0.9%
Total (high and medium-high technology)	**12.1%**	**2.3%**
High and medium-high technology		
20.02	11.9%	2.3%
20.03	15.9%	4.8%
20.04	10.9%	0.6%
21	14.1%	2.8%
27.1	8.9%	1.4%
27.2	11.7%	4.9%
27.3	8.6%	1.9%
27.5	12.1%	0.9%
28.3	9.0%	1.4%
29	6.2%	1.2%
30.1	11.6%	0.9%
30.2	9.0%	3.5%
30.3	9.0%	3.0%
32.5	14.2%	3.6%
Total (high and medium-high technology)	**11.5%**	**2.3%**

H5 was not supported, as illustrated by Table 3. Both for high/medium-high technology and low/medium-low technology, shares of applications filed jointly by science and industry (public-private co-ownership) were approximately equal, amounting to 2.3% of all applications, so no distinctive difference was observed.

H6 was supported for most of the analyzed industries (see: Figure 3). Private sector outperformed public sector only in NACE sub-classes 20.02, 23.3 and 31. This means that public sector organizations are more likely to submit patent applications that would lead to successful grant.

Fig. 3: Success rates of patent applications filed by representatives of public and private sectors in specific industries. Source: own elaboration, based on data from the database of the Polish Patent Office.

H7 was supported for the majority of industries, as illustrated by Figure 4. Private sector applicants have lower failure rates than public sector only in three NACE classes (15, 18 and 30.2). For other industries, private applicants perform worse than public organizations and have more applications rejected.

Fig. 4: Failure rates of patent applications filed by representatives of public and private sectors in specific industries. Source: own elaboration, based on data from the database of the Polish Patent Office.

H8 was confirmed for majority of the industries, albeit the tendency is not uniform across all fields (Figure 5). Private owners are less willing to pay maintenance fees in classes: 12, 15, 16, 17, 23.3, 23.4, 25.7 and 30.2. Public organizations cease the maintenance more often in classes: 10, 11, 13, 19, 20.2, 20.3, 20.4, 21, 22, 23.5, 27.1, 27.2, 27.3, 27.5, 28.3, 29, 30.1, 30.3, 31, 32.4, 42 and 43, i.e. majority of the industries. NACE classes where public owners frequently discontinue financing of patents include high and medium-high technology industries.

Fig. 5: No maintenance rates of patent applications filed by representatives of public and private sectors in specific industries. Source: own elaboration, based on data from the database of the Polish Patent Office.

Conclusions

The paper presented results of a patent analysis in Poland, looking into applications filed by public and private sectors, from various industrial sectors.

More patent applications were filed in high/medium-high technologies than in low/medium-low technologies (H1). Low technology industries were dominated by applicants from private sector, while the situation in high technology industries was more nuanced, with dominance of public sector only in pharmaceuticals and batteries & accumulators (H2). The analysis of granted patents revealed a dichotomy between low technology dominated by the private sector and high technology, where the majority of patents was granted to public sector (H3). No distinctive differences were identified in joint patent applications when comparing public and private sector or various industries (H4, H5). Outcomes of patenting were different depending on the sector of applicants: the public sector was characterized by higher success rates (H6), and the private sector has more applications rejected by examiners (H7). Shares of patents that are not maintained by their owners were higher in the public sector than among private owners (H8).

The analysis offers interesting insights for management science. It reveals the institutional diversity of organizations pursuing R&D activities, with heterogeneous approaches and differing outcomes. Aggregate measures of patenting, used to compare innovation systems, might be misleading as they include patent applications filed both by public and private sectors, and only some of them are subsequently commercialized. Researchers might benefit from more granular indicators, as demonstrated by the present paper. For management practitioners, the research can also offer useful information about tendencies in various sectors and industries, facilitating search for potential collaboration partners, and providing inputs into the valuation of intellectual property in technology transfer transactions. Future research directions include further decomposition of the dataset of Polish patent applications, analyzing individual sectors, technologies and regional applicants. Comparable research approach could also be adopted for patent data from other countries, with a view to analyze activities of private and public sector organizations.

Abstract

This paper presents the main characteristics of Lake Baikal, which is a UNESCO World Heritage Site. Various environmental problems that harm the lake are considered. Forest cover problems due to "black loggers" and fires caused by natural or human causes. Problems with the fauna of the lake due to poachers hunting mainly for omul and grayling. Pollution problems due to the improper cleaning system of nearby enterprises, the lack of special boxes accepting garbage from other vessels, as well as the activity of tourists near the lake. The discussion includes measures taken by the state to protect the lake and the surrounding territories, as well as social actions related to protection. Further, a system for the protection and restoration of Lake Baikal with specific steps and a sequence of problem solving was developed and presented.

Keywords: Lake Baikal, protection, loess massifs, the fauna, pollution, world heritage.

Introduction

Currently, Lake Baikal is a UNESCO World Heritage Site, and in Russia it is the only geographical object that has protection in the form of the federal law. The UNESCO World Heritage Committee on December 7, 1996 at the XII session in Merido (Mexico) included Lake Baikal on UNESCO's World Heritage List under No. 754 for all four criteria of the UNESCO Convention on the Protection of the world Cultural and Natural Heritage (1972). Lake Baikal is unique. It is the deepest lake in the world. The bottom of Lake Baikal is 1167 meters below the level of the World Ocean, and the mirror of its waters is 453 meters higher. The lake stretched from northeast to southwest for 620 km. The width of Lake Baikal ranges from 24 to 79 km. Among the largest lakes in the world, Baikal takes the sixth place in terms of the area of the water mirror (31,722 km2 excluding islands). The coastline is 2100 km long. Baikal has the largest fresh water supply - 23,615.39 km3 (about 19% of the world's reserves of lake fresh water), it has more water than all five Great Lakes of North America taken together (https://spravochnick.ru/geografiya/geografiya_baykala/, Geography of Baikal).

1. In its turn, there is The Federal Law "On the Protection of Lake Baikal", which was accepted special for protection this «pearl of Siberia». Moreover, not just the lake Baikal, but the territory around too. So, turning to the law: «Baikal Natural Territory - a territory that includes Lake Baikal, a water protection zone adjacent to Lake Baikal, its catchment area within the territory of the Russian

Federation, specially protected natural territories adjacent to Lake Baikal, as well as an area up to 200 wide adjacent to Lake Baikal kilometers west and northwest of it.» (http://base.garant.ru/2157025/, Federal Law of May 1, 1999).

Also the Federal Law identifies three ecological zones - the central, buffer and atmospheric zones. As a result of special work, their borders are defined, justified and proposed for approval by entities operating in these territories. (Figure 1)

Fig. 1 : Specially protected natural areas around Lake Baikal in Russia and Mongolia, (http://bic.iwlearn.org/en/atlas/atlas/124-specially-protected-natural-areas-map/specially-protected-natural-areas-map, Specially Protected Natural Areas Map).

The preservation of such a unique object of world significance and the largest fresh water resource for present and future generations is an important task of the Russian Federation and the whole World.

The Forests

1. One of the threats to the safety of Lake Baikal is a reduction of loess massifs. The primary reason is the deforestation, as well as the destruction and damage of forests. Deforestation occurs in the Irkutsk region and the Republic of Buryatia, including in the catchment area of the lake. Most actively this occurs north of the Selenga River. Even though all types of deforestation, except for sanitary felling, are prohibited in the catchment area, satellite imagery and the testimonies of local people show that there are still protected forest areas that were cut down. “Black lumberjacks,” as they are commonly called, most often sell mined wood abroad, thereby enriching themselves and contributing to the destruction of the ecosystem of the sacred lake, (https://novayagazeta.ru/articles/2018/02/18/75550-topor-lesnoy-voyny, Forest War Ax).

Another problem is forest fires most often occur due to human faults. This may be due to careless handling of fire, non-compliance with the standards of forestry organizations working in the forest, or intentional burning of forests. The latter is most often resorted to by the already mentioned "black lumberjacks" in order to hide traces of their activities.

The Fauna

What is a lake without its inhabitants? The fauna is an integral part of the Baikal ecosystem, and the reduction in the number of one species affects the populations of other species and the environment.

An example is the extermination of the great cormorant in Soviet Union. It was believed that the cormorant eats a significant number of commercial fish - omul. However, after the cormorant practically disappeared, the omul population began to decline even faster. This is because cormorant excrement that has fallen into the water becomes food for epishura (Baikal plankton), which is also food for omul. Thus, the disappearance of one of the links in this chain resulted in a serious decrease in the abundance of two other species.

1. Currently, all three species are out of danger. However, poaching leads to serious fluctuations in the numbers of many animal species, primarily commercial fish. The scale of illegal catch is such that every year the number of detained violators is within ten thousand people! According to experts, the catch on the quota and outside it can be comparable in volume, (https://1baikal.ru/ekologiya/ekologicheskie-problemyi-bajkala-ne-spirogiroj-edinoj, Environmental problems of Baikal: not a spirigual one)

The main goals of poachers are Baikal omul and grayling. One can only guess about the real reserves of the latter in the lake, about how much of it is caught. However, the fact is that in almost any coastal settlement they are engaged in its fishing very intensively. In 2005, alarming information came from the Baikal Reserve. His workers said that the entire coast near the village of Tankhoi was laden with nets and grayling had practically disappeared.

Pollution

The main sources of pollution of the lake basin are industrial and household waste from such large settlements as Irkutsk, Ulan-Ude, Severobaykalsk, Baikalsk, Slyudyanka, where the treatment facilities are either outdated and cannot cope with the increased load or are absent. The Irkutsk region and Buryatia, especially their centers Irkutsk and Ulan-Ude, are one of the most environmentally hazardous territories in Russia. In the environmental rating for the summer of 2019, in which the indicators of the state of air, water, discharges, emissions, as well as the responsibility of the authorities, the activity of public environmental organizations and others were analyzed in 85 regions, the Republic of Buryatia took the 75th and the Irkutsk region – the last (Trifonov, I et al. 2019), (https://tass.ru/obschestvo/6962500, Ecological rating of subjects of the Russian Federation). Industrial and household waste, petroleum products, phosphates, pesticides and other substances enter the lake mainly through its largest tributary, the river Selenga.

2. Another problem causing pollution is shipping on the lake. Now there is only one ecological vessel operating on lake Baikal, on which the owners of other vessels can take waste. It is non-self-propelled and is far removed from the northern regions of the lake. During navigation, about 700-800 tons of oily waste and wastewater are delivered to it, and a significant part of the existing fleet on Lake Baikal dumps them into the lake. According to experts, annually from 160 to 400 tons of oil products and wastewater gets into Baikal (https://irkobl.ru/sites/tour/law/%D0%9E%D1%82%D1%87%D0%B5%D1%82%20%D0%BD%D0%B0%20%D1%81%D0%B0%D0%B9%D1%82%20%D0%B7%D0%B0%202018%20%D0%B8%D1%81%D0%BF%D1%80%2004.03.2019.pdf, Report tourism agencies of the Irkutsk region about

the work done in 2018).

1. In recent years, the anthropogenic load on the lake coast has increased significantly due to the active development of tourism. Baikal is a popular destination among tourists visiting the Irkutsk region, 90% of them go to the lake. In 2018, the region was visited by almost 1.7 million guests. According to the regional agency for tourism, annually the tourist flow increases by 3-4% (http://pravo.gov.ru/proxy/ips/?docbody=&nd=102158919, Protection of Lake Baikal and socio-economic development of Baikal natural territory for 2012-2020). Winter holidays on Baikal are becoming popular, people from all over the world go to see the transparent ice of the lake, known as the deepest on the planet and as the cleanest in Russia. However, the cleanliness of Lake Baikal and its shores has recently raised more doubts, especially due to the large amount of garbage. From the mass tourist pilgrimage and especially from the "wild" tourism, the environment is polluted.

Having examined Table 1, one can note the steady growth of tourists visiting the Irkutsk region. Moreover, the share of foreign citizens visiting this region is increasing, which should be noted. In contrast to the increase in the percentage of visitors, the increase in foreign citizens shows excellent results.

Table 1: Analysis of the volume of tourist flow in Irkutsk region

Name of indicator	**2016**	**Dynamics 2016/2015 (+/-),%**	**2017**	**Dynamics 2017/2016 (+/-),%**	**2018**	**Dynamics 2018/2017 (+/-),%**
The volume of tourist flow in Irkutsk region (thousand people), including:	1525,8	+8,1	1597,8	+4,7	1655,8	+3,6
The number of foreign tourists	156,8	+21,7	211,0	+34,6	295,3	+40,0

It is necessary to say separately for 2019: According to estimated data for 9 months of 2019, the total number of tourist arrivals increased by 5.2% compared to the same period last year and amounted to 1278.0 thousand people (http://pravo.gov.ru/proxy/ips/?docbody=&nd=102158919, Protection of Lake Baikal and socio-economic development of Baikal natural territory for 2012-2020).

It is just some of the main problems, connected with ecological situation on Lake Baikal. The unique nature of Lake Baikal is not sufficiently studied to responsibly declare what exactly can cause it the greatest damage. But there are basic, accurately established sources of such problems.

Results and Discussion

Earlier, there were already described the main ecological problems in this paper. But what did the society and government do to safe Lake Baikal? At the government level, the basic achievements, on our opinion, in the field of protection Lake Baikal are:

- adoption of the Law “On Lake Baikal” in 1999;
- suspension of the operation of the Baikal Pulp and Paper Mill;
- reduction in the number of toxic substances discharged into the Selenga River;
- tracking and full support of the activity of parks and reserves located on the territory of the lake.

Lake Baikal is the only natural object, that has a federal law on its protection in the Russian Federation: No. 94-ФЗ On the Protection of Lake Baikal (http://base.garant.ru/2157025/, Federal Law of May 1, 1999). In addition, the law establishes the zoning of the Baikal natural territory, the borders of the

Baikal natural territory, the basic principles of protecting Lake Baikal, and special modes of life in the zone of the Baikal natural territory, the order and forms of state regulation in the field of protection of Lake Baikal. In particular, the elements of state regulation of protection of Lake Baikal in accordance with the law provide for the existence of a specially authorized body for the protection of Lake Baikal, the implementation of state environmental control and monitoring in the field of protection of Lake Baikal. The law is special, and, in this regard, it occupies a special place in the hierarchy of other federal laws regulating relations in the field of nature conservation and the management of natural resources, in addition, it provides for the adoption of several documents for its implementation. By-laws and regulations have been adopted and are in force (Koryakov, A.G. & Zhemerikin, O.I., 2019).

Also, we need to mention Federal Target Program «Protection of Lake Baikal and socio-economic development of Baikal natural territory for 2012-2020», which is on the way to finish now.

The total funding for the Program for 2012 - 2020 at prices of the corresponding years is 32765 million rubles, including:

- at the expense of the federal budget - 26946.7 million rubles (82.2 percent),
- at the expense of the consolidated budgets of the constituent entities of the Russian Federation - 3875.8 million rubles (11.8 percent);
- at the expense of extrabudgetary sources - 1,942.5 million rubles (5.9 percent) (Tumin, V.M. & Koryakov, A.G., 2013).

1. It should also be noted the attitude of society towards the protection and conservation of Lake Baikal. For the first time, Greenpeace activists spoke of the magnitude of the problem. In 2001 and 2002, the organization held international events on Lake Baikal. The last visit of this organization took place in the summer of 2019 (https://esquire.ru/articles/117412-eks-zhemchuzhina-rossii-kak-ozero-baykal-zadyhaetsya-ot-plastika-reportazh/#part0, Ex-pearl of Russia: how Lake Baikal suffocates from plastic). The Zero Waste project team spent a week on Lake Baikal to find out how much the lake suffers from plastic. “In seven days, we found 3813 garbage fragments on small sections of the Baikal coast, most of them are plastic” (https://1baikal.ru/ekologiya/kto-spasaet-bajkal-ot-musora, Who saves Baikal from garbage).

Another famous project: “360 minutes” is the largest all-Russian eco-marathon, which is implemented on the initiative and support of Oleg Deripaska and the Volnoe Delo Foundation. Every year, the volunteers of the action spend six hours cleaning garbage and landscaping protected areas to preserve picturesque natural places. For five years, eco-marathon volunteers have collected more than 3 thousand tons of garbage (https://regnum.ru/news/society/2662754.html, The study found out the causes of pollution of Lake Baikal). After the action, it is recycled and partially recycled. Since 2016 the number of types of work that volunteers did was increased. For example, near the visit center of the Baikal Reserve, activists removed heavy metal and concrete structures using a tractor and a truck with a crane.

Considering all the above, we have developed a system for solving environmental problems in the territory of Lake Baikal. (Figure 2)

Fig. 2: Scheme of the author's system for solving the environmental problems of Lake Baikal and adjacent territories

First, since there is a lack of proper control and a peculiar unsystematic nature in solving the problem. To monitor all activities to preserve the "pearl of Siberia", implement a unified integrated management system for Lake Baikal and the Baikal Natural Territory or a special government agency responsible for this area. This system or body will be engaged in state and public supervision, monitoring, as well as combine the accumulated research base of the institutions involved in monitoring Lake Baikal and adjacent territories and support their interaction.

According to the latest data from the press conference "Protection of Baikal: Environmental Threats and Solutions", July 9, 2019, only 18 out of 100 settlements located in the immediate vicinity of Lake Baikal have sewage treatment plants. According to Vladimir Burmatov, Chairman of the State Duma Committee on Ecology and Environmental Protection, these structures either do not function or do not fulfill the norm of permissible impacts on the ecosystem (Koryakov, A.G., Zhemerikin, O.I. & Kulikov, M.V., 2019).

Thus, the next item in our system for solving the problems of Lake Baikal is the construction of special treatment facilities at all necessary enterprises. As well as carrying out full-fledged research and searching for new local cleaning schemes focused on Baikal. Due to the remoteness of some settlements from large cities, to improve the access of the hotel sector and villages to the best technologies for wastewater treatment. It is also necessary to implement the proposal to increase the size of economic sanctions and fines in case of violation of the rules for the discharge of waste into Lake Baikal.

To solve the problem of shipping, it is necessary to put into operation a larger number of environmental ships and, in general, points for the reception, removal and processing of ballast water and household waste from ships. Introduce fines for the discharge of oil products and pollution of Baikal water by ships.

The rules for organizing tourism adopted at the end of September in the Irkutsk region will help to reduce the negative impact on the Baikal ecosystem. "11 recreational areas were identified where it was recommended to organize tourism. Each of them had its own rate calculated (the number of tourists the territory can accept), and the types of tourism that were possible in each zone were also spelled out.

How can you regulate the flow of tourists? By the number of accommodation facilities. Accordingly, parking lots with a certain number of tent places should be allocated for those who love shawls, "the head of the Irkutsk Tourism Agency, Ekaterina Slivina, told reporters earlier (https://rg.ru/2019/08/13/reg-sibfo/pochemu-gorit-tajga-i-kak-vazhen-les-dlia-bajkala.html, Without a forest there will be no Baikal). In addition to this decision, which will be introduced, we would like to add a ban on the sale and use of disposable plastic and household chemicals containing phosphates in the lake and Baikal natural territories. Thus, the introduction of tourism with a maximum environmental focus. And, the organization of proper work with the tourist flow, the importance of preserving the nature of Lake Baikal through special events (https://rg.ru/2019/08/13/reg-sibfo/pochemu-gorit-tajga-i-kak-vazhen-les-dlia-bajkala.html, Without a forest there will be no Baikal).

The Baikal ecosystem is suffering from a disturbance in the flora surrounding the lake; it is necessary to strengthen control over felling in the catchment area of the lake. It is necessary to increase the size of fines and introduce an independent service to monitor this problem. The same method of economic impact through fines should also be introduced for poaching, another major problem that destroys the fauna of Lake Baikal.

We propose to indirectly influence the two previous problems through the development of measures in the nearest cities from the lake to educate the population about the importance of preserving Lake Baikal. Also, it will be important to conduct a program to develop the economic situation in these regions.

In the summer of 2019, the news of a forest fire in Siberia caused a massive resonance. The situation has reached other states, the world community and stars. At the beginning of August 2019, over 2 million hectares of taiga were exposed to fires in the Irkutsk Region and the Krasnoyarsk Territory (Trifonov, I., Sankov, P., Dikariev, K. & Kapshuk, O., 2019). It is necessary to pay attention to the work and coordination of fire services, to identify the potential for improving work efficiency for a better fight against forest fires.

Conclusion

Lake Baikal and the surrounding areas are world heritage. Containing 19% of the world's drinking water and being the deepest lake in the world. The beauty and grandeur of the lake every year attracts huge flows of tourists who want to look at the clear waters of Lake Baikal. Scientists from all over the world consider this lake to be unique and with trepidation relate to the importance of preserving the natural heritage.

The problem of pollution of Lake Baikal, which is known around the world, is becoming increasingly acute. Now the “pearl of Siberia" is experiencing many problems: it is littered shores due to the increase in tourists, and deforestation with poaching, and emissions, and fires. Even though some scientists claim that the rumors about the pollution of Lake Baikal are clearly exaggerated, we believe that the alarming statements of other scientists about the disaster are fully justified. Pollutants negatively affect the ecosystem of the lake and reduce the quality of water in Lake Baikal.

The government and public organizations are making efforts to save the rare lake. Only Baikal has a separate federal law on protection in addition to countless legal documents.

It is possible to save the “Pearl of Siberia” only by solving problems systematically and comprehensively, thereby we have developed a system of measures to neutralize the most acute problems of Lake Baikal. Among them: a ban on the sale of plastic products, the introduction of fines, economic development programs for neighboring regions and much more.

Baikal is an invaluable gift of nature, which must be wisely used and protected with all we might.

Abstract

In the last decade, trade unions have become an important social partner in the European Union countries, including Latvia, where, within the National Tripartite Cooperation Council, they ensure influence on taking important decisions. Surveys on working conditions in Latvia show that working conditions in companies with a trade union are significantly better than in those without a trade union. A survey of members of the Latvian Trade Union of Education and Science Employees (LIZDA) was conducted in one institution, namely a University (Demonstration Organization), to find out the trade union members' views on the role and activities of the trade union, as well as their needs for improving working conditions. To find out the opinion of the trade union members about the role and activities of the trade union, as well as the needs of the trade union members to improve their working conditions, a survey of members of the Latvian Trade Union of Education and Science Employees (LIZDA) was organized in one institution, namely, a university. The results of this survey are used both theoretically to identify employees' perceptions of the importance of trade unions in creating a comfortable working environment, and in practice – to coordinate the work of the union within the given university. In general, the results of the survey can be used to determine the strategic direction of the union's work as well as to improve its prestige. The sociological data were obtained by using two approaches – quantitative and qualitative. The quantitative survey was conducted between 10 February 2019 and 10 April 2019 at one of the universities in Latvia.The organized study has allowed for the identification of areas of trade union's work that need further consideration. (1) The trade union should more actively disseminate news about its activities in the media, including e-environment, informing about the pedagogues' situation, popularizing what has been done and linking it with the performance of the organization. (2) The circulation of information on the trade union activities should be significantly wider and more diverse. Special attention should be paid to informing and educating young teachers, including work with students (Student Council). (3) Cooperation with the social partners of the organization should be intensified, thus encouraging members and potential members for wider and more active participation, as well as strengthening the influence of

the trade union at local, regional and national levels. (4) It is important to develop the exchange of experience with interregional institutions by more actively integrating the good practices and experience of other trade unions, thus making the trade union of the organization more up-to-date and attractive to new potential members.

Keywords: Trade Union, Higher Education, Working Environment, Employees, Social Partners

Introduction

Today, globalization processes have a significant impact not only on national economies and policies, as well as on international cooperation, but also on individual citizens, changing their identity and worldview, and influencing behavioral practices and work habits (Romanovska, 2019). As a result of globalization, significant changes affect both objective working conditions and people's subjective feelings related to the working environment – competition is increasing, ways of working are changing, companies are undergoing restructuring, staffing policies are being revised and more and more people's duties are performed by mechanisms. All of these contribute to the increase in unemployment or the fact that part of the employees of enterprises are employed only part time (Baglioni, 2006; Rigby et al., 2006, 135). Such threats become an incentive for strengthening the role of trade unions in the global and national context. In the last decade, trade unions have become an important social partner in the European Union countries, including Latvia, where they ensure influence on important decision-making within the National Tripartite Cooperation Council. Several studies focused on working conditions in Latvia testify to the fact that working conditions in enterprises with trade unions are significantly better than in those where there is no trade union.

In recent years, trade unions in Latvia have significantly developed their potential, by developing not only in public sectors, such as education or medicine, but also in the private sector. Because enterprises in the private sector are the ones that make the biggest tax contributions to the state budget. Collective agreement and the presence of a trade union in an enterprise are one of the indicators that the employer is out of the shadow economy. Therefore, the strengthening of trade union positions can also be seen as a national interest.

The development of trade unions in Latvia is determined by the conditions of their existence in the past. Namely, Latvia belongs to the Eastern countries of the European Union, where the trade unions have undergone a paradigm shift. From mandatory memberships, they have become voluntary employee associations. Therefore, they face a new problem, which is the motivation of employees to join or continue to be a member of a trade union.

To find out the opinion of the trade union members about the role and activities of the trade union, as well as the needs of the trade union members to improve their working conditions, a survey of members of the Latvian Trade Union of Education and Science Employees (LIZDA) was organized in one institution, namely, a university. The results of this survey are used both theoretically to identify employees' perceptions of the importance of trade unions in creating a comfortable working environment, and in practice – to coordinate the work of the union within the given university. In general, the results of the survey can be used to determine the strategic direction of the union's work as well as to improve its prestige.

Trade unions in Latvia: the history and the present

To date, there has been relatively little research on the functioning and importance of trade unions in Latvia; significant researches have been done by R. Karnīte, I. Kalniņa, Ch. Woolfson, M. Hazans; T.

Paas and R. Eamet, as well as S. Stacenko, who focused on the involvement of trade unions in public administration decision-making and research on issues of social partnership. (Līne, 2016)

From the economic point of view, trade unions' activities and their work in general are often seen as additional costs and obstacles historically associated with the restrictions in working time, minimum wages, etc. But nowadays, trade unions have a much broader range of issues. Successful social dialogue at the micro-level of the organization, including trade union's influence on the cohesion of team of the organization, the development of corporate social responsibility and business ethics, the improvement and more active implementation of team building and decision making, problem solving, as well as more effective use of soft skills such as trust, influence and conflict treatment in managing the organizationa. (Pender, Elgoibar, Munduate; Prins, Stuer, Gielens; Eurofound). With the growing importance of diversity and partnership, the significance of trade unions to the economy also increases. Employee retention in the workplace is also becoming increasingly important, thus reinforcing the importance of social dialogue within organizations. (Casey, Gold). Therefore, the impact of trade unions is also significant at the macro level: engaging in sector challenges and unemployment insurance, researching, gathering, and identifying directions for satisfaction of other needs of employees. Thus, trade unions are institutional systems that ensure a balance between social and economic development. It often happens that, the economic conditions improving, less attention is paid to social conditions and the balance is lost. Trade union activities, on the other hand, focus on the elements of social well-being in organizations and workplaces, thus rebalancing and strengthening social support systems. (Grimshaw, Koukiadaki, Tavora) In addition, trade unions as members of the Tripartite Cooperation Council represent Latvia's interests in the EU (Tripartite Social Summit, and other institutions), and the influence of such institutions in solving various issues is increasing. More favourable interpersonal relations influence social and economic policies, promoting the development of business culture and employment, as well as creating favourable social conditions.

Historical evidence suggests that the first unions in Latvia were established in the early 20th century, during the post-revolutionary period. As a result of the occupation of Latvia, within a few months of 1940 those organizations were reorganized and became part of the USSR trade unions. Shortly after the restoration of Latvia's independence, in May 1990, Latvian trade unions decided to leave the USSR trade union institutions and formed an independent trade union association – the Free Trade Union Confederation of Latvia (Kluinis, Pētersons, 2006). Thus, the development of the Free Trade Union Confederation of Latvia went hand in hand with the development of Latvia as an independent state during the period of economic restructuring. Trade unions were given the right to negotiate the issues of wages, employment, working conditions and economic restructuring (Rajevska, 2005, 88). The restoration of Latvia's national independence posed new challenges for trade union leaders – the need to acquire new knowledge and forms of activity, such as wages, the development of the spirit of collectivism, solving social dialogue, going into labour safety and labour law issues.

Latvia as an independent state has existed for little longer than twenty years and this period has not been sufficient to establish lasting traditions of effective social dialogue. Moreover, the status of trade unions in Latvia compared to the "old" EU Member States is not yet established and, despite the relatively extensive trade union rights, they are not always considered as a serious social partner. Currently, there are trade unions of various branches operating successfully in Latvia, for example, Latvian Trade Union of Health and Social Care Workers, Latvian Industrial Sectors Trade Union, Latvian Forest Sector Trade Union, etc. 20 trade unions have united in the Free Trade Union Confederation of Latvia, which is the largest trade union federation in Latvia. The largest sector trade union is the Latvian Trade Union of Education and Science Employees.

There is a legal framework for the functioning of the trade union in Latvia. The Trade Union Law states that "a trade union is a voluntary association formed to represent and defend the labour, economic, social and professional rights and interests of employees" (Arodbiedrību likums, 2014). Trade unions are

therefore considered to be non-governmental organizations. Non-governmental organizations can be identified as a separate type of organizations; they are also called "third sector" organizations because they operate in parallel with the public and the private sectors. (Daftt, 2012)

Different legislation specialists and researchers offer different definitions of trade unions, emphasizing a particular function of this organization. One of the most accurate definitions of trade unions is given by T. Hannigan, who states that trade unions have nine basic functions: social dialogue, organization, legal protection of members, administration, management, political activities, implementation of public activities, improvement of trade union activities, and international cooperation (Hannigan, 1998, 7). According to Hannigan, the successful fulfilment of key functions directs the trade union toward its goals. The specific difference between trade unions and other types of organization is determined by the importance of members in the trade unions – their power and influence on management. The nature of trade unions presupposes a high level of participation of its members in the life of the trade union, including its management.

Methodology

The aim of the study was to find out the opinion of the trade union members on the functioning of the demonstration organization and the role of the trade union in the sector of education in Latvia in general, focusing on the wishes and needs of the trade union members. The sociological data were obtained by using two approaches – quantitative and qualitative. The quantitative survey was conducted between 10 February 2019 and 10 April 2019 at one of the universities in Latvia. The previously approbated questionnaire contained a number of questions to allow for a comparative analysis with the results of the previous survey "The needs of educators to ensure employment stability and decent working conditions in collective agreements", but it also takes into account the specifics of these different actors. The study target audience is the university employees.

The questionnaire was designed to clarify the respondents' views on the importance of the trade union and the specifics of their work, as well as to outline future perspectives. The survey was carried out in the e-environment by using the form *google.docs*. The survey included 16 questions. The survey instrument – a questionnaire – is structured in three sections: 1) general information on the respondents' demographic data 2) opinions and attitudes concerning LIZDA work, directions of activity, availability of information; 3) evaluation of the work of the University LIZDA Professional Committee and suggestions for achieving the goals.

The survey contains both closed and open questions that are aimed at obtaining the evaluation of LIZDA performance on a Likert scale of 1 to 5, where 1 – very poor, 2 – poor, 3 – satisfactory, 4 –good, 5 - excellent. It took about 10 minutes to complete the questionnaire and the participation in the survey was voluntary.

Research results

Of the total number of the respondents, 76% are female and 24% male; 62% of them are general and 38% – academic personnel. The respondents represent all age groups, but most of the respondents – 60% – represent the age group 41-60. This also is the basic age of the university staff. The survey mainly involved long-serving university employees: 44% of the respondents have 11-20 years of work experience, but 38% – over 21 years. More than 90% of the respondents are LIZDA members, 70% of them have been the union members for more than 11 years.

Attitude to LIZDA work

Attitude is important in any area of human activity. Attitude is a complex, multidimensional concept that includes different contexts: employee attitude towards work, employer attitude towards employee as the most important resource in the labour market, the state's attitude towards the citizen. Attitude is an ability of the consciousness to evaluate the processes, with which a person comes in contact, changes in consciousness, or human behaviour. Attitudes can be defined as an integrated attribute of the individual that is formed in the unity of life experience, knowledge acquisition, experience and effort of will and is expressed in values, goals, ideals, and norms. Attitude is one of the components of characterizing the human being. (Špona, 2004). Attitude is expressed not only in human actions and values, but also in political decisions. In the context of this study, the attitude of higher education institution employees' towards LIZDA is analysed.

The respondents' responses indicate that the university employees generally have a positive attitude towards the work of LIZDA, as the trade union acts as a bridge representing the interests of employees and ensures social dialogue with education policy makers. About half of the respondents (47%) have a clear understanding of the union members' rights and obligations; they believe that "union is power". About 15% are ready to join the trade union work or working group and volunteer for fulfilling various duties – thus the respondents indicate in the survey, but only a few individuals show initiative. (see Fig.1)

Fig. 1: Respondents' attitudes to the trade union's work at the organization (number of people)

At the level of Latvia, the respondents have provided the evaluation of the activities of the trade union of Latvia's education employees as a social dialogue partner. Half of the respondents admit that LIZDA is actively involved in the social dialogue. The views of the educators surveyed concerning the process and groups of social dialogue as well as the institutions participating in it are rather different. From the pedagogues' point of view, those are the administrations of educational establishments that have the

highest level of involvement, since in 80% of cases they always or almost always are social dialogue partners. The respondents' opinions about the role of local governments, trade union leaders of educational establishments, LIZDA and MES (Ministry of Education and Science) in the development of the sphere of education are rather diffused and contradictory. (Izglītības darbinieku vajadzības…, 2013) Some respondents express support and gratitude to the LIZDA management and regional representatives. (see Fig. 2)

Source: Izglītības darbinieku vajadzības nodarbinātības stabilitātes un cienīga darba apstākļu nodrošināšanai un šo jautājumu aktualizēšanai kolektīvajos līgumos (The Needs of Educators to Ensure Employment Stability and Decent Working Conditions in Collective Agreements), 2013

Fig. 2: Respondents' opinions on the involvement of social dialogue partners in solving development issues in the sphere of education (%, only responses "always" and "almost always")

About 7% of the survey respondents admit that they have no interest in trade union activities and their attitude is indifferent, possibly because they have not directly experienced LIZDA activities or support. In turn, about one fifth (20%) of the respondents are concerned about the trade union's ability to improve working conditions. The small number of respondents in general also implies the need to improve the organization's culture and awareness that its main driving force is the employees. The culture of an organization is directly related to its effectiveness – the stronger the culture of the organization, the more effective the organization is (Psihosociālā darba vide, 2010).

Awareness and Information Acquisition

Effective access to up-to-date information is the key to purposeful activity. According to the survey data, about half of the respondents obtain information about LIZDA activities electronically, mainly from the university website. Other sources are used too – the LIZDA website, conversations with colleagues, attending joint events. The survey data testify that, in general, the availability of information is ensured, but the interest of respondents varies.

Source: demonstration organization's survey

Fig. 3 : Respondents' evaluation of the circulation of information in the trade union (number of people)

About 8% of the survey respondents regularly inquire and obtain information about LIZDA news from the University website, 47% sometimes show interest, and about the same number of the respondents does not show any interest in LIZDA activities. (see Fig. 3)

LIZDA Activities at the Demonstration Organisation

The responses concerning the work of the University Trade Union show a diversity of views. There are positive evaluations, critical remarks, and indications of the lack of information for one to be able to evaluate. As the most important activities are mentioned those which directly concern the employee: accident insurance, provision of material assistance, organization of leisure activities. However, it has to be noted that a significant number of the respondents – 49% – emphasize the insufficiency of information to be able to evaluate the work of the trade union. This means that existing members, not to mention the potential ones, do not get enough information about the union's activities. (see Fig. 4)

Source: demonstration organization's survey

Fig. 4: Respondents' evaluation of the trade union's activities (number of people)

Employees are largely satisfied with the work of the trade union in addressing problems related to improving the working environment and working conditions, but unsatisfactory is the evaluation of work aimed at influencing the state's and partially also the university management's policies towards reducing the employees' workloads and the amount of work.

For the employees it is unacceptable that the university lecturers are not paid for the methodological work, control of students' independent work and consultations. The academic workload of lecturers, senior lecturers, professors is disproportionately high, and employees expect more serious involvement of the trade union employees in solving the issues of workload reduction and salary increase. It has to be admitted that the employees' requirements are fully in line with the requirements of LIZDA, which prioritizes the achievement of stable financing of higher education and science, including the financial reference amount for science in accordance with the Law on Higher Education Institutions and the Law on Scientific Activity.

There are also a lot of critical statements about the trade union's work in Latvia in general. An overwhelming majority of the respondents urge the trade union to become more active, assertive and unyielding in trying to find other forms of communication with the ministry. It is emphasized and recommended to more actively share the information on their activities in the media, to inform about the situation of educators, to raise their prestige in the society by popularizing their work. Special attention should be paid to informing young pedagogues about the union's activities and their involvement in the union. (Izglītības darbinieku vajadzības..., 2013)

Overall, the work of the professional committee is assessed as satisfactory: 60% of the respondents evaluate the work of the professional committee as satisfactory and 16% – as good. What is evaluated particularly positively is the dissemination of up-to-date information. The respondents appreciate the LIZDA employee survey, suggesting that surveys of similar content should be carried out more frequently in order to plan work more effectively, solve problems and improve the organizational culture. The most important recommendations of the survey respondents for the improvement of the work of the professional committee are the following: 1) to organize thematic discussions in departments / working collectives more frequently; 2) to maintain social dialogue with the university management in order to

solve current problems; 3) to disseminate current information, inform employees about the activities implemented and the results achieved, and popularize the role of trade unions.

Conclusion

The influence of trade union manifests itself in corporate decision-making, organization of work in enterprises, organization of training, responsible ethical management, and respect for human rights. Corporate social responsibility is also linked to the development and implementation of trade union strategies (Preuss, et al., 2006, 258). Corporate responsibility ensures better economic growth in the long term if, in addition to economic aspects, the social and environmental aspects of all interested parties' well-being are equally taken into account (Büchner, 2012, 50). Latvia, as a state that has restored its independence relatively recently, has certain problems with activating trade union organizations' work and building employee loyalty to trade unions. By using a variety of motivational mechanisms, promoting the active social positioning of union members and creating feedback, it is possible to achieve the best results. The research results testify to the fact that the respondents expect that the trade union will be able to solve various problems existing in the particular university and the country in general in the field of higher education, such as salary increase, reduction of workload, increase of financial reference amount for science. The majority of education employees believe that social dialogue is a very necessary and recognizable way of addressing both specific issues of daily work and broader questions of the sphere of education, but some respondents consider the existing social dialogue organized by the trade union to be ineffective and formal. However, the trade union members often lack the awareness that significant changes can only be achieved through joint and active participation in decision-making and trade union membership. It is therefore the responsibility of the trade union leader to explain the benefits of corporate responsibility, thus developing active social position in the trade union members.

Abstract

Modern conditions of socio-economic development are a prerequisite for the transition to a new technological structure. According to Russian and foreign experts, it will be based on a new - information, knowledge - model of the economy. This places high demands on the systems of the formation, replication and dissemination of knowledge, i.e. to the education system. Therefore, in the transition to a digital economy, priority is not given to solving technical issues, but to problems associated with the formation of a training system, the transfer of knowledge, its accumulation and productive use.

Keywords: Educational Technologies, Knowledge Model, Digital Technologies, The Provision Of Educational Services, Training Programs.

Introduction

The proliferation of digital technologies over a long period of time determines the path of development of the economy and society and has already led to dramatic changes in people's lives more than once. The development of the digital economy is one of the priority areas for most developed countries; it also dictates trends in education. Now the most valuable thing is the ability to constantly develop skills. Accelerating the pace of technological change creates new challenges in all sectors, including education. Companies are waiting for new, and sometimes completely different competencies from their employees, the educational process has long gone beyond schools, universities and other educational institutions.

By 2025, Russia will need at least 5.8 million highly qualified personnel for the digital revolution and the transition to a knowledge economy, 62% of employers are confident that in the next couple of years they will have to retrain almost 35% of their employees, about half of the companies in our country now More than half of its employees need retraining.

Employment agencies and business representatives complain that training programs do not meet the new realities and market requirements. In a world where the economy is constantly changing, we need specialists who can quickly learn new business practices and skills. “A feature of the current era of digital transformations at tremendous speeds is the obsolescence of technical solutions and business models in the horizon of only a few years, new technological needs are constantly being created, which, in turn, need to instantly build up competencies. Thus, the most important factor now is the growth rate of new educational opportunities” (Daria Nosova - Head of Fintech O2 Consulting).

The unconditional trend in education today is its flexibility, which in practice means constant monitoring of requests for new examinations and the immediate adjustment of educational programs and teaching courses. Education is sometimes perceived as the sphere most resilient to changes, while it is most susceptible to crisis and loss of effectiveness in responding to new trends of the time. Education innovations can help improve its quality, as well as provide more stability during “budgetary pressures” and growing demand. The elasticity of the education system is the key to successful digital transformation, as can be seen in many countries, where such an approach is strategically provided at the level of national and private programs.

According to many experts, the most valuable skill is the ability to acquire new skills, the understanding that you will have to change your occupation many times. “The need to have fundamental knowledge will recede into the background - all knowledge is now immediately available, but the ability to analyze, systematize and visualize complex processes and related professions will most likely be relevant for a long time” (General Director of Oblakoteka Maxim Zakharenko).

A few years ago, at the Davos Economic Forum, we compiled a list of key skills necessary for successful work in 2020, including critical thinking, the ability to solve problems comprehensively, creativity and communication. All these skills belong to communicative (soft skills), and in this segment there is now a gap in the ocean of educational projects and programs.

Leading Russian universities announced dozens of programs in various specialties that are connected with the digital economy, but it is still difficult to draw any conclusions about their effectiveness. Not all universities today meet the new challenges and requirements of the time. Although, in our opinion, medium-sized universities are likely to be able to adapt to rapidly changing requirements. “Their information systems are less loaded than large universities, and the modernization process does not take so much time, effort or money. In the next few years, they can make a significant transformation and become fully competitive in the digital economy.” (The head of the group for work with academic organizations of the Softline group of companies in the Northwestern Federal District Alexei Shcherbakov). At the same time, departments specializing in Big Data, blockchain or cybersecurity already exist in the technical departments of most major universities, but the real need for a large number of such specialists will appear on the market in the next three to seven years, but many universities need to make changes in the training of professional frames now. In addition, the digital economy is not just the future, but also the present, and therefore the training of such specialists should be widespread.

If we talk about completely new professions and types of activities, it must be said that universities will never be ready for them immediately, because the training programs for the profession arise too quickly, and the training process is long and requires at least three to four years. And this will not be a ready-made specialist, but only a graduate. At the same time, Russian universities, as it seems to us, respond to a market demand for versatile skills, that is, dynamics of thinking, variability of activity, constant ability to self-education. Of course, educational institutions will have to make several changes to their work, and this primarily concerns the transition to the most practice-oriented model of training (project activity). Now it is being declared, but poorly implemented. Soon, it is necessary to move away from the obsolete model of "one educational diploma for life." This is no longer working.

Lifelong learning should become a standard for a modern person, that is, constant updating of their knowledge, free reorientation to new specialties, and regular development of competencies. One of the trends in education is the emergence of many distance learning programs and online courses. And if in the case of full-time forms, Russian universities practically do not compete with Western ones because

of the relatively high cost of living in Europe and the USA, then in the case of distance learning programs, the situation is completely different.

For example, the cost of an annual distance education undergraduate program at Open University in the UK is about € 2,500 per year, that is, 90 thousand rubles per semester, which is comparable to Russian prices. “At the same time, many Russian universities regard distance learning programs as something secondary and practically do not develop these areas, and therefore more and more Russian students receive distance education in Western universities. In addition, the advantage of Western institutes is that their diplomas, unlike domestic ones, are recognized in Europe and the graduate does not have to further confirm their qualifications” (Crimson Education CEO Jamie Beaton).

Online courses hosted on numerous MOOC (Massive Open Online Courses) platforms are also very popular today. the demand for the MOOC platform motivates many universities to revise curricula and create mixed programs, including both traditional lectures and seminars, as well as online programs, the demand for which is constantly growing. Of course, the process is complicated by the need to coordinate new training plans with the requirements of federal standards, since the transfer of interaction of the main participants of the educational process to the online mode requires educational institutions to modify the IT landscape as well as major internal transformations.

The need for changes in the education process is dictated by new trends in the organization of business, and, accordingly, the labor market. Requirements for specialists are changing, as the boundaries between the “white” and “blue collars” are blurred. In the structure of the modern labor market, a slice of mass digital professions is being highlighted - mid-level specialists who produce products "in digital" using various automation solutions.

Already today, a large segment of professions related to online markets can be considered massive: call center operators, copywriters, database operators. According to some estimates, by 2025 the number of representatives of mass online and offline professions in the country can reach 9.2 million people. Today, around the world there is a shortage of specialists in the labor market who can create and implement complex IT projects using artificial intelligence, virtual reality or big data in their work. And those who know how to do this are under the scrutiny of "bounty hunters."

Several trends stand out in the transformation of the labor market - new mandatory points. This knowledge and application of modern digital products and solutions. In addition to basic professional competencies, you can now find a whole block of requirements in the field of digital technology. Professionals with the skills to implement modern digital solutions are the most competitive.

Another trend is the acceleration of processes in the organization and increasing transparency and business efficiency. This means moving away from a clear focus on basic business knowledge and common functions. Digital companies need to be universal (generalist). Previously, employees engaged in production, such as petrochemicals, were tasked with effectively managing only this process. Today they are required to dive into procurement, sales, and even customer service. This happens because digitalization allows you to track all processes from beginning to end in their relationship. I must say that in industries where the digital transformation is most visible, the labor market is transforming now. So, such professions as an operator in a bank or an insurance agent “die out”. But the digital transformation, especially in Russia, is far from comprehensive, and the sales consultant is still the most sought-after profession.

As for the most relevant professions in the wake of digitalization, these are all kinds of IT specialties: developer, project manager, data analyst and others. But “pure” IT is not enough for life, therefore, “subjects” who know and actively use IT will be even more in demand. For example, an architect of virtual worlds, a genetic analyst, a house builder using 3D printing technology. For example, many of them are updated and more narrowly focused “versions” of obsolete professions. All this allows developers to create all kinds of services and programs, analysts, testers. They all grew out of programmers in the sense that was relevant in the 2000s.

It is also necessary to speak not about professions, which are a rather narrow positioning, but about roles in the digital economy. Depending on the size of the organization, one person can combine several roles or devote himself entirely to one role. From this position can be called completely differently

(Head of the analytical department of the personnel company Manpower Group Russia & CIS Mikhail Tuzov). There is another side of the influence of digital technologies on education - the use of new technical developments directly in the learning process. As a rule, technological implementations in education today do not require any additional skills and abilities from the teaching staff, management or schoolchildren themselves.

In most cases, a short introductory briefing on the rules for handling equipment for teachers will be enough. Universities and most teachers today are friendly towards technological solutions and understand that progress should cover all spheres of life, including education. Moreover, learning with the help of interactive panels, virtual and augmented reality can be made many times more effective and interesting.

In Russia, qualified and well-trained teachers are annually graduated from universities who are aware of the important role of technological solutions in modern education, but there are also skeptics who believe that, for example, VR-technologies can negatively affect the health of students.

Nevertheless, virtual reality technologies have a place to be, for example, to reduce the gap between theoretical education and practical skills. Most experts confirm that graduates, as a rule, are perfectly "knowledgeable" theoretically, but rarely can perform even simple actions in the framework of specialized education in practice. This seriously affects both the graduates themselves in finding a job and business. Companies must spend huge amounts of time and money on training interns or even training them from scratch. If VR technology takes root in universities, then in many ways this problem will be solved. It is important not only to introduce new technologies into the work of secondary and higher educational institutions, but also to carry out continuing education of teachers, as well as involve them in innovative projects implemented based on educational institutions.

The average age of teachers is still from 40 years old, in universities it is even higher. As a result, the level of digital literacy and IT culture of the most experienced teachers often leaves much to be desired. Knowledge management is based on the idea that the most valuable resource in an organization is its skilled workers. Consequently, the success of a company will depend on how effectively its employees can create new knowledge, share it and use it effectively.

If you start to consider any organization anywhere in the world, it is indisputable that in the course of their work, employees communicate and exchange information with each other. But if the desire for communication is inherently human, then the desire to share your knowledge and share it needs to be instilled. If we turn to the modern theory of management, knowledge is one of the key sources of creating and maintaining long-term competitive advantages of the organization in the market. Therefore, today, for many companies, the tasks of managing various processes at different levels, especially in high-tech organizations that are somehow related to knowledge, come to the fore.

Knowledge becomes an economic object, and the exchange of knowledge - a type of economic activity that affects the attitude of the subject to other economic objects. On the one hand, knowledge is exchanged between individuals and organizations (for example, in partnerships). They can be bought, saved, transferred, invested, accumulated and, accordingly, can be depersonalized.

On the other hand, knowledge differs from information in that it includes a personality component - an estimated attitude to information, its subjective significance for an individual or organization.

As well as the relation to any other economic objects - property, wealth, money, etc. the attitude to knowledge gives them many meanings, (see the works of Russian psychologists O.S. Deineka, A.L. Zhuravlev, A.B. Kupreichenko, A.D. V.A. Khashchenko and others) and can be considered as an opportunity to communicate, a means of ensuring personal security, etc.

Various forms of intellectual capital such as, for example, copyrights, technologies and trademarks can be transferred in the literal sense of the word and be impersonal, but this attitude to knowledge is not applicable, since they are, firstly, the result of learning, that is, they are formed and represent a process; secondly, they include those psychological relationships that arose during their creation, acquisition and assimilation.

Many large multinational companies operating in areas such as information technology (IBM, Hewlett-Packard, Microsoft, Oracle), consulting services (PricewaterhouseCoopers, Bain), oil and gas production and refining (BP, Shell, LUKoil), manufacturing (General Motors, Ford, Boeing), have implemented and continue to develop their own knowledge management system.

Increasing their capitalization and improving the financial results of their activities prove the important role of knowledge in the functioning of a business, which is a confirmation of the need to identify modern areas and forms of knowledge sharing (A. Urintsov, 2014). Usually in practice, the knowledge carrier does not seek to share them with other employees, as he considers the possession of knowledge as some competitive advantage over others that he may lose in the process of transfer or exchange. The task of the leadership of any organization is to convince employees of the need for the exchange of experience and knowledge, that is, to create a supportive atmosphere in the team.

Let us now analyze the characteristics of an employee who is positively inclined towards the exchange of knowledge and can successfully participate in it. There are, for example, personal qualities that can stand in the way and impede the transfer and exchange of knowledge, such as a tendency to advance and develop only one's own ideas, the pursuit of individual achievements and orientation to one's own interests, respect for hierarchy and formal authority (Husted, K., Michailova, S. 2002.).

It can also lead to the opposite quality of others, such as orientation to the interests of groups and group recognition, a tendency to cooperate, relationships to a group, emotional stability, extraversion, the ability to participate in the exchange of knowledge. Thus, it is possible to group some of the characteristics listed by us (Table 1):

Table 1: Characteristics of the individual

Parameter	Prone to the creation of new knowledge, focused on innovation	Knowledge prone
Thinking	Original / Custom	Stereotyped / Standardized
Group behavior	Independent behavior, non-conformism	Involvement, conformism
Authority	Self-orientation	Orientation to external authoritative guide
Motivation	Self-realization, recognition	Security, involvement
System of values	value of achievements	relationship value
Attitude towards goals	hard to reach goals as a motivator	hard to reach goals as a demotivator

Compiled by E.Borkova

According to these characteristics, given in the table, it is not difficult to notice that the simultaneous combination of these opposite qualities within the framework of one person is difficult, and they counterbalance each other, which may not contribute to the creation of new knowledge and facilitate the exchange of information. All these nuances must be known and considered in the selection of personnel and the search for new employees, since an individual cannot simultaneously be focused on innovation and replication.

Knowledge includes not only information and personality characteristics of an individual, but also elements of group consciousness, which can be formed in a joint activity and include the cognitive and emotional components of a group attitude to reality. This means that understanding the factors and mechanisms of knowledge exchange requires systematic theoretical models of those processes that were previously studied independently in the psychology of interpersonal relations and communication, social cognition, small groups, intergroup relations, etc.

Today, it is recognized that competitive advantages are on the side of those companies that are able to quickly learn and share knowledge, not only within their structure, but also outside it, this is one of the

reasons for revising a number of traditional ideas about the factors of teamwork. For example, on the one hand, it is obvious that cohesion in a small team can increase the level of mutual assistance and coordination of actions, but on the other, it can lower the level of motivation of group members to build external relations - with other teams and stakeholders in the organization.

Thus, the baggage of knowledge of team members does not become so important as “knowing who knows” - the “transactional memory” of a unit, department, group and the greatest contribution to its development are made by the joint training of members of this team, in which they have the opportunity to form for themselves an idea of the knowledge, skills and abilities of each other. The formation of adequate representations of the enterprise employees about each other's expert resources step by step becomes a special managerial task.

To solve such problems in organizations through the introduction of information technology, the so-called "knowledge cards" of employees are collected, and the exchange of information between them about the knowledge, experience and skill of each other is increasing. Company management can organize conferences, special thematic forums so that employees have the opportunity to voice their ideas on key organizational, innovative and scientific issues, conduct so-called “knowledge fairs” and “knowledge lunches”.

In turn, the existence of cognitive limitations in the transfer of knowledge from an expert to a beginner was discovered. With the growth of skills and experience, knowledge becomes more abstract and it is more difficult for an expert to transfer them effectively. Experts tend to algorithmize and simplify understanding of the problem. Most often, in practice, they are not able to restore complex relationships, individual nuances and a way to solve the problem so that it becomes accessible to beginners.

To overcome this barrier, enterprises should apply special techniques for transferring experience: keeping a diary for a novice to observe more experienced colleagues, receiving structured feedback from them based on the results of their work, performing tasks together, etc.

Organization of the exchange of experience is carried out using:

- ***Trainings.*** During the training, where private questions are asked, it allows for a short time to a large number of young specialists to get acquainted with effective ways to solve certain problems that are currently relevant for those who have received theoretical knowledge, but do not have practical skills.

- ***Individual workshops.*** Master classes help to master the skills of working with certain programs. For example, if a more experienced specialist is fluent in Excel, and a young specialist is poorly versed in opportunities, just a few lessons are enough. Then check the results. As a rule, without additional training, such lessons are learned as quickly as possible.

- ***Mentoring.*** For an inexperienced employee, a mentor is attached for a long time. The task of mentors can be facilitated by developing sets of regulations, instructions and memos, as well as tables in which reference data are presented in the organization.

- ***Brainstorming.*** An operational method for solving the problem based on stimulating creative activity, in which the participants in the discussion are invited to express as many solutions as possible, including the most fantastic ones.

- ***Introduction of a database of useful sources.*** With the help of the database, any employee will be able to take advantage of useful articles, books, informational reference material, and with the help of useful information complete the task. Employees need to be encouraged so that they can replenish this database with useful information. For example, if a specialist attended a thematic conference, you should take care of creating a thematic report, which can be put in the database of useful sources.

- ***Collaborative training in webinars.*** Reception of transfer and exchange of experience is not expensive. The webinar mainly runs on Skype. Participants ask the facilitator a series of questions to which they receive answers. In addition, participants communicate with each other, discussing specific problems, receive recommendations and ready-made solutions.

Internal marketing is the conduct of regular surveys regarding the company's development opportunities. It is rational to be interested in what problems exist in a company where weak links are identified. In the future, such work will help organize training for inexperienced specialists or develop training programs that will eliminate all weak links in the organization.

There is also such a tool as an exchange of experience, which is considered as a key one in the framework of the knowledge management initiative. If we consider the simplest option, then these are the lists of general rules of action that are familiar to us, such as, for example, operating instructions or instructions “how to do”. The next step is to identify and share best practices and is the most effective way to achieve a specific goal.

Exchange of experience between organizations - this can be an exchange between specialists working in the same industry, carried out with the introduction of new technologies, programs where there will be a real opportunity to get acquainted with innovations in the field of technological and information technologies, at special events, forums and seminars. You can also send your employee to exchange experience with another company for borrowing, for example, a new technique in the production process.

Training is conducted by mentors or specialists who have mastered the relevant skills and technological processes, can teach beginners. However, when concluding an agreement, it is necessary to consider that in the process of interaction between organizations that are partners, it is important to ensure mutually beneficial cooperation. If the company has installed new equipment, but none of the working specialists knows how to manage it, partners who have been working on such equipment for some time can help.

The essence of secondment is that in practice, employees acquiring the necessary skills and knowledge in another company returning “home” to train other specialists. Internal secondment is the same process, but within the framework of one organization.

Thus, knowledge management is a new vector in the management activities of organizations aimed at the accumulation and effective use of intellectual capital. It should become one of the main tools to increase the competitiveness of organizations. The main obstacles to the implementation of knowledge management will most often be the low culture of Russian organizations and the insufficiently high level of use of information technology.

The fact that a huge, if not to say that a large part of the cost of many goods is created not so much at the stage of material production as at the stage of research, development and technological work, testifies to the increasing influence of knowledge on the formation of competitive advantages of companies.

Studies show that value added created with the help of intellectual capital exceeds that created with the help of tangible assets, equipment. The classic of IR theory, T. Stuart, back in 1997, said that “benefits became a product of knowledge, and in turn, knowledge became a very important production factor” (Steenkamp N., Kashyap V., 2010). Productivity and competitiveness of material production in the modern economy depend mainly on the ability to generate added value, process, accumulate and efficiently use information based on knowledge (Murtazin A.S., 2011).

Thus, it is fair to say that the types of activities related to the generation, transformation and use of knowledge i.e. the presence of a knowledge component in each product and service. As an example, “the cost of production of a car consists of only 30% of the cost of a Mercedes car, and the rest is compensation for the cost of developing a car, that is, costs to support the activities of engineers and managers ... ”(Pakhchanyap A., 2002).

The economic parameters of companies that have high intellectual capital and actively use it, significantly differ from the parameters of companies focused on the traditional principles of the industrial economy (Table 2). The main difference is manifested in the volume of investment in research and development (R&D), in knowledge.

Table 2 : Comparison of some companies focused on the industrial economy and the knowledge economy

Companies	Physical assets, billion dollars	Number of employed, thousand people.	R&D costs for the number of employees, thousand dollars	R&D costs to sales, %
Companies focused on the industrial economy				
Chrysler Group LLC	372	441	14	2,9
General Motors	315	594	13,5	4,9
Ford	284	345	17,4	4,1
Nippon Steel	34	26,3	11,9	4
Knowledge Oriented Companies				
Microsoft	59,3	50,6	86,6	16,9
Intel	44,4	80	36,8	9,4
IBM	88,3	319	16	5,5
CISCO	35,2	35	63,4	10,8

One way or another, knowledge is turning the economic picture of the world. Here are some examples. Everyone knows the electronic game Tetris. It was invented by the programmer of the Computing Center of the Academy of Sciences Pazhitnov, and she personally brought him $ 15,000. The computing center sold the rights to distribute the game to Nintendo. received $ 4 million, while the company received more than $ 1 billion. Another example is the famous Microsoft company. Its market value is estimated at 350-400 billion dollars, profit value is 50-70 billion, and the book value is only 510 billion. Russia is just entering this area, but we also have examples of high-tech business, in which knowledge prevails. The market value of the Russian company Paragraph International is $ 40 million with a book value of $ 1 million.

Conclusion

All this suggests that today, when society is developing rapidly, one should not underestimate the role of human knowledge and their contribution to the development of both individual companies and the national and world economy. Knowledge is becoming the engine for the development of mankind in various fields and with limited resources, such as financial, material and others, intellectual capital can become the key to success for many enterprises, organizations and entire industries.

