Compensation denotes suggestions, directions and improvement exchanged between the leadership and members of the organisation. The highest percentage on the compensation indicator shows that 93.8% of OPZ X employees displayed moderate compensation and 6.2% showed high compensation, in the sense that employees had begun to get directions from the leadership of the organisation regarding their work. Conservation refers to respect for the rules and regulations of the organisation. The highest percentage of conservation indicators showed that 53.8% of OPZ X employees were entirely compliant, and 46.2% of the employees were not compliant with organisational regulations. Employees showed respect for the organisation. They sought permission from the leadership before late arrival. However, OPZ employees were not found to be compliant with regulations as sick employees rarely tendered illness certificates from doctors.

In this study, the performance variable consisted of four indicators: work quality, the quantity of work, attribution and competence and comparability. The investigation disclosed that 93.8% of the OPZ X respondents presented moderate performance characteristics, and 6.2% were high performing. The analysis of performance indicators also highlighted this assessment.

From the quality and quantity of work, we calculated the work results. Based on the work quality questionnaire items, employees were able to display optimal work quality. Employees were also found to be responsible for their work. The work quality indicator showed that 92.3% of OPZ X employees delivered moderate work results, and 7.7% were high performing. From the work quantity questionnaire item, employees were able to display work quantity based on the number or volume of work per day or per week. The employees had sufficient quality and quantity.

Work behaviour consisted of two indicators: conduct while executing work and attitudes towards coworkers. The work behaviour indicator evidenced that 89.2% of OPZ X employees showed reasonably polite work behaviour and 10.8% of OPZ X employees were very courteous at work. The questionnaire items regarding attitudes towards coworkers proved that employees were willing to help their coworkers with work-related problems. The attribution and competency indicator revealed that 81.5% of OPZ X employee respondents owned the characteristics of attribution and competency and 18.5% presented with high attribution and competency characteristics. Attribution and competence involve knowledge and planning. In the sub-indicator of knowledge, employees master general knowledge (theory) that supports the implementation of their work.

About the planning and presentation sub-indicator, an employee was expected to devise a plan to accomplish all tasks and to create a presentation target. On the indicator of comparative attitude, 96.9% of employees were adjudged to have a moderate mindset, 1.5% were evaluated low, and 1.5% were assessed as high in their relative percentage of approach. The conclusion is the employees valued their coworkers to be partners rather than competitors in terms of their work. The research also found that employees rarely entered into conflict situations with their coworkers.

Table 2: Attitude Toward The Colleagues at OPZ X

Comparative			
		Frequency	Percentage (%)
Valid	Low Comparative	1	1.5
	Moderate Comparative	63	96.9
	High Comparative	1	1.5
	Total	65	100.0

The results also divulged that 85.11% of the OPZ Y respondents presented the characteristics of moderate motivation, 2.1% showed low motivation and 12.8% were highly motivated. The analysis of motivation indicators also verified this outcome. Existence indicators proved organisation fulfilled 70.2% of the physiological and security needs of OPZ Y employees. Nonetheless, as with the OPZ X, OPZ Y employees also stated that their salaries were not commensurate with their workloads. The relatedness indicator shows that the organisation gave satisfaction to 72.3% of the social needs of OPZ Y employees adequately and also fulfilled 27.7% of their social needs. As with their OPZ X counterparts, the highest social need scores also proved the existence of a strong brotherhood (*ukhuwah*) among employees. The growth indicator evidenced that organisation adequately fulfilled 87.3% of the self-actualisation needs of OPZ Y employees.

The investigation further disclosed that 87.2% of OPZ Y's respondents are quite disciplined, and 12.8% are very disciplined. The analysis of disciplinary indicators also corroborated this result. The disciplinary quality indicator displayed that 70.2% of OPZ Y's employees were entirely compliant with organisational regulations. Employees came to work on time and registered their presence. Employees also attended the morning prayer activities held regularly by their organisation. The discipline quantity indicator showed sufficiency at 78.7%. The quantity of discipline was found to be low, with 4.3% of the respondents, and 17% revealed an elevated amount of discipline.

The compensation indicator exhibited moderate results for 87.2% of OPZ Y employees and high outcomes for 12.8% of the respondents. Meanwhile, conservation indicators proved that 66% of OPZ Y employees were entirely compliant with organisational regulations, and 34% were compliant. Employees showed respect for the organisation and asked for permission from the leadership for delays in attendance. When sick, employees were required to provide a certificate from a doctor.

Conclusion

There is a correlation between employee performance and the traits of the commitment of workers at two FBOs in Indonesia: X and Y. However, our study showed that the performance of the majority of the respondents in both organisations showed average scores. Based on the findings, we claim that commitment is not enough for formal organisations. Motivation and discipline contributed to the performance of the workers, whether it belonged to the government or the private sector. Emotional and psychological aspect for workers as an individual is a crucial matter for the existence of “human” as essential raw material, the input, process, and output of an organisation. To get professional performance, FBOs need to build supporting system and culture. Organisations system must appreciate the existence of factors that influence employee performance in addition to commitment, motivation, and discipline. Other attributes that can affect employee performance include job satisfaction, leadership styles, organisational culture, and corporate environment. In the future, the employees' performance will continue to improve through organisations attending to these factors.

Abstract

This study estimates the effect of dividends tax rate reduction on income shifting behavior of top-bracket taxpayers in Indonesia by natural experiment. Income shifting behavior is measured by the Directorate General of Tax (DGT) data in the period of tax rate reduction (2008-2012). Descriptive statistics and dynamic panel data analysis show that the decrease of dividend tax rate causes income shifting to dividend income on top bracket personal taxpayers. Based on descriptive analysis, income shifting behavior occurs in quartile one and quartile four of the top bracket individual taxpayers with an average income of IDR 390 and IDR 10 billion in 2008.

Keywords: Tax rate, income shifting, tax on dividend

Introduction

In 2008, the Indonesian Personal Income Tax (PIT) rate was changed by law number 36/2008 that amended law Number 7 of 1983. This law that took effect on January 1st, 2009, changed the tax treatment for dividends. As a result, individuals that receive dividend income pay lower income tax after the enactment of the law. This dividend tax cut aimed to increase investment by lowering the cost of capital. Based on Kartikasari (2013), simplification and dividend tax cuts in 2009 have a positive impact on individual shareholdings. Single tariffs on dividends also increase competitiveness in tax competition (Pirttila & Selin, 2011).

Although simplification and dividend tax cuts have a positive effect, they also create incentives for tax avoidance through income shifting. Income shifting is the process of income transfer between periods, type of income, and tax bracket to reduce total tax payment (Pirtilla & Selin, 2011). Income shifting is a form of legal tax avoidance and does not have a direct impact on the actual income earned. Income shifting has some negative impacts on the welfare of society. Income shifting increases the tax system's cost efficiency due to the transition from the non-dividend income tax base to the dividend tax base. Income shifting also reduces the progressiveness of tax rates, thus increasing the wealth gap (Pirtilla & Selin, 2011). Income shifting between tax bases also lowers tax revenues as well as distorts aggregate statistics (Slemrod & Gordon, 2000; Slemrod J., 1995).

Based on empirical research, income shifting occurs mostly among self-employed and high-income individuals. Ramonov (2006) suggests that income shifting between private and corporate tax bases has occurred in Israel. Gordon and Slemrod (2000) and Devereux et al. (2014) obtained similar results in the US and UK, while Pirtilla and Sellin (2011) showed an increase in the share of capital income among business owners after-tax rate reduction. Although income shifting is legal and financially rewarding, some eligible individuals still do not do it. Empirical research indicates a difference in individual response to changes in tax policy. For example, some eligible individuals do not take welfare

benefits (Chetty et al., 2013). Based on Chetty et al. (2013), people do not realize capital gains at the most optimal time. Stephens and Ward-Batts (2004) show that there are eligible individuals who do not reallocate asset ownership for tax savings. There are several explanations for various responses to income shifting opportunities. Based on Further et al. (2016), the complexity of the confusing tax system has led to an unintentional response. Meanwhile, Chetty et al. (2011) indicate that response occurs if the tariff changes are significant enough.

The Indonesian Tax Reform in 2008 led to a difference in tax rates between non-dividend income and dividends, especially in high-income groups. The marginal tax rate on the non-dividend income of top bracket personal taxpayers is three times the marginal tax rate on dividends. Theoretically, the high rate difference encourages profit shifting from non-final income to dividends. Nevertheless, there is no empirical research that proves income shifting behavior as a result of the Indonesian tax rate reform in 2008.

This study investigates the existence of income shifting on the top bracket individual taxpayers because of the difference in tax rates between dividends and other income. This research is the first research on income shifting behavior that uses micro tax data in Indonesia. Previous research has mostly been carried out in European and American countries, which have different taxation systems. According to Saez, Slemrod, & Giertz (2012), system taxes and responses to changes in tax rates are closely related.

Literature Review

New Tax Responsiveness Literature

Economists, at first, analyzed the impact of tax rate changes on labor supply reflected by hours worked. However, empirical research indicates that taxes have a minimal and even negative effect on working hours except for married women (Pencavel, 1986; Heckman, 1993). This result is contrary to the hypothesis that taxes decrease the job's incentives. In 1995, Feldstein measured responses to changes in tax rates by using taxable income. The Feldstein (1995) study became the beginning of The New Tax Responsiveness (NTR) literature.

Feldstein (1995) used panel data to analyze the response of tax rate changes in 1986 in the United States. The results showed an enormous Elasticity of Taxable Income, ranging from 1-3. The study conducted after Feldstein (1995) tried to improve the estimation method by paying more attention to the instruments of the net-of-tax rate as well as the non-tax factors affecting the income distribution. With these modifications, the results showed a much lower elasticity estimate than Feldstein's elasticity (1995). Based on some empirical studies, ETI ranges from 0 to 0.6. Based on Gruber and Saez (2002), the magnitude of ETI is 0.18 for the middle-income group and 0.57 for the high-income group. Further research was conducted to assess the reliability and consistency of ETIs with various tariff policies and net-of-tax rate instruments.

Using Swedish data, Blomquist and Selin (2010) estimated the size of the ETI in the range of 0.2 in males and 1 in females. Also, there is a positive elasticity for wage rate as well as significant income effects. Kleven and Schultz (2014) use panel data on some tax rate changes in Denmark. The result indicates that the ETI is 0.3. Chetty (2011) conducted the same research in Denmark and produced a very small ETI. Aarbu and Thorseen's (2001) studies in Norway show an insignificant ETI. According to Poterba (2007), the tax rate affects the taxable income of individual taxpayers through two channels. First, changes in tax rates affect the behavior of individuals in generating revenue or also called the labor supply effect (Doerrenberg & Duncan, 2014). For example, an increase in tax rate leads to a reduction in working hours. Thus, the increase in tax rates will lower taxable income.

The second channel is the behavior in reporting taxes. If there is an increase in tax rates, there will be a tendency to lower the reported earnings. For example, an increase in payroll tax rates causes employees to choose income benefits, such as health insurance, rather than cash compensation. This behavior lowers taxable income and consequently increases other compensation. Another example is the behavior of time-shifting income recognition through deferred income, thus decreasing the current

reported income. Although taxpayers have deferred income in the future, current revenue will not reflect that information.

Tax reporting behavior consists of avoidance and evasion (Slemrod & Yitzhaki, 1996). Tax reporting behavior is classified as tax avoidance if done legally and vice versa. High-income responses to changes in tax rates are higher than in other income groups (Feldstein, 1995). This difference is because wealthy individuals have greater control over income and deductions (Poterba, 2007). The high-income response to tax rate changes comes from three channels: labor supply, tax avoidance, and compensation bargaining (Piketty, Saez, & Stantcheva, 2014).

An increase in tax revenues due to tax rate cuts in high-income individuals, initially, are considered to be labor supply responses (Feldstein, 1995; Lindsay, 1987). Through the labor supply channel, tax rate cuts will stimulate the economic activities of the affluent group. Financial incentives will increase the intensity of work, entrepreneurship, and investment while increasing taxable income and tax revenue. However, Slemrod (1995) showed that response from the high-income group is dominated by tax avoidance behavior, including income shifting between tax bases and periods.

Responses from the high earning group to changes in tax rates can come from the compensation bargaining channel (Piketty, Saez, & Stantcheva, 2014). There is a correlation between tax rates and high-income behavior in demanding compensation. If the marginal tax rate is high enough, then the utility of earning high income among the rich will decline. Thus the demand for high payment will also decrease and vice versa. Through these three channels, theoretically, a decrease in the marginal tax rate will lead to an increase in the taxable income of the rich.

Income Shifting

Stiglitz (1985) classify the income tax avoidance in 3 (three) basic principles: suspension of tax payments in the lower tax rate period, transfer of tax burdens to tax agents at lower rates; as well as income reclassification to get lower tax rates. Tax avoidance occurs because of differences in tax rates across periods, individuals, and income classifications. Tax avoidance is often a combination of these three principles.

Income shifting is the most relevant form of tax avoidance for business owners and high-income groups (Slemrod & Gillitzer, Tax Systems, 2014). Income shifting is also suspected to be the primary cause of the high elasticity of taxable income among the top income (Gordon & Slemrod, 2000). The difference in tax rates between cash wages and other types of income drives high-income earners to choose non-cash fees, while workers outside the high-income group do not have that option. If the tax consideration is excluded, the cash wage income is more profitable, and the lower-income group is in the corner solution. Thus low- income group behavior is less responsive to changes in tax rates. Conversely, the high-income group would be susceptible to the tax rate of income classification (Gordon & Slemrod, 2000).

The distinction between real responses and income-shifting is crucial because it affects the accuracy of policy recommendations (Slemrod J. 1995, Piketty, Saez, & Stantcheva, 2014). The existence of income-shifting between earning bases can lead to inaccurate deadweight loss calculation since the decrease in taxable income due to income-shifting is not entirely a deadweight loss if the income transferred will also be taxed (Saez E., 2004). Thus, the deadweight loss due to income-shifting is smaller than the real response (Chetty R., 2009). If the income-shifting response is not separated from the actual response, then the optimal tax rate determination is less accurate, as well as the strategy in increasing the income tax. Information on the magnitude of income shifting responses is the key answer to the debate over effective tax revenue policies, closing income-shifting gaps, or tax rate cuts.

Three conditions must be met before a person decides to make income shifting, i.e., incentives, access, and awareness (Alstadsaeter & Jacob, 2017). A person does tax avoidance if the expected benefit exceeds the cost incurred for tax avoidance. Benefits derived from tax avoidance include the expected disposable income increase due to a reduction in tax payments. Meanwhile, the cost of tax avoidance

includes monetary expenditure such as the cost of the consultant and non-monetary expenses such as tax morale (Andreoni, Erard, & Feinstein, 1998; Fortin, Lacroix, & Villeal, 2007). In contrast to tax evasion, tax avoidance is influenced by tax rates since there is no punishment for "unsuccessful avoidance."

Another thing required by individuals who want to do tax avoidance is access to perform such activities. For example, someone must be an entrepreneur to practice tax avoidance (Pirtilla & Selin, 2011; Kleven, Knudsen, Kreiner, & Saez, 2011) or have stock options (Goolsbee A., 2000). The opportunity to do tax avoidance is reserved. For example, to make income shifting from labor income into capital income, a person must have the ability to get paid salary in the form of capital income or to negotiate so.

In addition to incentives and access to tax avoidance, another requirement that must be met is the awareness of the tax rules. The tax-consciousness level is influenced by information about the tax system and the ability of taxpayers to process information (Chetty, Looney, & Kroft, 2009). Consequently, the taxpayer may not be aware of any incentives to undertake a strategy to minimize taxes.

Dual Income Taxation

Dual Income Taxation is a tax scheme that divides revenue into income from assets and labor income and classifies it as a different tax base. Dual income Taxation based on various economic activities (business, self-employment, employment, land rent) is separated into capital income and labor income. Capital income includes dividends, interest income, rent, and capital gains from real capital and property. Employment income consists of wages and salaries, benefits in kind, pension payments, and social security transfers. The capital income is subject to a flat tax, whereas labor income is subject to progressive tax rates.

Taxes on capital earnings made under the flat withholding tax mechanism at low rates will significantly reduce tax compliance and collection costs. The flat capital tax also reduces the difference in tax rate between domestic tax and source tax in foreign countries, thus preventing the occurrence of capital flight.

Research on dual-income taxation reform in the Nordic countries shows incentives for small business owners to convert labor income into capital income (Sorensen, 1998; Lindhe, Sodersten, & Oberg, 2004). Fjaerli and Lund (2001) research indicate that taxpayer's decision to choose income in the form of salary or dividend in the double taxation system in Norway is determined by tax and non-tax factor, such as access to social benefits.

Methodology

Model

To measure the income shifting response, we assume that there are two personal income tax bases, namely, non-dividend z_{ND} and dividend z_D. So, the total taxable income (z_Y) can be formulated as $z_Y = z_{ND} + z_D$. The non-dividend tax rate is τ_{ND}, whereas the dividend tax rate is τ_D. Assume $\tau_{ND} > \tau_D$, and both are exogenous variables.

The income owner is assumed to have the opportunity to make income-shifting but not changing the amount of taxable income. If the size of income transferred from non-dividend to dividend is α, the budget constraint can be formulated as follows:

$$c = (1 - \tau_{ND})(1 - \alpha)z_Y + (1 - \tau_D)\alpha z_Y + R \quad (1)$$

In equation (1), $(1-\alpha)z_Y = z_{ND}$ is taxable income on non-dividend, $\alpha z_Y = z_D$ is taxable income on dividends. The utility function of the income owner is formulated as follows:

$$\mu_i(c, z_Y, \alpha) = c - \theta(z_Y) - \phi_i(\alpha) \quad (2)$$

In equation (2), $\theta(z_Y)$ is the cost incurred to obtain income while $\phi_i(\alpha)$ is the cost incurred to move income from salary to dividend. Following the model used by Piketty et al. (2014), to simplify the model, it is assumed that both cost functions are separate convex functions. The first-order condition to maximize utility is as follows:

$$(1-\tau_{ND})(1-\alpha) + (1-\tau_D)\alpha = \phi_i'(\alpha) \quad (3)$$

$$(\tau_{ND} - \tau_D)z_Y = \phi_i'(\alpha) \quad (4)$$

Based on equation (3), if the amount of income-shifting α is fixed, then total taxable income is the increasing function of the net tax rate. According to equation (4), if the total taxable income z_Y is fixed, then income-shifting is an increasing function of the difference in the tax rate $(\tau_{ND} - \tau_D)$. Based on theory and previous empirical research, the hypothesis proposed in this study is that the magnitude difference of net of the marginal tax rate of dividend income and non-dividend income will have a negative impact on non-dividend income.

The data is collected from the Individual Tax Return of top-bracket taxpayers from 2007 to 2012. Based on tax regulation in 2007, the top bracket taxpayer is an individual taxpayer who reported income exceeds 200 million rupiahs per year. The data covers all critical information needed in this research, such as taxable income and composition and taxpayers' demographic data including age, assets, debt, residence, job classification, and the number of dependents. With this information, the author can calculate the amount of marginal tax rate and the average tax rate.

Empirical Specification

The empirical method in this study is based on Saez, Slemrod, and Giertz (2012) and Harju and Matikka's (2016) models. The empirical model used is as follows:

$$\log y_{ti} = \alpha_0 + \alpha_1 \log(\mathrm{NMTR_D} - \mathrm{NMTR}) + \alpha_2 \log \mathrm{NMTR_{ti}} + \alpha_3 \log y_{t-1i} + \alpha_4 \mathrm{mariage} + \alpha_5 \mathrm{joint} + \alpha_6 \mathrm{kids} + \alpha_7 \mathrm{age} + \alpha_8 \mathrm{age2} + \alpha_9 \log \mathrm{net\ asset}_{t-1i} + \alpha_{10} \log non - \mathrm{dividend}_{t-1i} + \Delta\varepsilon_{ti}.$$

Where:

y_{ti}	= non-dividends income
$\mathrm{NMTR_{ti}}$	= net marginal tax rate of y_{ti}
$\mathrm{NMTR} - \mathrm{NMTR_D}$	= net marginal tax rate of y_{ti} minus net marginal tax rate dividend \ income
marriage	= dummy marital status (0 = unmarried; 1 = married)
joint	= dummy spouse status (0 = partner not working; 1 = working partner)
kids	= total dependent in tax return
age	= age of
age2	= age square
$\log \mathrm{net\ asset}_{t-1i}$	= natural logarithmic of the net asset in year $t-1$
$\log non - \mathrm{dividend}_{t-1i}$	= natural logarithmic of non-dividend income in the previous year
dummy quartile	= quartile groups of non-final income

The estimation method used is the system and difference generalized method of moments (GMM) estimators developed by Holtz-Eakin et al. (1988), Arellano and Bond (1991), Arellano and Bover (1995) and Blundell and Bond (1998). This method is used for several reasons, including:

- Non-final taxable income is a dependent variable that is affected by the same variable in the past.
- There are arbitrarily distributed fixed individual effects, so the size of the dependent variable changes more quickly in specific individuals than in the other individuals
- Some regressors are endogenous
- A small number of years within a period

Results and Analysis

Descriptive Analysis

Average gross income or total dividend and non-dividend income in 2007-2012 had positive growth except in 2010. The average growth rate of gross income was 26%, with the highest growth being 72% in 2009. The amount of gross income growth comes from dividend growth of 66% and non-dividend growth of 11%. The highest growth of dividends and non-dividends was 214% and 26%, which occurred in 2009.

Figure 1: Average Income

In 2009 there was also a growing number of taxpayers who had dividend income. In 2008 the number of taxpayers who had dividend income amounted to 140 taxpayers. In 2009, the number of taxpayers who had dividend income rose to 287 taxpayers. The proportion of the number of taxpayers who have dividend income from each quartile can be seen in Chart 2. In 2011 there was a change in the Information System of the Directorate General of Taxation, which caused fewer data available than other years. The decline and simplification of the dividend tax rate led to an increase in the number of taxpayers in 2009.

Figure 2: Number of Taxpayers who had Dividend Income

The growth of the non-dividend income of taxpayers who had dividends in the quartile one and four is more significant than the growth of the non-dividend income of taxpayers who did not have a dividend. In contrast, in quartile 2 (two) and 3 (three), the growth of the non-dividend income of taxpayers who had dividends was smaller. These different behaviors ware indicative of income shifting.

Figure 3: Average Non-Dividend Income (IDR in millions)

The taxpayer in quartile 1 (one) had an average non-dividend income of 360,000,000 rupiahs up to 400,000,000 rupiahs. This group had an incentive to keep a non-dividend income below 500,000,000 rupiahs to get a lower tax rate. While the taxpayer in quartile 4 (four) had the highest average non-dividend income, thus the incentive to make income shifting is also the greatest.

Estimation Result

Indication of income shifting in this research is measured by the relationship between the net marginal tax rate (NMTR) and non-dividend income reported by personal taxpayers. Net of the marginal tax rate is one minus the marginal tax rate. Identification of income shifting behavior using taxable income proxies and NMTR is in accordance with previous empirical studies (Harju & Matikka, 2016).

The result of model estimation using panel data in 2007-2012 is presented in Table 2. The estimation used the generalized method of moments (GMM) estimators developed by Holtz-Eakin et al. (1988), Arellano and Bond (1991), Arellano and Bover (1995) and Blundell and Bond (1998). The estimation method is designed for situations with small T, large N, as happened to be in this research.

Table 1: Estimation Result

	Model (1)	Model (2)	Model (3)
Lagged Log non-dividend income	0.973***	0.918***	0.755***
	(0.000)	(0.000)	(0.000)
NMTR Dividend - NMTR	-0.659*	-0.765*	-0.245
	(0.093)	(0.086)	(0.595)
NMTR	1.120	2.086	0.894
	(0.294)	(0.178)	(0.597)
Log Dividend		0.019	0.005
		(0.377)	(0.803)
Dummy Quartile			
Quartile 2 (two)		-0.046	-0.020
		(0.828)	(0.924)
Quartile 3 (three)		0.257	0.390*
		(0.259)	(0.056)
Quartile 4 (four)		0.237	0.606*
		(0.383)	(0.097)
Age			0.1***
			(0.007)
Age2			-0.0***
			(0.003)
Log Net Asset			0.1
			(0.199)
Joint Income			0.1
			(0.390)
Kids			-0.0
			(0.461)
Marriage			-0.1
			(0.420)
Observations	672	558	537
Arrellano Bond test	0.992	0.995	0.738
Sargan test	0.135	0.083	0.079
Hansen test	0.531	0.799	0.751

Based on the estimation results shown in Table 2, the difference between NMTR Dividend and NMTR non-final income negatively affects the non-final income. This result is consistent with previous empirical results (Harju & Matikka, 2016). A more significant dividend rate decrease causes NMTR from dividend income to be higher than NMTR non-final income. As a result, taxpayers prefer income

in the form of dividends, and there is an indication of income shifting from non-final income to dividend income.

Conclusions

This research investigates the indication of income shifting due to the tax rate difference between dividend and non-final income. Indication of income shifting is measured through the non-tax final income reported on an annual notification letter to the Directorate General of Taxes. The results of estimation and descriptive analysis indicate that the change of dividend income tax rate from progressive tariff to single tariff tends to cause income shifting behavior on top bracket personal taxpayers. Based on descriptive analysis, there is an income-shifting indication in groups with an income close to 500 million rupiahs and the highest income group.

The results of this study have implications for strategic public policy formulation. The difference in tax rates between dividends and other taxable income causes income shifting. This behavior can increase tax cost efficiency as well as decrease the progression of tax rates that may increase the income gap. Therefore, simplification and a decrease in dividend rate must be followed by other rules that minimize income shifting opportunity, especially for top bracket personal taxpayers.

Acknowledgment

This research is supported by a grant from PITTA Universitas Indonesia 2018. Special thanks to Directorate General of Taxes for the data and Yulianti Abbas for rigorous comments on the early draft of this paper.

Abstract

External trade and foreign economic activity are essential in ensuring national economic development. As a rule, the export-import operations have a strong effect on the country's economic indicators (especially, the GDP). Export operations are one of the key factors that ensure the growth and sustainable development of the national economy. In terms of sanctions and trends of decrease in the world economy caused by various factors, it is crucially important to analyze Russian export structure and export policy, and to draw out the most important instruments of financial support for exports.

Keywords: Export, Economic Growth, Development of Foreign Trade, Financial Insurance

Introduction

The main systemic factors that constrain the development of exports are the high risk of financial losses of exporters in foreign economic activity, unfavorable conditions for crediting of export operations, and insufficient competitiveness of individual goods and services. Thus, the participation of in the global exchange of goods and services is ensured by a stable position on world markets.

However, the multipolarity and heterogeneity of the world economy of the twenty-first century determine the need to find new directions for the development of foreign trade. In these circumstances, increasing of the national exports (especially the export of high-tech production), can become an important element of the country's structural adjustment and technological modernization.

Main Body

To build an innovative economy, it is necessary to further support and develop the innovative industry, diversify the economy to solve structural problems, ensure economic security and achieve strategic development goals (Ustyuzhanina, E.V., Komarova, I.P., Novikova, E.S., Sigarev, A.V., 2018). The development of foreign trade operations also contributes to the sustainable development of the economy, with exports being singled out among factors that directly affect economic growth.

A promising direction for the leading countries could be exporting to the South-East Asia, the Middle East, South Africa and North Africa, and Latin America regions (Petrov A.M., Kosolapova M.V., Yshanov I.G., Muravitskaya N.K., Nurmuhamedova N., 2019). As it seems, the most perspective goods for export will be:

- universal, power and electrical equipment;
- ready-made food;

- plastics;
- textile materials and products;
- pharmaceutical products;
- clothes;
- chemicals and materials, ready-made chemical products;
- hardwares;
- industrial products;
- electronics and home appliances;
- grain and milling products;
- telecommunication equipment;
- ferrous and non-ferrous metals;
- special industry equipment.

Despite the negative consequences of the economic crisis of 2014-2016, introduction of the import substitution and the overall decline in production, construction and industry, there is still a stable demand for metals and metal products due to active participation in investment and infrastructure international projects (Golubtsova, E.V., Zvereva, A.O., 2019). However, the policy of import substitution stimulated "simple" industries and has hit high-tech. The diversification of the economy can be achieved by removal of the trade barriers. The point of international trade is that, by purchasing imported goods at a lower price (even taking into account shipping costs), one can focus resources on areas having a competitive advantage. Modern trade theory emphasizes that trade liberalization helps identify the sectors and firms that are most effective for the country, reduces production costs and increases the competitiveness of the economy. In this regard it is necessary to make a comparative analysis of the Russian and American export structures.

The contribution of top exporters in Russia and the United States to manufacturing exports is very similar, so it is interesting to draw attention to the differences. Thus, in the United States, large exporters (those that supply five or more goods to five or more countries) make up to 11% of the total number of exporters and account for 92% of manufacturing exports. In Russia, such exporters make up to 6% of the total and provide only 53% of the manufacturing exports. Small exporters ("one product to one country") in Russia provide 4% of exports, and in the United States only 0.2% of exports, accounting for about 40% of exporting firms in both countries.

This gives reason to believe that in Russia there are not enough large non-resource exporters with a diversified goods structure of the export portfolio, while the existing ones are not large enough. This means that measures to support and develop exports should be focused primarily on large exporters.

Agricultural products, grains, and milling products have significant export potential to African countries due to increasing food demand, ongoing political instability, and growth of population. The increase in exports is also facilitated by the tariff policy implemented in the import of food from the abovementioned countries, despite the measures of state support for the agricultural sector.

The potential for increasing exports of chemicals and materials is provided by the growth of demand in the petrochemical and pharmaceutical industries of the economies of South-East Asia, the Middle East, South Africa and North Africa, and Latin America, due to projected GDP growth. The increased demand for imports of chemicals and materials from foreign enterprises is based on the implementation of state programs to expand and modernize the construction and petrochemical

sectors. A positive factor for increasing exports is the absence of customs barriers and low import duties.

Russian exports of pharmaceutical products can be increased due to insufficient provision of medicines and medical care to the growing population of developing countries, as evidenced by the absence of import duties on pharmaceutical products and the small number of national manufacturers of medicines.

Construction of solar power plants and power lines, supply of solar panels seem to be a promising opportunity. Africa and Latin America constantly face a shortage of electricity, the share of electrification of these regions remains low. The problem can be solved through the construction of power plants and renewable energy sources. Absence of import duties on light-emitting diodes and solar panels, as well as the absence of equipment manufacturers for the construction and operation of renewable power plants, can have a positive impact on the Russian exports (Lehoux, L., Duck, H., Akhmadeev, R., Morozova, T., Bykanova, O., 2019).

The measures of state export support allow domestic producers to be more confident in the international market, to receive additional benefits by entering into contracts with foreign partners, which ultimately has a positive effect on the economic development, and contributes to the growth of the welfare of the Russian citizens. The main directions of stimulating Russian producers to export products and services include:

- preferential loans;
- preferential terms of investment, credit obligations and export factoring;
- state guarantees;
- simplification of customs clearance procedures;
- attractive conditions for products to enter the world market;
- elimination of administrative barriers;
- information support and consultations of specialists in foreign economic activity.

The combination of financial and non-financial measures to stimulate Russian exports increases the competitiveness of domestic products and increases the potential of the main sectors of the national economy (Sotnikova L.V., Polenova S.N., Mislavskaya N.A., Petrov A.M., Basova M.M., 2019).

From the perspective of the classical economic theories, the export promotion strategy at the country level is based on the principle of comparative advantage: when a country specializes in a specific product that it can produce on a competitive basis. Empirical studies show that the most effective export incentives are export credits, tax refund schemes, grants and bonuses from export support funds, duty-free import of semi-finished products for production and raw materials, as well as exemption from value added tax, foreign exchange deductions, exemption from corporate income tax, and other forms of subsidies (Akhmadeev, R., Morozova, T., Voronkova, O., Sitnov. A., 2019).

Thus, in order to maintain competitiveness on world markets and increase export potential, Russia needs to develop instruments, typical for world practice:

- instruments for financing the foreign economic activities: pre-export financing, issuing guarantees, direct lending to a foreign buyer;
- implementation of international projects and tenders;
- insurance;
- expert advice on taxation, law, customs administration, logistics, and currency control.

The analysis of the mechanism for export development support shows that to the present day, Russia has developed the following financial directions:

1. Partial compensation of national producers' expenses for transportation and delivery of agricultural and food products to customers via export routes. To manage the costs of manufacturers, special attention should be paid to the organization of accounting;

2. Wide-format consulting on legal regulation of foreign economic activity and taxation of exporters;

3. Practical assistance in preparing documentation, as well as research and analytical reviews of the current market for export sectors, segmental analysis of potential for national producers (Korableva, O. N., Kalimullina, O. V., Mityakova, V. N., 2018);

4. State guarantees in the form of written financial obligations issued by the Government or the Ministry of Finance to a national exporter or credit institution (both national and foreign) on full or partial responsibility for the performance of obligations under trade contracts;

5. Preferential terms of lending to foreign buyers in foreign trade contracts with national producers. This supposes providing the exporter with a loan or credit line and insurance to finance the purchase of national products by foreign buyers;

6. Insurance of export credits and investment operations, the most common insurance products currently include:

- credit insurance (to protect national or foreign bank from the risk of loan default), while coverage extends on the loan to the foreign borrower to perform its obligations under the export contract signed with a Russian exporter;

- supplier credit insurance (to protect national exporters and their financing banks from the risk of non-payment by a foreign buyer for individual deliveries basing on deferred payment);

- comprehensive insurance of export credits for exporters and banks that finance them against the risk of non-payment by a foreign buyer;

- insurance of a confirmed letter of credit used by foreign banks that have secured and confirmed a letter of credit for payment of an export product of a national manufacturer, against the risk of non-receipt of compensation.