Comparative Characteristic of Conditions and Results of SME Operations in the Russian and European Economies

Olga Nikolaevna KALACHEVA

Plekhanov Russian University of Economics, Moscow, Russian Federation,
olgaklchv@rambler.ru

Abstract

This article discusses practical aspects of SME's operations in the Russian Federation and the E.C. It researches the relationship and difference of recognition criteria as well as results of SME's activities, their contribution to the economies of the European states and Russia. A lot of attention is paid to the most important positions of SME's support. The article reveals SME's contribution to the economies of the countries under consideration as well as creation of new jobs, support of social stability. The work focuses on the problems in SME's development, such as budget financing, organizational and administrative barriers, accounting systems, the tax burden. The research will be useful not only for the existing entrepreneurs, but also to the top management of banks and governments, who are able to promote the development not only of a handful of companies but the economy as a whole.

Keywords: Small and Medium Entities, Entrepreneur, The Value Added, The Number of Employees, Support, Tax Burden, Innovations.

Introduction

Small businesses represent a significant part of the global economy, and can be one of the strongest factors in economic development and employment when given the right support, access to financial services and a favourable regulatory environment. The Understanding of SMEs by the leaders from around the world will help practitioners build successful small business operations. Small and medium entities do not require heavy investment and guarantee high velocity of resources (Adham, 2019). They react rapidly to market changes rendering the economy the necessary flexibility. These businesses are able of solving economic restructuring problems, forming and saturating the consumer goods market fast and cheap in a modern economy amid restricted financial sources. Besides, SMEs help solve the unemployment problem, help the appearance of the middle class and the class of medium-sized owners, who are interested in a stable economy of any state. Their taxes, being a leveraging instrument for the economy, are the backbone of budget revenue. This is why incentives for the development of entrepreneurship is an important government instrument.

Literature Review

The first scientific definition of the word entrepreneur appeared in the works of English economist of the end of the XVIIth - the start of the XVIII century R. Cantillon (1755), an entrepreneur was someone who operated in a risky environment, because merchants, farmers, craftsmen and other small owners buy things at one price and sell at another. In return, A. Smith (1776) believed that a businessman is an owner of capital, who takes risks to implement his commercial idea and get a profit. At the same time, J. Baudot (1797) defined an entrepreneur as someone responsible for the business he undertakes. This is a man who plans, controls, organizes and owns a company. Jean-Baptiste Say (1803) not only developed the three production factors theory (land, labour, capital), which are the sources of the society's riches, but viewed a businessman from the risk-oriented point of view, as they invested their own money. Schumpeter J. in 1934 underlined the primary role of entrepreneurship in creation of an

innovative economy (Say, 1803).) Filion L. (1997) was one of the first to consider businessmen's features from the point of view of different sciences.

The Russian Civil Code says that entrepreneurial activity is independent operations done at businessman's own risk aimed at a stable profit from the use of property, the sale of goods, work or services by the persons registered as such in accordance with the procedure established by law.

Theoretical Background

To start our research, let's turn to the 'company' category. The Russian Federation defines the 'company' term in the Civil Code, article 132. It says that a company is a combination of property, supposed to be used for entrepreneurial activities. This view means that a company comprises all property purchased for its activities, including land, buildings, constructions, equipment, implements, raw materials, products, claims, debts, as well as the right for the designations that individualize the company, its products, works and services and other exclusive rights. In European Union the economic essence of enterprise is determinated by Commission Recommendation 2003/361/EC of 6 May 2003.According to it, «an enterprise» is any entity engaged in an economic activity, irrespective of its legal form. Self-employed persons and family businesses engaged in craft or other activities, and partnerships or asso- citations regularly engaged in an economic activity are included in this definition.

In mind the provisions of article 3 of Federal Law 209 defines Russian SME as the subjects (companies and individual entrepreneurs), which satisfy the legal requirements and are entered in the Unified Register of Small and Medium Business Subjects. Under Federal Law 209-FZ, the SME criteria includes such "numeric" parameters as the number of employees and annual turnover (Table 1).

Table 1: definition of SMEs in Russia

Indicators	Enterprise Category		
	Micro SME	Small SME	Medium-sized SME
1	2	3	4
Employees	<= 15	100 to<250	<=250
Turnover	<=120 million rub.	<=800 million rub.	<=2000 million rub.

Source: compiled by the author

In the European Union, the number of employees and the turnover or total balance are also key indicators for classifying entities as SMEs. (Table 2).

Table 2: definition of SMEs in EU

Indicators	Enterprise Category		
	Micro SME	Small SME	Medium-sized SME
1	2	3	4
Employees	0 to < 10	10 to< 50	50 to <250
Balance sheet total	< €2 million	< €10 million	< €43 million
Turnover	< €2 million	< €10 million	< €50 million

In the E.C., the key factor of classifying as a SME is the number of employees. The employees are the people who worked full-time for a whole year as well as the company owners, the partners with managerial duties, who participate in company operations. The financial criteria is secondary in classifying a company as SME. For example, the turnover of a non-retail company is much lower than that of a retail firm. In such cases the overall balance is used apart from the net turnover.

An important difference of classification as SME in the E.C. is meeting at least one financial criteria. For example, if the total balance of a company exceeds a 45 mln euro limit, while the net turnover is below the acceptable level of 40 mln euros, the company will not lose the SME status. In Russia, this company will not be classified as SME, because it has to meet all the criteria for this. This study of the criteria shows that the Russian procedure of acknowledgement as SME is more difficult, because the criteria is higher, for example, the employee count is two times as high. This means that the number of potentially new SMEs in Russia will be smaller, other things being equal.

According to a Unified Register of SME Subjects, there were 6 mln SMEs in the Russian Federation, including 2.7 mln companies and 3.3 individual entrepreneurs as of the end of 2018. According to the Tax Service, the number of SMEs increased until August in 2018. Since August 10, 2018 the number has been falling. Analysts explain the slump by an annual deletion of non-operating SMEs from the database. This means that we cannot talk about the growing numbers of SMEs in Russia. However, 64% of the SMEs, which functioned in January 2016, are still working. Russia registers 56,000 new SMEs a month, while 28,000 stop their operations.

Figure 1: The number of SMEs for the period from 12/10/2017 to 12/10/2018
Source: compiled by the author https://ec.europa.eu/growth/smes/

In 2018, there were slightly more than 25 million SMEs in the EU, of which 93% were micro-SMEs. SMEs accounted for 99.8% of all enterprises in the EU-28 non-financial business sector (NFBS). They generated 56 .4 % of value added and 66.6% of employment in the NFBS. The number of enterprises in EU in 2018 is shown on Figure 2.

Figure 2: Number of enterprises in EU in 2018
Source: compiled by the author https://ec.europa.eu/growth/smes/

There are 27.6 enterprises registered per thousand Russians compared with 57 in the E.C. and the international level of 32.2 (Figure 3). This indicator fluctuates strongly in Europe – from 29 in Romania

and 115 in the Czech Republic. These figures demonstrate significant involvement of Europeans in entrepreneurship.

Figure 3: Data of SME's number of per 1000 people

Source: compiled by the author https://ec.europa.eu/growth/smes/

Figure 3 shows that the number of SMEs in Russia per 100 people are two times lower than in Europe and below the international indicator. However, according to the Russian Tax Service, 15.9 mln people were employed in small business as of the end of 2018. Consequently, SMEs account for about 25% of Russian employment compared to 61% in France, 62.9% in Germany and 65.6% in the Netherlands. Labour productivity has grown in EU SMEs, first of all due to the growth in the value added. Overall, in 2018, EUSME value added grew by 4.1% and EU SME employment by 1.8%. Micro SMEs have driven this recovery - they recorded by far the strongest value added and employment growth of all SME size classes.

Figure 4: Number of persons employed in EU in 2018

Source: compiled by the author https://www.moodys.com/research/

We should agree with Commissioner for the protection of entrepreneurs ' rights under the President of the Russian Federation Boris Titov, who said that "only a higher turnover of small and medium enterprises, hi-tech facilities in industry and agriculture, innovative companies will ensure a wider taxation base, creation of new highly paid jobs, solution of social problems." Almost 50% of EU SMEs undertook some innovation activity over the last years. The participation of SMEs in innovation activities varies greatly across the EU, with the share of innovating SMEs in the total SME population ranging from 10% in Romania to 66% in Portugal. As an undoubtedly positive factor for the appearance of new SMEs, we see development of competition and entrepreneurship, which leads to a wider spread of innovations, and a higher efficiency of economy on the whole. Schumpeter, J.A. told, that those people who have implemented successful innovations can be found in the capitalist class. From this point of view, entrepreneurial activity can provide an excellent mechanism for social mobility, that is, achieving a higher social status for a person and his family (Croitoru A., 2012).

According to research the Stolypin Growth Economy Institute, total contribution of small business to the Russian economy amounts to a meagre 22%, as cited by the RBC news agency. Europe's average indicator amounts to 50-60% -- in Germany, the share of small and medium-sized business in GDP amounts to 53%, in Switzerland to 60%, and in the Netherlands to 63%.

Figure 5: Value added in EU in 2018

Source: compiled by the author https://www.moodys.com/research/

On average, in the EU, SMEs have generated ca. 60 % of the increase in value added. Micro SMEs generated 28.5% of this increase, while small SMEs accounted for 16.9% and medium-sized - 14.1%. This increase in value added in EU was generated, mostly in less knowledge-intensive industries. There are more than 3⁄4 SMEs concentrated in only three areas: trade, construction and manufacturing, - 10.6% in Russia. Of course, state support of SME will stimulate economic growth and development of the country and increase social advantages of higher competition. This is why the SME development problem is solved through creation of a competitive business environment (Ayyagari, 2007)

Results and Discussion

The role of the government and its support in the development and duration of active SME functioning cannot be underestimated. CEER (2016) confirmed that the companies, which receive state support, have a higher chance to improve their financial indicators and survive fierce competition. In 2014-2020 €57 billion or ca. 20% of funding from the European Regional Development Fund (ERDF) were dedicated explicitly to SMEs support in European Union. The Russian government does not provide such huge support for SMEs. One of the most systemic and most efficient SME supporting programmes of the Economic Development Ministry is shrinking constantly – in 2015, total support of 85 Russian regions amounted to 16.9 bln rbls, while in 2018 it amounted to 5.02 bln rbl. (Kharakoz, 2018). At that, this programme finances the most important projects in most regions – creation of the innovative infrastructure. The government has the primary role in support of the innovative activities of SMEs. Many social achievements of the country are based on significant success of its small companies, such as SMEs (Cirera, 2017; Golubtsova, 2019.). The need for this type of support is explained by the existence of a closed circuit. The innovations developed by the SMEs, will, in their turn, have a positive impact on the growth of the size and number of SMEs, and, consequently, on the national economy growth (Petrov 2019; Tulio, 2019).

In particular, improvements in the overall innovation environment would have positive effects and stimulate innovation by SMEs especially in those Member States which rank less highly in the EU Innovation Scoreboard. Such policies would need to be complemented by policies directly targeting innovating SMEs and those that currently do not plan innovation activities (Bykanova, 2017; Kuznetsov, 2017). The main instruments of such policies may be: providing funding (grants, vouchers, tax credits), helping SMEs access the skills required for their innovation activities, and providing mentoring, advice and networking opportunities. Public funding of some of the SME's innovation activities would be especially valuable in those Member States as well as in Russia where such funding has declined in recent year (Kosolapova, 2019).

One of the most important factors of operation and especially establishment of a private business is undoubtedly the possibility to attract additional financial resources. That is why an affordable credit is an indispensable leverage on SME's activities. On the one hand, banks are not eager to cooperate with SMEs, on the other hand, they realize SME's hidden potential. The Moody's posits that in considering lending, the size of the company has a significant impact. Thus, higher default rates should be expected for smaller companies than for larger ones.

However, total outstanding amount of SME loans in EU decreased from a maximum of ca. EUR 85 billion in 2013- Q3 down to less than EUR 60 billion in 2018-Q4, that is ca. 30 %. According to the Expert Ra agency, the share of overdue credits among Russian SMEs amounted to 12.4% at the end of 2019 compared to 14.9% at the start of 2018. The total volume of overdue credits shrank by 16.2% to 521.8 bln rbl in 2018. The positive dynamics of SMEs' credit portfolio is confirmed by the data from 41 leading Russian banks. Despite a rise of credits issued to SMEs in 2018 (to 6.8 trln rbl, a record volume since 2015 and a 11% rise on 2017 levels), the crediting problem is seen as one of the most pressing and requires a solution from the very high levels of management. Many authors note that simplifying the registration procedure and reducing the tax burden are indirect measures to support the development of SMEs. The cross-country analyse of the burden of tax accounting and documentation processes in EU results in Figure 6.

Figure 6: The burden of tax accounting and documentation processes in EU
(Source: KPMG 2018)

The most complicated system of tax accounting and documentation processes (fig. 6) exists in France, and the most simple - in United Kingdom. Empirical evidence shows that there is a robust, negative relationship between the complication of registration process, the amount of tax burden and the quantity of active SMEs in Russian Federation due to the very intricacy tax system (Ivanova, 2018; Akhmadeev, 2019). Case studies show that tax burden on business is still enormous in Russia. The current tax policies do not favour business development; they limit themselves to their fiscal function. Russia's payroll burden is 130% higher than the world's average (Turishcheva, 2019, Korableva, 2019). The situation with the administrative burden on SMEs in Russia is similar - 52% of businessmen had from 1 to 6 checks, including 5.6% who had more than 6 checks.

Conclusion

When comparing development of small and medium-sized businesses one should keep in mind the differences in defining SME subjects in different countries. The obvious solution to increase the number of Russian SMEs is a change of their criteria. According to the researches, Europeans'

involvement in entrepreneurship is on average two times higher than in Russia. At the same time the criteria for attribution to SMEs by workforce numbers in Russia is also almost two times higher.

Despite active development of small and medium-sized businesses in Russia, the indicators, which characterize their operations are much lower than those in Europe. The necessary and important step here can be a revision of economic policy, its targeting affordable loans, a more loyal tax burden, reduction of administrative barriers, higher professionalism of businessmen. The state SME support measures as the strongest lever should primarily include state preferences and guarantees offered in the form of credit guarantees, subsidies, training of entrepreneurs, access to the state order. Russia's tax burden does not comply with its labour productivity, which is much lower than in the developed states. The burden on the small and medium-sized businesses is higher than the burden on large business. This curbs SME's development, does not stimulate their growth, but encourage their splitting and going into shadows. The states with a higher GDP per capita ensure more loyal credit conditions and, consequently, a greater probability of successful functioning of SMEs. Finally, SMEs remain an underutilized resource of the Russian economy, and in European Union are the most effective and powerful tool in the development of an innovative economy as well as all over the world.

Elena Bobkova, Moscow State University of Technologies and Management, Moscow, Russian Federation, vica31@yandex.ru

Abstract

The potential for digitalization in countries continues to face a number of challenges that hinder both the sustainability of digitalization initiatives and the expected benefits. Taking a critical approach to a realistic perspective, this article examines the main cause-and-effect factors and indices that characterize the digitalization of the economy of a country or business entity. .New digital technologies are rapidly penetrating the economy of various countries and regions, having a significant impact on the development of its infrastructure and economic efficiency. The effectiveness of the latest digital technologies is becoming a key element of international economic competition. The increasing use of modern information and communication technologies is becoming a prerequisite for the emergence and development of new effective management technologies, business practices and successful business operations. Therefore, most countries and regions stimulate these processes at the state and regional levels. To ensure the systematic implementation and development of digital technologies, it is important to develop methodological approaches to assessing the level of digitalization of countries and regions.

Keywords: Digitalization, Digital Transformation, Digital Economy, Big Data, Artificial Intelligence.

Introduction

There are several approaches to defining digitalization in the literature. According to Reddy and Reinartz (2012), digitalization has two definitions and one of them is the use of the Internet and the computer to create effective economic value relative to the traditional sense.

The other definition fully asserts the new technology's changes in operation, interaction, configuration, and wealth creation in relation to the broader meaning. Schallmo et al (2017) investigate the definition of digitalization and the proposed definition of digital transformation for business model research. According to Schallmo et al. (2017) digitalization involves networking business, customers, segments and requires data analysis to achieve the information used to evaluate the options that performance in order to increase value.

Berman (2012) proposed the value of digitalization based on consumer value and transformational operations based on digital technology to achieve customer collaboration and interaction for successful digital transformation. The digitalization of countries can be measured with six key attributes: ubiquity, accessibility, reliability, speed, convenience and skills.

Westerman et al. conducted an Executive study on digitalization in terms of three aspects: buyers, business models, and operational process.

In the literature, Schwarzmuller investigated how digital transformation affects organizations. Majchrzak et al (2016) conducted a study on the implementation of digitalization. Balyer and Oz (2018) investigated the impact of digitalization on education according to the point of view of academics. Bouwman investigated the effects of digitalization on small and medium-sized businesses.

Motta also investigated the impact of digitalization on socio-economic development. Lee investigated the ability of small and medium-sized businesses to digitally transform.

Loonam investigated some case studies on digital transformation. Digitalization affects the world economy, contributes to the emergence of such concepts as the digital economy (UNCTAD, 2017).

Russia, like other countries that have a significant impact on the global and political arena, has entered the digital technology race. This is also facilitated by the fact that, according to most indicators characterizing socio-economic development, Russia is among the countries that are world leaders.

So according to the CIA Fact book 2018 Russia:

by occupied area - takes first place in the world;

by population - ranks ninth in the world;

in terms of GDP (purchasing power parity) the sixth place in the world, after Germany and Japan;

in terms of exports of products in 15th place in the world Singapore, Mexico and Canada;

by the number of Internet users in 6th place in the world after Japan and Brazil;

by the ratio of the number of Internet users to the total population in twenty-eighth place in the world, ahead of the United States and lagging behind countries such as Israel and Spain.

Despite the leading places in the world in the level and dynamics of indicators, Russia lags behind most countries in the dynamics of socio-economic development.

For example, in terms of happiness, Russia is in 68th place in the world after countries such as Peru, Portugal and Pakistan. Also, the residents of Russia have a rather low level of GDP per capita in terms of which, amounting to $ 27,900, Russia ranks 74th in the world.

This necessitates the speedy development of digital technologies in Russia, as their speedy implementation will significantly increase the efficiency of economic processes. The result of increased efficiency will be an increase in the level of happiness and income of the population.

Formulation of the problem

New digital technologies are dynamically penetrating the economies of various countries and regions, having a significant impact on the development of its infrastructure and economic efficiency. The effectiveness of the latest digital technologies is becoming a key element in international economic competition. The expanding use of modern information and communication technologies is becoming a prerequisite for the emergence and development of new effective management technologies, entrepreneurial practices, and successful businesses. Therefore, most countries and regions stimulate these processes at the state and regional levels.

The effective development of digital technologies and the planning of their development cannot be carried out without constant monitoring of the digitalization level of Russian society, both as a whole and by regions. Therefore, the development and improvement of methodological approaches to the evaluation of digitalization processes is relevant.

Results

Currently, there are many ratings and indices that characterize the digitalization of the economy of a country or business entity. Among these studies, the following research and development should be highlighted.

a. Digital Evolution Index rating developed by MasterCard and the School of Law and Diplomacy named after Fletcher at Tufts University.

The results of the study show the competitiveness and development potential of the digital economy in 60 countries. The Digital Evolution Index 2017 rating evaluates each state according to 170 unique parameters.

They describe 4 main factors that determine the pace of digitalization:

- level of supply (availability of Internet access and degree of development

infrastructure);

- consumer demand for digital technology;

- environment (state policy, legislation, resources);

- An innovative climate (investments in R&D and in digital startups).

The MasterCard study proposed a way to study and measure the level of “digital trust”, as well as assess the state and speed of digital development.

In addition, the Digital Evolution Index considers various examples of the introduction of digital services around the world, which allows each state to study the practices of other countries.

The disadvantage of this rating is that this rating reflects the progress in the development of the digital economy throughout the country, in terms of integrating the global network into people's lives.

b. ICT Development Index, an IDI that is measured annually by the International Telecommunication Union, a specialized UN entity.

The index consists of 11 statistical indicators reflecting the availability and use of ICT, as well as practical skills in the use of ICT by the population of 190 countries

The IDI is comprehensive and is based on the following three basic factors (sub-indexes).

The basic factor (sub-index) “Access” (Access): the number of subscribers of fixed telephone lines per 100 inhabitants, people .; the number of mobile phone owners per 100 inhabitants, people; width of the cross-border channel in terms of one Internet user, Bit / s; share of households with a computer,%; share of households with Internet access,%.

The basic factor (sub-index) “Use”: the percentage of Internet use,%; fixed wired access per 100 inhabitants, people; the number of active subscribers to mobile broadband access per 100 inhabitants, people

Basic factor (sub-index) “Skills”: average number of years of study, year; primary education enrollment rate,%; indicators of secondary and higher education coverage,%.

The main drawback of this rating is that it provides the basic parameters for the development of ICT in the country (regions), but does not answer many questions related to the introduction of new technologies, such as cloud computing, the Internet of things, big data, which significantly determine the degree advancement of the country (regions) on the path to building a digital economy.

c. PwC's The Future is Coming Rating

The study provides a rating of large cities in terms of their readiness to introduce new digital technologies, as well as their current capabilities, readiness and elaboration of the implementation of technological solutions and products in various social spheres: health, education, security, tourism and culture, transport, economy , Housing and communal services, urban planning, interaction with citizens.

The readiness of the city was assessed by a number of parameters: infrastructural readiness (availability of basic infrastructure), regulatory and technological readiness (availability of strategies, regulations and examples of innovative solutions), as well as the social readiness of citizens to use future technologies.

Index “Virtual services”: “E-democracy and budgeting with the support of citizens' initiatives”, “City as a service”.

Digital Economy Index: A Shared Economy (a shared economy means the physical or virtual association of people to use resources and skills effectively, the sharing of cars (Carsharing) or group trips (Ridesharing) are typical examples of a shared economy); “Innovative financial technologies” (as examples of innovative financial technologies, the authors call decision-making technologies based on big data analysis in the financial industry, as well as block chain-based decisions); “Industry 4.0” (production based on robotics and process automation, including innovations such as the use of industrial IoT and 3D printing).

Infrastructure Readiness Index (readiness to implement 5G technology that provides data transmission with high bandwidth and minimal latency (including to support unmanned vehicles), and IoT networks with low power consumption and a large number of connected devices (including for personalized medicine), the development of data analysis centers using intelligent analytics and artificial intelligence, as well as providing online information about the city and its development based on data (received from city services, residents and companies): “Data Infrastructure”; "Data usage"; "Data analysis".

The Smart Home and Utilities Index (smart lighting systems, smart electricity networks, the use of sensors in housing infrastructure and utilities to monitor and optimize resource consumption): Smart buildings and systems for efficient use of resources; “Intelligent Electric Networks”.

“Unmanned transport” index (the index determines the willingness to switch to unmanned electric vehicles, which will optimize travel time, reduce the number of traffic jams and incidents, improve the environmental situation in the city, as well as readiness for aerial drones, which will take on many functions of transport and monitoring services): “Unmanned ground transportation”; “Unmanned aerial vehicles”.

Index “Digitalization of Culture and Tourism”

Smart Health Index

Open Adaptive Education Index

Proactive Security Index

Index "Virtual city".

One of the drawbacks of PwC's The Future is Coming rating is that the PwC rating assesses a greater degree of readiness to introduce technologies than the effect of their introduction; The rating is aimed at researching megacities.

d. Global Connectivity Index (GCI), Huawei

When calculating this index, the country's status in the field of digital economy development is determined, which is determined by investments, implementation, experience and potential in building the appropriate ICT infrastructure.

The GCI index takes into account the degree of development of such technologies in the country as big data, cloud technologies, data centers, the Internet of things and broadband data transfer. The degree of implementation and commercialization of these technologies is evaluated in various categories, including supply, demand, quality and potential.

The main drawback of the GCI index is the lack of official statistics for most countries and the world and their subjects. The development of the entire spectrum of digital technologies is not disclosed.

e. The Digital Russia Index, which allows one to evaluate each subject of the Russian Federation by a wide number of criteria using weighting factors, including based on:

assessing the level of public coverage in open sources of development in the constituent entity of the Russian Federation of normative regulation and administrative indicators of digitalization, ensuring the digitalization of the economy at a particular point in time;

assessment of the level of public coverage in open sources of development in the subject of the Russian Federation, specialized personnel and training programs that ensure the processes of digitalization of the economy at a particular time;

assessment of the level of public coverage in open sources of development in the constituent entity of the Russian Federation of the availability and formation of research competencies and technological groundwork, ensuring the processes of digitalization of the economy at a particular point in time;

assessment of the level of public coverage in open sources of development in the constituent entity of the Russian Federation, the direction of the information infrastructure that ensures the processes of digitalization of the economy at a particular point in time;

assessment of the level of public coverage in open sources of development in the subject of the Russian Federation, the direction of information security, ensuring the processes of digitalization of the economy at a particular point in time;

assessment of the level of public coverage in open sources of financial and economic efficiency of the development of digitalization in the subject of the Russian Federation at a particular point in time;

assessment of the level of public coverage in open sources of the social effectiveness of the development of digitalization in the subject of the Russian Federation at a particular point in time.

As conceived by the creators, the Digital Russia Index allows you to get an expert assessment of this parameter in the context of each subject of the Russian Federation, the accuracy and reliability of which corresponds to the accuracy and reliability of information obtained from open sources.

In our opinion, this approach to the level of digitalization has its drawbacks, as it is associated with the level of public coverage of one or another aspect of digitalization in the region of the Russian Federation. Also, this rating can be used to a limited extent to assess countries and regions of the world as a whole.

Conclusions

The study showed that at the present time the introduction of the latest digital technologies can improve the efficiency of the economic activity of the country in its regions and the world economy as a whole. Digital technologies, including indirectly affect the overall level of socio-economic development of the country, which makes them a relevant tool for the development of modern society.

Formation of plans for the development of digital technologies and their development is impossible without an objective assessment of the current state in a particular country and its regions, as well as in the world as a whole. Therefore, most of the participants in digitalization form their methodological approaches to assessing the level of digitalization.

The analysis above showed that each of the assessment methods has its own characteristics and disadvantages.

In our opinion, the main drawback of existing methods is the lack of assessment of the negative impact of digitalization on society. The most striking examples of the negative impact of digitalization include the emergence and explosive increase in the number of cybercrimes, cases of dependence on the Internet and computer games in children and adults.

Therefore, in our opinion, the complex of assessing the digitalization level of socio-economic objects (the subject of a particular country, country, region of the world and the world as a whole) should consist of several main blocks:

a. Assessment of the technological level of digitalization in a particular region.

b. Digitalization assessment in relation to socio-economic processes.

c. Assessing the negative impact of the digitalization process on society.

The following indicators can be used as indicators for assessing the negative impact: the number of cyber-attacks (theft of cash from credit and debit cards, suicide using social networks, theft of vehicles and real estate using electronic means of registration, theft of personal data), cases of dependence from the Internet and games, including mental illness, the average time spent by children and adults in social networks and games, in comparison with the standard, I provide general normal physical and mental condition of a person, without consequences for health and psyche.

The calculation of such an indicator will allow us to identify not only the overall development of digital technologies in a particular region or country, but also to assess the negative consequences of their implementation.

Integration and Safety of Immigrant Students: Implications for Migration Governance

Dorota DOMALEWSKA

War Studies University, Warsaw, Poland
domalewska.dorota@gmail.com

Abstract

Immigration-driven population growth has a considerable impact on schools. The aim of this paper is to investigate factors associated with successful integration of immigrant students: student safety and integration policies. More specifically, the study focuses on the following research questions: (1) To what extent does safety in the classroom affect successful integration of immigrant students? (2) What are the educational solutions adopted by schools in the countries that are the most successful at educating foreign students? (3) Do safety in the classroom and integration policies affect educational attainment of immigrant students? The study shows that creating safe space in the classroom empowers learners and facilitates their development. It is a space that enables learners to take risk and tackle challenging issues. Furthermore, immigration policies foster the integration of migrants and help them achieve academic success. In fact, strict immigration policy and effective integration policies are the key indicators of high academic performance of immigrant children. In increasingly diverse schools, policy interventions should aim at providing language, social and emotional support. The analysis also provides implications for migration governance.

Keywords: Immigration, Safety, Immigrant Integration, Intercultural Education

Introduction

Increased migration flows lead to rapidly changing demographics and social structure, especially in urban areas. Immigration-driven population growth has a considerable impact on schools that should provide learning, social and emotional support to empower disadvantaged students and facilitate immigrant integration. However, immigrant students face a variety of challenges that become an obstacle to successful social integration. Challenges, such as low income, informational gaps as well as language and cultural barriers, affect their social and cognitive development, academic performance (Gonzalez, 2003; Lacoe, 2016), restrain their educational and occupational choices, and prevent social inclusion (Gitlin *et al.*, 2003; Plenty and Jonsson, 2017). Educational institutions need to buffer the negative effects experienced by foreign students during their acculturation process.

Safety of immigrant children is another important issue that needs to be considered. Research shows that immigrant minors' safety may be at risk, e.g. circa 10% of migrants in the farm work force in the US are unaccompanied minors (McLaurin and Liebman, 2012). Furthermore, foreign students struggle with learning, well-being (Oliveira, 2017) and mental health issues (Fawzi, Betancourt and Marcelin, 2009). They also tend to attend disadvantaged, violent, and disorderly schools (Peguero and Bondy, 2017). Finally, they struggle to assimilate into the local community as the local population is preoccupied with migration affecting local labor markets, causing potential violence and lowering levels of academic performance at schools (Gitlin *et al.*, 2003).

Successful integration of foreign students at school is a complex process. The aim of this paper is to investigate factors associated with successful integration of immigrant students. The study seeks to address two of the most significant factors related to immigration: student safety and integration policies. More specifically, the study focuses on the following research questions: (1) To what extent does safety in the classroom affect successful integration of immigrant students? (2) What are the

educational solutions adopted by schools in the countries that are the most successful at educating foreign students? (3) Do safety in the classroom and integration policies affect educational attainment of immigrant students? The study is based on a thorough literature review and the analysis of the results of the Programme for International Student Assessment (PISA) and immigration policies adopted by the countries where immigrant students scored highest in the PISA assessment. The study contributes to a comprehensive understanding of effective integration of immigrant children in schools.

Safe space at schools

Safety in the classroom is a prerequisite for academic performance (Piaget, 1936; Maslow, 1970). Students who do not feel safe in the classroom underperform on standardized rates, are more frequently absent from school (Lacoe, 2016), do not activate higher level thinking (Maslow, 1970). Creating safe space in education is also essential to empower learners, to let their ideas grow and creativity develop. It is a space that enables learners to take risk and be involved in challenging issues such as diversity, multiculturalism and injustice (Holley and Steiner, 2005, p. 49) that immigrant students face on a regular basis. In order to deal with difficulty, students also need to put themselves at risk and dare to be vulnerable. Therefore, not only a safe space but a 'brave space' needs to be created where diversity and injustice immigrant students face will be challenged (Arao and Clemens, 2013) and where constructive feedback will be offered. As Kislyakov et al (2014) argue, "[s]ocially safe and functioning education environment defines the success of formedness of students' professional competencies that relate to the life in multi-cultural society, harmonization of inter-ethnic and cultural relationships, prevention of xenophobia, strengthening of tolerance in education environment."

The feeling of safety, just as perceptions of disciplinary fairness, racial tension and disorder, differ among students of various ethnic and racial backgrounds. For instance, Black and Hispanic students tend to report feeling unsafe more frequently than their Caucasian or Asian classmates who attend the same classroom (Lacoe, 2015). Minority students are frequently targeted by bullying (Hjern *et al.*, 2013), have low peer status and are marginalized (Plenty and Jonsson, 2017). Discipline and disorder affect more deeply the safety of minority students than their non-minority classmates. Therefore, creating safety in the classroom should be educators' major objective.

School plays a very important role in the integration and upward mobility of disadvantaged groups as its positive structural and relational features can help address the barriers disadvantaged students face (Hao and Pong, 2008). Structural aspects include curriculum, specific programs, enrollment size, demographics and other attributes whereas relational features refer to collective responsibility for student learning, academic standards, and student-teacher relations. Research shows that low-income and minority students succeed in schools with narrow curriculum and strong academic focus (Lee and Smith, 1993; Lucas and Berends, 2002), controlled variations in demographic composition (Griffith, 2010), and small enrollment (Lee and Smith 1996). As for relational attributes, disadvantaged students benefit from teachers' high expectations, emotional student-teacher relationship (Crosnoe, Kirkpatrick Johnson and Elder, 2004), and increased collective responsibility for students' development and academic achievement (Hao and Pong, 2008).

Educational attainment of immigrant students

Educational attainment refers to "the quality and quantity of knowledge, skills and positive attitudes, behavior and philosophy that students acquire" (Tamanja, 2016, p. 110). First, it needs to be emphasized that students across culturally contrasting groups adopt similar approaches and strategies that help them achieve academic success (Entwistle, Tait and McCune, 2000; Domalewska, 2017). However, a large body of research points at barriers that impede immigrant students' academic success (Gonzalez, 2003; Lacoe, 2016). First, academic success is associated with factors such as socio-economic status, parents' education level, parental involvement over child academic achievement, learner attitudes to learning, and school environment factors. Therefore, immigrant

families face the same challenges as their similarly disadvantaged native counterparts, namely economic and sociodemographic factors as well as bureaucratic complexity or distrust of government programs (Karoly and Gonzalez, 2011). However, immigrant students face additional challenges, such as informational gaps, language and cultural barriers, well-being (Oliveira, 2017), and mental health issues (Fawzi, Betancourt and Marcelin, 2009).

On the other hand, a large body of research proves that some countries are effective in educating foreign students. OECD (2015) present the results of the Programme for International Student Assessment (PISA) and compare the scholastic performance of first- and second-generation immigrants with comprehensive immigration policies adopted by the country. The findings prove that the academic success of foreign students depends mainly on the immigration policy rather than systemic solutions adopted by schools. Foreign students achieve academic results similar to native pupils in Singapore, the Chinese region of Macao, Hong Kong, Canada, and Japan, whereas the greatest difference in school performance between foreign and native students was observed in Slovenia, Sweden, Denmark, Finland and France. Table 1. presents the results of several indexes related to migration of the countries that scored highest in the PISA assessment. The indexes include overall migrant integration policy index, education, permanent residence, anti-discrimination, immigration policy, and PISA score.

Table 1: Determinants of academic achievement of immigrant children

	Singapore	**Canada**	**Japan**	**Hong Kong**
Overall migrant integration policy index (MIPEX 2015)	N/A	68 (6th in the ranking)	44 (27th in the ranking)	N/A
Education (MIPEX 2015 score)	N/A	65 (4th in the ranking)	21 (29th in the ranking)	N/A
Permanent residence (MIPEX 2015 score)	N/A	62 (16th in the ranking)	59 (20th in the ranking)	N/A
Anti-discrimination (MIPEX 2015 score)	N/A	92 (1st in the ranking)	22 (37th in the ranking)	N/A
Immigration policy	skill-based, supply-driven system	skill-based, supply-driven system based on points	skill-based, supply-driven system based on points	skill-based, supply-driven system based on points
PISA score (OECD 2015)	564 in Math (1st in the ranking) 535 in Reading (1st in the ranking) 556 in Science (1st in the ranking)	516 in Math (10th in the ranking) 527 in Reading (3rd in the ranking) 528 in Science (7th in the ranking)	532 in Math (5th in the ranking) 516 in Reading (8th in the ranking) 538 in Science (2nd in the ranking)	548 in Math (2nd in the ranking) 527 in Reading (2nd in the ranking) 523 in Science (9th in the ranking)

As presented in Table 1., the academic success of immigrant students correlates with restrictive immigration policies, but rather not with indexes measuring integration of immigrants. Immigrant policies in most top-ranked countries in the OECD report have adopted restrictive immigration policies that encourage top professionals to settle down permanently in order to ensure work efficiency and economic stability (Singapore is the only country that favors short-term migration to fill labor gaps). Immigrant integration policies do not correlate with foreign students' academic achievement. Japan's integration policies are under-developed. Foreigners, for example, live in separated residential areas. The country also lacks coordinated policies to support newcomers. Hong-Kong fails to promote civic and social integration of immigrants. What is more, state policies lead to

discrimination against migrants (e.g. unfavorable welfare policies and territorial segregation of newcomers in the poorest districts) (Law and Lee, 2006). Both in Japan and Hong-Kong strict immigration policies contribute to the stigmatization of foreigners and social exclusion.

Singapore and Canada, on the other hand, are rigorous in accepting immigrants but at the same time value integration of newcomers. Singapore is a unique country as its population is mostly composed of immigrants. The country's economic development is closely related to the country's policy to attract foreign manpower to overcome the shortage of local human resources[i]. However, the country has been curbing immigration since a high level of migration resulted in social problems. At present Singapore's immigration policy is highly selective based on labor demand in the market favoring temporary immigrants as a temporary response to labor shortages without granting them residence, family reunion right or welfare entitlement (Lian, 2016). Singapore's education is based on multiculturalism since early childhood when children internalize knowledge, attitudes and skills necessary to participate successfully in a pluralistic society. Educational policy both promotes diversity through preservation of the cultural identity of the ethnic groups and maintains social cohesion among different groups (Berthelsen, Karuppiah, 2011). Foreign students' needs are effectively catered for as they can enroll in supplemental English language courses, orientation and induction programs whose goal is to facilitate adjustment to life in Singapore. Additionally, special programs enable integration of foreign students, such as life-skills workshops, teacher mentors, local buddy schemes (buddies introduce newcomers to Singaporean school system and lifestyle easing their transition to a new culture) (Ministry of Education in Singapore, 2010).

Canada has long been an immigrant receiving country; therefore, the country has developed effective integration policies. Canada was ranked first out of 38 countries for its anti-discrimination policies and has reached the top five in terms of family reunification, education and labor market mobility (MIPEX 2015) (see Table 1.). The country has implemented a 'human capital' immigration model based on a point system. However, recently Canadian immigration policy has been undergoing restrictions with longer wait for permanent residency and more complex naturalization process.

In Canadian schools 22,7% of 15-year-old students are 1st and 2nd generation pupils (MIPEX 2015). High academic achievement of immigrant students is mainly attributed to generous funding on education, teacher support (e.g. training), and school programs to further foreign students' academic pursuits (e.g. language courses, mentoring programs, tutoring, and afterschool clubs). Social support is also offered for students and their families when immigrants may receive guidance from counselors, social workers and psychologists to assist in their effective social, economic and cultural integration (Cardoza, 2018). Finally, Canada promotes the recognition, retention and fostering of cultural and ethnic identities to facilitate integration (Griffith, 2017), as it encourages "the feeling of differentiation from others, the recognition of one's own difference, the sense of belonging, and consequent mechanisms of inclusion and exclusion, which are in turn created, maintained, and reinforced through public policies and the law" (La Barbera, 2015, p. 9).

To sum up, the educational solutions adopted by schools in the countries that are the most successful at educating foreign students, share one underlying principle: restrictive immigration policies. A large body of research (Levels, Dronkers and Kraaykamp, 2008; Hartwich, 2011) proves that strict immigration policy is the key indicator of high academic performance of immigrant children. High educational and occupational status of foreign students' parents as well as ambitious family background ensures that immigrant students enjoy familial support and are eager to succeed, which is the best predictor of academic success.

Parental socio-economic status is a significant variable that determines the academic performance of immigrant students. However, familial socialization may buffer the negative effects of low socio-economic status. As Yamamoto, Liu and Liu (2016) show, low-income parents hold stronger beliefs about parental responsibility for education whereas middle-class parents offer more reading engagement and enrichment activities, which boosts students' educational attainment. Other factors that influence high academic outcomes include maternal education, maternal supportiveness, and

literacy stimulation (Mistry *et al.*, 2008). Therefore, socialization processes in the family influence academic disparities of foreign students.

Yamamoto, Liu and Liu (2016) also prove that low-income parents offer less stressful environment, which is a factor that correlates with academic success. Increased parenting stress negatively influences child development through early exposure to parental maladaptive behaviors (Ritchie *et al.*, 2009; Zajicek-Farber, Mayer and Daughtery, 2012) and through being brought up in a stressful environment (Kendler and Prescott, 2006; Timko, Cronkite and Moos, 2010). In fact, stress is a factor that exerts negative impact on mental health and well-being. Immigrants face numerous stressors upon arrival to the target country, including discrimination (Żakowska and Domalewska, 2019), language barrier, loss of social support, isolation, and culture shock.

Conclusions, Research Recommendations and Practical Implications

The study aimed to contribute towards the understanding of successful integration of immigrant students at schools, which can be observed when students feel empowered to develop socially, emotionally and cognitively. Therefore, academic excellence is one of the factors that indicate successful integration. Two dependent variables were analyzed to explain immigrant integration at schools: safety in the classroom and integration policies. The results of the study indicate that the migratory background does not determine the academic success of students as in many countries (such as Singapore, Canada, Japan, and Hong Kong) foreign students attain educational success at a level comparable to non-immigrants. Immigrant families face economic and sociodemographic challenges similar to other disadvantaged groups. Additional obstacles that impede integration include informational gaps, language and cultural barriers. These barriers should be addressed to implement policy options in order to help migrants overcome them. Therefore, policy interventions should aim at providing language, social and emotional support.

Safety in the classroom facilitates students' social, emotional and cognitive development. When students study in a safe environment, they can tackle challenging issues, discuss conflicting ideas and deal with tension and difficulties they experience on everyday basis. As minority students are frequently targeted by bullying, have low peer status and are marginalized, creating safe spaces offers a buffer zone that is necessary to help students deal with negativity. Another factor that correlates with the educational attainment of immigrant students is strict immigration policies because they foster the integration of migrants. Restrictive immigration policies favor immigrant families with high educational and occupational status as well as ambitious family background, which ensures that immigrant students enjoy familial support and are eager to succeed academically. However, immigration policies should be accompanied by effective social, economic and cultural integration.

In increasingly diverse schools, education should be based on multiculturalism because students need to internalize knowledge, attitudes and skills necessary to participate successfully in a pluralistic society. Culturally responsive curriculum should be promoted. Teachers need to adapt classroom practice to the changing needs of students. Furthermore, teacher education programmes need to effectively prepare preservice teachers to handle increasingly diverse schools. Teachers need to acquire different strategies to empower disadvantaged and immigrant students and help them feel safe in the classroom. Effective strategies include culturally responsive teaching, establishing a bond with students, and creating caring and safe communities. New technologies offer a variety of didactic tools that can be easily implemented in the classroom to provide a safe learning environment for students (Gawlik-Kobylińska and Maciejewski, 2019).

Finally, given shifting immigration trends and demographics, coordinated integration policies that support newly-arrived immigrants need to be implemented. School helps to overcome the obstacles immigrant students face; therefore, it facilitates immigrant integration. However, further research is needed to point at the correlation between integration policy and specific educational outcomes across countries.

[i] International migrant stock rose from 18,1% in 2000 to 30% in 2016 (Yang, Yang , Zhan, 2017). Most migrants come from Malaysia, China, Hong Kong, Macau and South Asian countries. In 2010 immigrants constituted 34,7% of Singapore's labor force. They either get high-paying jobs in e.g. high-tech industries or fill low-skilled ends of the labor spectrum doing jobs that Singaporeans are reluctant to take up such as in the construction, manufacturing, domestic labor, or marine industries. The latter group of migrants remain a transient workforce managed through strict policies of the work-permit system, the dependency ceiling regulating the number of migrant employees in the company and the foreign-worker levy. When the foreign-born worker's employment relationship terminates, the work permit expires and the migrant has to leave Singapore within 7 days (Yeoh and Lin, 2012).

Multivariate Analysis and Modeling of Sources and Financing Structure of Innovative Enterprises in The Russian Regions

Abstract

The identification of the innovative growth determinants, as factors affecting the innovative activities performance at the regional, level and the assessment of the impact of the structure and sources of funding on the effectiveness of innovative development in the region are one of the relevant research areas in the context of the countries' strategy of innovative development. The article presents the tools, models and findings of multivariate analysis and modeling of the influence of sources and structure of financing of innovations on manufacturing innovative goods in 80 Russian regions. Based on the various mathematical models of regression analysis - the least-squares, least modules and minimax criteria - the structural changes in the sources of funding innovative enterprises were assessed in two groups of Russian regions - in leading regions and in regions with an average share of innovative goods in GRP for the period 2011-2017. It was inferred about the stronger effect of the equity of innovative enterprises on the volume of innovative goods related to the spatial specificity of regional capital markets and the lack of an effective mechanism for capital spillover on them, insufficiently effective financial mechanisms and high risks of innovation investment. Strong regions conduct innovative activities based on their own investment resources. Regions with a mean level of innovation development increase the ratio of funds raised from the business sector, but this is not enough to become a leader. There are identified the directions for the development of instruments and mechanisms of innovation financing.

Keywords: Innovation Financing Sources, Region, Economic Modeling, Minimax.

Introduction

At the current stage of development, public policy, regions and enterprises in all advanced countries of the world focus on fostering innovations. One of the most important components of the innovation development strategy is to increase innovative activity and expand the range and forms of sources of innovative activity financing.

The problem of identifying the determinants for innovative growth, analyzing innovations financing sources and assessing the impact of their structure on the effectiveness of innovative development in the region is one of the relevant areas of research in this field.

The aim of the study is to analyze the current state and dynamics of innovations financing sources in Russian regions from 2011 to 2017, as well as to design mathematical tools for assessing "noisy" data on financing innovative enterprises and innovative development of the regions.

The object of the study is the assessment of structural changes in the sources of financing of innovative enterprises in the Russian regions from 2011 to 2017 in order to determine the dominant sources and the direction of their development.

To solve the set problems the study went through the following stages:

- assessment of the dynamic series of socio-economic indicators in the regions to characterize the structure and dynamics of innovative regions financing in the Russian Federation and the grouping of Russian regions into three homogeneous groups in decreasing order of innovative goods in GRP;
- selection of research tools, the testing of relevant use of various mathematical models of regression analysis - least squares, least modules and minimax criteria - for the development of mathematical tools for assessing the dynamic series of socio-economic indicators;
- determination of the presence and nature of the influence of innovative activities financing the structure and volumes on the dynamics of the innovative products production in regional economies, modeling of the correlation among indicators and the assessment of influence of financing sources on the results of innovative activities using methods of economic and mathematical tools in each group of regions;
- identification of directions of the financing sources for innovation development, elaboration of measures to improve the efficiency of the enterprises' innovative capital structure in the context of regional economies.

The study applies a minimax approach based on a problem generalization by P. Chebyshev, which is improved for its application to two-factor dependencies. Computational experiments were performed to evaluate the economic and statistical dependencies in the innovation sphere, and regression parameters were evaluated in the "production and innovation function" model within two groups of regions. Elements of the novelty and scientific significance of the study consist in the elaboration of approaches to assessing the effectiveness of regional innovative development using the minimax criterion and in posing the problem of studying the interconnections of the financial structure of innovative capital, economic growth and determining the degree of influence of financing sources on it.

Theoretical Framework

Problem of innovation financing

The problems of developing sources of financing innovation are relevant and characteristic of all countries. The success of innovations as one of the main conditions for economic growth is largely determined by their financial support and investments (Davidson, Mariev & Pushkarev, 2018). In advanced countries, the bulk of R&D funds come from the private business sector and industrial companies (Firsova, Novoselova & Vavilina, 2018). The experience of advanced economies indicates that the leaders in R&D are those countries where the demand for innovation from the private sector of the economy is high, and this is the driver of an innovative economy (fig. 1).

Fig. 2: R&D cost structure by source of funding by country
Compiled by the authors based on data from Rosstat (Rosstat, 2019)

The most significant part of the private sector is in R&D financing in countries that hold leading positions in international competitiveness ratings: USA, Sweden, Finland, Japan (66 - 75%), EU, Belgium, Germany, France (55 - 60%). The share of public funds in domestic spending on R&D in the EU countries is 33%, the United States - 28%, China - 25% (Kang, Baek & Lee, 2017).

In Russia, public funds are the main source of innovation financing. The figures presented in fig. 2 differ from most developed economies (fig. 2),

Fig. 2: Structure of domestic R&D costs by sources of financing according to Federal Districts of Russian Federation, 2011- 2017
Compiled by the authors based on data from Rosstat (Rosstat, 2019)

Despite a twofold increase in the funds invested into innovation by the state over the past 20 years with respect to GDP, the imbalance between public and private resources in financing innovation remains an urgent problem. In 2018, government sources investments into R&D accounted for 67% of total gross domestic spending on innovation, essentially replacing the funds of private and corporate investors in innovation processes (Firsova, 2017). The lack of own financial resources

aimed at innovation and the inaccessibility of external sources for innovative companies, in most cases, leads to a low rate of innovative activity and low efficiency of economic entities. Such a structure of innovation financing sources cannot provide opportunities for structural shifts in the economy and modification in the technological structure in Russia. Regional disparity strengthens the processes of concentration of innovative financial resources in the leading regions, pushing them from economically weak regions of the periphery.

Obviously, to increase the R&D financing level, it is needed a detailed analysis of the sources composition and innovation financing structure in dynamics in terms of assessing the effectiveness of their financing mechanisms. This explains the significance of the sources analysis in the structure of R&D financing and investment processes in order to determine the directions for the development of public incentive policies

Since public funds are the dominant source of financing innovation in Russia, in this study we determine the significance and rate of the influence of two other components of innovation financing sources: own funds of innovative enterprises and funds of the enterprise sector on the key indicator of the innovative development in the region - the volume of innovative products.

While examining dynamic processes in the economy, a cause-and-effect analysis of events applying mathematical methods of economic and statistical modeling is relevant to study the properties of the objects in question, to quantify the time series indicators (Korolev, 2011; Podinovski, Potapov, 2013; Akopov, Beklrayan, 2004).

Literature Review

Time series in economics and finance are analyzed is the works by G.E.P. Box, Taleb, A. Gorshenin, R. Nizhegorodtcev and other researchers who today widely use economic-mathematical and statistical methods (ARIMA, ARMA, GARCH, spectral analysis, neural networks, wavelet analysis) to solve these problems (Box, Jenkins, 1970; Taleb, 2007; Gorshenin, 2017; Nizhegorodtsev et al. 2017). The development of the apparatus for assessing statistical dependencies in the economy is studied in the different works (Granger, 1980; Seo, 2000; Demyanov, Malozemov, 1972; Sidorov, Faizliev, Balash & Korobov, 2016). Classical approaches to evaluating innovative regional growth on the basis of a regression approach were developed by Z. Griliches, F. Jaffe et al. (Griliches, 1979; Jaffe, 1989).

For the econometric measurement of the influence of factors on the outcome of innovation, the relationship between regional factors and regional innovation development is studied empirically. Based on the works by M. Feldman and R. Florida, they are described by a logarithmic linear dependence using a neoclassical production function of the Cobb-Douglas type, which is transformed into a modern production-innovation function, which consists in the fact that a regional innovative "output" is created from a number of factors which multiplicatively join (Feldman, Florida, 1994; Cobb, Douglas, 1928).

1. Existing methods of analysis usually require a sufficiently large sample of source data, which is not always available, especially when the modeled indicator depends on several variables (Shapchits, 2012). They underestimate the possibility of key events occurring, smooth out extremely rare events that create high heterogeneity in the initial time series, and pass noise data that misrepresent the distribution pattern of the indicator in question. The consideration of several factors and the "noisiness" of the initial data led to the choice of models and a multivariate approach to the analysis of the structure of innovation financing. The traditional apparatus, based on minimizing the sum of the squared approximation errors, in many cases makes it possible to obtain a qualitative model, but with significant differentiation, minimax methods have proved to be effective, the idea of using which to estimate the parameters of regression dependencies belongs to Petr Chebyshev. The use of minimax methods in an innovative economy is underdeveloped, that is why the research in this direction is topical. t is advisable to supplement the analysis with the minimax criterion (Vygodchikova, 2015; Vygodchikova, 2017), which was used in this study to increase the reliability

of the modeling results.

Research Methodology

Variables Description

To analyze the sources of innovative activities financing at the regional level, an analysis of the financing structure for 2011-2017 was implemented; and the following indicators were analyzed:
Y (IPV) - Innovation Product Volume;
X1 (IE) - Own Funds of Innovative Enterprise;
X2 (BS) -Business Enterprise Sector.
As the assessment of the correlation matrix according to regional statistics for the period under examination showed, these indicators most significantly affect the volume of innovative goods in the regions.

Data and Methods

To construct models, qualitative models of the production and innovation function were built in two groups of active in innovation and middle groups of Russian regions.

The authors proceeded from the assumption that if the models constructed by various methods are close in coefficients, this confirms that the sample turned out to be homogeneous enough to reliably predict the behavior of the output parameter (Y) depending on the input (X1, X2), and it can be used in the analysis and modeling. In this study of the funding sources structure, we use a multivariate analysis: firstly, it was necessary to take into account correlations in the sample of indicators, which allowed us to obtain a meaningful model and a reliable forecast, and secondly, to confirm or refute the result by a separate analysis and minimax criterion.

To analyze the sources of financing structure for innovative activities at the regional level, an analysis of data on financing domestic expenditures for research and development in 80 regions of the Russian Federation for 2011-2017 was conducted (CSRS, 2016). The data are not available in official statistics and were collected in a special way according to the annual reports of the statistical research institute “CSRS” in the context of regions for 2011-2017.

The Russian regions were grouped into three homogeneous groups in decreasing order of innovative goods in GRP (see Table 1) and then the analysis was carried out separately for two groups (Rosstat, 2019):

Table 1: Grouping of regions by the share of innovative goods in GRP, %

1 group: leading regions	Share in GRP, %	2 group: regions with an average share of innovative goods in GRP	Share in GRP, %	3 group: regions with a small share of innovative goods in GRP	Share in GRP, %
Republic of Mordovia	27,5	Kostroma Region	9,9	Jewish Region	2,0

Production-Innovation Function Model

Let $\{X_1^0 < \ldots < X_1^N\}$ – be the volumes of own funds of innovative enterprises, $\{X_2^0 < \ldots < X_2^N\}$ – the volumes of funds from the enterprise sector (mainly sources of money borrowed), and Y the volume of innovative goods in the region.

Dependence in the form of a model of the "production and innovation function" (PIF), that is, the dependence of the volume of innovative goods produced on own and borrowed financing can be represented as:

$$Y = AX_1^{a_1} X_2^{a_2}, \quad (1)$$

The coefficients of the model serve as parameters of elasticity Y by X and show approximately how many percent the indicator Y changes with one percent change in the indicator X1 (X2). Therefore, when constructing a model, it is necessary to focus on the analysis of the quality of the obtained dependencies; the center here is the adequacy of the constructed model to the described object.

Since the scale and units of measurement of different indicators for regions are different, the linear scaling method for each regional indicator is used and its normalized analogue is recalculated (Awrejcewicz et al., 2015).

$$\hat{X} = \frac{X - X_{\min}}{X_{\max} - X_{\min}} + 1,$$

where X is the actual value of the indicator for this group of regions, the minimum and maximum are taken for the same indicator among all regions of this group. Thus, the minimum value of this

indicator is one, the maximum is two (for finding a logarithm, a scale from one to two is more relevant than from 0 to 1).

To obtain the model parameters, the logarithm of initial data is taken; an estimated model is obtained (2).

$$\ln Y = a_0 + a_1 \ln X_1 + a_2 \ln X_2 , \quad (2)$$

Estimates of the model coefficients (2) are based on the criterion of the least squares method (5). However, if there is a clear dependence between the factors, which are various sources of financing, the application of the method of the least squares criterion can lead to a distortion of the model coefficients. Therefore, it is necessary to apply more stable criteria to the initial data perturbation. This will confirm the stability of the model coefficients when changing the approximation method, and justify the quality of the conclusions obtained as a result of modeling.

The article also applies the minimax criterion (6) and the criterion of the least modules method (7) for an alternative assessment of the influence of the factors on the effective indicator. The model quality is tested through standard methods of regression analysis, as well as using new estimates obtained from achieved additional approximation criteria (maximum approximation error, the sum of the absolute approximation errors).

Estimates of the model coefficients (2) are based on the criterion of the least squares method (3), the criterion of the least modulus method (4) or the minimax criterion (5); and then the multiplicative dependence (1) is constructed.

$$\sum_{k=0}^{N} \left(Y_k - a_0 - a_1 X_1{}^k - a_2 X_2{}^k \right)^2 \longrightarrow \min_{A=(a_0,a_1,a_2)\in R^3} , \quad (3)$$

$$\sum_{k=0}^{N} \left| Y_k - a_0 - a_1 X_1{}^k - a_2 X_2{}^k \right| \longrightarrow \min_{A=(a_0,a_1,a_2)\in R^3} , \quad (4)$$

$$\max_{k\in \overline{0,N}} \left| Y_k - a_0 - a_1 X_1{}^k - a_2 X_2{}^k \right| \longrightarrow \min_{A=(a_0,a_1,a_2)\in R^3} . \quad (5)$$

With a strong correlation dependence between the explicative variables in the model (multicollinearity of input variables), it is advisable to conduct a separate analysis for each variable. For example, for the first variable X1, the method is as follows. The model is analyzed:

$$Y = A X_1{}^{a_1} , \quad (6)$$

To obtain the model parameters, the logarithm of initial data is taken:

$$\ln Y = a_0 + a_1 \ln X_1 . \quad (7)$$

The following models are considered: least squares (8), least modules (9) and minimax (10).

$$\sum_{k=0}^{N} \left(Y_k - a_0 - a_1 X_1{}^k \right)^2 \longrightarrow \min_{A=(a_0,a_1)\in R^2} , \quad (8)$$

$$\sum_{k=0}^{N} \left| Y_k - a_0 - a_1 X_1{}^k \right| \longrightarrow \min_{A=(a_0,a_1)\in R^2} , \quad (9)$$

$$\max_{k\in \overline{0,N}} \left| Y_k - a_0 - a_1 X_1{}^k \right| \longrightarrow \min_{A=(a_0,a_1)\in R^2} . \quad (10)$$

All procedures are repeated for the second variable X2.

Modeling Quality Indicators

When analyzing noisy data, the use of standard quality criteria, such as the sum of the squared approximation errors, the standard deviation of the indicator from the average, the coefficient of variation, does not always lead to reliable estimates of the constructed model adequacy. For example, in a two-variable model obtained on the basis of the least squares method, a significant model (regression equation) can be obtained, but the coefficients of individual variables may turn out to be low-significant. Therefore, conclusions about the influence of variables (model factors) on the final indicator (volume of innovative products) may not be reliable; the coefficient may turn out to be negative. However, it is obvious that an increase in resources cannot lead to a decrease in output. Hypersaturation with innovative capital, in principle, is not possible, therefore, only the presence of multicollinearity (strong dependence) between the factors of the model, which is not always possible to diagnose in a small sample, can interfere. Therefore, alternative methods need to be applied: robust estimates, separate analysis, the criterion of the minimum maximum approximation error, combining robust noise immunity and approximative model quality.

Therefore, along with the traditional indicator (the sum of the squared approximation errors, the sum of the error modules), the following two indicators are used in this study: the maximum approximation error and the sum of the absolute approximation errors for model (1) (the errors are analyzed for the output function obtained by exposing the model (2)) (Awrejcewicz et al., 2015). The last indicator shows the high quality of the minimax model when working with heterogeneous and very noisy data on the structure of innovations in the second group of regions.

To assess the quality of the models, standard statistical indicators are used (the significance of the regression equation according to the Fisher criterion, the significance of the regression coefficients according to the Student criterion), as well as the average and maximum approximation errors according to the obtained multiplicative dependences (Seo, 2000).