- insurance of guarantees of those national exporters who provided the guarantee against the risk of its execution for reasons not related to the violation of obligations on the part of the exporter.

7. Financial incentives for a number of export-oriented industries at all stages of the export cycle, including:

- financing expenses of the national supplier under the export contract;

- financing current expenses for export deliveries;

- financing the exporter's commercial credit;

- financing a trade turnover with a foreign buyer for the period of waiting for revenue receipt under export contracts;

- direct credit to a foreign buyer if the terms of loan provision are less attractive in the country of its residence;

- financing through a confirmed letter of credit;

The abovementioned financial products are provided by specialized national banks with the state participation, established to support the national export development. In practice, the basic line of bank guarantee products is represented by the following:

- a tender guarantee that provides support to national exporters in terms of financial support for their participation in competitive procedures and auctions organized by foreign buyers for the conclusion of foreign trade contracts (Workman, D., 2019);

- guarantee of advance payment refund as a measure of financial security of competitive advantages of national exporters in terms of the possibility of providing foreign buyers with bank guarantees of advance payment refund. This direction assumes an obligation of the guarantor to pay the guarantee amount to the beneficiary, which the foreign buyer previously paid to the exporter acting as the principal, in the form of an advance payment, if the principal does not fulfill its obligations to return part or all of the advance payment amount in cases stipulated by the terms of the foreign trade contract;

- guarantee of proper fulfillment of obligations under the export contract when implementing the competitive advantages of the national exporting company (bank guarantees of proper fulfillment by the exporter (principal) of its obligations under contracts concluded with foreign buyers and customers) (Cuervo-Cazurra, A., Inkpen, A., Musacchio, A., Ramaswamy, K. 2014);

- a payment guarantee that provides financial security for the national exporter payment obligations as a principal to a foreign counterparty – beneficiary under a contract for the supply of goods, works, or services.

The study allows us to conclude that the combination of state measures of financial support for national exporters allows us to expand foreign markets and ensure sustainable development of the world economy.

All the instruments described are deemed as key in the context of international and regional economic integration. These instruments and methods of state support should be used in combination together with the strategic planning of exporting operations.

The Role of Information in The Process of Unemployment Reduction

Agnieszka SZEWCZYK

University of Szczecin, Institute of Economics, Szczecin, Poland
agnieszka.szewczyk@usz.edu.pl

Abstract

The unemployed can often view available employment information negatively when viewing job offers and many hope for a change in this area. These kinds of opinions were revealed in a survey accepted as the basis of formula that was prepared and is presented in this paper. The formula utilises algorithms and element connection models and aims to connect three main determinants regarding the development of the information society which have a fundamental effect on the labour market: information features, informational process phases and IT professions. This paper aims to assess the role of information in struggles in finding work faced by the unemployed. In order to complete the assessment, the author used a custom-made method to analyse the relationship between certain IT professions, which lead to the achievement of successive information process phases and a final conclusion to this process, i.e. acquiring information regarding the required features and focussing specifically on the IT professional labour market, as well as work opportunities in this area, in the reality of the information society. This was seen as a priority to depict the relationship between information as a driving force of information society development and unemployment.

Keywords: Labour Market, Unemployment, IT Professions, Information Society.

JEL Classification: E24, J64, J24

Introduction

When listening to comments made by long-term job seekers it is impossible to remain indifferent to the issue of unemployment. Many authors (Eichhorst, Marx, Wehner, 2017; Deelen, de Graaf-Zijl, van den Berge, 2018; Connolly, Sheehan, 2018; Axelrad, Malul, Luski, 2018) have debated whether this problem can disappear or is set to increase ever greater in the future, especially within the information society, so desired by some, and perceived as a key to welfare (Steger, 2015; Stern (Eds.), 2002; Targowsky, 2004; Blaha, 2012). When considering scenarios relating to the development of societies, unemployment is usually predicted as high in almost every one. Therefore, it should be a priority to minimize this issue at the initial stage in the creation of the information society. When analysing literature concerning this problem (Lim, Lee, 2019; Naisbitt, 1998; Masuda, 1980), it was noted that the relationship between information (as a driving force in the development of the information society) and unemployment is not captured. This problem requires an urgent solution and could be an excellent opportunity to improve the difficult situation of a great number of unemployed individuals. This situation occurs because within the information society, the greatest dynamics of growth are characterized though informational resources and determine the level and dynamics of any social potential. Work aimed at solving this problem is regarded as necessary because it is based on a difficult situation in which hundreds of thousands of people find themselves. An individual from this group might begin by looking for employment information about jobs, and the first issue that should be considered is the precision of the information and its quality. Appropriate information, i.e. that will meet the unemployed person's expectations is the first link of its so-called duality. However, the second link in the chain involves regarding information as an element of a causative factor in the development of workplaces.

One of many hypotheses determining transition to the information society is, as emphasized by many authors (van der Lippe, Treas, Norbutas, 2018; Biewen, Fitzenberger, de Lazzer, 2018; Passaretta, Wolbers, 2019), increasing the supply of individuals in professions connected with computer science and providing traditional professions holding qualifications that are related to informational technologies.

The dichotomy of information (about and on the labour market) has resulted in the need to investigate the form of information around labour and act in a form that can lead to its improvement. However, the counterpart of the discussion allows labour market research with regards to traditional and new IT professions and the analysis of perspectives in this area. The return of information onto "the common way" from a dualistic perspective is fulfilled in this paper through a so-called information dichotomy formula. This formula, using algorithms and element connection models connects three main determinants in the development of an information society: information features, informational process phases and IT professions.

This assessment of information from different perspectives can be the basis of a method of interpreting its dual nature, considering the role of an unemployment reduction process. The first is "labour information", which includes mainly vacancy offers, the second is "information forming workplaces", through the use of information and telecommunication technologies.

From the perspective of an unemployed individual, it is essential to discover what the desirable features of "labour information" might be and the course of informational processes which create it. Describing information feature relationships with informational processes can answer the question of which processes are "responsible" for the lack of desirable information features, and consequently to attempt to improve them.

Summing up, this paper aims to assess the role of information in the fight to reduce unemployment. In order to complete the assessment the author utilised her own method to analyse the relationship between specific IT professions, the fulfilment of successive information process phases and the result of this process, i.e. information having desirable features and leading to specifically focusing on pinpointing the IT profession labour market, as well as perspectives in this area, in the reality of the information society.

The accepted priority is to depict the relationship between information as a driving force of the development of an information society, as well as unemployment.

The dysfunctional character of information on the labour market

Through the process of rectifying incorrect information in the labour market, it seems useful to focus on the "informational condition" of information sources relating to the labour market. These can be press advertisements, online proposals, and offers available in agencies to monitor job opportunities. Even after a perfunctory glance at various advertisements, which include job offers, can give the impression that there is an abundance of vacancies in different professions. They are often pages and pages of announcements or ads in larger or smaller formats, as well as announcements purchased by employers in daily or specialist publications. Unfortunately, it seems common that many vacancies are out-of-date or some only placed in official outlets, which are in fact already reserved for friends or relatives.

These kinds of opinions were frequently expressed unofficially and "between the lines" by potential employers, and on being told that the job "has already been taken", unemployed individuals gradually lost their trust in these sources of information. Survey conversations with individuals seeking employment clearly confirmed these facts. The unemployed often repeated opinions that information on job offers were incomplete, too short or too general, or in some cases displayed false information.

Rising unemployment results in many individuals being more active on the Internet when looking for work (Kureková, Beblavý, Thum-Thysen, 2015; Chowdhury, Mukherjee, 2016). While at the same

time, companies and employment agencies fall back on the medium to facilitate the process of recruitment. Over the past number of years several hundred online services have sprung up there which either supplement the activity of the existing employment agencies, or are companies that offer their employment services solely online. In connection with the process of creating of the information society it is predicted that this trend will remain.

Representatives of e-employment agencies have seen a distinct growth of popularity of their sites in the past few years. There has also been a considerable growth of sites that collect the professional data of those seeking work. This has had a twofold influence on unemployment agency websites, on the one hand, there is an increase in the number of individuals registering on their databases, on the other, this has led to a decrease in the number of job offers advertised by employers on those websites. There is also the same trend as in online personal consultancy companies or newspaper advertisements, i.e. there are fewer vacancies and employers, while at the same time a reduction in personnel budgets, often preferring to not employ staff through employment agencies.

Offers made available to unemployed individuals by various agencies monitoring job opportunities should be prepared professionally. One of their tasks is to expand the "outflow" of the unemployed to employment by effectively associating them with vacancies and collecting information about the labour market more efficiently.

This practically involves sifting through job offers and training for employment agency customers, creating databases on employers, planned redundancies, vacancies that are offered and requirements regarding worker qualifications.

Individuals looking for work were asked to comment on whether they were satisfied with the form and content of the information in job vacancies on offer, but most of the individuals questioned mentioned numerous shortcomings in this area. The most frequent complaints were those concerning insufficient, incomplete or even out-of-date information and over-advertised vacancies.

The report of frequent dissatisfaction made by unemployed individuals on the quality of available information of vacancies should be sufficient reason to take action improving information in job offers in the labour market. In the light of the above considerations, it seemed proper to set out 48 information features and carry out research among individuals seeking jobs. This diagnostic survey took the form of a direct inquiry and it consisted of two questions for respondents on whether given features appeared in information about job offers, which they analysed and then to state which features should be in every job offer. The survey was carried out on a test sample of 1500 people, who were randomly selected from a group declaring themselves as unemployed. They group was made up of representatives of several European countries. Itemized information features and answers provided by unemployed individuals to the second question translated into determination of weights of those features by experts when applying the formula presented in the fourth part of the paper.

Information as a job creator

The aforementioned rule of the duality of information in the case of unemployment show a second, apart from informing, role. To clarify, it can be stated that information, especially through informational and telecommunication technologies, can be a causative factor of jobs, as well as an informational and telecommunication economy is regarded as a key impulse of social development.

The foundation for the running of the information society is the provision of an activity that is connected to the production and distribution of information with economic activity indicators that can draw measurable profits.

Separating the so-called informational sector and placing it next to agriculture, industry and services have been proposed by many information society researchers. However, there is no agreement as to what belongs in the informational sector and what functions should be outside it. It must be reiterated

here that differences in the approaches of F. Machlup and M.U. Porat to an informational economy (Crawford, 1984; Porat, 1997) are clearly observable.

While Machlup tried to clearly separate parts that deal with the "production" of information and information services from the national economy, Porat aimed at defining the degree to which informational activities are widespread in each production branch. However, E. Eliasson et al indicate that the both approaches lack the criterion of a function fulfilled by information (Eliasson et al, 1991). In compliance with those authors' idea, the information sector identified according to Machlup's criteria is only a small and inessential part of an information economy. Moreover, information and information services do not form a compact sector, but they are dispersed in various economy branches where they support and often dominate production cycles (Dziuba, 1998).

New phenomena and economic forms appear in economies where information plays a leading role, with good examples being the electronic economy or virtual enterprises. These novel approaches are accompanied by a change in location, roles and manners of human functioning (also as an employee) in the economy and society (Garnham, 2000; Martin, Halls, 2009).

The essence of the formula of reciprocity of information features, professions and informational process phases

It has been observed that the dysfunctional nature of labour information has created a powerful challenge for the information society, involving improvement of information condition. On the one hand, to list many of the features of the information that would be desirable for unemployed individuals related to the jobs they want, and on the other examples of unsatisfactory information in this area which does not fulfil their expectations in many cases, it is proper to wonder what the relationship of determined phases in informational processes are, which product is actually information with determined "result" features. This will allow us to respond to the question of what phases of an informational process producing a given item of information demand special observation and, in the event of this information item having unsatisfactory features, offering the chance of immediate intervention into the fulfilment of this process. Obviously, on the other hand, knowing which information features are desirable in a given situation, emphasis can be put on the proper course of particular determined phases of the aforementioned information process. It will also be possible to define which informational process phases are, in a sense, "responsible" for possessing or not possessing desirable information features.

Bearing in mind the goal to reduce unemployment, it might be useful to try and find a connection between the specified phases of informational processes, as well as professions or jobs connected with them, especially in the area of IT professions.

Since the informational process can be, so to speak, an "employer", it can be determined on this basis which phases of informational processes are fulfilled by which IT professions, and consequently, maintaining certain professions are dependent on the necessity to fulfil those informational process phases.

Continuing the discussion regarding the problems of the desirable features of information, it seems advisable to note their relationship with IT professions, because work carried out by individuals employed in computer science positions and fulfilling certain informational process phases is directly related to the shape of the product in this process, i.e. information.

The aforementioned problems are illustrated by figure 1.

Fig. 1: The complex depiction of the formula

Source: The author's study

In order to create a complex depiction of the three problems illustrated above, the following connection can be made: information features – informational process phases – IT professions. It can be achieved with the support of so-called element classification (connection) models (Dattola, 1969; Avison, Fitzgerald, 2003).

It is widely accepted that usually the basis of connecting is a so-called "residual", i.e. a measure of the proximity (resemblance) of elements (Gitman, Levine, 1970; Salton, 1974; Pawlak, 1981; Nowak, 1990; Ho, Hull, Srihari, 1994). The analysis of connecting methods leads to the conclusion that the connection method from a two-aspectual automatic designer approach will be the closest to the assumptions accepted in this paper. The designer's representation creates the possibility of connecting elements with the omission of limitations resulting from the actual state of any examined system. A dual-aspect approach allows us to consider two fundamental criteria for element connection, i.e. proximity and significance (of weights).

The starting point in the described study was to establish a list of 48 information features and their weights, specifying the required degree of occurrence of a given feature. A method of connecting similar elements based on the Gitman-Levine algorithm was used. Techniques for building a similarity matrix of the examined elements (e.g. information features, IT professions) were used.

The findings and discussion - application aspects of the information dichotomy formula

The practical assessment of the presented information dichotomy formula was effected on selected model data. Symbol X indicates the occurrence of a group of information features generated in a specific phase of the informational process (see Table 1) and a group of professions responsible for carrying out these processes (see Table 2). The location of symbol X in the tables was determined on the basis of diagnostic tests, i.e. interviews with employees in specific IT professions. The first elements subjected to the process of connecting information features, similarly consider the phases of the informational process that create it. Carrying out a connection formula resulted in the following findings (Table 1).

Table 1: A list of featuroids and phases of the informational process

Number and name of the phase of the informational process / Featuroid	1 Generating information	2 Gathering information	3 Information storage	4 Transferring information	5 Information processing	6 Making information available	7 Information interpretation	8 Information use
SC_1	x				x		x	
SC_2	x	x		x			x	
SC_3	x	x			x			
SC_4	x	x				x		x
SC_5		x		x	x	x		x
SC_6			x	x		x		
SC_7	x						x	x
SC_8							x	x
SC_9			x		x			
SC_{10}	x	x	x	x	x	x	x	x

Source: the author's study

Featuroids, from SC_1 to SC_{10}, include the following groups of information features:
SC_1 – Accuracy, Purposefulness;
SC_2 – Explicitness, Precision;
SC_3 – Completeness, Aggregation;
SC_4 – Value, Accurateness;
SC_5 – Speed, Effectiveness, Age;
SC_6 – Cheapness, Activity;
SC_7 – Adequacy, Preciousness, Fullness, Decision-making ability, Quantity, Priority, Prospectiveness;
SC_8 – Usefulness, Reasonableness;
SC_9 – Safety, Productivity;
SC_{10} – Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements.

Later, according to the same formula, IT professions were subjected to the connection process, comparable with regards to the phases of the informational process performed by those professions.

After carrying out a connection formula resulted in the following findings (Table 2).

Table 2: The list of fractions and phases of the informational process

Number and name of a phase of the informational process / Fraction	1 Generating information	2 Gathering information	3 Information storage	4 Transferring information	5 Information processing	6 Making information available	7 Information interpretation	8 Information use
SF_1	x		x	x	x	x	x	x
SF_2		x		x	x	x	x	x
SF_3		x	x	x	x	x	x	
SF_4	x	x			x			
SF_5					x			
SF_6				x	x			
SF_7	x		x		x			
SF_8	x	x	x		x			
SF_9					x	x		
SF_{10}		x	x		x			
SF_{11}	x	x	x	x	x	x	x	x

Source: the author's study

The fractions (SF) include the following groups of professions:
SF_1 – IT Systems Manager, Chief IT Specialist, Implementation Consultant, Project Manager, Exploitation Manager;
SF_2 – Auditor, IT Consultant;
SF_3 – IT Systems Designer and IT Uses Specialist;
SF_4 – IT Systems Analyst, IT Tool Programmer, Graphics and Animation Designer;
SF_5 – IT Systems Engineer, IT Technician, Computer Installation Technician, IT Systems Operator, IT Systems Maintenance Technician and IT Infrastructure Operation Worker;
SF_6 – IT Network Engineer, IT Systems Safety Inspector and IT Network Administrator;
SF_7 – Application Programmer and Multimedia Application Programmer;
SF_8 – Databases Programmer and Web Designer;
SF_9 – IT Communications Systems Programmer and IT Communication Specialist;
SF_{10} – SAP Software Specialist, Multimedia Applications Designer, Screen Designer and IT Systems Administrator;

SF_{11} – IT Department Manager, IT Unit Manager, IT Systems Analyst, Database Analyst, Dataflow Specialist, Implementation Specialist, IT Service Specialist, Multimedia Project Manager, Database Administrator, Application Idea Creator, Information Broker, IT Services Agent, IT Products and Services Sales Worker.

Connecting separated fractions and featuroids was used during another execution of the formula and concluded with the following results (Table 3).

Table 3: The category list: professions and information features

Category	Profession	Feature
$SZ_1=SF_1 + \{SC_1, SC_7, SC_9, SC_{10}\}$	IT Systems Manager, Chief IT Specialist, Implementation Consultant, Project Manager, Exploitation Manager	Accuracy, Purposefulness, Adequacy, Preciousness, Fullness, Decision-making ability, Quantity, Priority, Prospectivity, Safety, Productivity, Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
$SZ_2= SF_2+\{ SC_{10}\}$	IT Auditor, IT Consultant	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
$SZ_3= SF_3 + \{SC_{10}\}$	IT Systems Analyst, IT Application Specialist	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
$SZ_4= SF_4 + \{SC_3, SC_{10}\}$	IT Systems Analyst, IT Tool Programmer, Graphics and Animation Creator	Completeness, Aggregation, Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
$SZ_5= SF_5 + \{SC_1, SC_3, SC_5, SC_9, SC_{10}\}$	IT Systems Engineer, IT Technician, Computer Installation Technician, IT Systems Operator, IT Systems Maintenance Technician, IT Infrastructure Operation Worker	Exactitude, Purposefulness, Completeness, Aggregation, Speed, Efficiency, Age, Safety, Efficiency, Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
$SZ_6= SF_6 + \{SC_5,$	IT Network Engineer,	Speed, Efficiency, Age, Being up-to-date,

SC_{10}}	IT Systems Safety Inspector, IT Network Administrator	Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
SZ_7= SF_7 + {SC_{10}}	Application Programmer, Multimedia Application Programmer	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
SZ_8= SF_8 + {SC_{10}}	Databases Programmer, Web Designer	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
SZ_9= SF_9 + {SC_5, SC_{10}}	IT Systems Programmer, IT Communication Specialist	Speed, Efficiency, Age, Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
SZ_{10}= SF_{10} + {SC_{10}}	SAP Software Specialist, Multimedia Applications Designer, Screen Designer, IT Systems Administrator	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements
SZ_{11}= SF_{11} + {SC_{10}}	IT Department Manager, IT Unit Manager, IT Systems Analyst, Database Analyst, Dataflow Specialist, Implenetation Specialist, Maintenance Specialist, Multimedia Project Manager, Database Administrator,	Being up-to-date, Flexibility, Honesty, Availability, Communicability, Responsibility, Comparability, Work consumption, Truthfulness, Assimilativeness, Reliability, Time flexibility, Ease of utilization, Stability, Confidentiality, Faithfulness, Redundance, Efficiency, Retrospectivity, Profitability, Conformity, Volume, Integrality, Special requirements

	Application Idea Creator, Information Broker, IT Service Agent, IT Products and Services Sales Worker	

SZ – categories – professions, having an influence on information features
SC – featuroids including groups of information features
SF – fractions including groups of professions

Source: the author's study

Conclusions

The research presented in this paper focused on assessing the role of information in the struggle with unemployment. The author identified the relationship between certain IT professions, fulfilling successive phases of informational processes and the product of this process, i.e. information related to gaining the most desirable features. As a result of the research, through the use of the author's classification method (the formula of reciprocity of information features, professions and informational process phases), initially, it was ascertained that each of the fractions had been connected to certain featuroids. Consequently, it can be accepted that a group of IT professions, classified in fractions, have a direct relationship with creating certain forms of information features, while performing successive informational process phases.

Secondly, an exact analysis of the scope of responsibilities of individuals employed in certain IT professions can provide the basis of a correction of those ranges, especially from the perspective of the quality of work, as well as an enhanced inspection of work effects, taking into account particular information features.

Thirdly, some information features are dependent on doing one's job properly by groups in certain positions. However, such “collective responsibility” should not diminish the efforts of individuals “producing” the information given.

Next, the content of tables with findings can be changed to a different arrangement of priorities of desirable information features (i.e. their different weights) or with another accepted profession hierarchy. This can occur during informational preference investigations, which are unlike the groups of individuals presented.

Finally, unemployed individuals approached the problem of labour information often in a very emotional manner, which is of no surprise. This was expressed in assigning many features of information of both very high and high priorities, which led to the following category arrangements: a great number of professions were connected with a large number of information features. Unemployed individuals attach huge importance to accurate information about jobs. In answer to the user expectations of this information a list of potential categories in which an individual performing a certain profession (in this case computer science) can find guidelines regarding what information features they have to pay particular attention to during the fulfilment of these informational process phases.

Improving condition of information, including especially information for the unemployed, and particularly depicting the relationship between information and unemployment, can be regarded as one of the most essential imperatives in the development of the information society.

Abstract

Information and educational technologies are currently a necessary for transforming society into a digital format. The increasing complexity of financial and accounting products and the need for responsible decisions focused on the use of special methods of preparing students based on e-learning, blended learning, as well as designing models of responsible financial behavior. This is connected with the fact that in short-term perspective young people will become a key segment in a new financial infrastructure. The article is devoted to the analysis of the modern trends in teaching methods of such directions as accounting and financial literacy. According to the authors' opinion, the study of particularly these directions allows students to form the first experience of rational behavior competences, conscious decision-making in finance management, as well as to undergo the effective socialization in the modern society.

Keywords: Accounting, Financial Literacy, E-Learning, Blended Learning, Financial Behavior.

Introduction

Nowadays, the issues of the financial development and accounting education became relevant due to the features of the modern financial life, increase of the financial products and services amount including the products based on digital technologies. Consumers of accounting and financial services must take more and more independent financial decisions, realizing the responsibility for the consequences and risks. Generalization of the existing pedagogical experience makes it possible to highlight the interactive way of learning as the most effective tool of accounting and financial literacy education. It is based on the interaction of all participants of the educational process, for example, in modeling life situations, organizing discussions and joint problem-solving. The interactive form of classes on the basics of accounting and financial literacy fully contributes to a more complete formation of the necessary competencies for students in the field of accounting and financial literacy.

E-learning was implemented in the classes covering the fundamentals of accounting taught at the Wrocław University of Economics to the first-year students of Finance and Accounting at the Faculty of Economic Sciences. The objective was to support classes in their traditional forms (lectures and classes). Students were obliged to enrol on the course, but they were free to decide about making use of it during the semester. The obtained effects were analysed on the basis of surveys and the observation of students' behaviour on the e-learning platform.

The reorganisation of classes and empirical research were preceded by the analysis of the literature on the implementation of e-learning in the teaching of accounting at the higher education level.

Thus, during the research at Kazan Federal University (Economic Faculty), in order to determine the level of financial literacy, a sociological survey was conducted among 50 students aged from 18 to 25 years old.

Methods

Deduction and reasoning by analogy, based on the analysis of literature and the analysis of own research (surveys and observations). The authors conducted a sociological survey among students, the results of which showed the main problems and tasks that need to be addressed in the methods of teaching accounting and financial literacy to modern students. As a result of the conducted research the correspondence between the assumptions adopted for designing complementary teaching and the expectations of the present generation of students could be verified.

Results

The process of teaching accounting is organised in the way which can be described as controlled discovering. An expert in accounting first becomes familiar with simple elements, which are then synthesised. However, at the higher levels of education the contents and terms become more complex and they are accompanied by multivariate solutions and controversial issues. Thus, the role of a guide (teacher, coach), who controls these discoveries, is growing.

The hermetic professional language of accounting and unknown terms (as well as the incorrect use of some accounting terms in the colloquial language) cause that students have difficulties with absorbing the material.

The development of technology and its increasing accessibility as well as the availability of various tools such as, for example, educational platforms, have caused that for many years already higher education institutions have been taking actions enabling them to support traditional teaching methods (lectures, tutorials, laboratories) with blended learning or to replace them completely with e-learning or remote teaching.

In the 90s, in the studies on educating in the field of accounting, researchers expressed considerable interest in the theory of learning through experience (ELT/LSI). These studies concentrated on comparing practitioners' preferences regarding styles of learning, taking account of their changes at different career stages and changes in the requirements imposed by the profession on its experts. In view of the generation changes taking place in the schools of higher education and changes on the labour market, it is necessary to continue research regarding this theory.

The literature review focused mainly on the studies related to the utilisation of e-learning in the teaching of accounting.

The present model of learning based on competencies requires modern tools enabling students not only to absorb the contents in a passive way, but also to acquire skills in an active manner.

The researchers point out that one of the major problems in education is to improve the learning process (Lopez et al., 2015). The conducted research shows that the introduction of e-learning to the teaching of accounting improves the learning efficiency of students with poor results (Concannon et al., 2005), (Lopez et al., 2015).

The team analysing the factors affecting the behaviour of students discovered that the level of acceptance for this way of learning was significantly affected by a hedonistic attitude and, therefore, that the pursuit of pleasure was a motivating factor in using e-learning in the learning of accounting (Kelana et al., 2017).

In the opinion of the research team the availability of blended learning in the teaching of accounting to large groups of first-year students improved both the learning efficiency and the integration of foreign students, owing to the possibility of cooperating on the Internet platform (Schaffhauser-Linzatti et al., 2008). Interesting results were also obtained by the team analysing the learning efficiency of students preparing together for certification in accounting. A blog was used as an educational platform. Students were divided into two groups, out of which one could use the blog for cooperation and for the other it was only a place for teaching, but the progress made by this group was controlled based on their learning outcomes. When the course was finished, it was discovered that in the group which was not controlled but whose members were cooperating the efficiency was higher (Liao et al., 2012).

In Poland, the experience of implementing e-learning in the teaching of accounting was analysed, among others, by P. Zieniuk (Management accounting), K. M. Klimczak (Financial accounting) and J. Krasodomska (International accounting and Bank accounting). In each case a change in the organisation of classes, which consisted in implementing e-learning, was positively received by students (Zieniuk, 2011), (Klimczak, 2008), (Krasodomska, 2012). This common opinion is contradicted only by the research conducted in the years 2012-2013, which showed, on the basis of the assessment of teaching aids used during the financial accounting classes, that students prefer to gain the knowledge from the literature on the subject and not from e-learning (Hinke, Svoboda, 2014).

The research on the use of the broadly understood e-learning in the teaching of accounting analyses also the possibilities of employing different tools. Positive results were obtained, The effects related to the use of e-books and e-television in the e-learning of accounting were also positively evaluated (Azaltun, 2009). The online platform, operating as an educational platform and as a place for looking for a job, was also considered to be useful. The use of various tools entails the issue of humanisation of e-learning. The usefulness of various tools and teaching methods in the e-learning of accounting was investigated also by Polish researchers in cooperation with their Bulgarian colleagues. The study included students and academic staff and employers in Poland and Bulgaria, because of the possibility of using e-learning in the training of employees (Jaworska-Białek et al, 2013)

In the opinion of the team investigating the influence of e-learning on the globalisation of education in the area of accounting, it can be used for the commonly accepted education of accountants at the international level, separating it from the education based on the national regulations (Ionescu et al., 2009).

Unfortunately, the research on the possibility of using e-learning in the teaching of accounting shows also that e-learning applications are still rarely implemented. Among the reasons for this situation the researchers have listed the incorrect selection of applications as such or their contents. Other obstacles include costs, poor or insufficient infrastructure or the lack of access to it or the lack of human resources (Kashora et al., 2016), or insufficient technical support, which makes it difficult to use the dedicated equipment (Wong et al., 2017).

Summarising, e-learning contributes to the improvement in the efficiency of learning, but the key to success includes cooperation and willingness to share knowledge, which are characteristic of the current generation of students, and not control. The research on students' attitude to e-learning and blended learning shows that this way of organising work stimulates their positive emotions and meets their expectation related to the flexibility of learning and freedom in managing their time.

Memory and learning are affected by both rational premises and emotions, which are inseparably connected with each other (Kolb, 2013, as cited in LeDoux J., 1997, Zull J., 2002, Damasio A., 1994). According to Kolb, feelings and emotions have priority when it comes to the determination of whether or not to learn and what to learn, and negative emotions (fear, anxiety) hinder learning, while the presence of positive feelings (attraction, interest) is indispensable, because learning something which is not interesting is very difficult (Kolb, 2013). The pursuit of pleasure is one of the features of

Generation Z, and, therefore, people with such disposition have a positive attitude to the use of e-learning in the learning of accounting.

The creation of a modern space for learning accounting may also contribute to solving the problem of students' passivity, as many of them, based on their prior educational experience, are passive recipients of what they learn. Enabling students to take control and responsibility for learning may significantly strengthen their ability to learn on the basis of experience (Kolb, 2013).

Such approach meets the expectations of the generation connected with the non-linear learning method and independent learning and ensures the flexibility of learning (working) hours. It also necessitates becoming involved in the process of acquiring knowledge and skills.Today's student will soon become (or has already become, while still studying) an employee, and also employers are interested in solutions that transfer the educational process, in part or in whole, outside the classroom. The time of being a student is appropriate to master how to learn making use of e-learning.

Accounting is receptive to e-learning. According to the research, blended learning as well as e-learning or remote teaching work well for the teaching of accounting. However, the higher the level of education in accounting, the more important the role of contact with the lecturer becomes, because of the multivariate nature of solutions (cf. Kasperowicz, 2011). It seems that this problem can be solved to a large extent, for example, by transferring theory to e-learning, and, consequently, gaining additional time for discussion during the traditional classes. It should be emphasised that young people also have to develop social competencies and acquire face-to-face communication and cooperation skills. The respondents were also asked to assess whether they needed e-learning and whether the materials used by them on the platform helped them in learning (Fig. 1).

Fig. 1: Is e-learning needed? Did the materials provided on the platform help in learning?

The usefulness of respective elements of the course is confirmed by the number of students' visits. Tests and tasks with feedback (making it possible to check if the solution is correct) as well as solved examples regarding the more difficult parts of the material were used most often. The students also willingly viewed the glossary, but in this group nobody made use of the possibility of editing its entries.

The latest news forum, which by nature is a place for discussion, was used only one-sidedly: the lecturer placed the information there and the students read this information. Instead of continuing, in case of questions, a given thread, which would be visible also to other students, the students wrote emails with questions. Perhaps the reason for this is the lack of anonymity of the forum users and, thence, they were afraid to 'post' a question. The author's impression is that the forum did not fulfil expectations – students were eager to ask questions, but in an oral form during the classes.

Enabling the students to undertake some tests unlimited number of times demonstrated that many of them made use of this possibility and the system showed the progress made by them in subsequent attempts.

In the next question the students were asked to assess, using a scale from 1 to 5 (5 – being the highest score), the usefulness of the provided materials.

Fig. 2: Assessment of the resources made available in e-learning

The survey included one open question, giving the students the opportunity to comment freely on their expectations (what they would like to receive in the new version of the course). The students could also write what they did not like. The replies concerning expectations were, after having been coded, presented in Figure 3.

Figure 3: Word cloud – expectations

The word cloud shows that the students taking part in the course would like to have more tasks and tests to solve on their own (with the possibility of verifying their answer) and examples. They would also welcome films to be used for learning, in particular the short ones, presenting the content provided in a traditional way during the lectures.

Critical comments concerned, among others, the visual qualities of the platform as such and difficulties in using the course.

In the questionnaires the respondents made comments on their difficulties in using the course, but, at the same time, during the time of students' activity the system had only 91 records showing all participants' activity in the tab entitled "How to use the course?".

Complementary classes improved the efficiency. From the group covered by the study and allowed to take the exam at its first date all full-time students passed and only four part-time students failed their exam. A year ago, for a similar number of students, ten full-time students and seventeen part-time students, from the group allowed to take the exam at its first date, did not pass it.