In the course of the study, for a comparative analysis of the structural differences in the sources of financing innovation in dynamics, we sequentially evaluated the coefficients for the three developed models (3), (4) and (5) based on the data on the structure of financing sources separately in two groups of Russian regions - in the regions- leaders and in regions with an average share of innovative goods in GRP for the two periods of 2011 and 2017. The third group of regions with a low share of innovative goods was not studied.

To justify the adequacy and feasibility of including variables in the model, normalization of primary quantitative data was carried out and a correlation analysis was performed in the Gretl.

Results

The following modeling results were obtained.

Analysis of the impact of funding sources in the first group of leading regions with a high share of innovative products in GRP

In 2011, own funds are of fundamental and important importance, despite their low amount, it is they that lead to a significant increase in the volume of innovative goods. A model based on the least squares (LSM) criteria (3) and least modules (4) with two variables is not highly significant (Table 1):

Table 1: Model 1- LSM, observations 1-19, dependent variable Y (IPV)

	Coefficient	*Std. error*	*t- statistics*	*P- value*	
const	0,110365	0,0527681	2,0915	0,05279	*
X1 (IE)	1,15477	0,56004	2,0619	0,05584	*
X2 (BS)	-0,306315	0,525166	-0,5833	0,56784	

Mean depended var	0,206359		S.D. depended var	0,229148
Sum squared resid	0,543817		S.E. of regression	0,184360
R- square	0,424628		Adjusted R- square	0,352707
F(2, 16)	5,904058		P- value (F)	0,012011
Log-likelihood	6,799197		Akaike criterion	-7,598393
Schwartz Criterion	-4,765076		Hannan–Quinn	-7,118883

When using the model with two variables, the coefficient at X2 turns out to be negative, which may be due to multicollinearity between X1 and X2.

Table 2: Model 2- Method of least modules, observations 1-19, dependent variable Y (IPV)

	Coefficient	*Std. error*	*t- statistics*	*P- value*	
const	0,0370375	0,0382719	0,9677	0,34757	
X1 (IE)	0,86874	1,33655	0,6500	0,52492	
X2 (BS)	0,130292	1,0393	0,1254	0,90180	

Median dependent var	0,116577		S.D. depended var	0,229148
Sum of error modules	1,995670		Sum squared resid	0,623684
Log-likelihood	10,64593		Akaike criterion	-15,29185
Schwartz Criterion	-12,45853		Hannan–Quinn	-14,81234

It should be noted that the method of least modules showed the less importance of the model and coefficients; however, the influence of companies' own funds on the volume of innovative goods is obvious and undeniable; the coefficient of 0.87 in the first variable is close to one, as in the previous model (LSM, model 1).

Therefore, an additional instrumental base was applied to obtain results, namely: a separate analysis for each variable and a minimax criterion for approximating the model parameters (minimum maximum approximation error). When applying separate analysis, the best result, in terms of regression statistics, was obtained according for model (8) (model 3, presented below).

Table 3: Model 3- LSM, observations 1-19, dependent variable Y (IPV)

	Coefficient	***Std. error***	***t- statistics***	***P- value***	
const	0,104698	0,0508495	2,0590	0,05516	*
X1 (IE)	0,863982	0,250131	3,4541	0,00303	***

Mean depended var	0,206359		S.D. depended var	0,229148
Sum squared resid	0,555380		S.E. of regression	0,180747
R- square	0,412394		Adjusted R- square	0,377829

F(1, 17)	11,93097		P- value (F)	0,003031
Log-likelihood	6,599317		Akaike criterion	-9,198633
Schwartz Criterion	-7,309755		Hannan–Quinn	-8,878960

Since exp (0.1047)≈1.11, we get the model:

$$Y = 1.11 X_1^{0.86}.$$

The model is significant and relevant in terms of regression statistics. Interpretation of the model with regard to the elasticity indicator: with a 1% increase in the equity of enterprises, ITI increases by about 0.86%.

A model based on the minimax criterion (5) (the minimax criterion allows one to get rid of multicollinearity without separate analysis); the parameters are calculated by the method from [22], and has the form:

$$Y = 1.33 X_1^{0.52} X_2^{0.08}.$$

The model is quite reliable, as evidenced by low approximation errors, that are lower than when using separate analysis by least squares analysis.

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.52%. With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.08%.

The resulting models show a high impact of own funds on the production of innovative goods in the group of leading regions, which is under examination.

The results of errors calculation show that, each of the criteria is "in the zone of influence" of reliability, errors by minimax are much lower than by the least squares criterion (Fig. 4).

Fig. 4: Group of Leading Regions, 2011

In 2017, own funds have an even more important influence on the volume of innovative goods, namely they lead to a significant increase in the volume of innovative goods.

Performing an analysis similar to the above one for 2011, we obtain high quality one-factor model (8), as evidenced by regression statistics (model 4).

Table 4: Model 4- LSM, observations 1-19, dependent variable Y (IPV)

	Coefficient	*Std. error*	*t- statistics*	*P- value*	
const	0,110612	0,0440536	2,5108	0,02244	**
X1 (IE)	0,85106	0,205178	4,1479	0,00067	***

Mean depended var	0,228257		S.D. depended var	0,202549
Sum squared resid	0,367021		S.E. of regression	0,146934
R- square	0,502999		Adjusted R- square	0,473764
F(1, 17)	17,20518		P- value (F)	0,000673
Log-likelihood	10,53452		Akaike criterion	-17,06904
Schwartz Criterion	-15,18016		Hannan–Quinn	-16,74937

Since exp (0.11) ≈1.12, we obtain a model based on the least squares criterion:

$$Y = 1.12 X_1^{0.85},$$

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.85%.

Model based on minimax criteria:

$$Y = 1.2 X_1^{0.96} X_2^{0.06}.$$

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.96%. With a 1% increase in the enterprise sector funds, volume of innovative goods increases by about 0.06%.

Both models demonstrate a high impact of equity on the output of innovative products, the estimation of approximation errors shows the absence of sharp contradictions and the high quality of each of the obtained models (Fig. 5).

Fig. 5: Group of Leading Regions, 2017

Thus, in group 1 of the leading regions of innovation development, own funds steadily and stably affected the growth in the volume of innovative goods, both in 2011 and in 2017, funds of the business sector have a lesser effect on the indicator under study. The criteria of minimax and least squares allow obtaining high-quality models, the criterion of least modules has high errors and its use is not advisable. Therefore, we further use the least squares method and the minimax method.

Analysis of the impact of funding sources in the second group of leading regions with an average share of innovative products in GRP

In 2011, a high-quality solution for all coefficients (according to regression statistics) is provided by a model based on the least squares criterion:

$$Y = X_1^{0.7} X_2^{0.3}.$$

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.7%. With a 1% increase in the enterprise sector funds, volume of innovative goods increases by about 0.3%.

A good justification of the above conclusion is the obtained regression statistics (coefficients are significant, the model is relevant) (model 5).

Table 5: Model 5- LSM, observations 1-34, dependent variable Y (IPV)

	Coefficient	*Std. error*	*t- statistics*	*P- value*	
const	0,0545878	0,012386	4,4072	0,00012	***
X1 (IE)	0,688815	0,129998	5,2986	<0,00001	***
X2 (BS)	0,29943	0,174426	1,7167	0,09602	*

Mean depended var	0,108586		S.D. depended var	0,156202
Sum squared resid	0,140472		S.E. of regression	0,067315
R- square	0,825538		Adjusted R- square	0,814283
F(2, 31)	73,34464		P- value (F)	1,76e-12
Log-likelihood	45,07095		Akaike criterion	-84,14191
Schwartz Criterion	-79,56282		Hannan–Quinn	-82,58031

For 2011, a model based on the minimax criteria has the form:

$$Y = X_1^{0.37} X_2^{0.25}.$$

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.37%. With a 1% increase in the enterprise sector funds, volume of innovative goods increases by about 0.25%. The influence of both factors is quite strong, own funds affect greater.
For 2017, a model based on the minimax criterion is more reliable, due to a significant reduction in approximation errors (Fig. 6):

$$Y = 1.19 X_1^{0.8} X_2^{0.07}.$$

With a 1% increase in the enterprises' own funds, volume of innovative goods increases by about 0.8%. With a 1% increase in the enterprise sector funds, volume of innovative goods increases by about 0.07%.
The LSM-based model for 2017 has the following form (the significance of the coefficient at X1 (own funds ratio) is too low to provide a high-quality model), approximation errors are quite large:

$$Y = 1.19 X_1^{0.3} X_2^{0.6}.$$

Fig. 6: Group of regions with an average level of innovation share in GRP, 2017

In the second group of regions, own funds and funds of the enterprise sector have a significant impact on the volume of innovative goods, while the influence on own funds have a stronger effect.

The influence of the criteria of mathematical models of the criteria of least squares, least modules and minimax on the results of the analysis of the influence of financing sources on the production of innovative goods, operations and services of innovative enterprises is presented in Table 6.

Table 6: Results - the influence of the criteria of mathematical models on the results of analysis

Methods	The influence of innovation financing sources on the volume of innovative goods Y (IPV):	Period	Coefficient value
Regions with a high level of innovation share in GRP			
LSM	X1 (own funds of innovative enterprises)	2011	0.86*
		2017	0.85*
Minimax	X1 (own funds of innovative enterprises)	2011	0.52
		2017	0.96*
	X2 (business enterprise sector funds)	2011	0.08*
		2017	0.06
Regions with an average level of innovation share in GRP			
LSM	X1 (own funds of innovative enterprises)	2011	0.70
		2017	0.30
	X2 (business enterprise sector funds)	2011	0.30
		2017	0.60
Minimax	X1 (own funds of innovative enterprises)	2011	0.37
		2017	0.80*
	X2 (business enterprise sector funds)	2011	0.25
		2017	0.07

Conclusion

The article presents a set of tools for multivariate analysis and modeling of sources and structure of financing innovative activities in the regions of Russia. There were built models of the funding sources influence on the production of innovative goods, operations and services of innovative enterprises in two groups in 80 Russian regions. Based on the application of various mathematical models of regression analysis: least squares, least modules and minimax criteria, an assessment was made of structural changes in the sources of innovative enterprises financing in Russian regions for the period 2011-2017.

In the field of developing mathematical methods, it should be noted that the estimation of approximation errors shows the absence of sharp contradictions and the high quality of every obtained model. As for choosing a modeling method, the criteria of minimax and least squares allow obtaining high-quality models, the criterion of least modules has high errors and its use is not advisable. Model evaluation results show that, of all the models under consideration, the more relevant one was obtained using the minimax criterion.

In terms of economic results, the obtained models show a significant impact of own funds on the volume of innovative products in the leading regions with a high level of innovation share in GRP. From 2011 to 2017, the influence of own sources on the volume of innovative products increased significantly and amounted to 0.96%, with a 1% growth in own funds in the structure of internal costs for research and development. The impact of business enterprise sector funds has changed slightly and remains very low. This conclusion allowed us to draw a model on the basis of the minimax criterion.

In the second group of regions with an average share of innovations in GRP from 2011 to 2017, the influence of own sources on the volume of innovative goods also increased and amounted to 0.8% with a 1% growth in own funds in the structure of R&D expenditures. The impact of business enterprise sector funds in financing innovations is weaker due to their low share in the total volume of funding sources decreased during the study period in the first group of regions from 0.08 to 0.06%, and in the second group of regions decreased from 0.25 to 0.07 % with 1% net growth in borrowed funds in the structure of R&D expenditures.

According to the criterion of the least squares method, during the analyzed period, the influence of business enterprise sector funds on the volume of innovative goods increased, which is a positive trend in the context of the need to attract long-term credit resources to invest in innovation. To confirm the conclusion about a higher effect of own funds on the volume of innovative products, the minimax criterion was used as an alternative criterion; it still confirms the high influence of own funds.

Thus, computational experiments showed a noticeable increase in the influence of own funds of innovative enterprises in both groups of regions. In the group of regions with an average share of the of innovative goods volume, the obtained models show a significant impact of companies' own funds, and a moderate increase in the impact of funds from the business sector (where significant resources are represented by credit resources of banks and similar financial institutions) on the volume of innovative goods. At the same time, their own funds still exert a stronger influence on the volume of innovative goods. We attribute this result to the specifics of regional capital markets and the lack of an effective mechanism for capital spillover, insufficiently effective mechanisms and high risks of investing innovations. Thus, strong regions conduct innovative activities based on their own investment resources. Regions with a mean innovation development in 2011-2017 increased the ratio of funds raised from the business sector, but this is not enough to become a leader.

These results provide further insight into the mechanisms for financing innovation in the Russian regions, the specific features of the innovative capital formation and the factors affecting the results of innovation at the regional level and contribute to the deepening of knowledge system on the structure and processes of financing innovation and regional development.

The main recommendation based on this analysis is to increase the financing of enterprises in the second group of regions. Therefore, it is important today to create mechanisms for investing in innovative activities that can overcome the asymmetry of innovative investment processes. We need new tools in the financial market that can eliminate risks and attract "long-term money" in the field of innovation.

It is extremely important at present to elaborate tools and mechanisms for financing innovation with private funds and promote innovation environment by expanding the interaction of private capital and

public sector, and it is also important to develop public policies based on data from an analysis of the Russian regional specifics aimed at supporting innovation.

Based on the analysis, it is possible to recommend directions for the development of sources of innovation financing in the Russian regions: development of reliable long-term investment instruments of the stock market as a source of financing for innovative projects; development of small innovative enterprises, venture capital and business angels, finances and private investment; creating incentives for investing private capital in innovation.

Acknowledgments

Abstract

Digital innovations affect company performance and results by changing business models, expanding markets, and attracting new customers. At the same time, an active role is played by the impact on the modernization of production processes at all stages of the product life cycle and the emergence of new business lines. Companies are concerned about the need to improve their competitiveness and strengthen their positions in the market based on innovation and the introduction of digital production. At the same time, internal effects are associated with improving various aspects of the company's life and its economic performance. External effects affect customer relationships, competitiveness, and the company's position in the market. Of particular interest for this purpose are sustainability studies, which provide a viable research model for evaluating and confirming the potential impact of digitalization elements on economic, environmental, and social sustainability. Thus, digitalization of processes in the enterprise can be considered as a kind of green IT-focused on digital transformation and sustainable business models.

Keywords: Digital innovation, sustainable, economic indicators, digital transformation, economic performance, costs.

Introduction

Digitalization causes a shift in the production paradigm and affects the activities of companies from different aspects. In the digitalization trend, innovative systems and management face new challenges. Digitalization refers to the use of digital technologies to change the business model and provide new opportunities for generating revenue and creating value. Digitization is the process of moving from an analog form to a digital form. Digitalization processes accelerate the need for innovation and accelerate the process of innovation implementation.

Worldwide, large companies embrace digital transformation through digital innovation. Digital innovation, that is, new combinations of digital and physical components for the production of new products (Yoo, Y., Boland, R. J. Jr., Lyytinen, K., & Majchrzak, A. (2012)), allow companies to strengthen their competitive advantages by differentiating from competitors. The introduction of digital manufacturing technologies involves the introduction of digital technologies in order to create value and improve the efficiency of the organization. Thus, the study of the impact of digital innovation on the economic performance of companies will be relevant.

Digital transformation leads to transformation of production, as well as a positive impact on the reputation of the company (Anderson, C. (2014)).

Organizations use digital technologies for establishing new products and services, to implement new business processes, or to operate new business models (Legner, C., Eymann, T., et al. (2017)).

Digital innovation can act as the core and represent the central element of digital transformation, and is a domain where the use of digital technology is manifested in organizations. In addition, we know that the implementation and implementation of digital innovation will not happen automatically, but requires a thoughtful approach that allows them to translate digital technology into digital innovation (Kohli, R., & Melville, N. P. (2018)).

According to a number of authors, effective adoption of digital innovations can have three advantages: obtaining new customers and experience; modernization of operations; and the emergence of new business lines (Fitzgerald, Kruschwitz, Bonnet, & Welch).

Through automation, the companies with the most success in implementing digital technologies in customer service and operations according to Fitzgerald are distinguished by improved customer service.

On the consumer side, digital innovation has revolutionized the way consumers seek information, buy, consume, and share their experiences about goods and services. From a corporate perspective, digital innovation opens up new opportunities «to reach, inform, engage, sell, learn, and provide services to customers» (Lamberton, C., & Stephen, A. T. (2016)).

Digital innovation is changing business models in the industry (Zott, C., & Amit, R. (2017)), leading to lower costs, cost of production and expansion of markets. Contactless payments, for example, have revolutionized banking. In addition, thanks to digital innovations, a huge amount of customer data is collected.

Since the adoption of digital innovation is associated with a high level of uncertainty for potential customers, it is especially important to understand how consumers may not accept digital innovation. Kuester, S., Konya-Baumbach, E., & Schuhmacher, M. C. suggest that digital innovation should primarily signal reliability and usability.

Nambisan, S., Lyytinen, K., Majchrzak, A., & Song, M. indicate that digital innovation refers to the use of digital technology in the process of innovation in production. Many innovations are based on digital technologies that enhance the human ability to acquire, produce, distribute and consume information at an unprecedented level and value (Teece, D. J. (2018)). In addition, value creation for companies is increasingly carried out through the production of digital information. This is due to digital production (Schallmo, D., Williams, C. A., & Boardman, L. (2017)). Schultz, D. E., & Peltier, J. argues that for most companies, the challenge is not to develop and launch digital innovations, but to make them more attractive and useful to consumers. We understand that this can be achieved by finding new markets and reducing costs.

Formulation of the problem

The aim to introduce digital innovation in enterprises is to increase economic efficiency of enterprises and product quality, reduction of terms of creation and the start of production, optimizing the use of available resources of enterprises, the mobilization of the reserves of production capacity, competitiveness of products on world markets, formation of the modern business model of the enterprise.

Organizations must innovate to succeed over time. A rapidly growing part of innovation comes directly from the latest digitalization tools. Many resources and much attention are focused on further developing methods, processes, tools, etc. around digitization.

Results

The introduction of certain digital innovations can have a different impact on the performance of the enterprise. Table 1 shows the impact of digital innovations on the economic, and social indicators of the enterprise in the framework of assessing the sustainable development of the enterprise.

Table 1: Impact of digital innovation on enterprise performance

Digital innovation	Influence on economic indicators of the enterprise	Influence on environmental indicators of the enterprise	Influence on social indicators of the enterprise
Additive technologies	Improving the design and use of materials The quality of the products Risk minimization Reduce development and prototyping time Reduction of production costs (labor costs, operating time of technological equipment, electricity, materials) Reducing the cost of the product by reducing the costs of the company	Reducing the amount of water used from all water sources Reducing the volume of contaminated wastewater discharge to surface water bodies	Increase employee satisfaction with the work performed Creating jobs for people with disabilities in organizations Improving compliance with safety requirements
Rapid prototyping	Quality control Reduce product development and testing time Reducing the cost of goods	Reduction of mass emissions of pollutants into the air from stationary sources Reducing the amount of water used from all water sources Reducing the volume of contaminated wastewater discharge to surface water bodies	Increase employee satisfaction with the work performed Increase in employee training costs
Cloudy computing	Optimizing the use of computing resources Access to the skills and abilities of professionals Increase productivity, reduce costs for deployment and maintenance of it infrastructure Reduction of capital costs The decrease in expenses for purchase of software	Reducing greenhouse gas emissions Optimization of expenses for the protection of the environment	Improve customer experience Improving compliance with safety requirements Accelerate the introduction and deployment of applications
Big data	Operational monitoring of all systems and processes Analysis of unstructured data sets Expansion of markets Reduction of costs for repair and maintenance of facilities Improving the quality of processed data for decision making The reduction of production costs	Reduction of consumption of fuel and energy resources Optimization of expenses for the protection of the environment Reduction of mass emissions of pollutants into the air from stationary sources	The basis for the development of the Internet of things

Digital innovation	Influence on economic indicators of the enterprise	Influence on environmental indicators of the enterprise	Influence on social indicators of the enterprise
	The increase in profits due to emerging opportunities		
Internet of things	Automation of tracking and forecasting of complex systems and objects Full implementation of object and process control automation Increased productivity Cost optimization and reduction of maintenance and repair costs Savings of the wage Fund	Reducing the amount of water used from all water sources	Attracting new qualified employees Increase in employee training costs
Digital double	Application of new production technologies Reduce development and prototyping time Reducing the cost of designing, testing and upgrading of products Reduction and elimination of losses from marriage Reducing the cost of finished products	Reducing the amount of water used from all water sources Reducing the volume of contaminated wastewater discharge to surface water bodies	Reduce design and prototyping errors Increase in employee training costs

Conclusions

Internal effects are associated with the improvement of various aspects of the life of the company and its economic performance.

These include the following effects:

1. Reduction of internal costs.

2. Increased productivity.

3. Acceleration of business processes (production, sales, service, development, etc.).

4. Increase efficiency in decision-making.

5. Improve the manageability of the company.

6. Improving awareness about the operation of equipment, transport, products.

7. Increase employee satisfaction with the work performed.

8. Attracting new qualified employees.

External effects include those related to customer relationships, competitiveness, market position:

1. Increase in sales.

2. The growing number of customers.

3. Increasing customer satisfaction

4. Improve customer awareness of the company's products/ services.

5. Better understanding of customer needs.

6. The emergence of fundamentally new products and services.

7. Reducing the backlog of competitors.

Thus, the introduction of digital innovations allows you to develop much faster, cheaper and with a much smaller number of employees, significantly reduces the risks of increasing time and reduces development costs, allows to significantly reduce the amount of field testing, finally allows to dynamically and efficiently manage changes of target characteristics and to consider new constraints that arise during design, production or operation. Thus, digitalization of processes in the enterprise will have a significant potential impact on indicators of economic, environmental and social sustainability.

Abstract

The article discusses the use of chat-bots as the elements of artificial intelligence in companies' marketing activities, as their further development may become the basis for the implementation of the concept of relationship marketing in the digital economy. Opportunities and advantages of chat-bots in marketing are presented; examples of successful application of this marketing tool in the practice of Russian and international companies of various industries are investigated. The work pays attention to the main tendencies for solving marketing problems using chat-bots, it also identifies tools for introducing chat bots-into the marketing activities of the company. The analysis showed that using of a chat-bot results in a new level of partnership in interaction between the brand and the target client.

Keywords: Marketing, Artificial Intelligence, Chat-Bot, Marketing Communications, Target Audience.

Introduction

Artificial Intelligence (AI) technologies are actively developing and are widely used in companies' business practice. Chat-bots, Big Data, targeted and contextual advertising are the elements of Artificial Intelligence that have found certain application in modern marketing (Ivanchenko, 2019). The purpose of using AI is to combine customer data from different sources and then to use them for marketing campaigns, that is:

- to make marketing communications with customers automated;
- to make marketing more individual for each client in each channel at any given time;
- to improve the customer experience on the site and in mobile applications;
- to understand which marketing channels of communication with a client work better and why.

AI technologies have attracted widespread attention from both businesses and academic community (Faggella, (2019), Thiraviyam, (2018), IAB-Europe Artificial-Intelligence-Report (2018), 9 Applications Of Artificial Intelligence In Digital Marketing (2019). Marketers tend to use artificial intelligence to analyze huge amounts of data from various points of interaction with a client and form marketing solutions with the aim of:

- Building trust through personalized customer interactions.
- Increasing loyalty and maintaining interest in a product, brand, company.
- Applying creative approaches throughout the entire cycle of interaction with the client.

In the conditions of further development of the information and communication space, the competitive advantages can be ensured by improving the quality of personal relationships between the company and the target consumer (Evdokimov N.,2017). In this regard, the study of AI usage experience in companies' activity seems to be quite relevant.

Short Literature Review

"A bot is a program that interacts with a user's application through an API (application programming interface), receives data and requests from it, and converts them into useful information" (Rodionov, 2017). This program is controlled by specified algorithms or artificial intelligence, while the user interacts with this program using a dialog box.

Consumers are gradually changing informational noisy social networks for more personalized communication channels - messengers. In addition, consumers spend more and more time in mobile phones (Bondarenko, 2018). Today, messaging apps have over 5 billion active users monthly, and at the moment it is the first time when people use them more often than social networks. (Why Chatbots Are the Future of Marketing, 2019). Therefore, companies are transforming marketing channels in order to increase the effectiveness of interaction with the target audience. In this regard, chat-bots are turning into a really powerful marketing tool.

Big business, banks and state corporations have already adopted this new tool. For example, in banks modern chat-bots not only relieve the pressure on call centers and technical support, but also perform more serious functions. Without leaving the chat-bot, you can pay a loan, utility bills, transfer money, etc. According to statistics, instant messengers are very popular now, and even social networks no longer enjoy such attention (Bazhenov, 2019).

Chat-bots help companies to solve marketing problems. They are used to create an additional marketing channel for communication with the target audience, promoting products and attracting leads. Another aim is to automate communication, thereby increasing the customer service quality level as most of the routine operations and typical issues can be solved by the bot 24/7, and managers deal with atypical, difficult situations. Using chat-bots improves customer experience, increase engagement and audience loyalty " (Evdokimov, 2017).

Brands create this virtual assistant with a chat-bot builder, and connect it with messaging apps like Facebook Messenger, WhatsApp, Snapchat, etc., or add to their website. According to Sendpulse (What is Chatbot Marketing? 2019), Chatbot Marketing provides the following benefits to companies:

- It saves time and money.
- Helps to segment traffic.
- Provides a quick response.
- Speeds up the payment process.
- Fits any business.
- Boosts engagement.
- Gives data for analysis.
- Helps in lead nurturing.

The appearance and development of chat-bots helps to improve customer service and it reduces costs. Artificial intelligence advises online stores customers. The development and machine learning of chat-bots helps to reduce call center costs as well as site's technical support costs. Now, round-the-clock support for online stores and services has become possible thanks to programmed and self-learning bots that can answer frequently asked questions. Artificial intelligence collects data about the client: behavior on the site, his preferences, etc. In the future, AI uses this information to communicate with the client (Dmitrieva, 2018).

There are two types of bots (Zhestkov, 2017):

1. Limited. Those that respond to the minimum number of phrases and only in case the request matches exactly;
2. Self-developing. That is, an "artificial neural network", which, when talking with a client, self-learns and can capture the context of the conversation.

According to experts (Protsenko, 2018), chat-bots in the marketing activities of companies can:
• cheapen the lead with the help of a sales funnel;
• do any mailing to subscribers with openness up to 90%;
• conduct surveys, game quizzes and segment users in regard to their answers;
• help to purchase and pay in online stores;
• book any services: from a hotel and a doctor to a test drive of a car;
• integrate with site analytics and CRM systems;
• implement up- and cross-sales depending on behavior, interests and preferences of the user;
• provide support to users, saving budgets for call centers.

Thus, chat-bots answer users' popular questions, select the right product according to the parameters, help with online payments or notify the user about the status of the order. However, sometimes bots with more unusual functionality are used in marketing.

Research Hypothesis

Under the influence of Internet technologies and social media, consumers are currently becoming more demanding and less loyal to brands. In this regard, the primary goal of relationship marketing in the digital economy is to improve customer experience. The use of Artificial Intelligence helps marketers to solve the problem of ensuring the maximum possible personification of marketing solutions for the target consumer.

Key Research Findings

Practical examples of Russian and international companies

«VkusVill» chain of stores has developed a bot in Telegram to reduce the technical support load. VkusVill bot helps to search for nearby stores, see the remnants of the desired product in a particular store, find out about discounts and promotions, purchase without presenting a bonus card, check information about each product's features, see electronic bills, information about manufacturers, change "Favorite product" (daily personal subscription with a discount on one of any goods). Developing a bot in Telegram is cheaper and faster than developing a mobile application. All the process from the idea to the launching the campaign cost $ 4,600. With the help of the bot buyers can contact VkusVill employees. The company receives about four thousand calls per month. This feedback collection channel is the second place in popularity and first in quality and usefulness of feedback. VkusVill taught the bot minimal responses to customer messages, and then every week it receives a report on unrecognized messages and teaches the bot to recognize more complex messages. Automation of routine processes allows VkusVill to grow without increasing the number of office employees, which affects the effectiveness of the company (Kretsu, 2017).

One of the brightest examples of chat-bot marketing is that of Volvo Cars Amberg, a German car dealership. More and more potential car buyers visit dealership websites these days to research the prices, so the company introduced a chat-bot with an integrated Typeform survey into their marketing site that provides an instant, totally customized price quote based on visitors' input. The Volvo dealership's chatbot provides instant price quotes to website visitors.

Here's the impact the chatbot had on the dealership's bottom line, according to their marketing manager Tobias Wamser:"We were able to increase lead generation on our website by about 300%. We are also able to prioritize high-quality leads and offer them an even more personalized experience". Not only that, but leads coming through the Volvo dealership's chatbot are 200% more

likely to purchase a vehicle than those acquired via their contact form, since they're able to get immediate answers to their questions or book a test drive online (Weaver, 2019).

As a part of the advertising campaign of the Green Jam festival in 2016, the beverage producer Tuborg Russia launched the VOTVOSDAT bot in Telegram. The bot was promoted on the official pages of the festival on social networks (Nozhkina, 2019) (Fig. 1).

Note: "I want to win a prize in an advertising contest. Draw me and post me on Vkontakte or Instagram with a hashtag…".

Fig. 1: Tuborg Russia and the chat-bot "VOTVOSDAT"

The bot communicated with users, invited them to participate in various brand contests and activities, sent funny gifs and videos, informed the participants about the festival program. At the same time, it gathered a loyal audience around the Tuborg brand and attracted attention to the festival even among those who could not get to the event.

The Khrusteam cracker brand launched a detective bot in Viber in 2017 as a part of the "Guess the Secret Taste" campaign. Users had to guess the taste of the company's new product, and one of those who guessed could win £ 20,000. The bot explained the conditions of the contest, offered riddles, gave hints and promotional codes for receiving consolation prizes, and it also subscribed participants to the official Khrusteam group in the messenger (Nozhkina, 2019) (Fig. 2). Users got a post-call banner in a promotional chat. According to Khrusteam, as a result of the campaign, 92% of the brand's subscribers managed to communicate with the bot, each sending 4 messages in average.

Note: "Try to guess the secret taste and win the main prize of 20 thousand pounds"

Fig. 2: A detective bot by Khrusteam

The Matryosha bot was created specifically for the BalticWeekend 2016 forum. The bot in Telegram talked about speakers, the forum program, sent jokes and stickers, and gave useful advice to the participants of the event. Using the bot, you could tell visitors about the forum news online. The user could control the bot on his own, choosing in the convenient button menu what he wants to know. Using the chat bot, visitors could communicate with each other or with the organizers (Fig. 3).

Note: "Hi. I am Matryosha artificial intelligence BalticWeekend. I know all about the Forum program, speakers,

and our secret chat"

Fig. 3: The Matryosha Bot at the BalticWeekend PR Forum

The bot still exists, it was actively used at Baltic Weekend-2019 as well. A new approach to creating this bot was to create a communication channel by combining the bot (which replaces the paper program), the channel (which transmits information in one direction) and the chat (involving people in the community).

At the end of 2016 the cosmetics company Sephora introduced a Facebook Messenger bot, which helps customers to choose lipsticks from its own brand line. The user only needs to upload a photo, and the SephoraVirtualArtist bot will find the perfect shade of a lipstick, based on the color of the face and eyes analysis. And then it will inform the customer about the price of the lipstick and the nearest store it can be bought today (Fig. 4).

Fig. 4: Sephora and a product selection chat- bot

You could switch to the bot from the Sephora group on Facebook. In addition, a banner hung on the store's website urging visitors to try a stylist bot.

The Unilever brand launched a Facebook bot in October 2016 as a part of the Little Brush, Big Brush campaign, which told children tales about how important it is to brush their teeth. In total, the bot knew 21 stories (in the mini-cartoon format) – the idea was that parents and children would learn something new about the lives of the heroes every day for 3 weeks. After all, it is believed that just 21 days are necessary for any habit to be developed. The "Little Brush, Big Brush" campaign was widely advertised on TV, Internet and social networks of the brand.

And at the end of 2018, Unilever launched another chat-bot - this time in Viber, to advertise Forest Balm mouthwash. The chat-bot had an image of a funny raccoon named Gelik and reminded people to rinse their teeth, and with the help of FaceRecognition facial recognition technology, the bot tracked the moment when the consumer used the rinse aid. Then points were given to the user, and according to the results of the contest, the participant with the most points could win an iPhone. If after rinsing a person showed a barcode from a packaging of "Forest Balsam" to the camera, the awarded points were multiplied. The competition and the bot itself were advertised by popular Instagram bloggers. According to the bot development agency, as a result of the campaign, 10,620 people added the bot to their messenger. Of these, 62% performed the intended target effect - they rinsed their teeth.

The GoProGuruchatbot on Facebook Messenger, which appeared in 2018, answers users' questions, provides recommendations for extreme travelers and helps to choose a good camera from the brand line. Its feature is the response format that is the bot attaches a beautiful GIF or an impressive video made using with the GoPro camera to each of its recommendations. That is, the bot not only gives the user advice on which camera to buy, but also immediately attests the reason why GoPro should be chosen (Fig. 5).

Fig. 5: GoProGuru chat-bot

Comunica, a Russian integrated communications agency, has developed a bot assistant not for its own marketing purposes, but as a tool that it sells to its customers. In 2017, the agency introduced the DigitalPressOffice chat bot for PR professionals. The bot works on Facebook or Telegram. It can help the company's press service gather journalists for the event: it will send them information about the event, speakers, timing. The bot will register those who wish to the event and send a list of all accredited journalists to the press service. It will also answer questions about when and how to get photos from the past event, provide detailed information about the speakers, and send a post release. This bot is not publicly available. The agency sells and sets up a chat-bot for each company individually.

Results and Discussion

The usage of chat-bots has grown exponentially and doesn't seem to slow down any time soon (Himanshu, 2019). Facebook has recently released a host of data proving the value of bots for business:

- 2 billion messages are sent among people and businesses monthly
- 56% of people would rather message than call customer service
-53% of people are more likely to shop with businesses they can message (The Complete Guide to Chatbots for Marketing, 2019).

The active practice of wide using chat-bots is due to the fact that bots can optimize personnel activity, in addition, the process of bots development is fast and cheap.

Chat-bots are used for various business processes: sales (auto-funnels); loyalty management (bonuses and promotional codes distribution); booking and reservation (tickets, services); feedback collection (interactive questionnaires); customer support.
From the point of view of customers, the company's chat-bot is a consultant which can answer various questions and find a solution to the problem. From a business point of view, chat-bot is a complete marketing tool leading a client through a sales funnel.

And for marketers, communicating with consumers via messenger app is a smart way to make sure messaging has been seen. Users are 80% more likely to open communication from brands if it comes via messenger. According to Gartner, by 2020, customers may manage up to 85% of their interactions with a company without ever even speaking to a human. A well planned chat-bot can serve as an engagement driver, lead generator, and can even help with market research. Treating chatbots as marketing tools, rather than virtual help desks, means better insights into customer behaviors, preferences, and pain points. This, in turn, drives better engagement and could even lead to higher sales (Alford, 2019).

Stages of implementing chat-bots in marketing activities:

1. Purpose definition. Depending on the purpose, different bot functionality is needed, and, therefore, the chat-bot will perform differently.
2. Site selection. Today such kind of chat can be introduced to almost all popular social networks and applications: for Vkontakte, for Facebook, Telegram, Viber, WhatsApp. But a chat-bot can be applied to a site as well by being simply pasted onto the page, in the form of a regular feedback window.
3. Choosing a service that allows you to configure all the necessary actions through its interface.
4. Setup and launch. The functionality of services is constantly being improved and allows creating more effective solutions.

Currently, there is a large number of special chat-bot constructor programs. For example, Manybot.io.is a Telegram chat-bot creating constructor. Robochat.io is a platform which helps to create a chat-bot for VKontakte communities. BotVK is a bot constructor for VKontakte with wide functionality. Manychat.com is a Facebook bot messenger constructor. Botmother.com creates a cross-platform chat-bot that will work in several instant messengers and networks: Telegram, FacebookMessenger, Viber, VKontakte and Odnoklassniki.

Chatbots are already widely used in various fields and industries, however, the next stage is call centers with artificial intelligence. Now many IT companies are working actively in this direction - voice assistants "Alice" from "Yandex", OK Google, SiriApple, CortanaMicrosoft and others is a bright proof of their activity. They analyze the user's speech and can give correct answers to simple questions. NeurointellectiPavlov, created by the laboratory of neural systems and deep training at MIPT, is able to understand people's speech and give adequate answers. This project is partially financed by Sberbank, which plans in the future to use iPavlov to communicate with customers. Google introduced the GoogleDuplex service, which can speak in a human voice and call and make an appointment at the hairdresser instead of the user himself, while his speech will be very natura. (Dmitrieva, 2018).

Conclusion

Summarizing the above, we indicate that empathy is the most important aspect when communicating with a client. Possessing this quality, chat-bots could understand the context of messages and customers intonations. The potential for the development of AI chat-bot is great, and it is really able to serve customers of different levels. It can be used in different business aspects. In general, AI technologies in marketing have enormous opportunities that significantly expand the channels of interaction with the target audience.

In the era of the information society the task of marketing is the use of new technologies and tools to improve consumer experience throughout the cycle of interaction with the client, which take into account his individual needs. Marketers need to form such relationships with customers that will persist even in the changing demands of evolving markets. This makes it possible to ensure the competitive development of the company.

Abstract

The article is devoted to the use of gamification in the activities of a company in order to develop marketing relations when working with clients and employees. While the digital economy is being developed, a significant part of marketing activity is transferred to the virtual space, as well as the use of social media for communication becomes more important. The involvement of the population in digital communication channels and the use of game content forces companies to turn to gamification to build confident relationships with both consumers and staff. The article discusses cases illustrating companies' use of internal and external gamification. The authors suggest that the use of this marketing tool will improve the overall performance of business.

Keywords: Relationship Marketing, Gamification, Digital Communication Channels, Internal Gamification, External Gamification, Company Cases.

Introduction

The information and communication infrastructure of relationship marketing is a part of the global socio-technological model of the information society, the development of which led to the virtualization of business and social relations. The information boom in the online and offline environment has predetermined the need for the development of communication technologies in various industries and spheres (Bezpalova, 2019). In modern business relationship marketing is aimed at managing relationships and communications between a company, personnel and consumers using digital channels. The development of the information and communication infrastructure of relationship marketing helps to improve the quality of individual interactions between a company, internal and external consumers, making them more trusting and open (Ivanchenko, 2017).

Gamification as a part of the modern digital environment is currently widely used in marketing activities of companies. Gamification involves applying computer games specific approaches to non-gaming areas in order to control the motivation and behavior of groups of people.

External gamification involves interacting with existing customers and attracting new ones, which in this case is a way to increase customer engagement and loyalty. The use of internal gamification is based on the approaches used in games development and aims at increasing the productivity of staff within the organization (Gamification in Business, 2016). Thus, game elements in marketing activity are used both within the company (for motivation and personnel management) and outside it (to attract consumers and increase loyalty).

Analysis of external and internal gamification as a new communication marketing practice is relevant, as it allows the complex mechanisms of forming long-term partnerships with customers and company personnel to be examined. The widespread development of computer games and consumer interest in them also stimulate attention to business gamification (Zickermann, 2014).

In general, it should be noted that gamification is not related to virtual games. But it is characterized by practical use of the games entertainment elements, the so-called game mechanics or game techniques. “Game mechanics are the rules of the game and its elements (points, badges, levels, ratings, awards / prizes), game dynamics are scenarios of user participation in the game” (Introduction to Gamification, 2013).

In the modern literature, there are six main game approaches that are aimed at increasing engagement (Table 1). Ether one or several approaches can be use in relation to any of two interested parties: employees or customers.

Table 1: types of game approaches aimed at increasing engagement

Types of game approaches	Description
Big challenge	Competitions in which participants receive a prize for victory
Quick response system	Scoring is in real time
Modeled discovery	Using of new models or ideas, as well as options for the development of something
Status marathon	Designed for a long time, such systems use various rewards for moving up the status ladder
Commercial / Negotiation	Such systems most often rely on a real or imagined global economy, including securities markets and auctions
Expressive	They are aimed at allowing the user to express himself, to show his personality

Source: Zickermann G., 2014

In marketing activities, gamification can be used to create different patterns of behavior. It is important to understand that gamification is not only holding contests in which one can get a prize for achievements, it is an approach that helps to motivate consumers and employees, as well as stimulate creative thinking and introduce innovations.

Key Research Findings

Examples of Internal Gamification in Staff Marketing

Staff marketing plays an active role in improving business performance (Bondarenko, 2017). “In the context of labor relations internal gamification implies influencing the labor behavior of employees by involving them in the game: using corporate software (application or social network), employees of a certain company are offered to perform various tasks or complete online quests related to the company directly, to training or the work process, all the interaction between employees is necessarily based on competition. In Russia, “Tele2”, “MTS”, “Odnoklassniki”, “Baby.ru”, the state corporation “Rosatom”, “M. Video”, “T-Systems CIS Russia”, "Orient Express" bank and many others use gamification in varying degrees” (Tsyplakova, 2016).

Here we consider the case of the Internet Marketing Agency, which is one of the largest agencies in Eastern Europe, where an internal gamification system has been implemented for two years.

The company developed indicators, upon reaching which employees receive virtual awards - badges that are displayed in the profile of each employee in the company's ERP system. For example, such indicators were “Maximum number of projects” or “Increase in turnover per month”. The agency’s gamification system is the aggregation of all points for all badges for all employees. “The rating is updated quarterly, so every three months employees have a new motivation to compete with each other. In this system, badges are given solely for actions that benefit the company” (Real Experience in Implementing a Gamification System, 2014).

The results of this gamification system functioning are:

- the system signals the effectiveness and activity of employees;
- it gives the staff additional motivation to take the company-benefit actions;
- increases corporate spirit and volatility in the company's activity;
- adds an entertainment element to the work.

According to the agency’s top management, “badges can very rarely act as the only motivation in the work of the staff, but at the same time they are a pleasant and well-deserved reward for employees of the agency” (Real Experience in Implementing a Gamification System, 2014).

The next case of internal gamification is a training project of a large company manufacturing baby food. The key task of the training project of the company - the baby food manufacturer was the development of loyalty to the products and brands of this company with its own staff and resellers (sales consultants).

The training project was developed in the form of a distance online learning. To engage and motivate students, all training modules included:
• motivational blocks and involving materials;
• interactive components for both developing knowledge and engaging students;
• visual representation of theoretical material with vivid illustrations;
• full or partial gamification of the module or the entire course.

Gamification of training courses in this case was used to make learning more effective during the training. The integration of online learning with game elements in the manufacturer’s marketing communications process resulted in several times increase of the number of courses taken by the target audience, which led in its turn to an increase in the level of company's products sales.

Examples of external gamification in the companies’ marketing activities

In the marketing practices of companies, gamification is usually a part of social media marketing and is carried out on various social networking platforms.

Old Spice company developed an online comic book style game “Choose Your Own Adventure” on Instagram. One of the posts on the brand’s official page contained marks that led to fake pages with the continuation of the game. The result is a large branched comic book filled with retro jokes, monsters and robots (Fig. 1).

Fig. 1: Instagram game by "Old Spice"

The story begins with a description under the photo: “So, you find yourself in a dark cave, on the side you see a faint light, and next to it is a bottle with Old Spice shower gel. What will you choose? ” When you click on the screen, two labels appear, one of which leads to the next level, and the second, unfortunately, turns out to be one of the possible endings to the script. However, there is a way out of any deadlock to the previous “location”.

The Old Spice game was a kind of parody of traditional computer quests. Users open the first photo, and then choose their further actions from the proposed options. At the same time, the end of the game contained an Old Spice advertisement.

The mechanics of modern Instagram quests are very similar to a computer game. Making a decision, the player interacts with the program by clicking the appropriate buttons or selecting certain dialogue branches. By opening this or that link, the user interacts with the plot, making a certain game action. This mechanic is suitable for various marketing purposes, including creating interactive online storefronts.

The next case is a joint competition from MVideo and the MoreMall multi-brand shopping center in Sochi. A contest was held on the social network Vkontakte platform, and a real prize was offered - a Jawbone UP3 Red fitness tracker and a modern Presigio tablet (see Fig. 2).

Note: «Friends, MoreMall together with M.Video holds a competition in the social network Vkontakte. Win a Fitness tracker Jawbone UP3Red. Win a Tablet Prestigio»

Fig. 2: Competition Information

Every day, the company published tasks on the social network Vkontakte (see Fig.3).

Fig. 3: Tasks of the competition from MVideo and the MoreMall

At the end of the competition, prizes were awarded to the subscriber who answered most of the tasks of the competition not only correctly, but also quickly.

As a result of the action, data on the involvement of the Shopping Center subscribers in the VKontakte social network before, during the competition and after it was analyzed (Table 2).

Table 2: The dynamics of the involvement of the Vkontakte social network subscribers

Indicators	Before the competition (07.02-19.02)	During the competition (20.02-08.03)	After the competition (09.03-21.03)
Number of likes	183	1983	1084
Number of reposts	83	407	157
Number of comments	53	727	81
Audience outreach	120 069	261 024	144 545

Source: MoreMall, Sochi

As a result of this competition with gamification elements, the audience coverage indicators were exceeded by more than 2 times, the number of comments increased by 14 times. The number of reposts increased 5 times, the number of likes increased 11 times.

The following case shows the game mechanics working in the banking sector. Tinkoff Bank together with the MasterCard payment system launched the quest for its customers - for 35 days participants got the tasks passing which they performed various online and offline operations. The more difficult the task, the greater the reward the client received. The prize fund of the stock was 1 million rubles. Initially, the company promised the winner one million rubles, but due to the large number of people who successfully completed all the quests, it divided the amount between them - each of the 444 winners received 2,252 rubles and 12 thousand miles with the opportunity to spend them on tickets of any airlines (Examples of Gamification, 2017).

The objectives of the Tinkoff Bank quest were:

• To increase the activity of using co-branded cards: ALL Airlines, OneTwoTrip and eBay;
• To attract new customers, to increase the number of cards issued;
• To increase interest in the Bank's loyalty programs and show that it is simple and profitable to use them.

The results of the "Tinkoff Bank" quest:

1. More than 15,000 participants.
2. The number of transactions on co-branded cards increased by 20%, among participants by almost 40%.
3. More than a thousand clients' publications in different social networks.
4. The number of cards issued has increased.
5. A large number of purchases were made from Bank partners (Tinkoff Quest, 2015).

The action was so successful that it was repeated in next year. This time the quest lasted only one day. 813 people reached the final. The main prize was shared among the five fastest players. The record of passing tasks - 56 minutes.

"Tinkoff Quest -2016" was much more dynamic, since all the tasks had to be completed in one day. The tasks themselves also changed - before completing the task had to be solved. Another change was that in 2016 the bank linked the quest with the city locations of Moscow.
According to the bank, the main prize of the "Tinkoff Quest - 2016" was about 1 million rubles. It was shared among the first 5 winners. Participants who took places from 6 to 10 received an iPad from "Svyaznoy" company. The remaining winners received 5,000, 2,000 or 1,000 bonus points on Tinkoff Bank cards, depending on the results of the quest (Tinkoff Quest, 2016).

The analysis of the Tinkoff Bank quest shows that gamification can be effectively used to solve marketing problems. It is used not only to attract the attention of consumers, but also to increase income.

Conclusion

In the era of digital marketing the success of a company depends on its opportunity and ability to use the Internet to promote the product and increase the competitiveness of the company. Using the techniques of external gamification in business can give the following advantages:

• being ahead of competitors who are accustomed to acting using outdated sales techniques;
• strengthening the brand with an innovative approach;
• increasing the level of trust in the company and the product, it is gamification that is aimed at entertaining and increasing subscribers;
• attracting new users thanks to the recommendations of those who have already participated in the developed game mechanics;
• a large stream of new leads from social networks, as the results of game mechanics are published or participants are invited to share it with friends;
• an active dialogue with the target audience gives feedback, as well as positive comments;
• savings on advertising, since gamification works like an advertisement;
• increasing the level of products sales at all stages of the game and a measurable result from investments.

The use of internal gamification as a new management practice gives management modern ways to manage employees and increase productivity, by electronic monitoring of employee activities and increasing employee engagement.

Games and quests differ from the traditional marketing tools as they more actively attract the attention of the media, which means they create news occasions. The game allows you to enhance the emotional experiences of the client and increase his involvement in the company.

To make users interested in playing, the following conditions must be observed:

1. The game must have specific goals and rules.
2. The actions that are required in the game should be affordable for any users.
3. Feedback on the actions of the client or employee is required.
4. It is necessary to exclude factors that may interfere with the game.

Thus, effective gamification involves the preliminary development and testing of the game, taking into account the business goals of the company, the needs and capabilities of the game participants, as well as the ability to manage the motivation and behavior of employees and customers. The use of game technologies in the company's activities accelerates customer feedback, and also allows companies to develop individual interactions with internal and external consumers based on the information and communication infrastructure of partnership marketing.

Improving Educational Management in Russia Based on Information and Communication Technologies

Lyudmila I. MIRONOVA

Ural Federal University after name the first President of Russia B.N. Yeltsin, Yekaterinburg, Russian Federation, mirmila@mail.ru

Olga V. RUZAKOVA

Ural State University of Economics, Ekaterinburg, Russian Federation, rov@usue.ru

Abstract

The article discusses the issues of improving educational management based on the use of information and communication technologies to create services that allow managing processes in the University. The relevance of the article is determined by the fact that research in the field of education management in Russia is mainly devoted to the study of its theoretical aspects. At the same time, some studies cover issues related to the process of Informatization of education in the field of building an information system of an educational organization. Transformations taking place in Russia, lead to changes in education, placing the graduates of higher educational institutions in new requirements for the quality of education, and the universities requirements new priority goals and objectives of the development of modern education. This issue is particularly acute in connection with the transition to a new stage of the Russian information economy – digital.

The purpose of the article is to identify specific processes in an educational organization, use the tools of the quality management system to develop documented procedures for their management and use them to create electronic services for improving educational management at the University in the information and educational environment of the organization.

Keywords: Educational Management, Informatization Of Education, Quality Management System, Process Approach, Management Services.

Introduction

The main tasks of educational management are to ensure the quality of educational services that meet educational standards and the needs of the main subjects of education, as well as to constantly monitor the effectiveness of educational activities, to coordinate the work of all departments and subjects of education.

One of the main aspects of education management, as a type of activity, is the educational aspect: the management of the educational process, during which the coordination of scientific, material and human resources necessary for the effective achievement of educational goals is achieved.

At the same time, we will consider the strategic aspect of educational management in the context of implementing the concept of managing an educational organization based on human resources as the basis of an organization that focuses on consumer needs, allowing for flexible regulation and timely changes that are adequate to the impact of the external environment, to ensure competitive advantages in the educational market.

The process approach in the management system of enterprises and organizations began to be applied in Russia from 2005-2010, and abroad even earlier. When building the enterprise information model, a process model of the enterprise was developed using business processes. Enterprise reengineering

involves the adoption of process thinking and the use of advanced information technologies in combination with an attempt to implement organizational changes (Ruzakova, 2010). Theoretical research and practice in the field of the process approach determine the relevance of this article in the application of this approach in educational institutions in Russia.

The purpose of this study is to concretize some processes of an educational organization, develop documented procedures for their management and, on their basis, create electronic services, the use of which is aimed at improving the educational management of a university in the information and educational environment of an organization based on its information system.

The management of an educational organization based on an information system is a key mechanism that will create advantages in a competitive environment. In this regard, the main activities in the process of education informatization are the creation of a reliable and effective infrastructure that provides unified ways to access corporate data, improves the manageability of the entire complex of information resources and is in line with the strategic goals of the educational organization (Mironova, 2017).

As a tool for developing documented procedures for managing specific processes at a university, the process approach of a quality management system (or TQM) was used (Mironova, 2019).

Issues of educational management are quite widespread in the research of Russian scientists (Asaul, 2007, Zernov, 2008, Ponomarev, 2007). These studies are mainly devoted to studying the problems of education as one of the leading branches of the Russian national economy. They consider the theoretical aspects of education management (system, strategy, personnel, methods, efficiency). In addition, the scientific basis of the development of marketing of an educational institution (research of the education market, marketing environment and communications, consumer behavior, marketing management) is considered. At the same time, a number of works are devoted to the development and functioning of the information system of an educational organization (Kryukov, 2007, Oleynikov, 2005, Mironova, 2020). There are practically no publications related to educational management based on the TQM process approach in the context of the functioning of the University's information system.

However, according to State standard ISO 9001-2015 “Quality Management Systems”, the fundamental principle and main component of the quality management of the educational process in a university based on the TQM is the process approach, the implementation of which involves:

-a meaningful description of the process of developing information and methodological support, with by which the desired result is achieved;
- identification of the relationship of this process with organizational and managerial processes taking place in the departments of the university;
- establishment of responsibility, authority of internal and external consumers and other interested parties involved in this process
- account the results of this process for managing it.

At the same time, the analysis showed that within the framework of the TQM existing in universities, the requirements of this State standard are not fully implemented, and the main work on quality management (Soloviev, 2003, Mironova, 2019) is focused only on:

-maintaining technological documentation presented on the websites of universities;
-regulation, mainly, the content of educational programs;
-fixing provisions on structural units and provisions on the exercise of various functions by them;
-presentation of quality plans and programs, internal audit plans, work plans.

The analysis of scientific publications on the issues of educational management made it possible to state that in the conditions of informatization of education, the goal of educational management of an organization is to ensure the quality of educational activity by rational organization of processes

(pedagogical, educational- methodological, organizational-managerial, science-research, educational) based on electronic services included in the information and educational environment of the organization, when used effectively and human resources and the development of its technical and technological base.

At the same time, we will understand the information and educational environment as a set of purposefully created conditions for the interaction of all categories of users responsible for the development and use of information and methodological support for the educational process based on the university's information system (Mironova, 2017).

The structure of the article includes an introduction, which defines the purpose of the study and clarifies the tools for its implementation, as well as the result of the analysis of scientific research, which showed that the management of the quality of education in modern universities is limited to recording on the websites of universities technological documentation regarding the content of educational programs and provisions on structural units University and their functions, as well as quality plans and plans for its checks. In terms of informatization of domestic education, this is clearly not enough.

Methodology for using TQM- Tools for Developing Management Services

In connection with the above, we will consider the management of some processes occurring in the University, using the tools of the TQM system. In scientific publications on quality management of education, it is noted that the basis of it should be the modeling of educational activities, while it is noted that the quality management system of the University is one of the tools to improve the efficiency of the educational process.

However, the analysis of research in the field of quality management system of universities showed that within the existing universities across the country all the work TQM quality management is to maintain, above all, technological documentation provided on the websites of the universities and regulating the content of educational programs, the provisions on structural subdivisions and the provisions of the implementation of the various functions, as well as plans and quality program plans of internal audits, work plans, etc.

The fundamental principle of quality management of education is a process approach that allows us to consider educational activities as a whole, consisting of a set of the following processes: educational and methodological, organizational and managerial, research, and educational.

Implementing the process approach involves performing the following actions:

- determining the process by which the desired result is achieved;
- definition and measurement of inputs and outputs of the process;
- identification of the relationship between the process and the functional divisions of the University;
- establishing responsibility, authority, and accounting for managing the process;
- identification of internal and external consumers and other stakeholders in the process (Vasilieva, 2008, Ruzakova, 2018, Mironova, 2017).

In the context of the study, the selected method seems to be universal, because almost any organizational process in a university can be represented as a sequence of deterministic steps, each of which has input and output information.

As an example, consider from the point of view of process approach of TQM of the University is the development of documented procedures to control the creation of electronic educational resources (EER), run by the Department of the University. The figure shows a diagram for managing the process of its development.

Figure-Managing the process of developing an electronic educational resource (EER) as a documented TQM procedure

Main blocks of the EER development process: 2, 4, 6, 8, 10, 12, 13, 14, 15, 16, 18, 20, 21, 22. Their contents and those responsible for their implementation are shown in table 1. The input information for the process of developing an EER for a specific discipline is the Federal state educational standard of

higher education (FSES HE) of Russia and the working program of the discipline for which the EER will be developed.

Table 1 : The main blocks of the development process electronic educational resource (EER)

Process Block number	Process Block Content	Responsible executor
2	Working programm Disciplines (WPD)	Leading subject teacher from the department of the customer
4	EER Content Development	Leading subject teacher, methodologist from the customer's department
6	EER scenario development	Leading subject teacher, methodologist from the customer department, teacher from the department of performer
8	EER code development	EER code developers, teacher from the department of performer
10	EER analysis by TQM tools	Specialist of the University Quality Department, Leading subject teacher
12	Trial operation EER in the educational process	Leading teacher from the customer department
13	EER analysis for pedagogical requirements	Leading teacher and methodologist of the customer department
14	EER analysis for technological compliance requirements	Leading teachers of the department of the customer and the department of performer, methodologist of the department of the customer
15	The introduction of EER in the educational process	Leading teacher of the customer department
16	Intermediate certification in discipline	Leading teacher of the customer department, employee of the dean's office
18	Determining the level of competency formation in the discipline	Leading teacher of the customer department, specialist of the university quality department
20	Analysis of the level of competency formation in the discipline	Leading teacher of the customer department, specialist of the university quality department
21	With a low level of competency formation, retraining	Leading teacher customer departments
22	Documentation on EER materials	Leading teacher customer departments, head customer department

The output blocks of the development process of the electronic educational resource (3, 5, 7, 9, 11, 17, 19, 23) of the discipline are presented in table 2.

Table 2 : The Content of the output blocks of the development process electronic educational resource of discipline

Output block number	Output Block Content
3	Work program of the discipline for which the EER is developed, approved by the rector
5	Protocol of the meeting of the customer department on the approval of the content of the EER
7	Protocol of the developers meeting on the approval of the EER scenario
9	Debugged EER code, approved by the head. customer department and head. department of the performer
11	EER quality assessment sheet, approved by a specialist of the university's quality department
17	Results of intermediate certification in discipline, approved by the dean
19	Protocol of the level of competencies of students studying the discipline using EER, approved by the dean and a specialist of the university's quality department
23	Protocol of the meeting of the customer's department on the decision to place the EER in the university Information System and the possible publication of the EER.

The result of the process approach is a documented procedure, TQM-regulated institution, which defines the input and output parameters of the process, identified all its relations, established responsible at each stage of the process, identified internal and external customers of the process.

In this article, the process of developing an EER based on the TQM process approach is considered as an example. Similarly documented procedures have been developed to manage the following processes at the University:

- in the learning process - managing the development of educational and methodical complex of discipline, managing quality control of teaching materials;
- in organizational and management – management of monitoring the satisfaction of participants in the educational process;
- in the research process-managing the process of forming students ' competencies in research activities;
- in the educational process-managing the process of forming a student's portfolio as the initial conditions for the graduate's career growth in the profession and healthy lifestyle skills.

The algorithm proposed in the article was used to develop the above-mentioned documented procedures. The developed documented procedures served as the basis for the development of the corresponding services, the functions of which are presented in table 3.

Table 3: A list of services functions that ensure the improvement of educational management at a University

Process	Process Objective	Service Function
Educational-methodical	Provision of the educational process with electronic educational and methodical complexes (EEMC), the formation of students design knowledge, skills and experience;	Management of the development electronic educational resources (EER), management of the process development EEMC, control of EEMC quality

Table 3 continue

Process	Process Objective	Service Function
Scientific research	The formation of knowledge, skills and experience in research activities	Management of the students scientific process activity, service ASSPRSR (Automated System for Statistical Processing of Results Scientific Research)
Educational	The development of the personality of students, the formation of a system of beliefs, moral standards, general cultural and business qualities	Management of the process of formation of the student's electronic portfolio, the formation of healthy lifestyle skills, the service ELECTRONIC PORTFOLIO
Organizational management	Improving the quality of student training	Management of monitoring the satisfaction of participants in the educational process (System Electronic Monitoring of Quality Educational Process service (SEMQEP))

Conclusion

Within the framework of the study, based on the TQM process approach, documented procedures were developed for managing certain processes aimed at improving educational management in the information and educational environment, on the basis of which services were developed that provide:

- in the educational and methodological process - management of the electronic educational resource development process, managing the process of developing electronic educational materials and monitoring their quality;

- in the organizational and management process-management of monitoring the satisfaction of participants in the educational process;
- in the research process-managing the process of forming competencies in the research work of students;
- in the educational process-management of the process of forming a student's portfolio as the initial conditions for the graduate's career growth in the profession and the formation of healthy lifestyle skills.

In the introduction of the article, the purpose of the research is formulated, which consists in specifying some processes of the University, developing documented procedures for their management based on the process approach of the quality management system and on their basis creating management electronic services. As a result of the analysis of scientific publications, it is shown that the process approach of TQM as a tool for managing the quality of education in modern universities in the conditions of Informatization of education is not fully used. The second part is devoted to a description of the methodology of the research, based on the process approach of quality management system for

example, the development of documented procedures to control the creation of electronic educational resources.

Further development of the research results involves the development of documented quality management system procedures for other processes at the University in order to intensify the process of Informatization of education in Russia and create effective and reliable educational infrastructures that allow implementing the strategic goals of educational management based on information systems of universities.

The academic consequences of funding are determined by the fact that the developed methodological and technological solutions aimed at improving educational management have a significant positive impact on the management of the educational process, including conducting training sessions; monitoring students knowledge; providing means of delivering educational materials from teacher to student.

The managerial consequences of financing consist in solving methodological problems of improving educational management in the context of Informatization of education in Russia using the process approach of the quality management system, aimed at developing the theory and practice of the evolution of society (industrial and information) and the development of a new stage of the information economy – digital.

At the same time, the results of the research can be used in the activities of educational organizations (universities, colleges and other educational institution) that have implemented information systems and plan to develop the information and educational environment of their organization in order to improve the manageability of the entire complex of information resources.

Acknowledgment

The article is prepared with the financial support of the Russian Foundation for Basic Research within the project No. 19-010-00886 «The comprehensive economic and legal study of improving the competitiveness of the agro-industrial complex of the Russian Federation in the context of the development and integration of information digital systems».

Abstract

Non-Currency transactions and counter trade form an important aspect of international trade in today's globalized economy. This type of transactions may be both for goods and services. This is an important form of trade from the point of view of developing nations. There can be several forms and variants of non-currency trade and each country follows whichever suits its current economic and social structure. This method of non-currency trade is especially helpful for middle- and low-income countries which lack sufficient fund of hard cash reserves. In politically and economically unstable countries, this form of trade can also help ensure protection from currency exchange rate fluctuations. It also helps avoid inflation since the trade is carried out in goods without the involvement of hard cash. As the world is becoming more prone to financial turmoil, many less developed and developing countries are resorting to such kind of transactions to avoid financial risks. In this paper, the analysis will be made of the three such forms of exchange in a detailed manner namely Barter deals, Buyback (Compensation) and Direct Compensation (Counter Purchase). Each variant will be studied as per their further classifications, advantages and disadvantages. The study would focus on the mechanism of such transactions, the salient features of such methods of exchange and the need for such a system in today's world.

Keywords: Barter, Compensation, Counter Purchase, Direct Compensation, Buyback.

Introduction

This mode of trade exchanges usually involves developing nations and is a means to reduce imbalances in trade between them and other advanced countries. Such mechanisms are used when there is a shortage of foreign exchange in a country or when there are foreign exchange controls

which restrict the availability of foreign currency in a country *(Robert, 2018)*. In simple terms, this mechanism helps countries to export their products across national borders to foreign countries or companies even when they are unable to pay using hard currency.

Literature Review

When writing this work scientific and educational literature, articles were used. The main sources, revealing the theoretical foundations of the compensation transactions mechanism, were works of Eric Martinez, Ian Jones W, Tim G. Richardson.

As per the United States Department of Commerce, 1978 "A Seller provides a buyer with deliverables and contractually agrees to purchase goods from the buyer equal to an agreed percentage of the original sales contract value". This is one of the first definitions of counter trade. According to Hennart, 1989, counter trade is a set of agreements in which the seller is involved in several compensatory activities to settle the sale. Some studies say that counter trade reduces risks associated with the purchase of high-end technological goods. Authors *(Hennart, 1989; Hennart, Anderson, 1993; Lecraw, 1989; Mirus, Yeung, 1986; Marin, Schnitzer, 1995)* support this claim. According to Lecraw, 1989 and Fletcher, 1996, the long term and close relationships between companies and foreign suppliers can benefit for both the stakeholders involved resulting in technological, managerial and commercial growth. Counter trade may help to train local labour and task force *(Forker, 1997)*. Hennart, 1990; Caves and Marin, 1992; Hennart and Anderson, 1993 suggests that counter trade usually establishes in places where market transactions are not well established or are in the developing phase. Studies on Williamson's transaction cost theory (1975) *(Hennart, 1989; Hennart, Anderson, 1993)* show that counter trade is an alternative to FDIs. Some studies underline the rapid growth that counter trade agreements have had over the years *(Erridge, Zhabykenov, 1998; US Department of Commerce, 2007)* both in the relations between Western countries and emerging economies and in the relations between developed economies.

Methodology

There are mainly three kinds of non-cash trade transactions commonly used around the world namely barter system, compensation agreement and counter purchase. Each of these three methods has been dealt with, individually. First attention has been made on the very concept of counter trade, its meaning and advantages of using such a system. The barter system has been studied on the basis of its main idea and definition, classification, advantages and disadvantages. For compensation Agreement also the first approach has been the main idea and the types of transactions involved. Then some of the ways to avoid penalties have been discussed in case there is a violation of the promise of payment. The similar approach has been used for buyback compensation and study has been made related to the main idea, advantages and disadvantages and some salient features.

Reasons for engaging in counter trade

Some of the main reasons for engaging in counter trade include:

1) If the trade deals are of very high value (over $1 million) or deals with a certain category of industry, then this mechanism supports that kind of transaction *(Barternews.com, 2019)*. For E.g. in South Korea, as per government regulations, telecommunication procurement above $1 million as to be carried out using counter trade.

2) As counter trade bypasses the use of hard currency and only deals with goods, so the risk of currency fluctuations can also be mitigated to a considerable extent *(Counter trade, 2020)*. This is a good method to hedge against inflation as well.

3) Counter trade is an effective way to recognize profits. The government of many countries restricts the flow of currency out of the nations. In such situations, counter trade acts as a useful tool to get back profits in the form of goods and products *(Martinez, 2019)*.

4) Many developing countries do not have access to ample credit facilities or funding to facilitate international trade. In such cases, counter trade helps.

5) Counter trade also helps countries enter new geographies for international trade.
6) It provides an opportunity for sellers to differentiate their products from their competitors.
7) It helps counter bad debt situations as the payment can be done through goods or products.
8) It helps developing countries retain their markets from competitors.

Phases of Countertrade

- Negotiation of Parties

The first and most difficult phase is the negotiation phase. Generally private companies have an advantage over state-controlled ones but this should not be taken as a rule and the strength and position of the parties are strictly determined by the economic condition of the company and the country. Although the concept of economic public order tends to be of a national scope, some principles should be accepted in international trade by the States involved. These principles should be taken into account by a mediator, a trouble-shooter and an arbitrator, so there is no chance the arbitral award is not accepted in another country.

- Initial documentation phases

Lots of documents, letters, etc. are exchanged among the parties which take considerable amount of time. The term "letter of intent" is used by parties in international trade with many meanings which adds a certain difficulty to the evaluation of the commitments undertaken by means of the document. These letters can be used to confirm the seriousness with which negotiations are approached, as a framework agreement that allows reaching partial agreements or as contracts.

- Execution Phase

It is difficult to draw concrete borders between the different phases. The exact start of execution is not well defined. The parties begin operations even before settling of the contract law. The transaction is not the actual phase either as deadlines can be extended usually by the parties involved. Modifications in the contract law involve mediation, conciliation and negotiation between parties, which are addition to the more traditional ways of arbitration and judicial means. These modifications are carried out by companies and governments situated in different parts of the world with totally different economic, legal, political and cultural backgrounds.

Table 1: Advantages and disadvantages of the countertrade

Advantages	Disadvantages
1) Allows entry into new and difficult markets	1) No personal use of goods offered by customers
2) Overcomes currency controls and exchange problems	2) Negotiations are time consuming and complex
3) Increases sales volume	3) Uncertainty
4) Overcomes credit difficulties	4) Increase costs
5) Allows full use of capacity	5) Difficult to resell goods by offsets
6) Allows disposal of declining products	6) Brokerage costs
7) Provides sources of attractive inputs	7) Getting businesses in which firm may have no knowledge

(Source: compiled by the authors)

GATT/WTO and Countertrade

- GATT had originally accepted countertrade agreements given certain restrictions such as use of countertrade measures on discriminatory grounds and in response to government policies.
- Article 1 of the GATT Agreement says that all GATT member countries should be treated equally without any discrimination. It does not mention anything about imposing restriction on countertrade. However, there can be no preferential treatments to selected countries.
- Trying to impose countertrade requirements in order to protect domestic industries however goes against Paragraph 1 of Article II *(McVey, 1981)*.

Types of Counter trade

1) Barter System

It is a system of trading where no money is involved. It is a very old technique and dates back to the age when money was not invented. Today it exists in a new form and using the latest technology like the internet. The value of a commodity can be negotiated for another and this process usually involves online auctions and swap markets. It can be of the following types

- Direct trade. This is a case of a simple transaction where one party gives item "X" in return of item "Y".
- Partial trade. Here one-party barters away products for partial trade + cash. It helps trade away the margin and pays for the "hard cash". By this method, one can get business without having to pay cash or green dollar bills.
- Associated Trade. Here a third party exists which brings together various businesses. A particular trader may sell some product to a person but might not necessarily exchange the latter's product for his own. He may choose to purchase some other product or service
- Conjoined Trade. In this method, a person may mix products and services to trade for other products and services.
- Investment Trade. In this method, investments of services are made but the payoff is not immediate. Instead one has to wait for years and build relationships which will pay off in years to come.

A barter contact consists of Parties, recitals, acknowledgement of obligation of first party to provide and accept goods, acknowledgement of obligation of second party to provide and accept goods, first-party goods, second party goods, bank guarantees providing for full payment in the event of the non-performance of one party, guarantee of quality, quality control, right to inspect, right to neutral surveyor, determination and settlement of claims and penalties.

Table 2: Advantages and disadvantages of the barter system

Barter system	
Advantages	Disadvantages
1) The system helps gain access to new markets, customers and thereby leading to increased sales (Mint.com, 2019). 2) It helps increase cash flow by allowing saving cash for the business. Saving cash is a kind of cash flow. 3) It helps increase profit by allowing purchasing goods and services on barter at a discount which is equal to gross profit margin less the barter fees incurred *(Notjustanentrepreneur, 2015).* 4) Flexibility. Even heterogeneous or unrelated things can be realized.	1) Each party should possess the goods or service which the other party needs and is willing to trade for. Availability of mutually desired goods is a pre-requisite. This is a remote possibility and does not always coincide. 2) There is no common unit to measure the value of goods being traded. Hence the values are arbitrarily fixed by the parties based on their individual needs of the products. Professor Culbertson had put forward a formula to measure the number of exchange rates which is n(n-1)/2. For e.g., if there are 100 types of goods involved in barter trade, then the number of exchange rates would be 100(100-1)/2 which is equal to 4950. This creates a problem in the calculation of final accounts because it is not possible to include a huge list of products in the balance sheet or Profit and Loss Account Statement *(Meghana, 2019).* 3) Certain goods cannot be divided such as in the case of trade between animals such as horse and sheep. One party may desire 5 horses but the other party may be willing to only part with 4. And since the goods here are animals and they are indivisible, the transaction may fail to happen. 4) Since there is no fixed measure of value, it is also very difficult to store value for the future. Perishable items such as rice, grains etc. are very difficult to store and depreciation happens very

	fast and is not predictable. 5) Deferred payments are also not possible due to problems in storage and quality of the goods to be exchanged at a later date. As we have seen perishable goods decrease in quality drastically so there might be disagreements over the type of goods to be used for exchange at a future date. 6) There is also a lack of specialization. With no experience of trading with a particular type of goods and also with the absence of proper monitory framework and transactions, this system of barter fails in a proper market economy.

2) Direct Compensation (Counter Purchase)

This is an agreement where the exporter agrees to buy a number of goods in return from the country to which it is exporting. The counter purchase is made of goods of equivalent value. A unique feature of this arrangement is that the exporter entering into purchase agreement has to have an agreement with a trading firm to market the goods they purchase *(Globalnegotiator.com)*. Most of the time the exporters do not use these goods themselves but however, there can be some buy-back conditions where they agree to purchase some raw materials to use them in their production process.

This agreement can help a firm to enter a new market and get a competitive advantage over others. Counter Purchase agreement can be of different types such as:

- Swap. Here, products are traded to different locations to save transportation costs. Most common commodities for such agreement include sugar, chemicals and oil *(Citeman.com, 2019)*. For e.g. in 1978, a swap agreement was signed for USSR oil bound for Cuba and Mexican oil bound for Europe and Asia. USSR transferred oil to Europe and Mexico supplied oil to Cuba. By this way, both countries saved considerable cost on transportation.
- Clearing. This is a bilateral agreement between two countries where one country agrees to purchase a specific amount of another country's products over a certain period of time. The type of currency to be used such as USD or French Franc is also mutually agreed upon by both the countries. This arrangement helps in maintaining better trade balances and is popular in many developing countries and new growth markets.
- Switch. This kind of agreement helps a country when its flow of international currency is weak and irregular. The country which initiates the agreement transfers its imbalances to another country or third party.

It is an agreement where the two parties agree to buy and sell from each other but under two different sales contracts. The mediation of a trading firm is required between the two parties entering into a counter purchase agreement. It is a type of counter trade where countries having a shortage of hard foreign currencies can trade by exchanging goods and services.

A typical case of Counter Purchase Agreements:

In order to sell $250 million worth of Apache helicopters to UAE, Us company McDonnell Douglas agreed to help them fight the whitefly, which is a menace to crops. McDonnell Douglas helped install an insect trap in Abu Dhabi (capital of UAE) to counter whitefly. In return, UAE accepted to buy Apache helicopters from them.

Risks in counter purchase trade can be avoided by hiring a sales assistant or local assistant who has experience in that country. Risks can also be avoided by hiring reliable third parties who will take the product from the exporter in advance and at fixed prices after the conclusion of the counter purchase contract. Third parties will also mitigate the risks of resale of the products. Finally, by legally fulfilling obligation by "bona fide" offers which transfer the risk on the exporting country or the country that has the obligation to sell products for counter trade.

Counter purchase agreements include penalties and demands guarantees of performance. In certain cases, the penalty is to be paid and still, obligations are to be fulfilled. In case of a penalty, the target should be to reduce the penalty as much as possible and a provision that allows the return of the penalty when the obligation is finally fulfilled. Some of the ways to reduce penalties include offering a simple corporate guarantee which can be accepted by the contracting party only when it has a corporate patent. Risks can also be avoided by offering a Performance bond which is actually an insurance contract. All stakeholders such as subcontractors, construction workers and suppliers are fully paid after the project is completed. If the contractor fails to perform, then the guarantor will pay the full amount *(Gordon, 2019)*. Also, by using a bank guarantee. It is similar to Letter of Credit (L/C) but in this case, the bank is not liable to pay if the presence of some legal argument. It works better than L/C. Finally, the last option is an L/C which is expensive and the bank is obligated to pay out under the given terms even if the dispute is legitimate except in case of obvious fraud. Counter Purchase contract consists of Protocol, Primary Sales Agreement and Secondary Sales Agreement.

3) Buyback (Compensation)

It is a form of trade where the exporter of heavy machinery and technology agrees to "buy back" or purchase a percentage of its output once the machinery is deployed for production in the importing country. One major advantage of this type of agreement is that it helps in the transfer of technology and production processes from developed to developing countries *(Globalnegotiator.com)*. It helps in establishing production facilities in such countries. The agreement also has longer-term than other forms of trade and thus helps build long-lasting and sustainable economic relations between countries. The importer pays for the goods in currency and also receives currency for sale of finished goods to the exporter. The payment can be in another form where the importer ships the manufactured goods to the exporter as royalty payment in place of cash. However, this variant is a kind of barter deal which is difficult to regulate.

Compensation agreements have two separate contracts. However, the exporter would aim at keeping them linked so that they import final goods produced from technology and machinery provided only by them and not from some foreign unknown entity. A compensation contract consists of Protocol, Primary Sales Agreement and Secondary Sales Agreement

Response of the business community to countertrade

Companies in low income and third world countries try their best to negotiate with the countertrade terms and change the rules and norms to their favour. Companies try to restrict the products which they agree to purchase to those which they can use in domestic market. They attempt to purchase products which it can use in its manufacturing process, such as raw materials or component parts, or occasionally, office equipment or goods suitable for distribution to its employees. As a generally less desirable alternative, the company will look to take back goods in anticipation of resale on the international market *(Palich, Ireland and Bagby, n.d.)*. This resale is generally accomplished through either the utilization of an in-house trading arm or the transfer of the countertrade obligation to an outside trading house. As a result of the increased frequency of the imposition of counter purchase requirements and the use of in-house trading subsidiaries, the in-house trading company is becoming an increasingly significant component in the overall corporate structure.

Future of Countertrade (A new model)

Small entrepreneurial firms can take advantage of the benefits that countertrade provides due to their dynamic and flexible structure. Countertrade has some unique demands which established giant companies may not be able to suit in. They might not deviate from established norms and regulations. Small firms producing unique products or offering special services but having low reserves of cash can take advantage of this position *(Vogel, 2000)*. Also entrepreneurial firms can demand premium prices for such countertrade contracts which other established companies may not agree with. In this way countertrade can check the supply while keeping the demand constant. This will increase the cost of products which they can use to their advantage to earn revenue and profits.

Results

We can find from the study that every form of trade is unique with their problems and benefits. Barter is a very old concept but even today it plays an important role in a modified manner. Today, it is not only restricted to goods but has been extended to services as well. Barter helps a country to exchange only in goods or services. So, it has the possibility to exchange the goods it has in excess for the goods that are deficit. Counter purchase enables a country to purchase from the same country to which it sells based on a single contract. This not only helps both the countries to meet their needs but also helps establish long term relationship between nations. Buyback option is a good way to utilize individual resources in a positive manner. Suppose country A has abundant raw materials but lacks the technical expertise to manufacture products using the available raw materials. It might export those raw materials to country B which has the technological expertise to manufacture finished goods from those raw materials. After manufacturing, country A again purchases the final products from country B. This helps generate employment in country B and solves the problem of scarcity of finished products in country A.

Discussion

By the above study, we can see that these mechanisms of trade without using hard cash holds advantages for several middles- and low-income economies, in today's globalized world no country can survive in isolation and trade and business forms an integral part of the income of any country. In such a condition, it becomes very difficult for a country to trade which has a deficit of hard cash. It may have several negative impacts on the local economy including inflation. However, such problems can be reduced if non-currency exchange trading systems are practised. Barter can be used for both goods and services as a country can sell either goods that it has in excess or may even sell some expertise or core competency in any particular sector in return for some other good or service that it lacks. A country which has a deficit of hard cash can first export some product to earn cash in return and later purchase products from the same country as part of the same agreement. It also helps the easy exchange of labour and resources across countries and helps hedge risks of the cash crunch.

Conclusion

Counter trade and agreements form an important aspect of today's economy. It helps companies to maintain existing markets and also expand to foreign countries. It increases sales and mitigates liquidity problems *(McVey, 1981)*. It cleans up bad debt situations, released locked capital and helps to maintain long term relationship with customers. It also helps gain contracts for future and finds low-cost sources for purchase. Some countries are in weak economic condition and cannot pay by hard cash and for them; counter trade provides a very efficient alternative *(Tim and Richardson, 2014)*. The political scenario in many countries and protectionist policies also makes them involve in counter trade with developed nations. It allows hedging against risks of inflation as trading in only don't in goods or services without the use of hard currencies. With the advent of new technologies, expansion of world trade and global business, this method of trade will gain more popularity and grow in future.

Abstract

Problem of complex objects management has become an important factor for the economic development of a country. A special role is devoted to acquisition of system thinking. Despite the vast scientific literature on system analysis, it is currently loosely connected totality set of technics and methods of informal and formal nature. Thus, what is called system analysis, presents not enough integrated corpus of methods, technics and tools for system activity. Nowadays, it is common knowledge, that the most urgent task of system research is the problem of an appropriate toolkit creation. This article deals with the problem of social-economic system comprehensive assessment. According to authors, it is possible to be solved on the basis of systematic approach under which condition description of this or that economic object is implemented not with individual indicators, but integrated set. Research purpose is to justify mythological approaches to system analysis on different socio-economic systems study using analysis of its ubiquitously internal structure and resources potential (space, time and energy). Presented algorithm of a consistent pattern intelligent search allows solving many system analysis problematic issues. These include: identification of system structure, removal of non-structural elements, establishment of analysed object basis indicators, emphasizing and description of subsystems and echelons of economic systems, models creation for final indicators, role of structure evaluation and determination in object organization.

A positive aspect of the proposed method is its versatility. This approach use allows identifying not only gaps in socio-economic systems and managing resource flows to achieve its best objective and effective use, but also to reveal mechanisms of socio-economic systems organization determining management ability.

Keywords: Socio-Economic Systems, System Analysis, Elements, Structure, Subsystems, Model and Ideal Model.

Introduction

The ideas of system city under various names, such as system synthesis, system ideology, system analysis become the leading scientific paradigm of the XX century. A whole "system movement" including different directions has appeared: general systems theory, system approach, system-

structural analysis, philosophical concept of the system of the world and knowledge *(Alekseeva and Vetrenko, 2020)*.

This process is caused by the fact, that in the middle of the XX century, scientists start talking about the need to change the scientific paradigm, as they realize that the old models no longer correspond to reality, they do not work, do not allow them to correctly assess present, predict and plan the future.
It is also can be applied to economic theory, which is based on a number of paradigms that are still often in opposition to one another. Economy based on plans ensures production and distribution processes. Classical political economy, which asserts market relations, describes exchange processes well. Government interventions in economy are justified with Keynesian theory. Economic liberalization is embodied in monetarism. Social research direction of social production is reflected in Marxism and institutionalism. Besides, there are a number of combined theories that are formed on the basis of mentioned above paradigms combination. At the same time, relevant description of real economic systems is not always possible within the frames of existing theories *(Papkov and Kulikov, 2019)*.

Crisis of economic theory manifests in the fact that it is unable to foresee and also to explain the causes of many economic transformations of recent decades, including economic crises. Implemented empirical studies are fragmented and do not lead to the discovery of fundamental laws or consistent patterns of ubiquitously nature, that could serve as a basis for theoretical constructions. In addition, a number of laws that has been empirically proven for decades are later refuted *(Volkova and Denisov, 2019)*.

In view of the foregoing, current problem of the development of modern economic theory is the choice or creation of a paradigm that could describe the main processes of economic development with a high degree of reliability and validity, anticipate and explain the causes of changes, and determine the mechanisms of their course.

Research purpose is to justify mythological approaches to system analysis on different socio-economic systems study using analysis of its ubiquitously internal structure and resources potential (space, time and energy).

Literature Review

System paradigm in economics represented the economy as a set of interacting, transforming and evolving systems acts, on the one hand, as an alternative to neoclassical paradigm with its economy division into macro- and microeconomics, and, on the other hand, as a concept, which integrates neoclassical, institutional and evolutionary approaches *(Edmondson, Kern and Rogge, 2019)*.

The goals of the vast majority of economic systems in market conditions are price maximization and profit. Elements of economic systems are structural divisions of an object and its management body, centres for processing material flows, sources, receivers, and information processing centres and etc. The more detailed system elements and their relationships are described, the more precisely system structure is determined and, consequently, its entropy (uncertainty) decreases.

There are different approaches to the study of socio-economic systems.

Hierarchical approach. This approach is based on an indication of a significant feature of a large system, namely the presence of a hierarchical structure of relationships between the general criterion for the entire system as a whole and private local criteria formed for individual subsystems of different levels of the hierarchy *(Alekseeva and Vetrenko, 2020)*.

The higher the level of the hierarchy, the less its elements have the properties of subjectivity and there are fewer degrees of freedom. All these limits the ability to extrapolate methods and models developed for analysing individual levels of the economy to other levels of its hierarchy.

Leading approach in the study of systems, including socio-economic approach, is the approach of structures assessment. Focus shift to the structural side of development is impossible without a holistic system perception of objects and a synthetic method of studying them as systems based on the "whole to part" principle implementation. Hence, the system approach and system analysis become the main tools of research in the economy *(Papkov and Kulikov, 2019)*.

The institutional approach is not supposed to divide structures considering significance level, studying both macroeconomic and microeconomic structures. It offers a special analysis apparatus based on methods of accounting and measuring transaction costs that determine organizations effectiveness and decision-making in management *(Alekseeva and Vetrenko, 2020)*.

An institutional subject is a carrier (information carrier) of certain specific rules and regulations as a result of individuals' coordination cooperation within the frames of this institution, which imposes economic restrictions on interacting parties' behaviour. At the same time, the institutional form, in which activity of subjects is, implemented for scientific and technical research and development, commercialization means "enterprise institute" *(Volkova and Denisov, 2019)*.

Evolutionary approach. This approach in economic science is not formed long ago. Since about the 1980s, it gains independent significance in scientific research works and has its development in the theory of systems along with models of system dynamics development.

Evolutionary approach develops four types of system models of different complexity levels: selection models, game models that take into account the effect of learning, and models of the "neural network" type allowing creating models of structural dynamics that are used in problem solving of economy restructure management *(Mahmoudi, Emrouznejad, Shetab-Boushehri and Hejazi, 2020)*.

Thus, the evolutionary methodology allows us to present system as non-equilibrium and identify the features of changes in its structure.

Cybernetic approach. The essence of the cybernetic approach is that in any system under consideration, which experiences a change in structure, there is a feedback mechanism that determines the dynamics of its characteristics *(Krajčo, Habánik and Grenčíková, 2019)*.

Synergetic approach. This approach considers behaviour of unstable nonlinear systems and conditions and assumes dynamic equations development of economic systems and the extension (revision) of the Samuelson correspondence principle, which describes stable systems. In terms of synergetic, there is a concept of multiple equilibrium, instability and structural instability/stability of the system. The transition from one condition to another is considered as a bifurcation that is a sudden and unpredictable violation of the continuity of development. According to the synergistic approach, all properties of the system are important, including its minor parameters and minor deviations. Thus, W.-B. Zhang, referring to the synergetic analysis, that stability is no longer assumed in science a priori, and minor parameter shifts can lead to structural changes in dynamic systems" *(Durmanov et al., 2019)*.

Synergetic approach is substantially related to the cybernetic approach and involves the implementation of several relevant features, namely the Law of Requisite Variety of Ashby, heterogeneity of systems and etc. Both approaches enhance ability of complex social systems effective management.

Structuralist approach. This approach is based on structural analysis methodology. It is based on the historical and descriptive method and includes sociological analysis of interaction of modern economy various subjects *(Roetzel, 2018)*.

Neoclassical approach. Models developed by neoclassical schools offer an explanation of management system economic development through descriptions of changes in its micro-level conditions. This approach is based on the Arrow-Debreu model, Samuelson correspondence

principle, the idea of economic efficiency according to M. Allais, the Solow model, the Lucas model, P. Romer and etc. The crown of the evolutionary method of analysing structural changes is the so-called innovation and technology school.

Innovative and technological approach. Success of innovations (their potential viability) is determined by properties of the objects on which they are reproduced. The organizational structure and management system of the economy substantially determine their effectiveness. Serious intersectoral analysis methodology generalizations are made by V. Leontiev's colleagues and students. Modern researches in the framework of the input–output model deals with the problems of combining consumption characteristics of different demographic groups *(Prestes Joly, Teixeira, Patrício and Sangiorgi, 2019)*.

Despite the vast scientific literature on system analysis, a number of issues remain insufficiently studied due to its complexity, connection with hierarchy and the variety of structural and functional relationships among elements. Sources of their probabilistic properties are not only an extremely large number of relationships between numerous parameters and difficulty of quantifying some of them, but also significance of external influences that change object condition forming and supporting the system of production and financial indicators. At the same time, the object itself must be considered as a higher-level system *(Koval, Nabareseh and Chromjaková, 2019)*.

Thus, data accumulated to nowadays show different approaches to analyse functioning of socio-economic systems, which is explained with complex relationships of their constituent elements due to their openness. These relationships are expressed in changing influence of environmental factors over time and space, arrival and removal of different quality resources, system components synergistic relationships, and complexity and diversity of the systems themselves. We conclude that their effective analysis is possible only in case of applying a systematic approach. Distinctive features of this approach are use of mathematical tools, logic tools, cybernetics and synergetic in comparison with the existing ones.

Methods

The study involves economic, statistical and economic and mathematical methods.

Results

Traditionally, conditions and causes of changes in the economic system are evaluated through production and financial indicators, although they are formed under the influence of many factors. That is, in-chain "factors – the economic system – production and financial indicators" the role of the enterprise, as a rule, not considered, which is caused, on the one hand, with description complexity and, on another hand, with approach absence for such a representation of an object *(Jin, 2019)*.

The efficiency of production process is the most important economic category that largely determines its existence in modern market conditions.

Practice has shown that the most attractive ones are general assessments of production efficiency based on the principles of a systematic approach. In this case, any economic object that combines a set of interacting material and financial characteristics is considered as a large system that maximizes its properties through mathematical models.

When combining elements within a system, qualitatively new properties and effects appear that are absent at the individual elements level – system properties, emergence effect, synergism and etc. They reflect generality and difference, stability and variability, repeatability and uniqueness of properties, connections and relationships of system elements, that is, they reveal their probabilistic and statistical nature.

An important aspect in understanding the properties of an element is its formation from the indicators of the object, which is possible, in our opinion, if the following conditions are met:

1) in the analysed matrix, there is a sufficiently large number of ≥ 3 x 5 features, that can create a common space, where indicators resourcefully interact with each other and create conditions for the structure organization;
2) each element is endowed with a higher-level system, in this case with an object, with special properties of communication with others that determine its resource capabilities;
3) elements interaction in the subsystem between subsystems and echelons of the pyramid are realized by moving resources determined with informational, energetically and material flows;
4) movement of resources is explained by the mandatory presence of resource-deficient (system-forming) and resource-owning (system-destroying) elements among all elements, which is determined with the higher-level system;
5) resource-deficient elements contain active contacts on their surface, while resource-owning ones contain passive contacts, through which resource flows are perceived and given away;
6) to solve the most important problems of the higher-level system, its elements are organized into subsystems;
7) inclusion of elements in subsystems is implemented considering the principle of minimal competition for resources between them, as well as the mandatory presence of one system-forming and two or more system-destroying elements;
8) if these circumstances are met, a structure is formed, a space filled with elements and exchanged resources, whose task is to solve the problems of the object (enterprise) most effectively based on environmental circumstances;
9) object indicators do not have all listed characteristics, they only have the opportunity to become an element if the above mentioned circumstances are met, transferring their potential energy to kinetic energy as a result.

Implementation of these circumstances leads to the creation of idealized elements that are organized with help of the higher-level system into an idealized hierarchical system.

Idealized element is an abstract element that lacks any physical properties, other than the ability to implement relationships with other similar idealized elements. Thus, the idealized element is completely determined by the nature and direction of its connections *(Volkova and Denisov, 2019)*.
Set of idealized elements united with the necessary connections forms system idealized model, which, obviously, can be conveniently and visually represented as a graph or a corresponding adjacency matrix.

This formalization of the system structure makes its presentation clear to the researcher and significantly simplifies its analysis. However, it should be taken into account that any element of the system can be considered as a system consisting of a number of other elements.

Thus, the idealized system of an object has, as a rule, a hierarchical structure, where elements are combined into subsystems located in echelons of hierarchical order.

System analysis usually begins with model building of investigated system. First and foremost, you must define the structure of the system.

Among many definitions of structure in the philosophical and methodological literature, the most adequate should be recognized as the formulation proposed by V. F. Sergeant describing structure as ".... a set of elementary objects and such material interactions between them, thanks to which this set forms a single material object with its qualitative and spatial-temporal certainty" *(Volkova and Denisov, 2019)*. Characteristically, this definition has not only morphological, but organizational meaning, because the structure is treated as a set of concepts: element, element connection, spatial structure and temporal organization of interaction.

Proposed approach includes the following steps:

1) evaluation of actual features of the system:
1a) checking for structure;
1b) rationing of all features to one parameter;
1c) removing outside structural elements;
2) analysis of the organizing structures of the system:
2 a) establishing for each feature its potential (resource capabilities) considering correlation sum for each feature;
3) assessment of the overall characteristics of the system:
3 a) determining location of the feature depending on the potential, identification of the stability index;
4) subsystems selection based on the principle of minimum filling of elements;
5) determining the load of elements in the subsystem;
6) building the actual and best model for the final element of the subsystem;
The main tool for these steps performing is the statistical software packages (for example, Statistica). Thus, for example, structure detection is performed using the main component method. When solving issue on the number of allocated structures (elements), two most important aspects are noted:
- system allocation can be talked, if there are at least three or more elements;
- increasing elements number leads to the complexity of the subsequent analysis.
In this regard, we propose to consider any system as a three-structure formation.

It should be noted; that analysis characteristic includes a large number of features usually heterogeneous by nature. In this regard, at the first stage of research, the problem usually arises of bringing all analysed features to a single base, which is a comparable form. Such problems are solved with data rationing. Least dependent indicators of a particular sample are used. In addition, rationing to bring the analysed features to a comparable form increases the data structure due to the fact that they become partially common to the entire structure.

Regression quality level depends on the degree of reliability of the source data and the size of the sample. Increasing the number of observations is one of the prerequisites for building adequate statistical models. Growth of the initial indicators "generates" the problem of multicollinearity, one of the indicators of its presence is the excess of the paired correlation coefficient of 0.8.

To eliminate it, we propose the following approach: sequential removal of object features using the method of clipping (iterations) considering the number of reliable correlations of the feature, which goes beyond $X+1\sigma$. For greater confidence in the absence and maximum removal of the influence of multicollinearity, it is necessary to remove all reliable pair correlations.

Practice has shown that with the help of the described method, non-structural elements of the system are removed, creating more expressed boundaries, reducing the degree of uncertainty of the structure, and improving the overall condition of the analysed system.

One of the most important regularities is that the system gives a higher level to all elements of system-forming (resource-deficient) or system-destroying (resource-surplus) features without exception. Hence, the selection of subsystems is carried out using factor analysis based on the principle of minimum filling, when they necessarily contain the maximum degree of system – forming (negative correlations) and the minimum-system-destroying (positive correlations) elements.

As long as, system-forming elements usually have a large weight (their number in the system is less), the organization of the subsystem follows the next principle: one system-forming element is supplemented with two or more destructive elements.

The number of organized subsystems is determined, on the one hand, with the potential of the system, and, on the other hand, with the level of adaptation of the system to the environment. As a rule, this is usually implemented as a larger number of organized subsystems.

From the remaining indicators, subsystems of the second and next orders are formed in the same way until the elements of this level (echelon) of the object's economic system are completely exhausted.

Determining the loading of elements in subsystems is based on correlation analysis based on the sum of the module of paired correlations in the matrix of their interaction.

The element with the minimum sum of the number modulus is an activating start: it changing causes the subsystem to start.

The element with the maximum amount is the result of the subsystem activity.

The resource bond in the subsystem between revitalization element and the final element is performed with an intermediate element whose number is determined randomly from the environment.

The next step is to build a model for the final element of the subsystem. For this purpose, multiple regression analysis is performed and a standard (actual) and best model is built based on its results.

Herewith the final element is always dependent variable, and the activation element and intermediate elements of the subsystem are independent features.

After elements are exhausted, they begin to form a higher-level (echelon) based on the "black box" effect, when the activation elements and the result of the activity of the lower subsystems rise structurally higher, and a new echelon is organized. In this case, the same steps are performed as in the first echelon, namely: identification of system-forming (resource-deficient) and system-destroying (resource-owning) elements; isolation of financial indicators from the economic system of subsystems; determination of the order of elements in the subsystem; construction of models of subsystems functioning.

After that, the next echelon will be organized from the activation elements and the result of the subsystems activity. This procedure is repeated until only one subsystem is structurally established or the structure for the remaining elements disappears.

Between echelon subsystems and the entire system echelons quite complex synergetic relationships are established and each subsequent subsystem obeys the previous one. The first subsystem launch is carried out by the higher echelon causes the next subsystem to automatically activation. Launch of control subsystem is started with environmental factors. Interaction between echelons is carried out on the principle of feedback.

Subsystems organization in the newly formed echelon is based on the same here-above principles. Operations are repeated until the presence of the control subsystem structurally established.

Conclusion

The presented approaches to the system analysis of socio-economic systems are, in contrast to the previously considered ones, one of the specific tools for implementing the system analysis of non-natural objects. A positive aspect of the proposed method is its versatility. This approach use allows identifying not only gaps in socio-economic systems and managing resource flows to achieve its best objective and effective use, but also to reveal mechanisms of socio-economic systems organization determining management ability.

Abstract

There is a lot of scientific research on the concept of trust and the impact trust has on business operations. Public decision-makers also try to avoid situations that negatively affect the level of trust in public organizations and may reduce the competitiveness of domestic economies. Although Supreme Audit Institutions (SAIs) through their activities support competitiveness in the business sector reducing the risk of opportunistic behaviours, their role in maintaining or enhancing public trust in SAIs is virtually an unexplored area. This preliminary study addresses this research gap. The objective of this research was to identify and describe specific activities that SAIs can take to mitigate the risk of loss of public trust in its operations without negatively affecting the benefits these organizations provide to society. This study was based on a literature review, an analysis of audit reports prepared by SAIs from Poland, USA, United Kingdom, Germany, Austria, Czech Republic, and an analysis of audit laws, regulations and standards. In addition, the study was based on information obtained from interviews carried out with SAI's representatives from Poland, the USA, Germany, and Austria. The results show that when SAIs take steps to mitigate the risk of losing trust they may create an epistemic injustice in the public audit process and they may limit their usefulness to their customers. The audit mechanisms that may enhance trust in audit institutions have been identified. The presented results may be useful for managers, practitioners and policy makers from different organizations in various ways.

Keywords: Performance Audit, Supreme Audit Institution, Trust, Epistemic Injustice.

JEL Classification: M 4

Introduction

While issues related to the strategies business institutions employ to enhance trust have been addressed by many researchers and business practitioners, the approaches employed by SAIs to strengthen trust in their organizations and the consequences of such approaches have not been the subject of much research. There is a need for such research because the audits and evaluations performed by SAIs provide critical information and recommendations to parliaments, governments, and other public and private customers.

SAIs' evaluations of public policy and the laws affecting public and private sectors have direct impacts on the private sector and the functioning of the whole innovation ecosystem and competitiveness. Therefore, the reliability of the SAIs' work is crucial to the proper functioning of the State, which is aptly highlight by the International Organization of Supreme Audit Institutions (INTOSAI), one of the biggest worldwide organizations that cooperate with the United Nations.
Although some of the research has been conducted on the nature and types of auditing activities performed by SAIs (Mosher, 1979; Pollitt et al., 1999; González-Díaz & Fernández, 2008; González-Díaz et al., 2012; Blume & Voigt, 2011; Bringselius, 2014; Dobrowolski, 2017; Dobrowolski &

Szejner, 2019; Cordery & Hay, 2019) there is a research gap regarding the actions that are or could be taken by SAIs to mitigate the risk of losing public trust in their activities and limit SAIs role in enhancing competitiveness in public and private sectors. The aim of this original research was to identify and describe specific activities that SAIs can take to mitigate the risk of loss of public trust in its operations without negatively affecting the benefits these organizations provide to society. The term "supreme audit offices" is understand in the following manner. There are nonpartisan public organizations, which are independent in relation to auditees, including the governments and subordinate only to parliaments. Basically, the do not belong to judiciary, although in some countries (e.g., Portugal, Greece) they are part of judiciary.

Theoretical Background

Trust has been defined, among other things, as an element of social capital (Tansley & Newell, 2007; Chen & Wang, 2008; Choudhury, 2008); an organizational resource, as pointed out by Tzafrir (2005) or Fang & Chiu (2010); the foundation of social interactions in organizations (Berg et al.,1995; Weber et al., 2004); the willingness to accept the behaviour of others (Schoorman et al., 2007); and the willingness of entrepreneurs to invest and trade (Aykens, 2005; Natalier & Willis, 2008; Styles et al., 2008; Dobrowolski & Szejner, 2019). Trust plays special role in the financial sector. Without trust, this sector could not exist (Cox, 2007; Ennew & Harjit, 2007; Devlin et al., 2015). Therefore, trust is a unique capital that always affects the cost of economic or public activity.

Social capital belongs to the most important values that constitute society's cohesion and proper functioning at the level of the state, organization or family is beyond doubt not possible without it. For organizations with large social capital, it is typically much easier to achieve outcomes beneficial for organization and its stakeholders, allowing to obtain prosperity and recovering entrepreneurship, leading eventually to competitive advantage for the organization (Burt, 2000; Marjański, Sułkowski, Marjańska-Potakowska & Staniszewska, 2019). Social capital should be a tie bonding together the society, businesses, and families, filling in the social gap between people and its sources should be rooted in the links and networks founded on principles of firm cooperation. Like in the case of other kinds of capital, social capital aims to facilitate the development and performance of the organization mainly by improving the relations between its members (Lin, 2017).

Over the past thirty years, social capital has grown to become one of the most influential ideas to explain social behavior at different levels (Lin, 2017). The concept of social capital is describe in many ways, and its relations with trust as well as human, cultural and relationship capital, which have the closest connection with social capital definitions, are multi-dimensional. Compared to related concepts, social capital with over 2,33 million references is closest to human capital (2,180,000), while cultural capital has 630,000 references and relationship capital – 7.750 (Scholar Google, 20.11.2019). There are also scholars whose position is that the concept of social capital is outdated. If we take a quick look at the classical definitions of social capital, we will surely see how diverse it is. Coleman (1988: 98) defined social capital in functional terms as "a variety of entities with two elements in common: they all consist of some aspect of social structure, and they facilitate certain actions of actors." For Bourdieu (1983) social capital is "the aggregate of the actual or potential resources which are linked to possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition". Putnam (2000: 19) sees it as "connections' among individuals and social networks and the norms of reciprocity and trustworthiness that arise from them", while Fukuyama defines it generally understood rules than enable people to cooperate. In this work, definitions dominating in the literature viewing social capital as social trust, connections, and social networks that facilitate cooperation and reciprocity will be used (Sułkowski, 2017).

State institutions that influence the cooperation of market participants by passing laws and regulations have a significant impact on creating and maintaining trust. While State policies can foster trust, the actions of the representatives of public organizations in implementing the polices can also erode trust. This statement leads to the generalization that SAI's role is to prevent the erosion of public trust.

Just as there is a dependency between business and trust, there is also a dependency between auditing and trust. Lack of trust in public organizations can contribute to the necessity of their frequent auditing. If audits are perceived as a tool to be used in the continuous improvement of organizations' outcomes, they may strengthen the audited entities, and enhance public trust. An audit can enable an auditee to correct errors and/or irregularities and it should be considered to be a regular process that enables organizations (that create a particular system) become predictable in pursuing desired goals. The loss of control over audit processes leads, among others, to formalism and destroys trust (Bradach & Eccles, 1989; Das & Teng, 1998; Caldwell & Karii, 2005). Audits may erode trust (Castelfranchi & Falcone, 2000).

If there is a correlation between trust and audit one may generalize, that the audit is more effective when is conducted in a trust-based environment. Taking into account that auditing can enhance trust in auditee' operations (Das & Teng, 1998; Caldwell & Karii, 2005; Skinner & Spira, 2003) it is clear that auditing organizations and auditing systems need to include mechanisms designed to mitigate the risk of the erosion or loss of public trust. However, such mechanisms should not reduce the effectiveness of the audit.

If opportunistic behaviors increase the cost of audit activity and may lead to the wrong decision (Williamson, 2000), the auditing instruments implemented by audit organizations, such as SAIs, should be designed to reduce incentives for opportunistic behaviors in auditees through enhancing integrity, reliability, and accountability. They should also reduce opportunistic behavior among their auditors. However, implemented mechanisms cannot reduce the appropriateness of public decisions through the reduction of available data when making a decision due to avoidance of the risk of losing trust. Otherwise, the regularity of decisions is always limited due to the inability to make use of all available data when making decisions.

In contemporary western and developed countries, the role of the SAI is critical because SAIs are important pillars of parliamentary democracy that assist legislatures in the exercise of their rights concerning actions carried out by executive branches. Although governments have a major responsibility for creating an environment that does not favor or enable the occurrence of irregularities, SAIs have a key role to play as an advocate of good governance. The important role SAIs plays in promoting good governance typically results from their special position in relation to the government. SAIs usually are subordinate only to their Parliaments, and their audits are independent of their executives and judiciary branches. Having broad audit rights, SAIs typically evaluate the functioning of all government operations and the execution of public funds. From such a broad perspective they can provide guidance on how to strengthen public institutions (INTOSAI, GUID 5270; INTOSAI, GUID 5260; Dobrowolski, 2017).

The nature and scope of the SAIs' important role in the public and private sectors can be demonstrated by an examination of the functions they perform. One can distinguish the following SAI functions: control, informative, regulatory, advisory, and preventive, investigative, educational, and political. How the SAI carries out its audit derives from laws and regulations. Audit effects depend not only on the SAI's efforts but also on inter-organizational collaboration. All SAIs' efforts are intended to establish the facts based on audit evidence, determine the cause and effects of irregularities or best practices, and make proposals (recommendations) to eliminate irregularities in and or improve auditees' activities. By providing decision-makers and the general public with fair and objective results of the audits, SAIs affect the activities of institutions using public funds by promoting an attitude of respect for the law, integrity, transparency and accountability. The results of SAIs' financial audits help to reassure policymakers that they have reliable data about the financial status of public sector entities. The SAIs' conduct analyses to determine whether auditees apply the best accounting practices. This means that SAIs do not only monitor compliance with accounting rules but also propose approaches to improve accounting systems (Dobrowolski, 2017; European Court of Auditors, 2019).

The Welfare concept that is well known in developed countries has been associated with significant increases in public expenditures. This affects the scope and manner of state audits. While the reliability of financial data is still a crucial element of the state audit, it is no longer sufficient. Currently, there is a

need to examine and evaluate the effectiveness of the executive power resulted from the need to maintain an "in check" of government spending. Such audits are defined as performance audits, or value for money audits and were introduced in most European democracies after World War II. In some new member states of the European Union, this was at the end of the 20th century after the reintroduction of a free market economy and democratic order in those countries. Among the reasons in favor of carrying out this kind of audit is accountability. Decision-makers are responsible for the efficient management of public organizations that includes legal and reliable spending of public funds and efficient, cost-effective implementation of tasks. The results of the performance audits give citizens an insight into the course and results of actions taken by state institutions or bodies financed from the State (public sector). The need to study the efficiency of public organizations results from the nature of governance. Representatives of the authorities try to meet the expectations of its citizens and gain their trust and thus obtain the chance of re-election. Therefore, they demand, on behalf of the citizens, efficient realization of public tasks (Dobrowolski, 2017).

The objectives of the performance audit vary in different countries. They may be defined in the SAIs' basic legislation or be a matter for internal decisions within the SAI. In general, most SAIs set to achieve one or more of the following objectives: 1) to provide the legislature or discharge authority with independent assurance as to the economic, efficient and/or effective implementation of policy; 2) to provide the legislature or discharge authority with independent assurance as to the reliability of indicators of or statements about performance that are published by the audited entity; 3) to identify areas where performance is poor and thus to help the audited entity, or government more generally, to improve their economy, efficiency and/or effectiveness; 4) to identify examples of "best practice" and draw these to the attention of government and/or audited entities (Contact Committee of Presidents of the SAIs of the European Union, 1998).

The audit objectives described above leads to a generalization about the SAI role. SAI audits play an important role in the information network. During SAI audits public organizations and the public may participate in by providing comments suggesting proposed solutions to problems identified. Although these suggested solutions may have been identified by the government directly, the gathering of such information in the audit work of the SAI (independent of the executive branch, which has no supervisory powers in relation to public organizations) helps in an impartial informing of decision-makers about the problems faced by the public administration. Using this process and enabling public consumers' inputs, SAIs promote the democratization of the public sector. Results of audits carried out by SAIs gives citizens an insight into the course and results of actions taken by organizations financed by the State, and the statements of the persons responsible for the execution of specific tasks. The aim of SAIs is to ensure the accountability of those who are responsible for resource management in the public sector. SAI analyses provide information on the extent to which public administrators' activities are based on the generally applicable legal standards. This helps to guarantee citizens that officials will be predictable, and on the other hand ensure citizens' equality before the law and impartiality of public officials in decision making. SAIs examine whether the activities of public organizations are reliable, but also whether better results may be delivered. Through their informative function SAIs also realize other functions, including civic and general education (Dobrowolski, 2017).

SAI plays an important role in maintaining the innovation ecosystem, which is defined as the network of interconnecting and interacting organizations. An innovation ecosystem models the economic dynamics of the complex relationships that are formed between entities whose functional goal is to enable innovation. In this context, parts of such ecosystem include the material resources and the human capital (Jackson, 2011; Dobrowolski & Szejner, 2019). The functioning of innovation ecosystem requires compliance culture, where preventive measures against opportunistic behaviors of different individuals are taken in place. This compliance culture should be maintained by SAI, which evaluates the conditions of ecosystem functioning (Dobrowolski & Szejner, 2019).

SAIs through their activities support competitiveness in the business sector reducing the risk of opportunistic behaviors. For example, SAIs identify constraints that reduce competitiveness of entrepreneurs and countries, in particular, SAIs assess the effect the deficit has on the country' competitive position in the world, focusing on the issues and challenges the deficit poses for the future

regarding education, health care, banking and capital markets, the environment, and transportation infrastructure. They analyze how do public organizations assess their progress in the ongoing improvement of public tasks, which helps implement the learning culture necessary to build intangible assets and using them create tangible outcomes. SAIs present audit findings in written reports addressed to the legislature. The right of the public disclosure of audit results is limited by the protection of the interests of the state and the auditee. Audit reports are typically available to the public unless they contain classified information. (GAO/RCED-92-16, 1991; GAO-18-656, 2018; Najwyższa Izba Kontroli, 2017; GAO, 1990; GAO, T-IMTEC-90-12, 1990).

Research Objective, Methodology, and Data

The theoretical reasoning and empirical evidence presented above suggests the following research question. Can efforts taken by SAIs to reduce the risk of losing trust in their activities negatively affect the benefits SAIs provide to society?

The following methods and techniques used to identify and describe the specific activities that SAIs can take to mitigate the loss of public trust:

- A comprehensive literature review.
- An analysis of audit reports prepared by SAIs from Poland, USA, United Kingdom, Germany, Austria, Czech Republic (listed in references), and an analysis of audit laws, regulations, and INTOSAI standards (listed in references).
- Informal interviews carried out with SAI's representatives from Poland, the USA, Germany, and Austria. These interviews were conducted with SAI officials in person (all – 6 officials who participated in meetings of INTOSAI Working Group Fighting Against Corruption and Money Laundering in 2008-2016. These officials were asked to provide information regarding which SAI's activities they perceived, as attempts to mitigate the risk of losing trust in their SAI.

The selection of the SAIs included in this study was based on the following criterion - the SAI's legal authority and capacity to conduct financial and performance audits. All selected SAIs report to legislative authority and they are independent on the executive branch of the State. The research methodology, presented above, was carried out is in line with the requirements of the triangulation of data collection and research methods used in management science.

Results and Discussion

Approaches that build trust in the supreme audit office

What follows is a presentation of results of the analysis of four major approaches that SAIs utilize to maintain trust in their organizations and an assessment of the effect of each approach.

SAI position in the macrostructure of the State

Trust can be considered as a key factor in the relations between the provider of goods or services and the client. The following values influence customer trust: 1) satisfaction with the services or products provided; 2) sense of justice and security (Pizzutti & Basso, 2012; Roman, 2003); 3) Customer loyalty, which can be explained to a substantial degree by customer satisfaction (Ball et al., 2004; Eisingerich & Bell, 2008).

These generalizations are also true in the case of SAIs' relationship with their clients. According to INTOSAI standards, SAIs have to continuously strive to increase their credibility. This enables them to fulfil their functions and ensure their potential value to citizens. SAIs only deserve trust if they are objectively judged as being credible, competent and independent. To make this possible, they need to be

model institutions, being an example for others in the public sector and the auditing profession to follow. (INTOSAI, ISSAI 12).

Although SAIs cannot be independent because they are typically subordinate to their Legislative Branches, they normally have functional and organizational independence required to accomplish their tasks (INTOSAI, ISSAI 1). This requirement established in official INTOSAI standards can help reduce the risk of losing public trust due to improper relations of SAIs with auditees. According to INTOSAI standard - ISSAI 1, Supreme Audit Institutions shall be provided with the financial means to enable them to accomplish their tasks. Supreme Audit Institutions shall be entitled to use the funds allotted to them under a separate budget heading as they see fit (INTOSAI, ISSAI 1). Review of SAI laws from analysed countries (Poland, USA, United Kingdom, Germany, Austria, Czech Republic) confirms, that these SAIs have financial independence from the executive branch. Of course, it would be naive to think that SAIs are financially independent of those ruling the State. The political parties that form governments have the majority in parliaments or are in coalitions ultimately decide about SAI budgets . An important characteristic of SAIs is that they are financially independent of auditees. This helps to ensure the basic requirement of audit objectivity. This requirement was pointed out by all interviewed SAI auditors as crucial for maintaining SAI impartiality.

The nature and type of work SAIs undertake

In general, SAIs do not carry out ex-ante audits. This approach makes it much easier to manage the risk of losing public trust. It is much easier to assess the process and its effects as part of the ex-post-audit. It is obvious that based on the auditee experience, having an overview of all the conditions accompanying the performance of public tasks, one can formulate assessments, comments, and recommendations from the long term "sage's perspective". Analysis of SAI reports (listed in references of this article) showed that the assessment of effectiveness, legality, reliability, and saving of auditees prevails in audit reports. Interviewed auditors confirmed that there is much easier to evaluate the activities of auditees that lead to savings than the efficiency of auditees. Their answers are convergent with research, where one pointed out the fact, SAIs avoid the assessment of efficiency of auditee's economical activities (Pollitt et al., 1999). Meantime, such an assessment is necessary for a comprehensive assessment of public activity.

It is clear that there is some ineffectiveness of SAIs in the fight against corruption or money laundering. This is pointed out in the results of a study published by Transparency International of the Basel Institute of Governance. The level of corruption or the threat of money laundering are significant in the countries analysed in this research study (Transparency International, 2019; Basel Institute of Governance, 2018). These two public diseases have disastrous effects on the economy and society. (Rose-Ackerman & Palifka, 2016; Chayes, 2016; Fisman & Golden, 2017; Dobrowolski, 2017).

There is a research problem related to the functioning of SAIs identified during this research work. There is a lack of scientific research on how SAIs select areas or organizations to be audited. For example, data is unavailable on how much of their work is directed by Parliament? Meantime, these questions are crucial from the point of SAIs benefits for societies. A good mix of parliamentary requests with SAI's own audit initiatives may increase the SAI usefulness for society in a short time. Audit recommendations, resulting from audits carried out from SAI initiatives, provided to auditees may help resolve some management and particular society problems. But this does not necessarily mean that such audits (initiated by SAIs, and not by parliaments) are crucial from the interest of whole country and society, specially from the long-period perspective. Interviewed auditors confirmed that their SAIs undertake audits that are based on SAI initiatives as well as parliamentary requests.

Undertaking self-initiative audits can be a way to build SAI image as society useful organization, and the same time, the way to avoid the risk of losing SAI reputation caused by examining the issues that SAI auditors do not have sufficient knowledge and skills. However, in order to increase the utility of SAI for parliament, the number of audits ordered by the parliament might be increased as a proportion of the total number of audits carried out by SAI.

Using arguments formulated by Fricker (2007) one can state that prejudice of auditors wrongly deflates judgement of the credibility of auditees. Such unduly deflated credibility of auditees may be not only an epistemic dysfunction but it may also be an ethical dysfunction. For example, if an auditee is wrongly assessed by the auditor with a lack of credibility. Such a situation can be understood as an epistemic injustice in public audit. To prevent this, a number of approaches have been introduced in the SAI. First, is the requirement that an auditor must be excluded from the audit when there is a conflict of interest. Secondly, the principle of many eyes is implemented. For example, draft audit reports are reviewed by several senior auditors. Thirdly, the audit process provides for the auditee's submission comments on audit findings including its methods, assessments, conclusions and recommendations. These approaches should reduce the risk of loss of public trust arising from epistemic injustice.

According to the INTOSAI standards "auditors should actively manage audit risk, which is the risk of obtaining incorrect or incomplete conclusions, providing unbalanced information or failing to add value for users. Many topics in performance auditing are complex and politically sensitive" (INTOSAI, ISSAI 300). The analysis of this statement leads to a generalization that INTOSAI representing SAIs may recommend that risky topics be avoided. Interviewed auditors confirmed that their SAIs do not audit politically sensitive issues such as assessment of advisability of actions undertaken by local government decision makers. However, such avoidance of risky topics may also limit the role of SAIs as the public auditor. Also, avoidance by auditors of some topics leads to unequal treatment of auditees by auditors. Taking into accounts this fact one can generalize that the solutions adopted by the SAI to limit the risk of loss of public trust in SAI through limitation audit scope may catalyse epistemic injustice in the public audit process.

There is also another problem that should be discussed in future research. Do SAI audits identify areas of good performance? Review of SAI audit reports (listed in the bibliography of this article) did not confirm that SAIs always focus their activity on identification of areas of auditee good performance. Also interviewed auditors could not confirm that their SAIs always identify examples of auditee good performance. Taking into accounts this fact, one of one's concerns may be that SAI audits mainly tend to focus on weaknesses and do not inform the public of positive aspects of government operations. Such a focus on negative aspects of realized government tasks could contribute to erosion to public trust in governments.

SAIs use various audit methods and techniques to reduce the risk of incorrect findings, conclusions, and recommendations

Today's SAIs are unable to review and evaluate all expenditures, due to the size of the public sector. This creates a problem with the credibility of certifying the correctness of keeping books and preparing financial statements. There are therefore solutions mitigating the SAI's risk of issuing an incorrect opinion about the financial statements or more broadly about audit findings, conclusions, and/or special considerations for recommendations. First, SAI uses the well know concept of materiality and audit risk (INTOSAI, ISSAI 1003). The application of the audit risk, materiality, and audit sampling approaches help to reduce or manage the risk of reaching an inappropriate audit conclusion and helps to mitigate the risk of losing audit trust (which one may define as the willingness of stakeholders to use the results of SAI audits when making decisions). However, it cannot be ruled out that even after employing the proper sampling techniques, the auditor can incorrectly assess the audited evidence. Based on interviews with SAI representatives, it was established that one approach to limiting such risk is the introduction of a requirement to place randomly drawn audit evidence in audit working files. The Polish SAI also requires auditors to digitize audit evidence.

Based on interviews with SAI representatives, it was established that typically it was the practice followed by SAI auditors was to make notes from the review of documents - "auditor's notes". Such a practice of allowing auditors to make auditor's notes from the document review may be considered as the weakness of the audit procedure. There is a risk that the information contained in such auditors' notes is unreliable. It was also established that audit methods enable auditors to treat the interviews with representatives of auditees as a valid source of information. Such an audit approach related to information provided by auditees can be considered as a manifestation of confidence in auditees.