The exam was held in the computer laboratory, making use of exam sets placed on the platform. Students had an equal amount of time (from the moment of logging in into the exam set, each student had the same amount of time), the commotion related to handing out and collecting paper sets was eliminated. The time for providing feedback to the students was reduced to a minimum. Everybody could see the grade and the number of received points and could analyse the made mistakes immediately after closing the exam page.

Even after passing their exams students were returning to the course for as long as it was available to them. It may demonstrate that the students were successfully motivated to take an active part in the process of teaching and learning.

Thus, no obligation to use e-learning, fully unconstrained access, asynchronous character of the course and no control over the progress made in e-learning were successful. These assumptions made it possible to adapt to the needs of the studying generation.

Sociological surveys, conducted by different organizations, fix sufficiently low level of financial literacy of the population in general. According to the results of the field research conducted by the Higher School of Economics in monitoring financial behavior and trust of the population to the financial institutions, 46% of the citizens admit their financial illiteracy. Among the other problems, the transformation of the regulatory framework of the financial markets can be highlighted, for example, continuous pension reformations, innovations in the deposit insurance system etc.

A number of risks connected with the low level of financial literacy of students influences the financial sector and the development of the economy, namely these risks are connected with the certain typical behavior of citizens, especially students in the financial market, first regarding lending and savings.

Therefore, high level of financial literacy of students must consider at least:

- high level of deposits in banks;
- low level of debt load (the ratio of the average credit payment to his monthly average income;
- low share of the delayed payments.

The research on the level of financial literacy of students are based on the questionnaires of experts and students. Practice shows that that the necessary data taken by this method can be used as indicators while assessing the financial literacy of students. During the study, we interviewed 50 people aged 18 to 25 years to determine the level of financial literacy.

Among the respondents, 92% are students, and 8% are people who combine work with studying. Around 34% of all respondents the level of month income per person is from 240 to 480 dollars. More than 20% falls on the group of respondents whose monthly income per 1 person in the family ranged from 80 to 160 dollars and higher. Slightly more than 14% falls on the category of respondents with income from 480 to 790 dollars for each family member.

To the question: “Do you keep records of your expenses?” 50% of respondents said that sometimes they keep records of their expenses. 35% of respondents answered positively, and 12% replied that they did not keep records of their expenses. During the survey, it was determined that more than half of the respondents do not borrow money at all, and the rest borrow funds for running expenses from relatives, friends and acquaintances (Figure 4).

Figure 4: Distribution of respondents' answers: Where do you most often borrow money for current needs?

Figure 5: Distribution of respondents' answers to the question: Do you keep a record of your expenses?

When asked if you have enough financial knowledge in everyday life, the answers of the respondents are distributed as follows (Fig.6).

According to the figure, 48% of the total number of respondents said that they lack knowledge on financial issues. Approximately 26% were unable to answer this question. 24% of respondents believe that they do not have enough knowledge on financial issues in their daily lives.

Figure 6: Distribution of respondents' answers: Do you have enough financial knowledge in everyday life?

To the question "How do you feel about introducing classes in financial literacy?" 72% of respondents answered positively, 14% negatively. The remaining respondents were not able to answer this question unambiguously. (Fig.7).

Figure 7: Distribution of respondents' answers to the question: How do you feel about introducing a subject of financial literacy?

In addition to the above issues, respondents were asked to undergo testing on a number of issues to determine the level of financial literacy. It was proposed to answer 8 questions on financial literacy. Table 1 shows the test results for each issue.

Table 1: Test results of respondents to determine the level of financial literacy

Questions	Percentage of respondents who answered the question correctly	Percentage of respondents who answered the question incorrectly
Choose which types of compulsory insurance are prescribed by law when obtaining a loan	44%	56%
What methods of securing an obligation can be provided for by a loan agreement?	68%	32%
Can a credit institution unilaterally change the interest rate on a loan agreement?	56%	44%
What services under a loan agreement the consumer cannot refuse to pay?	80%	20%
Is the bank entitled to charge an additional fee for depositing cash through the bank's cash desk for a loan payment?	38%	62%
At what point of time is the payment schedule provided to the borrower?	48%	52%
In what cases is a consumer entitled to repay a loan ahead of schedule?	66%	34%
What is the maximum amount of compensation for a deposit established by law?	38%	62%

We have conducted a sociological survey for 50 people aged from 18 to 25. According to the received data none of the respondents answered all the questions correctly. The largest number of incorrect answers were received on the following questions: «Is the bank entitled to charge an additional fee for depositing cash through the bank's cash desk for loan payment?» and «What is the maximum amount of compensation for a deposit established by law?». These questions were incorrectly answered by 62% of respondents. 56% of the total number of respondents incorrectly answered the question about the types of compulsory insurance prescribed by law when obtaining a loan.

In general, it should be noted that increasing the level of financial literacy remains important not only for people of retirement age (as evidenced by various sociological surveys of working and non-working pensioners), but also for young people - students. In other words, this issue is relevant for categories of people of different ages.

It can also be noted that the population survey should be considered not only as a research method, but also as a tool of influencing the object of study. The person who answers all the questions from the questionnaire already has a different level of financial literacy.

In general, the studies and analysis of expert opinions indicate that the following aspects are inherent to the consumer of financial services:

- certain financial behavior settings that are associated with assigning responsibility for personal financial decisions and financial risks on the government (paternalism);
- passive attitude to control over personal finances.

These are caused by the following problems:

a) the first group of problems is related to the fragmented nature of teaching the basics of financial literacy in educational institutions, the lack of accessible educational programs and educational materials for students, as well as the lack of qualified teachers of the basics of financial literacy;

b) the second group of the problems is related to:

   1) low awareness of the protection of consumer rights of students,

   2) the imperfection of legislative and regulatory support, the absence of a mechanism of interaction between the state and society, which provides the increased financial literacy of the population of students and the development of their financial education,

   3) an insufficient level of resources, including financial, human resources, information technology, provision of the necessary programs and activities,

   4) the absence of a mechanism of interaction between the state and society that ensures the increase of financial literacy of students and the development of their financial education.

The economic development of a country largely depends on the general level of financial literacy of the country's population. The low level of financial literacy leads to negative consequences for consumers of financial services, the government, the private sector and society as a whole.

Conclusions

The professional future will comprise improving competencies, gaining knowledge and acquiring new skills on a continuous basis. In the work environment the active participation in the process of learning will gain in importance. The implementation of modern forms, such as e-learning and blended learning, especially at the lower levels of education in accounting, makes it possible to use the personality traits of this generation and provides a response to its needs. Entrusting students with control over education in e-learning (in the complementary system) supports the process of developing the skill of independent learning of accounting, without the risk of losing control by the lecturer, as tests and exams are carried out in accordance with the rules set out in the study regulations.

The first version of e-learning is just the beginning of our work on it. Owing to the cooperation with students it will be possible to eliminate from the course its “early age diseases” and to enrich it with additional materials and activities. The development of this course may lead to its transformation into a course completely based on e-learning. It should also be highlighted that meeting the young generation halfway, by making e-learning available, may not lead to the abandonment of developing their social competencies and face-to-face communication and cooperation skills.

It is very important to share experience of implementing specific, more or less advanced solutions in the e-learning of accounting. Thus, the relevant good practice can be disseminated.

In the short term, young people will become a key segment of the financial structure. The received experience and the formed competencies of financially rational behavior will allow the younger generation to make conscious decisions, responsibly manage personal finances and analyze the possible consequences that will help to improve the person's financial well-being. These are important factors for person's successful socialization in society. The circumstances mentioned above allow us to conclude that it is necessary to use the capabilities of the education system as one of the elements of state policy to influence the financial behavior of students.

Information technology in education is currently a necessary condition for the transition of society to a digital format. Digital technologies play a significant role in expanding access to financial services and improving the welfare of the population. At the same time, the complication of financial products, the transition to remote formats, the emergence of new providers, as well as unfair practices in the sale of financial products increase the risks for consumers, first of all for socially vulnerable groups, including students. In such conditions, financial education and the availability of adequate mechanisms to protect the rights of consumers of financial services are becoming increasingly important.

Successful integration of financial literacy in the education system also depends on:

- the programs that harmoniously fit the necessary financial knowledge into training programs with connection to real life and age-related interests (problems) of students;
- teaching staff for the formation of necessary knowledge among students, which involves the organization of a reliable and effective system of assistance in training;
- stimulating mechanisms for both students and teachers.

New educational products are the following:

- creation of information and educational resources (websites, portals, computer games, print media, etc.);
- cognitive educational events, various business games and quests (debates, competitions, excursions and other events). Particularly effective are case studies such as the ABC of Financial Literacy and the Financial Literacy Championship.

New training technologies include online courses, e-learning, interactive, communication technologies, etc.

A generalization of the existing pedagogical experience makes it possible to highlight the interactive way of learning as the most effective tool of financial literacy education. It is based on the interaction of all participants of the educational process, for example, in modeling life situations, organizing discussions and joint problem-solving. The interactive form of conducting classes on the basics of financial literacy fully contributes to a more complete formation of the necessary competencies for students in the field of financial literacy.

In conclusion, we would like to note that interactive methods and technologies for teaching the fundamentals of financial literacy for youth are finding more and more practical application, since they have advantages over traditional forms of education (memorization is not supposed, the focus is not on theory, but on a specific life situation, conditions are created for inclusion of all students in active work and for working in small groups, based on the construction and design of various models

of financially competent behavior). Such technologies provide a direct link between acquired knowledge and their practical application, which has a positive effect on young people and forms their responsibility for financial decisions.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

patrycja.bryczek-wrobel@wat.edu.pl

Abstract

A philosophical movement that advocates for, among others, "exporting" best human qualities to machinery has been increasingly popular in the modern world. It is described by the term transhumanism (abbreviated as: H+), coined by one of its most important precursors - Max More. An intensive debate is currently on-going both on the undoubted chance for the rapid development of humanity as well as the threats associated with the transition of this movement from the conceptual to the practical implementation phase. Cognitive science has a special place in H+ philosophy, besides neurotechnology, biotechnology or other sciences combating the limitations of a human body. It is an interdisciplinary science that studies cognitive systems, with particular emphasis on the human mind and artificial systems, i.e. computers that would ultimately reveal higher intelligence than the one encountered in humans. Simultaneously, a growing number of business entities expose themselves to a stream of economic transformations, which consist in favouring a "knowledge-based economy". They are in the process of a gradual transition from a material-consuming economy to the economy dominated by modern technology and access to knowledge. This impels us to try to be open-minded towards challenges and threats associated with such processes, in the context of international security. Theoretical research methods were widely applied in the research process, i.e. bibliographic query, critical analysis of the subject literature, selection and serious assessment of source materials. Owing to the analysis and synthesis, gradual abstraction, comparison and generalization, the inference phase has begun. The possibility of contact with high-class specialists, scientists from the Military University of Technology, involved in the development of new technologies, allowed for interviews and confrontation of theory and practice.

Keywords: Transhumanism, Cognitive Science, Changes In The Labour Market, Technological Threats

Introduction

The modern times, brimming with innovations, new opportunities and threats, are more and more strongly vocalizing the philosophical movement, characterized, among others, by its pursuit of a new reality, which replaces the natural environment with an artificial system. To a large extent it involves "exporting" the best human qualities to machines. The movement is described as transhumanism (abbreviated as: H+), a term coined by one of its most important precursors - Max More. According to the English philosopher and futurist "*transhumanism is a class of philosophies that seek to guide us towards a posthuman condition. Transhumanism shares many elements of humanism, including a respect for reason and science, a commitment to progress, and a valuing of human (or transhuman) existence in this life rather than in some supernatural "afterlife". Transhumanism differs from humanism in recognizing and anticipating the radical alterations in the nature and possibilities of our lives resulting from various sciences and technologies such as neuroscience and neuropharmacology, life extension, nanotechnology, artificial ultraintelligence, and space habitation, combined with a rational philosophy and value system*" (More M., 1990). This quote best recaps the gist of the phenomenon.

The main representatives of this philosophy (Natasha Vita-More, Anders Sandberg and Nick Bostrom) assume that man is not the last link in the development of humanity and civilization, but only a transitional stage. The development of technology, science and robotics strives for the human

body to go to a higher level of readiness, significantly and even completely exceeding the natural capacity of a human being.

The modern world does not leave any room for natural processes, feelings, ethical values and moral norms; their place is being taken by lies and violence at an alarming rate, and Social Darwinism seems to be a growing global "religion" leading to a very difficult social structure. Civilization starts to be governed by intelligent energy networks, the Internet of Things, robotics and artificial intelligence, geoengineering and technotronics. These changes are closely related to GRIN technology (i.e. genetics, robotics, computer science and nanotechnology), which forms the axis of basic tools ensuring the development of humanity, while maintaining its fundamental impact on the direction of societal changes. Transhumanists suppose that the final stage of transhumanist evolution of humanity will be a "posthuman" with supernatural power and superintelligence.

An intensive debate is currently on-going on the undoubted chances for the rapid development of humanity (Czajkowska A., 2018) as well as the threats associated with the transition of this movement from the conceptual to the practical implementation phase [Bostrom N.N. 2003]. Cognitive science has a special place in H+ philosophy, besides neurotechnology, biotechnology or other sciences combating the limitations of a human body [Miller G. A. 2003]. It is an interdisciplinary science that studies cognitive systems, with particular emphasis on the human mind and artificial systems, i.e. computers that would ultimately reveal higher intelligence than the one encountered in humans. Certain elements and concepts of this science have already been implemented by organizations most open to innovative solutions.

Changes in The Labour Market

The results of "Global Human Capital Trends 2019" research conducted by Deloitte company on approximately 10,000 leaders of Human Resources and Information Technology as well as management board members in 119 countries show that we are in the initial phase of diametrical, in particular employee-related changes, that will need to be addressed by entrepreneurs around the world. Despite the widespread digital transformation, 84% of respondents say they will have to change their approach to employee experience to increase the employees' productivity, because a driver for innovation is and will be the human potential, yet supported by artificial intelligence, cognitive technology, automation and robotics. It is assumed, that machines will take over repetitive activities, people's activities will lose their routine character, and men will work hand-in-hand with robots (Ezequiel A. Di Paolo, 2003).

This issue is naturally related to what every person is currently thinking about, namely their sense of existence as an employee in the context of the forthcoming changes in the labour market. We are inevitably headed towards key problems arising from the conflict between the development of technology and the disappearing labour market.

The report prepared by the Millennium Project expert group Work / Technology 2050: Scenarios and Actions, which focuses on social and governmental responses to problems associated with work and technology development, shows that global society is exempt from criticism in its movement towards a labour market conflict involving a natural employee and a technologically improved robot, whose development cannot be fully anticipated.

Due to too strong of a focus on political conflicts, no attention was paid to how quickly artificial intelligence, robotics, 3D / 4D printing or bioengineering contribute to the today's business being out-dated. In addition, a gap in income and economic growth is widening despite there being no increase in employment, while an average number of people working in services and products have dropped significantly.

Currently, among the global workforce of over 7 billion citizens, only about 2 billion are employed by others or self-employed. The new technologies introduced in recent decades have not created more jobs than they ousted. As a result, today two-thirds of the world's workforce is in the grey economy

or unemployed, and the economy and financial systems cannot support aging societies and mass youth unemployment. This exacerbates social conflicts, cyber-crime, terrorism and organized crime. McKinsey Global Institute experts forecast that the highly economically developed countries, e.g., Germany or the United States, will be most affected by these changes, and the most seriously aggrieved persons will be machine operators, food sector employees, mortgage brokers, accountants and administrative employees. Occupations that are based on the need to maintain interpersonal contacts, complex tasks of perception and manipulation, or tasks of creative intelligence will be less susceptible to automation.

Knowledge-Based Economy

Global corporations, i.e. Google or Facebook made sure the Internet can be accessed even from the poorest parts of the world. As a result, many remote villages in poor countries gained access to virtual space, which, in addition to such significant benefits as tele-education, tele-work, tele-medicine or tele-commerce, gave people the ability to be much more destructive while their privacy has become a complete illusion.

Representatives of management sciences perceive modern transformations differently and carry on a very intense discussion about the memory of an organization (Walsh J.P.and Ungson G. R., 2006) and the ways in which it can be managed. This type of memory can be treated as an exported, shared, and in an organization-specific way, organized memory and patterns of its employees. It often constitutes a key element of resources of those companies, which base their activities on the intellectual capital of employees. Interestingly, such entities fit perfectly into the trend of economic change, currently supported by the European Union. The trend promotes a "knowledge-based economy", or "a gradual shift from a material- consuming economy based on economies of scale to the economy based on knowledge and modern technologies."

Hence, only those with intellectual potential and the latest knowledge in the field of science and technology have a chance to develop countries. Therefore, the competitiveness of the "new economy" lies in the advantage based on knowledge and innovation being a function of at least three variables: people's creativity, demand for innovation and the appropriate pro-innovative climate of the state (Almeida H. and Sequeira B., 2019).

Widely available 24-hour virtual reality and engaging social media just like ("cyber heroin") have lulled people into a false sense of security in the context of new revolutionary movements. Social divisions have arisen and continue to arise between honest taxpayers and the unemployed. New social divisions between technologically advanced citizens and "natural people" are becoming apparent. The evolution of technology is so extensive that no matter how good the initial intentions of the inventors of new technologies were, immoral personalities turn them against the good majority.

It may therefore turn out in the future that "human intelligence, the driving force of which is creativity and the ability to describe the surroundings in a logical way, has led to a stage that can be a dead end of evolution - with all the accompanying consequences" (Pasieka T., 2018).

Technological Threats

The efficiency and pace of information flow in the 21st century is gradually increasing, gaining in dynamics. It mostly results from a snowball increase of technologies and changes in general global trends. The development of the idea aims to ensure that in the manufacturing process every item of daily use is equipped with appropriate micro-chips having the functionality of, among others, a wireless network adapter connecting to the Internet. Such connections communicate with other "machines" independently and as needed (*machine-to-machine* – M2M). The concept is called the Internet of Things (Miller M., 2016). Artificial Intelligence - AI, to put it simply, consists in expanding the current capabilities of electronic devices and device-controlling software with certain cognitive functions, which humans associate (or have associated) only with the human mind, such as learning. Contemporary types of self-learning AI are based, among others, on the analysis and

synthesis of natural languages (e.g. speech synthesizers and translators, with some of the functions that are currently being refined such as the so-called virtual assistants); logical reasoning (inference based on knowledge and reasoning algorithms, and by the same token the processing of information from the database); neural networks and broadly understood machine learning involving independent decision making based on a knowledge base and algorithms.

Another element affecting the dynamics and scope of impact of the discussed threats in the context of national and international security is the progress in miniaturization and automation, with the flagship example being MEMS technology (*Micro-electromechanical Systems*), which consists in the integration of mechanics, sensors, actuators and electronics in a single sub-millimetre system. MEMS elements are sometimes surprisingly small. Probably the most common example of the application of this technology are components of modern "smartphones", such as acceleration sensors, elements of movable optics, microswitches or other additions. It is estimated that the turnover for the whole MEMS-related industry increases annually by 14%, which is comparable to the pace of development of the artificial intelligence market.

Conclusion

The rapid development of technology already affects many aspects of the security of citizens and entire countries, ranging from miniaturization and Internet infrastructure to the most advanced methods of data processing. They are gradually dominating an increasing share of the global goods and services market, giving countries that have decided to take part in this race a chance to raise their position in the global economic system.

The examples of threats related to new technologies may be multiplied here: from economic aspects and block chain technology, being the foundation for the existence of cryptocurrencies that could potentially destabilize the current financial system, to a technology bordering on biochemistry and research on ways of inducing genetic mutations of plants, animals and even people. The above examples do not exhaust to a smallest extent an enormous range of various threats associated with the development of science and technology for both the individual and entire societies. One could, however, be tempted to make a certain generalization referring to the 4th industrial revolution - almost every field of science (social sciences and humanities as well) has been equipped with powerful tools in the form of supercomputers, the Internet, Big Data and other elements that require more and more computational power. They allow to precisely design modern materials at the molecular level, forecast weather on a global scale, or even predict the effects of conflicts, including the detonation of nuclear bombs. Therefore, two things seem to be the most important elements in this race. The first one involves control over the full supply chain of modern technologies, from research and concept to production. Whereas the second key element is setting standards in the software layer, which allows constant access to the analysis of behaviours of network users, their preferences, mood modifications, etc. and, based on this data, development of further, increasingly better generations of algorithms. Nowadays, the coupling between modern technologies, software and specialized human resources is a kind of recipe for successive movement up the ranks of the most developed countries in the world. The national security of each country is increasingly dependent on the technological potential, which means that the development possibilities of this potential determine the position of the country and its real defence capabilities against the challenges of the future.

Thus, using a futuristic analogy, it can be assumed that not only humans, but also technology will have a potential to generate technology. Falling behind this global race of progress may ultimately be detrimental not only to the standard of living of a given society but also to its security.

Decomposition of GDP Growth Rate in Poland Over the Years 2010-2019. Exposition of The Problem

Marian NOGA

WSB University, Wroclaw, Poland

marian.noga@wsb.wroclaw.pl

Abstract

Public authorities [central and local] implement a specific fiscal and monetary policy of the state, they have to have a particular information base. Public authorities make short-term, medium-term and long-term decisions. The information base for taking decisions by the public authorities is provided by:

- natural measures
- statistical measures proposed by science
- monetary measures

Considering the need of making decisions in the global economy, statistical offices in the world agreed that the Gross Domestic Product (GDP) will be such a measure. GDP is used by governments, politicians, international organizations such as OECD, the World Bank, the International Monetary Fund, financial markets, UN agencies. In practice, we use GDP per capita and GDP real growth rate. Therefore, it is important to know factors affecting the GDP growth rate. It may be done through decomposition of a GDP growth rate which involves a final breakdown of the GDP into a domestic and foreign demand. This paper will evaluate the impact of components of a domestics and foreign demand for Poland over the years 2010-2019 in the quarterly view (39 observations – each observation comprises 6 variables, 234 variables in total).

Key words: GDP, Private Consumption, Public Consumption, Investment, Stock, Net Exports, GDP Growth Rate.

Introduction

According to the System of National Accounts (SNA) and the European National Accounts (ENA) GDP may be calculated and analysed from the two points of view:

a) on one hand GDP measures the output being the sum of value added manufactured by all business entities (enterprises, financial institutions and insurance, governmental institutions and local governments, households and non-commercial institutions) operating in the entire country increased by indirect taxes imposed on products and decreased by subsidies granted to products.

b) on the other hand, GDP also shows a final division of the output into various types of demand meaning its final consumption. The final division of GDP of an enterprise is presented as follows:

$$\mathbf{PKB \equiv C + G + I + \Delta R + (E\text{-}M)}$$

where:

C – private consumption
G – public consumption
I – investment (gross expenditure on fixed assets)

ΔR – a change in inventory; inventory is understood as a difference between the production and the sales
E – exports
M – as imports
(E-M) – exports net
entities may be used to satisfy domestic demand comprising:

- private consumption
- public consumption
- investment
- changes to the inventory
  and foreign demand including net exports.

In the book by Noga, finally, the use of GDP meaning the final division of goods and services into categories of the final demand (domestic and foreign) is referred to in economy as decomposition of GDP [2018].

Decomposition of Real GDP Growth Rate in Poland Over the Years 2010-2019 From the Quarterly Perspective.

Table 1 presents decomposition of GDP growth rate for 2010-2019 (39 quarterly observations). The entire period witnessed the GDP growth rate ranging 0,0% ÷5,5%.

The range (from minimum to maximum) of particular components of GDP decomposition was as follows:

- Private consumption 0,0% ÷ 2,9%
- Public consumption – 1,1% ÷ 1,9%
- Investment – 1,6% ÷ 2,8%
- Changes to inventory -1,9% ÷ 2,6%
- Net exports – 2,1% ÷ 2,8%

The division of components into domestic and foreign demand shows the following ranges:
domestic demand -1,9% ÷ 2,9%
foreign demand -2,1% ÷ 2,8%

The first analyses of the GDP growth rate in Poland over the recent 10 years show that the GDP growth rate is equally affected by domestic as well as foreign demand as their ranges of impact almost align. The mode for particular factors of decompositions amounts as follows:

- Private consumption 2,6%
- Public consumption 0,8%
- Investment 1,5%
- Changes to inventory 0,1%
- Net exports 1,0%

Whereas the median (the central value of the set) for these factors of decomposition is as follows:

- Private consumption 2,1%
- Public consumption 0,6%

Table 1: Decomposition of real GDP growth rate of Poland over the years 2010-2019 broken down in quarters in %

	I 2010	II 2010	III 2010	IV 2010	I 2011	II 2011	III 2011	IV 2011	I 2012	II 2012	III 2012	IV 2012	I 2013	II 2013	III 2013	IV 2013	I 2014	II 2014	III 2014	IV 2014	I 2015	II 2015	III 2015	IV 2015	I 2016	II 2016	III 2016	IV 2016	I 2017	II 2017	III 2017	IV 2017	I 2018	II 2018	III 2018	IV 2018	I 2019	II 2019	III 2019

Source: Own work on based NBP Report on Inflation, November 2019, nbp.pl [access29.01.2020]

- Investment 1,1%
- Changes to inventory 0,5%
- Net exports 0,9%

I have also calculated an arithmetic mean of all decomposition factors and I have received the following results:

- Private consumption 1,72%
- Private consumption 0,69%
- Investment 0.67%
- Changes to inventory 0,39%
- Net exports 0,44%

Conclusions

A. In the entire surveyed period consumption was the main source of economic growth in Poland. According to my research, this consumption was mainly private. Out of 38 observations in 22 quarters the impact of private consumptions on the GDP growth rate was higher than the average 1.72%.

B. Undoubtedly, the second source of the GDP growth rate is generated by investments as reflected by the modal value, the median, the impact on the GDP growth rate (2.8%). My research has shown that. The following facts should be emphasised:

Firstly, in decomposition of GDP growth rate the investment factor refers only to expenditure on gross fixed assets. The analysis does not consider portfolio investments (in financial products and intangible assets)

Therefore, from the macroeconomic point of view, we divide investment into:

- public welfare investment
- non-profit investment

The classification is according to sectors. However, in research by Noga , the macroeconomic classification of investments in terms of tangible investments is as follows: a:

- fixed assets of enterprises
- housing
- inventory [2018]

Secondly, in macroeconomics there was a dispute between classical economics and Keynesian economics. Classical economists claim that before you can invest you must save first. Whereas Keynesian economists claim that investments "generate" savings. However, the theory and practice have revealed mistakes in reasoning of Keynesian supporters. They did not take into account that making investment through a bank loan is nothing else than using savings deposited in the bank by other entities. Thus a conclusions may be drawn that first we have to save than we can invest.

Thirdly, the above deliberations lead to the conclusion that in the relation between savings and investments there is a feedback. On one hand, investments result from transformation of consumption demand into investment demand. The research study by N. Nehrebecka and A. Białek-Jaworska has revealed that investment in fixed assets depend first of all on the cash flow from corporate operational activities and a smaller dependence of starting investment on conditions in the lending market. On the other hand, the investment will increase consumption demand, private and public consumption in the future [2016].

Fourthly, the level of investments in a country depends on the so called investment climate which is determined by:

1. macroeconomic factors including:
   a) a fiscal policy of the state,
   b) a monetary policy of the state,
   c) a state of economic cycle (expansion phase vs recession phase),
   d) a growth in sales revenues,
   e) expectations of households and enterprises,
   f) changes to the law;
2. microeconomic factors related to the financial standing of an enterprise (cash flow, finance standing);
3. structural factors related first of all to the ownerships structure of an enterprise and the type of an enterprise (a stock company, a partnership, a limited liability company etc.).

C. According the research carried out, the third place among the sources of growth is taken by net exports denoting a positive indictor which involves exports greater than imports. It entails Poland's aspirations to a greater share in the world foreign trade.
D. Public consumption is on the fourth place as regards sources of GDP growth in Poland with greater aspirations for a higher position.
E. Changes to inventory are residual factor and from the point of view of general balance it would be favorable for this indicator to range near 0.,0%.

Abstract

Data governance emerges as an increased challenge in the context of Big Data, as it increases the heterogeneity and variety of data sources. Data governance covers a few subareas, namely Metadata Management and Data Quality, which can also be extended to the Data Profiling concept. These areas offer a set of processes to support and manage the complexity in the integration of different data sources. It is not only about increased data volume, but also about the increased number of business processes within an organization, requiring additional knowledge about this data. The objective of this work is to propose a graph-based model for the cataloging and governance of a Big Data Warehouse, in order to make its content available and show, among others, how it is evolving over time. The proposed model also allows the tagging and lineage of the data sources and the storage of the collected metadata in a graph database.

Keywords

Big Data Warehousing Governance, Graph Data Model, Big Data Management, Metadata Management.

Introduction

The high availability of data sources motivated by the increasing use of smartphones, tablets, social networks and IoT devices, providing huge amounts of data, produced at different velocities, having high degrees of heterogeneity, leads to new research challenges Cassavia et al. (2014). Big Data brings a new era in the usage and exploration of data, where characteristics like high volume, variety and velocity do not allow data processing or analysis by traditional tools. For integrating data from several data sources and supporting decision-making environments, Big Data Warehouses (BDWs) can be seen as flexible, scalable and high-performance repositories Costa and Santos (2018).

The governance of BDWs is a challenge that emerges associated with the context of Big Data, due to the

complexity of governing massive volumes of data, coming from distinct sources, with different purposes, different target audiences and, consequently, different constraints Hashem et al. (2015). Thus, without adequate tools, managing a heterogeneous environment and defining access policies for all scenarios can become almost impossible Costa and Santos (2017). Moreover, due to the data heterogeneity, the ability to automatically generate metadata about the data will be essential Katal et al. (2013); Labrinidis et al. (2012).

When the number of business processes in a BDW increases, data volume also increases, and the complexity of managing this repository can become complex and only possible with adequate tools. It is necessary to know which tables and attributes were stored, when they were created and which business processes they support, as well as the several updates they had (when and how many rows were included).

This work enhances Big Data Warehousing by proposing a graph-based data cataloging system for the tagging and lineage of data sources and for the storage of the relevant metadata in a graph database. In addition to gathering the basic characteristics of data, the proposed system records information about access policies, profiling, similarity, key performance indicators and business processes. This graph-based data model supports the governance of the data model of a BDW and its evolution over time.

This paper is structured as follows. Section 2 presents the related work. Section 3 describes the proposed graph-based model and Section 4 presents its instantiation and validation. Section 5 concludes with highlights of the presented and future work.

Related Work

Data Governance

Based on the principles identified by Costa and Santos (2017), the Big Data Governance challenge arises as a key issue for managing data. Data Governance describes how organizations manage all the data that pass by their business processes and implies a structure of responsibility, which it encourages the behavior in the evaluation, creation, storage, use, cataloging and deletion of data Smallwood (2014); Soares (2013).

In Khatri and Brown (2010) work, a Data Governance strategy is presented to guide the organizational decision-making processes, structured as five interrelated domains: (1) the data principles, that is, which policies, standards and guidelines are appropriate, so that organizations recognize the data meaning; (2) the data quality, as organizations must establish standards to ensure that data is up-to-date, complete and reliable; (3) the metadata, which provides a mechanism for a concise and consistent description of the data representation, helping to interpret its meaning; (4) the data access, where organizations should define data access policies, establishing rules for accessing the data and by whom, in order to manage the compliance with the data policies; and, (5) the data life cycle, as organizations must understand and document how data comes from, or progresses, throughout their business processes.

Considering the Data Management Body of Knowledge (DAMA-DMBOK) DAMA (2014), Data Quality is directly related to Data Profiling and consists of defining, monitoring and maintaining the integrity of the data, defining metrics, regulations or standards for obtaining knowledge about the data (metadata) Dai et al. (2016); Juddoo (2015). Data Profiling, aims to systematically detect errors, inconsistencies, redundancies and incomplete data Dai et al. (2016); Rodrigues (2017). Also, it is associated with a set of activities and processes to identify the metadata of a data set. There are metadata that are simple to obtain and can be called simple statistics, as for example the number of nulls, distinct values, data type or the most frequent patterns of a certain column. However, there are other metadata that are more complex to obtain, because they imply the correlation between several columns Abedjan et al. (2015).

Tagging and Lineage

Considering that in the area of data governance, works about tagging and lineage of a BDW are inexistent, to the best of our knowledge, it is necessary to research and analyze these concepts in a more traditional context, like Data Warehouses or Data Lakes, to later extend them to their role in a BDW context.

Some of the repositories that usually support Big Data contexts are known as Data Lakes (DL), which store data in its original format, or as BDWs, which store data in its structured format Terrizzano et al. (2015). To support data scientists in data analysis tasks, there should be control over the data, in order to describe and perceive its content, using metadata. Consequently, the metadata play an important role in understanding the data sets and how they related with each other, e.g. duplicate attributes, joinable attributes or outliers Alserafi et al. (2016); Morton et al. (2014).

To deal with this challenge, the work presented in Alserafi et al. (2016) proposes a process for cataloging the data schema of a DL, as well as proposes the systematic extraction, management and exploitation of metadata about the content of the data sets and their relation by means of schema matching. The work integrates automatic techniques to support the discovery of the DL content, with a formalized Metadata Management Walker and Alrehamy (2015).

Several research works explore the extraction of the schema and metadata content, providing an overview of techniques, algorithms and approaches for schema matching and finding patterns in the data content Murthy et al. (2012); Touma et al. (2015). The ontologies alignment and the schema matching techniques, which are based on finding similarities between data schemas and data instances, can also be used to integrate data sets Bernstein et al. (2011).

Graph-Based Model For Big Data Warehouses Cataloging And Governance

This section proposes a graph-based model for BDWs cataloging and governance based in the BDW model proposed in Costa (2019).

The graph-based model proposed in this work is implemented in the Atlas tool, as it is an open-source project and highly customizable. The base model of Atlas is here extended to answer the following requirements:

(1) How entities (tables and columns, among other entities/nodes) are classified in order to organize them in a hierarchical way, allowing to relate similar meanings (e.g. Customer, can be divided in the requirements Customer, the payer, or who get the goods)?
(2) What words/terms that are used in the organization and how the entities are associated with them (e.g. OEM (Original Equipment Manufacturer))?
(3) What actions can be performed on an entity?
(4) How does the data flow in the BDW?
(5) Based on the BDW model, what is the type of each table and attribute?
(6) How was the data evaluated in terms of its quality?
(7) How different tables can be integrated considering different similarity measures?
(8) Which permissions are defined on users and data?
(9) Which business processes are included in the BDW and what data each one uses?
(10) What are the organization's performance indicators and what data is used to compute them?

The various data sources and technologies that are used in this work to feed the BDW governance model and implement the graph-based governance system are summarized in Fig 1. The graph-based system includes Atlas as one of its core components, importing with a REST API all its metadata. Hive and HDFS are storage systems used in the implementation of a BDW, also they are used to feed the metadata to Atlas. A profiling tool Magalhães (2019), allows the monitoring of the data quality, computing data quality statistics and similarity measures. Ranger is the technology used to collect data policies and permissions

Fig 1. Data source and technologies for the Big Data Warehouse Governance.

information. Spark interacts with the profiling tool, collecting the relevant metrics and feeding the supporting graph-based model Magalhães (2019).

In this paper, and due to the complexity of the whole graph, only the most relevant nodes and attributes are presented in detail. The overall graph-based model is available at Costa (2019). Fig 2 and Fig 3 gives an overview of the BDW graph model, pointing its nodes and the relationships existing between them. The model includes nodes already available in Atlas, some of which extended with new attributes, while other nodes are here proposed to fulfill the defined requirements. In Atlas, whenever a classification/tag or term are created, it is possible to associate them with any node of the graph.

Fig 2. Legend of the graph model

Each ***Tag*** type node corresponds to a classification that aims to organize information, within a hierarchy, allowing to relate similar meanings and identifies the data itself, for example, may refer to data quality (eg. tag: DATA_QUALITY); this node answers requirement (1). The ***Term*** node is a glossary term associated to the business rules/terms; this node supports requirement (2). The ***Audit*** node represents each action performed on entities and shows, for example, the details of their creation ("Entity Created") or change ("Entity Updated"), information already stored in Atlas; this node supports requirement (3).

Fig 3. Big Data Warehouse Catalog Metadata Model

The ***DataBase*** node contains databases' metadata, in this work metadata about BDWs. Each database has associated a set of tables, so the ***Table*** node describes the characteristics of each one. Besides the Atlas metadata, this work adds the following attributes Inuwa and N. D. Oye (2015); Santos and Costa (2019); Santos and Costa (2016):

- *accessesCounter*: counts the number of table updates;
- *scores*: corresponds to the average user score of the table (on a scale of 0 to 5 points);
- objectType: A table can correspond to: (1) Analytical Object; (2) Complementary Analytical Object; (3) Materialized Analytical Object; (4) Date and Time Object; (5) Spatial Object.

The ***StorageDescription*** node represents the attribute *sd* in the tables and describes the storage of *Managed Tables*, namely providing information about their location (*path*) in the repository (*file system*).

Each of the tables contains a set of associated columns. The columns can be described through the metadata definition present in the ***Column*** node. In addition to the metadata extracted from the Atlas, another one is added Kimball and Ross (2013); Santos and Costa (2019):

- *attributeType*: Can be "Descriptive", "Factual", "Predictive" or "Identifier".

The lineage of each column is traced by the attributes of node *ColumnLineage* of type *hive_column_lineage*, for example, when a certain table is created by a certain process, the lineage of the

columns that indicates the columns of the inputs and the columns of the outputs and is associated to this process. Consequently, the data flow can be analyzed from these nodes (requirement (4)).

In addition, the new metadata added to the *Table* and *Column* nodes make it possible to know the tables and columns that the organization/business has, in order to understand how to use/apply the data, according to requirement (5).

The ***Job*** node arises to see what a job of a process (type *ProfilerProcesses*) performs and what its state is. Each job is identified by its "id" that corresponds to its name. These metadata were obtained from the Spark Job application:

- *startTime*: Job creation date;
- *endTime*: End date of job creation;
- *duration*: Duration of the job in milliseconds;
- *sparkUser*: Spark user;
- *completed*: Matches the job state; if it fails, it indicates "false"; if it was successful, it returns "true".

The ***Process*** node is created to describe a process that happened. The *ProfilerProcesses* process type is created, the input that receives is a table and the output is the table statistics (*TableQualityStatistics*). This profiling component was elaborated in collaboration with another work called *Smart Crawler for Big Data Integration,* as this generates the data profiling process in Spark, using the metadata defined here.

When the process of type *ProfilerProcesses* is triggered, it originates the type *TableQualityStatistics* and, therefore, the type *ColumnQualityStatistics*. Thus, the ***TableQualityStatistics*** node includes the metadata obtained from Atlas and describes the general quality characteristics of a certain table Abedjan et al. (2015):

- *columnStatistics*: Column statistics to which the table is associated;
- *numcategoricalColumns*: Number of columns of nominal type;
- *numDateColumns*: Number of columns of date type;
- *umObservations*: Number of rows in the table;
- *numVariables*: Number of columns in the table;
- *numNumericalColumns*: Number of columns of the numeric type;
- *numOtherTypesColumns*: Number of columns of another data type;
- *size*: Table size in megabytes.

Still following the characteristics related to data quality is defined ***ColumnQualityStatistics*** node that describes the general quality characteristics of a certain column Abedjan et al. (2015):

- *dataTypeCol*: Data type associated with the column;
- *numEmptyValues*: Number of empty values;
- *maxValue*: Maximum column value;
- *minValue*: Minimum column value;
- *maxFieldLength*: Maximum number of characters;
- *minFieldLength*: Minimum number of characters;
- *numNullValues*: Number of null values;
- *numFalseValues*: If the data type is Boolean, it returns the number of false values;
- *numTrueValues*: If the data type is Boolean, it returns the number of true values;
- *percentFillRecords*: Percentage of filled values;

- *percentUniqueValues*: Percentage of unique values;
- *numUniqueValues*: Number of unique values;
- *numRecords*: Number of rows;
- *frequencyValues*: Frequency of certain column values.

There are metadata classified as simple statistics, for example, the number of nulls, distinct values, the data type data or the most frequent patterns. Thus, when a profiling process is triggered, it origins the *TableQualityStatistics* and *ColumnQualityStatistics* nodes that are developed to evaluate data quality (requirement (6)).
To save measures about the joinability between columns of different tables, the ***InterStatistics*** node is created, which gathers two similarity metrics. The metadata associated with this node, essentially allows to understand the percentage of common values between the attributes of the two data sets, this is, between columns of different tables Abedjan et al. (2015); Maccioni and Torlone (2018):

- *columnMain*: Column to be compared;
- *columnToCompare*: Second column to be compared;
- *headerSimilarity*: Calculates similarity using similarity metrics to compare column headers;
- *contentSimilarity*: Calculates similarity using similarity metrics to compare column content;
- *thresholdFilter*: Value that is defined as the limit on which the similarity of headers is filtered.

On the other hand, as a way of analyzing the relationship (correlation) between the column values of the same table, the ***IntraStatistics*** node is created. The metadata associated with this node allows to perceive the percentage of common values between columns Abedjan et al. (2015); Maccioni and Torlone (2018):

- *columnMain*: Column to be compared;
- *columnToCompare*: Second column to be compared;
- *correlationValue*: Columns correlation.

However, there are metadata that are more complex because they imply the correlation and association between columns. Thus, the *IntraStatistics* and *InterStatistics* nodes that identify dependencies and similarities between columns (requirement (7)) are outlined.

According to the needs in a policy (permission) creation, and based on the Apache Ranger tool, the ***Policy*** node is created in association with a certain database, and/ or tables and/ or columns and with a succession of metadata:

- *policyType*: Type of policy, for example, "Access";
- *policyID*: Policy identifier;
- *policeEnabled*: If the policy is active it returns "true" and "false," otherwise, in the latter case, the policy is disabled;
- *dbExcludes*: If the databases are included it returns "false" and "true", otherwise, in the latter case, the databases of the policy are being excluded;
- *tableExcludes*: If the tables are included it returns "false" and "true", otherwise in the latter case, the tables of the policy are being excluded;
- *columnExcludes*: If the columns are included it returns "false" and "true", otherwise, in the latter case, the columns of the policy are being excluded;
- *description*: More detailed description about policy;
- *group_user_permisson_delegateAdmin*: It gathers the user group(s), the user(s) to whom permission is given, as well as the permissions defined.

Thus, the *Policy* node responds to requirement (8), since it contains the characteristics that allow to investigate the permissions and accesses provided to databases, tables and columns, and also, which users or groups have articulated these privileges.

Business process includes a set of activities that produce a service or a specific product to certain stakeholders, a node called ***BusinessProcess*** is added in the model. This node is constituted of metadata that describe the business process in general Dijkman et al. (2008):

- *stakeholder*: Is the entity that is engaged with a business process;
- *input*: Inputs associated with the process, basically relate to what motivates and feeds the execution and existence of the process;
- *activity*: An activity can be a task or a subprocess. A task is a detailed activity and represents the work to be executed. A subprocess is a composite activity and is defined as a flow of activities;
- *gateway*: There are parallel gateways (AND-split) to create simultaneous flows (sequence), parallel-join gateways (AND-join) to synchronize simultaneous flows, among others;
- *output*: The outputs correspond to what the process originates in the end.

The ***BusinessProcess*** is related to requirement (9), describing the organization's business processes, and how they are associated with the BDW.

In reply to requirement (10) and based on the work of Imhoff (2019), the ***Indicator*** node is used to classify the Key Performance Indicator (KPI) according to its importance to the business and the process in question. This node allows the representation of the performance of an organization during a specific time window. Based on Imhoff (2019); Chan and Chan (2004); Kerzner (2017); Turner (2009), it is identified and defined a set of metadata associated with Indicators:

- *isKPI*: If the Indicator is identified as a KPI (isKPI: true, otherwise, isKPI: false);
- *businessObjective*: The business objective corresponds to the long-term goal;
- *stakeholder*: Is the entity that is engaged with a business process Indicator;
- *csf*: The Critical Success Factors (CSF) are determined by several factors, ranging from the market in which the company is inserted, to what differentiates it;
- *targetFrame*: Temporary window associated with Indicator. For example, "Annual", "Semi-annual", "Monthly", among others;
- *calculationFormula*: Method for the Indicator calculation;
- *trend*: Measures performance over a period;
- *realValue*: The value in that particular period;
- *upperBound*: Maximum limit;
- *averageBound*: Average limit;
- *lowerBound*: Minimum limit;
- *status*: Performance against the target;
- *percentToleranceBound*: a given percentage of tolerance;
- *variance*: Difference between the actual (*real*) value and the objective (*upperBound*) value;
- *percentVariance*: The percentage of variance;
- *type*: Two types of Indicators are distinguished: (1) Absolutes: Individual number, sum, difference and average; (2) Relatives: Quotas, reference numbers and index numbers;

- *group*: Indicators can be divided into two groups: (1) Objective: Time, cost and amount; (2) Subjective: Quality, functionality and satisfaction.

Demonstration Case

Graph Instantiation for TPC-DS

The demonstration case uses the TPC Benchmark DS (TPC-DS) Nambiar and Poess (2006), transforming the original data model into a BDW model, and implementing that model in order to later use it to feed the graph for governance and cataloging.

The implementation of the BDW model help this demonstration case in feeding, with the TPC-DS data, the nodes of the proposed graph. Due to the complexity of the graph, only a subset of the nodes is shown. The bottom of each node contains the metadata that is added, while the upper part includes the metadata acquired from the Atlas tool and, from that set, the mandatory attributes, which are underlined.

The *ProfilerProcesses*, *Policy*, *TableQualityStatistics*, *ColumnQualityStatistics* and *Job* types are shown in fig 4.

Fig 4. Instantiation of *ProfilerProcesses*, *Job*, *TableQualityStatistics*, *ColumnQualityStatistics* and *Policy* types.

The node of type *ProfilerProcesses*, originates the nodes of types *TableQualityStatistics* and *ColumnQualityStatistics*. Therefore, *ProfilerProcesses* is generated from a data profiling process executed in Spark, so the node is named “Profiler Table store_sales” and translates an operation of type "Profiler Quality Operation" that has as input the table “store_sales” and output the quality statistics of this table,

also called “store_sales”. This process has associated the *Job* called “*application_1563382939181_0012”*, whose status is "complete" (*completed: true*) and its duration is "37589" milliseconds. These quality statistics gather a set of metadata that describes characteristics of the table, such as the total number of columns in that table *(numVariables: 23*) and how many of them are numeric (*numNumericalColumns: 23*). It should be noted that when generating the quality statistics of a table, the quality statistics of each one of its columns is generated together, so the *TableQualityStatistics* node also gathers the names of the various statistics of the associated columns (*columnStatistics*). Through these statistics, it is possible to verify that the column “ss_customer_sk” is of the integer type (*dataTypeValue*), and it does not have empty values (*numEmptyValues*), although it presents "1296253" null values (*numNullValues*). Frequencies of values (*frequencyValues*), among other metadata, are still available.

The Policy node in the figure characterizes the policy named *tpc*, whose creator and modifier is the “Admin”, is of the “Access” type, its identifier is "27" and is active/enabled *(PolicyNameEnabled: true*). The policy is associated with several data sets, including the “tpcds”, “tpch”, “storesale_er”, “storesale_sf” databases, the “store_sales”, “customer” tables and the “ss_customer_sk”, “ss_wholesale_cost” columns, between all other tables and columns of each of the databases. In a policy, there can be multiple permissions, and a group or multiple groups of users can be associated to that policy. Also, permissions can be granted to a user or to a specific set of users. After selecting the user and the permissions, it is possible to indicate if the permission is associated with the administrator role (*delegateAdmin*). After this, all mentioned metadata are exposed in one of the attributes of the node, the *group_user_permisson_delegateAdmin*.

To improve the visualization of the proposed graph-based model, full images can be accessed in the folder named “Graph_Demonstration_Scenarios” at Costa (2019).

Graph Implementation for TPC-DS

For implementing the above metadata in Atlas, it is necessary to develop a JSON file to create or edit each node type through an Atlas REST API. In the folder named “Atlas Type Structure” at Costa (2019), the JSON files used to edit and create some of the node types are available. The several types are added/edited

Key	Value
Column	*
DataBase	tpcds, tpch, storesale_er, storesale_sf, storesale_st, storesal
Table	*
columnExcludes	false
createTime	Fri Mar 01 2019 11:56:47 GMT+0000 (Hora padrão da Europa Ocidental)

Fig 5. *Policy* "tpc" in Atlas

(POST/PUT) by Atlas REST API. The *TableStatistics*, *ColumnStatistics*, *IntraStatistics* and *InterStatistics* types are filled by running a data profiling process on Spark. The policy information is transcribed from Ranger to the *Policy* type created in Atlas from the REST API that allows you to parse and retrieve metadata from the returning XML. *Job* attributes are filled by invoking the REST API of the Spark Job application. At this time, part of metadata is already being fulfilled in an automated way. Other metadata like *hive_table*, *hive_column*, *Indicator*, and *BusinessProcess* types are manually filed by the user in the Atlas interface, with the exception of the *hive_table*, where the accessCounter attribute is only filled and modified when the table with the quality statistics is triggered or updated.

Fig 6. Quality Statistics of the "store sales" table in Atlas.

The fig 5 shows a part of the implementation in Atlas of the “tpc” policy whose metadata comes from Ranger. In fig 6 a part of the quality statistics of the *store_sales* table is displayed in Atlas, with the metadata already filled out.

Conclusions

This paper presented a cataloging and data governance system that is based on a graph model, aiming the support of governance tasks in a BDW, in order to better deal with the growing data and business processes of an organization. In this way, the tagging and lineage components were defined, and how they should be represented and stored in a graph database. As the main goal is essentially to collect and assemble the metadata catalog of the BDW, it does not make sense to develop a new tool or API, since Atlas already exists and can be extended for this task (as foreseen in this paper). Atlas incorporates a REST API where users can read, edit and create new data types, and allowing the automatic tagging and lineage of a database, considering information derived from numerous sources, such as Hive.

The graph-based model for the BDW stores its metadata. Its components, such as tagging, have several uses according to the business process or with security and privacy. In the lineage component, it is verified how the content of the BDW is evolving over time. Although the importance of the proposed graph, in the future, Atlas must be extended in order to allow the automatic collection of some relevant metadata, so far manually introduced in the system. With the necessary improvements, it is expected that, in the future, Atlas will be more automatically feed and interactive, allowing, for example, the representation of graphs for data quality statistics.

In conclusion, it can be affirmed that this work makes an important contribution to the Data Governance area, a current research topic, with almost no contributions in Big Data Warehousing. Thus, the result of this work provides a set of components that can be used and applied to various business contexts.

Knowledge Transfer in Enterprise Intellectual Capital Management

Agnieszka SOKOŁOWSKA-DURKALEC

Wroclaw University of Economics and Business, Wroclaw, Poland;
Agnieszka.Sokolowska-Durkalec@ue.wroc.pl

Abstract

Dynamism and multidimensionality of knowledge as an enterprise strategic resource is associated with its transformations both between individuals and groups of an enterprise and its environment. These transformations relate to the conversion of knowledge, i.e. the process of multidirectional exchange, which involves tacit/hidden and explicit/available knowledge as well as overall organizational transfer of knowledge. The above mentioned transformations and their effectiveness condition transformation of knowledge resources into intellectual capital, whose management is based on identification, measurement, use and development. The problem of conversion and knowledge transfer combines the issues of knowledge management (KM) and intellectual capital management (ICM). Therefore, it can be assumed that *the streams of transformations within the framework of knowledge-based intellectual capital combine the dimensions of intellectual capital and their management with particular elements of knowledge management. The purpose of the epistemological article* is to present the problem of knowledge transfer in enterprise intellectual capital management. The study consists of considerations on: integration of intellectual capital management and knowledge management, transformations and transfer of knowledge and their relationships with intellectual capital; as well as presentation of a knowledge transfer grid in enterprise intellectual capital management. The argument is summarized in a list of management dilemmas regarding knowledge transfer in an enterprise.

Keywords: Knowledge, Intellectual Capital, Knowledge Transfer, Knowledge Transfer Grid, Knowledge Management, Intellectual Capital Management.

Introduction

Knowledge as a multidimensional, dynamic and strategic resource of an enterprise has the ability to create new intangible assets that become intellectual capital. Dynamism, inexhaustibility, simultaneity and non-linearity of knowledge is associated with its transformations both between individuals, groups, organizations and beyond. These transformations relate to knowledge conversion, i.e. the process of multidirectional exchange, which involves tacit/hidden and explicit/available knowledge as well as overall organizational transfer of knowledge. The above mentioned transformations and their effectiveness condition transformation of knowledge resources into intellectual capital, whose management is based on identification, measurement, use and development. The problem of conversion and knowledge transfer combines the issues of knowledge management (KM) and intellectual capital management (ICM), which constitute a mosaic of managing intangible resources of an enterprise.

Intellectual capital is also subject to transfer processes both within an enterprise and between it and the environment. The mere fact that an enterprise has intellectual capital (human and structural) is not sufficient to increase the efficiency of its functioning. It must be transferred externally through structural - external - relational capital, meaning continuous exchange of added value between an enterprise and its environment participants, as well as internally increasing the value of intellectual potential. In this context, intellectual capital can be treated as a category that somehow constitutes the intelligence of an enterprise, which should be supported by the process of organization learning, combining its individual dimensions, but also facilitating the above-mentioned transfer.

Models of intellectual capital management (including measurement) functioning in theory and used in practice do not propose clear ways of transforming intellectual capital, focusing more on developing

new standards and tools for registering all possible intangible assets items than on capturing subtle relationships between them (cf. Khavand Kar, Khavandkar and Mottaghi 2013; Loyarte, Garcia-Olaizola, Marcos et al. 2018), hence there is a need to search for such solutions.

The purpose of the epistemological article is to present the problem of knowledge transfer in enterprise intellectual capital management. The study consists of considerations on: integration of intellectual capital management and knowledge management, transformations and transfer of knowledge and their relationships with intellectual capital; as well as presentation of a knowledge transfer grid in enterprise intellectual capital management. The argument is summarized in a list of management dilemmas regarding knowledge transfer in an enterprise.

The considerations are accompanied by *the assumption that the streams of transformations within the framework of knowledge-based intellectual capital combine the dimensions of intellectual capital and their management with particular elements of knowledge management.*

Intellectual capital management and knowledge management - characteristics and areas of concept integration

Defining the notion of knowledge is a serious epistemological and methodological problem. It is a broad, ambiguous and multi-faceted concept, and its definitions can be grouped into those that in the traditional sense define it as a result of the accumulation of experience and learning process, as well as the ones that emphasise the importance of knowledge as an intangible resource of an enterprise. In the context of a modern enterprise functioning, knowledge becomes a strategic resource, the basis for achieving competitive advantage, but also the basis for generating new - occurring in various forms - intangible resources. Knowledge can take many forms. One can speak of tacit, hidden, silent, secret, inaccessible, informal knowledge, but also its contrast, i.e. explicit, available, formal knowledge. Knowledge can also be individual, group, organizational, inter-organizational. There are many proposals for managing this resource (cf. Davenport and Prusak 1998; Bukowitz and Williams 2000; Probst, Raub and Romhardt 2002; Nonaka and Takeuchi 2000).

Generally, the set of activities that constitute the knowledge management process relates to the process (according to T.H. Davenport and L. Prusak)[1]:

- knowledge creation (e.g. by acquiring/purchasing/borrowing knowledge - purchasing databases, computer programs, recruiting highly qualified employees; through knowledge creation centres - innovations, patents, licenses, creating own centres, research and development departments, knowledge universities; by combining: joint work, teamwork, managing organizational behaviour, creating task groups, clash of views, conflict management; through adaptation - creating adaptive abilities, responding to changes in the environment, environment monitoring, cooperation with stakeholders; through networking - formal and informal networking, building an experience exchange community, learning processes, etc.);
- codification (e.g. by gathering knowledge, giving organizational knowledge an appropriate form, facilitating access to it by people who need it most; by identifying knowledge in its various forms, assessing knowledge from the point of view of its usefulness and coding capabilities, identifying the codification and distribution medium of knowledge etc.);
- knowledge transfer (e.g. through training, conferences, seminars, practical workshops, spontaneous, informal meetings, individual teaching, coaching, mentoring, group work systems; through document circulation systems, knowledge bases, expert systems, etc.).

Intellectual capital is based on knowledge, while knowledge-related processes facilitate creation of intellectual values. Intellectual capital consists of components of different levels of aggregation, most often one can talk about human[2] and structural[3] capital: internal and external-relational. [4] Intellectual capital is a combination of intangible assets, their ordering and conscious dimension. It does not match the traditional accounting model that tries to value activities such as employees' competences or customer loyalty, which may not affect enterprise's profits for many years. This type of capital is less

likely to appreciate short-term benefits that have less impact on an enterprise's position in the future. Intellectual capital bridges the gap between market perception and accounting reality, i.e. between market and accounting value, and includes all the immeasurable elements that create the difference between the total value of an enterprise and its financial value (the difference between the total value and traditional, material capital including financial).

Proper management of intellectual capital provides an enterprise with the basis for obtaining competitive advantage. The intellectual capital management process can be more or less formalized. Formalized ways of knowingly disposing of the intellectual potential of an enterprise are presented in the form of models and "try" to name and organize "scattered" and hidden elements of intellectual competence. The most important management models (including measurement) include: Konrad Report, Intangible Asset Monitor, Balanced Scorecard, Skandia Navigator, Value Platform, Danish intellectual capital measurement project (Danish Guideline), Value chain card, Tobin Index, Economic Value Added and human resource accounting methods, etc. The models are multi-faceted and diverse attempts to present a simplified reality. They affect many areas of an enterprise's operations, focusing on the opportunity to create benefits on the foundation of unique intellectual values. However, quite a lot of achievements in the area of the model creation gives a possibility of a wider choice to enterprises diversified in terms of size, object of activity, type of environment, industry features, etc[5].
Based on an in-depth analysis of the assumptions, spectrum of tools, indicators, solutions, etc. of available models, intellectual capital management can be unified by proposing the process that includes: *identification of elements of intellectual capital, their measurement as well as their use and development.* The above elements form a kind of intellectual capital management triad (cf. Sokołowska 2005, p. 18).

Intentional impact on intangible assets in the form of knowledge and intellectual capital results in the concepts of management: knowledge management and intellectual capital management. Both concepts coexist with each other, and considering the essence of intellectual capital management, it is impossible not to notice the issues of knowledge management and vice versa.

Similarities can be found, among others, in the following aspects:

- *adaptive* – the concepts can be a response to the turbulence of the environment and constitute a comprehensive attempt of an enterprise to adapt;
- *competitive* - their effective use creates opportunities for achieving competitive advantage;
- *structural and organizational* - their implementation requires favourable organizational conditions: an organizational structure shape, a specific organizational culture, acceptance by managers and employees, existence of communication, IT and technological possibilities and means; both concepts support creation of modern forms of organizations: learning, intelligent, virtual, etc., as well as R&D departments and positions for knowledge and intellectual capital management;
- *personal* - coordination of processes by people with appropriate competences and understanding the importance of these issues: knowledge employees/practitioners, i.e. knowledge operators, knowledge specialists, knowledge engineers, project managers, knowledge management managers, intellectual capital management managers;
- *tool/instrumental* - they have common tools, techniques, media, activities, e.g. Internet, Intranet, e-mail, groupware, innovative activities, etc.

Differences, however, can be observed in the following dimensions:

- *systemic* – in an intangible resource management system intellectual capital management can be strategic, superior while knowledge management can be tactical and operational, subordinate. Although in a situation of different optics, the configuration of both concepts may assume their integration at the strategic level (intellectual capital strategies as well as knowledge personalization and codification strategies);
- *dynamic* - intellectual capital is treated as a more static category than knowledge; it is the result of dynamic knowledge-related processes;
- *objective* - intellectual capital management seeks to develop new standards and tools for registering all possible items of intangible assets, while knowledge management aims to

develop methods that allow an efficient course of the processes of creation, acquisition, gathering, sharing and use of knowledge;

- *measuring* - components of intellectual capital in the form of human and structural capital can be measured using a set of quantitative and qualitative indicators, and elements of both explicit and tacit knowledge are more difficult to describe and measure.

The characteristic features of the concepts in the above aspects indicate existence of many common points, but also divergences. Both concepts complement and penetrate each other. They can create a system that covers the entire enterprise. The individual elements of the concepts can be considered both in the *human* (individual, group), *organizational* (structural internal) and *inter-organizational* (structural external - relational) dimensions. The processes make a network of cyclical, conscious actions directed at individual components (in the case of ICM - human and structural capital, in the case of KM - tacit, explicit, formal, informal, individual, group knowledge). The instrumentation in the form of models proposing a set of methods and tools has been developed for the needs of effective intellectual capital management and knowledge management. It seems that ICM dominates in this respect (especially in the scope of measurement models). Concepts creating a coherent system, can either be considered at the level of equivalent management concepts, or on the basis of subsidiarity and superiority. Then one of them is leading and the other supporting. Generally, the complementarity of concepts assumes their integration. The intellectual capital management process may be more or less formalized.

As part of the intangible assets functioning in an enterprise, including knowledge, components of intellectual capital are *identified*. Knowledge, both individual and group, is a very important element of *human capital*. Employees' knowledge can be contained in their heads, coded in a set of their formal and informal skills, ways of action, but also in an employee's ability to learn (his absorptive mind, imagination, analytical and creative thinking ability). Group knowledge is also important, as it is stimulated by the synergy effect and it is determined by the proper selection of group members and management of their behaviour (coherence, dynamism, roles, tasks, creation phases and crises of a group and team, leadership). Whereas, s*tructural capital* is disclosed and codified organizational knowledge. It is a product of directed actions of people (organizational structure shape, developed organizational culture and strategy, management methods, communication and IT systems, innovation, etc.) and consists of the effects of intellectual activities. It has an internal dimension, creating an internal structure, i.e. how an enterprise operates, but also an external one that is related to intangible market assets (commercial brand, contracts and contracts, marketing strategies, etc.) based on relations with external entities (customers, suppliers, local community, etc.), also in the aspect of creating and transferring knowledge.

The next stage of the process is the *measurement* of individual components. Intellectual capital management models propose a set of indicators that facilitate quantitative and qualitative measurement of intangible assets, among them are knowledge resources that are also subject to estimation.

The last element of the process is *the use and development* of intellectual capital with the supporting role of management methods, manners and techniques that facilitate creation of the value of human and structural capital. At this stage, the integration of both concepts is most visible, as knowledge management is becoming the leading concept supporting effective management of intellectual capital, consisting of creation, accumulation and use of knowledge (use of knowledge management strategies and methods is also important). Integrated intellectual capital management and knowledge management assumes a combination of the components of both concepts, indicating a close relationship between creating the value of an organization based on intangible assets. The assumption that an enterprise is able to create its value based on the intellectual capital at its disposal is becoming dominant only when all its components will coexist, cooperating harmoniously, also in connection with the knowledge management process, leading to transparent flows between individual components. The degree of this cooperation ensures effectiveness of integrated management implementation, and value is created not only directly from the operation of individual components of knowledge and intellectual capital, but from the entire system of interactions between these elements. Cooperation should be expansive, dynamic, continuous and holistic.

Transformations of knowledge and their relationship with intellectual capital

The basic problem in effective management of intellectual capital and knowledge are multidirectional exchanges within various types of knowledge, called knowledge conversion. The main roles in this process are played by *tacit and explicit knowledge*.

Tacit/hidden knowledge is of a process-dynamic character, but it is also primary and personal. It is invisible, difficult to express, articulate, present, identify, and is not subject to traditional codification. It is usually used intuitively, involuntarily, subconsciously. In principle, it is impossible to copy fully and follow. It is based on accumulated experience, daily activities, practical skills, intuition and individual level of intelligence. It usually occurs in two forms: non-codified skills and abilities as well as beliefs, views, thoughts, insights, patterns of reasoning and behaviour and thought models. It should be spread and obtained by accompanying the master, observing and codifying his judgements that value phenomena and problems, ways of formulating thoughts, views, approaches to problem solving, behaviours, choice of words, used associations, references to analogies, metaphors, models. Transferring tacit knowledge requires the use of various means of communication, primarily conducive to informal, spontaneous and personal contacts.

Explicit/available knowledge is of a static-receptive character, it is secondary and impersonal, visible and easy to identify, express, articulate, formalize and present, it is subject to codification. It is created by understanding tacit knowledge and giving it functional features, ensuring its universal use by various users in different problem contexts at different times. It is based on developed and widely accepted rules, principles, algorithms, processes and procedures. It is used consciously, deliberately, taking into account premises, effects and limitations. Explicit knowledge occurs in the form of organizational documents (e.g. organizational regulations, position descriptions), programs, reports, codes of conduct, instructions. It is spread and obtained by others mainly through access to relevant documents saved in paper or electronic form. The transfer of explicit knowledge is primarily ensured by available information technology.

Nonaka and H. Takeuchi distinguish four ways to convert knowledge (Nonaka and Takeuchi 2000, pp. 85-98):

- from tacit/hidden knowledge to tacit/hidden knowledge (socialization);
- from tacit/hidden knowledge to explicit/available knowledge (externalization);
- from explicit/available knowledge to explicit/available knowledge (combination);
- from explicit/available knowledge to tacit/hidden knowledge (internalization).

Socialization is a process of sharing experience, and thus creating tacit knowledge such as mental models and skills. An individual can acquire tacit knowledge directly from others, without using language, through observation or imitation. Experience, emotions and the context of specific meanings that help to adapt one's own thoughts and cognitive codes to other people's thinking are crucial in acquiring tacit knowledge. In *intellectual capital management*, it is important to anticipate (at identification, use and development stages) that among current and acquired human resources there are individuals with specific mental characteristics and skills. Socialization takes place both in direct contact on the employee-manager line and in conscious creation of specific thought patterns embedded in organisation cultural values in teamwork and in written but also invisible principles of its operation (structural capital). It is important here to respect cognitive codes of members of an organization, as well as their formation for needs of synchronization, to get out from employees reserves of their knowledge, transferable into specific solutions and activities.

Externalization is a process of expressing tacit knowledge with the help of available concepts. It is a complex process of creating knowledge in which tacit knowledge is made available through metaphors, analogies, concepts, models. Externalization is usually initiated through dialogue or collective thinking in the process of developing ideas (combining deduction and induction). When *managing intellectual capital*, it is important to implement such methods and tools as: competence management, coaching,

mentoring, but also to provide training in which model, image and abstract forms of presenting concepts are used.