However, relying only on interviews with individuals from auditees instead of analyzing documentary evidence also generates the risk of incorrect audit findings and evaluations. This may undermine trust in SAIs.

To minimize the risk of an incorrect assessment of the activities SAIs typically reach agreement on draft reports that outline the audit findings and conclusions with auditees. Agreeing on the draft documents should be considered not only as a way to reduce the risk of wrong auditor's assessment but also as a tool of reduce the risk of weak implementation by auditees SAI recommendations. In such situations, SAI may ask about the implementation of recommendations despite the absence of the legal authority to oblige auditee to implement recommendations. Through making available to the public "agreed with auditees" audit findings, opinions, comments, recommendations, SAI may require the implementation of recommendations, arguing that audit reports have not been questioned (INTOSAI ISSAI 1003). In the well-known concept - change management, trust plays an important role in communication and allows decision-makers to carry out any change more effectively (Neves & Caetano, 2006; Lee & Teo, 2005). The process of agreeing to SAI's audit reports with auditees can be considered as the tool of increasing trust in change management.

The SAI's inability to assess the advisability of actions undertaken by auditees, as well as, the replacement of ex ante audit by the ex-post audit favors limiting the risk of loss of public trust. Another SAI approach that limits the risk of losing trust is the optional nature of SAI audit recommendations. Audited entities are not required to carry out SAI audit recommendations. SAIs' recommendations typically only point to the possibility of improving audited activities; with the final choice of solutions improving the operations of the audited entity belongs to its management (INTOSAI, ISSAI 300). If relevant and allowed by the SAI's mandate, auditors should seek to provide constructive recommendations. However, they should be phrased in such a way that they should not encroach on the management's responsibilities. In other words, while auditors can make recommendations, they need to take care that they do not assume the responsibilities of the responsible parties (INTOSAI, ISSAI 300). The optionality of audit recommendations is therefore, a tool that limits the risk of losing trust in SAIs. However, the optional nature of SAI recommendations can limit the overall effectiveness of SAI's activities. Because of the optional nature of recommendations, auditees may adopt an approach of avoiding proposed changes by claiming that steps to realize SAI audit recommendations are in progress.

SAIs treat their audit reports as products, which should be properly advertised and promoted to enhance public trust.

Information is a product of SAI, like in the case of mass media. The adoption of this statement as obvious allows one to determine the dimensions of trust and use of research results regarding trust in the media. There are the following dimensions of trust: credibility (Audi, 2008; Ganesan & Hess, 1997), competence, predictability, relevance, and brevity (Audi, 2008). All those dimensions are taken into accounts in SAIs and their audit reports (National Audit Office, 2006; U.S. GAO, 2019; Rechnugshof Österreich, 2018; Czech Republic Supreme Audit Office & Bundesrechnungshof, 2019; Najwyższa Izba Kontroli, 2019).
Analysed audit reports have a specific structure. Typically the initial section of an audit report presents the principal audit findings, recommendations or special considerations for recommendations. Detailed information is presented in other parts of the audit reports. The audit reports are concise, precise and written in an un-bias manner. SAIs use a standardized physical makeup for their products to help make them recognizable as SAI products (National Audit Office, 2006; U.S. GAO, 2019; Rechnugshof Österreich, 2018; Czech Republic Supreme Audit Office & Bundesrechnungshof, 2019; Najwyższa Izba Kontroli, 2019).

In all studied SAIs press releases are prepared that focus on the most important findings and conclusions of audits. Interviewed auditors confirmed that SAI employees responsible for media policy have the task of determining when to provide the media with information about the results of the audit. Of course, the audit reports are delivered first to the statutory organs such as parliamentary committees, and appropriate members of the government. The moment of making the information available for other

stakeholders is important. Information about the results of the audit should not be secondary or tertiary information of the day. Appropriate SAI internal entity has primary responsibility for ensuring the media receive accurate and timely information about SAI activities. Information about audit results is presented in such a manner that they have to focus the attention of decision-makers and the public on SAI activity. Interviews with SAI representatives and the author's observation show there is the requirement that audit information should consolidate the positive image of the SAI and enhance public trust in SAI. The generalization about the promotion of SAI audit reports (SAI advertisement) is justified.

Conclusions

This research study found that: 1) Audit trust can be defined as the willingness of stakeholders to use the results of SAI audits when making decisions; 2) SAIs use different activities for limiting the risk of losing public trust in SAIs. One of them is the process of reviewing SAI's audit reports with auditees. This process, however, needs special security tools to prevent auditor's opportunism; 3) Epistemic injustice in public audit can be understood as a situation whereby the auditee who receives a prejudicially deflated degree of credibility from an auditor is wrongly assessed; 4) The exclusion of certain areas of public activity from the SAI audit due to the avoidance of risky topics and protection against weakening trust in SAI is a manifestation of epistemic injustice; 5) To prevent opportunistic behavior among SAI auditors and do not reduce SAI usefulness for society SAIs should convince themselves that lack of mistakes in their audit activities should not be perceived as the indicator of professionalism but also it may be indicator of improper SAI activity. SAIs have the right to make mistakes and correct them; 6) In order to counteract the negative consequences of SAI artificially increasing its audit's utility for parliament and society, parliamentary verification of SAI audit initiatives is necessary. Audits undertaken on the own initiative of SAI and not commissioned by parliament should be the subject of a periodic evaluation carried out by the special parliamentary commission to establish the necessity of such audits for the country and society and their benefits. Such review, however, should not limit the SAI audit's independence stated in INTOSAI standards.

The research assumption was also to identify research problems that need to be solved during future scientific research. This goal has been achieved. The following research questions were identified during this research: 1) To what extent SAIs focus in their audits mainly on weaknesses in government activities? 2) Do they realize how such activity (described in question 1) influence on public trust in the State?; 3) How does such SAI activity erode the public trust in the State? 4) How does SAI select areas or organization to be audited if audits are undertaken from SAI own initiative? How much of SAI audit work is commissioned by Parliament? To what extent audits undertaken by SAI on its own initiative covered key problems of the functioning of the state and its institutions?

The generalizations formulated in this article are not an attempt to create a new paradigm but indicate the direction in which further research into public auditing and its impact on public trust should be pursued.
One can formulate the following perspective of the competitive role of supreme audit institutions in building trustworthiness for customers. SAI should constantly develop the informative function of state audit knowing that strengthening this function provides ongoing accountability within the government and the SAI, and will create a preventive environment that does not favour organizational pathologies in the State. The informative function of the state audit should be realized by presenting complete and accurate audit findings, conclusions and recommendation in audit reports. SAI should precisely explain and public present audit methodology used during the audits, especially audit sampling. SAI should consider the public access to digitalized audit working papers, where audit evidence is gathered which are the base for audit reports. This will strengthen SAIs' trustworthiness for their customers.

Abstract

Wages and labor productivity are important indicators of the standard of living and economic development of the country. Based on data on the manufacturing industry and the economy of Kazakhstan, the article analyzes the dynamics of labor productivity and average wages under the influence of the introduction of new technologies. The results show that there is a gap in labor productivity and wages depending on the degree of diffusion of new technologies in various sectors of the economy. Analysis of statistical data on wages and other indicators was carried out for the period 2010—2018. A relatively stable level of wage inequality was discovered, which was largely due to the influence of new technologies.

Keywords: Product and Process Innovation, New Technologies, Wage, Labor Productivity, Kazakhstan

Introduction

In developed countries, there is a process of structural transformation of the economy under the influence, first of all, of the introduction of the latest technologies. Technological innovation has been identified as a key driver of long-term macroeconomic growth (P. Romer, 1986). Kazakhstan has focused on the transfer and development of new technologies and achieving sustainable economic growth based on them (Nazarbayev N. (2017). But its practical implementation has revealed a number of complex problems. New technologies are created mainly in leading developed countries of the West. Transfer and development of new technologies, the subsequent creation of local technologies based on them turned out to be a long process. Until now, the innovative component of the Kazakhstani economy remains insignificant. According to the WEF Global Competitiveness Report 2019, Kazakhstan ranked 95th in the “Innovation capability” indicator (The Global Competitiveness Report, 2019).

Researchers typically classify innovation as process innovation and product innovation. Enterprises are introducing technological innovations to save costs, product innovations - to expand demand. A large amount of research is devoted to the above considerations, a small number of studies examine the impact of process innovations on wages and labor productivity.

In this regard, the study of the impact of technological innovation on labor productivity and wages in Kazakhstani practice is of particular interest. In our study, we used empirical data on the effect of technological innovation on the wages and labor productivity at the level of the economy as a whole

and of an individual industry for a comparative analysis. Studying the relationship between the variables in question makes it possible to identify many different factors that impede the development of an innovative economy in Kazakhstan.

Methodology and Analysis

It is well known, that in recent years in the developed countries of the world there has been a high rate of introduction of the latest technologies. In the extensive literature on this topic, the main attention is focused on employment and unemployment, the creation and destruction of jobs. And the important issues of the impact of new technologies on wages and labor productivity are not sufficiently explored. The work of a number of researchers, including D. Acemoglu, and D. Autor (2011), G. Cortes, N. Jaimovich and H. Siu (2017), G. Lordan and D. Neumark (2018), OECD (2017), B. Dachs (2017),: Ya. Kuzminov, L. Ovcharova, L. Jacobson (2015) and others. New technologies mean new more productive jobs, that require high professional skills and knowledge from workers. It can be said that in the final analysis, economic growth depends to a decisive degree on the number of created new jobs. The use of new technologies is associated with an increase in labor productivity and with a higher level of wages. New technologies affect labor remuneration in the industries where they are applied: professional diversification in the labor market is deepening, new activities are emerging, etc. It is also important to emphasize one feature of the Kazakhstan model of the labor market. It consists in the fact that the adaptation of the labor market to changes in the economic situation occurs mainly due to changes in wages, and not due to changes in employment. But high employment and low unemployment is achieved due to low labor productivity and low wages, insufficient investment in new technologies.

We are investigating the question of whether technological innovations play a significant role in increasing labor productivity and wages in Kazakhstan. Does our assumption that the difference in productivity and wages in sectors of the economy is generated by the different scales of the funds they spend on the development and development of new technologies is confirmed. For analysis, we used statistics from 2010-2018, which cover the manufacturing industry and the economy as a whole (Statistics Committee of the Republic of Kazakhstan). Labor productivity we measured the ratio of production to the number of employees.

We limited ourselves to comparing the paths of changes in the average nominal wage in the economy of Kazakhstan and in the most innovative industry - manufacturing. Figure 1 shows that 71.32% of the total cost of innovation in the economy is in manufacturing.

Figure 1: The share of costs for product and process innovations by type of economic activity, % (2018)

(Created by authors based on data of Committee on Statistics of the Ministry of National Economy of Kazakhstan Republic)

Figure 2 presents data characterizing the following data in dynamics: the sum of the costs of technological innovation in the economy and manufacturing industry in absolute figures (billion tenge) and, accordingly, their ratio as a percentage of GDP and the volume of manufacturing industry output. As we see, over the period under review, the average annual value of the growth of costs for technological innovations in the manufacturing industry exceeded 4.5 times that of the economy as a whole. Nationwide, manufacturing is the most active innovation industry.

Figure 2: The costs of technological innovation in the economy and manufacturing of Kazakhstan

(Created by authors based on data of Committee on Statistics of the Ministry of National Economy of Kazakhstan Republic)

We examined the issue of the impact of new technology on wages in comparison with the dynamics of its productivity. Figure 3 presents a comparison of the dynamics of labor productivity and wages in the economy and manufacturing in 2010–2018. Over this period, labor productivity in the economy grew by about 1.29 times, in manufacturing - by 1.22 times. The average wage increased 2.10 and 2.36 times, respectively. A phenomenon paradoxical for a market economy is observed: firstly, in both cases, the growth rate of wages is much faster than the growth rate of labor productivity; secondly, in the manufacturing industry, the rate of labor productivity is lower than in the economy, but wages in it are growing faster. That is, the growth rate of wages in the economy lags behind the growth rate of wages of workers in an active innovation industry.

As can be seen in Figure 3, the trend of the long-term relationship between these indicators is almost unchanged. The reasons for this situation can be briefly summarized as follows:

- the increase in labor costs caused by the excess of the growth rate of wages over the growth rate of labor productivity is offset by a more significant increase in prices for manufactured products (see table 1). If the average annual price increase for industrial products of manufacturers in the European Union amounted to 1.2%, in Germany - 1.1%, then in Kazakhstan - 8.2%;
- in developed countries, wage growth is in a more stringent relationship with the growth of labor productivity. In turn, an increase in labor productivity in these countries is achieved on the basis of V and VI technological structures. In Kazakhstan, medium and low technological patterns prevail Dnishhev, F., F. Alzhanova (2014);

- the inertia of the behavior of the subjects of the labor market that has developed under the conditions of the previous labor legislation and the policy of the authorities that prevent dismissals;
- the low level of the competitive environment does not contribute to increasing the interest of the private sector in introducing new technologies, etc.

Figure 3: Dynamics of wages and productivity (2010 = 100%) (Created by authors based on data of Committee on Statistics of the Ministry of National Economy of Kazakhstan Republic)

Table 1: Annual increase in industrial producer prices, % (Created by authors based on data OECD and of Committee on Statistics of the Ministry of National Economy of Kazakhstan Republic)

	Annual increase in industrial producer prices, %								
	2010	2011	2012	2013	2014	2015	2016	2017	2018
European Union (28 countries)	3	4,7	2,3	0	-1,4	-1,6	-0,9	2,9	2,2
Germany	2,6	3,5	1,5	-0,2	-0,2	0	-0,7	1,9	1,5
Kazakhstan	12,9	20,3	2,1	-0,5	-1,6	-4,8	15,5	17,6	12,4

Results

The results of this study as a whole confirms the thesis that wage growth in the innovation industry is ahead of wage growth in the economy as a whole. The impact of new technology on this growth through increased labor productivity was negligible. One of the main reasons is the lack of interest of private sector enterprises in the implementation of the latest technologies in the current conditions.

.Summary

There is a non-linear relationship between technological innovation, wages and labor productivity, which depends on the level of implementation costs and the degree of novelty of most technologies. The Kazakhstan example also shows the need to normalize the relationship between the growth rate of labor productivity and wages. This will allow enterprises to pay more attention to accelerated technological modernization of their production. As a result, one can count on sustainable economic growth.

Annotation

The relevance of the research topic is due to the fact that human capital acts today as the basis for the formation and development of post-industrial society. It is this fact that has led to an increase in the interest of theorists and practitioners to study the processes of formation of human capital, its place and role in social-economic development. Physical force was the leading factor of production in pre-industrial society, machinery in industrial society, and human capital in post – industrial society.
The purpose of the study is to assess the impact that the quantity and quality of human capital have on the volume of national wealth and the level of socio-economic development of society. The paper analyzes the following on the global economy scale: the sectoral structure of employment, which acts as one of the criteria for the formation of a post-industrial society, the structure of national wealth and the state of human capital. The article presents the assessment of these indicators in the Russian economy. Underestimating the consequences of losses and a decline in the quality of human capital can permanently consolidate Russia's economic and social lag on the world stage. Today, Russia's priority task is to ensure the quality of human capital and achieve high rates of economic growth on this basis.

Keywords: Human Capital, Post-Industrial Society, National Wealth, Human Development Index, Economic Growth.

Relevance and problem statement

The formation of the post-industrial system has led to an increase in the interest of theorists and practitioners to study the processes of formation and development of human capital. Post-industrialization meant a transition from material factors of production to spiritual and intellectual ones. Physical force was the leading factor of production in pre-industrial society, machinery in industrial society, and human capital in post – industrial society. Today, human capital is the basis for the formation and development of a post-industrial society.

Labor, as a factor of production, was the most accessible resource at all stages of human society development. Therefore, we can only talk about modifications of its content in the evolution process of technological methods of production. At each subsequent stage of socio-economic development, human labor becomes more and more intellectual, successively passing through manual and mechanized stages. In post-industrial society, the largest social group is employees with higher education. The role of the labor activity motive passes from material incentives to the possibility of creative self-realization. In a post-industrial society, the labor force received the qualities of capital-human capital.

The degree of the problem development

The development of human society is viewed through the upward growth of its complexity as a social-economic system. The historical classification of the stages for society development, in addition to the modern system, should include systems of the past and the future. In the theory of post-industrial society, pre-industrial, industrial and post-industrial systems are distinguished. D. Bell is considered the founder of the post industrialism theory (Bell, 1974). In modern Russian science, the leading expert on the concept of post-industrial society is V. Inozemtsev (Inozemtsev, 2000).

Pre-industrial society	**Industrial society**	**Post-industrial society**
Leading sector of economy		
Agriculture, mining industry	Manufacturing industry	Service sector
Type of technology		
Labour-intensive	Capital-intensive	Science-intensive
Limiting factor		
Land	Capital	Information
Type of consumption		
Products satisfying the primary needs	Durable goods	Leisure services and products
Content of labour		
Physical manual	Mechanized physical	Intellectual
Labour motivation		
Traditions and non-economic coercion	Financial incentive	Creativity
Education level		
Transfer of experience within the family	Secondary general	High
Dominant social group		
Farmers	Workers	Employees

Figure 1: Main features of pre-industrial, industrial and post-industrial society

The preindustrial society was a mining society. The leading sector of the economy in this era was agricultural production, and the limiting factor was land. The industrial society had a manufacturing character. This period is characterized by the dominance of industrial production over agricultural production. Capital has become the main productive resource. A post-industrial society can be considered as a processing society, since data processing, understood as the exchange of information and knowledge, takes place through information and communication technologies. The leading industry of post-industrial society is the service sector, and the leading resource is information. The process of historical development of economic systems is shown in figure 1. In developed countries, the formation of post-industrial society began in the last third of the XXth century. It is expected to reach its peak in the United States by 2020, in Japan and Western Europe by 2030-2040, and in Russia and other CIS countries by 2050.

According to some scientists, the sectoral structure of employment can be considered as a criterion for the society to transit from the industrial to the post-industrial stage of development. Each new stage of social development was accompanied by the transformation of employment in three sectors

of the economy – agriculture, manufacturing and services. A common pattern observed in the global economy is the loss of a leading role for rural households in the economy, first in favor of industrial production, and then in the service sector. These structural transformations, acting as a necessary stage of the country's economic development, are called industrialization and post-industrialization. In the era of industrialization, the share of people employed in agriculture decreased from 70-80% to 10-15%, which increased the share of people employed in industry and other non-agricultural sectors. One sign of post-industrial development is the high employment level in the service sector, it is more than 50%.

The idea of human capital has long roots in the history of economic thought. The first attempts to formulate it can be found in the works of W. Petty, A. Smith, A. Marshall, K. Marx, and J. S. Mill and other major scientists. However, as an independent section of economic analysis, the theory of human capital took its shape only at the turn of the 50-60s in the twentieth century. The merit of its nomination belongs to T. Schultz (Schultz, 1963), and the basic theoretical model was developed in the works of G. Becker (Becker, 1964).

Today, economic science has not developed a single interpretation of both the category of human capital and its types. However, most scientists identify such important components as the capital of education, the capital of health and the capital of culture, which include a number of their constituent elements. All these forms of capital can be converted to income in one way or another.

Research Result

As mentioned above, the high level of employment in the service sector is one of the signs of post-industrialization. Table 1 shows the sectoral structure of employment in some countries in 2008 and 2018. The formation of a post-industrial society is accompanied by a high proportion of the population employed in the service sector. For example, in the Netherlands, the share of people employed in the service sector was 78.9% in 2008, and 83.5% in 2018; in Mexico, 60.8% and 61.1%, respectively.

In Russia, 62.8% of the workforce was employed in the service sector in 2008, and 67.4% in 2018. A comparative analysis of the sectoral employment structure of the Western European and Russian economies allows us to conclude that our country is close to the average European indicators in terms of employment in the service sector. The structure of employment in the Russian economy roughly corresponds to Western European States and is ahead of Eastern European ones.

Table 1 : Sectoral structure of employment in the economies of OECD and some other countries in 2008 and 2018, % (ALFS Summary tables, 2019)

Country	Employment in agriculture, %		Employment in manifacturing, %		Employment in Service sector, %	
	2008	2018	2008	2018	2008	2018
Australia	3.2	2.6	22.4	20.4	74.4	77
Austria	5.2	3.5	26.3	25.6	68.5	70.9
Belgium	1.6	0.9	24.6	21.2	73.8	77.9
Estonia	3.9	3.3	35.6	29.8	60.5	66.9
Finland	4.5	3.7	25	22.3	70.5	74
Germany	1.8	1.2	29.3	27.3	68.9	71.5
Japan	4.2	3.4	27.9	24.8	67.9	71.8
Mexico	13.7	12.8	25.5	26.1	60.8	61.1
Netherlands	2.9	1.9	18.2	14.6	78.9	83.5

Country	Employment in agriculture, %		Employment in manufacturing, %		Employment in Service sector, %	
	2008	2018	2008	2018	2008	2018
Brazil	19.9	9.2	21.7	20.1	58.5	70.7
Russia	8.5	5.8	28.7	26.8	62.8	67.4

The distribution of the employed population aged 15-72 by type of economic activity according to Rosstat data is shown in figure 2. As follows from its data, 6.7% of the employed population of Russia was involved in agriculture in 2015-2016, its share decreased to 5.8% only in 2017. The share of those employed in industrial production is stable (19.7-19.8%) during the analyzed period. In 2017, there was a trend of growth in the share of people employed in trade, hotel and restaurant business from 18.2% in 2015-2016 to 18.5% in 2017.

As mentioned above, human capital at the present stage of social and economic development has become the main source of national wealth. In the next report, the Changing Wealth of Nations 2018, the organization's experts note that «Another finding is that estimates of human capital wealth are highly correlated with GDP per capita. The orders of magnitude are different, with human capital wealth per capita typically 7-10 times larger than GDP per capita. However, as expected, the two measures remain highly correlated» (The Changing Wealth of Nations 2018, 2019).

Figure 2: Distribution of the employed population at the age of 15-72 by the type of economic activity in 2015-2017, % (Labor market, employment and wages, 2018)

According to the World Bank's methodology, national wealth consists of produced capital (factories, roads, etc.), natural capital (forests, water, etc.), human capital (knowledge, skills, etc.), and net foreign assets. As for 2014 data, the total national wealth of all countries in the world was $ 1143249 billion, per capita – $ 168580 billion, and the total cost of human capital in the same year was $ 73.1679 billion. Figure 3 shows the structure of the national wealth for countries with different levels of wealth in 2014. In all countries, human capital, measured as a person's projected lifetime earnings, is the most important component of well-being. In low-income countries, the share of human capital

in the national wealth structure was only 41%, while in high-income countries that are members of the OECD, its share was 70%. It should be noted that natural capital per capita in low-income countries was $ 6,421, and human was $ 5,564. In 2014 in high-income OECD countries, the amount of natural capital per capita in the same year was $ 19,525, and the human was $ 498,399.

As for 2014, the total wealth of Russia was $ 188,715 per capita (U.S. dollars per capital), produced capital was $ 48,807 (25.9%), natural capital was $ 46921 (24.9%), human capital was $ 90,812. (48.1%). To compare, in 2014 Brazil also had a large amount of national wealth per capita - $ 1,88883, including produced capital - $ 32,067, natural capital $ 36,978, human capital $123,696. In China, the total wealth per capita in 2014 was $ 108,172, including produced capital – $ 28,566, natural capital - $ 15,133, human capital - $ 63,369. In Russia, the value of human capital per capita is comparable to such countries as Colombia ($87,674) and Croatia ($90,549). The Russian Federation is significantly inferior to Luxembourg in terms of human capital per capita ($881,629).), Iceland ($733,612), Canada ($730,832), Australia ($585,737), Denmark ($538,947), Ireland ($ 473,656), Germany ($ 467.668), Finland ($460,082), Austria ($421,846), Belgium ($404,997).

Figure 3: Structure of national wealth of countries with different Levels of wealth in 2014, %

(The Changing Wealth of Nations 2018, 2019)

The countries listed above, according to the world Bank's methodology in the Gross National Income per capita 2019 ranking, are classified as a group of countries with a high level of per capita income (from $12,616 and above). The Russian Federation, which had a gross per capita income of $ 10,230 in 2018, was classified by experts as a group of countries with average per capita income (from $1,036 to $12,615) (Rating of countries and territories by gross national income per capita in 2018, 2019). The positions of some countries in the world in this rating are shown in table 2.

Table 2 : GNI per capita 2018 (constant 2010 US$) in different countries (GNI per capita 2018, 2019)

Ranking	Economy	Income ($)	Ranking	Economy	Income ($)
1	Liechtenstein	116.430	72	Turkey	10.380
2	Bermuda	106.140	73	Russia	10.230
3	Switzerland	83.580	74	Grenada	9.780
4	Norway	80.790	80	Bulgaria	8.860
5	Isle Of Man	80.340	90	Gabon	6.800
6	Macau	78.320	100	Bosnia and Herzegovina	5.690
7	Luxembourg	69.420	110	Albania	4.860
8	Iceland	67.950	120	Georgia	4.130
9	USA	62.850	130	Mongolia	3.580
10	Qatar	61.190	140	Egypt	2.800
20	Germany	47.180	150	Uzbekistan	2.020
30	Italy	33.540	160	Pakistan	1.580
40	Bahrain	21.890	170	Mauritania	1.190
50	Lithuania	17.350	180	Rwanda	780
60	Hungary	14.590	190	Sierra leone	500
70	Nauru	11.240	198	Burundi	280

According to Rosstat's guidelines, the national wealth "represents the total value of all economic assets (non-financial and financial) in market prices that are owned by residents of a given country at a given date, minus their financial obligations to both residents and non-residents" (Russia in numbers 2018, 2019). A significant disadvantage of the methodology is that non-financial non-produced values are not taken into account at all when assessing national wealth. Meanwhile, experts at Financial and accounting consultants believe that this group is potentially the most significant part of the national wealth (How much Russia costs: 10 years later, 2014). Among the reasons why a significant part of Russian assets is not taken into account in practice when assessing the value of national wealth is still the secrecy of relevant information (The law of the Russian Federation "About government secret", 2018). Thus, a significant part of the Russian national wealth falls out of the field of assessment and does not allow us to judge the size of human capital in its composition. The balance of assets and liabilities reflecting the statistics of the Russian national wealth is presented in table 3.

Table 3: Assets and liabilities balance 2011-2016. (Russia in numbers. 2018, 2019)

	2011	2012	2013	2014	2015	2016
Assets	447.255	518.381	585.883	691.133	787.077	817.360
Non-financial assets	224.091	256.262	275.962	302.799	340.334	361.430
Financial assets	223.164	262.119	309.921	388.334	446.743	455.931
Liabilities	218.353	257.796	305.610	370.888	422.421	442.459
National wealth	228.902	260.585	280.273	320.245	364.656	374.901

As mentioned above, human capital acts today as the main production factor and it is a strategic resource for social and economic development. The human development index (HDI) developed by UNDP specialists is used for its evaluation and for international comparisons.

In 2019, UNDP submitted a progress report on the development of human potential, Human Development Report 2019. The study covered 189 States. The group with a very high level of HDI consists of 62 countries, with a high level of 54 countries, with an average level of 37 countries, and with a low level of 36 countries. As shown in figure 4, Norway, Switzerland, Ireland, Germany, and Hong Kong topped the 2018 ranking, while Niger, the Central African Republic, Chad, South Sudan, and

Burundi have the lowest HDI scores. Russia gained the 49th place in the ranking, ahead of Bulgaria and Montenegro, but could not surpass Oman and Argentina. The world HDI rating of Russia is declining mainly due to the value of life expectancy. The gap between our country and the leader of the rating by this indicator was 12.3 years.

Figure 4 – The human development index of some countries in 2018
(Human Development Report 2019, 2020)

Conclusions and suggestions

The processes taking place in the world economy indicate that at the beginning of the 21st century, human capital became the main productive resource. Only thanks to the leading role of human capital, a number of countries (Japan, Taiwan, Hong Kong, South Korea, etc.) were able to achieve a high level of social-economic development. At the same time, there are no examples of long-term economic development based on the use of natural capital in the world economy today. In this regard, the quality and quantity of human capital should be considered as the main factor in the social-economic development of countries.

In Russia, the attitude to a person has always been quite indifferent. This indifference came, obviously, from the fact that the country has enough population and workers. Today, the situation with human capital has changed radically. The reduction in the population and the lack of human resources is becoming almost the main constraint on social-economic transformations. Our country has passed the stage of economic recovery based on the use of previously created production facilities and previously trained labor force. An underestimation in the consequences of losses and a decline in the quality of human capital can permanently consolidate Russia's economic and social lag on the world stage.

Ensuring the economic growth and well-being of the people is the main goal of a civilized state. Today, the first task for Russia is to ensure the quality of human capital and achieve high rates of economic growth on this basis. This process is connected with constant and significant investments of the country in the social sphere. Investing in human capital leads to higher labor productivity and, consequently, production efficiency.

Abstract

The urgency of the research is based on the fact that in the modern world the education system is the foundation of the emerging post-industrial society and any changes in it have a significant impact on all socio-economic processes. In this respect, determination of the national educational system's effectiveness as a whole and the higher education system in particular is of high importance. The professional level and scientific and pedagogical workers' labor efficiency directly determine the quality of the educational services provided by the university as well as efficiency level of an educational organization. Therefore, it seems no less urgent to research the main directions to increase the efficiency of employees' labor activity among educational organizations in frames of the higher education system.
The purpose of the study is to evaluate the higher education system as well as scientific and pedagogical workers' effectiveness in different countries of the world, including Russia. The given work considers the ratings' results concerning the strength of the higher education system, the rating of the national higher education systems' effectiveness, the rating of universities, the rating of scientific and pedagogical staff's publication activity. The presented work gives an assessment to the position of Russia in these ratings.

Key words: Higher Education, Scientific and Pedagogical Staff, The Higher Education System's Effectiveness, Labor Efficiency, Educational Expenditures.

Relevance and Problem Statement

Postindustrial society formation means moving from tangible production factors on to the spiritual and intellectual ones. Today, the world economy is seeing a high degree of dependence on the human capital development level. In a post-industrial economic system, one of the criteria for economic success is the quality characteristics of the human capital, the possibility of its accumulation, multiplying (provided further efficient use), i.e. developing those areas of economic life that predetermine the development of man himself (Rudakova, O.V. and Samorodova, E.M., 2007). In about every country human capital measured as projected lifetime earnings of a person is the most important component of welfare. In the countries with a low per capita income the human capital share in national wealth was only 41%, whereas in high-income countries, which are members of the OECD, its proportion was equal to 70%

(The Changing Wealth of Nations 2018, 2018).

Education capital is an important component of human capital. Education is a purposeful process of education and training, corresponding to the interests of the person, society and the state, accompanied by a statement of achievement of the educational levels established by the state (Prokopyeva, A.V., Rybakov, L.N. and Pchelkina, V.V., 2012). Currently, the educational level of the population is one of the global competition elements, which is due to the increasing impact of education on the successful development of states and their advance in global labor markets and new technologies (Zelenina, T.Yu., 2014). Education today is seen as national capacity and capital and, as a condition for the competitiveness of the State and society. In today's world, the educational system is undoubtedly the basis of the emerging knowledge society and any changes in it have a significant impact on all the social and economic processes. In this regard, the national educational system effectiveness determination is of particular importance. The professional level and efficiency of the academic staff work directly determine the quality of educational services provided by the academic institution and the level of the educational organization effectiveness. Therefore, it is no less urgent to study the main directions of improving the efficiency of the higher education system academic staff work.

The level to which the problem is developed

The theoretical basis of the research is the works by the founders of control theory, efficiency theory, and the theory of human capital. The modern society stays in the process of accelerated transformation followed by increase in the role of mental labor in the society, which determines the particular importance and urgency of its comprehensive study. The above-mentioned problems were researched in the works of such scientists as Aron R., Becker G., Bell D., Gelbraith J.K., Drucker P., Clark K., Naysbit J., Toffler O., Furastier J., Schulz T ., Danilin G., Krasilshchikov V., Lvov D., Nizhegorodtsev R., Tolokina E., Antipina O., Inozemtsev V.I. etc. The problems of efficiency and labor productivity were studied in the works of many foreign and national scientists, such as Drucker P., Clark JB, Marx K., Marshall A., Samuelson P., Sink D., Smith A., Taylor F., Emerson G., Abalkin L., Anchishkin A., Kapelyushnikov R., Lvov D., Odegov Yu., Strumilin S., Sukharev O. The studies of labor productivity's possibilities were reflected in the works of Taylor F.U., Gilbreth F., Fayol A., Urvik L., Muni D., Reilly A., Arjiris K., Herzberg F., Likert R., MacGregor D. Management problems of labor productivity were researched in numerous works of Russian scientists, such as Abalkin LI, Gavrilov RB, Ivanchenko A.A., Ignatovskii P.I., Kapustin E.I., Karpukhin D.N., Kostin L.A., Morozova E.V., Odegov Yu.A., Strumilin S.G., Frenkel A.A., Cherkovets V.N. Recent studies presented in the works of Adamchuk V.V., Andreev B.F., Genkin B.M., Germanova O.E., Kuchina E.V., Morozova E.V., Petrov A.Yu., Semenov A.N. and etc. are urgent as well.

The educational arrangement of higher education, like any other organization, needs the effective implementation of managerial functions. However, nowadays higher education institutions are poorly studied both from the standpoint of theoretical and practical management. There are no unified scientifically substantiated and approved standards and methods of higher institutions' management. In Russia, a scientific and practical direction, so called 'university management is under the current formation. Foreign theories and practices of university management, in our opinion, are not always applicable due to the difference in the condition's educational organizations' existence. To our mind, university management should combine both characteristics: general of economic processes' management in any organization and unique to educational institutions of higher education.

The Results of The Study

The expenditures on education are a fairly large budget item in most countries and they are considered one of the key indicators of socio-economic development, as they reflect the level of attention paid to the education of citizens by the state and the society. The level of national education spending is a relative indicator, expressed as a percentage of gross domestic product. The indicator is calculated for the calendar year as the total amount of public and private expenditures on education, including state budgets of all levels, as well as private funds, external borrowing, donations and grants from international institutions and non-governmental organizations.

However, it should be noted that this indicator does not take into account the income equality to education for various social groups within a particular state, it gives no idea either of the ratio of public and private spending on education or the spending structure.

The top 10 countries that are leaders in the level of education spending are shown in Figure 1. The ranking leader, according to the World Bank, in 2016 was Grenada, where the share of education spending in the country's GDP was 10.24%. It should be noted that a relatively large number of developing economies have demonstrated a high level of public expenditure on education, primarily due to mass illiteracy elimination programs funded by international institutions and charitable organizations. In developed economies, the level of spending on education is 5-8% in the GDP of these countries. Among the developed countries, the leader is Norway, where the share of spending on education is 7.98%. According to the data of 2016, education spending in Russia was 3.74% of GDP. It should be noted that in 2014, 4.0% of GDP was allocated to support the education sector. According to the level of spending on education, Russia was outpaced by Uzbekistan (6.87%), Moldova (6.66%), Uruguay (4.76%), Georgia (3.78%).

Figure 1: Top 10 countries in terms of education spending in 2016, % of GDP (Government expenditure on education, total (% of GDP), 2017)

According to the Higher School of Economics data, in Russia government spending on education at current prices grew steadily from 2006 to 2014 (Fig. 2a). The same dynamics was demonstrated by their value in constant prices (fig. 2b). Between 2014 and 2016, it was reduced in current prices as well, but little growth in constant prices could be recorded.

Higher professional education acts as a system-forming element of the national economy, because it forms personnel potential for all sectors of the economy. Since 1970, the higher educational programs' coverage of the world population has increased more than 6 times, and the growth of the gross world product in this period has been only 2 times higher. In 2007, the OECD published a new methodology for a comprehensive assessment of the higher education impact on socio-economic development of regions (Higher Education and Regions. Globally Competitive, Locally Engaged, 2007). At the beginning of the XXI century, higher education programs became the main segment of the international educational services market.

Figure 2: Expenditures on education in the Russian Federation in 2006-2016 years (Bondarenko, N.V., Gohberg, L.M. and Kovaleva, N.V., 2018)

Today, there are several methods which allow to carry out a comprehensive assessment of the national system of higher education through the compilation of world ratings. In our opinion, among the instruments aimed at fixing the integrated position of the development of national higher education systems, one can single out the Higher Education System Strength Rankings, compiled by QS and the rating of the effectiveness of national higher education systems (Ranking of National Higher Education Systems) represented by Universitas 21.

The leading countries of the Rating of the higher education system's strength in 2016 are presented in Figure 3. As one can see from the data in the Figure and the Appendix, the United States became the leader in the 2016 rating, having received 100 points for all rating indicators. Great Britain took the 2nd place in the Rating of the higher education system's strength, receiving 98.5 points. At the same time, the best scored and high-ranked was the country's leading university (99.8 points), the worst rating was scored for the accessibility of world-class higher education (96.7 points). Germany, having received 94.0 points, ranked the third in the QS Higher Education System Strength Rankings. The country's higher education system has achieved the best results in terms of accessibility (97.9 points), and the worst in terms of the economic context (91.9 points). Pakistan has ranked the last, the 50th, the best result is obtained by the country in terms of economic impact (31.3 points), and the worst by accessibility (0 points).

Figure 3 : Top 10 leading countries in 2016
(Higher Education System Strength Rankings 2016, 2017)

The Ranking of National Higher Education Systems is a research project implemented by the international network of universities Universitas 21 (U21), being devoted to the higher education achievements assessment all over the world. The top 10 countries-leaders of the higher education efficiency rating of national systems in 2017 are shown in Figure 4. According to the data presented, the leader in this rating is also the USA. It should be noted that the North American system of higher education, which has been formed in the USA and Canada, is today an indisputable leader among the world educational systems. The five leaders also included Switzerland, Great Britain, Denmark and Sweden. The European system of higher education has long academic traditions in such countries as Great Britain, France, Germany and Italy. Indonesia has ranked the last, the 50th.

Figure 4: Top 10 countries-leaders of the higher education efficiency rating of national systems in 2017
(Ranking of National Higher Education Systems 2017, 2018)

The BRIC countries are presented in the ranking of the effectiveness of national higher education systems. In the ranking of 2017, China takes the 30th place, Brazil has the 42d place, India is located at the 49th place. One should note that in the ranking of 2014, China was at the 35th place, Brazil took the 38th place, India was located at the 50th place (Ranking of National Higher Education Systems 2014, 2015). Our country is located at the 33rd place in the ranking of U21 Ranking of National Higher Education Systems 2017, skipping ahead Taiwan (the 21st place), Malaysia (the 25th place), China (the 30th place). It should be noted that in the 2014 ranking Russia was the 35th (Ranking of National Higher Education Systems 2014, 2015).

In the modern society, universities act out as the main providers of knowledge; they possess the leading positions in sphere of providing a high-quality theoretical information base. Nowadays, universities are increasingly being seen as drivers of regional development. The number of universities in the world is

growing not only because of the developed countries, but also due to developing ones. At present, world university rankings act as indicators of the higher education system's efficiency in the country. Universities' world rankings, in difference from the performance ratings of national higher education systems, measure not the entire higher education system of a particular country, but only the indicators of its higher education institutions.

There are about a dozen of global university rankings. Nowadays, QS World University Ranking acts out as one of the most significant university ratings. In the ranking of 2017, there were 935 universities of the planet already which took part. Four of the first five places in the QS World University Ranking 2017 belong to the United States, and another one belongs to the United Kingdom. The USA is represented in the ranking by universities such as the Massachusetts Institute of Technology (1st place), Stanford University (2nd place), Harvard University (3rd place), and the California Institute of Technology (5th place). British Cambridge University is one of the five leading universities worldwide (World University Ranking 2017, 2018).

QS World University Ranking included 22 Russian universities in 2017. It should be noted that the leading university of the country, Moscow State University named after M.V. Lomonosov ranked only the 108th according to the rating. The general assessment of the university, according to the experts, is only 62.1 points; academic reputation being 77.1 points, reputation among employers being 69.3 points, the ratio of teachers and students being 99.7 points, the share of foreign students being 51.9 points. Indicators such as the citation index and the foreign teachers ratio were not even evaluated by international experts.

In 2017, the rating agency RAEX (Expert RA) made the sixth annual rating of Russian universities. The rating of RAEX universities (Expert RA) is an integral university graduates' training quality assessment, determined by quantitative parameters of educational and research activities of universities and qualitative characteristics reflecting the opinion of key reference groups: employers, academic and scientific circles representatives, as well as students and university graduates (Methodological approaches to ranking Russian universities, 2020). The top-10 rating of the RAEX for 2017 is presented in Table 1.

Table 1: Top-10 of "The best 100 of Russian higher institutions" Rating of 2017 according to RAEX (100 best universities in Russia. 2017, 2017)

Place, 2017 year	Place, 2016 year	Name	Rating functionality	Conditions for obtaining quality education, rank	The level of employers' demand for graduates, rank	Research activity level, rank
1	1	Moscow State University after M.V.Lomonosov	4.729	1	2	1
2	2	Moscow Institute of Physics and Technology (State University), MIPT	4.603	3	5	3
3	3	National Research Nuclear University (MERhE)	4.424	7	4	2
4	5	St.Petersburg State University	4.244	4	12	5
5	7	Moscow State Institute of International Relations, MFA of the Russian Federation	4.223	2	7	34
6	6	National Research University "Higher School of Economics"	4.216	5	6	15
7	4	Bauman Moscow State	4.136	10	1	11

		Technical University				
8	8	National Research Tomsk Polytechnic University	4.100	6	15	7
9	9	Novosibirsk National Research State University	3.957	8	16	6
10	11	Peter the Great St.Petersburg State University	3.890	12	13	8

The leaders in the rating of 2017 were the universities, which ranked the first last year (Moscow State University named after M.V. Lomonosov, MIPT and National Research Nuclear University MEPhI. The above-mentioned universities are among the best universities in Russia in terms of conditions for obtaining qualitative education and the demand for graduates by employers. Moscow State University, MIPT and MEPhI demonstrate the highest level of research activity among all Russian universities for the second year in a row. In the team of leaders in 2017, in comparison with 2016, there were significant changes: MGIMO advanced from the 7th place (in 2016) to the 5th place (in 2017); MSTU named after Bauman worsened its position, ranking the 7th place in 2017 compared to the 4th in 2016.

At the current stage of development, the effectiveness of the organization's activities is determined by the efficiency of its staff. In other words, the personal effectiveness of each employee is seen as the basis for achieving the organization's strategic and tactical goals. The effectiveness of the activities of both a separate educational organization of higher education and the entire system of higher education depends on the main academic staff of universities, since it is the academic staff which is the main generator of scientific ideas and knowledge, the evaluation of which is carried out by external parties concerned.

In the international practice it has become widespread to use the publication activity indicators of scientists and educational organizations to assess the effectiveness of their work, assess the effectiveness of the organization itself and even the state of science in some countries. The idea of the country's place in the scientific world is judged upon by the total number of its scientists' publications in databases, indexed by international scientific publications. Figure 5 shows the top 10 countries which are the leaders in the rating of publication activity in 2017. The United States took the first place in the number of documents presented in the Scopus database in 2017 (683,590 documents). China ranked second in the 2017 ranking (534,879 documents). Russia took the12th place (89,492 documents), it was 7.6 times behind the United States and 6.0 times behind China.

Figure 5 : Top 10 leading countries in publication activity rating 2017 (based on the number of documents contained in the Scopus database) (Publication Activity Rating (by number of publications) in the world in 2017)

Scopus data analysis makes it possible to determine that from 2003 to 2010, Russia's position in the world scientific market had a tendency to deteriorate, so in 2011 our country ranked 11th in the publication activity of SJR in terms of the number of documents placed in the database, then in 2010 –

the 16th. Since 2011, the improvement has become obvious: in 2017, our country returned to the 12th place in the rating (Fig. 6).

Figure 5: Russia publication activity rating according to the number of documents contained in the Scopus database, in 2003-2017, according to the SJR version

(Publication Activity Rating (by number of publications) in the world in 2017)

It should be noted that the number of scientific publications indexed by international databases is considered by the Russian authorities as an important indicator of the national science development. According to the passport of the national project "Science" by 2024, Russia is to enter the top five countries in terms of priority areas for science for the country (National Project Science, 2020). From the point of view of the science-based indicators, this should lead to a double increase in the number of publications of national scientists.

Conclusions and offers

The given data indicate that the key policy for Russia in order to improve results among the world competitiveness of the higher education system is its integration into the global educational space, accompanied by an increase in its functioning effectiveness.

The professional level and labor efficiency of higher education's employees directly determine the quality of educational services provided by the university. In this respect, it seems urgent to develop directions to increase employees' labor efficiency concerning Russian higher education system's organizations.

The system of labor efficiency management is based on three following aspects: the development of criteria for personnel labor efficiency; monitoring of their implementation; employees' motivation. It lets classify personnel basing on its efficiency, which makes it possible to reward efficient employees, stimulate ineffective employees or optimize personnel, considering inefficiency. Management of scientific and pedagogical workers' effectiveness is carried out by the managing subsystem, which is a university's administration. The managed subsystem is represented by scientific and pedagogical workers of the higher educational organization. Management information represents by itself a collection of information about the processes which take place both in the organization itself and beyond it.

The management of scientific and pedagogical workers' effectiveness starts with collection, accumulation and processing of information which comes both from the external environment of a higher educational institution (the state, employers, applicants / students), and from its internal environment (the university itself). Requirements and the amount of funding that enter the institution of higher education on the part of the state, employers, applicants / students serve as the basis for the system's formation concerning the educational organization's performance indicators. Based on this system of indicators, there is created a system of indicators concerning the activity of scientific and pedagogical workers. This system is supplemented by the indicators reflecting the requirements for implementing the university's development strategy. It should be noted that the implementation of performance indicators by academic staff of the university has a decisive influence on the performance indicators of the university as a whole. Planned labor efficiency indicators of one employee are established on the basis of a system of performance indicators among scientific and pedagogical workers. Some indicators are obligatory and are paid from the wage fund, while other indicators are advisory and are paid from the stimulating part of the wage fund. At the same time, default of the obligatory indicators deprives a scientific and pedagogical worker of the right to receive incentive payments for the recommended indicators.

It is necessary to form an end-to-end system of performance indicators, the values of which are set at the federal level and are subject to execution at the level of scientific and pedagogical workers. The formulation of state priorities and the setting of target indicators that determine the effectiveness of the national education system take place at the federal level. They are supplemented with their own part of the established system of indicators at the level of constituent entities of the Russian Federation, municipalities and higher educational institutions. The signing up of an effective contract with a scientific and pedagogical worker containing indicators of the effectiveness of the latter is the ultimate level of the considered system. Due to this system, it is precisely the scientific and pedagogical workers who will definitely ensure the direct achievement of the necessary targets.

The process of reforming the higher education system in Russia should help to increase its effectiveness. It is expected that a reduction in the number of universities will increase competition between applicants, which will lead to an increase in the overall level of education in the entire country. It is also assumed that a reduction in the number of students will result in a reduction in the number of educators and that will increase competition between them. The consequence of these processes will be an increase in the quality of teaching in the country. The closure of inefficient universities, according to the reformers, on the one hand, should reduce a financial burden on the country's budget (higher education in Russia is mainly budgetary), and on the other hand, it will help to direct the released funds to the development of effective educational organizations.

The Role of Non-Financial Sector Deposits in The Activity of Commercial Banks on The Example of The Polish Banking Sector

Sylwia STACHERA-WLODARCZYK

Czestochowa University of Technology, Faculty of Management, Czestochowa, Poland,
sylwia.stachera-wlodarczyk@wz.pcz.pl

Abstract

The aim of the publication is to specify the characteristics of bank deposits obtained from the non-financial sector, indicating their role in commercial banks' functioning and presenting the most important aspect of the bank's financial economy, that is, funding its activity. The discussion is based on the analysis of quantitative data concerning the activity of the banking sector in Poland in the scope of funding sources. The data covered by the object of the research has been obtained from financial reports of Narodowy Bank Polski (the National Bank of Poland) and the Polish Bank Association. The obtained research results underline the significance of bank deposits not only from the point of view of a commercial bank, but also the whole banking sector.

Keywords: Bank Deposit, Non-Financial Sector Deposit, Bank's Capital, Financial Economy, Bank's Funding Sources

Introduction

The activity of banks as participants in the financial system has a specific character. It primarily results from the economic and social meaning of the bank's activity. Furthermore, the role of banks in the economy is also related to their function of a public trust institution.

The activity of banks, similarly as the activity of any economic entity, depends on the held capitals. With regard to the need to ensure proper amount thereof, banks are obliged to conduct financial economy aimed at providing coverage for costs incurred during activity with the amount of generated revenues.

The fundamental task of commercial banks is to obtain funds and transform them into investment. Funds collected by banks come from various sources and constitute grounds for functioning thereof. The activity of commercial banks is primarily funded with foreign capital. The key role in their structure is played by deposits. In fact, accepting deposits constitutes the basic area of each banking activity.

Literature Review

Banks are a special type of enterprises, the activity of which consists in collecting funds from people in a form of deposits and sharing them in a form of loans (*Rose & Hudgins, 2012; Apostolik, el. al., 2009).* In principle, proper functioning thereof depends on the level of held capitals. In the case of banks, however, their balance structure is significant, that is, the relation between foreign and own funding sources, which is different from other enterprises. In general, the division of the capital is the same – equity and foreign capital, however, in the case of the equity capital, banks are obliged to fulfil certain capital requirements. As a matter of fact, in compliance with the binding prudential standards, in order to ensure economic security, the banks are obliged to have own funds adjusted to the size of conducted activity. Whereas, foreign capital constituting the prevailing part of the bank's equity and liabilities, cannot be treated as a typical external source of funding its activity – as in the case of enterprises *(Nyoka, 2019; Iwanicz-Drozdowska, et al., 2017; Matten Ch., 2000).*

In order to implement the adopted policy, banks, as other enterprises, act while using various funding sources. Some tasks are funded with equity and others can be performed with the use of foreign capitals, especially in the situation of having insufficient own resources. Therefore, the selection of funding sources constitutes an important decision-making area in the bank's functioning. Nevertheless, the characteristics of banks' activity causes the decisions, to be taken by the banks in this area, to play an extremely important role. (Kolari & Gup, 2005). Therefore, from the point of view of proper functioning of a bank, an important role is played by its financial economy, which consists in proper management of held resources so that they generate expected profits *(Trinugroho, et.al., 2016; Podstawka, 2010).*

Among activity funding sources available to banks, an especially important role is played by deposits. The share of other sources in increasing the bank's resources is much smaller and usually does not exceed a few or several percent of its liabilities. The essence of bank deposits consists in executing the customer's instruction as ordered, at their responsibility and risk and with resources held by the customer. The bank does not take any substantive decision and is restricted solely to the control of correctness and legality of received instructions *(Apostolik, el.al., 2009, Matthews & Thompson, 2008; Matten Ch, 2000, Safiat, et.al., 2019).*

Deposits are included in the bank's balance sheet as liabilities to customers (predominantly from financial and non-financial sectors). They constitute a basic form of foreign capital of any bank. Accepting cash from people, business entities and other institutions is commonly defined as bank deposits. These funds are kept on various bank accounts, which decides on classifying them to more specifically defined sources of funding bank's activity *(*Melnychuk*, et.al., 2018; Świderska, et.al., 2016).*

In the subject literature, bank deposits are often the object of research of many various authors in different countries. It primarily results from the fact that the level of thus obtained funds determines the possibilities of funding banks. Therefore, deposit operations constitute a key element in managing bank's finances. Thus, in order to obtain as many customers as possible, banks compete among themselves in the scope of presented deposit offers. Therefore, they differentiate deposit products not only due to terms or interest rates, but also encourage customers with additional, related services. One of the factors with a significant impact on the level of bank deposits is also, as underlined by many authors, the deposit guarantee scheme. *S. Lobozynska* believes that proper bank deposit guarantee scheme has a significant impact on the customer's trust in bank services. The purposefulness of the existence of deposit guarantee schemes, social premises for developing them and consequences thereof are discussed in a similar manner by, among others, *Bergbrant, et. al.* Whereas, *Cooper and Kempf* underline their role in limiting in the loss of depositors' confidence regarding the banking sector in times of disturbances and crisis, and they indicate that the rules of deposit guarantee schemes become a significant element reinforcing relations between depositors and banks. On the other hand, *Demirgüç-Kunt, Kane and Laeven* write about the reasons for establishing deposit guarantee schemes and indicate that the development level of the banking system and legal-regulatory environment in a given country also have a significant impact on the establishment thereof. Additionally, *Huizinga and Nicodème* believe that the existence of an effective deposit guarantee scheme can be treated as an additional advantage of a given banking system.

Methodology

The article has been drawn up on the grounds of the analysis of quantitative data obtained from financial reports of Narodowy Bank Polski (NBP) (the National Bank of Poland) and the Polish Bank Association (ZBP). This data was used to diagnose the characteristics of funding the activity of the commercial banks' sector in Poland. The object of the analysis predominantly covers non-financial sector deposits. Simultaneously, the research period presented in the analytical part of the article covers the years between 2014 and 2018. The year 2019 has not been included in the research due to the lack of comparable data from this period. Taking into consideration five consecutive years in the analysis allowed in-depth comparison thereof as well as indicating the trend of changes in analysed values in time.

The research conducted herein has been carried out with the use of simple statistical methods the main aim of which was to analyse the structure and dynamics of studied quantitative data in the scope of funding the activity of commercial banks. The use of the dynamics of the studied phenomenon allowed determination of changes in its level i.e. an increase or a decrease in distinguished time units, as well as determination of the rate of the changes in question.

Results

The data included in table no. 1 implies that in the analysed period of time the structure of funding commercial banks was stable. The main role was played therein by foreign capitals, that is, liabilities. Deposits of the non-financial sector had a prevailing share among them.

Table1 : The level of funding sources of commercial banks in Poland in the years 2014-2018 (billion zloty)

Funding sources	years				
	2014	**2015**	**2016**	**2017**	**2018**
Central Bank	0.12	0.01	0.01	0.01	5.85
Financial sector	258.5	258.9	250.2	230.5	227.9
Non-financial sector	849.3	933.4	1,021.1	1,062.5	1,151.2
General government sector	60.6	48.4	63.5	69.0	83.4
Debt instrument	54.5	57.6	67.2	85.3	87.8
REPO transaction	26.6	19.4	11.9	12.6	18.3
Derivatives	40.5	32.7	25.1	17.2	16.7
Other liabilities	73.1	69.3	83.6	95.8	91.5
Total liabilities	**1,363.22**	**1,419.71**	**1,522.61**	**1,572.91**	**1,682.65**
Equity capital	**166.0**	**175.2**	**183.4**	**203.9**	**204.5**
Total equity and liabilities	**1,529.22**	**1,594.91**	**1,706.01**	**1,776.81**	**1,887.15**

Source: Own study "Development of the Financial System in Poland" NBP reports for the years 2014-2018.

Liabilities of the commercial banks sector in 2014 amounted to PLN 1,363.22 billion, which constituted 89% of the balance sheet total. Their value in the consecutive years was growing and at the end of the analysed period, i.e. in the year 2018, the level of liabilities amounted to PLN 1,682.65 billion, that is, by PLN 319.43 billion more than at the beginning of the research. Thus, the share of liabilities in the balance sheet total oscillated around 90%. On the other hand, the analysis of own funds of commercial banks implies that their capital equipment in the analysed period of time was also gradually increasing. It predominantly resulted from the accumulation of retained profits from previous periods, as well as (although, to a significantly smaller extent) issuance of shares and subordinated debt. The biggest increase in own funds was noted in 2017, as they grew by PLN 20.5 billion (in 2015 the nominal increase amounted to PLN 9.2 billion and in 2016 – PLN 8.2 billion, whereas, in 2018 to only PLN 0.6 billion). Apart from the accumulation of retained profits from the previous year, increasing the share capital Tier I by PLN 13.3 billion and capital Tier II by PLN 2.7 billion also contributed to the increase in the value of own funds in 2017. Whereas, the low increase in these funds in 2018, in comparison to previous years, resulted from the structural changes that occurred at the end of that year and losses suffered by some banks. In comparison with foreign capitals, the value of own funding sources of commercial banks was small, approx. 10%. Nevertheless, such a relation of equity capital to foreign capital is completely correct. It results from the characteristics of the activity of banks that base their operations predominantly on foreign capital. The manner in which commercial banks' capitals were developing has been presented in diagram no. 1.

Fig. 1 : Value of capitals of the commercial banks sector in the years 2014-18 (billion zloty)
Source: Own study: "Development of the Financial System in Poland" NBP reports for the years 2014-2018.

The rate of changes (year/year) in the values of commercial banks' capitals noted in the period of analysed years has been presented in diagram no. 2.

Fig. 2: The rate of changes in banking sector's capitals in the years 2014-18 (%)
Source: Own study: "Development of the Financial System in Poland" NBP reports for the years 2014-2018.

As has already been mentioned, a dominant role among foreign funding sources of the activity of commercial banks' sector is played by non-financial sector's deposits. Those are deposits of households that include: private persons, individual entrepreneurs and farmers, as well as enterprises. Over the years 2014-2018 their value was gradually growing. The nominal increase in non-financial sector deficits in 2015 amounted to PLN 84.1 billion, which was an amount slightly higher than the one generated in 2014 (PLN 78.6 billion) and significantly higher than the one generated in 2013 (PLN 51.3 billion). The noted increase in non-financial sector deposits resulted from the even rate of increase in funds on accounts of households and business entities. In the consecutive years of the analysis, the non-financial sector deposits were also gradually growing. At the end of 2018 they reached over 61% of the value of all equity and liabilities (table no. 2) and amounted to over one billion zloty – PLN 1,151.2 billion. Thus, the nominal increase in non-financial sector deposits in 2018 amounted to PLN 88.2 billion and was decidedly higher than in 2017, when it amounted to PLN 42.3 billion and was the lowest for several years. For comparison purposes, it is worth mentioning that the result form the year 2018 was comparable to the results from previous years: in 2016 the increase nominally amounted to

PLN 89.2 billion, in 2015 – PLN 84.1 billion and in 2014 – PLN 78.6 billion. The increase in the value of non-financial sector deposits was caused by a better situation of households and relatively good financial results of many enterprises.

At the same time, the share of the second most important funding source of commercial banks – funds obtained from financial sector entities – was decreasing (table no. 2). In consequence, as of 2014 financial sector deposits decreased by PLN 30.6 billion. Thus, their share in the funding structure of the commercial banks sector decreased from 16.8% in the year 2014 to 12.1% in the year 2018. Whereas, the share of other equity and liabilities items in the balance sheet total was relatively stable.

Table 2: Funding structure of commercial banks in Poland in the years 2014-2018 (%)

Funding structure of the banking activity - share in the balance sheet total	**years**				
	2014	**2015**	**2016**	**2017**	**2018**
Central Bank	0.01	0.01	0.00	0.00	0.31
Financial sector	16.80	16.60	14.70	13.00	12.10

Due to the fact that non-financial sector deposits constituted, in compliance with the binding model of Polish banking, a dominant position in equity and liabilities of commercial banks, they have been covered with more in-depth analysis.

The increase in the non-financial sector deposits, observed in the research period, was predominantly the increase in both, household and enterprises deposits. As results from the data included in table no. 3, a dominant role in the structure of non-financial sector deposits was played by funds obtained from households. Their value was growing year by year and from the amount of PLN 606.3 billion in 2014, the amount of PLN 838.8 billion was obtained in 2018, which constituted a nominal increase by PLN 232.4 billion (i.e. by 38.3%). It should be underlined that the increase in non-financial deposits in 2018 (as in the previous years) occurred in the conditions of low interest rates and outflow of some bank deposits to other forms of allocating free funds. Simultaneously, it was influenced by the decidedly better financial situation of households, which, due to the improvement of the situation in the labour market and transfer of funds, among others, from the 500+ programme, allocated their financial surpluses to banks. Furthermore, the relatively good financial results of many enterprises associated with the limited scale of decisions on initiating investment projects caused an increase in the value of deposits. Therefore, the share of household deposits in equity and liabilities of commercial banks oscillated around 40%. In comparison, deposits of enterprises constituted approx. 15% and other – only 1%.