Combination is a process of organizing and incorporating a concept into a specific knowledge system. It includes combining various components of explicit knowledge. Individuals share knowledge through conversations, documents, meetings and IT networks. Processing of explicit knowledge through selection, unification and categorization of information can lead to the emergence of new knowledge. It is important to encourage employees to share their insights, thoughts, suggestions and raise objections (*human capital*) by creating appropriate organizational conditions (*structural capital*).

Kombinacja to proces porządkowania i włączania koncepcji w określony system wiedzy. Obejmuje on łączenie różnych składników wiedzy dostępnej. Jednostki dzielą się wiedzą za pośrednictwem rozmów, dokumentów, spotkań, sieci informatycznych. Przetwarzanie wiedzy dostępnej w drodze selekcjonowania, ujednolicania i kategoryzowania informacji może prowadzić do powstania nowej wiedzy. Ważne jest mobilizowanie pracowników do dzielenia się swoimi spostrzeżeniami, myślami, propozycjami, zgłaszania zastrzeżeń *(kapitał ludzki)* poprzez tworzenie odpowiednich warunków organizacyjnych *(kapitał strukturalny)*.

Internalization is a process of incorporating explicit knowledge into tacit knowledge. It is closely related to learning by doing. When experience, due to socialization, externalization and combination, penetrates the ground of individual tacit knowledge, in the form of shared mental models or skills – it becomes a useful resource. Conversion of explicit knowledge into tacit is supported by verbalization, record in documents, as well as verbally transmitted stories. Documentation helps people to internalize what they have experienced, thus enriching their tacit knowledge, and also facilitates the transfer of explicit knowledge to other people, helping them indirectly experience the experience of others. However, for creation of organizational knowledge to be effective, tacit individual knowledge must be socialized by other team members, which begins another spiral of knowledge creation (cf. Nonaka and Takeuchi 2000, pp. 86-93). Internalization is the foundation of an organizational knowledge creation loop. It can be a virtually never ending process which, after proper design (making employees aware and creating an environment for directing employees' intellectual products - *human capital embedded in structural capital*) is self-propelling when habits of creating, codifying and transferring knowledge are developed.

Creating organizational knowledge is a constant and dynamic interaction between tacit and explicit knowledge. This interaction is shaped by transfers between different conversion methods. These, in turn, are activated by several forces. Conversion through socialization begins with building a field/ground of interaction that facilitates dissemination of experiences and mental models of organization members. Externalization is initiated by meaningful dialogue or collective reflection, where the use of an appropriate metaphor or analogy helps team members to articulate knowledge that would be difficult to convey without it. Combination is created by combining new and already existing knowledge and is expressed in a new product, service or management system. Finally, learning by doing triggers internalization.

Knowledge Transfer Grid in Enterprise Intellectual Capital Management

A knowledge transfer process combines transmission, i.e. presentation and sending of knowledge and its absorption, i.e. acceptance. Transmission involves acquisition of knowledge from a database or other element of a knowledge management system and sending/transfer or presentation of knowledge to a potential recipient. Then there must happen absorption or acceptance of knowledge and its assimilation for later use. If knowledge is not decoded and accepted by a recipient, despite the fact that transmission has taken place, one can not recognize it as a transfer. To transfer knowledge, it is necessary for both processes to occur (Morawski 2006, p. 166)). Knowledge can be transferred in a variety of ways, and it is not difficult to transfer explicit, decoded and formalized knowledge, but, on the contrary, tacit, encoded and informal knowledge.

An enterprise in which intellectual capital is managed uses its intellectual assets in the form of character traits, abilities, skills, cognitive code sets, experience, rational verification of reality, intuition of its employees, noticing variety of their intellectual profiles and diversity of their needs. Bearing in mind their well-being, a managers bring out the best from them in order to use these values for measurable effects in an enterprise's operation and, consequently, its growth and development. In an enterprise that treats individuals as a dynamic whole, opportunities to share knowledge thanks to teamwork, shared training, close contacts, and informal meetings are provided, while at the same time striving for comprehensiveness and flexibility of an individual in performing tasks. Solutions that provide every human resource with access and a possibility of using mechanisms that enable him/her to achieve his/her full potential taking part in enterprise's operations, as well as help in activating hidden resources and focusing on strengthening their value, creating structural conditions and applying properly selected actions, methods and techniques are invaluable in this aspect.

Knowledge transfer can occur in various forms and depends on the type of knowledge, but also on organizational, management and social conditions. Integration of intellectual capital management and knowledge management results in an impact of knowledge transfer directions on the realization of an intellectual capital management process.

Identification of relationship areas between components of intellectual capital can be carried out by exploring *the knowledge transfer grid* (cf. Sbeiby 2001, pp.348-353), in which the following configurations matter:

- *knowledge transfer between employees*, i.e. the relationship between *human capital - human capital*, both in the configuration of *individual human capital - group human capital* and *human group capital - individual human capital*. The important question here is: *how can transfer of competences and knowledge among employees, management staff (at different levels and among them), and between management staff (at different levels and among them) and employees take place*?

- it is facilitated by building an efficient communication and IT network, but also, above all, building trust in an organization, encouraging teamwork and facilitating it, creativity and creative solutions, interdisciplinarity of employees, position rotation, adaptation programs, communication training.

- *Transfer of employees' knowledge and individual competences from them to the internal structure*, in the configuration: *human capital - internal structural capital*. The important question is: *how can one stimulate intellectual activities of employees and managers towards creating the internal structure?*

-enabling conversion of individual competences into management patterns and tools by creating strong organizational values (organizational culture) and strategic solutions, as well as using favourable management methods (e.g. human resource management, including competence management, talent management, coaching, mentoring, but also innovation management, including social innovation). It is also creation of best practices, databases and procedures whose principles of operation and use can be easier and more efficiently spread among employees.

- *Transfer of employees' knowledge from them to the external structure,* in the configuration: *human capital - external-relational structural capital.* The important question is: *how can employees create relationships with an enterprise environment participants, enriching competence of customers, suppliers, etc.?*

- it is facilitated by methods helping employees to provide information on products, organization of trainings, courses, seminars on products, ensuring customer education in this area, reducing bureaucracy and information bottlenecks, but also creating positive relationships with other stakeholders from an enterprise's environment by identifying their goals, expectations, scope of power. It also means formulating and applying effective marketing strategies.

- *Transfer of knowledge from the internal structure to employees and their individual competences,* in the configuration: *internal structural capital - human capital.* The important question is: *how to*

increase intellectual potential of employees through the use of organizational systems, methods and tools?

- here one must focus on improving interpersonal relationships, the flow of knowledge and information, but also on computer links, process learning, improving system interfaces, simulations and interactive tools. Competences that are in the system must be available to others so that they can increase their ability to act.

- *Knowledge transfer in the internal structure,* in the configuration: *internal structural capital - internal structural capital.* The basic question is*: how to effectively integrate processes, products, management concepts, organizational tools?*

- it is facilitated by integration of management concepts, an organizational structure adequate to the type and direction of activity (process-ability, short paths of information flow), a consistently implemented and used strategic program with strong values, creating awareness among employees of coherence, community and importance of information flow, building integrated IT systems, database availability, reconstruction of functional office systems, especially those related to customer service, etc.

- *Transfer of knowledge from the internal to external structure,* in the configuration: *internal structural capital – external structural capital - relational.* The basic question is: *how do organizational processes, systems, etc. improve relations with key stakeholders?*

- this type of transfer is favoured by well-organized customer service processes (customer databases, after-sales service, loyalty programs, etc.), cooperation with suppliers (long-term cooperation programs), marketing activities, identification of stakeholder expectations and application of social responsibility programs targeted at specific individuals and groups directly and indirectly interested in the activities of an enterprise.

- *Transfer of knowledge from the external structure to employees,* in the configuration *external structural capital - relational - human capital.* An important question: *how do stakeholders enrich knowledge and competence of employees?*

- firstly, it should be assumed here that stakeholders provide not only material values to an enterprise, mainly in the form of money, but also intangible assets. Employees can get ideas, new experience, opinions about a product, sometimes suggestions for its improvement, new technological knowledge from them. It is mainly facilitated by creating and maintaining good personal relationships between an organization employees and the environment participant. It is about creating procedures that regulate acquisition of knowledge from the environment (for example, entering the role of a client, pilot projects, engaging clients in the client development process, understanding the language of clients, etc.). Quite often, however, such procedures regulating acquisition of knowledge from the environment are dispersed, immeasurable and have a slight impact on the strategy formulation process.

- *Knowledge transfer from the external to internal structure,* in the configuration *structured capital - relational external - internal structural capital.* That is why the important question is: *how can knowledge and competences of key environment participants be used to improve the internal intellectual architecture - processes, systems, products?*

- it can be done by means of obtaining information from market participants as feedback on the quality of products offered by an enterprise, e.g. opinion polls, customer satisfaction surveys, telephone switchboards registering and interpreting customer complaints, cooperation with other enterprises / organizations to generate new ideas, joint research and development projects etc.

- *Knowledge transfer in the external structure,* in the configuration *external structural - relational - external relational structural capital.* Therefore, the key question is*: how to ensure transfer of knowledge between enterprise's stakeholders?*

- communication between stakeholders can have a great impact on the success of an organization, which should support growth of competences, e.g. clients, suppliers, and affect transfer of competences between stakeholders that contribute to the value of external-relational capital. It is important in this case to focus on partnership, cooperation, alliances, improving the image, brand and quality of products, conducting courses and seminars on products and technologies, organizing meetings to which loyal, regular, "old" clients, suppliers and others contractors are invited (but also those who are new, undecided and even dissatisfied with products offered by an organization), providing seminars promoting an enterprise's offer among local community, support programs for local community, programs for retired, former employees, etc.

Conclusion

Prioritizing intangible assets in enterprise management obviously does not exclude or limit existence and use of tangible assets. But it encourages competent combining and balancing both to create unique competences. And the key competence of an enterprise in the area of this "balancing" of resources and "emphasising" the intangible dimension can be effective management of intellectual capital and knowledge, integrated into the intangible asset management system of an enterprise. Knowledge-based intellectual capital is a multi-dimensional and dynamic category, hence it is subject to transfer processes both within an enterprise and between it and the environment. As it is a category that somehow constitutes enterprise's intelligence, it should be supported by the process of organization learning, combining its individual dimensions, but also facilitating transfer of knowledge.

In conclusion, it should be stated that managers have to solve the following dilemmas (cf. Perechuda 2005 pp. 62-64; 87-89; 93;102-103):

- *Creating tacit knowledge.* Tacit knowledge continually created at all levels of enterprise management is most often created unconsciously, which means that a significant part of it is incompatible with the bundle of enterprise's goals. However, its creation is a positive phenomenon, because it expands employees' individual awareness and collective awareness. The basic criterion for success is to create opportunities for employees to create their own tacit knowledge, as well as to create mechanisms to verify usefulness of knowledge and outflow of worn out internal knowledge.
- *Intuitiveness of tacit knowledge* is available through the use of intuitive cognitive techniques, it requires seemingly static cognitive self-reflection. Tacit knowledge in an enterprise is created from within, and its effectiveness is based on its internal circulation, its external transfer is irrelevant, and sometimes it can be dangerous. Explicit knowledge obtained through rational methods can, deceptively, have little practical value or it can require internationalization that is "subjective digestion" (being the reason of, among others, ineffectiveness of many modern management concepts and methods imposed on employees by top management and consulting companies).
- *Filtering knowledge through organizational structures.* Tacit knowledge generated by employees must be diffused within an enterprise in all directions. Knowledge must be created and consumed in real time. The most useful are process structures, flattened, matrix, network, virtual and fractal. However, these are highly fuzzy structures that give a lot of freedom to the members of an organization, and therefore require them to be more knowledge workers than simple executives of managerial orders.
- *Lifting mental blockades, changing organizational culture and strengthening strategic direction.* The basic determinant of implementation and realization of the intellectual capital and knowledge management concepts is a change in an organizational culture, which is associated with an extremely difficult and evolutionary change in employees' mentality from passive to practical and creative. A strategic direction is necessary to adopt strong organizational values and ways to achieve competitive advantage through implementation and realization of personalization and codification strategies. The most valuable knowledge is developed inside an enterprise, which gives an opportunity to give up imitation and emulation strategies and increases possibilities of control over the near and distant environment segments. In this type of enterprises, so-called "information filters" are created, which select inflows and outflows of managerial, economic, social, political, technical and technological knowledge, etc. Maps of strong-signal signals (strategic, significant) and low-signal signals (irrelevant, so-called "information garbage") are also created, enabling efficient selection of knowledge.
- *Indivisibility of knowledge and a need to share it.* An immanent feature of knowledge is its indivisibility; it is of a holistic character, which means that it is homogeneous. In addition, it is created for here and now and is non-transferable, and usually information about knowledge and its creation is transferred. But on the other hand, the "illusionary" optics of knowledge assumes its inexhaustibility and simultaneity. A type of knowledge and a wider situational context of knowledge management are relevant in resolving this dilemma.

The problems identified above are correlated with both the intellectual capital dimensions in the form of human and structural capital, and the management triad, i.e. identification, measurement, use and development. One of the most important effects of multidimensional transformations should be a change of employees and management staff's behaviour, whose natural consequence will be changes within an enterprise (organizational, social, etc.) that can lead to the transfer of a traditional organization into a learning organization and further into an intelligent organization managed with full awareness of intangible asset importance. Success in the process of transforming knowledge and intellectual capital, the quality and dynamics of its course will depend on a number of internal and external factors of a social, organizational and systemic character, etc. Identification of these factors will also certainly facilitate a reliable assessment of the process. The review character and limited scope of the study did not exhaust the described issues. There is a need to indicate its methodological, empirical and application aspects, i.e. research assumptions and results of empirical research together with a list of recommendations for managers in various types and groups of organizations.

---

[1] Other suggestions for components of the knowledge management process include, among others: knowledge localization, acquisition, development, sharing and spreading, use, preservation (according to G. Probst, S. Raub, K. Romhardt); acquiring knowledge from the environment, using knowledge in an organization, estimating knowledge assets in an organization, maintaining and developing knowledge assets, selling knowledge in the form of new products, technology services (according to W.R. Bukowitz, R.L.Williams), organization learning, knowledge production, knowledge distribution (according to M. Sarvay), acquiring knowledge, sorting and classifying knowledge, filtering, gathering, synthesis and organization of knowledge, storage, distribution (according to Ernst & Young), identification of knowledge sources, creation, formalization, sharing and spreading, use, application of knowledge, learning (according to KPMG), knowledge acquisition, knowledge localization, knowledge creation, use of knowledge, retention (according to B. Buckman) (see, among others: Davenport and Prusak 1998; Bukowitz and Williams 2000; Probst, Raub and Romhardt 2002; Grudzewski and Hejduk, 2004; Sokołowska 2005 a, pp. 166-167).

[2] Human capital is knowledge, experience, presence and possibilities of human activity in an organization. It is also a combination of traits brought by an employee (intelligence, commitment, energy, positive attitude to life, reliability, honesty, credibility), an employee's ability to learn (absorbency of the mind, imagination, ability to think analytically, creativity), employee motivation to share knowledge, ability to work in a team, pursuit of goals. Capital is the property of employees, it cannot be appropriated, it can only be subject to "lease" (Sokołowska 2005, p. 17).

[3] Structural internal capital is technologies, methods and processes that enable an enterprise to function. Examples include organizational culture, company history, management concepts and methods, organizational structure, trade secrets, patents, licenses, design rights, copyrights, trademarks and service marks, innovation, and the ability to organization learning. External-relational structural capital is e.g. commercial brands, clients and their loyalty, relationships with clients and other stakeholders, contracts and agreements, marketing strategies, including product quality shaping, pricing strategies, distribution channels, promotion measures that are used, enterprise reputation and image (Sokołowska 2005, p. 18).

[4] Other divisions are: intellectual capital assigned to an individual (individual capital), intellectual capital assigned to an organization (structural capital) (according to Konrad Group in Konrad Report), internal structure, external structure, individual competences (according to Sveiby in Intangible Assets Monitor), customers, enterprise's internal structure, processes: learning and innovation, finance (according to Kaplan and Norton in Balanced Scorecard), human capital, structural capital (according to Edvinsson in Scandia value scheme, the foundation for Navigator), human capital, client capital (relational), organizational capital (structural) (authors: Petrash, Edvinsson, Onge, Armstrong, Bukowitz, Williams in the Value Platform), competences, mutual relations (according to Haanes, Lowendahl in the classification of intangible assets), market assets, human factor assets, infrastructure assets, market value (according to Brooking in identifying components of human capital), human capital, structural capital, customer related capital (according to Stewart in identifying components of intellectual capital), social capital, human capital, organizational capital (according to Bratnicki and Strużyna in the company value tree)), human capital ("thinking assets"), structural capital ("non-thinking assets") (according to Ross in measurements of the intellectual value of an enterprise), human capital, intellectual assets, intellectual property (author: Sullivan, in elements of intellectual capital (cf. . Edvinsson and Malone 2001; Bratnicki and Strużyna 2001; Ross and Ross 1997; Stewart 1997; Brooking 1996; Kaplan and Norton 2001).

[5] And so, for example: Konrad Report is an uncomplicated model with transparent rules, which was the starting point for creating the new ones; good at the beginning of the "struggle" with measuring immeasurable; its special features are: a clear strengthening of the intellectual capital position assigned to an individual and relatively small instrumentation for creating human and structural capital. On the other hand, Intangible Assets Monitor clearly touches on accounting issues, most of the proposed indicators match the reality and extensive structures of large

enterprises, the division of the indicators into: growth and renewal, efficiency and stability allows to capture development trends and the intellectual layer condition of an enterprise's activity, but some of the proposed indicators are unintelligible. Balanced Scorecard are a model with an interesting proposal of qualitative indicators, emphasizing the area of clients, the internal structure as well as the process of learning and innovation as a place for seeking competitive advantage; the model concept is directly related to an enterprise's strategy and its development vision, and the implementation procedure is adapted to construction and functioning of large enterprises, etc.

Résumé

La présente recherche étudie l'image d'une destination touristique libanaise, la ville de Tyr. Afin de comparer les différences existantes entre l'image complexe par les visiteurs de la destination et l'image voulue par la municipalité de la ville, deux études complémentaires ont été effectuées. Les résultats obtenus ont montré l'existence d'une divergence significative entre des composantes essentielles de l'image perçue et celles de l'image désirée de la ville, et par le fait même la nécessité d'un apport d'améliorations au niveau opérationnel et commercial pour garantir une satisfaction des touristes et susciter l'intérêt des touristes potentiels pour cette ville.

Mots-clés : Image Induite, Image complexe, Destination touristique, Tyr-Liban.

Introduction

Le marketing touristique intéresse la plupart des villes du monde et en constitue, pour plusieurs d'entre elles, la base de leurs rentrées touristiques (Frochot et Legohérel 2017). Dans un contexte de compétition touristique mondiale, certaines destinations touristiques tentent de s'imposer en développant des stratégies d'attraction. Se distinguer en créant une image forte, devient aujourd'hui pour toute destination, un objectif capital (Bédard 2011). Cette image requiert une stratégie cohérente et de mise en valeur de la ville et ce n'est pas exagéré de dire que pour exister, une destination touristique doit être présente sur la carte mondiale des pratiques touristiques (Piriou 2011). Au XXIème siècle, « vendre une image » aux touristes ne suffit pas. Il faut que cette image soit « partagée » ; plus précisément, l'image « désirée » par les décideurs doit aussi être l'image « vécue » par les touristes (Barthès 2005). À ce sujet, Piriou (2011) affirme qu'une destination touristique ne peut être considérée comme « excellente » que si elle est co-construite par les deux parties. Ainsi, l'image d'une ville est la combinaison de deux images, celle de l'image voulue et celle de l'image perçue. Ces deux images doivent se compléter et doivent donner une même vision de la ville en question (Chon 1991).

La ville de Tyr

Au Liban, la ville de Tyr tente, par le biais des efforts déployés par la mairie, de devenir une destination touristique prisée aux yeux des visiteurs. Connue pour son riche patrimoine, elle cherche à se différencier en créant une forte notoriété. En dépit de ces efforts, l'activité touristique de la ville est en régression. Cette ville n'arrive pas à exploiter convenablement ses sites archéologiques impressionnants, ce qui affecte ses autorités ainsi que tous les acteurs du tourisme qui y sont impliqués et à tous les niveaux.

Dans ce contexte concurrentiel, notre problématique porte sur le fait que l'activité touristique de la ville balnéaire de Tyr n'est pas à la hauteur de son patrimoine exceptionnel et ne fait que régresser. La mairie de la ville est satisfaite du travail entrepris et considère que cette régression est principalement due à la conjoncture du pays, indépendamment de la perception de la ville par les touristes qui l'ont visitée. En se basant sur la perception de la destination de Tyr du point de vue des membres principaux de sa municipalité ainsi que du point de vue des touristes qui ont l'ont visitée, notre objectif est de déceler et d'analyser les différences existantes entre l'image perçue et l'image voulue de la ville. De surcroît, nous visons d'une part à comprendre la situation et à savoir quelles sont les activités que la municipalité implante pour attirer et séduire de plus en plus de touristes et d'autre part comment les touristes locaux et étrangers perçoivent cette destination en termes d'image et de notoriété. Afin de répondre à notre objectif de recherche, nous avons procédé en trois étapes. La première partie présente le cadre théorique de la recherche. La seconde partie détaille la méthodologie de recherche. La troisième partie s'appuie sur les résultats de notre cadre d'analyse ainsi que leur discussion.

Cadre Théorique : Image D'une Destination Touristique

En nous basant sur les travaux antérieurs, nous allons dans une première étape définir et analyser l'image d'une destination touristique puis, dans une seconde étape identifier ses différentes composantes.

Définition de l'image d'une destination touristique

L'association d'une image positive et distincte à une destination touristique est un phénomène qui permet à la ville d'occuper un positionnement important dans l'esprit du voyageur. Ceci pousse les destinations à adopter des stratégies communicationnelles dans le but de la création, la valorisation et la promotion d'une image forte et satisfaisante (Leisen 2001).

De nos jours, les villes sont contraintes d'adopter des stratégies de marketing touristique afin de mettre en avant leurs atouts touristiques (Baloglu et Magaloglu 2001). La concurrence entre les territoires expose les villes aux mêmes défis qu'une entreprise ; elles possèdent une image, un nom, un positionnement qu'elles doivent développer afin de mettre en valeur leurs différences. C'est pourquoi il est important d'analyser le processus de formation de l'image d'une destination touristique, ses composantes et ses déterminants (Jenkins 1999).

Il n'existe pas de consensus sur une définition précise de l'image d'une destination touristique. Selon Crompton (1979, p.20) elle représente «*l'ensemble de croyances, d'idées et d'impressions qu'une personne a sur une destination ou la somme agrégée de croyances, d'idées, d'impressions et d'attentes qu'un touriste a à propos d'une destination touristique*». De même, les travaux de Tapachai et Waryszak (2000, p.39) la définissent comme «*les perceptions ou les impressions sur une destination détenues par les touristes sur la base des bénéfices attendus ou des valeurs de consommation*». Finalement, Kim et Richardson (2003, p.218) la représentent comme «*la totalité des impressions, des croyances, des idées, des attentes et des sentiments accumulées au fil du temps sur une destination*».

Nous remarquons à travers cet amalgame de définitions que plusieurs termes comme «impressions», «perceptions», «idées», «conceptions», «sentiments», «attentes» et «croyances» se répètent quand il s'agit de définir l'image d'une destination touristique, ce qui confirme son caractère subjectif,

multidimensionnel et complexe (Bigne et al 2001). L'image d'une destination joue un rôle primordial dans le choix de la destination puis qu'elle constitue un facteur décisif pour le visiteur, affecte sa prise de décision ainsi que ses choix futurs (Baloglu et McCleary 1999 ; Chon, 1990). Ce choix étant lié à la capacité du lieu à véhiculer une image positive capable de susciter l'intérêt du touriste. L'image va de même guider le comportement touristique du visiteur, Hunt (1975), influencer le processus de sélection de la destination ainsi que ses intentions comportementales (Qu et al 2011 ; Wang et Hsu 2010). La stratégie marketing touristique mise en place par la destination doit être placée au centre des stratégies de la destination en question. La formation de l'image résulte de plusieurs facteurs interagissant ensemble, comme des facteurs physiques, historiques et culturels (Kotler et al 2017).

Par ailleurs, l'image d'une destination touristique est aussi influencée par les distances culturelles que partagent certains territoires et qui affectent les préférences et les comportements des touristes (Crotts, 2004). De surcroît, cette image qui selon Richardson et Crompton (1988) change en fonction de la nationalité et des origines du touriste, est formée grâce à la combinaison des caractéristiques physiques ou fonctionnelles de la destination en question (Crompton 1979). Cela nous mène à dire que plusieurs motivations interviennent de manière consciente ou inconsciente, directe ou indirecte, lors de la formation de l'image d'une destination touristique (Moutinho 1987 ; Baloglu, 1997 ; Gartner 1993). L'image d'une destination touristique n'est alors que l'ensemble des perceptions des attributs individuels de la destination et l'impression globale qu'elle reflète Echtner et Ritchie (1991).

Les composantes de l'image d'une destination touristique

Gunn (1988) affirme que l'image d'une destination touristique évolue en fonction des étapes du processus d'achat et qu'elle est capable de créer une confusion chez le touriste potentiel et rendre son choix difficile. Il distingue entre trois différentes composantes de l'image qui sont l'image organique, l'image induite et l'image complexe. L'image organique provient de l'exposition du voyageur à des informations non touristiques. C'est l'image formée dans l'esprit du visiteur, avant d'avoir effectué le déplacement. Il s'agit d'une image souvent incomplète qui peut être influencée par l'image du pays et qui est parfois difficile à modifier par les acteurs touristiques. L'image induite est diffusée par la communication des acteurs touristiques. Elle a pour objectif de «vendre la destination» mais aussi d'agir sur l'image organique formée initialement et la changer pour inciter le touriste à voyager. La médiatisation de la destination lui apporte donc une multitude d'images encourageant le déplacement du touriste à travers de nombreuses informations qui l'aideront à se projeter dans le lieu choisi (Violier 2007). L'image complexe est formée suite au voyage du visiteur ; elle joue un rôle dans l'appréciation de la destination ainsi que dans son évaluation et est capable de modifier les images organique et induite. C'est à partir de son séjour que le touriste pourra développer une image positive ou négative du lieu visité (Frochot et Legohérel 2017). C'est pourquoi, il existe une grande différence entre l'image formée avant et après la visite de la destination qui s'explique par le manque de connaissances et d'informations de la part du voyageur.

L'image complexe qui reflète la véritable image d'une destination touristique est selon Chon (1991, p.72) «*plus diversifiée, plus différenciée et plus réaliste que les précédentes car seul le séjour permet de l'évaluer*». Elle provient de l'expérience personnelle du touriste lui laissant la possibilité d'évaluer correctement la destination en question (Marchat et Camelis 2017). Cette image représente la réalité de la destination touristique et joue un rôle primordial dans les intentions de recommandation et de revisite qui, selon Qu et al (2011) sont à l'origine de la fidélité du visiteur (Lee 2003). Pour saisir les comportements des touristes Prayag et Ryan (2012) parlent de «*l'intention de revisiter la destination*», de «*l'intention de la recommander à d'autres*» ou encore du «*bouche à oreille*» qui, s'il est intentionnel, représente un indicateur pertinent de fidélité (Chen et Phou 2013). Certains auteurs comme George et George (2004) ; Veasna et Huang (2013) ont affirmé que l'image est capable de provoquer des « émotions fortes » qui renforcent l'attachement et la fidélité du voyageur. Ces « sentiments forts » développés par les visiteurs, représentent une véritable source de liens émotionnels (Yuksel et al 2010). À la fin de cette revue il serait prudent d'explorer, à travers les lunettes du touriste, l'image globale d'une destination, cette image qui qui a un caractère multidimensionnel et subjectif est, selon Stylidis et al (2017) la base du succès d'une destination quelconque dans l'attraction des touristes.

Cadre méthodologique : Cas de la ville de Tyr

La ville de Tyr

Appelée « Reine des Mers », la ville de Tyr jouit d'un patrimoine historique et culturel très riche. La ville possède un potentiel touristique remarquable que les membres de la municipalité essayent d'exploiter et de développer à travers la diversification des activités touristiques présentes dans la ville. Cette revue de littérature nous conduit à formuler notre question principale à laquelle cette recherche vise de répondre :

Compte tenu du potentiel touristique remarquable de la ville de Tyr, quels sont les éléments d'attractivité touristiques que les décideurs doivent renforcer afin que Tyr occupe la place d'une destination compétitive et dont l'image complexe reflète le positionnement aspiré par la municipalité ?

Méthodologie

Nous avons privilégié dans cette recherche la triangulation qui consiste à associer systématiquement dans la même étude des méthodes qualitatives avec des méthodes quantitatives (Caillaud et Flick, 2016). Ceci permet de recueillir des informations et des données provenant de différentes sources en faisant usage à plus d'un outil afin de les confronter pour pouvoir dégager les informations capables de nous donner une réponse à notre questionnement de recherche. Comme il existe différents modèles de recherche s'appuyant sur les méthodes mixtes (Tashakkori et Teddlie 2010 ; Creswell 2009), nous avons adopté un modèle qui s'appuie sur le principe de complémentarité. Ainsi deux études une qualitative et une quantitative, ont été effectuées pour saisir et analyser la perception des touristes visitant la ville de Tyr et de ce fait répondre à la problématique de la recherche.

L'étude Qualitative

Il s'agit d'une étude exploratoire qui a été réalisée par le biais de trois entretiens semi-directifs qui s'appuient sur un guide d'entretien dont la revue de littérature a facilité son élaboration. Ces entretiens ont été menés auprès du directeur adjoint de la municipalité de Tyr (D.ad), du responsable du tourisme au sein de la municipalité (R.t) ainsi que du directeur des sites archéologiques de Tyr et du Liban Sud (D.sa). L'objectif était de saisir l'image de la cité telle que désirée par la municipalité et d'en tirer les informations concernant les divers attraits touristiques de la ville. Le traitement des données recueillies a été effectué par le biais de l'analyse de contenu (Bardin 2013). Les entretiens ont été enregistrés suite à l'accord des personnes interviewées. Chaque entretien était mené en face à face et a duré entre 60 et 90 minutes. Après une lecture attentive de tous les propos recueillis, une analyse thématique a été effectuée pour ressortir des «unités de sens - éléments clefs» dont l'occurrence est significative. Les éléments clés principaux ont été regroupés en variables afin de formuler les hypothèses à tester et à développer le questionnaire ayant servi à recueillir les données de l'étude quantitative.

L'étude Quantitative

L'étude quantitative menée sur un échantillon de 118 individus durant la période s'étendant entre le 15 avril 2019 et le 10 juin 2019, a constitué la seconde partie de cette recherche. L'analyse statistique descriptive élaborée a permis de présenter les caractéristiques socio-démographiques et les motivations des personnes appartenant à l'échantillon puis à travers une analyse statistique inférentielle à tester les hypothèses déduites de la seconde partie d'un questionnaire auquel les touristes visitant la ville de Tyr ont pu répondre durant leur séjour. Ce questionnaire a constitué l'outil qui a permis de déceler l'image complexe de la cité par les touristes. Il a été élaboré suite aux résultats obtenus par différents entretiens réalisés au préalable.

Le questionnaire comprenant 18 questions a été développé en français et en anglais en trois sections. La première section comporte des questions qui concernent le séjour et les motivations du visiteur. La seconde partie comprend 18 affirmations pour l'évaluation des opinions des touristes vis-à-vis des

composantes de l'image perçue de la ville de Tyr. Ces items sont incorporés à une échelle de Likert comprenant 5 options de réponses (allant de 1 «Tout à fait d'accord» jusqu'à 5 «Pas du tout d'accord») pour lesquelles le répondant exprime son degré d'accord ou de désaccord. La troisième partie comprend des questions d'identification qui concernent le touriste.

Pré-test du questionnaire

Avant d'administrer le questionnaire à notre échantillon, nous avons effectué un pré-test sur onze individus. L'objectif était d'augmenter la validité des données de l'enquête en réduisant les erreurs de mesure, et de ce fait augmenter la validité des conclusions dérivées (Snijkers 2002, p.224).

En focalisant sur la façon dont les gens répondaient à nos questions et les interprétaient, ce pré-test nous a fourni les preuves les plus directes de la validité des données du questionnaire pour la plupart des items. Notre procédure était basée sur l'approche rétrospective de l'interview cognitive où nous avions posé des questions verbales à tous les participants après avoir rempli le questionnaire.

Administration du questionnaire

Le questionnaire a été administré en face à face aux touristes et visiteurs dans les hôtels de Tyr où ils résidaient (25 répondants) ainsi que dans les sites touristiques et archéologiques qu'ils fréquentaient (40 répondants). Le même questionnaire, créé sur *Google Forms* a été administré en ligne aux visiteurs qui ont exprimé leur désir de répondre ultérieurement (53 répondants). Il n'y a pas eu de cas de refus et tous questionnaires ont été remplis complètement.

Ces deux études complémentaires avaient pour objectif de confronter l'image perçue de Tyr par les touristes avec l'image désirée par les membres de la municipalité et les responsables des sites touristiques de la ville. Cette démarche nous a non seulement permis de faire cette confrontation, mais également de formuler des recommandations utiles sur le positionnement de la ville.

Choix des échantillons

Le choix des participants de l'étude qualitative a été fait par choix raisonné, c'est-à-dire non aléatoire. Il a été réalisé sur la base d'une caractéristique particulière (Fortin et al 2005) qui est essentiellement leur compétence et expérience dans le domaine du tourisme à Tyr. C'est en fonction de la richesse et de la pertinence de l'information que les informateurs-clés dans cet échantillon ont été sélectionnées. Cependant, le nombre de ces participants n'a pas été décidé à l'avance puisque la représentativité statistique n'en était pas essentielle. La taille de l'échantillon (trois personnes interviewées) a été déterminée en fonction de la saturation (Bertaux 1981 ; Savoie-Zajc 1997) obtenue par les données recueillies qui n'apportaient plus de nouvelles informations au bout du troisième entretien.

L'échantillon de l'étude quantitative a été choisi aléatoirement et sur la base de la définition donnée par l'Organisation mondiale du tourisme (OMT) sur le tourisme comme étant les activités de loisir, d'affaires ou autres et qui sont «*déployées par les personnes au cours de leurs voyages et de leurs séjours dans les lieux situés en dehors de leur environnement habituel pour une période consécutive lqui ne dépasse pas une année*» (Lozato-Giotart et al 2014, p.6). Nous avons donc choisi les répondants au hasard. Il s'agissait des voyageurs « visitant » rencontrés à Tyr définis par les mêmes auteurs comme étant l'ensemble des voyageurs ou touristes dont la visite n'entraîne pas une nuit passée, ceux qui passent 3 nuits consécutives et ceux dont le déplacement entraîne au moins quatre nuits consécutives hors du domicile habituel (Lozato-Giotart et al 2014, p.7). Ils incluaient des étrangers et des libanais vivant au Liban ou résidant à l'extérieur du pays mais venant en visite à Tyr.

Plusieurs auteurs s'accordent que des variables ordinales avec cinq catégories ou plus du type Likert, peuvent souvent être considérées comme continues et utilisées sur cette base sans que ceci puisse nuire à l'analyse dans laquelle on prévoit les utiliser (Norman 2010 ; Sullivan et Artino 2013 ; Chimi et Russel 2009). Pour les données continues, Bartlett et al (2001) ont déterminé la taille minimale de

l'échantillon comme étant 119 pour une population ≥ 10 000 et pour un niveau α = 0,05. Le choix de notre échantillon composé de 118 individus correspond donc à cette catégorisation.

La présentation des résultats de l'étude qualitative

Les informations collectées grâce aux entretiens réalisés ont permis de mettre en lumière l'image de la ville telle que projetée par la municipalité. Elles ont de même permis d'identifier les éléments sur lequel repose le potentiel touristique de la ville. Elles ont été regroupées par thèmes et analysées à l'aide d'une grille d'analyse. Les trois personnes interrogées ont mis l'accent sur plusieurs éléments clés constituant le tourisme à Tyr. Ces éléments regroupés par thèmes et illustrés par des verbatim tirés des propos des interviewés sont récapitulés dans le tableau 1.

Le D.ad et le R.t se sont mis d'accord pour affirmer que la ville de Tyr a été placée au premier rang au niveau touristique pour l'an 2018 et qu'elle fait partie de l'une des plus belles villes touristiques du Liban grâce à sa plage, ses quartiers anciens, ses souks et son port traditionnel. Ils ont également précisé que malgré sa petite surface, la ville de Tyr renferme une diversité d'activités touristiques culturelles et balnéaires. De son côté, le D.st nous a expliqué que la particularité des sites archéologiques de Tyr réside dans le nombre et la diversité des civilisations qui l'ont traversé, dans leur emplacement et leur dimension mais aussi dans leur conservation car il s'agit de ruines qui datent de plus que mille ans. Tous les interviewés s'accordent à dire que les mesures proposées par la municipalité pour la mise en valeur et la protection du patrimoine de la ville sont suffisantes mais ils attribuent la faiblesse de la fréquentation touristique de la ville au contexte de crise économique et financière qui prédomine dans le pays.

Tableau 1 : Les thèmes abordés illustrés d'un extrait de *verbatim* et complétés par les éléments clefs ressortis.

Thèmes	Verbatim	Les éléments clés ressortis
Patrimoine historique	*«Patrimoine historique très riche inscrit à l'UNESCO.»* *«C'est le principal atout touristique de la ville de Tyr.»* *«Tyr, l'image importante dans l'histoire, à travers plusieurs civilisations et époques archéologiques.»*	Sites archéologiques inscrits à liste du patrimoine mondial de l'UNESCO.
Diversification du tourisme à Tyr	*«Le tourisme à Tyr est très diversifié et repose surtout sur les activités balnéaires et culturelles, ainsi que plusieurs évènements et festivals.»* *«Présence de quartiers et souk à caractères traditionnels, mais aussi la page et le port.»*	Tourisme très diversifié. Plusieurs activités touristiques, culturelles et artistiques.
Diversité culturelle	*«Diversité culturelle et religieuse à Tyr, vie communautaire multiculturelle, paix civile, liberté d'expression et politique de fraternité.»*	Une diversité culturelle et religieuse.
Festival de Tyr	*«Evènements diverses très important pour le tourisme, comme le festival de Tyr.»*	Evènement annuel traditionnel très attendu.
Vie nocturne	*«La vie nocturne à Tyr est très animée, les restaurants restent ouverts jusqu'à 2 h durant l'été et les kiosques ne ferment jamais.»*	Très belle ambiance, vie nocturne très animée.
Quartiers anciens	*«Tyr est connue pour ses anciens quartiers comme «Hara», son vieux «Souk» et son ancien port «Sidonien», qui conservent leurs caractères anciens.»*	Souk et Port à caractère traditionnel.
Plage de Tyr	*«La plage représente l'atout principal de la ville de Tyr.»* *«C'est l'une des meilleures et des plus propres plages du Liban.»* *«Emplacement des sites archéologiques face à la plage.»*	Tourisme balnéaire dynamique et plage très propre.
Hôtels de Tyr	*«Hôtels de Tyr offrent un service satisfaisant et sont contrôlés régulièrement.»* *«12 Hôtels très variés, motel, guest house... et l'architecture varie aussi.»*	Variété d'hôtels et motels avec un service satisfaisant.
Restaurants de Tyr	*«Contrôle quotidien et régulier de la qualité au niveau culinaire.»* *«90 Restaurants très contrôlés au niveau de la qualité de la nourriture et de hygiène.»*	Contrôle culinaire régulier. Une alimentation bonne et saine.
Propreté de la ville	*«Contrôle du nettoyage de la ville pour s'assurer du niveau de propreté de la ville.»*	Nettoyage régulier et quotidien des rues.
Sécurité à Tyr **Parking**	*«Tyr est une ville très sécurisée ce qui est agréable pour ses visiteurs.»* *«Sécurité et sûreté importantes pour préserver l'ordre de la ville.»* *«Manque de parking car Tyr est une ville limitée géographiquement.»*	Ville sécurisée par la présence de police. Un manque d'espace pour les parkings.
Circulation	*«Circulation compliquée et beaucoup d'embouteillages.»*	Sérieux problèmes d'embouteillages.
Population locale	*«Population locale très hospitalière et conviviale avec des habitants très accueillants, des interactions et des échanges faciles avec les gens.»*	Habitants accueillants et hospitaliers.
Piétons	*«Présence de trottoirs partout à Tyr.»* *«Corniche rendant agréable les promenades dans la ville.»*	Ville accueillante pour les piétons, présence de trottoirs et corniche.
Prix	*«Prix convenables à toutes les classes économiques et sociales.»* *«Entrées aux sites fixées par le ministère de la culture.»*	Prix convenables à toutes les classes économiques et sociales.

Ces descriptions et affirmations recueillies ont permis d'illustrer l'image touristique désirée de la ville par la municipalité. Elles ont été d'une importance fondamentale pour le déroulement de cette recherche. Leur interprétation a permis de reconstruire l'image induite de Tyr par la municipalité, de révéler son identité touristique et de mettre la lumière sur ses multiples facettes du tourisme.

Variables dégagées et hypothèses formulées

À la suite des éléments clés recueillis par l'étude qualitative, les variables suivantes ont été dégagées : Patrimoine historique, tourisme diversifié, diversité culturelle, festival de Tyr, vie nocturne, quartiers anciens, plage, services des hôtels, propreté de la ville, sécurité, parking, circulation, population locale, sites touristiques, cuisine, accueil, vivacité et prix.

Les hypothèses formulées en fonction de ces variables sont :

H1 Le patrimoine historique de Tyr constitue une composante de l'image perçue positive de la ville

H2 Les sites touristiques de Tyr constituent une composante de l'image perçue positive de la ville

H3 La diversification du tourisme à Tyr constitue une composante de l'image perçue positive de la ville

H4 La diversité culturelle à Tyr constitue une composante de l'image perçue positive de la ville

H5 Le festival de Tyr constitue une composante de l'image perçue positive de la ville

H6 La vie nocturne à Tyr constitue une composante de l'image perçue positive de la ville

H7 Le caractère ancien et traditionnel des quartiers de Tyr constitue une composante de l'image perçue positive de la ville

H8 La plage de Tyr constitue une composante de l'image perçue positive de la ville

H9 La propreté de la ville de Tyr constitue une composante de l'image perçue positive de la ville

H10 Les services offerts dans les hôtels à Tyr constituent une composante de l'image perçue positive de la ville

H11 La cuisine locale saine constitue une composante de l'image perçue positive de la ville

H12 Les parkings à Tyr constitue une composante de l'image perçue négative de la ville

H13 Le caractère accueillant et convivial de la population locale de Tyr constitue une composante de l'image perçue positive de la ville

H14 La vivacité de Tyr constitue une composante de l'image perçue positive de la ville

H15 La circulation à Tyr constitue une composante de l'image perçue négative de la ville

H16 L'accueil à Tyr constitue une composante de l'image perçue positive de la ville

H17 La sécurité à Tyr constitue une composante de l'image perçue positive de la ville

H18 Les prix à Tyr constituent une composante de l'image perçue positive de la ville

Analyse et interprétation des résultats de l'étude quantitative

La base de données obtenue a été traitée sur SPSS et le logiciel tableur Excel. Dans une première phase, des analyses statistiques descriptives portant sur l'aspect socio-démographique ainsi que sur les motivations de l'échantillon des touristes et des visiteurs de Tyr ont été effectuées. Dans une deuxième phase les hypothèses monovariées construites ont été testées grâce à une analyse statistique inférentielle.

Analyse descriptive des données socio-démographiques

Les données obtenues de l'enquête ont été traitées sur le logiciels SPSS et le logiciel tableur Excel. Les résultats statistiques descriptifs révèlent que 70% des répondants ont un âge compris entre 18 et 34 ans et que 95% de ces touristes « visitant » ont un niveau d'études universitaires et sont presque également répartis entre femmes (53%) et hommes (47%). 53% des répondants sont des libanais résidant dans leur pays natal et 70% sont célibataires. Quant au revenu mensuel des touristes, plus de 50% d'eux ont un salaire mensuel qui ne dépasse pas 1500 dollars américains tandis que celui de 18% seulement dépasse les 3000 dollars américains.

Analyse descriptive des motivations des touristes

33% des touristes ont visité la ville une seule fois et 55.% deux fois. Presque 60% des répondants sont restés une seule journée et 84% ont été motivés de la visiter en raison de ses attraits naturels, touristiques et culturels. Parmi les visiteurs 65% ont connu la ville grâce au bouche à oreille tandis que 18% l'ont connu à travers des brochures et 16% à travers internet et les réseaux sociaux. 42% sont venus en famille et 43% en compagnie d'amis.

Ces résultats nous permettent de déduire que le profil général du touriste visitant Tyr est celui d'un homme ou d'une femme indépendant(e) et éduqué(e) appartenant à une génération jeune et qui cherche à découvrir, apprendre et jouir des attractions touristiques à Tyr. Ce touriste « visitant » est du type excursionniste et est fortement motivé par les attraits naturels, culturels et touristiques et de la ville. Il est généralement accompagné soit des membres de la famille soit d'amis. Il a connu Tyr surtout grâce au bouche à oreille mais très peu par le biais d'une documentation écrite ou en ligne ou à travers les réseaux sociaux.

Tests d'hypothèses

18 hypothèses déduites des variables précédemment dégagées ont été testées. L'objectif de ces tests était de déterminer si les variables étudiées forment des composantes de l'image perçue par les touristes et de confronter par la suite les résultats de cette analyse avec l'image désirée par la municipalité de Tyr afin d'en tirer les conclusions. Ces hypothèses monovariées n'ont pas été testées à travers des associations mais à travers des comparaisons entre les réponses des deux groupes de touristes et de voyageurs «visitant » qui ont constitué l'échantillon composé des 118 individus.

L'approche suivie est celle qui a été préconisée par Gosavi (2015). Nous avons utilisé la distribution binomiale pour développer un test de signification statistique. Nous avons en premier lieu inversé la valeur de réponse pour chacun des éléments puis combiné les cinq catégories de réponse en trois (accord, désaccord, neutre) selon deux groupes de répondants $L1$ et $L2$ avec le groupe des répondants «neutres» alternant dans l'analyse statistique avec l'un et l'autre de ces deux groupes. Les proportions de répondants dans chaque groupe ont été calculées afin de tester les hypothèses $H_0 : p_1 \leq p_2$ et $H_1 : p_1 > p_2$ au taux d'erreur $\alpha = 0{,}05$ sur la base du chevauchement ou du non-chevauchement des valeurs délimitant les intervalles de confiance pour les proportions des groupes étudiés de l'échantillon p_i.

Les résultats obtenus seront acceptés car la taille de l'échantillon est > 100 (Gosavi 2015). Sur la base du chevauchement des valeurs des limites minimales et maximales des intervalles de confiance, ces résultats ont permis de rejeter H_0 pour les hypothèses H_2, H_3, H_4, H_5, H_6, H_7, H_8, H_{11}, H_{12}, H_{13}, H_{15}, H_{16},

H_{17}, H_{18} et de ne pas rejeter H_0 pour les hypothèses H_1 (dans la seconde étape de l'analyse) et H_{10} (dans la troisième étape de l'analyse).

Pour les hypothèses H_9 et H_{14}, l'analyse statistique effectuée dans la première étape n'a pas permis de tirer une conclusion définitive quant à savoir si l'hypothèse nulle est vraie ou fausse.

Analyse et discussion des résultats

La confrontation des résultats de l'analyse quantitative avec ceux de l'étude qualitative a permis de souligner les points de différences et de similitudes entre les affirmations faites par la municipalité et les avis des touristes concernant l'activité touristique de la ville. Elle montre que l'image désirée par la municipalité concorde dans la majorité de ses aspects avec l'image perçue par les visiteurs excepté deux aspects qui ne sont pas concordants et qui démontrent une divergence entre l'image désirée et l'image perçue.

Pour les touristes, Tyr est une ville perçue comme ayant un aspect traditionnel à travers ses anciens quartiers, une plage remarquable et des sites impressionnants avec des festivals considérés comme des évènements importants, et dans laquelle le tourisme est diversifié et la vie nocturne est agréable. Tyr est également perçue comme une ville à pluralité culturelle, sécurisée et accueillante avec une population conviviale ayant une cuisine locale saine et où la vie n'est pas chère. Cependant, le patrimoine historique de la ville n'est pas perçu comme étant très riche et les services des hôtels comme satisfaisants. Par ailleurs, les problèmes des parkings et de la circulation sont perçus comme importants.

Selon la littérature existante le produit touristique est défini comme tout bien tangible ou service qui peut être acquis durant un voyage pour satisfaire un besoin ou un désir (Kotler *et al.,* 2017), l'attraction touristique comme un produit associé à un acte de promotion et un touriste (Leiper, 1990) tandis que l'attrait est définie comme toute ressource naturelle et culturelle présente dans une région et qui pourrait contribuer au produit touristique (De Grandpré 2007), et ce indépendamment de la présence des touristes (Laplante 1983).

Le tableau 4 regroupe les différentes composantes de l'image perçue en 3 groupes principaux les attractions touristiques, les produits touristiques et l'attrait. Les deux composantes de l'image perçue qui sont surlignés en rouge à savoir le patrimoine historique en tant que ressource naturelle qui appartient au groupe de l'attrait, ainsi que les services hôteliers en tant que bien tangible appartenant au groupe des produits touristiques, sont les éléments vis-à-vis desquels les touristes et les décideurs se sont désaccordés.

Tableau 2 : Regroupement des composantes de l'image perçue en groupes

Composantes de l'image perçue	Groupes
Sites touristiques	**Attraction touristique**
Festival de Tyr	
Patrimoine historique	**Attrait**

Vie nocturne	
Quartiers traditionnels	
Plage	
Propreté	
Accueil	
Sécurité	
Cuisine	
Parkings	
Circulation	
Tourisme	**Produit touristique**
Hôtels	
Prix	

L'image de Tyr comme cité touristique doit être améliorée. Comme la base du tourisme dans cette ville est le service dans ses divers aspects, celui-ci doit être matérialisé pour qu'il apporte une valeur ajoutée à son image globale. Les attractions touristiques sont perçues comme satisfaisantes, cependant la municipalité de Tyr doit, en tirant des conclusions des résultats de cette étude, apporter des modifications en termes de service et de marketing afin d'affermir l'attrait de la ville et la valeur de ses produits touristiques. La création de parkings publics et l'organisation de la circulation par la police municipale et la mise en place d'une signalisation adéquate dans les rues est importante pour faciliter le séjour des visiteurs et touristes. L'installation de panneaux explicatifs ainsi que l'accessibilité des brochures et autres informations touristiques au sein et en dehors des sites restent d'une grande nécessité car ceci permettra une meilleure visibilité des attractions et produits touristiques. La performance des services au sein des hôtels existants en fonction des aspirations de la clientèle réelle et potentielle, ou même la création de nouveaux hôtels, doit constituer une priorité. De surcroît, le patrimoine historique de Tyr n'est pas mis en valeur, la communication doit donc porter sur cet aspect à travers une forte médiatisation tant au niveau local qu'international.

Nous déduisons des résultats obtenus de l'enquête que de nombreux touristes n'ont pas eu la possibilité de visiter toute la ville et d'explorer son patrimoine historique ou même de connaitre ses hôtels et leur service car un grand nombre d'entre eux étaient des visiteurs excursionnistes qui sont venus pour passer la journée et n'ont pas pu fréquenter tous les lieux de la ville ; ce qui les a empêchés de les noter correctement.

Finalement et sur le plan théorique, ce travail confirme l'existence de plusieurs images d'une destination touristique (image induite et complexe) qui diffèrent l'une de l'autre et souligne l'importance de l'image complexe pour une destination. Cette dernière qui est formée suite au séjour du touriste, joue un rôle primordial dans le degré de satisfaction ou d'insatisfaction du visiteur tel que signalé par Oliver (1997), dans l'intention de recommandation et de revisite déjà évoquée par Bigné (2001) et aussi dans l'intention de fidélité du touriste au lieu (Lee 2003).

Le but principal de cette recherche était de déceler et d'analyser les différences existantes entre l'image perçue et l'image voulue et de mettre en lumière les éléments d'attractivité touristiques de la ville afin d'éclairer les membres de la municipalité de la cité sur la réalité du tourisme dans la ville. Il est donc essentiel d'informer les décideurs touristiques des divergences ressorties afin de les inciter à améliorer et renforcer la situation touristique de la ville, et d'unifier très rapidement son image. Il s'est avéré nécessaire et urgent, dans un milieu fortement concurrentiel, de faire un repositionnement clair et durable de cette destination afin de garantir une image unique qui produirait une satisfaction chez les touristes tant potentiels qu'actuels.

Conclusion

L'image d'une destination touristique est le thème central de cette recherche qui a étudié la possibilité de divergence entre l'image induite et l'image complexe d'une destination touristique. Elle a de plus mis en relief, l'importance de l'image perçue et son influence sur l'activité touristique d'une ville.

Tyr est une ville phénicienne libanaise qui renferme un potentiel touristique remarquable et qui peine à occuper la place touristique qu'elle mérite. Grâce à cette recherche, les perceptions des décideurs et des touristes visitant la ville ont été saisies et analysées afin de déterminer d'éventuelles recommandations.

Le patrimoine historique fait une partie des éléments qui influencent la perception envers une destination touristique. La perception par les touristes du patrimoine de Tyr -un attrait primordial de la ville- n'est pas telle que voulue par la municipalité. Il serait donc pertinent que l'industrie touristique prenne en considération cette ressource culturelle et élabore des actions durables pour sa préservation.

Les opinions des touristes visitant une destination touristique représentent une source de progression primordiale pour la ville en question. Sur la base de ces idées, il est essentiel pour toute destination de développer une image forte et un positionnement solide et clairement lisible opérationnalisé par un ensemble d'éléments de communication et de commercialisation capables de répondre aux attentes des touristes afin d'assurer un niveau de satisfaction capable de les faire retourner de nouveau à cette cité.

Notre étude montre la nécessité pour une destination touristique, d'adapter l'image induite à l'image complexe. En effet, si l'effet multidimensionnel de l'image est difficile à gérer, des enquêtes permanentes et sur une grande échelle sur les aspirations et les besoins des visiteurs d'une ville spécifique, menées par les décideurs municipaux, peuvent être utiles. De plus, une étroite collaboration entre les décideurs municipaux, les fournisseurs de service et les résidents d'une destination touristique est recommandée ce qui des approches participatives en gestion. Ces approches facilitent la valorisation des ressources locales et garantissent des améliorations accommodées à leur contexte de mise en œuvre. Une idée forte de ces approches consiste à mettre les valeurs et les préférences des acteurs au centre de l'action publique parce que le «*mélange des valeurs des experts et de celles de la société devraient être plus réalistes que les valeurs de la société auscultées de façon normative par les experts*» (Wagle 2000).

Dans la lignée de cette étude, plusieurs perspectives de recherches ultérieures seront envisageables. Qu'en est-il de de la divergence entre l'image induite et l'image perçue par les touristes locaux et celle perçue par les touristes étrangers ? Pour conclure, il pourrait de même être utile de réfléchir à des mesures et des démarches à mettre en œuvre et qui permettent de corriger les perceptions erronées de l'image d'une destination touristique.

Genesis of The System of State Communications of Authorities in Ukraine

Kateryna S. MISHCHENKO
PhD in Public Administration, Associate Professor,
Institute for Personnel Training of the State Employment Service of Ukraine,
Kyiv, Ukraine,
e-mail: ekmischenko@ukr.net

Abstract

The issue of the establishment in Ukraine of a system of public communications of the authorities with representatives of civil society was researched. The legislative and organizational principles of information and communication activity of the authorities of Ukraine in the conditions of transformational changes are considered retrospectively. It was revealed that in Ukraine the institutionalization of the system of state communications of the authorities was evolved. It was established that in the conditions of modernization of public administration, which processes are rapidly spreading in Ukraine today, there is an increasing necessity to establish effective public communications of the authorities with civil society actors on the basis of modern information technologies. A number of problems are identified in the field of public communications, which hinder Ukraine's further progress on its democratic development.

Keywords: communication, state communication, communicative interaction of the authorities with the public, public relations.

Introduction

One of the prerequisites for sustainable democratic development of society is the informational openness of the authorities and the transparency of their activities. The government's adherence to these modern principles of democratic governance is the key to guaranteeing effective policies, facilitating civil control, and strengthening people's credibility. Achieving this goal is closely linked to the desire and ability of the authorities to carry out clear procedures to inform citizens of their activities and to use mechanisms to involve them in forming public policy and assessing the quality of its implementation. In current conditions of the rapid development of the information society, the active expansion of social networks, the formation of many forms of self-organization of the population, such as public movements, unions, associations and alliances, it is of great importance to create an effective system of interaction between the state power and society. Ukrainian scientist L. Chupryna (2015) believes that the ability of the authorities to maintain such interaction is becoming one of the important indicators of public administration.

In countries with a democratic vector of development, the necessity for communication is enshrined in law by the obligation of the authorities to inform the population of their activities, and the population has the right to express public opinion. The implementation of the legally established principles of communication requires the authorities to establish a communication process, its main purpose is to establish close interaction with civil society actors and to maintain a constant dialogue with them. This ensures the authorities with the opportunity to understand the changing needs of society, to respond to them adequately and in a timely manner, to involve the population in the joint development and adoption of the necessary management decisions. How has the system of communicative interaction between the authorities and society formed in Ukraine? What were the tasks of the Ukrainian authorities for the establishment of such a system? Have the authorities'

approaches to the organization of public communication evolved in the course of the transformational changes that took place in Ukraine over the last 30 years? This research is dedicated to finding answers to these questions.

The main purpose of this study is to retrospectively analyze the processes of formation and development of the system of state communications between the government and the public after Ukraine's independence. Achieving this purpose foresees the following tasks:

(a) exploring the modern views of scientists concerning communication, determining the essence of state communication;

(b) an analysis of the legal foundations of the establishment in Ukraine of a system of communication of state authorities with civil society actors;

(c) to understand the importance of communication between the authorities and the civil society in the context of the modernization of public administration;

(d) substantiation of the feasibility of introducing in activity of system of state communications modern information technologies and communication interaction tools.

Literature Review

The origins of the definition of the essence of communication were M. Weber, G. Godet, G. Lasswell, P. Lazarsfeld, M. McLuhan. The theory of communication was elaborated by representatives of the communicative philosophy Y. Habermas, K. Jaspers, A. Toffler, philosophers futurists D. Bell, J. Gelbraith, J. Gerbner, N. Luman, T. Parsons and others. The communicative interaction of state authorities with society was explored by S. Black, D. Dorothy, F. Jeffkins, P. Jackson, D. Grunig, S. Katlip, R. Harlow and many other foreign scientists. In the works of Ukrainian scientists, various aspects of state communications were covered by V. Bebik, V. Korolko, V. Kobzanenko, S. Kvit, G. Pocheptsov, V. Rizun, O. Kholod. The interaction of the authorities with the civil society in Ukraine was researched by V. Bakumenko, N. Dragomiretska, A. Kolodiy, O. Kruti, O. Litvinenko, N. Nizhnik, V. Rebkalo, Y. Surmin, V. Tertichka and many other scientists.

Research Findings

Most scholars consider communication as a multidimensional social phenomenon. From the standpoint of a systematic approach, they consider communication to be the basis of functional management interaction. In the theory of social organization, scholars view communication as an important determinant of managerial behavior in social institutions and organizations. The marketing approach in communication research reveals the dependence of the development of administrative and political organizations on the external and internal conditions of communication interaction. According to the concept of change management, which is especially relevant for the business sector, a continuous improvement of communication strategies is a prerequisite for improving management and maintaining competitiveness. The concept of cognitive management implies the modernization of the administrative foundations of administration through structural restructuring, innovation, creation of an innovative model of social and communicative interaction of a qualitatively new level.

The results of the research of the role of communication in public administration testified that the level of public trust in state institutions depends on their consistent, systematic, objective, high-quality, open and transparent information and communication activities. For the authorities, an important condition for establishing effective communication with the structures of society is the continuous implementation of state communications.

From the standpoint of the theory of public administration, state communication is a stable social interaction of the participants of the management system, which is a complex of communicative exchange of messages, information, knowledge necessary for the decision of management tasks, achievement of goals, realization of strategies. According to the process approach, state communication is the process of information exchange carried out by state authorities and local self-government bodies with various institutions of society (subjects of communication). The actors in

this process are state institutions, business structures, public institutions (parties, movements, unions, etc.).

According to the method of communication interaction, there are two types of state communications: propaganda and marketing. The propaganda type of state communication involves rigid information control of the authorities by the consciousness of the people, which often turns this process into a manipulation of consciousness. History testifies that different states of the world, if they are interested in propaganda or even war, often use manipulative techniques such as misinformation (fakes), “white noise” technology (glut of information), spin-doctoring (change of meaningful accents of information) and other techniques for influencing human consciousness. Marketing type of communication interaction is formed on the basis of the laws of supply and demand for information services. Peculiarities of marketing communications include the use of indirect, weak (or soft) communicative influence rather than direct propaganda.

In the process of state communication, the bodies of executive power are the transmitter of information, and at the local level, if it concerns the information of local importance - the bodies of local self-government, at the same time its recipients in the first and second case are citizens. State authorities, bodies of local self-government are interested in assimilating the communication of the information transmitted by the participants, but they cannot fully rely on its correct understanding, because there is a risk of divergent attitude towards the information message. This risk can be mitigated if the appropriate conditions for communicative interaction are created that maximize the interests of all participants in the communication.

Public relations are a tool to facilitate the harmonization and convergence of interests of communicating entities. Most researchers share the view that public relations (PR) is usually aimed at building understanding and agreement between people, social groups, classes, nations, states through purposeful public opinion formation and management.

Revealing the essence of communication, Ukrainian researcher L. Borysenko (2008) refers to the definition of American scientists D. Forrestol and R. Dilenschneider, who defined communication as "the use of information to influence on public opinion". In this case, influence on public opinion is understood as bringing to the consciousness of people information that is true. Revealing the essence of PR as one of the tools of communication, the scientist V. Komarovsky (2001) gives the definition of the American researcher R. Harlow, who claimed: "Public relations is one of the functions of governance that facilitates the establishment and maintenance of communication, mutual understanding and the establishment of cooperation between the organization and the public. It involves addressing a variety of issues: ensuring guidance to public opinion information and assisting in the development of appropriate measures; ensuring their activities in the public interest; keeping managers ready for different changes by anticipating trends in a timely manner; use of research and open communication as the main means of activity”.

Researching the multidimensional nature of public relations, Ukrainian scientist S. Pushnyak (2015) defined RR as “a constant communicative psychological direct and feedback contact of governing bodies of any system with the public with a view for creation, forming and functioning of a positive management image that influences the emergence of a favorable environment for interaction of both parties”.

The purpose of public relations for state authorities and local self-government bodies is to establish bilateral communication in order to identify common interests and to achieve mutual understanding between citizens and authorities based on knowledge and full awareness. The tasks of the PR structures created in the authorities include the reproduction of the internal and external socio-political and psychological environment, favorable for the successful work of the body, ensuring the desired behavior of the public towards it. According to Ukrainian researcher D. Tereshchenko (2009) the authorities are interested in gaining public support and reducing resistance to their actions. State authorities also require public relations to create an image of effective and competent leadership that can solve problematic issues without undermining the legitimate rights of citizens to access timely information.

In Ukraine, the establishment of the public relations Institute dates back to the 1990s. Awareness of the necessity of introducing PR into the activities of the authorities became a reaction to the social changes that were taking place in Ukraine towards the formation of economic and political institutions of democracy. The real process of creation of the basic principles of PR activity began from the moment of organization in 1992 in the structure of the Presidential Administration of Ukraine of the press service of the Head of State. In the same year, the Law of Ukraine "On Information" was adopted (1992), which was the beginning of the creation of a national legal framework concerning information and communication activities of the authorities. This Law first defined the right of public entities to information, which was guaranteed by the creation in the state bodies of special information services or systems that would ensure access to information in the prescribed manner. In addition to determining the right of citizens to receive information from state authorities, Article 5 of the Law foresaw its openness, accessibility, freedom of exchange, objectivity, reliability, completeness and accuracy, as well as the lawfulness of receiving, using, disseminating and storing information. The special importance of the information in the relations of the authorities with the citizens was enshrined in other articles of the same Law. Thus, Article 10 guaranteed the establishment of a mechanism for the exercise of the right to information and established liability for breaches of the law on information; Article 21 identified the main sources of information concerning the activities of state authorities, and Article 28 established a regime for access to information.

The adoption of the Law of Ukraine "On Print Media (Press) in Ukraine" (1992) had great importance for public relations, which established the right of citizens to receive publicly disseminated information from the authorities and their officials.

Another Law “On the Procedure forReporting the Activity of State Bodies and Local Self-Government Bodies in Ukraine by the Mass Media” (1997) established the procedure for accreditation of journalists and media technicians at state bodies and local self-government bodies by registering them on the basis of official submission of applications. In turn, the authorities were obliged to inform the accredited journalists in advance of important activities, plans and assistance in organizing their activities.

In Ukraine the regulation of relations between citizens and authorities is enshrined in the Constitution (1996). Thus, Article 40 of the Constitution reads as follows: “Everyone has the right to send individual or collective written appeals or to personally address the state authorities, local self-government bodies and officials and civil servants of such bodies, who are obliged to consider the petitions and give a reasoned answer within the time limit established by law.

The practical implementation of this constitutional right is carried out within the framework of the Law “On Citizens' Appeals”, which was adopted in October 1996 (Verkhovna Rada of Ukraine). In 2015 this Law was amended according to it, state authorities are obliged to respond to e-appeals and e-petitions. The same year, the President of Ukraine issued Decree No. 523/2015, which approved the Procedure for Consideration of an Electronic Petition.

The Law of Ukraine "On Access to Public Information" (2011) became enough democratic according to European norms, which established the right to free access to information from state authorities and local self-government bodies, affirmed the necessity for governmental institutions to communicate with civil society actors in the public sphere.