Table 3: Non-financial sector deposits (level, structure and dynamics) in the years 2014-18

Non-financial sector deposits - on an entity basis	years				
	2014	**2015**	**2016**	**2017**	**2018**
	value in billion zloty				
business entities (enterprises)	229.4	253.3	274.9	284.9	293.6
households	606.4	665.7	730.8	761.3	838.8
other	18.3	19.7	22.4	24.1	26.2
	% of the balance sheet total				
business entities (enterprises)	15	15.8	16.1	16	15.5

households	10.6	9.8	9.7	4.2	10.2
other	4.6	7.9	7.6	7.7	8.9

Source: Own study: "Reports on the economic situation of banks" ZBP for the years 2014-2018.

The study on non-financial deposits showed that the dynamics of enterprises' deposits in 2015 was slightly higher than the dynamics of liabilities from households, whereas, in the previous year the banking sector experienced a reverse phenomenon. A slower increase in household deposits can be related to some customers taking a decision on other manner of allocating at least some of their financial resources. Whereas, in the years 2016-18 a situation could have been observed. The dynamics of household deposits was slightly lower than the dynamics of liabilities from households. A faster increase in the household deposits could have been associated with the aforementioned conditions, i.e. improvement of the situation in the labour market or their financial situation due to transfers of funds from the 500+ programme. This increase contributed to the stability of funding the activity of the commercial banks sector.

Additionally, the analysis covered non-financial sector deposits as divided into deposits of households and deposits of business entities by term and currency, as presented in table no. 4.

Table 4: Nominal dynamics of household deposits and business entities' deposits by term and currency in the years 2014-18 (%)

	years				
	2014	**2015**	**2016**	**2017**	**2018**
household deposits					
by term					
overnight	108.6	113.7	117.9	112.8	115.5
term	111.3	105.9	100.7	93.3	101.7
by currency					
zloty	111.0	109.0	109.2	101.9	110.2
currency	107.0	117.5	115.6	120.0	110.3
business entities' deposits					
by term					

overnight	110.4	117.5	116.3	113.6	106.8
term	107.3	101.6	96.1	91.6	99.2
by currency					
zloty	111.1	108.3	104.7	98.8	106.7
currency	100.3	123.0	128.3	124.3	90.5

Source: Own study: "Reports on the economic situation of banks" ZBP for the years 2014-2018.

In 2014 overnight household deposits increased by 8.6%, whereas, term deposits increased in the same time by 11.3%. Changes in the term structure of household deposits most probably resulted from better economic situation of the country in the last year. In the next year covered by the analysis, the term structure of household deposits changed. In 2015 it was heading in the direction opposite to the one observed in the previous year, that is, overnight deposits were growing much faster than term deposits. Overnight household deposits increased by 13.7%, whereas, term deposits increased in the same time by 5.9%.

Changes in the term structure of household deposits observed in the years 2016-18 were heading in the similar direction as in 2015 – overnight deposits were growing much faster than term deposits.
For comparison:

-in 2016 overnight household deposits increased by 17.9%, whereas, term deposits increased in the same time by 0.7%;
- in 2017 overnight household deposits increased by 12.8%, whereas, term deposits decreased in the same time by 6.7%;
- in 2018 overnight household deposits increased by 15.5%, whereas, term deposits increased in the same time by 1.7%.
This phenomenon seems to be natural due to functioning in the conditions of low interest rates.

While analysing the term structure of household deposits, it can be noticed that a characteristic feature of this segment of customers constituted a stronger growth of amounts of overnight deposits and slower rate of increasing term deposits in the whole period covered by the analysis. For comparison:

- in 2014 the growth rate of overnight deposits amounted to 10.4, whereas, the value growth of term deposits of enterprises amounted to 7.3%;
- in 2015 the growth rate of overnight deposits amounted to 17.5%, whereas, the value growth rate of term deposits of enterprises amounted to only 1.6%;
- in 2016 the growth rate of overnight deposits amounted to 16.3%, whereas, the term deposits of enterprises decreased in this year by 3.9%;
- in 2017 the growth rate of overnight deposits amounted to 13.6%, whereas, the term deposits of enterprises decreased in this year by 8.4%;
- in 2018 the growth rate of overnight deposits amounted to only 6.8%, whereas, the term deposits of enterprises decreased by only 0.8%.

The analysis of the data included in table no. 4 implies that in the currency structure of household deposits, in 2014, a faster growth in the significance of zloty deposits as compared to currency deposits (contrary to the previous year) was observed. Zloty deposits from households increased in 2014 by 11.1% and at the end of the year generated the value of PLN 533.6 billion. In the case of currency deposits, the value growth in this category of deposits amounted to 7%. It may be the effect of smaller transfers of funds from abroad to households, as well as it may result from the lack of profits from exchange differences. The opposite situation took place in the consecutive year, when faster growth in significance of currency deposits as compared to zloty deposits was noted. Zloty deposits from households increased in 2015 by 9% and at the end of the year generated the value of PLN 603.6 billion. In the case of currency deposits, the value growth in this category of deposits amounted to as many as 17.5%. Determinants of those changes could include: the increase in the transfer of funds from abroad to households and, which seems to be the most important, the change in the exchange rate regarding several most important currencies in the world. In the consecutive two years of the analysis, i.e. 2016-

17, faster growth in the meaning of currency deposits as compared to zloty deposits was observed. Respectively:
- in 2016 zloty deposits from households increased by 9.2% and at the end of the year generated the value of PLN 659.1 billion. In the case of currency deposits, the value growth in this category of deposits amounted to as many as 15.6%.
- in 2017 zloty deposits from households increased by 2.8% and at the end of the year generated the value of PLN 677.4 billion. In the case of currency deposits, the value growth in this category of deposits amounted to as many as 17.1%.

Changes that could have been observed in these years predominantly resulted from transfers of funds from abroad to households; partially they could have resulted from exchange differences and partially - from decisions of deponents. Whereas, the interest rate of deposits was of small importance, where the difference in the level of the said interest rate in comparison with zloty and currency deposits was further decreasing.

In the last year of the analysis zloty deposits from households increased at almost the same rate (10.2%) as currency deposits of those customers (10.3%). At the end of the year, zloty deposits reached the value of PLN 746.3 billion. Whereas, the growth rate of zloty deposits was clearly higher than the result from the previous year and in the case of currency deposits – lower than a year before.

In 2014, similarly as the year before, the banking sector noted a stronger growth of zloty deposits from enterprises (by 11.1%) than currency deposits (by 0.3%). The situation changed in 2015, which marked a return to the situation observed in the years 2011–2012, that is, to higher dynamics of currency deposits from enterprises than zloty deposits. Dynamics of currency deposits was high and amounted to as many as 23% per year, whereas, zloty deposits noted an increase by 8.3%. In the year 2016 a situation observed in 2015 was repeated, that is, a significantly higher dynamics of currency deposits (28.3%) of enterprises than zloty deposits (4.7%). Dynamics of these deposits was record-high in the recent years, even if the impact of fluctuations in foreign currency exchange rate as compared with zloty is taken into consideration. Also in the year 2017 the dynamics of currency deposits was again very high and amounted to as many as 24.3% per year. In comparison, zloty deposits noted a small drop by 1.2%. A high growth rate of currency deposits in the years 2015-17 was especially noticeable in the period of strong growth of the Polish export in the recent years, including also the increase of its significance for financial results of Polish enterprises. The year 2018 marked a reversal of the situation observed in the years 2015–2017, that is, divergence from the higher dynamics of currency deposits of enterprises than zloty deposits. In this year the dynamics of currency deposits was very low, as there was a decrease in the amount thereof by 9.5% per year. In the same period of time the value of zloty deposits increased by 6.7% per year.

Conclusions

While assessing the situation of the banking sector, it may be stated that in compliance with the binding banking model in Poland, commercial banks conduct their activity mainly on the basis of foreign capital. The conducted research indicated that non-financial sector deposits are, from the point of view of their proper functioning, a very important component of their liabilities. Additionally, the said research underlined the significance of household deposits in the funding structure of Polish commercial banks. Predominantly due to the fact that they constitute approx. 40% of the balance sheet total and each increase in the value thereof has a positive impact on the manner of maintaining financial stability of commercial banks. Therefore, contemporary commercial banks undertake a series of measures both, in the scope of soliciting new customers and maintaining the existing ones. It is undoubtedly a difficult task owing to the fact of functioning in the conditions of continuous competition, growing globalisation, as well as the increase in the significance of new technologies.

Abstract

Electrical installation construction projects are among the most specialized within the electrical sector, with a very high degree of difficulty compared to other construction projects. Total costs of elements to be installed for such a project can reach US$ 7,000,000.00. Therefore, delays in this type of project result in high cost overruns. Accordingly, the present work proposes an improvement model that integrates the Plan-Do-Study-Act (PDSA) methodology, Takt Time Planning (TTP), and Failure Modes and Effects Analysis (FMEA) tools to improve efficiency in the design and planning of electrical assembly projects.

Keywords: Plan-Do-Check-Act, Plan-Do-Study-Act, cost overruns, Takt Time Planning.

Introduction

At present, companies responsible for assembling electrical substation equipment are subject to customer requirements, including the performance of quality services that ensure adequate future operational results. Therefore, the tools and capability to manage projects in the most efficient way are essential for fulfilling and participating in the power generation, distribution, and transmission projects of large companies.

However, despite their specialization in assembling devices for the electricity sector, these companies face high cost overruns in their projects, mainly due to delays. The causes determined for this problem are bad programming, misestimation of budget, inappropriate timeframing, and the failure to identify risks based on key project planning and design processes.

Given the problem as described, this paper proposes an improvement model that integrates the Plan-Do-Study-Act (PDSA) methodology with Takt Time Planning (TTP) and Failure Modes and Effects Analysis (FMEA) tools to improve efficiency in the design and planning of projects to reduce cost overruns in their execution.

State of the art

Various methodologies or tools are currently used for project planning. Among these is the Project Management Body of Knowledge (PMBOK) guide, which proposes best practices for project management. However, the degree of uncertainty is admittedly high in the execution of these best practices. Therefore, Biotto (2017) and Cristóbal (2016) state that the PMBOK project execution guide in the Project Management Institute (PMI) approach is not very useful for the management of construction projects because of the high degree of uncertainty it creates. These researchers thus defend the implementation of Lean Construction (LC) tools as a better way to manage such projects.

Indeed, some propose that LC be made a part of the PMI approach to create a model possessing the best aspects of both methodologies.

Delay and Cost Overrun Factors

Because of the complexity, large scale, long duration, high investment, and site conditions, various researchers agree that projects are exposed to greater risks than traditional project construction. Andrić (2019) and Lozano (2018) suggest this greater risk as the reason that such projects are likely to incur cost overruns. In other studies, researchers highlight the time overrun on various projects. These studies indicate that less than 30% of such projects are completed on time, although the average time excess is less than 30% (Assaf (2006), Akogbe (2013), Chan (2002)).

Among construction projects, electrical installations require a spectrum of essential and specialized work services (Yik, 2008). Failure to complete an electrical installation on time causes delays in the configuration of site provisions. For this reason, many contractors fight for better planning to improve time management (Chiu, 2017).

According to various studies, the most frequently reported causes of cost overruns are underperforming contractors, an environment of uncertainty, recurring financial issues, general price escalation, high capital cost, delays in the supply of equipment, poor administration, poor work supervision, poorly prepared subcontractors, schedule delays, inadequate planning of activities and schedules, lack of experience, inadequate modifications of times and costs, changes in designs, risks and uncertainties, inadequate evaluation of the duration or time of the project, complexity of the work, and subcontractor non-compliance. As mentioned, these authors agree on the planning factors and the inadequate evaluation of risks and costs (Lozano, 2018; Chiu, 2017; Narayanan, 2019).

Takt Time Planning (TTP)

The Last Planner system has exhibited greater reliability in planning and creating an environment for continuous improvement. Frandson (2013), Dlouhy (2018) and Binninger (2017) reported that the use of Takt Time Planning (TTP) is more efficient with a control system such as the Last Planner. Equally importantly, Binninger (2018) documented more than 80 construction projects of various sizes for which the TTP tool was used successfully. One of these was a medium-sized pilot project in southern Germany, characterized by a non-repetitive workflow. This project achieved a substantial (70%) reduction in time vs. the initial estimate.

The main benefits of TTP are variability reduction, project duration reduction, and project cost minimization (Yassine, 2014). Similarly, they reported the importance of working together to achieve the takt goals of eliminating downtime, avoiding interruptions, and saving resources, all of which ultimately result in enhanced productivity.

Failure Mode Analysis and Effects

Barbosa (2018) reported a successful application of Failure Modes and Effects Analysis (FMEA) in 10% reduction of complaints regarding the design of a product. To analyze non-conformity in product quality, they integrated Lean tools such as six sigma, quality function deployment (QFD), and FMEA in analyzing various stages of production and logistics. Similarly, Izaguirre (2017) reported the application of FMEA integrated with 8D, providing a manufacturing company with a total cost savings of 40% with respect to the initial estimate. This application also improved the percentage of satisfied customers by improving the design of the production process. Izaguirre (2017) and Rojas (2019) also agreed that FMEA can be effectively combined with other tools; that is, it presents flexibility for adapting or linking up with other methods according to project requirements.

Plan-Do-Study-Act

The Plan-Do-Study-Act (PDSA) continuous improvement cycle is considered to be the descendant of the Plan-Do-Check-Act (PDCA) cycle developed by Deming in 1950 and modified in 1993 (Moen, 2009). Chakraborty (2016) reported the importance of the application of the PDSA cycle methodology in medium-sized companies, for which these authors indicate that it must be applied on a smaller scale at first, that is, to some specific process of the company. This advice is aimed at minimizing interruptions in the area of interest and is bound to achieve greater success in its implementation.

Similarly, Arnao (2006) reported the implementation of continuous improvement in which different tools are integrated with the PDSA cycle, such as the Pareto chart, 5S methodology, cause–effect analysis, and QDF. This research obtained an average productivity increase of 34% for the relevant products.

Contribution

The model proposed herein seeks to apply Lean tools, namely TTP and FMEA, through the PDSA methodology. In this way, the companies that use these tools can reduce their cost overruns by avoiding delays and obtaining satisfactory performance in their projects and processes.

Based on Section II, a comparative matrix was developed that presents the different attributes of selected tools. Insights from this matrix facilitate the development of the model proposed below.
The attributes of the model according to tool type are as follows:

- A1: orientation to continuous improvement,
- A2: analysis of customer-oriented methods,
- A3: productivity increase,
- A4: reduction of operating costs,
- A5: process knowledge and reliability and
- A6: capacity for integration with other tools.

Table 1: Matrix of attributes and tools

Tools /Attributes	A1	A2	A4	A5	A6	A7
TTP		x	x	x	x	x
FMEA	x			x	x	x
PDSA	x		x		x	x
PROPOSAL	x	x	x	x	x	x

Model Design

Figure 1 illustrates the proposed model, which is guided by the PDSA methodology or modified Deming cycle. This guidance allows proper implementation of the model. Although this technique is used here for drastic or radical continuous improvements, it can also be adapted to smaller improvements than those of other methodologies.

Fig. 1: Improvement model to reduce cost overruns in assembly projects

The model starts with Plan (Planar), in which the diagnosis is made, the objectives are defined, and the improvement plan is proposed. In Do (Do), the proposed plan is carried out by applying the tools. In Study, the results are analyzed. Finally, Act adjusts if necessary what has been done in Do, and returns to the Plan to continue improving or to forge a new plan.

Main Components of the Model

Takt Time Planning: TTP is a planning tool that aims to design the development system of a process or workflow that maintains its operations at a balanced work pace matching the customer's demands. For the proposed model, the TTP tool allows resources and time to be distributed equitably, providing a better work sequence to be accomplished on a shorter time scale.

Failure Mode Analysis and Effects: The FMEA methodology is a technique that serves as an alternative to risk management. FMEA allows risk assessment to be centered on the analysis of identification, evaluation, and prevention of possible failures. FMEA helps reduce the risks associated with the development of the project. The implementation of this technique provides greater detail regarding the service to be improved while reducing the percentage of costs subject to project risks.

5W-H Matrix: The 5W-H matrix is a method that inquires (who, what, where, when, why, and how) about a process or problem. For the proposed model, this technique organizes those responsible for each activity of the implementation. In this way, the dates, managers, methods, and places of elaboration are established.

Checklist: The checklist is a list of predefined tasks or, interchangeably, steps to follow. For the proposed model, a checklist of the client's requirements must be prepared. In this way, the checklist verifies that the plan complies with the request.

Matrix of critical processes: This matrix allows the selection of those critical processes that require greater control or review. This matrix was applied to the proposed model in the plan phase, since the matrix helped in determining processes that caused the problem(s) and then analyzing the root causes.

Implementation Guide

Figure 2 illustrates a step-by-step guide to the phases of the proposed model as observed through a scheme. This scheme is divided into phases: Plan, Do, Study, and Act.

Fig. 2: Proposed Model Implementation Guide

Validation

Case study

The improvement proposal presented was implemented in a microenterprise dedicated mainly to offering maintenance and assembly services for power transformers in the electricity sector in Peru, with a trajectory of more than 25 years. The company has been presenting large cost overruns in its projects due to the poor project planning and design processes.

Indicators for the case study: Table 2 presents the indicators designed for the case study. The main indicator is the cost overrun percentage, as it represents the problem to be solved. Three indicators measure the reduction of the impact generated by the problem. Established indicators served as a basis for analysis of the company's current situation regarding power transformer assembly projects. This analysis determined that the average project cost overrun is 31%. Nearly half (14%) of this average overrun is costs for penalties; approximately one quarter (8%) is costs for unplanned days; and another quarter (9%) is due to unidentified or controlled risks.

Table 2: Definition of indicators for the case study

Indicator	Formula	Purpose	Interpretation		
			Acceptable	Significant	Unacceptable
Percentage of cost overruns	$\frac{(Real\ Cost - Estimated\ Cost)}{Estimated\ Cost} \times 100$	Measure project cost overruns in percentage	Less than 15%	Between 15% and 45%	More than 45%
Decrease in cost due to penalties	$\frac{Total\ Penalties}{Cost\ overruns} \times 100$	Measure the costs for penalties in percentage	Less than 5%	Between 5% and 20%	More than 20%

Cost reduction for unplanned days	$\frac{Cost\ of\ unplanned\ days}{Cost\ overruns} \times 100$	Measure costs for unplanned days in percentage	Less than 5%	Between 5% and 20%	More than 20%
Cost reduction due to unidentified risks	$\frac{Cost\ of\ unidentified\ risks}{Cost\ Overruns} \times 100$	Measure risk costs as a percentage	Less than 5%	Between 5% and 20%	More than 20%

Model Implementation

PLAN:

- Step 1 – Problem Statement: The problem determined is the cost overrun on power transformer assembly projects. Likewise, the results (Fig. 3) obtained from the matrix of critical processes indicate that the main processes causing the problem are the design and project planning processes.

Fig. 3: Critical process matrix of the case study

- Step 2 – Diagnosis of the case study: From the TTP tool, the takt zones were determined: The current design proposes an execution of a 50 V transformer assembly project in a period of 17 days.
- Step 3 – Improvement plan: Once the diagnosis was made, a plan was prepared, indicating how, who, when, where, why, and what through the 5W-H matrix. This plan indicated a duration of 30 days to make the improvement plan and eight operators in total to participate in the improvement plan.

DO:

- Step 4 – Preparation of a planning and design team, The team from the corresponding areas and those involved together on this project must be trained and informed about the proposal to be implemented, so that it can be successfully carried out.
- Step 5 – Analyze customer / process requirements, A checklist was prepared to summarize the fundamental points from which to develop the project and by which to inform the team's approach.
    - Requested duration: 17 days
    - Place: ES Piura WEST
    - Customer: -
    - Start date: 4/11/2019

  Restrictions: The security engineer will not carry out any operational activity other than supervision.
- Step 6 – Prepare FMEA: An FMEA analysis was performed that identified more than 60 failure modes in total. On average, three failure modes were possible for each activity. More emphasis was given to those tasks related to activities that had the highest Risk Priority Number (RPN). Corrective actions to be included in the design were established.

- Step 7 – Detailed project design: According to the results obtained from the diagnosis in the Plan stage and the FMEA results, corrective actions are taken in the design to reduce risks. In addition, details of each procedure regarding the relevant functions and resources are elaborated.
- Step 8 – Define zones and takt time: The client's requirements in the present case included an approximate duration of 10 days, whereas our estimated time was 17 days.

$$Takt\ time: \frac{17\ days}{10\ days} = 1.7 \quad (1)$$

The above formula yields a result of 1.7. This means that the delimited areas have an average duration of 1.7 to be completed in the time requested by the client.

- Step 9 – Balance workflow: When the zones are balanced, the distribution of work is more orderly and equitable. This process has allowed the work plan schedule to change from 17 to 11 days.
- Step 10 – Prepare schedule and budget: According to the results in terms of time, the project schedule is prepared. This has been done in a Microsoft Excel format that allows the projection and control of implementation results. Thanks to the detail of the project design and the analyses performed, a much more realistic work budget was elaborated.
- Step 11 – Work team preparation: Training is carried out with the planning team, as well as those hired for the execution of the work, so that they know the new work plan to be carried out.

Study

- Step 12 – Analyze results: For this step, the execution of the planned project has ended. An analysis of the results obtained is then carried out.
  Results of applying TTP: Regarding the work plan and defined takt time, the work was distributed in a more equitable and collaborative manner.
  Figs. 4 and 5 indicate that, according to the characteristics of the task, more operators available for a given activity have been added, allowing the project to complete on a timeframe closer to that requested by the client.

Fig. 4: Activities balance before TTP

Fig 5. Activities balance after TTP

Results of applying FMEA: Implementation of the recommended actions in the FMEA caused a significant decrease in the RPN of the prioritized activities in most cases (Fig. 6).

Fig 6. Initial and final RPN of the project

Results for indicators designed for the case study: Table 3 indicates that the total cost overrun per project was reduced from 31% to 11%, including cost reductions for penalties and for unplanned days. However, the costs associated with unidentified risks remained unchanged.

Table 3: Results of indicators designed for the project

Indicator	Value without improvement	Projected value with improvement	Resulting value with improvement
Percentage of cost overruns	31%	10%	11%
Decrease in cost due to penalties	14%	0%	0%
Cost reduction for unplanned days	8%	5%	2%
Cost reduction due to unidentified risks	9%	5%	9%

ACT

- Step 13 – Summarize what has been learned: The results obtained demonstrate that an even more thorough risk analysis should be carried out, since costs associated with unidentified

risks dominate the improved cost overruns. However, it is noteworthy that the penalties category, which previously dominated overall cost overruns, was fully zeroed out thanks to the implementation of the takt time planning tool. Also, according to the observations of the operators, teamwork was one of the fundamental means by which assigned tasks were fulfilled, leading to the completion of project execution in the determined time.

- Step 14 – Changes to be made: According to the results, it will be necessary to carry out a risk analysis of the project with the observations given by the operators and to evaluate the recommended actions.
- Step 15 – New cycle: According to its characteristics, the proposed model can be implemented in the other services of the company, including other projects of smaller scale. This companywide implementation would serve to optimize all the processes of the company in the long term.

Conclusions

The FMEA tool is a tool that easily adapts to other tools; that is, it can be included in different work methodologies. For its part, the PDSA tool has been found to be widely adaptable to any sector or organization that is required.

The results of the present analysis demonstrate that, based on the design, it is ideal to add more control tools that allow both planning and project execution to be integrated. The same can be said for tools that allow a deeper analysis of the topics to be investigated or improved.

The implemented design allowed the company to reduce its cost overruns in transformer assembly projects and thus obtain greater utility per project. However, a more thorough risk analysis and more effective action plans remain pending.

Finally, it can be concluded that the proposed model managed to reduce the time and cost overruns in the case study project. This success will allow it to be applied in the company's other services and is likely to increase sales while improving the company's image. It is recommended that every project have a manager in charge of management control, as it is important to follow up and guide when deviations occur.

Abstract

Previous studies revealed that semiautomated electrical cable manufacturing companies in Peru have high production costs due to high levels of machine breakdowns, high mean time to repair, and poor/inadequate training provided to a plant's staff. Hence, this paper addresses the abovementioned issues through a management model based on lean manufacturing techniques and total productive maintenance philosophy by measuring their impact on a pilot project.

Keywords: Lean Manufacturing, TPM, Losses, Metalworking.

Introduction

In Peru, the metalworking industry plays a vital role due to its contribution and dependence on the mining sector, production of the auto parts, wood products for export, food and fishing sectors for direct human consumption, energy and construction sectors; in addition, a variation in any of these sectors directly impacts the metalworking industry.

In the manufacturing sector, the metalworking companies dedicated to the production of electrical conductors are highly dependent on the mining sector with respect to copper production; owing to the high costs related to variations in production, the problems related to the manufacturing sector aggravates with production losses, high reprocessing levels, and late order delivery.

To solve these problems, we combined the value stream mapping (VSM), 5S, and total productive maintenance (TPM) methodologies because these methodologies have been implemented in various industries for eliminating all types of production system waste.

As difficulties faced in eliminating all types of production system waste are the major problems in today's highly competitive business environment, companies are concerned about improving the quality of their products and services to achieve sustainable growth and advancing their position and reputation in the market. This paper thereby proposes an implementation model that integrates 5S, TPM, VSM, and the overall equipment effectiveness (OEE) indicators.

We validated the proposal by addressing the problems of Celsa, a metalworking company, dedicated toward manufacturing and marketing of electrical conductors for the construction, mining, telecommunications, and manufacturing sectors.

State of the art

Krajewski (2013) argues that lean manufacturing eliminates waste and delays in every process conducted by a company, thereby maximizing the added value of its products. Similarly, Bhamu (2014) states that lean manufacturing is mainly dedicated to transforming a company to be highly competitive and responsive to customer demand by waste elimination.

Lean manufacturing offers various tools and techniques, such as VSM, 5S methodology, and TPM, to increase a company's profitability.

Al-Ashraf (2012) reports that VSM is a main tool that is employed to identify improvement opportunities. Yu (2009) describes a comparative matrix used to choose lean techniques and presents VSM implementation research conducted in different manufacturing industries.

Moreover, several problems have been addressed by different studies that have designed various proposals as solutions. According to Randhawa (2017), Chapman (2005), and Randhawa (2018), the 5S method is used to improve the organization's workplace and reduce waste, costs, and time spent in production; 5S initiatives allow employees to organize and manage their workspace, time, and capital investment to reduce the rejection rate in production.

Management commitment or support, full employee involvement, education, motivation toward continuous improvement, and training play a significant role in the successful implementation of 5S in any organization; this tool consists of five fundamental elements that act as the basis of a good production system. 5S focuses on maintaining workplace organization, maintaining cleanliness, standardizing techniques and regulations, and facilitating discipline in the workplace to sustainably improve organizational productivity, efficiency, cost optimization, and waste reduction Osada (1989).

Studies conducted by Bhamu (2014), Hooi (2017), and Bataineh (2019) have reported problems such as breakdowns and high mean time to repair, which need to be resolved to meet the TPM implementation's success factors focused on top management leadership, maintenance practices, and TPM implementation initiatives.

Input

Our proposal combined three tools, namely, 5S, TPM, and VSM, to integrate and resolve the main problems related to an organization's low profitability.

We made a comparative analysis of tool dimensions and achieved the following eight dimensions.

Table 1: Comparative Matrix Proposal vs. Dimension

Problems	**D1**	**D2**	**D3**	**D4**	**D5**	**D6**	**D7**	**D8**
5s	X	X	X	X	X			
TPM			X			X	X	
VSM								X
Proposed Model	X	X	X	X	X	X	X	X

The proposed model was the sum of VSM, 5S, and TPM tools. The five S' in 5S were sort, set in order, shine, standardize, and sustain; furthermore, the factors of TPM methodology included equipment effectiveness and autonomous maintenance. Finally, in the comparative matrix, the VSM indicator was production control.

Randhawa (2017) describes the 5S method employed as a quality improvement tool in Wellex Corporation (USA). After two years of the 5S implementation, the corporation's productivity improved by 26%, reaching a turnover of USD 23 million. In another company (C&K Systems), the 5S was used to improve the product quality and work environment's quality and increase the percentage of trained employees.

Lai Wan Hooi argues that although traditional maintenance initiatives significantly affect factory performance, they do not affect top management and maintenance practices; furthermore, the author states that TPM implementation initiatives will gradually enable commitment, proper planning, appropriate execution, and continuous improvement Chang (2014).

A study conducted in a manufacturing plant revealed that the maintenance department spent 67.6% of its time on corrective maintenance repair, 24.3% on preventive maintenance, and 8.1% on other activities. In addition, the surveys conducted showcased that 70.5% of the workers were aware of the TPM concepts; 14.7% of the workers believed that TPM would help improve the current maintenance system; and 14.7% of the workers were unsure Mwanza (2015).

The proposed model consists of three tools addressing the issue of low profitability in a power cable manufacturing company.

Fig. 1: Integrated 5S and TPM Model

Figure 1 shows the proposal used to solve the identified problem, which is formulated on the basis of an input and output model, i.e., the company's system receives input elements that result into generating a transformation through processes and achieving the expected results.

On the basis of business planning, we implemented the VSM tool to understand the process, identify the waste, and non-value-added activities. Later, we performed the 5S audit, and in parallel, we used the OEE indicator to measure the equipment effectiveness. After the business diagnosis, we aimed at achieving a 5S audit higher than 70 points and an OEE indicator of 75%. Control and supervision would only be performed when the abovementioned goals have been achieved; otherwise, the implementation of the two proposed methodologies (5S and TPM) must be continued. Moreover, both the tools provide indicators to measure the implementation effectiveness of the proposed model.

Implementation Phases

The model will be implemented in two phases.

Phase 1: Business analysis and diagnosis: Consists of collecting all the information from the organization's production area under study and understanding and obtaining the current state of the area to be treated.

- **Define the implementation scope and goals**, and seek top management commitment.
- **Model policy** specifies that the whole organization must be committed to and motivated with the changes to be implemented.
- **Task assignment** includes assigning responsible people in the pilot area who will be in charge of assessing and enforcing the new implementation.
- **5S audit** is a documented process used to assess the current state of the company's compliance with the existing standards.
- **OEE indicator** is used to measure the equipment effectiveness.

Phase 2: Methodology implementation: On the basis of the literature review on 5S and TPM, we designed a proposal that combined both the tools comprising 2 phases and 11 activities.

1. Staff training plans were developed for providing training in terms of basic concepts and according to the employees' requirements related to their daily work, and then, surveys were conducted with each employee.
2. A blackboard was used to seek the employees' attention for attending the training sessions.
3. Responsible people were assigned to each area, and they classified the instruments or tools in their work area.
4. Staff training plans were developed with respect to basic knowledge related to implementation, such as an induction on TPM and 5S, basic mechanics, and machine cleaning.
5. Training was conducted according to the needs of each employee's work area.
6. After the workplace organization, easily accessible storage places were defined and prepared to store the process tools and/or materials; it was recommended to work on this activity together with other areas.
7. The tools and/or materials were classified into three groups, namely, necessary items, occasionally used items, and unnecessary items.
8. In the workplace organization, necessary items were identified from unnecessary items by using visual elements such as "red card." In this way, an employee would identify the unnecessary items and take corrective measures.
9. Storage places were defined and prepared where process tools and/or materials were to be located. In this way, unnecessary activities would be avoided, and employee efforts would be minimized.
10. The visible tools and places were identified and labeled to achieve a better visual control.
11. A thorough cleaning was performed at least twice a year, which was called "The Great Cleaning Day," because a thorough cleaning of machines, work tools, offices, and other areas of the company was vital.
12. A cleaning kit was placed in each area with the necessary tools for proper cleaning management.
13. Machines were divided into three sections, and a person was assigned for each part; this person was in charge of keeping the space clean during each shift.
14. A cleanliness and order inspection was conducted on a monthly basis. The area that would score the best would be given incentives. In this way, we promoted employee motivation for task completion.
15. We proposed a continuous evaluation of the first steps, which would involve a supervisor and a scoring system to acknowledge and reward the best area.
16. A meeting was held every week with the people responsible for the assigned tasks to inform about the achievements and improvements required for attaining the goals.
17. Two panels were setup. Panel 1, i.e., the 5s panel, reported about the implementation progress and team members, showcased pictures of the conditions before and after the implementation of the model, and displayed winners of the monthly inspection. Panel 2, i.e., TPM panel, recorded the employees' observations about the equipment and displayed a TPM progress chart.
18. Finally, the implementation must be controlled and supervised.

The abovementioned steps were executed on the basis of the models described below.

The first model identified for proposal comparison was based on preventive maintenance that aimed at guaranteeing the production plant equipment availability and operational reliability in an efficient and safe manner to meet the company's quality policy; this model integrated the TPM and 5S methodologies. From this proposal, we used the fundamental concepts of maintenance types and then selected the model based on preventive maintenance.

The second model was a proposal solution for an integrated production and maintenance system to reduce the company's costs. It consists of a training plan for the production area employees, alongside material requirements plan (MRP). We first used the TPM to develop an autonomous and planned maintenance and later used the VSM lean manufacturing technique and the 5S'. Owing to the fact that we used this model to prepare and develop the training plan in the production area, we did not use the MRP because the selected combined methodologies adequately resolved the existing issues.

The model implementation phase began with the VSM development to identify waste, time loss, etc. Then, in parallel, we diagnosed the equipment effectiveness and performed the 5S audit. The OEE indicator was intended to increase equipment effectiveness by 100%, and the goal of the 5S audit was to achieve more than 71 points. If the results were not positive, the implementation of the proposed model was commenced, alongside implementing the 5S and the TPM. In addition, the employees should be periodically trained and given incentives to keep them engaged and motivated, respectively, to continue with the implementation because they are the stakeholders who are mainly involved.

Following steps were taken for the implementation of the model.

Fig. 2: Proposed Model's Flowchart

Interpretation Phases

Interpretation of Phase 1 indicators: The survey measured the percentage of employee satisfaction, an indicator used to assess the employees' degree of conformity toward their working environment and conditions. Further, the results were directly proportional to the company's good practices, work quality, and productivity and profitability indicators.

Data collection was another indicator used to identify the company's problems. In this case, we identified the percentage of waste, reprocessing, and delayed delivery and problems related to employees and machines that prevent the company's growth in the manufacturing area.

The job description manual was a work tool that contained the rules and tasks that each employee followed and performed, respectively, as a part of their daily activities.

Step-by-step guide for Phase 1 indicators:

- We collected data to identify the root causes of the company's low profitability.
- Responsibilities were assigned to each employee so that they feel committed toward the new implementation.
- The OEE indicator was measured to determine the equipment effectiveness.

Interpretation of Phase 2 indicators: Gross profit margin was a profitability indicator that relates gross profit to the company's total sales.

The OEE indicator provided insights into the losses incurred during the manufacturing process; it consisted of the availability, rate of return, and quality rate multiplication.

The quality indicator measured the level of compliance with the manufacturing process specifications.

Step-by-step guide for Phase 2 indicators:

- We measured profitability so that it can be assessed after the model's implementation to further make a comparison.
- A quality indicator was used to determine the rejection rates, the percentage of production losses, and delayed delivery.

Validation

We implemented the production area model proposed to improve organizational profitability in a manufacturing company dedicated to manufacturing of power cables. Further, we analyzed the tools proposed for each phase.

Phase 1. We analyzed the company's production processes to find out how and where they were performed. We also found unused equipment and dirty and messy work areas. Furthermore, we performed the 5S audit and achieved a score of 63 points. In addition, we assessed the equipment effectiveness and achieved 70%.

Phase 2. We selected the pilot area, i.e., extrusion process area, which was the most affected by the existing problems. Employee training on basic concepts and awareness about the benefits of the proposed model implementation were commenced. After each training session, we conducted a survey to measure the performance and understanding of each employee. To disseminate information and motivate the employees to attend the training sessions, a blackboard was made available for everyone to read and be enthusiastic about the topics covered in these sessions. A space marked by a red tape was provided in the extrusion process area so that the employees could separate the necessary from the unnecessary tools; further, red cards were used to classify the tools, and two

panels were established to encourage the employees. The 5S panel detailed about the team structure and recorded the progress with respect to the implementation process on a monthly basis, while the TPM panel was used by the employees to write comments on equipment sounds or any observation regarding the equipment.

Fig. 3: Comparison of the Extrusion Work Area Orde

Fig. 4: Comparison of Equipment Maintenance

Phase 1 indicators were reanalyzed to measure the implementation progress. We achieved 80% of the OEE indicator and an increase of 29 points in the 5S audit, thereby providing all the employees with an excellent and more comfortable working environment.

The implemented model was effective in addressing the root causes of “low profitability,” reaching an improvement of USD 151,999, i.e., a 72% improvement in the Celsa’s profitability.

Conclusions

The pilot plan test conducted in the extrusion work area reveals improvements in waste reduction, reprocessing, and late order delivery. Therefore, we conducted the implementation simulation in the entire company and achieved 72% of improvement, saving USD 152K for the company and providing reliable solutions for the existing problems. Moreover, the 5S and TPM methodologies played a crucial role in addressing these issues. The implementation shows that these two methodologies can work together to upgrade the staff and improve and organize the workplace.

Acknowledgments

The authors would like to thank all the participants who provided invaluable information, including Celsa for allowing the authors to conduct this study successfully.

Abstract

The aim of the paper is to present main findings of the research project "People with disabilities as actors in motion capture sessions" held in 2015 and sponsored by Polish Ministry of Science and Innovative Economy European Union Programme. Project is a part of "University of Young Inventors" programme and supports close collaboration between universities and high schools. We were working with a team of 8 young researchers from The 3rd High School in Wroclaw. The aim of the project was to show strengths and limitations of collaboration with disabled people as actors in motion capture shots. We are working with young people visually impaired, in a wheelchairs and with the deaf ones and this way are able to examine their sometimes very unique movements and behaviors mapped into virtual creatures and personas. Motion capture system is used in this project as a tool to bring out potentials of disabled people that abled ones don't have. In the same time mocap is also a technology that brings new findings regarding inclusive design.

Keywords: Motion Capture, Disabilities Studies, Inclusive Design, 3d Animation.

Introduction

The contemporary video game developers and CGI/animation studios typically seek new, more profound fictional patterns on the one hand, and on the other they aim at creating a film and game environment even more perfect in terms of credibility of the world presented. Thus the purpose of this research was to discuss to what degree these tendencies can be developed with the participation of people with disabilities and motion capture technology, which is frequently used in games and animations. At present, these systems have numerous technological versions, which are employed in various ways. Nonetheless, the animation and game design industries seem to benefit the most from it and they are exactly the target of the following study.

The research project "People with disabilities as actors in motion capture sessions" has been held in 2015 and sponsored by Polish Ministry of Science and Higher Education as well as Innovative Economy European Union Programme. Project was a part of University of Young Inventors" programme and supports close collaboration between universities and high schools. We were working with a team of 8 young researchers from The 3rd High School in Wroclaw. The aim of the project was to show strengths and limitations of collaboration with disabled people as actors in motion capture shots. We were working with young people visually impaired, in a wheelchair and with the deaf ones and this way are able to examine their sometimes very unique movements and behaviors mapped into virtual creatures and personas.

The main purpose of this research was to elaborate on the strategies for working with people with disabilities and showing a grand potential of this type of co-operation when developing computer games and animations. We have made a point of a thorough investigation and formulating conclusions, which would allow representatives of game design and animation industries to prepare and organize sessions which people with disabilities could participate in, bearing in mind technological, acting and communication conditioning. In the research, the method of open and controlled participant observation, was employed, connected with the analysis of video materials recorded during sessions. The project can be described in terms of scientific and practical assumptions of occupational therapy as subjects were directly and indirectly involved in the process of developing animations. Motion capture system serves in the project as a tool to bring out potentials of disabled people that abled ones don't have. In the same time mocap is also a technology that brings new findings regarding inclusive design.

We began with an attempt to develop the idea of inclusive design. The central conviction here is the necessity to design products and services addressed to a wide range of users, including those from typically marginalized groups, e.g. people with disabilities and the elderly . While inclusive design mostly focuses on an end user (Persson et al. 2015), we aim at including a marginalized group in the course of designing a product, even if this product is not targeted at this group (e.g. working with the blind to develop computer games and animations, even though they themselves cannot benefit from them).

The hypothesis which we would like to suggest here could be verbalized in the following way: people with disabilities fail to participate in commercial motion capture sessions, which impoverishes characters' motions present in games and animations. This means that people with special needs suffer from design exclusion not only as end-users of various technologies but also as producers of a media content.

Simultaneously, we wanted to address the following research questions:

1. Which unique motor capabilities are typical of people with disabilities?
2. What limitations appear during motion capture sessions involving people with disabilities?
3. How to organize sessions involving people with disabilities?
4. What challenges for animators appear in the course of processing materials from mocap sessions involving people with disabilities?

Literature Review

During literature study period of the project it has been found out that research on motion capture systems can be divided into several main areas: biomechanics and movement tracking, application of motion capture systems in medicine, rehabilitation and support for people with disabilities, mocap and sport , mocap in games and animations, mocap in speech, face, and hands examination, artistic projects and performative arts measurements , motion capture systems in recording animals movement. The study proved the broader lack of studies devoted to analysis of acting techniques and positioning motion capture as a tool for therapy.

Biomechanics and Movement Tracking

A lot of current research concentrates on teaching motion capture system how to be sensitive to the specificity of human body movement or one's particular organs, such as knees (Worsley et al.

2010), feet (Shultz et al. 2010), elbow (Zhang et al. 2011) or jaw (Pinheiro et al. 2010). Researchers also work on technologies which would make the most exact measurements or would have the greatest advantages in tracking the specificity of body positions, hence the interest in markerless systems or Kinect (Corazza, Andriacchi 2009, Schmitz et. al 2014, Bonnechere et al. 2014). This research is then applied in more specific areas, for instance medicine, post-traumatic rehabilitation, or supporting people with disabilities and sport.

Application of Motion Capture Systems in Medicine

Motion capture tracks the trajectory of movement of each part of the human body in a three-dimensional space, permits a detailed investigation and precise computing with little error. It is highly significant whenever this kind of system is to serve as a basis for developing new solutions for medicine. Collected data is then used for creating simulations of human movement and predicting it for clinical uses (Xiang et al. 2012). Motion capture systems provide opportunities for the development of diagnostic medicine through comparing an average movement of healthy, able-bodied people with patients suffering from various disorders of joints or muscles (Otake et al. 2005, Klotz et al. 2013). Computational collecting of characteristic parameters and differences of movement trajectories from program data and graphs (Halit, Capin 2011) or more directly from the observation of three-dimensional recordings give a precise picture of faulty functioning of the musculoskeletal system and let discover any underlying causes (Vignais, Marin 2014).

Rehabilitation and Support for People with Disabilities

The analysis of movement by means of a motion capture system provides us with a wide spectrum of biological knowledge about human body and the musculoskeletal system in humans. Movement tracking is essential for learning and detecting numerous diseases and medical conditions, it contributed to many innovations in medicine, discovering cheaper and more effective solutions in treatment and diagnosis. Since it provides valuable data, mocap finds its use also in rehabilitation. Restoring people to physical fitness after serious injuries (Engsberg et al. 2013) or helping them overcome some inborn defects or palsy can become more effective and take much less time. Motion capture helps investigate such issues as correct functioning of upper and lower limb joints, potential threats which can accompany fixing a prosthesis or the impact of rehabilitation on improving physical fitness (Yurtman 2013). It monitors the temporomandibular joint and muscles taking part in chewing, provides new information about brain centres, monitors the behaviours of human body during physical activity, e.g. horse riding (Garner, Rigby 2015) or cycling (Lai et al 2013).

Mocap and sport

Since motion capture systems can capture even the slightest movement, they are widely used in many disciplines of sport where impeccable technique and a precise trajectory of movement are crucial: racket sports – tennis, badmington (Fuji et al. 2011, Kwan et al. 2010), soccer (Shan et al. 2012), tai-chi (Chao et al. 2004), cycling (Shan 2008).

Mocap in Games and Animations

A lot of research related to the use of motion capture systems in film and game animation is devoted to solving particular problems and responding to challenges which appear on different stages of creating an animation. Interactive generation of falling motions for virtual character with realistic responses to unexpected push, hit or collision is a popular issue in many games or film

animations. Tang et al. (2006) prove that the desired effects can be achieved by means of a method based on simulated trajectory prediction and biomechanics inspired adjustment. Smooth, cyclic human motion is the point of interest of other scholars. One of the methods of modelling uses functional analysis (Ormoneit et al. 2006). In yet another project (Urtasun 2004), the authors focus on representing motions as linear sums of principal components, which has become a frequently used animation technique in video game development.

Mocap – speech, face, and hands (in the context of non-verbal communications)

The nature of our project where on the one hand we use performance capture techniques and on the other we focus our attention on working with deaf people made us differentiate between various sample groups related to animating speech and nonverbal gestures, as well as face and hand animation. Registering motion does not pose a problem for motion capture systems at present. Their result, though, is not always convincing. There is a considerable difference between a mere change of the position of a particular extremity or trunk and designating a means of communication by body language. The orally and aurally challenged, for whom facial expression and gesticulation are crucial for effective communication, are well-aware of that. Non-verbal communication is a key factor to express oneself and act properly in interpersonal relations. Its analysis has contributed significantly to the understanding of human communication. It is not surprising then that scientists are continuously developing methods of effective measurement and analysis of such behaviours. So far non-verbal messages have been observed and coded by means of evaluative schemes. This approach is plagued, though, with a number of nuisances, as a result of which scientists launched automatic measurement with motion capture devices. Poppe et al. (2014) offered a shared methodology of conducting such research, which facilitates effective comparison of non-verbal behaviours both in the whole body and selected extremities. Interesting research has also been conducted on improving facial expressions of models used in motion capture systems. One important study is the work by Deng and Neumann (2008), who examined four facial expressions: neutral, happy, angry and sad. They claim that their system effectively adopts a 3D model to recite in one of these emotional states. Chin et al. (2013) approach this issue from a different perspective. They abandon the attempt to render realistic emotional states. They venture the opinion that the audience prefers exaggerated facial expressions when watching a film or playing a computer game. They offer a system which exaggerates character's facial expression automatically. A separate group of scientific works related to registering and animation of hand motion and facial expressions are sign language studies. In the United States, Motion Capture Corpus of American Sign Language has been collected for quite some time (Lu, Huenerfauth 2012). A similar project called Sign3d, whose purpose is to register FSL - French Sign Language, is developed at Gallaudet University in the USA (Lefebvre-Albaret et al. 2013).

Artistic Projects and Performative Arts Measurements

Recording performative arts is an area which has been developing for quite some time. At the turn of the 20th and 21st century, a number of artistic and educational sessions with a French mime Marcel Marceau were recorded in the Advanced Computing Center for the Arts and Design (ACCAD) at Ohio State University in the USA. In the same research centre, American choreographer Bebe Miller, who was the man in charge, put to life another artistic project with the use of mocap. Meanwhile, at the University of California in Irvine at the Department of Dance, artistic dancer and researcher Lisa Naugle carried out her first artistic projects (e.g. AVA in 2002). With the passing of time, more and more artistic projects used mocap, often engaging artists as well as researchers. One such project which is titled "Collapse (suddenly falling down)" received the Izadora Duncand Award for visual arts in 2009 (Neff et al. 2010). A similar interdisciplinary

team was created in England in 2009 by the representatives of a few research centres. Recent findings embraces new methods of capturing and analyzing dance movements: Volkova et al. 2014, Deng et al. 2011, Oshita et al. 2013.

Motion Capture Systems and Animals

Motion capture systems serve to detect not only movement of the human body. They can also be used in veterinary or other applications related to animals. One example might be dogs therapy and rehabilitation (Foss et al. 2013). Animals whose movement have been studied through mocap sessions also include: rats (Johnson et al. 2012), horses (Skrba et al. 2009), and even spiders, ants (Gibson et al. 2007), fish or octopuses (MacIver and Nelson 2000).

Methods

The research method is a combination of several tools. Within the scope of the sessions we applied the experimental method. Before the start of respective sessions, we adopted a particular typology of motions which we intended to observe. Also, we collected comments from our participants with disabilities and we were the witnesses of their motor actions in preparatory sessions and during two sessions of theatrical workshops. The typology of motions and observational data collected during initial meetings gave us the incentive to compose frame scenarios with respective groups of subjects. The outcome of our sessions are experimental animations, which should be regarded as more as specimens since aesthetic effects were not our major purpose. Instead, we aimed at stressing the specificity of motion among people with disabilities. The animations show the potential of working with such people during mocap session and the uniqueness of their motor actions.

Second part of our research focused on the analysis of the sessions. By that we meant to reach conclusions which could be useful for further work with people with disabilities as mocap session actors. In our research, we employed the method of participant observation connected with the analysis of video materials recorded during sessions. Direct analysis of sessions and video materials was conducted with the use of observation worksheets composed specifically for this study. Since the suggestions and solutions included in this report are addressed mainly to representatives of animation and game design industry, who are directly involved in conducting such sessions (directing, system support, production support) and to people responsible for postproduction (editing the material from sessions, rigging a character and animation), we divided the analysis into several important levels such as:

1. The course of the session.
2. Comments on disability (crucial issues related to disability, body limitations and ways of dealing with difficulties, unique skills).
3. Technical comments related to conducting the sessions.
4. Comments on developing good communication with people with disabilities.

Research Group

At the turn of January and February, 6 people with disabilities were invited to participate in the project. In the course of sessions, one person quit the project due to the lack of time and was replaced with another one. The final shape of the group was influenced by several factors. The first one was the readiness for cooperation – not all participants had enough time to take part in the project. The choice of participants was also determined by an attempt to diversify kinds of

disability, which was supposed to add to the richness of unique motions we meant to investigate. Bearing in mind the shape of our research group – consisting of senior high school students – we intended to select young people, which would ease communication. As a result, most of the subjects were people at least in senior high school (4 people), and the team was completed with one junior high school student and one forty year-old person.

Fig. 1: People with disabilities who took part in our experiments together with the members of the research group.

The research group consisted of: 2 people using wheelchairs, 2 people with hearing impairment and 2 blind people.

Marcin M. – was a junior high school student suffering from muscle weakness involving lower extremities. His body type is stocky. The specificity of his disability forces him to use a passive wheelchair in a public space, while at home he moves on his knees. He is interested in computer games.

Paweł – was a forty year-old journalism graduate. He is tall. As a result of spine injury at a high level, he suffers from quadriplegia, upper body weakness including partial palm weakness, and he has to use an active wheelchair.

Łukasz – was this year's graduate of the massage educational centre. He suffers from an inborn and complete vision loss. He is an athletic body type and his hobby is bodybuilding.

Krystian – was a first grade senior high school student. He also suffers from complete vision loss. He is fairly slim and actively practises goalball and showdown.

Ola – was a second grade senior high school student. She has a partial hearing impairment corrected with a hearing aid, which makes it possible for her to communicate with other people smoothly. Ola's disability is not really a nuisance in her everyday life but she knows a variety of sign language called "signed Polish".

Marcin – was a student at a vocational education centre. He has an advanced hearing impairment and on a regular basis he communicates with sign language and lip reading. He is of slight build and he is interested in new technologies.

Pic. 2: One of the participants Marcin M. assuming the starting position (T-pose), example of a passive wheelchair.

Project Schedule

The selected group of examined people with disabilities participated in a test session and two theatre workshops in March and April, 2015. In May and June 2015, we held three day-long mocap sessions with three two-person teams divided with respect to the same kind of disability (for organizational reasons). In July and August, first animations were created. We also conducted an analysis of video materials shot during sessions.

Typology of Motions

During the conceptual stage of preparatory phase of the project, we developed a typology of motions which were substantial from the point of view of the project and which we intended to examine. The typology reflects potential benefits of motions generated by people with disabilities in animation projects.

1. Basic motions:

In this category, one can find typical body motions which are used in animations and computer games. Taking into account the underrepresentation of people with disabilities in films and computer games, we found it crucial to register sequences which could be directly used by animators. Effectively, part of basic motions discussed here are fragments of motions which mostly appear in games such as walking, running, turning around, aiming at an opponent, etc. In this category, we place the following motions: walking, running, squatting, walking on tiptoes, sitting down, bending over, stopping in front of an obstacle (abyss, wall), reloading guns, inactivity, turning around, etc.

2. Motions unique to disability:

We assumed that a considerable benefit of working with people with disabilities can be derived from using motions which can hardly be performed by professional actors. We mean here such kinds of motor activity, which are determined by a particular disability. In this category, we place the following motions and activities: overcoming an obstacle on a wheelchair, an exchange in sign language, everyday activities of blind people (e.g. pouring liquids or eating) and people with arm weakness (signing documents, eating, turning pages in a book or a newspaper).

3. Professional motions:

Apart from motions unique to disabilities, we distinguish a category of motions regarded as professional since we believe that people with disabilities take up various activities where they reach higher levels of proficiency than able-bodied people. What is meant here are some unique sports disciplines, e.g. goalball or showdown.

4. Comparative motions:

The reason why we regard this group as separate is that people with disabilities participating in game and animation projects will perform certain motions more credibly than an able-bodied actor. For that reason, it is an interesting experiment to capture the same motions of an able-bodied person and, then, by a person with disabilities in order to observe differences between these two modes of acting. In this category, we place the following motions: sitting on a chair at the desk done by the sighted and by the blind, using a wheelchair by an able-bodied and disabled person, using a mobile phone by an able-bodied person and a person with hand weakness.

5. Simulations:

In this category, we place acting tasks related to mutual mimicking motions of able-bodied people and people with disabilities. We meant to investigate limitations of moving and doing everyday tasks on both sides. Motions of non-humanoid characters: during our experiment, we paid special attention to a great potential motions of people with disabilities seem to have in animating non-humanoid characters. Our assumption was that having a body working according to different mechanics, which can act other motions and emotions, is here a competence. In this category, we investigate motions of the following creatures: quadrupeds, robots, birds, dinosaurs, creatures of unspecified shape with a different number of extremities or without extremities.

6. Improvisations:

This category features motions which were new for the participants, e.g. a space for the blind with specially arranged obstacles, which they had to find and get used to. Short role play scenarios: here, one can find short role play scenarios acted in various configurations: an able-bodied person and a person with disabilities, two people with disabilities, etc. We were eager to construct acting tasks which would reveal acting potential related to disability.

Results

Very rich data which was collected during sessions became the basis for developing eight sample animations.

Animation one

First animation features specialized movements performed by Krystian who is blind. Goalball players have to hear a passing ball. The animation shows trained offence and defence goalball movements, which are hardly repeatable for an unprofessional actor.

Animation two

Second animation is also based on Krystian's movements related to goalball. We observed that the way he catches the ball reminds of an animal attacking its victim. We used the mocap material to render a model of an attacking spider.

Animation three

The animation features Łukasz, who is also a blind person, acting as master Yoda from "Star Wars". This material proves that not only people fully capable of controlling their body can be employed for such roles. During the workshop and sessions, Łukasz did not feel too confident in acting tasks, which let him act credibly the movement of characters also having problems with moving.

Animation four

This animation was prepared on the basis of sessions involving Marcin, who suffers from paraplegia. As it has already been mentioned, since he normally moves on his knees, he was a perfect match for the role of a knight appearing in the computer game "Castle Crushers". A disabled actor is a much better candidate for this role than an able-bodied person when his movement is coordinated with a character without a knee joint.

Animation five

The animation is based on the material obtained during sessions involving Marcin who moves on a wheelchair or on his knees. In several Hollywood films, producers decided to employ motion capture systems to produce scenes involving characters requiring prostheses elongating limbs (e.g. "Rise of the Planet of the Apes", "Real Steal" or "King Kong"). In the animation of a dragon, we used primitive prostheses elongating Marcin's hands. In this material, we can observe poor mobility of dragon's rear limbs and actor's disability added to the impression that it is wounded.

Animation six

A sequence featuring Marcin and an able-bodied member of research group, Oliwier was used in this session. What was the most important in the fight scene was coordinating the shape of Marcin, who was kneeling, with the model of a character with only one lower extremity – a tentacle. It is clearly visible here that, animating the character with his movements, Marcin behaves in a natural way and fights without any effort.

Animation seven

This animation was rendered on the basis of a mocap session involving Paweł, who uses a wheelchair. The film is the example of integration activity ensuing from great opportunities provided by a mocap system. One interesting Hollywood strategy is a digital integration of bodies of two actors. It was employed in films, such as "The Curious Case of Benjamin Button" and "Capitan America". Paweł took part in a gripping take where an actor with disabilities was supposed to act as the upper part of the body of tyrannosaurus, while an able-bodied actor was supposed to act as the lower limbs. His minor hand weakness (matching the nature tyrannosaurus's movement) made the whole part look really natural, even though it was performed by two people simultaneously.

Animation eight

The animation was developed on the basis of the material involving Marcin and Ola. The actors performed short utterances revealing a great potential of mocap technology in animating characters using sign language.

Discussion

As it has been stated in the hypothesis and in the subsequent detailed questions, attention needs to be paid to a great movement potential of people with disabilities in motion capture sessions, even though it is not directly related to their acting skills. The uniqueness which is manifested by people with disabilities in this respect results from their perceptual and motor limitations, which they try to compensate naturally and neutralize creatively.

Movement skills of people with disabilities proved difficult to be recreated by able-bodied actors, which was discovered mainly during comparative sessions when subjects performed the same movements (e.g. clumsiness of able-bodied people using a wheelchair or difficulties with imitating blind people). The sessions proved then that the credibility of disabled characters, which can appear in games and animations, acted by able-bodied actors, is debatable. The subjects also demonstrated non-standard strategies of using everyday objects and dealing with daily activities. This knowledge can broaden the movement repertoire which can potentially occur in games and animations in a considerable way and also enrich the storyline of a game.

People with disabilities also prove to be "motor" specialists in narrow areas, such as dedicated sports disciplines, as well as in acting non-humanoid characters. In the latter case, dynamic properties of the body seem to be less important than passive motor skills of their body originating in their limitations. Motor barriers, as well as inhibitions against performing some acting tasks, may prove not to be a downside. They become a competence which helps to construct a kind of "body credibility". A limited plasticity of Łukasz's body boosted the credibility of the character he performed, namely elderly Yoda.

It is also worth to mention that one of the greatest virtues of working with people with disabilities was the exploration of their individual potential originating in the specificity of their disability but also unique strategies of dealing with it. Marcin M. has one such property, that is unusual dexterity of movement on his knees crucial in rendering some of the scenes. Another participant, Paweł, who suffers from quadriplegia, invented extraordinary strategies of using gloves and mouth in order to improve the grip or dealing with some basic activities.

As for organisational aspects of sessions involving people with disabilities, a few recommendations and suggestions need to be considered, which are related to communication, technical aspects or acting tasks.

During the sessions, people with disabilities as actors will demand more attention paid both to the preparation of sessions and additional support during production stages. For instance, wheelchair users can experience problems with dressing in a costume. A wheelchair will also require fixing markers correctly. People with disabilities may also need help with leading them to the toilet or eating. Our experimental sessions lasted 6 hours. None of the examined groups showed any symptoms of fatigue.

An important aspect to consider when organizing sessions for people with disabilities is hiring a professional who will look after them. In the case of sessions with blind people, a professional audio descriptor should become part of a team so that he or she can describe everything that is happening during a session. In the case of sessions with deaf people, a sign language interpreter can facilitate contact with a recorded deaf person. During the sessions it is recommended to employ people with total hearing loss, because it gives an opportunity to record very natural ways of using sign language and very clear facial expressions and gesticulation.