It is worth noting that the characteristic feature of all the above mentioned laws was their orientation to exert unilateral information influence on citizens. The adopted Law “On the Basic Principles for the Development of the Information Society in Ukraine for 2007-2015” (2007) laid another, broader approach to the information sphere. In particular, the task of establishing an information society in Ukraine was identified. The provisions of the Law foresaw the reorientation of public administration to a more modern form of public development management - a system of public administration, which envisaged a transition from a model of unilateral informing of citizens of the actions of the authorities to a bilateral model of communication with feedback by the type of “citizen-public body-citizen”. The Decree of the President of Ukraine “On Promoting Civil Society Development in

Ukraine" of February 28, 2016 No. 68/2016" and "On Approving the Strategy for the Development of the Information Space of Ukraine for the Period until 2020" substantially supplemented the legal framework for public communication of the authorities.

The modernization of public administration, which began in Ukraine in the first decade of the new millennium, necessitated the introduction of new components of public communication, including:

(a) planning and conducting public consultations;
(b) informing of the activity and clarification of the goals and content of public policy in the respective sphere of public administration to society and individual segments (groups) of the population;
(c) ensuring the activities of advisory and consultative bodies;
(d) promoting the development of civil society;
(e) facilitating public examination of the activities of executive bodies and public anti-corruption expertise of draft legal acts (Ivano-Frankivsk Center for Science, Innovation and Informatization (2012).

In terms of the direct implementation of practical tasks of public communication, it should be carried out by specially created units within the structure of the authorities, which may be called differently: information ensuring department, press center, press service, public relations center (department) for public relations, department (division) for public communication etc. The diversity of the names of communication units is explained by the lack of a regulatory act that requires the unification of their names. The main function of these structures is to establish effective public relations, and the main task is to develop a positive image of the authorities and their officials, to increase the level of public confidence to the state authorities.

In Ukraine PR subdivisions use the following organizational forms of work to disseminate information concerning the activities of the authorities in the society:

(a) issue and distribution of newsletters, press releases, reviews, photos, videos, information collections, express information;
(b) holding press conferences, briefings, political dialogues, television debates, roundtables, press clubs, organizing interviews with government leadership and officials;
(c) preparation and conducting of television and radio programs;
(d) provision of publications (speeches) in the media by the heads or other officials of the authorities;
(e) creation of archives of information concerning the activity of the authority;
(f) making web pages on the Internet concerning the authority and its activities.

The recognition by the Ukrainian authorities of the importance of the use of PR-technologies in public administration makes it possible to identify public relations with the management of public interest, during it, on the one hand, public interests are transformed into a supportive expectation of a management initiative and, on the other, a management initiative is brought into compliance with expectations of the public.

The characteristic feature of recent years in the field of public communications became the introduction in Ukraine into activities of state authorities of modern information and communication technologies. On this basis, innovative social forms of communication between the government and the society were created, among them "E-Government", social media, "Civil Initiative" web portal, "Public television", online conferences with the President and the Head of Government, members of the government, heads of bodies of local self-government etc.

The introduction of the latest information and communication technologies gives the possibility to carry out information providing of process of adoption of organizational-administrative decisions in bodies of public power with participation of citizens and their institutes. Possibilities for that are growing first of all through widening of audience of Internet-users. Today many Ukrainian state actors became active users of social network in the Internet. According to National center of e-governance among them who is represented personally by the page in social networks for close

cooperation with population, NGOs and media there are 50 representations of state authorities (National eGovernment Center). The activities of the authorities in the social networks opens additional ways for the construction of effective communicative spaces between society and the authorities,. This, in particular, the establishment of communities where state bodies contact with citizens, creating blogs, where state services are presented and discussed, involvement of society to the work concerning improvement of the legislation – access on-line of citizens to information of state sector, laws in force and draft laws, direct accountability of officials to citizens, immediate discussion and solution in online environments of problems which arise in the country and regions.

Improvement of public communication of governmental structures, achievement of openness and transparency of their activity was facilitated by creation of the Unified web portal of executive authorities in Ukraine. The portal is a central part of the electronic information system "Electronic Government", which integrates websites, other electronic information systems of all executive bodies. Studying the experience of other countries convinced the national authorities that computer technologies of "E-government" significantly facilitate the interaction of executive authorities and their structural units, reduce the unproductive work, increase the effectiveness of adopted state-management decisions, which projects are placed on the web site for public discussion. Scientists, entrepreneurs, experts, ordinary citizens have the opportunity to submit to the authorities their suggestions and original ideas for solving important economic and social problems.

The official publication on the web-site of the Cabinet of Ministers of materials of meetings of governmental committees, agendas and all adopted resolutions and orders of the Government became a new aspect in the development of public communication of the Government of Ukraine with the public. The new tools of public communication of the authorities with members of the public, which are widely used by the authorities, include the social networks Facebook, Twitter, Youtube, Telegram, WhatsApp etc. A new form of public communication, which has already earned the sympathy of Ukrainian citizens, is a short video which are shot by specialists of the Press Center of the Presidential Office of Ukraine, in them the Head of State V. Zelensky voices his position for solving the most pressing issues that are of most concern to society.

Discution Issues

The study of the history of the formation of relations between the government and the civil society gives grounds to state that a system of public communications has been created in Ukraine. However, we believe that the following issues need further discussion. The power mainly performs the obligation to inform the public of its activities through the system of public relations, which became a mandatory element of the government structure at all levels of governance. At the same time, despite the positive developments, a number of problems in the field of public communications remain unresolved. Public information management needs improvement; there are problems with the promotion of state policy. Timely explanations of changes in government, sometimes fundamental, in government policy, actions by the Government and Parliament became not sustainable character, often blurred, spontaneous, unclear to the public and often unpredictable. This is to a certain extent explained by the lack of standards of communication activity, the presence of mistakes and gaps in the state information policy.

Conclusions

In Ukraine the process of institutionalization of the system of communicative relations between the authorities and society continues, the institutionalization became stable and continues to deepen, and the development of the system is evolutionary.

State communications as a system of public interaction between state authorities, mass media and the public are recognized in Ukraine as a prerequisite for democratic development, the emergence of civil society, the provision of conditions for widespread public participation in the formulation and implementation of public policy, and the strengthening of public confidence in the public.

With the development of the information society, the attitude of the authorities to the importance of communication changed. Recognizing that old methods of communication with society no longer work for effective communication policy, now the task of state and local authorities in the field of public communications recognizes the necessity to introduce new methods, instruments and tools. In order to optimize their activities in the context of ensuring a transparent and open dialogue with the public, representatives of the authorities began to actively use social networks.

In the system of information law of Ukraine, which regulates public relations in the field of information and communication technologies, new legal institutions are being formed: electronic government, electronic administrative and technical regulations, remote provision of public services, etc. Today, these institutes are actively developing.

At the present stage of the development of Ukrainian society with its characteristic transformation processes in different spheres of public life, the communicative interaction of the authorities and society should foresee permanent, honest, open, equal, clear public and other civil society format in a fully public dialogue in the format subject-subject horizontal relations, which is an absolute guarantee of the democratic development of the state.

The Role of Design Thinking in Creating Innovation in Business: A Literature Review

Katarzyna ROZPONDEK

Czestochowa University of Technology, Czestochowa, Poland
katarzyna.rozpondek@pcz.pl

Abstract

The dynamic development of the world economy and the increase in competition affect enterprises that are taking actions aimed at increasing the attractiveness of their business processes as well as products and services. The use of innovative techniques and tools focused on the problems and needs of users became an important element. In recent years, Design Thinking is one of the methods that have gained the attention of practitioners and theoreticians dealing with the problems of innovation. The aim of this paper is to present the concept of Design Thinking as a tool used in the process of creating innovation in business activities. An attempt was also made to show the most important differences between Design Thinking and the traditional approach typical for business. The research was conducted on the basis of the literature in the field of innovation and Design Thinking, as well as using data analysis from reports and consulting studies from Poland and foreign countries. The paper also uses examples of the practical use of the Design Thinking method. It has been found that Design Thinking is important in terms of introducing innovative activities in enterprises. The use of this method leads to the production of new or improved products, technological processes or organizational systems. There are many advantages of this method. The most important are, above all, an unconventional approach to solving the problem and an empathic understanding of the user perspective of the proposed idea.

Keywords: Design Thinking, Innovation, Business, Decision Making

Introduction

Driven by new technologies and globalization, new trends in the business environment affect enterprises in offering new solutions to meet the current or emerging needs of individuals, business and the public sector. Frequently observed factors affecting the current business environment are the ever shorter product life cycle, resource scarcity and growing competition. As a result, there is a conflict between the business tools, methods used in recent decades and the existing or evolving business environment. This situation often causes chaos in the minds of business directors about how to maintain their business in ever-changing circumstances. There is a growing need to look for new business thinking opportunities by using new tools and methods to create value for customers. It results from the need to maintain competitiveness and profitable business results in the long term (Volkova and Jakobsone, 2016).

Nowadays, the key to business competitive advantage is to introduce innovation. It is becoming more and more common to use a creative approach throughout the decision-making process, including usage of the Design Thinking method in business (Ben Mahmoud-Jouini et al., 2019). Design Thinking is important when developing products and services (Bianchi et al., 2018), as well as gaining importance in the entire corporate structure. By combining a creativity-based approach with business decision-making, the company's value is increased both internally and externally (Brooke, 2010). The functioning of enterprises, in the environment of growing competition, requires taking actions to increase the attractiveness of the goods offered. It is therefore necessary to search for tools and techniques to meet the growing demands of customers (Curedale, 2013).

The aim of this paper is to present the concept of Design Thinking as a tool used in the process of creating innovation in business activities. An attempt was also made to show the most important differences between Design Thinking and the traditional approach typical for business.

Methodology

The research was conducted on the basis of the literature in the field of innovation and Design Thinking, as well as using data analysis from reports and consulting studies from Poland and foreign countries. The paper also uses examples of the practical use of the Design Thinking method. It was assumed that the combination of this type of data will allow obtaining satisfactory results from the point of view of formulated research aims.

Literature Research

Literature sources point to the huge role of innovation in all spheres of life, ranging from new solutions for economic or social life, to new mental and cultural currents (Edwards-Schachter, 2018; Chen et al. 2018; Chen, Yin and Me, 2018; Lundvall, 2016). Despite the extensive literature that is available, it is very difficult to give a complex definition of this term and clearly describe its character. Innovation is a multidimensional concept encompassing different meanings and definitions from the perspective of different disciplines (Edwards-Schachter, 2018). The concept of innovation has evolved over the years. In the initial sense, the term was understood as something new in relation to existing solutions, currently, innovations are increasingly associated with refinement or improvement. Currently, one of the most recognized definitions is contained in the Oslo manual. This definition indicates that „innovation is a new or improved product or process (or a combination thereof) that differs significantly from the unit's previous products or processes and that has been made available to potential users (product) or brought into use by the unit (process)" (OECD/Eurostat, 2018). Innovation (understood as a process and outcome) are considered one of the main factors contributing to continuous business success. It was the subject of many research studies in which special attention is increasingly paid to the relationship between design, innovation and business results (Hernándeza et al., 2018).

Much attention in the literature has been devoted to innovation processes. One of the latest concepts is the User-Driven Innovation process (UDI) (Tacer et al., 2018). The UDI concept, which began to evolve since 2005, is based on the belief that consumers (users) are increasingly influencing the available commercial offer. They actually take part in the process of creating the products and services they buy. Therefore, UDI can be defined as a process that is based on user knowledge to develop new products, services and concepts. Thanks to this, the obtained solutions are based on a real understanding of users needs and systematically involve users in the enterprise development process (Szymańska, 2017). Figure 1 presents a proposal for a UDI concept.

Figure 1: User-Driven Innovation process

Source: Own study based on Szymańska, 2017

The implementation of the process as an innovative strategy also requires the company to take the following steps: recognizing the needs and expectations of customers, creating new ideas and designing solutions, analyzing technological potential and production capabilities, identifying the capacity of the market, attaching new solutions to business activities, and then introducing the solution for the market (Rosted, 2005). In this connection, Design Thinking deserves special attention, which is an example of a method of solving problems in a way that takes into account creative processes focused on the receiver of the proposed solutions (Ingle, 2013; Micheli et al., 2019).

Design Thinking is one of the innovation tools that respond to the challenges of the present day related to changing economic, political and social conditions. This concept can be defined as an action that requires complex commitment, focused on finding optimal solutions and answers to the needs of people and the environment in which they live. According to the definition adopted by the International Council of Societies of Industrial Design, design is the main factor in the innovative process of humanizing technology as well as cultural and economic exchange. According to the assumptions of the European Commission, by 2020 design should be a fully recognizable element of innovation policy in Europe, both at the Community, national or regional level. Design is a comprehensive process that includes both the way of thinking and the end result, which can be a business model, object, product or service (PARP, 2020).

According to literature sources Design Thinking is defined as a research approach to the analyzed problems, containing creative thought processes (Rudkin Ingle, 2015). This concept is applicable not only to products but also in the service and process offer. It is primarily a systematic way of searching for a solution, from defining the problem, implementation, to prototyping and in-depth evaluation of the results obtained (Plattner, 2010). According to Lockwood (2010), this term is an innovative process that puts people and their needs at the center of attention. Design thinking can be used to create new products and services, but also to solve business problems and challenges. Brown (2009) defines this as a messy creation process by people who were not considered to be associated with design in any way. In this process, it is important to focus on human needs and use a diverse set of design tools (Bianchi et al., 2018).

Design Thinking is based on the assumption that this method can be helpful in solving problems and challenges that go beyond the traditional and common approach. Another characteristic feature of the described method is that the considered tasks should be implemented in multidisciplinary teams. Design groups should include people from the production, research and development, marketing and

sales departments, as well as designers. The mentioned procedure causes a diversity of competences among team members, thanks to which it is possible to stimulate creativity and develop unconventional solutions (Chasanidou et al., 2014). One of the most important components of this method from a business perspective is the team's deep understanding of the target users needs (Liedtka and Ogilvie, 2011; Baker and Moukhliss, 2020) through a specific learning process (Holzle and Rhinow, 2019). As part of an innovative solution to the problem, Design Thinking is based on detailed research related to the product or service development process (Curedale, 2013). The Design Thinking process is considered to be a system of overlapping three perspectives: available technology, business and client (Figure 2).

Figure 2: Design Thinking innovation as overlapping area
Source: Own study based on Chasanidou et al., 2014

The first issue concerns the technical aspects of the implemented solution. In this step the answers to the following questions are important: does your technology allow you to implement the solution? Can implementation take place at a sufficiently fast pace? Is the solution easy to maintain? The second perspective refers to the business requirements related to the specific solution. This stage concerns the analysis of the current market situation, as well as forecasts regarding profitability and return on investment. The third perspective draws attention to placing the real needs of users at the center of operations. Understanding the beliefs and leading motivations of clients allow creating a useful and innovative solution. Innovation increases when all three perspectives are taken into account (Chasanidou et al., 2014; Pavie and Carth, 2015).

The literature on the subject does not provide a clear classification of the stages that make up the process of implementing the Design Thinking method. Some authors have three basic stages: searching for needs including defining the problem through observation, generating ideas and prototyping (building models that facilitate the development and selection of concepts) (Seidel and Fixson, 2013). Most papers distinguish five design thinking components including empathize, define, ideate, prototype and test (Steinke et al., 2017) (Figure 3).

Figure 3: Design Thinking concept
Source: Own study based on Steinke et al., 2017

The first stage includes a set of actions to determine the requirements for the new concept and to orientate on user expectations. Empathy is an attempt to understand the thinking of the potential user of the proposed solution. Innovation often begins with an inspirational and non-obvious discovery

that deals with understanding intuitive motivations that affect human behavior and choices. Research phases based on qualitative, usually ethnographic or anthropological methods are of fundamental importance here. The customer often unknowingly makes certain product-related choices, which is why these studies allow discovering new life contexts or unmet needs (Lockwood, 2009). It is worth noting that it is not recommended to carry out these studies among focus groups or in laboratory conditions, because people in these situations tend to avoid authentic comments (Curedale, 2013). The next challenge is to define the problem. Design Thinking allows to discover the leading aspects of current situation and draw conclusions from the information that was collected during interviews and observations of users. All of that combined can form a solid basis for identifying correct problem. Proper definition of the problem makes it much easier to determine the right direction of the solutions sought. An important assumption of this stage is to look at the issue from a broader perspective, which is not limited by the standard thought framework and habits of team members (Steinke et al., 2017). The next step in Design Thinking is the ideate phase. The basic tool here is brainstorming, i.e. a group process in which techniques that promote the search for new solutions are used. It should be noted that brainstorming is not an end in itself, but only a starting point for determining the next course of action (Ingle, 2013). The next stage is prototyping, in which innovative ideas are transformed into a preliminary model, enabling the assessment of a given approach, as well as the potential for further changes. Prototyping is the physical transfer of ideas and concepts into a form that allows them to be visually presented and to collect opinions on the solution. It grants you an ability to explore ideas developed by preparing tangible models. The building and continuous improvement of prototypes reduces the risk of failure for the final product (Geissdoerfer et al., 2016). Testing is a way to get feedback from prototypes and ideas created in the previous phase. Testing allows you to repeat the empathy process of how users experience the prototype and compare opinions with their initial notes. Thanks to feedback from the testing phase, prototypes can be improved, which in the end will indicate whether the defined problems are properly solved (Steinke et al., 2017).

Empirical Researches

Modern business is focused on efficiency and constant change. A change understood as a mutable market environment (new technologies, competitors' activities), but also a change as continuous improvement of services, processes or products. Descriptive research on the practical use of the Design Thinking method by enterprises is contained in a report prepared by the Hasso-Planter Institute at the University of Potsdam in cooperation with Stanford University. In the study, respondents had the option of multiple-choice answers. Enterprises of various sizes and from various industries participated in the study. The results of the study showed that the size of the enterprise or industry is not the factors that determine the use of Design Thinking by organizations. Most of the surveyed enterprises use the analyzed method in the Research and Development (60,1%) and Marketing (40,9%) departments, while the smallest percentage of use was recorded in Finance & Accounting (5,3%). In the surveyed enterprises, Design Thinking is used to solve various types of problems. Among respondents, 69% say that innovative processes in their organization are more effective thanks to the Design Thinking (Figure 4). Despite the undoubted advantages of the method, respondents also pointed to its barriers and limitations, as well as to the problems associated with measuring its results (Schmiedgen et al., 2015).

Figure 4: Impact of Design Thinking for organization

Source: Own study based on Schmiedgen et al., 2015

Another example is a study that attempts to clarify the relationship between Design Thinking and innovation as well as business results. The survey was conducted among 525 companies listed on the Thai stock exchange. The obtained results showed that there is a strong, positive correlation between the Design Thinking method and innovations, as well as between innovation and the company's results. There was no correlation between Design Thinking and the results of enterprises. The results of the study show that this relationship is indirect due to the generation of non-obvious ideas that are transformed into innovation and then into the profit of the organization (Wattansupachoke, 2012).

The Design Thinking method significantly influenced the creation, development and conquering of the market by products and services of many enterprises, including Airbnb, Amazon, Apple, Coca-Cola, Conversem FedEx, General Electric, IBM, Simens, SAP, Toyota, Uber (Chybowski and Idziaszczyk, 2015; Vetterli et al., 2016; Sutton and Hoyt, 2016). Table 1 presents selected examples using the presented method among recipients of the private sector and administration units from Poland and the world.

Table 1: Selected applications of the Design Thinking method

Orderer	Contractor	The result of using Design Thinking
Apple	IDEO	Development of the computer mouse project for Macintosh Lisa.
Fabbrica d'Armi Pietro Beretta	Design Factory, Aalto University	Improving safety during hunting.
Boeing	IDEO	Marking the occupation of toilets on planes. Development of aircraft window lighting.
Łomża Brewery	Touch Ideas, Poland	Visual identity of the Łomża Unpasteurised beer, base with shelves for beer display, the first fridge pack cardboard on the Polish market.
North Face	IDEO	Extending the product recipient area to the Chinese market.
LEGO	Cloud Design, Poland	Developed packaging LEGO (SCA Challange final in Brussels).
Shimano	IDEO	Development of a simple walking bike design for adults.

Source: Own study based on Chybowski and Idziaszczyk, 2015

Design Thinking has also found its practical application at IKEA. The company commissioned to study social, technological and demographic connections that will affect the future appearance of the kitchen and what functions they will perform in 2025. IKEA commissioned IDEO to design and build the developed solution. The designed kitchen was tested during EXPO in Milan by a large number of visitors. Another example of the use of Design Thinking by IDEO was the development of a solution for Bayer. Bayer Diabetes Care, a division of Bayer Healthcare, is a global leader and innovator in

health self-control solutions. The solutions introduced by Bayer include, among others, a blood glucose meter or test strips. The result of cooperation with IDEO was the launch of Bayer CONTOUR USB, which monitors blood glucose levels. In addition, healthcare professionals gain immediate access to patient blood sugar data and impacts efficiency and speed of optimization of diabetes management (Ideo, 2020). An additional example where Design Thinking was used is the Millennium Bank. This method has been used, among others, for analog solutions, such as the employee-customer conversation model in the facility. Thanks to the Design Thinking method, Bank Millennium has developed a model in which communication with the client takes place according to a certain scenario. This scheme causes the client to become a very active party in the process. Thanks to the designed tools, each conversation can be different, and at the same time, they ensure that during it all necessary elements will appear, which the bank employee must inform the customer about (Millennium Bank, 2019).

Discussion and Summary

Literature sources demonstrate varied definitions of Design Thinking. It is worth noting that all these definitions of Design Thinking contain the following main elements: goal setting (the goal is to develop a new solution to the problem being analyzed), orientation (user orientation), process (structured structure) and participants (interdisciplinary teams) (Schallmo et al., 2018). Design Thinking based on the problems and needs of users differs from the commonly accepted approach to process improvement. For example, this method is most useful in the early stages of innovation creation when problems are not specifically defined. This creates opportunities for its multi-dimensional solution. In turn, standard process improvement finds its application in less complex situations (Roberts et al. 2016).

Due to the continuous development of the concept of innovation as well as models of innovative processes, there is a need to search for new methods affecting the creation and implementation of innovation in business. In recent decades, processes leading to the growing interdependence and integration of countries, societies, economies and cultures that have led to the gradual similarity of products and services on the world market can be observed. In addition, customer requirements and expectations for the offered solutions have grown. Therefore, companies are forced to carefully analyse their clients requirements. Design Thinking is one of the methods that support the creative and innovative process of creating or improving the products and services offered.

Design Thinking plays an increasingly important role in designing innovative services and products. This method is a way of introducing a series of actions in enterprises, which in turn lead to the production of new or improved products, technological processes or organizational systems. The concept based on Design Thinking creates a chance to solve an unusual problem or improve an existing solution, which in the long run gives business a chance to achieve competitive advantage on the market. Other authors also received similar observations (Micheli et al., 2019; Pap et al., 2019, Pamfilie and Croitoru, 2018).

The analysis of the practical application of Design Thinking confirms that many modern product and service solutions have been developed or improved thanks to the presented method. The undoubted advantage of this method is the empathic understanding of the user's point of view. In addition, Design Thinking allows you to quickly define potential failure. It also focuses on action and not on theorizing. In turn, this method is based on the cooperation of people from many disciplines, environments, and industries, which entails the exchange of experience among the members of the project team.

A review of literature sources as well as data analysis from reports and consulting studies indicates the importance of the design thinking method for the practice of enterprises in the field of creating and implementing innovations. Due to the wide scope of this problem, the work carried out should be extended to other aspects of business operations that may be affected by Design Thinking.

Abstract

The purpose of this paper is to explore the effects of banking competition on the lending behaviour of commercial banks specifically towards Micro, Small, and Medium Enterprises (MSME) in Indonesia as a developing country. This paper uses provinces data to produce a more robust result due to MSME in Indonesia spread over 34 provinces throughout the vast archipelago. The authors measure competition within the banking sector using concentration ratio and Hirschman Herfindahl Index (HHI) based on data of all commercial banks in Indonesia every six months over the period between 2013 to 2018, then examine the effects of banking competition on credit supply and interest rate for MSME by applying panel regression model. Overall, the findings reveal opposite effects on credit supplies for MSME when banking competition is measured using concentration ratio compared to HHI. Further, it was found that banking competition is not associated with interest rate charged to MSME in Indonesia. Results in this paper raises concern on using structural approaches of market concentration to measure banking competition conditions in examining bank-firm relationships. There are other approaches to measuring bank competition such as the non-structural approaches, the H-statistic approach, and the conduct parameter approach that could be added for future research.

Keywords: Banking Competition, MSME Lending, Concentration Ratio, Herfindahl Hirschman Index.

Introduction

In 2017, the Indonesian Ministry of Cooperatives and MSME reported that the number of MSME dominated the market by having a share nearly 99,9% or around 63 million business units in Indonesia. The large number of MSME contributes to achievement of more than half of GDP and almost whole of the national workforce. Therefore, MSME holds the main role for national economic development in Indonesia. Policies regarding to fund MSME were made to establish and ensure opportunities, support, and development of MSME business activites. Accordingly, in 2012 and 2015, the central bank of Indonesia which is Bank Indonesia established regulations for banks to achieve the minimum ratio of lending to MSME compared to total loans at 20% by 2018. However, Bank Indonesia (2018) reported that until 2018 only 25,8% of MSME population that received credit loans from banks. This low amount of bank lending is out of the ordinary for small firms with limited financing options compared to large firms. In several studies such as Carbo-Valverde et al. (2009), Saeed & Sameer (2015), and Mercieca et al. (2009), mention in their studies that small firms, SME in specific rely more on bank financing.

Reflect on MSME in Indonesia spread over 34 provinces throughout the vast archipelago, in general the decision-making process for MSME lending are carried out by each bank's branch offices. Each provinces has varied total of banks which create different market structure. In a research study by Claessens & Laeven (2004), industrial structure of banks in Indonesia is classified as monopolistic competition. Cetorelli (1997) mentioned that this is considered to have a positive impact on developing

countries, including Indonesia, whilst Beck et al. (2004) observed the negative impact of monopoly competition especially for MSME. Therefore, this paper tries to inform how banking competition effects MSME lending using provinces data.

There are numerous studies focus on the impact of banking competition towards access to financing and lending rate such as Beck et al. (2003), Berger et al. (2004), Carbo-Valverde et al. (2009), Cetorelli & Gambera (2001), Cetorelli & Strahan (2006), Claessens & Laeven (2005), Guzman (2000), Mercieca et al (2009), Petersen and Rajan (1995), and Saeed & Sameer (2015). Some studies find that concentrated market leads to financial constraints dan high loan rates for firms, yet other studies believe competitive condition cause credit loan is more accessible and lower pricing.

In measuring competition, we use the measurement of concentration, which there are previous empirical studies that use the structure-conduct-performance (SCP) hypothesis using Concentration Ratio (CR_k) as used by Abadi (2016), Ahamed (2012), and Berger et al. (2004) and HHI used by Agostino & Trivieri (2010), Ahamed (2012), Hannan & Berger (1991), and Petersen and Rajan (1995). In addition, CR_k and HHI measurement tools have been used to ensure the implementation of antitrust law in banking by various regulators.

The remainder of the paper is organized as follows, literature review, empirical approach and data, results, and conclusion in the end.

Literature Review

In literature studies, there are two opposing views related to banking competition, market power theory and information-based theory. The market power theory argues that higher concentration hence banking competition decreases, will lead to higher lending rate and financing constraint. According to the study by Berger et al. (2004) that included developing nations database, suggests low levels of competition due to regulatory restriction for participation limits contribute to less competitive interest rates and difficult access to credit facilities. Furthermore, studies by Guzman (2000) and Cetorelli & Gambera (2001) mentioned that monopolistic bank structure causes higher credit rationing compared to competitive banking and charging higher rates on loans. Cetorelli & Gambera (2001) has the same outcome, but with In US banking markets, Cetorelli & Strahan (2006) find that new entrants encounter difficult access for bank financing in a concentrated banking market than in a competitive market. Claessens & Laeven (2005) find evidence that competition able to reduce the financing constraint and lower the financial costs, therefore it provides opportunities for dependent firms seek external financing and leads them to grow faster. In broader view, the level of competition is important as an aspect of financial sector development and economic growth. Relating to SME financing manner, Mercieca et al. (2009) find that lending relationships between banks and MSME increases with more competition and decreases with more concentration. In a research study by Beck et al. (2003), the effect of market power theory is stronger towards small and medium firms than large firms.

On the contrary to market power theory, information-based theory argues that market power enables banks have lending relationship with debtor, hence more credit availability and lower price of credit. Petersen and Rajan (1995) argue through a framework that shows within a concentrated market, lower financing constraint especially for young firms than older firms. Higher concentration enable banks to obtain information about their debtor thereof better in mitigating asymmetric information and decrease constraints in accessing external financing. Another study by Abadi et al. (2016), lend support to information-based theory in emerging countries where the impact of high level of concentration in banking market help higher firm leverage. In addition, banking industry with a low level of competition or a high level of concentration, has rigidity in the change or understanding of interest rates, especially for MSME. Rigidity was found to be more an adjustment for a decrease in lending rates than an increase in lending rates, as studied by Hannan & Berger (1991).

Further studies concentrate the analysis of bank competition to SME such as Carbo-Valverde et al. (2009) and Saeed & Sameer (2015). A study by Carbo-Valverde et al. (2009) using Spanish SMEs data shows that concentrated market increases firm financing constraints, which is bank-dependent SMEs.

Saeed & Sameer (2015) analysis based on the Pakistani banking sector, find that SME as opaque firms confront financing constraint more in competitive market than in concentrated market.

It was found that banks in Indonesia had a category of industrial structure classified as monopolistic competition (Claessens & Laeven, 2004b). This is considered to have a positive impact on developing countries, including Indonesia (Cetorelli, 1997). However, it can also have a negative impact, which is to give rise to developing country finances, especially for MSME (Beck, Demirgüç-kunt, & Maksimovic, 2004).

Empirical Approach and Data

The present research is based on processing of bank financial data extracted from Regular Bank Reports (LBBU) and also using data from Central Bureau of Statistics and Bank Indonesia. This study includes all bank-level data over the period between 2013 to 2018, since the category of MSME credit was regulated in 2012. Despite there are 34 provinces in Indonesia, one of the provinces which is East Kalimantan still merge with North Kalimantan in bank reporting. The data is a combination of time series data and cross section data that is suitable for use in research with one or more variables over several time periods. Therefore, this study uses 2 (two) independent variables and 6 (six) control variables with every 6 months of observation for 6 years.

For bank market concentration measures, we adopt two methods, concentration ratio and HHI. We assess both measures on province level as independent variables. Following, the control variables consists of the aspect of provinces and macro variables which are Regional GDP (RGDP), population, Non Performing Loan Ratio for MSME outstanding credits (NPL), total credits (TOTAL_CREDIT), Bank Indonesia rate (BI_RATE), and inflation .

Taking the literature review into consideration, we decided to set the following hypotheses:

H1: There is effect of banking competition towards credit supply for MSME in Indonesia.
H2: There is effect of banking competition towards interest rate for MSME in Indonesia.
Overall, the following results of descriptive statistical processing:

Tab. 1: Descriptive Statistic (Years 2013-2018)

The independent variables CR_4 and HHI as proxies of banking competition in each Indonesian province, have different p values or significance levels. CR_4 has a p value above the critical limit of 0.05 which is worth 0.21 so it receives H0, while HHI has a p value below the critical limit so it accepts H1. Thus, HHI has a positive effect on the total distribution of MSME loans. The difference in results for the two concentration measurement approaches can be due to HHI reflecting the entire distribution of market share compared to CR_4 which is a composition of four banks in the market.

Furthermore, for other independent variables as control variables for the characteristics of provinces in Indonesia, the Regional GDP, population, total credit, and NPL have a positive influence on MSME credit distribution. For the independent variable as a characteristic of Indonesia's macro conditions, the BI rate and the inflation rate do not have a significant effect on total lending. This can be seen both in the regression model with CR_4 and the regression model with HHI, both of these variables have p values above the critical limit.

Taking the result of regression model approach with HHI measurement tool that has a positive effect on the level of MSME credit distribution shows support for the results of empirical studies which state that a high level of concentration or a low level of competition can reduce financial constraints for MSMEs thereby increasing the level of lending to MSME (Abadi et al., 2016; Petersen & Rajan, 1995). Overall, the results of Tab. 2 and Tab. 3 in which CR_4 and HHI as concentration indicators showing different results in which one is significant to effect the amount of MSME lending while the other is not. This result lend support to the research by Carbo-Valverde et al. (2009) that raise doubt concentration indicators as measures for competition banking market. Additionally, this result implisitly supporting the literature study by Claessens & Laeven (2004) which states that the level of competition is not determined only by the level of concentration but by the number of foreigners allowed to enter or restrictions on entry or exit that do not strictly determine competition effective.

Independent variables as characteristics of banking competition in each province and characteristics of provinces in Indonesia, namely CR_4, HHI, population, total credit, NPL, and Regional GDP have p values above the critical limit so that these variables do not affect the MSME interest rate.

In contrast to the independent variables as characteristics of Indonesia's macro conditions namely the BI rate and the inflation rate have an influence on the MSME interest rates. This can be seen in both the CR_4 regression model and the HHI regression model, both variables have a p value below the critical limit. These results support the study of literature by Hannan & Berger (1991) which states that there is rigidity in lending rates in markets that have high levels of concentration.