It should be also taken into account that the sessions may vary in length. It takes relatively more time to work with blind people because of the need to verbalize instructions more vividly, direct "work with the body" of an actor and a greater number of necessary attempts. In our project it was possible to register significantly less materials than in other groups.

As for communication with people with disabilities, one needs to consider both the type of disability and individual characteristics. One aspect of the project we found crucial was to verbalize the instructions clearly, which required a different approach each time. In the case of blind people, it turned out necessary to touch their body since verbal messages could prove insufficient and, as a result, the proxemics of sessions varied significantly from other sessions.

These aspects overlap with individual conditioning – Paweł, who suffers from quadriplegia, asked us to stand in front of him when speaking as he was not able to turn around. People who were the subjects of the project also differed significantly in their attitude to sessions. There were observed extrovert people, who were willing to cooperate and, above all, developed the specifics of their disability. On the other hand, there were some introvert people, who would be less willing to open themselves to instructions and cooperation. Even in the latter case, however, there was a lot of potential, which we tried to exploit to develop credible animations.

As far as technical aspects of sessions are concerned, using a wheelchair proved problematic for people with hearing impairment. Some types of wheelchairs have a number of chrome elements which may interrupt the work of markers capturing movement. In sessions involving deaf people, as long as it is possible, motion capture systems should be equipped with individual cameras registering actors' faces (e.g. Vicon CARA). These systems guarantee better synchronization of capturing sing language and facial expressions. All sessions involving people with disabilities

should be recorded with additional cameras, which will facilitate the developing of animation in the postproduction stage.

In postproduction stages and when rendering the final animation, one needs to take into account the fact that the software supporting motion capture and its digital editing is not fit for purpose in the case of working with people with disabilities. In this case, one may use the category of software exclusion or software apartheid. Programs such as Autodesk Motion Builder are more appropriate for constructing the skeletons of able-bodied characters. That is why, certain limitations of people with disabilities should be considered when writing software and algorithms should make it possible to adjust automatically their silhouettes to skeletons of constructed characters (either humanoid or non-humanoid). During the stage of developing animations, people with disabilities should be invited as consultants, which seems indispensable when animated characters are to use sign language. Skills and knowledge of a hearing animator may prove insufficient to build a correct sequence of movements of a character which uses sign language.

Fig. 3: Example of software exclusion – Paweł, a disabled participant of the project, is not capable of performing the initial position well enough (so called T-pose).

Conclusions

The project proved that working with people with various degrees of disability opens the way to new opportunities. They appear in the context of realistic performance of different movement features and motor limitations, which can be directly applied to the realistic movement of characters or indirectly to the sequences of non-humanoid characters' movement and characters with different skeleton structure. Working with people with disabilities let us investigate many interesting strategies of dealing with some activities in early stages of recording motion capture

material, which can inspire the development of storylines in computer games and animations. People with disabilities, as we tried to show it in the report, very often play an additional role in storyline and their silhouettes are not developed in any interesting way. We hope that our project discovered a large potential of people with disabilities, who can be perfect matches for the roles of protagonists in games and animations. Even though this potential has already been exploited in films, computer games and animated movies have a lot to make up for in this respect. We would also like to emphasize a new approach to the idea of inclusive design, that is employing people with disabilities to design during the development stage, even if a product is not addressed to this group directly. In this way, integration thinking about design takes on a new dimension disregarding the idea of being different and creating a product "adjusted" to the needs of people with some limitations. Here, our starting point is a competence. Effectively, the category of disability loses its significance.

Acknowledgment

The authors acknowledge financial support from the Polish Ministry of Science and Higher Education as well as from Innovative Economy European Union Programme. Project was a part of "University of Young Inventors" Programme. The authors would like to thank all the young participants of the project from both teams: the research team (Natalia Kamińska, Mariola Rumlova, Emilia Zięba, Jakub Gajda, Oliwier Kurdziel, Mateusz Lentner, Krzysztof Strzelecki, Jakub Zadrożny) and the actors with disabilities (Aleksandra Puch, Marcin Mizik, Łukasz Kizmet, Krystian Kisiel, Paweł Parus, Marcin Adamek.). The authors great acknowledgments goes also to Mr. Janusz Gajdecki from GrupaMY motion capture studio who helped them in recording sessions and making animations.

Abstract

This study aims to analyse the effect of consumer engagement with Instagram and Instagram Ads on the evaluation of advertisements and purchase intention. This study refers to the experience engagement framework that analyse engagement with experience dimensions to analyse consumer engagement with social media and social media advertising. All 407 respondents who are active Instagram users were participated on this quantitative study. The data is then processed and analysed using Structural Equation Model. The results show that engagement with social media (Instagram) positively influence the social media advertising engagement and further influence advertising evaluation. However, no direct effect found from social media engagement toward advertising evaluation. This study also shows that advertising evaluation positively influence purchase intention.
Providing an empirical analysis about the influence that engagement with Instagram and Instagram Ads have to advertising evaluation, this study resulted in several contributions such as, provides discussion related to the evaluation of several advertising to purchase intentions on products that promoted through social media advertising. This study also gives insights to marketers on how to develop consumer engagement by the experience users had from advertisement on social media.

Keywords: Social Media Engagement, Social Media Advertising, Advertising Evaluation, Purchase Intention

Introduction

The use of social media has been increasing in the last few decades. There is a nine percent annual growth in active user of social media worldwide (Wearesocial, 2019). The three social media with the most active users are Facebook, Youtube, and Instagram. This phenomenon occurs almost all over the world with no exception in Indonesia, it is estimated that in 2019 there will be 20 percent active social media users reaching 150 million users in Indonesia (Wearesocial, 2019). The report from Instagram also shows that Indonesia is the 4th country with the largest Instagram users (Instagram, 2019). The growing number of active social media user has triggered marketers to integrate their marketing activities on social media, especially advertising. It also supported by advertising features launched by the social media.

The number of advertisers on Instagram has increased in line with the increasing number of active users. So it is necessary to analyze the effectiveness of Instagram ads seen from how the ads are evaluated and purchase intention on the goods advertised on Instagram. A study in US analysed the impact of media engagement on perceived value and acceptance of advertising within MSN (Mobile Social Networks). The study confirms that there is positive influence of media engagement on advertising effectiveness in the context of mobile social media (Wu L. , 2016). In this study engagement was chosen as an important factor in the context of social media so that this study was

conducted with the aim to determine the impact of engagement on Instagram and Instagram ads on how Instagram ads are evaluated and the purchase intentions of the product that advertised on it.

The increasing use of social media platform as a medium for advertising still has limited empirical studies. The limited studies that have been conducted to analyse effectiveness of advertisements on social media usually examine the engagement based on the number of likes, comments, and shares (Voorveld, Noort, Muntinga, & Bronner, 2018). This study postulates that there are other approach that can be analysed beside those quantitative metrics, such as the experiences received by the public when using social media and the experience felt when viewing social media ads. Those experiences became part of the engagement variable that examined. In the context of Instagram, there is also currently limited academic research that studies the effectiveness of Instagram Ads addressing the increasing trend of using the Instagram Ads by the marketers. With the increasing use and unique characteristics, the effectiveness of advertising in Instagram is worthwhile to be examined.

Some studies tend to focus on the aspects of advertising content and the products offered by the advertisement (Ashley, Christy, & Tuten, 2015). However, previous research (Voorveld, Noort, Muntinga, & Bronner, 2018) thought that there are other aspects rather than content, the effectiveness of advertising is also determine by context of the media used (platform). Previous studies have shown the effect of engagement on media in advertising evaluations, especially on traditional media. So it is worthwhile to analyse if similar relationships could also happen in the context of social media. Other study found that there is a relationship between social media engagement and social media advertising engagement (Voorveld, Noort, Muntinga, & Bronner, 2018). We also found the research that refer to the Ducoffe web advertising model (1995), analysed how advertising can influence the purchase intention (Martins J. , Costa, Oliveira, Gonçalves, & Branco, 2019).

Theoretical Review

Engagement

There are quantitative metric and qualitative approaches regarding to engagement with many distinctive definition exist (Hollebeek, 2011). This study refer to the understanding which states that engagement is a multilevel and multidimensional concept that arises from thoughts and feelings about one or more experiences involved in achieving personal goals (Calder, Mathew S, & Mathouse, 2016). The central of this view conclude that engagement is manifested in various experiences. Although this is an emergent view in the literature, it has been analysed by multiple studies. For example, it was demonstrated that engagement with TV programs is predictive of evaluations of embedded advertising (Calder, Mathew S, & Mathouse, 2016) and also been previously reviewed in a study that analyse the role of social media platform regarding to social media engagement and social media advertising engagement (Voorveld, Noort, Muntinga, & Bronner, 2018).

Social Media and Social Media Advertising Engagement

Engagement with social media and advertising on social media are the result of how media and advertising are experienced. Referring to Calder, Isaac, and Malthouse (2016), who argue that engagement is a context specific concept (varies between contexts). This context is defined as the advertising environment where this ad is placed which in this case is the social media (Voorveld, Noort, Muntinga, & Bronner, 2018). To strengthen this approach, this study chose one of the social media with the most active users in the hope of more reviewing the intensity of engagement with a large scope of active users.

Experiences in relation to engagement are defined as intuitive experiences or emotional perceptions that people experience when using certain media. This experience can be multidimensional, therefore in this study there are several dimensions of experience that are analysed in building the engagement. Refer to that approach, we define social media engagement as special experiences that people experience during the use of social media. In line with how social media engagement is defined,

social media advertising engagement is defined as intuitive experiences or emotional perceptions that people experience when faced with advertising on the social media platform. Media engagement can be seen as an important context characteristic that drives a response to an advertisement (Calder, Malthouse, & Schaedel, 2009). Therefore, the engagement with media could drive how people engage with the advertising embedded in particular media platform.

H1: Social media engagement has an influence on social media advertising engagement.

Advertising Evaluation

Social media platforms can be seen as a context for advertising where it provides an advertising environment. The study of media context provides strong evidence for the idea that the same source conveys the same message to the same audience on separate occasions producing different effects depending on the context in which the message appears and can be seen as essential context characteristics that encourage responses to an advertisement (Norris & Colman, 1992; Calder, Malthouse, & Schaedel, 2009). Advertising evaluation is interpreted as a subjective evaluation perceived by consumers of social media advertisements that respondents meet when accessing a particular social media. This indicator of measuring advertising evaluation variables is taken from previous research (Hilde A. M. Voorveld, Muntinga, & Bronner, 2018; Martins J. , Costa, Oliveira, Gonçalves, & Branco, 2019).

From previous study, it was found that the more engaged someone engaged in television programs, magazines, or online newspapers, the better the evaluation of the advertisements available in the media (Calder, Mathew S, & Mathouse, 2016). The same thing is also obtained when social media is used as a medium for advertising (Voorveld, Noort, Muntinga, & Bronner, 2018), where Instagram is included. With the relationship between social media engagement with social media advertising engagement and social media engagement relationships, a study examines the possibility that social media engagement can also influence the evaluation of advertisements on that social media. The study also concluded that the more people engaged with an advertisement, the more positive they evaluated it (Voorveld, Noort, Muntinga, & Bronner, 2018).

H2: Social media engagement has an influence on advertising evaluations.
H3: Social media advertising engagement has an influence on advertising evaluation.

Purchase Intention

Purchase intention shows the possibility that consumers will plan or want to buy certain products or services in the future (Wu, 2016). Previous research has shown that increased purchase intentions reflect increased buying opportunities. If consumers have positive purchase intentions, and also with positive brand engagement will promote a purchase (Martins, Costa, Oliveira, Gonçalves, & Branco, 2019). One of the goals of making an advertisement is to increase people's desire to buy the advertised products. Previous study has found that advertisement value had a significant impact to purchase intention of the promoted product (Martins J. , Costa, Oliveira, Gonçalves, & Branco, 2019).

H4: Advertising evaluation has an influence on purchase intention.

Fig 1. Conceptual Model

Method

Design and Procedure

In this study we chose to focus on Instagram. The reason for the selection is because Instagram included in the three social media that have the most active users besides Facebook and Youtube both in the Worldwide and in Indonesia, and among the three social media, Instagram has advertising features that are designed and positioned as in their main content. Instagram with the Instagram Ads feature is also able to make users take real action by clicking on the link listed in the description of the ad to the site of each product that can give users the opportunity to immediately buy the product.

Data collection in this study uses a single source approach. At the beginning, respondents were asked whether the respondent is an Instagram active user (proven by Instagram account ownership and accesses it at least once a week) and whether they have seen an ad from the Instagram Ads feature. Then they were asked about the experience of accessing Instagram and their experience when they came across Instagram Ads. Respondents were then asked to give their opinions on statements regarding evaluations of the advertisements (Instagram Ads) in general and their intentions in the products advertised in the Instagram Ads feature.

The collected data then processed using SPSS version 25.0 and Amos ver. 24 for Structural Equation Modelling (SEM) analysis techniques. Before the data is ready for testing, pre-test is conducted to test the validity and reliability of the questionnaire used.

Participant and Data Collection

Data are obtained from filling out the questionnaire distributed among Indonesia resident using an online questionnaire. To be able to become a respondent, a person must meet the requirements that are checked with the screening questions and 407 respondents are participated in this study. The number of respondents is considered sufficient because according to Hair, Black, & Barry J. Babin (2010), the minimum sample calculation is the number of indicators multiplied by five. This study has 74 indicators so that the minimum number of samples needed is 370 respondents. The respondent profile can be seen on Table 1.

Tab. 1: Respondent Profile (N = 407)

Indicator	Item	N	%	Indicator	Item	N	%
Gender	Male	127	31.2	Instagram Usage Frequency	1 – 7x/week	98	24.1
	Female	280	68.8		8 – 14x/ week	101	24.8
					>14x/ week	208	51.1
Age	<19	26	6.4	Instagram usage duration	<15 minutes	131	32.2
	19 – 24	173	42.5		15 – 30 minutes	177	12.5

Measurements

Referring to previous research on social media engagement and social media advertising engagement (Voorveld, Noort, Muntinga, & Bronner, 2018), social media engagement uses 10 experience dimensions consisting of entertainment, negative emotion, pastime, stimulation, identification, practical use, social interaction, innovation/trendsetter, topicality, and empowerment. which then formed 36 indicators with a 7-point scale. Social media advertising engagement is analyzed using an approach similar to social media engagement, the experience dimension that is still relevant to use. It uses 8 dimensions consisting of entertainment, negative emotion, pastime, stimulation, identification, practical use, social interaction, and topicality which then formed 26 indicators with a 7-point scale.

Advertising evaluation is measured using a combination of indicators from 2 previous studies (Voorveld H. A., Noort, Muntinga, & Bronner, 2018; Martins J. , Costa, Oliveira, Gonçalves, & Branco, 2019) consist of 5 indicators with a 7-point scale. As for the purchase intention variable is measured using 5 indicators with a 7-point scale (Alalwan, 2018; Martins J. , Costa, Oliveira, Gonçalves, & Branco, 2019).

Table 2: Measurement Instrument

Contructs	Dimensions	Measurement Items	References
Social Media Engagement & Social Media Advertising Engagement	*Entertainment*	*Gave me enjoyment; made me cheerful; gave me pleasant feeling; made me happy*	(Voorveld, Noort, Muntinga, & Bronner, 2018)
	Negative emotion	*Annoying; irritating; disturbed me; difficult to understand*	
	Pastime	*Suitable for free time; accessed when have free time; accessed when there is no busyness*	
	Stimulation	*Interesting;* made me enthusiastic; *unique; offered something new*	
	Identification	*Recognized myself in it; empathized with it; made sure I could vent my opinion*	
	Practical Use	*Gave useful idea; gave useful advice; motivated me to find more information; gave me opportunities to contact with new things*	
	Social interaction	Enabled me to share something with others; gave me the possibility to know how it is with others*; made sure I am in contact with others; gave subject of conversation; enabled me to gain knowledge of the opinions of others*	
	Innovation	Made people pay more attention; made sure I was ahead of others; made sure that others like me	
	Topicality	*Made sure I was quickly informed; made sure I was up to date; gave me useful information*	
	Empowerment	Made sure I could help others; provided freedom of interaction; made me feel that I had influence on others;	
Advertising Evaluation		I like Instagram Ads; feel satisfied with Instagram Ads; feel that Instagram Ads is important; provided relevant information about product; feel the number of Instagram Ads is too many.	(Martins, Costa, Oliveira, Gonçalves, & Branco, 2019); (Voorveld, Noort, Muntinga, & Bronner, 2018)
Purchase Intention		Intent to buy products advertised on Instagram Ads; Will try to buy products advertised on Instagram Ads; Will try to buy products advertised on Instagram Ads; It is possible to buy products advertised on Instagram Ads in the future; Feeling purchasing products advertised on Instagram Ads is worthwhile.	(Alalwan, 2018); (Martins, Costa, Oliveira, Gonçalves, & Branco, 2019)

Note. Italics = also measured for social media advertising engagement.

Results

This study used structured equation modeling (SEM). First, in order to analyze the indicator validity, the loadings should be higher than 0.50 (Hair, Hult, Ringle, & Sarstedt, 2014). There are 2 indicators that have loadings < 0.50 each come from negative emotion dimension both social media and sosical media advertising. Secondly, the reliability of the measurement items seen from the value of construct reliability (CR) and variance extracted (VE). The construct is said to have good reliability if it has a construct reliability value (CR) ≥ 0.70 and a variance extracted value (VE) ≥ 0.50. All items has CR ≥ 0.70 and VE ≥ 0.50. For the structural model, first we analyze the model fitness. The fit indices (GFI = 0,83, AGFI = 0,80, RMSEA = 0,51, CFI = 0,89, NFI = 0,82, and CMIN/DF = 2,06) of the structural model were found to be within their suggested values, that are marginal fit to good fit.

As for the main research hypotheses, except for H2 (Social media engagement to advertising evaluation) (C.R = -1,249, P-value = 0,212), the rest of the research hypotheses were supported as presented in Table 3. In detail, social media engagement was found to have significant impact to social media advertising engagement (C.R = 8,545, P-value < 0,001), social media advertising engagement was found to have significant impact to advertising evaluation (C.R = 4,641, P-value < 0,001), and advertising evaluation also found to have significant impact to purchase intention (C.R = 4,614, P-value < 0,001).

Table 3: Hypotheses Results

Hypotheses		T Value (CR)	Estimates	Remarks
H1	Social media engagement has an influence on social media advertising engagement	8.545	0.447	Hypothesis supported
H2	Social media engagement has an influence on advertising evaluations	-1.249	-0.041	Hypothesis not supported
H3	Social media advertising engagement has an influence on advertising evaluation	4.641	0.924	Hypothesis supported
H4	Advertising evaluation has an influence on purchase intention	4.614	0.790	Hypothesis supported

Discussion

The results of this study are in line with previous studies analyzing the context of media experience on advertising effectiveness. The study had results that indicate that engagement with TV programs, magazines, and websites can have an effect on how an advertisement in the media is evaluated (Malthouse, Bobby J., & Tamhane, 2007). Another study also found that there was a significant relationship between social media engagement and social media advertising engagement in the context of Instagram (Voorveld H. A., Noort, Muntinga, & Bronner, 2018).

The results of this study indicate that the strongest dimensions in social media engagement variables are the empowerment (SLF: 0.972) and stimulation dimension (SLF: 0.941), as can be seen on Table 4. The empowerment dimension shows that in using Instagram, respondents feel they have an influence on other people, as well as having freedom to interact. As for the stimulation dimension, respondents feel that Instagram is interesting, unique, and provides something new. In social media advertising engagement variables, the strongest dimension is stimulation (SLF: 0.951) followed by the practical use dimension (SLF: 0.931). The stimulation dimension indicates that respondents feel Instagram Ads are unique, interesting, and offer new things. While the practical use dimension shows

that respondents feel Instagram Ads provide useful ideas and suggestions, provide opportunities to connect with new things, and motivate to find more information about the advertised product.

Table 4: Loading Factors of Dimensions

Dimensions of SocMed Engagement	Loading Factor	Dimensions of SocMed Advertising Engagement	Loading Factor
Entertainment	0.769	Entertainment	0.768
Negative Emotion	0.258	Negative Emotion	0.392
Pastime	0.511	Pastime	0.667
Stimulation	0.941	Stimulation	0.951
Identification	0.772	Identification	0.709
Practical use	0.872	Practical use	0.930
Social interaction	0.863	Social interaction	0.860
Topicality	0.858	Topicality	0.910
Innovation	0.670		
Empowerment	0.972		

Social media engagement has no significant effect on advertising evaluation. From the definition of social media engagemetn can be seen that this type of engagement has nothing to do with advertising so it is very possible that there is no direct relationship between the two variables. The results of this study are also in line with the results of previous that postulate investigating the direct relationship between social media engagement and advertising evaluation of the ads contained is not the right thing, because there may be variables that encourage an effect (Voorveld H. A., Noort, Muntinga, & Bronner, 2018). The variable that proposed to be analyzed to explain the relationship between those two variables is social media advertising engagement where is proven to have an influence on advertising evaluation. In line with this study, The results of previous study conclude that the more someone is engaged with an ad, the more positive that person evaluates the ad (Voorveld H. A., Noort, Muntinga, & Bronner, 2018). This results prove that social media advertising engagement is the variable that is needed to analyzed the effectiveness of advertising in social media.

Advertising evaluation has an influence on purchase intention. In line with previous studies, the research successfully proved that consumers' purchase intention is influenced by how customers evaluate smartphone advertising (Martins J. , Costa, Oliveira, Goncalves, & Branco, 2019). Other research that analyzes the effect of advertising features on social media on purchase intention also concludes that customers who find social media advertising useful and profitable, will tend to be willing to buy products advertised on social media advertising features (Alalwan, 2018).

The results of the study which states that social media engagement has an influence on social media advertising engagement can be the basis for marketers or advertisers to be able to carefully choose social media. Furthermore, social media advertising engagement has a significant effect on advertising evaluation. This result also can becomes the basis for advertisers to be more focused in building consumer engagement on advertised advertisements so that evaluations of these advertisements are better. Another contribution of this study is that it provides specific implications based on the dimensions of engagement that can be improved to create better engagement for both Instagram and Instagram Ads.

This study shows that there are some points that can be analysed for future research. Future studies can consider the duration and frequency of Instagram usage and analyze whether there are different effects on engagement on Instagram Ads and Instagram Ads. In the context of Instagram ads, future research can also consider the type of Instagram Ads as a moderating variable that might play a role in the influence of Instagram engagement and Instagram ads engagement. In addition, the type of product advertised can also be analyzed whether this can affect engagement on Instagram Ads.

Conclusion

The results show that social media engagement has an influence on social media advertising engagement, social media engagement is not proven to have a significant effect on advertising evaluation, social media advertising engagement has an influence on advertising evaluation, and advertising evaluation has an influence on purchases intention. From the results of this study it was found that from the ten dimensions analyzed to measure social media engagement in the Instagram context, it appears that the three dimensions that have the strongest relationship are the dimensions of empowerment, stimulation, and practical use. Meanwhile, from the eight dimensions analyzed in measuring social media advertising engagement on Instagram Ads, it appears that the three dimensions with the strongest relationship are the dimensions of stimulation, practical use, and topicality

Abstract

Today there are powerful incentives for the development of green technologies in the field of energy efficiency, in particular in the field of expanding the use of renewable energy sources and reducing specific fuel consumption. According to many experts, in the foreseeable future, green technology is the largest area of technological innovation. The analysis based on a comprehensive economic and statistical analysis of volumes, structure and directions, an analysis of markets and current trends in the development of green energy efficiency technologies in the context of sustainable development in various countries is carried by authors. The stimulation of green technology markets and the expansion of their implementation are of primary importance for sustainable development, which means that this area requires a comprehensive review to identify developmental features and the risks associated with it. From the perspective of sustainable development, it is worth noting that the development of "green" energy efficiency technologies will have an effect not only on the economic, environmental and technological side of the process, but will also make its own social changes.

Keywords: "Green" Energy Efficiency Technologies, Innovative Technologies, Renewable Energy Market.

Introduction

The development of the world community in the 21st century is accompanied by a number of challenges arising from natural and socio-economic reasons. The global problems of mankind, combined with the growing needs of society, have posed the modern generation the need to reorient existing economic practices. The key vector of development in this situation was the concept of a “green economy”, which is designed to change the trends and become the main vector on the path to sustainable development. At the same time, the main feature of the “green” economy is a radical increase in energy efficiency, the obligatory nature of energy conservation and the development of a “low-carbon” economy, which makes up the development priorities of the leading world powers (Matraeva etc. 2017).

So, in the last decade, a course has been taken towards sustainable "green" growth, which implies stimulating economic growth and development while ensuring the preservation of natural assets and the uninterrupted provision of the required resources and ecosystem services. (HSE portal).

The green growth strategy is one of the proposed recommendations (here you can also cite the 2016 OECD Plan of Action for Sustainable Development Goals) and indicators (such as, for example, “green” accounts of the World Bank and others) developed by international and intergovernmental organizations for governments of different countries to solve the key task for today - the implementation of the Sustainable Development Goals (SDGs), adopted in the UN Agenda for Sustainable Development until 2030, and the implementation of the principles expressed in them, its management and at the national level (UNEP, 2011).

The transition to the rails of sustainable development and green "growth" is possible due to the implementation of the "green" economy concept. In the modern sense, according to official UN documents, a “green” economy is understood as “an economy that enhances people's well-being and ensures social justice, while significantly reducing environmental risks and its impoverishment” (OECD, 2017). Thus, from the point of view of OECD experts, for further socio-economic development and progress, ensuring not only the well-being of the current generation, but also the possibility of sustainable growth in the future, it is necessary to reduce dependence on natural resources as sources of growth (Klochkov, 2013).

In this regard, the key direction of “green” growth is the conservation and rational use of natural resources, in particular, the implementation of the concepts of energy conservation and energy substitution in the energy field in order to structurally change the existing order of energy consumption and environmental attitudes.

Methodology

The study used the following general scientific methods: a content analysis method aimed at analyzing the semantic content of text arrays in the subject of the study, as well as inductive and deductive analysis, graphic analysis tools that allowed to combine individual conclusions on this issue and formulate the author's vision of the problem. Principles of an integrated approach were also utilized. The research was supported by information taken from the official statistical and analytical materials of the United Nations Environment Program, as well as by scientific publications in periodicals and on official websites.

The General State of The Renewable Energy Market

Despite the simultaneous development of primary energy resources having a high energy content - coal, oil, gas, uranium - the increased needs of society and economies were not satisfied, which was reflected in the energy crisis of the 1970s. The 21st century has preserved the trends that have taken shape in the 20th century: energy consumption continues to increase even taking into account periodically occurring economic crises leading to short-term reductions in energy consumption; the world community continues to be dependent on oil and other fossil fuels (Matraeva etc. 2019).

According to the report of the International Renewable Energy Agency (IRENA), by the end of 2018, the global renewable energy capacity amounted to 2351 GW, which amounted to about a third of the total world energy capacity (Renewable capacity highlights, 2019). In 2018, half of all installed capacity generated by renewable energy sources fell on the hydropower sector, which amounted to 1,172 GW. The capacity of wind and solar energy amounted to 564 GW and 486 GW, respectively. Other RES accounted for the remaining 6% of the total global renewable energy capacity, of which 115 GW was bioenergy, 13 GW - geothermal energy and 500 MW - ocean energy (Fig. 1). The largest players in renewable energy markets continue to be the United States and China, which occupy first positions in such major areas of renewable energy as hydro, solar and wind energy. It is interesting to note the centers of development of ocean technologies - Korea, France, Great Britain. RES has gained much development in small EU countries, for example, in Denmark.

Fig.1: Distribution of world renewable energy capacity by energy sources,%, 2018

Source: composed by authors based on (IRENA, 2019 and database of IRENA)

In a regional context, the largest share of renewable energy capacities is currently concentrated in Asia (43.47%) with its undisputed leader - China. The next place is Europe, most of which is located in countries such as Germany, Great Britain, Italy. North America closes the top three (15.58%) (IRENA, 2019). In 2018, the world renewable energy continued the ten-year trend of capacity growth, the growth of which at the end of the year amounted to 7.9% (+171 GW) compared to 2017 (Fig. 2). At the same time, 84% of this increase (144 GW) was provided by the commissioning of new capacities in the fields of solar and wind energy, which indicates the continued rapid spread and commercialization of these energy generation technologies. The total increase in solar energy capacities in 2018 amounted to 95 GW (or + 24%), wind energy - 49 GW (+ 10%). The contribution of hydropower to the total increase in RES capacity was slightly more modest - only 12%, which amounts to 21 GW (+ 2% to the level of hydropower capacities in 2017). The introduced bioenergy capacities accounted for only 3% of the total value of the renewable energy growth, however, this sector increased about 5% (5 GW) from the level of own capacities in 2017. The growth of geothermal energy amounted to a little more than 500 MW, and the development of the "oceanic" technology sector led to a capacity increase of 2 MW.

Fig.2 : Contribution to the total increase in RES of selected sectors in 2018

Source: composed by authors based on (IRENA, 2019)

The generating capacities growth dynamics of renewable and non-renewable energy sources (fossil fuels and nuclear energy) deserve special attention, noting the rapid increase in renewable energy capacities - from 20 GW in 2001 to more than 160 GW annually from 2016, which amounted to about 63% of the total volume of commissioned generating capacities (IRENA, 2019).

In turn, energy generation from non-renewable sources, on the contrary, does not have such a clear tendency to increase or decrease the commissioning of new generating capacities - on average, the increase was about 115 GW per year. However, it is worth emphasizing that in Europe, North America and Oceania, non-renewable generating capacity has decreased by 85 GW since 2010, while in Asia and the Midwest an increase of 725 GW and 100 GW has occurred over the same period, respectively. Consequently, these two regions have become the main driving forces for increasing generating capacities from non-renewable energy sources (Renewable capacity highlights, 2019).

Thus, despite the fact that the last decade has been characterized by a transition to a qualitatively new energy generation based on increasing renewable energy capacities, transition to a low-carbon economy and energy efficiency requires not only the spread of "green" technologies, but also a reduction in the generation of energy from fossil species fuel.

Market Analysis of Renewable Technology

The renewable energy technology market in 2018 can be described as stable. The main progress of renewable energy in 2018 was concentrated in the energy sector, which is due to increased competitiveness of renewable energy compared with traditional energy generation. Thus, the electricity generated by wind and solar photovoltaic (PV) power plants in many places has become more economical than the energy received from power plants operating on fossil fuels (REN21, 2019). For example, in the US, the use of wind and solar energy is now cheaper than the operation of coal-fired power plants in most of the country (IEA: renewable energy growth is slowing, 2019).

In addition, it has become more economical to build new wind and solar photovoltaic power plants than to continue to operate existing fossil fuel power plants. For example, Enel Generación Chile, a subsidiary of the Italian Enel in Chile, won a tender in November 2018 for the construction of a complex of RES-based power plants, although the projects involved in the generation of energy at thermal power plants. The commissioned wind, solar and geothermal stations will sell electricity at a price of $ 32.5 per 1 MW / h, which is lower than the price of electricity generated by gas and coal-based power plants (Renewable energy beat fossil fuels, 2018).

Thus, the record low tenders held in many countries of the world, especially for solar photovoltaic and wind energy, as well as the rapid development of technologies in this field, made a significant contribution to the development of renewable energy generation.

By the end of 2018, renewable energy provided, according to experts, more than 26% of global electricity production. For several years, renewable energy has been recognized worldwide as the main source of electricity production (REN21, 2019). At the level of individual countries, the production of electricity from renewable energy is even more important. The leader in this case is Denmark, 69% of the electricity for which is generated from renewable sources. Among the larger economies of the EU, we can distinguish Germany and the United Kingdom, whose share of renewable energy in the energy sector is 32% (BP, 2019). At the same time, the reliability of the energy systems of Denmark and Germany, integrated among themselves, is considered one of the highest in the world (Deloitte, 2018). Among other countries in which renewable energy accounts for more than 20% of energy generated, they include: Spain, Italy, Portugal, Finland, Ireland and New Zealand (BP, 2019).

A much smaller increase in renewable energy is observed in heating and cooling systems, as well as in transport, progress in which is still constrained by the lack of stable political support from the state and the slow development of technologies, such as advanced biofuels. In 2016, modern renewable energy sources provided about 10% of the global demand for heating and cooling, but their growth in the sector remains insignificant (less than 5%) (REN21, 2019). Despite the fact that heating and cooling systems account for about half of the total final energy demand, this area is characterized by insufficient attention to the development of renewable energy in this sector by states: in 2018, only 47 countries had targets in the field of organization of cooling systems and heating from renewable sources, while the number of countries with regulatory policies in this sector fell from 21 to 20.

Meanwhile, the integration of renewable energy technologies in the residential sector and industrial This is necessary both to reduce the demand for heat and increase energy efficiency, and to expand the use of modern renewable energy sources in general and achieve the goals of decarbonization of economies.

The share of renewable energy sources in the transport sector increased slightly compared to the previous year and reached 3.3%, 3% of which are represented by liquid biofuels. Between 2013 and 2017, the use of biofuels in the transport sector (mainly ethanol and biodiesel) increased by about 18%. This sector is becoming increasingly open to electrification, which suggests new perspectives and opportunities for further integration of renewable energy sources. Despite the increase in ethanol and biodiesel production in 2018, the growth in the use of biofuels for transport is still constrained by policy uncertainties and slow progress in the development of renewable fuels, for example, for markets such as aviation.

In the fuel context, as of 2017, renewable energy provided about 18.1% of total final energy consumption. Of these, modern renewable sources accounted for 10.6% of final consumption, while, according to estimates, demand for them increased by 4.4% compared to 2016. The remaining share of final energy consumption from renewable sources came from the traditional use of biomass (mainly in developing countries for heating and cooking). Most of the energy consumption from modern renewable energy sources was in the field of heat energy (about 4.2% of final consumption), followed by hydropower (3.6%) and other renewable energy sources, including wind energy and solar photovoltaic installations (about 2 %), as well as biofuel (1%).

Renewable Energy Investment Analysis

Global investments in renewable energy in 2018 amounted to $ 288.9 billion (or $ 304.9 billion, including large hydropower plants with a capacity of more than 50 MW) - 11% less than in the previous year, which was primarily due to a significant reduction investments in China (in 2018, investments in renewable energy in China amounted to $ 91.2 billion, and in 2017 they amounted to $ 145.9 billion). However, for the fifth year in a row, global investment in renewable energy sources has exceeded the mark of 230 billion US dollars.

Since 2015, developing countries and countries with economies in transition have been leaders in terms of investments in renewable energy sources; in 2018, their share was 53%. Of course, the main driver of growth in this group is still China, which accounted for 32% of the total investment. For the seventh consecutive year, China has occupied the largest share in the volume of global investment flows in the renewable energy sector, despite a significant drop in the indicator in 2018 (by 37%, the lowest since 2014). A key factor in this decline was the change in the state's tariff policy, which halved investments in solar energy (to $ 40.2 billion, compared with $ 89 billion in 2017). Investments in wind energy in China decreased over the same period, decreased by 6% to $ 50.1 billion. Nevertheless, it is China that is the most dynamic market for renewable energy investments. The next major investor is Europe (21% in 2018), the United States (17%) and Asia and Oceania (excluding China and India; 15%).

However, it is worth noting that over the past two years, investment activity in the group of countries with developing and transitional economies increased by a record 6%, due to the expansion of investment activities in the field of solar and wind energy in most countries of Asia, Eastern Europe, the Middle East and Africa. So in Vietnam in 2018, the volume of investments in renewable energy sources reached $ 4.1 billion, which is 7 times more than in 2017 - for the first time the country has shown itself to be a multi-billion dollar market of solar PV cells. And in the Middle East and Africa, the largest prospective region of solar and wind energy with such large markets as Egypt, Kenya, Morocco and South Africa, investments grew by 57% to a record $ 15.4 billion.

Renewable energy markets of developing countries and countries with economies in transition are not only the most promising and have the greatest potential for the development of renewable energy, but

they also serve as “incubators of innovations” in this area (Deloitte, 2018). For example, the tendency to hold auctions for the sale of renewable energy supplies is formed primarily by emerging markets, which leads to cheaper prices for renewable energy throughout the world. In addition, one can observe the process of “reverse innovation” (the flow of innovation from developing countries to developed countries) when products developed and intended for use by developing countries are used in developed countries, mainly in the field of solar and wind energy. For example, this is how microenergy networks, used for electrification of territories not served by traditional energy grids, have found application in developed countries, and have become used in remote mines. However, of course, international corporations creating an international technology transfer play a decisive role in this process.

The key areas of renewable energy investment are still solar energy technologies. Nevertheless, the total volume of investments in this sector decreased by 22% compared to the level of 2017, which, however, is associated primarily with the reduction in the cost of solar energy generation technologies and, consequently, a decrease in specific capital costs for it, as well as significant changes in China's photovoltaic market. An increase in investments in photovoltaic installations could be noted on the Spanish market, which was facilitated by the equalization of electricity prices through competitive energy auctions and the implementation of corporate agreements for the purchase of electricity, which could reduce the price of introducing renewable energy without subsidies; and, as mentioned above, investment growth was observed in the markets of Africa and the Middle East.

Wind energy is in second place in terms of investments, which in 2018 increased the volume of investments by 2%, which amounted to a record 134.1 billion US dollars. This was mainly due to the financing of large wind energy projects in China, the USA, South Africa, India and Sweden, as well as a number of offshore projects in Europe. Among the largest are onshore wind projects in the Scandinavian countries - Sweden and Norway, due to agreements on the purchase of electricity (SES), as well as offshore projects in the waters of Belgium, Denmark, the Netherlands and the United Kingdom. In general, investments in offshore wind energy grew by 2% per year, to $ 109.8 billion (a record high), while investments in offshore wind energy grew by 7%, to $ 24.6 billion (the second largest indicator).

Together, wind and solar energy attracted 94% of the total investment in renewable energy in 2018. In other areas of renewable energy, one can note the financing of several large projects in the field of biomass in Japan, as well as the conclusion of agreements on financing large enterprises for the conversion of waste into energy in Serbia, the United Arab Emirates and the United Kingdom. One can also note an increase in investment in ocean energy (+ 12%, which left $ 203 million). However, these technologies continue to face financial difficulties, so the prospects for political support for their development in key markets such as France and the UK are not clear.

It should be noted that the experts of REN21, an international non-profit organization based on the United Nations Environment Program (UNEP), emphasize that the observed net increase in renewable energy capacities, combined with a decrease in the absolute level of investment in renewable energy technologies, is a result of a fall in system costs and the development of more attractive renewable energy financing models, which means “a larger number of capacities can be installed for less money” (REN21, 2019).

Particularly rapid development is observed for battery-powered energy storage systems, although pumped storage systems still dominate. According to experts, battery storage is a key technology in the global transition to a sustainable energy system. Such technology can be used not only at large power plants, but also as “energy reservoirs” in electric vehicles, and will allow modernization of mini-grids, which will support individual energy production using installations on roofs of houses.

The wider adoption and commercialization of new battery storage technologies has led to rapid cost reductions, especially for lithium-ion batteries, as well as high-temperature sodium-sulfur (“NAS”) and so-called “flow” batteries. For example, in Germany, spending on lithium-ion batteries for small

households has fallen by more than 60% since the end of 2014. According to the IRENA forecast, by 2030, the total cost of installing electricity storage systems can fall by 50-60% (even more for rechargeable batteries) due to the optimization of production capacities, modernization and reduction of materials used, in turn, improving the technical characteristics of the equipment will reduce the cost of the equipment provided services (IRENA, 2017).

The competitiveness of dispersed power generators, for example, solar installations on roofs of houses, so far is determined not by price advantage, but by the ability to provide hard-to-reach areas with electricity. At the same time, a price advantage can be achieved when individual energy generation is cheaper than invoiced by energy companies. This situation is already typical for some regions of the USA, as well as several regions of Australia and Germany, where photovoltaic panels installed on the roofs of households are becoming more widespread (Deloitte, 2018).

Conclusion

Thus, the need to not only rapidly increase the use of “green” technologies, but also to abandon the most “polluting” traditional methods of energy generation, i.e. comprehensive decarbonization of the energy sector is required. And for this, it is necessary to increase political support for the sphere of "green" technologies, expand the use of both financial and market incentive tools (corporate procurement agreements, etc.), and incentive measures on the part of governments (tax loans, subsidies), as well as the establishment of more ambitious goals for landscaping economies.

From the perspective of sustainable development, it is worth noting that the development of "green" energy efficiency technologies will have an effect not only on the economic, environmental and technological side of the process, but will also make its own social changes.

According to the forecast of experts of the International Labor Organization, by 2030, thanks to environmentally sound policies of states to deploy green technologies, 24 million jobs can be created, 6 million of which compensate for the loss of various sectors of the economy due to the reorientation of economic practice. In particular, in the energy sector, namely in the field of oil refining and distillation, job cuts are projected for 1 million people. Nevertheless, the development of new technological solutions will allow to collectively receive an increase in labor market offers by 18 million jobs (TASS, 2018).

Summing up the analysis, we can say that the development of "green" energy efficiency technologies is one of the fastest growing trends in the modern world. The need and extreme importance of their dissemination and improvement is emphasized at the international level, and the growth of investment activity and the rapid development of renewable energy markets indicate their technological and economic attractiveness. In addition, the Sustainable Development Goals and the adopted course on sustainable green growth impose additional obligations on “green” technologies, in particular renewable energy, to reduce CO2 emissions and improve the quality of life of the population: from increasing the availability of electricity and reducing its cost to creating new jobs. Therefore, the stimulation of green technology markets and the expansion of their implementation are of primary importance for sustainable development, which means that this area requires a comprehensive review to identify developmental features and the risks associated with it.

Abstract

The article is devoted to the study of the experience of building national systems of technical regulation and standardization operating in different countries of the world. An analysis of systems in more than 30 countries of the world revealed two basic development models, the features of their modifications and formulated recommendations for the Russian system. The first model is characterized by an essential component of state regulation, and the second type by the independence of the institution of the system from direct subordination to state authorities. The tendency of convergence of models and the potential for the formation of an adjacent variant of the organization of processes are also identified.

Keywords: Technical Regulation, Standardization, Energy, National Models, Harmonization.

Introduction

In modern conditions of state energy policy development, it is necessary to take into account existing trends and international experience in the formation of a national system of technical regulation and standardization.

Technical regulation refers to the non-tariff form of regulation and consists in the establishment, application and implementation of technical standards characterizing the material nature of the object and the assessment of these standards. The theoretical basis of regulation is the creation of a two-level system for establishing requirements for products, processes, works and services aimed at creating favorable conditions for business development and at the same time protecting the interests of purchasers. The first level of requirements is related to the fact that it involves the creation of conditions under which the state must ensure the safety of products for life, the health of citizens, the safety of their property and environmental protection. The second level of the system is associated with providing entrepreneurs with a certain degree of freedom in establishing requirements for the quality of regulatory objects.

Technical regulation also becomes an integral part of antitrust policy, as it creates equal conditions for market entities through obligations to maintain standardized quality indicators for products, processes, works and services. This circumstance reduces the influence of unfair competition and creates conditions that exclude the possibility for market leading companies to dictate their technical standards to the detriment of other participants in the relationship.

Information provided through technical regulation tools: technical regulations, standards, certificates, rules, etc. provides citizens and interested business entities with information about the quality of products and services. This implements the economic function of the state to create conditions for citizens to obtain reliable information that does not mislead them.

The implementation of the functions of technical regulation is associated with the use of administrative and economic methods of influencing market entities, therefore, two main approaches to the study of this tool are distinguished.

According to the first approach, technical regulation by some authors as Baldwin, Cave (1999), Morgan, Yeung (2007) and Ogus (2004) is considered as a legislative, executive and controlling mechanism used by authorized state structures, public organizations in relation to market entities in order to establish, apply, execute and assess the compliance of mandatory and voluntary requirements for products, processes, works and services and other objects ensuring the safety of life and health of citizens, environmental protection, property safety, as well as the development of fair competition.

The second approach is technical regulation, as a managed system that can be represented as infrastructure elements. Many researchers of the institutional foundations of technical regulation such as Kay, Vickers (1990), Zvorykina, Platonova (2011) Zvorykina (2005), analyze the elements of technical regulation and come to the conclusion that the following can be considered its main elements: regulation; standardization at the national level and organization level; declaration of conformity; compulsory certification; accreditation; authorization; state control (supervision); voluntary certification; tests; registration, etc.

A comprehensive approach to the task of achieving orderliness in this area, providing for the possibility of harmonizing systems at the regional and international levels, as well as improving the national one, is possible only when conducting research on the experience of building national systems of technical regulation and standardization operating in different countries of the world.

Methodology

The analytical coverage in the implementation of research tasks regarding the development of national systems of technical regulation and standardization includes more than 30 countries. The selection criteria for these countries were:

- the role of the fuel and energy complex as a backbone (one of the key) complex of the country's economy;
- the presence of bilateral (multilateral) foreign trade relations in the Russian Federation in the field of fuel and energy complex;
- participation in integration associations and international organizations, of which the Russian Federation is a member country.

The approach to the description and classification of national models of technical regulation should be defined as structural-functional, that is, the model is based on the system of management of technical regulation in the country and the distribution of functions for individual state and public institutions. Therefore, it is proposed to understand the model of technical regulation as a set of institutions responsible for the development of requirements for technical regulations and national standards, as well as procedures for assessing compliance with these requirements stated in works of Kucherov (2016) and Shulginov (2014). By establishing the rules and the procedure for applying regulatory elements in their interconnections, an appropriate model of technical regulation and standardization is being formed.

National Experience

Brazil Experience

Brazilian experience demonstrates the fragmentation of technical regulation and standardization functionality among several independent organizations – fig 1.

Fig. 1: Brazilian National System of Technical Regulation and Standardization

The legal status of the regulator is specific to Brazil's national governance model: a strong public sector determines the state status of the regulator. At the same time, the differentiation of powers among several management institutions depends on many criteria: the country's participation in regional integration associations, the size of the country, the volume of foreign trade, the maturity (level of development) of the system of technical regulation and standardization, the country's participation in the international division of labor, the structure of the national economy and etc.

Norway Experience

The Norwegian experience indicates the existence in the world experience of the possibility of the distribution of powers by industry (sectoral) grounds (fig 2). The specification of powers on a sectoral (sectoral) basis involves the separation of a number of sectors of the national economy into a separate category and the formation of a special regulatory center that takes into account the characteristics of this sector of the economy, for example, a number of European countries highlight the field of electrical engineering and / or communications, fixing technical regulation and standardization issues separate structures.

Fig. 2: Norway National System of Technical Regulation and Standardization

Paraguay Experience

The experience of Paraguay is an illustration of the distribution of powers of government by functional attribute (fig 3). The functional distribution is based on a clear delineation of powers and areas of responsibility, based on the tasks assigned to the relevant structures. For example, in Paraguay, organizations that carry out product certification, research activities, supervisory functions, and so on can be distinguished as separate entities of the system.

Fig. 3: Paraguay National System of Technical Regulation and Standardization

Germany Experience

The German experience is interesting in that the regulator is the non-governmental organization - Deutsches Institut fuer Normung (DIN), which coordinates the entire standardization process at the national level, and is also responsible for organizing Germany's participation in European and

international work standards - fig 4. DIN He is also responsible for overall project management, ensuring uniformity and consistency in the collection of German standards.

Fig. 4: German National System of Technical Regulation and Standardization

DIN standards are developed in 73 committees, most of which are combined into several National Technical Committees (TCs). Any organization can place an order to develop a standard. In the process of working on the new standard, both the manufacturing and consumer sectors, trade organizations, scientific institutions, government bodies, as well as regulatory institutions are involved. All these structures send their experts to numerous DIN technical committees, which in turn form more than 70 regulatory committees, divided by industry. DIN employees coordinate the development process and carry out project management.

Results

The obtained information base made it possible to conduct a comparative analysis of national models of technical regulation and standardization of the studied countries - Tabl. 1.

Table 1: Results of a comparative analysis of national models of technical regulation and standardization

Benchmarking Criteria	National Models of Technical Regulation and Standardization			
	Brazil	Paraguay	Norway	Germany
The presence of a public authority endowed with a regulatory function in the studied area		+		
The presence of non-governmental organizations with regulatory influence in the system	+		+	+
Compliance of national standards with international standards			+	+
The presence of a developed system of technical committees *	+	+	+	+
Availability of a voluntary standardization system	+	+		+

* Technical Committee - an organizational unit consisting of representatives of business, government and the scientific community responsible for the development of standards.

Source: compiled by the author.

As a result of the study, two basic models were identified.

The model of the first type is one of the most widespread in the organization of the system of technical regulation, has no regional specifics, does not depend on the state structure and the dominant type of management. Historically, it was the first one, the issues of technical regulation were the prerogative of the state, and the outline of the organizational and legal framework was developed "from above". The model was not static, it developed, relations between the subjects of technical regulation were complicated, but the fact that the responsible subject of the national system of technical regulation was directly subordinate to a certain ministry or other state institution, most often the executive branch, remained unchanged (Fig. 5).

Fig.5: Model of the technical regulation system of the first type

Source: composed by authors

Having a defined circle of competencies and functionality, over time, such organizations ceased to be structural units of the ministries themselves (departments), separated into an independent institute of a system of technical regulation.

This model is still relevant, and in many national economies the system of technical regulation and standardization has exactly the same organizational and functional structure. The main argumentation of the advantages of this model comes from the point of view that technical regulation is a reaction to the classic market failures associated with information asymmetry and the presence of external effects, while the standards and technical regulations themselves have some characteristics of a "public product". Therefore, legislative support of this process is an effective way to mitigate market failures, and the formation of a request solely from the business environment cannot provide all the advantages of their application. Firstly, because the one who creates the standards controls the market, and, therefore, acquires the tool for forming industry barriers that impede the development of competition. Secondly, a number of companies are inclined to evade national standardization, encouraging the development of their own corporate technical conditions, in particular, in order to reduce the existing competitive field. Rational state policy is designed to remove the problems of creating and implementing technical regulations and standards, and in the interests of the whole society. This is ensured by the direct subordination of the regulator to the state executive authority.

Modifications of this type of model are possible by the legal status of the main governing body (state or non-state) and by whether the functionality is fragmented among several independent

organizations, for example, in Brazil, Argentina, Finland, or is absolutized in one institution, for example, in Denmark, Kazakhstan, New Zealand.

And if giving the right status is determined by the characteristics of the national management model, and often, the presence of a traditionally strong public sector leads to giving the state status to the regulator, then the separation of powers among several management institutions depends on a number of reasons and occurs on the basis of various criteria.

Powers can be distributed between institutions on a functional, sectoral or tier basis. The functional distribution is based on a clear delineation of powers and areas of responsibility, based on the tasks assigned to the relevant structures. For example, organizations that carry out product certification, research and development, supervisory functions, and so on can be distinguished into individual subjects of an organization. An example is the national system of the Republic of Paraguay.

The specification of powers on a sectoral (sectoral) basis involves the separation of a number of sectors of the national economy into a separate category and the formation of a special regulatory center that takes into account the characteristics of this sector of the economy, for example, a number of European countries distinguish the field of electrical engineering and / or communications, fixing technical regulation and standardization issues for separate structures.

The formation of collegial management on a level basis depends on how actively the country takes part in regional integration associations and whether special work is required to develop, improve and / or harmonize the system of national technical regulation with regional or international systems. For example, in Argentina, at the national level, IRAM (Instituto Argentino de Normalizacion) is an organization that performs the task of standardization in all areas of activity. At the transnational level: AMN (Asociación MERCOSUR de Normalización) is the only body responsible for managing voluntary standardization within the framework of MERCOSUR.

The second type of model is less common, but it was he who became the target model in the context of the New Global Approach. The main difference is the independence of the institute of a system of technical regulation from direct subordination to executive authorities (Fig. 6). In extreme cases (Germany), it is an absolutely self-regulating system.

The model was formed in those countries where the position of large and medium-sized businesses was initially strong, which, in order to streamline the movement of goods and services, as well as to determine the “rules of the game” in industry markets, created professional associations, communities and industrial chambers, in which a variety of initiatives lobbying for the interests of the business environment, including the creation of technical regulations, professional standards, and a voluntary certification system.

Fig.6: Model of the technical regulation system of the second type
Source: composed by authors

Thus, the system of technical regulation and standardization grew "from below" and initially provided that the request for the formation of technical standards should come from enterprises and firms, and this is the responsibility of industry, as is the case, for example, in the USA. Associations and standardization experts have taken joint efforts to convince policy makers to adopt the principle of reference to standards in the development of draft legislative acts and to achieve high appreciation of the productivity and usefulness of such an approach for the state.

As the model developed, one principle remained unshakable - the vital importance of self-regulation of industry as a fundamental element for any kind of standardization. For this, various technologies were actively used, demonstrating the advantages of reducing state participation compared with the approach according to which all requirements should be included in technical legislation. This implies a comparison of the benefits of reducing government participation and potential government spending on standardization.

On the basis of progressive legislation, a clear line has been drawn between areas where regulatory measures are needed and those areas where standardization can be effective (the state sets forth the legislative framework in the field of regulation and determines the essential requirements). In the political context, the inclusion of the results of the work of standardization bodies in technical legislation makes the work of lawmakers easier, and thus standardization effectively contributes to reducing the amount of government intervention in the economy. Directives in most cases formulate their specifications on an international basis in order to minimize restrictions on products, technologies and services both domestically and in international markets.

The relationship between the national technical regulatory authority and the government is regulated by a special document, for example, in the UK - this is a Memorandum of Understanding between the Government of the United Kingdom and the British Standards Institution (BSI), in which the parties declare the identity of positions on a number of issues in this area.

The transfer of standardization issues into private hands does not mean, however, the removal of state bodies from participation in the development of standards. For example, the number of representatives of state inspection bodies in the technical committees of the Council on the International (Construction) Code (USA) is at least 30% of the number of committee members. Government officials participate in the process of discussing and approving private sector standards

on a common basis and do not differ in status from other voting members of the development organization.

Despite all the initial differences in national models, their rapprochement is currently being observed; the general development vector is aimed specifically at implementing the principles of the New Approach. Foreign experience confirms that at a certain level of economic development, the state is not able to provide regulation ("keep track") at the same time of all processes occurring in science, technology and non-strategic sectors of the economy, see work of Matraeva etc. (2019). Moreover, at higher levels of economic development, when the size of the gross national product reaches several trillion dollars, the involvement of the state in standardization processes at the level of developing specific standards becomes economically inexpedient.

If, under the conditions of the formation of the system of national regulation, the model of the second type initially provided for the strong influence of the business community, self-regulatory organizations of manufacturers and public organizations in this field, then in those countries where historically the initiative to form the conditions of technical regulation belonged to the executive branch or specially allocated structures (model of the first type), the need to involve business and production efforts, and Reforms are being promoted that contribute, if not to a change in the management system of technical regulation, then at least to the formation of alternative sources of requests and initiatives.

Reforms in the model of the second type can go in several directions, the main of which are as follows:

1. Deregulation, i.e. reduction of state intervention in the system of technical regulation and standardization. In the future, deregulation should lead to the fact that only legislative, control and oversight functions remain with state bodies. Moreover, it envisages the implementation of the principle of the inadmissibility of duplication of functions in regulatory bodies and, in turn, administrative barriers and corruption.
2. Formation of a broad institutional system that replaces the functionality of state structures (technical and professional communities, industry associations, independent expertise, public councils under the regulator and industry departments, arbitration organizations, bodies for accreditation of subjects and certification of products, consortia created by large corporations implementing development of standards in new, dynamically developing industries and so on), with the provision of wide public discussion adopted technical standards.

The presence of a comprehensive system of institutions that act as a “counterweight” to the current state regulator allows decisions to be made as balanced and verified as possible, taking into account the interests of the majority, since each participant in these relationships not only balances, but also limits other participants.

Conclusion

Thus, an analysis of the experience in building national systems in the field of technical regulation and standardization of different countries of the world revealed two basic models of the formation and functioning of technical regulation and standardization systems. At the same time, the analysis also shows that the two models are moving closer together in the course of their development, and it is potentially possible to establish an adjacent variant of the organization of processes that combines the strengths of both basic models. This trend and the features of constructing basic models were taken into account in the analysis of the national model of technical regulation and standardization in the Russian Federation, as well as in the formation of the organizational and functional diagram of the organization of processes within the framework of a single industry system of technical regulation and standardization in the fuel and energy complex, including the need for separation of the regulatory, coordinating and executive functions in the specified area.

Abstract

The authors analyzed the experience of developing microfinance organizations in order to support small businesses based on cases from the USA, France, Mexico, Japan and other countries. As a result, the main criteria for their differences are identified: mission, tools for supporting small businesses and the level of digital development. The authors propose, in the light of modern trends in the development of microfinance organizations, to identify 4 basic models for the development of microfinance organizations. A description and comparison of these models is provided. The conclusion proves the feasibility of using microfinance institutions as socially significant organizations focused on supporting priority groups of small and medium-sized enterprises, requiring special attention of the state and society, contributing to the growth of self-employment of the population, improving the quality of human capital and reducing social tension in society.

Keywords: Microfinance Organizations, Microcredit, Small and Medium Business.

Introduction

Micro-enterprises in some countries play an important role in ensuring employment, with a large role in countries in countries with high unemployment and persistent imbalances in the labor market by Matraeva etc. (2018). In Spain, Portugal and Italy, employment in microenterprises makes up more than 40% of the total employment of the country's population, and in Greece - almost 60%, however, only 12% of the total number of microenterprises were able to use bank loans as additional sources of financing in work of Kraemer-Eis etc. (2017). From this point of view, microfinance can be a tool that can be adapted to support the needs of small businesses, including those from disadvantaged segments of the labor market specified by Utkin (2018).

The microfinance field does not have strictly defined boundaries, a clear organizational structure, unified methods and rules for conducting operations. A variety of microfinance organizations (hereinafter referred to as MFIs) act as lenders and financial service providers, differing from each other in goals, forms of organization, clientele, the range of services provided, funding methods and other parameters by Kaurova etc. (2019).

The activities of microfinance institutions show successful growth around the world, as evidenced by the figures of the annual analytical report “Microfinance Barometer 2019”. In 2018, 139.9 million borrowers used the services of microfinance organizations, compared with 98 million in 2009. At the

same time, the initial mission of microfinance institutions, which was to open access to financial resources for low-income individuals to organize small businesses, is still relevant. this is evidenced by proportions that have remained unchanged over the past ten years, despite an increase in the number of borrowers: 80% of women and 65% of rural residents in Microfinance Barometer (2019).

Since the efforts of Professor M. Yunus to develop and promote the ideas of microfinance have gained international recognition, microfinance institutions have begun to spread throughout the world, including those countries where the level of social well-being and disposable income is significantly different from the home country stated by Khandker (2005). However, the problem of supporting small businesses in more developed countries remains relevant, and microfinance institutions successfully fill a niche where traditional methods of stimulating SMEs have shown low efficiency.

Each country, adopting the experience of introducing microfinance institutions, has formed unique national models, within which a whole range of specific microfinance practices has arisen. However, all MFI countries tried to solve similar socio-economic problems: reduce unemployment, increase the availability of financial services for the population, increase economic activity and well-being of the population, and form a focus on long-term sustainable development.

Over 20 years of spreading in international practice, MFIs are interesting in that they have developed new management and technological solutions that overcome various barriers that impede access to traditional sources of funds for individuals to organize small businesses. Therefore, the main objective of the study was to analyze the best international practices of the formation of an MFI system, with the aim of identifying conceptual models, the introduction of elements of which will contribute to increasing the efficiency of the functioning of the national microfinance system.

Methodology

The selection of countries to analyze the best international practices of the MFI system to support small businesses was built on the following methodological principles:

- the principle of completeness of coverage on a regional basis, i.e. a requirement was laid for the analysis of international practices in various regions of the world.
- the principle of compliance with the goals laid down, in the formation of an MFI system with the basic requirements of a developing small business sector;
- the principle of taking into account the unity of the substantive and procedural aspects of the development of the microfinance sector and small business;
- the principle of structural integrity of the functioning of the microfinance sector in the country and the stimulation of the development of small business at different levels, which involves mutual proportionality, complementarity and harmony.

Based on these principles, the following selection criteria for countries follow:

- the criterion for a holistic reflection of the main components of the financial system: building experience, development prospects, multilateral development objectives in conjunction with small business.
- the criterion of the high importance of the MFI system for supporting the development of small business and self-employed, i.e. the selection of countries in which the most universal, necessary elements of the microfinance system can be identified to stimulate small business.
- the criterion of compliance of the financial system of the country for the possibility of “importing” the positive experience of building and regulating the system of MFIs.
- the criterion of conformity of time, the experience of countries where the MFI system is relevant, tested and has shown stability over a certain period of time is studied.

Thus, the indicated principles and criteria are of a specified nature, and their application should satisfy both the development conditions and the current trends in the microfinance system, and the targets for the functioning of small business.

For the initial selection of countries, the specialized program for solving infometric research problems in the field of scientometry and bibliometry CiteSpace was used, which supports the structural and temporal analysis of various networks arising from scientific publications and has a set of functions that facilitate understanding and facilitate the interpretation of these models.

As part of the task of selecting countries, a statistical-bibliometric analysis of a given scientific direction was carried out. As the initial array, we used data obtained from the Web of Science database at the request of microfinancing for the last 16 years.

The frequency of scientific articles on this topic suggests that countries in which publication activity is high use this tool extensively in practice, discuss the testing of new tools and mechanisms for providing microloans to small businesses, and, therefore, can become the base units in the formation of a sample of countries whose experience it is advisable to take as a basis the study of national models of MFIs.

Results

Statistical-bibliometric analysis made it possible to single out a group of countries that formed the basis for further research of national MFIs (Fig. 1)

If we analyze the global publication flow presented by WOS by country, then the leaders in this direction were scientists from the USA, Great Britain, Bangladesh, India, Australia. These countries met all the basic principles of selection and entered the sample. A further selection of countries was formed by experts from the list presented, while maintaining relevance to the objectives of the study, which provides an applied analysis of empirical information on the microfinance sphere. Such a methodological approach is justified in the formation of the sample, which reduces the likelihood of distorting the idea of the internal structure and essential features of the microfinance sphere.

An analysis of the existing systems of microfinance institutions in different countries included in the presented sample allowed us to identify 4 modern microfinance models that differ primarily in mission, tools for supporting small businesses and the level of digital development.

The Basic Model

The basic model is characterized by the presence of the social orientation of microfinance institutions and a high level of state requirements for the creation and construction of their activities. The refusal of banks, as traditional financial institutions, to provide loans to low-income citizens for small businesses, initially led to the introduction of state credit support programs in these countries, which also did not give the expected results: loans often fell to those who did not need them, were not used to organize small businesses and did not return after the deadline. The loan scheme implemented by microfinance institutions helped to avoid banking restrictions and public sector errors.

The basic model for the functioning of microfinance institutions is built on the basis of the Grameen Bank model proposed by M. Yunus, which has become the benchmark for the development of microfinance institutions in underdeveloped countries. Elements such as: group responsibility; dynamic lending regime; frequent loan repayments; lack of requirements for securing a loan or non-traditional forms of collateral; small loan amounts - have become classic attributes of financial activities of MFIs by Amin (1994) and Amin (2001).

The basic model is most widely used in countries with a low per capita income, the predominance of agricultural production. The formation and implementation of this model can be recognized by the average loan amount of less than $ 100 provided in the country.

The principle of operation of microfinance institutions in this system is based on the availability of a reliable creditor, capable of providing financial support, taking into account the financial exclusion of borrowers and the inability of the latter to use banking services.

However, according to the totality of conditions and signs of implementing the basic model of organization and promotion of microfinance institutions, it can be stated that for the realities of many countries, including the Russian Federation, it is not suitable for several reasons:

1. Starting positions and priority tasks

The fundamental factor determining the growth vector of the microfinance sector is the mission of microfinance institutions, the tasks that they should contribute to. For many countries, they are formulated in such a way that does not correspond to the basic model.

2. Legal

In the conditions of the national system of economic and social relations, it is impossible to use credit schemes embedded in the basic model, for example, a mechanism of shared responsibility, which is not applicable in the absence of a close commonality of production and moral family ties.

3. Socio-economic

The level of socio-economic development of countries initially forms a different solvent demand for financing, in terms of qualitative and quantitative indicators, approaching more advanced models of functioning of microfinance institutions.

Banking Model

In some countries, microfinance institutions, initially formed on the principles of the basic model, have outgrown the inherent functionality over time. The essence of the banking model is that microfinance organizations are increasingly acquiring the features of specialized banks as financial institutions. Expanding their functionality (issuing loans, depository functions, issuing bonds, etc.), MFIs began to gradually transform into an element of the banking system, subjecting not only to the regulatory impact very similar to banking, but also to the functional content. Such a movement towards rapprochement of the two sectors up to the formation of a two-tier banking system, taking into account the creation of the institution of “local banks” (banks with a limited license), is observed in Bolivia, Mexico and other countries in works of Mosley (2001) and Griffin (2015).

Bolivia is a country with a relatively mature microfinance market, with a high concentration of specialized banks and other non-bank deposit organizations in the microfinance sector. For example,

Banco Solidario (BS) arose in the mid-80s. as a non-governmental organization (PRODEM), which provides small business loans. By the beginning of the 90s. the fund had more than 17 thousand customers, and the total amount of loans issued amounted to $ 4 million. In 1992, PRODEM was transformed into the commercial bank Banco Solidario. By 2007, the bank had a network of 48 branches in 7 cities of the country, the number of its customers increased to 110 thousand people, and loans - up to 172 million US dollars. BS used elements of the basic model in its work: a group contract for 3 to 4 people, "dynamic stimulation" with a gradual increase in the loan amount with a good credit history. But at the same time, BS from the very beginning set a course for serving more affluent customers and achieving high profitability.

In 1990, Compartamos was established in Mexico as a non-governmental organization that provides loans based on a group contract to finance revenue-generating activities. In 2002, Compartamos entered into a strategic alliance with Accion International, and in 2006 became a commercial bank. It is one of the first microfinance institutions in the world to list bonds on the stock exchange. This allowed the bank to reduce the cost of funding, improve financial performance and expand the range of services. Currently, the bank has 630 thousand customers, the loan portfolio is 285 million US dollars stated by Klyukin (2016).

In Indonesia, while maintaining and complying with the general principles and regulations of banking legislation, incentive mechanisms are used to facilitate the expansion of retail banking services to lower-level microfinance markets.

The emerging microfinance policy in India is decisively changing the status of microfinance institutions, turning them into specialized banks. Microfinance activities are constantly supported by core banking activities as part of an accelerated financial integration program. RBI has used banking licensing and regulatory mechanisms to encourage large microfinance players to become full-blown banks. In 2014, it granted a universal banking license to one of the largest MFI-NBFIs, Bandhan Financial Services, and a small financial bank (SFB) license to eight others in 2015.

In 2010, a tendency towards convergence with the banking model has been outlined in Germany, since banks that currently lend for short periods both to the population and entrepreneurs who need funds to develop a business play an active role in issuing microloans. Banks lend money quite willingly, which is understandable: the return of microloans is guaranteed by the state, which manages a special microcredit fund. The main clients of such programs are small businessmen, owners of small family-owned companies, and the procedure for providing microloans, for example, at Berlin Investitionsbank and other similar banks, is simpler and more profitable than receiving similar amounts from purely commercial banks.

The merger of microfinance institutions with the banking sector is objective in nature, since the instruments of microfinance organizations are similar to banking financial instruments provided to similar groups of business entities as microfinance organizations. Similar intersection in other models can be called the microfinance identity problem. In the banking model, the separation of the two lending sectors and determining their place in the credit system is gradually leveled, the banking sector increasingly includes microfinance tools in its functionality, thereby further blurring the differences that consist only in the way these services are provided and their consumers. A bank may have microfinance goals, for example, supporting segments of the population with socio-economic problems.

However, there are a number of arguments that cast doubt on the feasibility of switching microfinance institutions to the banking model. The fusion of the banking sector with microfinance organizations will inevitably lead to an increase in risky assets in the structure of the portfolio of banks. And as the financial crisis of 2007-2008 showed, an overuse of risky loans with a simultaneous investment burden in the stock markets can lead to a "domino effect" that will affect the entire financial market.

Marketplace Model

To increase the reliability of microfinance institutions, it is not necessary to follow the path of merging them with the banking sector. Today, in a number of countries where government participation is high in organizing the functioning of MFIs, microfinancing based on digital platforms is transforming into a financial ecosystem that provides for the implementation of a marketplace model, where on the one hand there is a global monitoring system (most often on a state platform), on the other - An affiliate network is being created to expand client opportunities. The model involves the breeding of the banking and microfinance sectors, with further systematization of disparate financial organizations into a single window system.

The marketplace model is a holistic approach to organizing the functioning of microfinance institutions, based on specialized management of the microfinance industry with a quick time response. If we talk about the advantages of this model, the implementation of the system provides continuous monitoring of the functioning of MFIs, while significantly reducing the time to identify possible problems. The model allows you to quickly bring together all the analytical information collected from various departments into one, and metric thresholds are built on the basis of the collected data, critical points are determined and, acting according to a given scenario, it is easy to determine the needs of the MFI system, diagnose business processes and prioritize actions. Also, based on these data, it is possible to proactively solve problems and predict possible development scenarios.

Financial ecosystems have spread in countries with a large number of disparate territories, as well as countries with significant participation of budget financing in this area. As an example of the implementation of the model, we can cite the Philippines, where in just 5 years, from scratch, with the virtual absence of a banking system, through the development of Internet banking institutions, a model has been formed and is currently operating stably, according to which any farmer, for example, in a rural area , using the Internet, it can easily get a small loan and solve other problems that it faces through standardized channels and the MFI model.

The Polish microfinance market is considered one of the most developed not only in Europe but also in the world. Poland is the flagship of digital change, gradually transforming into a model of marketplaces and according to the Raiffeisen group in its review of fintech ecosystems in the region of Central and Eastern Europe, Poland is one of the three leaders in the transition to a model of marketplaces.

The transition to the financial ecosystem also involves a number of problems, the main of which are the level of customer readiness, technological challenges and the adequacy of ecosystem partners.

The level of willingness of clients in different regions to interact with the financial ecosystem is considered the main barrier to unlocking the model's potential. This indicator is highest in the Asia-Pacific region, where 80% of consumers are willing to work with the ecosystem stated in Regulatory Framework in Bolivia.

Another barrier is technological challenges. The creation of such ecosystems became possible only under the condition of the proper level of development of IT systems that allow you to collect and process a huge amount of user data both online and offline, build effective communications through any available channels and provide many services remotely.

The third problem is called the availability of adequate ecosystem partners. When launching the model, one should focus on partners performing the task of bringing new offers to the largest number of potential customers with the subsequent provision of services at the declared level. Microfinance institutions do not just sell their product separately, but are embedded in a certain chain of relationships of other economic counterparties (supplier - buyer).

Segment Model

In a number of countries, a sufficiently powerful banking sector is initially present, but it does not try to absorb microfinance institutions and does not try to form a single platform based on the principles of complementarity. On the contrary, they are intentionally divorced both in terms of functionality and by sector. The banking sector serves the traditional client segment that meets the scoring and risk management requirements of commercial banks, MFIs take on a higher risk segment, but also with higher social responsibility: depressed regions, startups, migrants, etc., while their activities it is a channel of strong support from the government. Therefore, in developed countries, a model began to take shape where there is close interaction between government bodies and intermediary organizations (microfinance institutions), while government bodies focus not so much on legislative support and regulation of the microfinance market, but on the development of standards and criteria to evaluate the activities of financial institutions, state-run; the procedure for providing state subsidies and targeted loans; development of legislative requirements governing the procedure for the provision of inexpensive and sought-after financial services. For example, the proportion of the population in the United States that is not covered by traditional banking services is only 5-6%, while about 400 MFIs operate in the United States. In the United States, microfinance is based on the interaction of government bodies (Small Business Administration, SBA) and microfinance institutions as intermediary organizations. Microloans should be targeted: for working capital, for the purchase of office equipment and equipment (loan capital cannot be spent on the acquisition of real estate and advance payments on it). Moreover, each loan is accompanied by a technical assistance grant, and the conditions for obtaining a loan may vary depending on: the size of the loan, interest rates (depending on the intermediary), the planned use of capital, the requirements of the intermediary, and the needs of the borrower by Shreiner (2003).

In addition to the AMB, other government organizations are widely involved in subsidized special-purpose loan programs, including: the Federal House for Mortgage Lending (Freddie Mac), the Federal National Mortgage Association (Fannie Mae), the Small Business Development Agency, and the Social Development Financial Institute, which invests in social development organizations serving depressed communities by Glasova (2016).

France, where microfinancing since 2005, has become one of the priorities of the national government, is a segmented model among the highly developed post-industrial countries of Western Europe. Within the framework of the specially created program, serious financial support is provided for the independent entrepreneurial activity of the population, and the creation of a new business is considered as one of the effective ways of transforming hired workers into a self-employed population, which, in turn, leads to a decrease in unemployment in the country. Microfinance programs in France are implemented by the Unity Social Fund, which provides loan guarantees for unemployed people who want to build their own business, and also gives social microloans ranging from 500 to 2,000 euros to low-income people in work of Balkenhol (2013).

In France, the mission of microfinance institutions is to integrate low-income people. MFIs in France provide microloans for projects related to increasing population mobility - their education, training, as well as improving employment and developing their own business.

In Japan, the activities of MFIs are based on the particularities of the country's labor market, where about 70% of the able-bodied population is employed in the field of small business (individual and family enterprises predominate by ownership). The segment model in Japan operates on the basis of state and private specialized organizations that clearly distribute the functionality among themselves: the Japanese State Corporation (financing of small business through preferential long-term loans to increase the fixed and working capital of enterprises operating in industries that are identified by the government as priority), Folk Financing Corporation (long-term microloans without property support), State Insurance Corporation of loans and small business financing (guarantees repayment of loans) as stated in works of Armendariz (2007), and Suzuki etc. (2011).

Conclusion

1. Thus, each country, when developing a national model and policy in the field of microcredit, uses a "multi-level" approach, which consists in creating a conceptual framework for the system of microcredit regulation as a separate area of activity. That is, specific types of financial institutions, legislative or regulatory “windows” are determined, which differ in:

- permitted activities (mainly, placement of deposits compared to the provision of loans);
- legal status (commercial versus non-commercial);
- approach to regulation and supervision (full prudential regulation or only licensing compared to the lack of regulation).

2. The highlighted models of the MFI system are correlated with the banking sector. The criterion for distinguishing became the place and role of microfinance organizations relative to banking institutions. The basic model assumes the lack of a full-fledged financial sector, either due to territorial features or due to solvent demand for traditional banking services. Therefore, microfinance organizations are in this model an alternative to banks, especially in the formation stage of the latter.

3. The banking model involves the gradual merging of banks and MFIs. The functionality of microfinance organizations is gradually being included in the tasks of specialized banks, which will replace MFIs in supporting small businesses and self-employed.

4. The marketplace model accompanies the digitalization of economies and becomes one of the most promising for countries whose development strategy is aimed at reducing transaction costs through the creation of digital aggregators for various financial market players whose services are complementary, while maintaining each individuality.

5. The segment model is designed to implement an MFI positioning policy that complements the banking system in the provision of financial services. Microfinance institutions contribute to the growth of self-employment of the population and the quality of human capital and reduce social tension in society, acting in a niche that, for various reasons, is not interesting to the banking sector.

6. Moreover, all models contribute to accelerate economic growth and improve the quality of the social sphere. The main factors determining the position of microfinance institutions are:
- willingness to cooperate with small business mainly at the initial stage of its development;
- the ability to determine a package of services, which includes not only financing, but also advice in the field of financial and managerial accounting;
- understanding of the regional and industry specifics of small business and the development of an adequate risk assessment system;
- availability of sufficiently trained personnel to service and attract customers;
- a significant impact on the development of microfinance infrastructure for small business government support programs in the field of microcredit.

Standard Operating Procedures for Vocational Training in Rehabilitation Centres: What Have We Missed?

Farhan MURSALIN
Ministry Of Social Services, Indonesia
farhanmoemursalin@gmail.com

Universitas Indonesia, Depok, Indonesia
sari.viciawati@ui.ac.id

Abstract

Private companies in Indonesia must employ People with Disabilities (PwD) at the rate of at least 1%. The National Vocational Rehabilitation Center (NVRC) or is an institution offering services for PwD to help them gain employment at formal institutions. At NVRC, PwD acquire skills that are useful in the workplace setting through education and training offered by experts, including social workers and instructors. In addition to job skills, many PwD require psychological support to cope with their workplace settings. The process by which NVRC delivers these services is fundamental because the competence of PwD in the workplace is strongly dependent on the quality of their education or training they receive. This study used a qualitative approach to examine the process. Our data was collected through in-depth interviews with 16 informants as well as group discussions and observation. This study noted various problems, especially regarding the practice of student recruitment and assessment for vocational training. Our findings indicate that standard operating procedures (SOPs) have been established at NVRC. Due to the lack of funds, however, the actual recruitment and assessment processes at NVRC are not in keeping with the SOPs. Another problem preventing the full implementation of the SOPs is that the local institutions referring PwD from other regions do not have an adequate selection process that can match the type of skills training to be undertaken at NVRC.

Keywords: Persons with Disabilities, Instructor, Standard Operational Procedure, Social Worker, Vocational Institution

Introduction

Every individual, including those with disabilities, has the same right to a decent life and should therefore have equivalent opportunities. Real life, however, is not always in line with these expectations. The difficulties experienced by persons with disabilities (PwD) include limited employment opportunity, which is related in part to society's failure to fulfil the rights of PwD and to the lack of support from related parties. One attempt to correct this situation in Indonesia is the regulation on workers with disabilities, wherein the national government has mandated that both government and private institutions should employ PwD.

This government regulation states that central government-, regional government-, state- and regionally owned enterprises are required to employ PwD at the rate of at least 2% of all employees, while private companies must employ PwD at the rate of at least 1%. In spite of this regulation, not all PwD are employed in government or private institutions or run their own businesses. According to the Ministry of Social Affairs' Data and Information Center (Pusdatin), PwD who do not work may be prevented from working by:

1. Insufficient education and training.
2. Lack of need for unskilled workers.
3. Small number of employees at enterprises subject to the regulation.
4. Concern about accidents and insurance costs.
5. Lack of awareness among employers of the needs and abilities of PwD.

6. Inadequate personal or technical assistance.

As many scholars have mentioned (Oud, 2018; Villanueva-Flores, Valle-Cabrera, & Bornay-Barrachina, 2014); Hassi, Foutouh, & Ramid, 2015); and Milner, Taouk, Disney, Aitken, Rachele, & Kavanagh, 2018), PwD face several challenges in the work setting. Business organisations and other sectors must make changes that will allow them to accept disabled workers more easily; PwD must also have the best possible education and training to gain employment and succeed in the workplace. Therefore, education for PwD is a crucial matter. As Žganec, Laklija, & Milić Babić (2012) have argued, education is the highest priority for uplifting PwD through the social welfare system.

The government and private sector certainly expect that individuals with disabilities whom they employ should have proper qualifications with regard to the level of education, work experience, abilities and skills and high motivation. To maximise these characteristics in PwD, the Indonesian Ministry of Social Affairs has established NVRC as a social rehabilitation service institution serving PwD. In collaboration with Japan International Cooperation Agency (JICA), NVRC focuses on providing vocational training and mental development to ensure readiness to work at companies and other places.

NVRC aims to develop and improve vocational rehabilitation systems in Indonesia so that PwD will have the skills and expertise they need for employment. The primary task of NVRC is to develop human resources, especially workers with disabilities, so that they will be able to compete to obtain decent work. NVRC equips individuals with physical disabilities with the knowledge, attitudes and work skills they will need to flourish in the world of work.

To improve the quality and employment rates of graduates from NVRC, social workers are needed to prepare PwD to function socially. Social workers aim to improve the performance of social institutions and services so that they effectively empower vulnerable groups and promote social and economic prosperity (Zastrow, 2004). Given the broad scope of the role of aid providers in service organisations, however, it may be more suitable to call them Welfare Workers or Community Workers rather than social workers, as they no longer come exclusively from a social work background.

In addition to Welfare Workers or Community Workers, NVRC also needs instructors (Johnson & Geal, 2009). Instructors are individuals with advanced abilities related to a skill or profession who intend to transfer these abilities to others. Instructors generally have high intelligence related to their specific fields, and they must not only understand the material but also be able help other people understand it so that the learners can apply their new knowledge to achieve their goals. Instructors at NVRC play a role in delivering skills training.

The skills taught at NVRC include sewing, computer skills, graphic design, electronics, metal work and automotive work. In addition to skills training, students also prepare to live in the community and to apply the results of their training in the world of work. Thus NVRC works to improve social welfare through training and social rehabilitation. Training is intended to provide students with work skills according to their individual talents and abilities, while social rehabilitation is designed to restore and develop the willingness and ability of students to successfully perform the functions of community life.

The tasks and functions of social workers and instructors are clearly defined. Social workers are involved in almost all the stages of the work that NVRC does, from assessment to termination. The activities undertaken by social workers are geared primarily towards preparing students to receive their skills training successfully and providing insight and mental guidance related to how to work at a company or another place. Instructors, meanwhile, are more involved in activities related to the instructor's competence, namely, skills training.

The institution has established standard operating procedures (SOPs) for student recruitment activities and for assessment to determine the type of training that will be offered to each student. Based on our preliminary information, however, these two stages of the training process do not comply with the SOPs in practice. The SOPs were established to ensure that the service activities carried out by NVRC meet the needs of the centre’s clients and will be useful for the PwD whom the centre serves.

Accordingly, we set out to clarify the extent to which SOPs are implemented at NVRC, especially the SOPs on recruitment and determination of skills training fields. Both stages are critical elements of the NVRC programme because they affect whether PwD who are NVRC graduates can be absorbed by the job market. As an educational institution, it is important for NVRC to prioritise the quality of the services it provides.

Research Method

The purpose of this study is to assess the SOPs implemented in the social rehabilitation services and vocational training programmes at NVRC and whether these further the goals of NVRC. The particular SOPs that we reviewed are related to the recruitment and assessment stages. This study used a qualitative approach and descriptive research. The data were collected in the field through in-depth interviews (Sugiyono, 2007), group discussions and field observations, as well as documentation studies.

The study location was the Bogor Cibinong Bina Daksa Vocational Rehabilitation Center (NVRC). This location was chosen because it is a training place for PwD that exists to help PwD become qualified workers who can be employed in the job market. Yet NVRC is different from other rehabilitation institutions in that it offers advanced skills training services. The knowledge received by students corresponds to the skills needed by the labour market. Because of its continuous enrolment practice, students at NVRC must go through an initial selection process consisting of the stages of recruitment and assessment.

To identify informants, the researchers used a purposive sampling technique. This technique allows researchers to identify informants who meet specific criteria. Our criteria for informants were developed based on a framework of thought that supports the achievement of research objectives. Each informant was chosen based on specific considerations and not convenience, based on an understanding of the material in this study. The criteria for informants that have been set out in this study are as follows:

Table 1: Informant Criteria

Informant	Criteria	Total
Social Worker	a. Social Worker has worked at the Cibinong NVRC for at least five years. b. Informant is a social worker who has a social work education background. c. Informant has participated in General Skills Training. d. Informant has participated in the Rehabilitation Aid Skills Training activity. e. Informant has participated in Vocational Rehabilitation activities.	Based on the established criteria, this study interviewed six social workers.
Instructor	a. Instructor has worked at the Cibinong NVRC for a minimum of 5 years. b. Informant has participated in General Skills Training activities. c. Informant has participated in the Rehabilitation Aid Skills Training activity. d. Informant has participated in Vocational Training activities. e. Informant is registered with the Ministry of Social Affairs ASN.	Based on the established criteria, this study interviewed two instructors.

Student	a. At least one student is selected from each of the skills training areas in NVRC. b. Informant is currently enrolled in a programme at the Cibinong NVRC and has been there for at least three months. c. Informant is from outside the Bogor/Jakarta area.	Based on the established criteria, this study interviewed six students.
Institution leadership:	Structural officials are essential informants because they are the ones who determine the policy. They also have a significant influence on the overall organisational system of the NVRC, including how social workers and instructors carry out activities according to the demands of their respective professions. Structural officials are also expected to carry out evaluations of the implementation of policies at the Cibinong NVRC.	Based on the established criteria, this study interviewed two people. They were as follows: a. One Cibinong NVRC Chief b. One Vocational Training Section Head.

The data analysis in this research consisted of several stages. After the data were collected, data from the interviews and field observations were sorted into several themes in keeping with the research objectives. The themes of the research results were thus confirmed and one theme was chosen as the main focus. We also examined the problems that arose with regard to each theme.

To increase data credibility and validity, the authors used triangulation techniques and also confirmed some information with other informants to ensure the quality of the data.

Results

As previous studies have noted, there are many obstacles to maintaining diversity management in a work setting. One solution to this is to make education for PwD ongoing and long-term (Žganec, Laklija, & Milić Babić, 2012). Workplaces also have to provide some education and training for their disabled employees, so that PwD in the workplace are not prevented from adapting to the workplace dynamic (Rashid, Thompson-Hodgetts, & Nicholas, 2018; Soldan, & Nankervis, 2014). In the social welfare system, realising ideal methods of inclusion is not an easy matter. Kemény, Kondor, & Tausz (2014) have observed that:

> '… although all the professional preconditions have been given to implement the right to rehabilitation since 2002, and on the surface the government supports the implementation of the Supported Employment and Back to Work occupational rehabilitation programmes based on American and British schemes, the lack of unambiguous political commitment hinders improvements in the field. Although up-to-date knowledge and more than ten years' experience on the procedures of complex rehabilitation is available in Hungary, this know-how is not adopted by the state-run services of rehabilitation.'

The situation is the same in Indonesia, where welfare services for PwD through Vocational Training are designed so that, ideally, disabled workers will be accepted in the job market. These SOPs have to be followed, but there are obstacles to developing the skills of disabled people that affect the process from the beginning, i.e. the recruitment and assessment phases. So that the social services from NVRC could reach its goals as social rehabilitation center. Suharto (2004) said social rehabilitation is a comprehensive and integrated social services, in order to help PwDs to do their social functions. Socia workers become crucial profession. Ministry of Social Affairs (about social welfare) based on the law

of Republic of Indonesia Number of 2009, Number 4 of of 1997 disabled people (about People with disability), and Number 8 of 2016 about People With Disabilities said that social rehabititation is a process of recreating and developing to enable a person to do his/her social function in society normally. Kirst-Ashman (2010) mentioned roles of social workers, they are: counsellor, educator, broker, case manager, mobilizer, mediator, and advocate.

Recruitment Process

As a government institution, NVRC directs its efforts towards service and social rehabilitation, especially the process of functionalisation and development to enable PwD to be able to carry out their social functions reasonably in mainstream life. One of its programmes is institution-based social rehabilitation and vocational training with social workers and instructors as the driving force. Social workers and instructors work with PwD to carry out the process established by the Ministry of Social Affairs regarding the standardisation of social rehabilitation services that should be adopted by every social institution.

Based on data from field findings, in the implementation of SOPs at NVRC, social workers were involved in several stages of activities, including recruitment and assessment activities, vocational training activities and resocialisation activities.

Recruitment and assessment in general at NVRC is related to the delivery of information on the service programmes offered by NVRC to city and provincial social services institutions, as well as to the selection of prospective students for the Technical Service Unit or *Unit Pelayanan Teknis* (UPT) in Bahasa. The findings in the field stated that the distributed information about the service programme activities offered by NVRC was obtained by prospective students from several sources, namely from the city and provincial social services institutions serving prospective students and from NVRC alumni.

NVRC has established criteria that must be met by prospective students; these are shown in Table 2 below:

Table 2: Requirements for Prospective Students

NO	Dissemination about NVRC		
1	Requirements for Prospective Students	General requirements	• Age 18 to 35 • Marital status = not married
		Special requirements	• Minimum education level • Basic skills (certificates)

This field data was collected by the authors from leaflets and booklets published by NVRC. One of the requirements for prospective students who want to receive training at NVRC is that they master certain basic skills as evidenced by a certificate, as explained by the following quote:

> ‘Yes, so [all students] must have basic skills from the UPT [in Bahasa] or Technical Service Unit) from specialised training institutions; only then will they be selected to enter here. Here they are trained to have skills so that they can later be placed in the work setting, industry, companies that do have standards. They are (from) almost all over Indonesia, as [NVRC is] part of the national referral system; basically those who get in here no longer need to get basic vocational [training], we just help them get advance skill level that matches the standard… for nine months.’ (AMA, March 2018, Management)

As this quote explains, to enter NVRC, students are required to have basic skills from training institutions prior to selection. This was confirmed by other informants:

> ‘Here, the requirement is having a basic skill. For instance, sewing skills, so that they must be able to do basic sewing.’ (IWG, March 2018, Social Workers)

Before being able to receive services at NVRC, prospective students are selected while they are at basic skills training institutions. This is also supported by the following quote:

> 'We chose the UPT [in Bahasa] or Technical Service Unit, ministry of Social Affairs before he graduated from there; we looked first, we selected him, we interviewed him, we assessed him, we were motivated… if you want to be here… and want to continue to get advanced skills, [it requires] coordination with parents [and] coordinating with social services as recommended. But what we need to look at is the ability in the institution… we see their ability first.' (M, March 2018, Social Workers).

Our field data explains the general recruitment stages that should be carried out by NVRC. Yet our data also mention things that are contrary to the SOPs, namely, the incompatibility of prospective student requirements. This can be explained based on the following interview excerpts:

> 'It can be seen from the students that maybe they don't have basic abilities, so they have difficulty following the subject in class … for example, in electronics or automotive class that requires skill at mathematics, yeah, you know that our children are from all over Indonesia and from that point … on the level of education… maybe lack of knowledge, on average … they have difficulties, … because finding PwD who have high marks at school is difficult, [even in] a large region.' (PA, March 2018, Management)

PA states that students who do not have basic skills will have difficulty with the training at NVRC. This is due to the difficulty of finding qualified students among PwD. Informants such as the social worker quoted below also mentioned matters related to students' basic skills:

> 'Those children … are primarily those who do not have basic [skills], even though the requirements [state that they] must (have basic skills), but the fact is there are still many, in fact many (who have no skill base).' (S, March 2018, Social Workers)

Our findings show that there are still obstacles to the recruitment process. These constraints include, among others, the process of socialisation and non-compliance with the requirements of prospective students. This can be explained based on the following interview excerpts:

> 'For the recruitment itself, we look for our children in the area, and there is a process of socialisation [that] is tasked to capture prospective PM.' (PA, March 2018, structural official)

As our PA informants explained, socialisation activities are carried out throughout the various regions as part of the recruitment process of prospective NVRC students. One PA informant, however, also mentioned the obstacles affecting the socialisation process, as explained in the following quote: 'Because of budget constraints [we] cannot reach all provinces.' (PA, March 2018, structural official)

This PA informant explained that, because of the limited budget available to NVRC, not all regions could be reached through socialisation and recruitment activities. This relates to prospective students who would be sent to NVRC by their own regional (city/provincial) social service organisation, as also explained in the following quote:

> 'The social services here have to guess, is this possible with the criteria? … can this student pass NVRC? … that's because there is no socialisation … we don't understand what kind of student is accepted at NVRC, as only [students from] a few regions were selected.' (S, March 2018, social workers)

Informant S mentioned that the regional office sent prospective students without knowing the criteria required by NVRC; according to S, this was due to lack of socialisation. Informant S also mentioned that prospective students could select only a few skill areas to work on. This claim is also supported by the following quote: 'If I don't have a filter from the social service, the assessment doesn't exist.' (IF, March 2018, student)

IF informants explained the lack of filtering conducted by the social services organisations in their area. This claim supports the previous statement that not all regions can carry out socialisation and selection.

Based on our field findings, the reason for this is the limited budget available to NVRC for socialisation activities.

Assessment Phase

The assessment stage at NVRC is carried out to determine the types of skills that are in keeping with the interests and talents of prospective students with disabilities and their degree of accountability. In general, the assessments carried out by NVRC are divided into two phases, namely, skills assessment and physical assessment. As one informant explained:

> 'This assessment looks at the abilities, talents and interests, [including] physical abilities, [to determine] whether he or she (a student sent by the disability facilitator) is suitable or not.' (AMA, March 2018, structural official)

This confirms that the assessment is carried out to determine the students' abilities, talents, interests and physical skills. That explanation is also supported by the following quote:

> 'We read the biodata [of the students] that will enter here, for example [whether their disabilities arose] from congenital disabilities or accidents, [and whether to date] he has studied in school and what skills he learned before.' (EN, March 2018, social workers)

Informant EN explained that, from the biodata submitted to NVRC, the staff can see what skills have already been learned by each prospective student. Regarding physical assessments of prospective NVRC students, Informant EN reports that 'later the assessment team will explain the child's physical potential, health and so on.' (EN, March 2018, social worker)

The activities carried out by NVRC related to the assessment stage can be classified into two types, namely, the choices made by prospective students based on their interest in a particular skill field and the adjustment of the availability of facilities and infrastructure at NVRC. This is explained in the following quote:

> 'This is where you (students) learn what you want first; the first one is the primary choice, and the second is the second choice (skill choice). If [a student] fulfils the requirements of the primary alternative, he is in. But if he does not, you can't help looking at the second option.' (S, March 2018, social worker)

Informant S explained that students who are unable to complete or not suitable for the training they are most interested in can move to their second-choice skill because each student is asked to name their top two choices in the assessment. This is supported by the following quote:

> 'During the evaluation, we (students) were told to choose two, and there was a primary choice [and] a backup option. Because maybe… the disability itself [plays a role], so perhaps there are friends who want to go to automotive, for example, but [due to] the condition of their own body, it is not possible.' (IF, March 2018, student)

As explained earlier, assessment activities are carried out to determine the ability of students so that they can be placed in appropriate skills training. One of the factors that influences this placement is the availability of facilities and infrastructure owned by NVRC, as explained in the following quote:

> 'Yes. There is indeed a quota; there are restrictions. For example, computer [classes have] a maximum of 20 because [more] computer seats are not available.' (S, March 2018, social worker)

Informant S explained that every training area has a capacity limit; this is related to the facilities and equipment owned by NVRC.

Our findings showed that there were obstacles affecting the assessment process. One of these constraints is that the choice of skill field is not based solely on the abilities of students; rather, it can be influenced by internal factors such as limited facilities and infrastructure, as well as on external

factors such as the determination of skills not following the interests of students who register. This is confirmed by the following interview excerpts:

> 'There was an assessment tool: [skills to be learned were chosen] not only according to desire or student requests, but also according to tested ability. There have been children who were interested in design, but did not have ten fingers to type on a computer so [their goals were] adjusted.' M, March 2018, social worker)

Informant M mentioned that, in determining placement in a training field, the assessment is carried out using specific tools and methods so that it is not only based on the wishes of the prospective students themselves. However, a different explanation was given by a student informant:

> 'Our placement is determined by [multiple factors], for example, when I joined the training in Banten, I joined cell phone service programme, [but] when I joined here, I joined metalworking because of my wishes.' (A, March 2018, student)

The results of our interviews reveal that the choice of skills training that each student follows is not based solely on the results of the assessment but is also based on the students' interests or willingness.

Discussion

Butcher (2004) has explained that, in organisational management, several elements are needed to ensure that the services provided by HSO play the most significant role possible. The primary components in service organisations are corporate culture, SOPs, management roles and organisational systems. As a whole, each aspect is interdependent rather than separate from one another. The implementation of SOPs is also closely related to cultural elements, management roles and organisational systems. As the system model, the sub-systems in the organisation interact with one another. Concerning NVRC, any problems related to the implementation of recruitment and assessment will ultimately affect various other things within the organisational system. These problems can be seen in coordination and control efforts, efforts to manage the quality of NVRC students (student acceptance in the world of work) and NVRC efforts to improve the quality of the organisation and of the staff, who often experience workload beyond their competence.

Coordination efforts can be carried out between NVRC and the provincial/district/city social services organisations in terms of recruiting students, yet students from the PwD population must be selected according to the provisions and needs of NVRC. Coordination efforts can also be made with other parties who conduct skills training, especially necessary skills, such as vocational training centres, both public and private. Monitoring activities for recruiting prospective students also play an essential role in recruiting students from qualified PwD circles, starting by providing transparent and sustainable information about the requirements. Furthermore, to produce trained workers who are also PwD, standards regarding the acceptance of prospective students at NVRC must be implemented fully and with integrity; this can be done by controlling and verifying the recommended prospective students from the provincial/district/city social service organisation or training centre.

Considering that the skills training provided at NVRC is at an advanced level, if students who get the skills training follow the requirements and conditions of their accessibility, it will undoubtedly affect the quality of services provided. This will affect the success of NVRC graduates at companies and in the world of work. The distribution of NVRC graduates in the work setting should be based on the skills that have been obtained through training at NVRC. Thus the aim of NVRC to produce qualified and professional workers who are also PwD will be achieved.

To achieve this, NVRC must improve the quality of its organisation by adjusting the rules and policies that are deemed necessary to achieve the organisation's goals. If a regulation or procedure is deemed appropriate, then its proper implementation must be prioritised, and each stage of the process must be properly supervised to ensure that this is the case, from the perspective of the implementation of the

process stages and from that of organisational quality. Of course, this must be supported by the staff associated with the programme.

The staff at NVRC plays an important role in the implementation of the programmes at NVRC. It is natural that NVRC will continue to make efforts to improve the quality of its staff, including social workers, instructors and other workers who carry out the activities and programmes. A prior inventory of needs would be useful to direct NVRC's efforts to improve the quality of its services, by revealing, for example, whether it is necessary to increase the number of workers in a particular field, or simply to increase the level of expertise or skills of the existing workforce. This will ensure that the expected performance of the organisation can run effectively and efficiently so as to produce optimal results.

Conclusion

The recipients of the service programme at NVRC are given skills training in accordance with their various needs and levels of disability. With this skills training, it is expected that the PwD who graduate from NVRC will become more independent, especially in terms of obtaining employment. The benefits of the training are also expected to be felt by their families and even by the surrounding community.

To achieve these objectives NVRC has divided the duties and functions of each profession or its workforce and has arranged every activity in accordance with the SOPs. In reality, however, not all of the SOPs that have been established can always be applied. One example is the requirement that prospective students who are accepted at NVRC must have followed and passed basic level training as evidenced by a certificate. Our field observations have revealed that the social workers and recruitment teams do not always consider these requirements before beginning the recruitment process.

Considering that NVRC is a training centre for PwD that aims to train and guide these individuals by giving them certain skills that will enable them to work in a company or another workplace, prospective students who are to join the skills training programme at NVRC are required to have basic skills obtained through basic training at training facilities or centres, both public and private. After they have these basic skills, they can continue applying the skills they have acquired towards higher skill training at NVRC.

Given the present situation, the researchers suggest the following:

1. Suggestions for Institutions:
    a) NVRC should cooperate with training institutions throughout Indonesia, including institutions run by government ministries, the private sector and skills training institutions (BLK) for the purpose of socialisation and recruitment of prospective students at NVRC. This will ensure that students are accepted only according to NVRC's stated requirements for basic skills that must be possessed by prospective students.
    b) The recruitment and assessment processes should be carried out in accordance with the existing requirements. Each prospective student should have complete and accurate documentation on file, and good communication with the candidate's area of origin is necessary so that all incoming students meet institutional requirements and are in a position to benefit from enrolment.
    c) NVRC should develop quality assurance, infrastructure, technology and supporting training in accordance with the needs of the institution.
    d) NVRC should establish communications with provincial/city/district social service organisations as a means of disseminating information about NVRC. This can be done without NVRC staff visiting each location directly if NVRC staff makes appropriate use of media.
2. Advice on Labour/Teaching
    a) NVRC should increase the number of workers/teaching staff according to the needs of the institution, so that the service activities carried out are provided by people who are truly competent in their fields.

b) Social workers should approach and communicate more effectively with relevant parties at the assessment stage, so that all students who qualify will meet the requirements, in terms of both general requirements and requirements regarding mastery of basic skills. Social workers should also develop methods of fostering a sense of independence and self-confidence among students so that they are better prepared to enter the world of work.

Abstract

This paper examines the relationship between employee performance and the traits of the commitment of workers in faith-based organisations (FBOs). This study used the quantitative method at the national level in two FBOs in Indonesia, and it confirmed the existence of the investigated association. Although the performance of the majority of the respondents in both organisations showed moderate performers, this paper showed that the commitment of workers in FBO is a tremendous potential factor. The respondents indicated their strong commitment to do their tasks, especially the obligation to serve the community at any time and outside their working hours. The readiness to serve the beneficiaries become the potential factors in FBO whether it belonged to the government or the private sector because the supporting system and culture at FBO that support affective dan normative commitment of the workers. These findings are helpful to our understanding of administrative policies implementation in a human service organisation. The practice in a human service organisation, especially FBO, have to make the existence of employees as individuals and as an integral part of the social environment within an organisation.

Keywords: Affective Commitment, Normative Commitment, Faith-Based Organisation, Social Environment

Introduction

Non-government organisations, both faith-based and non-faith-based, are essential contributors to the improving the quality of life in the social service structure in Indonesia (Canda and Furman, 2010; Machdum, Daryanti, Imelda, and Adi, 2015). The existence of faith-based organisations (FBOs) is notable for providing assistance and developing businesses that promote social welfare. The characteristics that distinguish FBO from other organisations include shared values and beliefs that underpin services provided to the community.

In Indonesia, FBOs influence the welfare of the people. One of FBOs is the organisation that manages almsgiving from 88.2% of the country's 240 million people in Indonesia (Khoiron, 2015). The benefit of national *zakat* reached Rp 286 trillion in 2015 (Puskabaznas, 2016). Indonesian people put a lot of effort to manage those tremendous potentials. As an organisation devoted to the service of humanity, an FBO must demonstrate professionalism in executing its duties. Machdum, Daryanti, Imelda, and Adi (2015) state that FBOs evince efforts to professional work as the emergence of *zakat* management institutions that have grown from foundations into companies.

In Indonesia, *zakat* is explicitly managed by *zakat* management organisations (OPZs), which comprise the National Amil Zakat Agency (BAZNAS) and the Amil Zakat Institution (LAZ). BAZNAS is a government organisation formed to administer zakat nationally. On the other hand, LAZ is an institution that aims to collect and to manage *zakat* funds. Whether it is under the auspices

of the government or non-government organisation, OPZ is very important to the social welfare system because of certain unique features that do not exist in non-sectarian social service organisations. Graddy and Ye (in Machdum, 2013) explain that one of the distinctive attributes of FBOs is the elevated level of commitment exhibited by their members to achieve the organisation's vision and mission.

This paper examines the relationship between employee performance and the traits of the commitment of workers at two FBOs in Indonesia: X and Y. Wahyuny (2016) has demonstrated that the two organisations evince very high-efficiency levels. However, our study showed that the performance of the majority of the respondents in both organisations showed moderate performers. We argue that commitment is not enough for formal organisations. Some other factors contribute to the performance of workers: motivation and discipline. Previous studies examined commitment, motivation, and discipline in profit organisation (Chung-Kim 2017; Erasmus and John 2016; Osella and Widger, 2018; Pandya, 2016; Abu-raiya 2015; Aziz and Shofiawati, 2014). Whereas human service organisation is a vital element in a society in delivering welfare services for the existence of "human" as crucial raw material the input, process, and output of an organisation (Hasenfeld, 1983). This paper uncovers what we can learn about workers' performance in FBO and its correlation with commitment, motivation and discipline. We found that commitment is the strong correlation between commitment and performance, especially the commitment to serve the community at any time and outside their working hours. The readiness to serve the beneficiaries become the potential factors in FBO whether it belonged to the government or the private sector because the supporting system and culture at FBO that support affective dan normative commitment of the workers. Motivation and discipline had a weak correlation with performance. However, FBO must pay attention to those factors so that the workers become an integral part of the Human Service Organisation (HSO).

Methods

The present study uses the quantitative approach, and the examination scrutinises the relationship between independent and dependent variables. The type and nature of the study mandated descriptive research. Neuman (2013) explains that descriptive analysis uses survey data collection techniques, in which a researcher defines a research subject in detail, describes the study accurately and elucidates the research results. Descriptive research aims to provide a more comprehensive image of a phenomenon and purposes to explain the mechanism of the investigative process. The independent variables selected for the present study were commitment, motivation, and discipline. Meanwhile, employee performance was the dependent variable. The purpose of this study is to find if there is a correlation between performance and commitment; there is no correlation between performance and motivation; there is no correlation between performance and discipline.

Sample

This research was conducted at OPZ X and OPZ from September 2017 to April 2018. The population for this study comprised all non-managerial OPZ X and OPZ Y employees who had worked at the organisations for at least one year before the survey. The non-managerial staff consisted of employees and the support personnel of the organisations. Based on the criteria of the respondents, the population for the study were about 65 people at OPZ X and 47 people at OPZ Y. The study utilised the total sampling technique that surveyed the full population.

Data Collection Procedure

Data collection technique through the questionnaires administered to the population of respondents. The research questionnaire consists of closed questions. In filling out the survey, respondents were only required to select answers following their opinions and attitudes (Bryman, 2012). A validity test and a reliability analysis were first conducted to assess the research instrument. Validity refers to the degree of accuracy of the measurement instrument for research. According to Bryman (2012),

validity denotes whether the indicators designed to quantify the research concepts can be measured. Also, Bryman (2012) states that reliability alludes to consistency in the size of a concept. The measure of reliability requires three main factors to be possessed: stability, reliability, and consistency. An instrument is said to be good if the test results obtain a minimum measure of 0.70 (Neuman, 2013). The present investigation expected to receive a reliability value above 0.70 alpha.

Data Analysis

Before analysing, it was processed using MS Excel and the Statistical Programme for Social Science Windows version 23. The data analysis encompassed three stages for the present study. First, we assessed the frequency distribution that described the characteristics of the respondents and obtained the profile of respondents consisting of age, gender, education level and years of service. Second, a descriptive analysis was conducted for each variable to define and ascertain the indicators for each variable. Third, we examined a bivariate comprising cross-table and correlation assessments between the independent variables and the dependent variable.

Reliability and Validity

First, we conducted validity and reliability testing on data obtained from the results of the pretest questionnaire. We distributed the pretest questionnaire to prospective respondents. The alpha conbrach reliability test results about OPZ X were 0.768. The OPZ Y alpha conbrach reliability test results were 0.852. The alpha coefficients obtained for this study (0.768 and 0.852) demonstrated the acceptability of the research instrument because the measures were more than 0.70 (Neuman, 2013). The research instruments were thus declared reliable.

Results and Discussion

The results of the analysis of performance proved that the majority of the respondents were moderate performers. The results described above evidenced moderate performance outcomes by employees at both study sites. However, as FBOs, both X and Y displayed similarities in the aspect of commitment. Thus, even though the two organisations evince differences in nuances because of discrete funding sources, FBOs both recorded the highest scores on the item "ready to serve the community at any time and outside their working hours". The high scores of commitment correlate with the characteristics of FBOs. Graddy and Ye (in Machdum, 2013) mentioned that one of the distinctive attributes of FBOs is the elevated level of commitment exhibited by their members to achieve the organisation's vision and mission. However, our study showed that both organizations had a moderate performance. As a professional organisation, FBOs can not only rely on commitment as single factors. Organisations need to support the workers so that they can achieve FBOs' goals.

Previous studies have examined aspects of commitment, motivation, discipline These and the correlation with the organisation's culture and leadership style. However, the majority of such research is still related to the management of a general organisation. Study in human service organisation still emphasises motivation, values, discipline, and the correlation with the performance of volunteers. Whereas, the workers at Human Service Organisation are not only volunteers (Chung-Kim 2017; Erasmus and John 2016; Osella and Widger, 2018; Pandya 2016; Abu-raiya 2015; Aziz and Shofiawati, 2014).

Fahrudin and Adi, Yusuf and Husmiati, Witono and Toton, and Mudzakir (2016) professional workers, including social workers, played essential roles in FBOs. They do professionals works that maintain some field to use zakat funding properly. The professionals' help that become part of social services in FBOs is social rehabilitation, empowerment, protection, and insurance. Even Hall and Midgley (2012, p. 227) described *zakat* as one of the essential subjects in the development of new human service programs. As a potential organisation in the welfare system, development of professional work at FBO became a crucial matter.

Strong Commitment: Why Faith Matters?

About comparability, or the attitude of evaluating coworkers, 74.5% of OPZ Y employees evidenced a moderate mindset, 4.3% were low in their approach, and 21.3% were highly positive in their relative outlook. The analysis of the questionnaire items also evidenced the existence of a high level of indirect competition in the organisation. Some employees considered their coworkers to be their competitors, but others thought of coworkers as work partners. The comparatives and competencies at OPZ Y evidence the desire for employees to advance over each other in their careers and job designations.

The results of the analysis revealed that 93.8% of OPZ X employees are entirely committed to the organisation. The commitment variable consisted of three indicators in the present study: normative commitment, affective commitment, and continuance commitment. We also assessed descriptive percentages for each indicator. 1.5% of OPZ X employees demonstrated a low commitment for the scrutiny of commitment indicators and 4.6% exhibited high commitment.

A similar analysis with the same parameters as described above for the OPZ X employees, the population of the OPZ Y were non-managerial workers and support staff. At OPZ Y, 78.7% (37 respondents) of employees were wholly committed to the organisation, and 21.3% (10 respondents) revealed high commitment (Graphic 1).

Graphics 1: Commitment Variable Description at OPZ Y

The analysis of commitment indicators also indicated this evaluation. The percentage of descriptive normative commitment evidenced that 66% of OPZ Y employees showed low commitment awareness and 34% displayed high commitment awareness. From the questionnaire items about normative commitment, the highest score was at the question "ready to serve the community at any time and outside their working hours ". The percentage of affective commitment proved that 70.2% of OPZ Y employees presented intermediate levels of commitment attachments, and 29.2% revealed high commitment commitments. The indicator of affective commitment proved that employees felt that they belonged to their organisation and that they had begun to feel an emotional attachment to their employer. The continuance commitment indicator showed that 83% of employees were moderately committed to the organisation, and 17% of OPZ Y employees exhibited a high commitment to the organisation. OPZ Y employees displayed moderate to high levels of loyalty to the organisation and thus found it difficult to leave their organisation (Graphic 2).

Graphics 2: ***Continuance Commitment Indicator Description at OPZ Y***

The high scores of both organisations in commitment variables are similar to Graddy and Ye's arguments about a characteristic of FBOs (in Machdum, 2013). The elements of faith and religion exert significant influence on the development of social welfare efforts to provide social services within a community. Adi (2013) asserts that religion is one of the drivers of performance in carrying out such community activities. In other words, the intrinsic motivation of an FBO can encourage the performance of its employees. Canda and Furman (2010) and Machdum (2013) also mentioned that the spiritual aspect of the social intervention in soybeans is significant because this religious feature accords individuals of more considerable influence in the control of human behaviour. For those reasons, FBOs have become a potential organisation in the welfare system. The workers automatically get the affective and normative commitment to work at FBO, whether it belonged to the government or the private sector.

Affective Commitment: working "from the heart."

The employees of both FBOs were also able to display optimal work quality and could be held responsible for the work they were asked to accomplish. Besides, employees were able to achieve the quantity of work and to evidence it by the number of tasks or volume of work performed per day or week. The employees of both organisations completed their assignments immediately and without delay.

Affective commitment pertains to the bond that involves the emotional feelings of employees towards their organisation. Employees with affective commitment feel a sense of belonging in the organisation and begin to forge an emotional attachment to their work environment. 80% of OPZ X employees who registered an intermediate level of commitment attachment reported the highest percentage of affective commitment, 6.2% were computed to show low commitment attachment, and 13.8% displayed high commitment attachment.

Machdum, Daryani, Imeda, and Adi (2015) also argued that FBOs evince efforts to professional work as the emergence of *zakat* management institutions that have grown from foundations into companies. Even FBOs become a proprietary organisation, spiritual aspect as a basic foundation in FBOs still existed. Similar to OPZ X and Y. Individually, the workers at OPZ X and Y had mental basic to work and use "the heart" in delivering social services for the needy people.

Moral obligation to serve the beneficiaries

Normative commitment is an awareness that work is part of personal responsibility. The highest percentage of normative commitment was shown by 98.5% (65 respondents) of OPZ X employees who demonstrated a moderate level of commitment awareness and only 1.5% (1 respondent) of the employees were found to exhibit a low commitment awareness towards the organisation and its work. From the questionnaire items regarding normative commitment, the highest score was at the question of "ready to serve the community at any time and outside their working hours" (Graphic 3).

Graphic 3: Normative Commitment Indicator Description at OPZ X

The readiness of the worker to help others any time and outside their working hours became the uniqueness of FBO. This is potential for developing administration in a human service organisation (HSO). Moreover, HSO is not similar to the other types of general organisation. HSO use different theory, technique and principle for managing their unique raw material: the human being. Moreover, Pujileksono, Abdurrahman, Yuliani, and Wuryanti (2018, p. 127) argued that the domain of human service organisation management, especially in Indonesia, is still limited. In contrast, the human service organisation is a vital element in a society in delivering welfare services. As mentioned previously, the context of “human” is crucial raw material the input, process, and output of an organisation (Hasenfeld, 1983).

Independent workers as of an individual: why motivation and discipline also matter?

Not similar to affective and moral commitment, continuance commitment at both organisation showed a different result. Normative continuity relates to the awareness that the organisation is an aspect of one’s life. 90.8% of OPZ X employees who recorded a moderate commitment awareness showed the highest percentage on normative continuance, 1.5% showed low commitment awareness, and 7.7% displayed high commitment awareness. OPZ X employees were already aware of the importance of the organisation and felt as if they belonged to the organisation. OPZ X employees also found it is hard to quit the organisation because of their moderate to high levels of loyalty to their employer (Table 1).

Table 1: Continuance Commitment Indicator Description at OPZ X

Continuance Commitment			
		Frequency	Percentage (%)
Valid	Low commitment awareness	1	1.5
	Moderate commitment awareness	59	90.8
	High commitment awareness	5	7.7
	Total	65	100.0

The organisational structure and environment and to varied aspects of the psychology of employees who form a significant part of an FBO (Hasenfeld, 1983; Jones and May, 1995; Skidmore, 1995). Thus other factors besides commitment must also be evaluated. Commitment is not always the primary fuel encouraging employees towards high performance, and other aspects require attention. Motivation is one such factor. According to Wibowo (2007), commitment occurs on its own in employees who are already highly motivated as workers become aware of the importance of their optimal performance for the progress of the organisation.

Motivation is the most crucial element in social services (Skidmore, 1995, p.194) Concerning social work administration; moreover, available resources are more critical directly for the service delivery process of FBOs.

Bauer and Erdogan (2012) define motivation as the desire of a person to achieve specific goals or levels of performance in an organisation. Motivation directs the expenditure of best efforts by employees and aligns the conduct of members to the organisational goals.

Many organisational features can motivate employees to execute their work optimally, and one of them is existence. The results of the present investigation in both organisations reveal that employees can obtain conducive employee relationships because the indicators of work behaviour and attitudes show that most employees have reasonably polite work behaviour. Primarily, the employees of both organisations consider their coworkers to be partners rather than competitors and rarely enter into conflict with colleagues. This work climate was an effort in developing social work administration within the scope of the organisation. In promoting social work administration, social workers must understand that an FBO is different from other enterprises as it is fundamentally a human service organisation.

In contrast to organisations in general, the raw material of an FBO is the human element (Hasenfeld, 1983, p. 4). The individual needs of employees in FBOs are indeed a primary concern in the development of social work administration (Jones and May, 1995, p. 20-21). Thus, whatever the form of the organisation, if it is related to social services, social workers must attend to human factors within the organisation (Skidmore, 1995).

The role of superiors is also critical because they are evidenced to consider the advice of employees and to accept the aspirational needs of their workers. Besides, employees have begun to get direction from the organisational leadership concerning their work. Leadership skills in developing social work administration are related to more than aspects such as persistence, time management, compromise,

and creativity. In FBOs, the quality of leadership also requires soft skills. Thus, employees must be made to feel that they have the freedom to express themselves within the framework of the vision and mission of the organisation (Skidmore, 1995, p. 154-156).

The findings evidence the implementation of the basic principles of social work administration (Skidmore, 1995, p. 26-28) in both FBOs. The intended values of democratic involvement in the formulation of agency policies and procedures and observed open communication.

Other aspects related to motivation require attention in both organisations. Respondents at both sites stated that their remunerations were not commensurate with their workloads. Thus, improvements in the aspects of discipline in both FBOs could be from salaries paid. Choirudin (2015) asserts that the level of discipline is a factor that influences employee performance. Discipline is essential to the shaping of employees who are orderly and who obey organisational rules. Besides, the discipline also promotes corporate harmony and can help to leverage the effectiveness of the organisation in the future.

The present investigation demonstrated that 90.8% of the respondents who were OPZ X employees showed moderate motivation characteristics, 1.5% registered low motivation, and 7.7% were found to be highly motivated. The analysis of motivation indicators also clarified these results. In this study, the commitment variable comprised the three indicators of existence, relatedness, and growth. Presence denotes the meeting of the physiological and safety needs of employees. The highest percentage on the existence indicator evidenced that the organisations have fulfilled 92.3% of the physiological needs and security needs of OPZ X employees. The fulfilment of physiological needs and security needs are from collateral funds such as loans, pensions, work accident reserves and death resources available from organisations. However, the OPZ X employees stated that the salaries they received did not match their workloads.

Relatedness indicates the fulfilment of social and interpersonal needs. To determine the magnitude of the relatedness indicators, knowing the extent of the satisfaction of a person's social needs is essential. The highest percentage of relatedness indicators demonstrated that organisation sufficiently fulfilled 72.3% of the social needs of the OPZ X employees. The social needs that received the highest score also indicated that a strong sense of brotherhood (*ukhuwah*). The organisation already established fellowship among employees.

Growth symbolises the fulfilment of self-actualisation needs at work. At the highest count, the growth indicator proved that 80% of the self-actualisation needs of OPZ X employees were appropriately satisfied. Employees felt that they were able to initiate new ideas at work, and they accomplished assignments without delay.

In this study, the discipline variable consisted of four indicators: discipline quality, the quantity of discipline, compensation, and conservation. The results of the analysis divulged that 87.7% of the OPZ X respondents were quite disciplined, 1.5 were undisciplined, and 10.8% were very disciplined. The study of disciplinary indicators elucidated through this outcome.

The quality of discipline is related to the compliance of employees with organisational orders. The highest percentage on the discipline quality indicator evidenced that 78.5% of OPZ X employees were entirely compliant with organisational regulations. Employees were punctual and registered their presence. However, employees rarely attended the morning prayer activities held by the organisation. The two locations inhabited by OPZ X attributed to the absence of employees during prayers: the employees who worked at areas that were not at the places where the implementation of morning prayer activities tended not to be present because of the distance between the offices.
The volume of output and contribution measures the quantity of discipline. The amount of discipline is satisfied when employees can contribute to the organisation through acts such as offering opinions at organisational meetings. Besides, the measure also encompasses the leadership's consideration of suggestions received from employees. The highest percentage on this discipline quantity indicator

revealed sufficiency of the quantity of discipline at 83.1%. Discipline was low for 1.5%, and 15.4% showed high levels of discipline quantity.