Conclusion

In this paper, we investigate the effect of banking competition on MSME loan availability and loan rate. The majority market of Indonesia is dominated by MSME which is spread over 34 provinces. This condition provides a unique setting for investigating this issue using provinces data. In particular, we find different results between 2 (two) concentration measurement approaches where CR_4 shows that the level of banking competition does not have an influence on the distribution of MSME credit in each Indonesian province, making it possible that there are other measures other than concentration to assess the level of banking competition. On the other hand, through HHI measures that is more closely reflect the distribution of the market share of all banks, it is found that the level of competition affects the distribution of MSME loans. Nonetheless, neither measures of market power affect loan rate for MSME.

Thus, we argue that our results lend support to market structure hypothesis and bring intention to concentration indicators as banking competition proxy. Therefore, other approaches to measuring bank competition such as the non-structural approaches, the H-statistic approach, and the conduct parameter approach could be added for future research.

Abstract

Youth labor market is an integral institution of a market economy. Its effective functioning contributes to the progressive development of the Russian economy as a whole, ensuring the financial stability of the country, and improving the living standards. The modern youth labor market in Russia as part of the world's labor market is characterized by a widening gap between the labor claims of the young people and the opportunities to satisfy them. The article raises issues of the dual position of youth in the labor market. Since young people most often do not have practical work experience (or it is not sufficient), their high salary requirements make it difficult to find a suitable job. The lack of appropriate work experience often becomes an obstacle when filling vacancies, as the heads of enterprises and organizations prefer to hire specialists with sufficient work experience. Incomplete use of the labor potential of the youth is a negative phenomenon, since the process of renewing the workforce and the rotation of personnel are slowing down (especially in those areas in which work for young people is not attractive). A waste of their labor potential nowadays is a loss of the quality of the workforce in the near future. In addition, the article considers the supply factors in the youth labor market, draws conclusions regarding the parameters of the population, demographic burden, and economic activity.

Keywords: The Youth, Youth Labor Market, Labor Supply, Labor Demand, Youth Employment.

Introduction

Youth is an important part of the country's human capital and determines the potential supply labor. From an economic point of view the youth is the most promising segment in terms of the labor supply in the labor market, and the productivity of the national economy depends on the level of its qualifications.

In the 21st century, a shortage of competent specialists, rather than the availability of capital, will be a constraint on innovation, competitiveness, and sustainable growth.

The study of the youth labor market is important in the context of socio-economic processes, since they are the basis of the economy and become an indicator of ongoing changes. Given the accelerating development of technology, the Fourth Industrial Revolution will pay particular attention to the ability of workers to constantly adapt and learn new skills and approaches in a variety of contexts. This will provoke a decrease in employment in segments of the labor market that demand low-skilled jobs, which will lead to increased competition for jobs and an increase in the burden on highly skilled labor. According to the Boston Consulting Group research "Russia 2025: From Personnel to Talent", the

rapid development of technology helps to ensure that the knowledge of older generations is less than ever in human history relevant to new generations.

With the growth of knowledge-intensive processes in the production and in the service sector, the requirements for professional skills and knowledge in each profession increase. As a result, the content of labor and the requirements for the level of professional knowledge are transformed, entailing an acceleration of the actual and moral depreciation and obsolescence of professional knowledge.

The solution of large-scale tasks of digitalization of society implies a more efficient use of the labor and intellectual potential of youth, which is the main source of updating labor resources, the bearer and "generator" of innovative ideas and professional knowledge.

Information on the youth labor market is very important for identifying youth employment problems at the national and local levels for the formation of policies and programs aimed at solving these problems.

Besides, a youth employment crisis is brewing in the world. Both developing and developed countries have to look for ways to solve the difficult task of creating decent and permanent jobs for a large group of young people who annually join the labor market. Increased attention to the problems of the youth labor market is given in international development programs (World youth employment trends, 2016; p. 3).

The labor market is the most striking reflection of the duality of the economic characteristics of the youth. A young man enters the labor market in his youth (on average, at age 20) and remains there until old age (Rudenko, E.O., & Krasova, E.V., 2015). Therefore, all the processes taking place in this market accompany a person and directly affect his life characteristics. On the one hand, the younger generation is able to overcome the existing ideological and psychological stereotypes associated with labor activity, create new value-oriented systems. From a demographic and economic perspective, the youth is seen as the foundation for the reproduction of society's labor resources (Rudenko, E.O., & Krasova, E.V., 2015; p. 8-9). Young people have all the objective prerequisites for this: the creative nature of thinking, high socio-economic mobility, professional motivation (career, financial independence, etc.), capacity for work, psychological flexibility, the desire to continue professional training, the desire to practically implement a system of new knowledge and values, openness to the perception of new arrays of knowledge, work methods, etc.

On the other hand, in the tough market conditions the youth is the most vulnerable social group. Young people are less economically independent and consolidated, do not have significant professional experience, the required skills and competencies, are strongly influenced by market forces, without having the experience and the ability to adequately respond to incoming challenges from the market, customers and employers.

The particular importance of this problem is given by the dynamism and inconsistency of socio-economic processes in modern Russian society. The situation in the Russian youth labor market in recent years is quite tense. An increase in the registered and hidden unemployment rate among young people and an increase in its duration lead to toughening the conditions for young people to enter the labor market, while the possibilities of young people are already limited due to their lower competitiveness compared to other categories of the population.

The youth labor market is a segment of the labor market where persons aged 15-29 are the subjects that form the labor supply. A feature of this labor market is the relatively low competitiveness of young workers due to the high costs of their adaptation and the risks for the employer when hiring. The specifics of the functioning of the youth labor market is in social, demographic, economic, political, cultural and other differences among youth groups (adolescents under 18 years old, youth 18-24 years old, young people 25-29 years old) (Kot, V.V., & Kuz'mina, A.G., 2016).

The youth is a social group that is just starting the process of secondary socialization, and therefore its position in society can be described as unstable, changing. The study of the social well-being of young people seems very significant, because people's life strategies (educational, family, professional, etc.) are formed during this period. Research interest is caused by youth perception of their position in the modern Russian labor market and assessment of professional development opportunities (Gorshkov, M.K., 2018; p. 46).
The problems of employment, including youth, have always been given great attention by scientists and specialists both in Russia country and abroad.

Features of youth as a socio-economic category are reflected in the works of Bel'tyukova, O.N., & Khoroshilova, E.N. (2016), Konstantinovskii, D.L., Voznesenskaya, E.D., & Cherednichenko, G.A. (2014), Gorshkov, M.K. (2007, 2014, 2017, 2018), Zagrebin, V.V. (2014), Tikhonova, N.E. (2005), Jeffs, T., & Smith, M.K. (1999).

The problems of youth employment, trends in the development and regulation of the labor market and youth employment are reflected in the works of Vishnevskaya, N.G. (2013, 2014), Lotareva, K.M. (2015), Ratslaf, A.A., & Sedova, A.V. (2014), Roshchin, S.Yu., & Slesareva, A.A. (2012), Ratslaf, A.A., & Sedova, A.V. (2014), Cherednichenko, G.A. (2015), Barham, C. (2009), Rivera-Aguilera, G. (2018).

The problems of the youth labor market and employment policy, the “school-to-work” transition are also considered by such researchers as Dolgova, A.V., & Zhukova, I.R. (2013), Klemeshov, A.M. (2005), Kolosovskii, V.V. (2004), Nikulin, A.G. (2014), Caliendo, M., & Schmidl, R. (2016), O'Reilly, J. (2015), Shi, L.P. (2018), Zuccotti, C.V., & O'Reilly, J. (2019).

The purpose of this study is to analyze the factors of supply in the youth labor market of Russia and to indicate the dual position of youth in the labor market.

Research Methodology

The research methodology includes theoretical analysis of literature, statistical analysis, comparison, calculation of indicators and coefficients. In solving a number of problems, methods of general scientific research, logical and functional analysis were used. The results are summarized using tabular and graphical methods.

Theoretical Ground for The Research

The theoretical basis of the paper is the conceptual conclusions presented in the scientific works of Russian and international scientists on the economics and sociology of labor, various practical aspects of the functioning of the labor market, and the characteristics of the youth segment of the labor market.

Supply Factors in The Youth Labor Market: Population, Demographic Burden, Economic Activity

The parameters of labor supply depend on two main circumstances: the population in the main demographic groups and the involvement of these groups in employment (employment levels). Neither the first nor the second are constant quantities (Russian labor market: trends, institutions, structural changes, 2017).

Due to an aging population, the distribution of employed by age will shift. If in 2015 the modal age group was 26-30 years, with each five-year period there will be a shift in the modal value of approximately 5 years. As a result, by 2030 the largest group will be the age of 41–45 years, and the number of employees under the age of 40 will significantly decrease (Russian labor market: trends, institutions, structural changes, 2017; p. 42).

Fig. 1 (Age pyramids construction, 2019) shows the age pyramid for Russia (for 2018). As we can see, the proportion of young people aged 15-29 is 16.8% of the population (including both men and women), which is below the global average (23.7%) (see Fig. 2) (Age pyramids construction, 2019). The majority of the population is a group aged 25-39. Moreover, according to the forecast (see Fig. 3) (Age pyramids construction, 2019), by 2036 the main part of the Russian population will be the age group of 40-54 years (the shift of the average age to increase), but at the same time the proportion of young people of 15-29 years old will increase to 19.5%.

The age pyramid of Russia in 2018 shows that there has been a slight increase in the number of young people aged 25-34 years, which is associated with a higher birth rate in previous decades with its subsequent sharp drop (this shows the narrow base of the age pyramid under a rapidly expanding area with a jump in population of the youth).

However, the general trend is that since 2004 the total population of 14–30 years has been sharply reduced and this process will be long-time (Gorshkov, M.K., & Sheregi, F.E., 2010). The reduction in the number of Russian youth is not an autonomous process, but a direct consequence of the depopulation of the Russian Federation as a whole (Tikhonova, N.E., 2005; p. 318-361).

Fig. 1: Age pyramid (Russian Federation, 2018)

Fig. 2: Age pyramid (countries of the world, 2018)

Fig. 3: Age pyramid (Russian Federation, forecast, 2036)

When considering population data, it is also necessary to analyze the age dependency ratio. Data for Russia (for 2014-2018) are presented in Table 1.

Table 1: Age dependency ratio in Russian Federation, % (2014-2018)

	2014 г.	2015 г.	2016 г.	2017 г.	2018 г.
Per working population (15-64 years old)					
Total	42	43	45	46	47
Children (0-14 years old)	23	24	25	25	26
Older people (over 65 years)	19	19	20	21	22
Per young people (15-29 years old)					
Total	143	154	164	176	187
Children (0-14 years old)	79	85	91	97	102
Older people (over 65 years)	64	69	74	79	85

As can be seen from the Table 1, the proportion of children still exceeds the proportion of elderly people, but the demographic dividend will soon come to an end. This can lead to the fact that the population will continue to age and will not be replaced (which means an increase in the burden on the working-age population, including young people, to ensure a system for paying old-age pensions).

In addition, there is a tendency of faster growth of the age dependency ratio by the elderly. Therefore, in this study, we made an attempt to predict the demographic burden on youth by the older population. Based on the data of the Federal State Statistics Service on the population in the selected age groups (from 15 to 29 years old and older than 65 years), as well as the demographic forecast until 2036 (Official website of the Federal State Statistics Service, 2020), a graph is constructed (see Fig. 4). To prepare the forecast values, data were used on the population by one-year ages (for the period until 2036), grouped by the selected ages.

Fig. 4: The demographic burden on youth from people over the age of 65 (according to factual data until 2018, and also including a forecast until 2036)

Fig. 4 shows the increase in the demographic burden on Russian youth from 1926 to 2018. Further are the values for high, average, and low forecast. As we can see, all three variants suggest a further increase in the demographic burden on young people with a peak in 2025-2027. Next a small recession is forecasted (an average and low forecast) or a recession ending with a new growth stage (high forecast). However, for any of the variant the demographic burden on youth by the end of the forecast period is significantly higher than the current values of 2018 (by 23.1%, 22.1%, 33.3% respectively for the low, high and average forecast variants).

Table 2 shows the number of potential labor force in Russia (among the youth). Potential labor force is unemployed people who express interest in getting a job, but the current conditions limit their active job search or their willingness to start working.

Over 5 years (from 2013 to 2017), there has been a decrease in potential labor force for all age categories of youth (both among men and women). The greatest decrease occurred in the age group of 20-24 years (-35.7% over the past 5 years). However, among men, the potential labor force in the age group of 25-29 years was most reduced.

Table 2: The number of potential labor force, thousand people

	2013	2014	2015	2016	2017	% of change (2017 to 2013)
total						
15-19 years old	126	114	111	99	98	-22,2
20-24 years old	193	157	156	139	124	-35,7
25-29 years old	136	124	119	108	89	-34,6
men						
15-19 years old	66	66	58	56	54	-18,2
20-24 years old	90	77	74	69	62	-31,1
25-29 years old	59	53	49	47	33	-44,1
women						
15-19 years old	59	48	53	43	44	-25,4
20-24 years old	104	79	82	70	62	-40,4
25-29 years old	78	72	70	61	56	-28,2

The main indicator when considering labor force is the level of youth economic activity, which is defined as the ratio of the economically active population (employed + unemployed) to the working-age population.

The level of economic activity of Russian youth aged 15-29 is shown in Fig. 5.

Fig. 5: The level of economic activity of young people aged 15-29 years, %

In recent years, the level of economic activity of young people, especially the younger and middle ages, has declined significantly. It can be noted that over 5 years (from 2013 to 2017), there has been a decrease in the economic activity of Russian youth by 2.8%. During this period the working-age population grew and economically active young population decreased. This can be attributed to the fact that young people are not forced to stop studying and go to the labor market, but to a greater extent began to devote themselves to study (Russia and China: 21st Century Youth, 2014; p. 296).

The Dual Position of Youth in The Labor Market

According to studies, it can be noted that young people in the modern labor market are in a dual position. On the one hand, some authors note that young people have a number of qualities that can contribute to their successful competition in the labor market (see Table 3).

Table 3: The youth strengths

Authors	Highlighted Qualities
Bel'tyukova, O.N., & Khoroshilova, E.N. (2016)	High mobility, working efficiency, easy learning.
Gornov, V.A. (2017)	Perspective, mobility, energy and openness to everything new.
Gritsunova, S.V. & Chepiga, K.A. (2016)	Ambition, creativity, intelligence, stress resistance and the desire to develop independently.
Il'inykh, S.A., & Kameshkova, V.G. (2018)	High social and labor mobility. Readiness for innovations, constant change of labor functions, active life position.
Kolesnik, E.A. (2015)	Young people have great ability to work and create in all spheres of society. Young people also have a great social and professional perspective, because only they are able to master new knowledge, professions and specialties faster than other social groups.
Kot, V.V., & Kuz'mina, A.G. (2016); Osipova, L.B., Kolesnik, E.A., & Goreva, O.M. (2018)	The creative nature of thinking, socio-economic mobility, professional motivation, working efficiency, psychological flexibility, the desire to continue vocational training.
Rudenko, E.O., & Krasova, E.V. (2015)	The desire to practically implement the system of new knowledge and values, openness to the perception of new arrays of knowledge, methods of work.

Savchenko, V.V., & Popova, M.V. (2012)	High mobility, flexibility, ability to adapt quickly, energy. A high degree of socialization, knowledge in the field of modern law, economics, social life. A high degree of learning, willingness to master new knowledge, the absence of strict stereotypes in professional activities.

Source: compiled by the author

On the other hand, many researchers note that young people in the labor market also face many problems that significantly complicate employment and have a negative impact on the position of this age category (see Table 4).

Table 4: Problems of youth in the labor market

Authors	Identified Problems
Bel'tyukova, O.N., & Khoroshilova, E.N. (2016)	Labor instability, unemployment, low wages and competitiveness, lack of experience and labor skills.
Vishnevskaya, N.G. (2013, 2014)	Structural imbalances in supply and demand. Inconsistency of the structure of demand and the structure of professional training of youth. Substantial regional differentiation. Overstated requirements of graduates themselves to their future place of work due to ignorance of the labor market conditions. Reluctance of many employers to take workers without work experience and high qualifications.
Gornov, V.A. (2017)	Lack of life experience, lack of work experience. Lack of knowledge and skills necessary to enter the post-industrial social order. Unwillingness to take full responsibility for their own actions.
Il'inykh, S.A., & Kameshkova, V.G. (2018)	Minimum work experience (as a result - low professional status).
Kozyreva, P.M., & Smirnov, S.A. (2017)	Lack of demanded professional knowledge, work experience. The imbalance between the demand for skilled labor and the specialties that young people receive in higher and secondary specialized educational institutions.
Kolesnik, E.A. (2015); Osipova, L.B., Kolesnik, E.A., & Goreva, O.M. (2018)	The intensification of the contradictions between the demand for labor of youth and its supply, the deformation of the regional and sectoral structure of employment, the complication of the process of attracting young people to the sphere of productive labor activity, as well as the imperfection of the mechanism of its state regulation.
Lyubenkova, E.P., Gorbatovskaya, N.N., & Tkachenko, A.V. (2013)	Lack of required work experience by employers, difficulty in obtaining this experience; the problem of imbalance of supply and demand in the labor market; the problem of lack of jobs in a particular specialty.
Petrov, P.V. (2017)	The widening gap between the labor claims of the young and the possibilities of satisfying them. Lack of practical experience. High wage requirements. Lack of relevant experience.
Pitukhina, M.A. (2017)	Lack of expectations from upcoming professional activities. Lack of clear knowledge and understanding of the basic mechanisms, patterns of the labor market. Lack of understanding of the requirements of employers for labor results. Lack of clear ideas about corporate culture, about the ability to work in a team. The increased ambitions of the vast majority of young people.
Solomatina, A.S., & Khalyukina, E.V. (2017)	Lack of necessary qualifications, lack of work experience, differences in the expectations of young specialists and employers regarding wages and available vacancies. Inconsistency of

	specialties in universities and the demands of the modern labor market; the contradiction of personal and social priorities, the lack of a regulatory framework for socio-economic support for graduates.
Sychevskaya, L.A. (2011)	Legal insecurity of young people. A lack of motivation to work, restrictions on territorial mobility.
Titova, M.N., Efimova, N.V., & Klimova, N.S. (2017)	Inadequate assessment of their professional potential, search for a high income and at the same time an increase in the number of "working poor" among young people. In addition to low wages, young people often work in the informal sector, part-time, or in temporary jobs. Lack of skills needed for available jobs. Lack of experience from the perspective of the employer. Lack of jobs suitable for entry-level skills. Mobility and increased readiness for migration.
Khishaueva, Zh.T., Kupavtsov, A.N. (2012)	Instability of supply and demand. Low competitiveness compared to other age groups. The pole nature of competition, due to the presence of primary and secondary workers. The difficult situation with female employment.

Source: compiled by the author

The Russian labor market shows an imbalance between supply and demand. The number of students and graduates of higher educational institutions has significantly increased over the past 10 years, but the state is faced with the problems of creating high-tech jobs. Specialists in technical profiles and skilled workers are in demand, while in the labor market there is a glut of lawyers and economists. In fact, universities are guided by the demand for specialties among applicants, and not by the needs of employers, and this is the result of educational reform, when a university is forced to survive through paid services, thereby sometimes creating the so-called "pseudo-education". The gap between the spheres of education and the labor market will soon increase, and young people will be forced to cope independently with difficulties in the way of employment, as well as in the process of work. Observing difficulties in the labor market, young people try to adapt, gaining the first experience of employment while still studying, thereby smoothing the transition between study and work. However, in recent years entry into the labor market has been increasingly delayed, and youth remains economically inactive. At the same time, one part of the youth continues to receive education, accumulating diplomas and certificates, while the other does not study and does not work. Thus, modern youth despite their adaptive properties remains a vulnerable group in the labor market (Youth employment in the motivational and structural dimension, 2017; p. 76).

Conclusion

The situation with youth employment is characterized as very controversial. On the one hand, there are differences in the wages depending on the type of employing organization (high salaries in the private sector of the economy and foreign companies) and industry (high-paying and low-paying industries). At the same time, employment in the "advanced" segments of the economy requires the applicant to possess communication skills and competencies along with professional education. On the other hand, there is a strong dependence on social origin and family resources, which does not allow us to consider education as a channel of mobility in Russian society. This leads to the degradation of the values of professionalism, doubts and anxiety for the future, skepticism about building a professional career.

Available data indicate several negative trends in the youth labor market in Russia, including a general decrease in the number of potential labor force among young people, and a drop in the economic activity of young people. Remains the trend of increasing the demographic and social burden on young people (especially from older people).

Thus, the position of young people in the market is dualistic. On the one hand, young people, due to their age characteristics, are more active and mobile, more susceptible to innovation and modernization

processes than the older generation, and therefore more competitive. On the other hand, this category is vulnerable due to the lack of sufficient professional experience and an unformed labor motivation system. It is not entirely legitimate to consider youth as the most vulnerable category of the population in the labor market. Adaptation mechanisms allow young people to adapt to the rapidly changing requirements of the modern economy much faster than the older generation. But young people, especially at the initial stage of their careers, need qualified help and support.

Abstract

An important problem for the mortgage is real estate valuation. A comparative approach to property valuation is the main method of property valuation because its principles are based on market behavior. It requires identification of the impact of various property features on transaction prices. Modelling of that influence is based on principles which are historically conditioned and which frequently do not take into account the contemporary data analysis research methods. Transaction prices datasets generated by broadly understood real estate market are characterized by heterogeneous dispersion and a tendency for local coincidence. This structure induces application of statistical methods based on recreating dependencies in the price set rather than assuming a parametric model ad hoc. In this work we present an assessment of the application of methods based on regression analysis as an example of a parametric method. We indicate advantages and imperfections of using these methods. Specificity of market information is presented which constitutes the basis for property valuation. We propose a canon of best practices for individual valuation and show the advantage of following the principles of best practice over the procedures followed in automatic solutions. Finally, we highlight the principle of primacy of experience and professionalism over technical solutions.

Keywords: Real Estate, Regression Analysis, Comparative Approach, Best Practice, AVM

Introduction

Property valuation is an important element of the real estate market. It usually accompanies decision making associated with investments, loans, mortgages, expropriation, planning and many more. In the global market era it is crucial that the process of property valuation, as well as the estimated value of the property be interpreted in the same way by all participants in the market. However, real estate is a type of goods characterized by high heterogeneity. There are no two identical properties, and even if they can be considered to be very similar, they are unlikely to be the subject of a transaction in the same moment. Therefore their transaction price is a product of a different time and social-economic situation. Real estate has both objective features (use, geographic location, area, floor, year of construction, number of rooms, etc.), and subjective ones (quality of the surroundings, standard, etc.), which are assessed in different ways by the buyers and sellers depending on their needs: financial standing, family situation, age, aesthetic needs, etc. Moreover, property buyers and sellers make many cognitive errors in the process of negotiating the conditions of sale, which result from their knowledge, personality traits and other factors accompanying the transaction (Majewska, 2014).

This characteristic of the real estate market requires the valuer responsible for valuation to analyse varied data and draw objective conclusions, based on limited and imperfect market data. The

transaction price specified in the notarial act is a concrete number. However, the property which is the object of the transaction has many defining characteristics which influence the investment decision of the transaction parties in different ways. International Valuation Standards define price as the amount that is expected, offered or payed for a given asset. However, they also take into consideration different preferences of transaction parties resulting from their different motivations, budgets or particular requirements of a given buyer or seller, which may result in an agreed transaction price that is different from the value attached to the given asset by other potential buyers or seller (Blackledge, 2017).

Data and Regression Methods

The object of our analysis is property valuation. We do not specify what property is analysed, but we assume that it is unambiguously stated and we have complete knowledge about it as far as its history, as well as its present state and its future are concerned. For a given property a valuation analysis is to be produced. Property valuation involves defining the nominal value of a property. Property value is the amount equal to a property's transaction price in the real estate market. At the preliminary stage the value of a property can be any amount and it is possible to model it using a theoretical mathematical object which we define as a random variable.

Therefore when we use the term 'property value' we refer to an element of a theoretical model that is a random variable. The assumption that the property value estimated by the valuer is treated as a random variable is crucial for the whole property valuation process and constitutes the foundation of the reasoning which lies at the core of property valuation. This is a standard approach in applied sciences. This approach is substantially different from the population approach, in which the result of observation is a value produced as an observation of one of the analysed objects in a group of objects called population. Population comprises property valuers and at best one can speak of randomness in choosing the person responsible for valuation, but the result of the valuation is deterministic. In statistics, these approaches are differentiated with the former referred to as descriptive statistics and the latter, based on modelling random variable distributions, as mathematical statistics.

In property valuation usually we do not have a satisfactory dataset which can be treated as a population. Therefore a normal and effective solution is an approach based on treating property value as a random variable characterized by a certain distribution. What interests us in the results of a valuation are the characteristics of that distribution. These may include the expected value (E(X)), median, quartiles, and variability scatter spread. One can proceed in the direction of parametrization procedures and attempt an estimation of the parameters of the distribution. Also allowed are methods based on non-parametric procedures or Monte Carlo simulations, but all these procedures are used based on the assumption of a model of randomness of property value (Kathmann, 1993 and Ahn at al, 2012). This preliminary stage of modelling of the property valuation process has usually met with a consensus of researchers and is not considered controversial. Modelling of property value by means of random variable implies treating transaction prices of other comparable properties as realization of random variables as well. This is a natural approach adopted today and in the past (Isakson, 1998 and Narula at al, 2012).

Differences of opinion between researchers emerge when further postulates are adopted. If the value of the property undergoing valuation is a random variable characterized by a distribution with a density f, then it is not necessarily the case that the values of other properties, taken into consideration in the estimation of the density of parameters, also have a distribution f. Usually researchers adopt this assumption, modifying the distribution parameters accordingly if needed. The approach adopted by the researchers is dictated by tradition and potential problems, solving of which goes far beyond the standard statistical methods. It is worth considering that in a traditional statistics course taught at virtually all higher education institutions around the world it is assumed that the distributions of the values of accompanying properties are identical (as far as parameters are concerned) as those of the analysed property, and what is more, the values of accompanying properties as random variables are independent. Such an assumption allows to carry out a series of statistical processes using simple random sampling. It is almost never the case that in this kind of

analysis an attempt is made to examine if the independence condition is met, which obviously does not occur, and that has far-reaching consequences distorting the model. For example, if the technical condition of a building is bad, then the prices of all the apartments in the said building drop simultaneously, and not independently from each other. If the independence postulate was to be given up, the kind of dependency would have to be determined and formally specified. In the present state of theoretical knowledge it is usually impossible to elaborate technical procedures which would allow for effective calculations in such cases. Certain procedures combining objects into groups and treating constituent results as independent results are permissible, but these are methods in which we attempt to adjust reality to fit the model, and not the other way round, which is the goal of modelling. Few researchers working on this problem notice such subtleties as independence, and attempts to get even marginally closer to modelling this problem are unheard of. Usually we assume without any scruples that property values have the same distribution as the property under valuation (as far as parameters are concerned). There is a lot of room for misunderstandings here as well. The often used attribution of the random variable to the normal distribution entails identifying certain characteristics of reality with characteristics occurring as properties of normal distribution. These properties are usually expressed in a highly complicated way and it is difficult to interpret them directly (Kagan at al, 1972). Generally, it can be said that Gaussian randomness is characterized by an enormous sum of minute influences with different directions and a self-similarity structure (stable distribution). This characteristic is completely alien to property value. It is characterized by some scattering around the mean, but the main empirical differences lie in the quality structure, and not associating randomness with self-similarity (fractality). The average researcher is not able to identify the characteristics of the random structure of the property, which would be reflected in a mathematical model such as normal distribution. Therefore assuming a Gaussian distribution is a serious misuse.

Let us consider a simplified example that will help demonstrate certain aspects of the regression approach. The object of the analysis is a dataset comprising transaction data from notarial acts of sale of residential property (apartment) situated in Żabianka district in Gdansk including 549 pieces of data. In Poland, valuers are statutorily guaranteed access to notarial acts of sale, stored, among others, in the poviat authority. In our dataset, the transaction parties were independent individuals. The properties in question had the same location in the city, in a district situated in the central area of Tricity, characterized by homogenous 1970s multi-family development. The transactions were completed between 2004-2016. It is important to note that these are all the transactions involving the same kind of property completed in the said area in that period of time. The market did not generate more comparative transaction data. Differences between properties resulted from their location in four-storey buildings without an elevator or ten-storey with an elevator; their surface area and their location on a given floor. Moreover, properties differed with regard to an unspecified characteristic of quality of standard and quality of the surroundings. For the purposes of this work, let us assume that the task of a valuer is to perform valuation of a residential property (apartment) located in the same neighbourhood, whose characteristics are specified and its current value is to be estimated.

In our model, let W_i where i =1,…,549 be the values of properties considered in the example (random variables). Empirical values (w_i, p_i) constitute empirical observations of values of comparable properties and values of their surface areas described in the example. Let us assume that the model of dependency of property value from its surface area is defined by the regression equation $W=\beta_0 +\beta_1 P+\varepsilon$, where β_0 i β_1 are the parameters of linear regression, P is the surface area (and is not a random variable), and ε is the error. Random variable ε has a normal distribution with the expected value of 0 and unknown variance σ^2. Using comparative data the model is defined by the equation $W_i= \beta_0 +\beta_1 P_i+\varepsilon_i$, i = 1,…,549, where the sequence of random variables ε_i, constitutes a sequence of independent random variables with the same normal distribution with an expected value = 0 and variance σ^2. Of course, these assumptions imply that property values are independent and have a normal distribution with the same variance and expected value constituting a linear function of surface area. By means of maximum likelihood estimation (MLE) we find the estimators of parameters β_0 i β_1, with β_0 = 5927.9 and β_1=-10.5 . It is worth noting that according to the adopted model an increase in surface area by 1 sqm implies a decrease in unit price by approx. 10 PLN. Of course, the model is far from being adequate, however, based on the data at hand we can incorporate into the model the information about the floor number, as intuitively it seems that it should have an important influence

on the value of the property in question. Having taken into account the information regarding the floor on which the comparative properties are located, a model emerges with 15 one-dimensional regression equations. Thus, the model becomes more complex, the estimators of parameters are less precise, and we will obtain results with a low diagnostic value that leave room for many different interpretations. For example, the transaction value of an apartment with the surface area of 53 sqm calculated using the model will be equal to:

Table 1: Slope coefficients and prices of 53 sqm apartments by regression model

Floor	0	1	2	3	4	5	6	7	8	9	10
β_0	-19.7	18	-14.7	-33.8	-11.4	-25.2	-16.4	-13.6	-32.7	-24.4	-28.7
Price [PLN/sqm]	5831	4715	6313	6958	5945	6576	6401	6017	7074	6484	6761

Source: Own study.

Looking at the results presented in Table 1 we can see that, when we increase the surface area by 1 sqm, the price of an apartment can increase or decrease from -33.8 PLN (4th floor) to 18 PLN (1st floor) and there is no regularity. It should not be expected that the results concerning the price of an apartment with a surface area of 53 sqm will be correlated in a sensible way with the floor on which it is located. The reason for that lies in an inadequate model and too rigorous assumptions. Two characteristics, surface area and floor number, are not enough to make estimates about property value even with a good model at hand. Dependencies shown in Figure 1 reveal the different dependencies of price from surface area on different floors.

Fig. 1: Regression of price vs. surface area for floors 0 to 5th

Source: Own study

The 'floor' property is found in our data and we could extend the model to take into account this dependency. However, there is a range of other properties which diversify the price of the property in a similarly dramatic way as the 'floor' property. We do not know the extent of influence these

characteristics have and we do not know their values for the comparative properties. If we make an attempt to enrich the model with additional dependencies, eventually the model will be good enough, but it may turn out that it will be very complex, comprising many different equations. If we proceed towards increasing the number of features, we reach the point that researchers have reached in economics, where models including up to tens of thousands of equations were created. These did not produce satisfactory results and a new direction, that of analyses of stochastic equations, was adopted instead, nevertheless a group of advocates of putting together linear equations is still visible amongst researchers. If the set of comparative properties analysed is homogenous (so that they have identical distributions), transaction prices are characterized by independence and additionally, a series of congruities are observed, then the model will usually be adequate and uncontroversial. There are valuers who attempt to use regression models in valuation, however, in practice the valuation is not based on a regression model, but the regression model is meant to justify the valuer's professional intuitions.

When modelling a phenomenon using regression it is important to note one other crucial aspect of the model. In standard cases we endeavor to obtain estimators of the parameters of the value prediction model, we test the coefficients, and in the case of multidimensional regression we try to identify the significant variables of the model (submodel selection). The next stage, referred to as model diagnostics, plays an important part as well. In 1973 Francis Anscombe published an example of regression which went down in history under the name of Anscombe's quartet (Anscombe, 1973). It includes four linear regression graphs for data characterised by different structures but identical parameters.

The means, x and y values, their variances, correlation coefficient and, of course, regression graphs are almost identical for each dataset. This example shows the importance of regression model diagnostics. Stopping the analysis of regression at the calculation of coefficients can lead to serious errors and the next stage, which allows to assess if the regression model is adequate, needs to be carried out. Further details regarding this issue can be found in many traditional monographies, but it is advisable to refer to publications which require using computer programs (e.g. Biecek, 2013).

Regression as a modeling method is a basic data visualization method and should always be used as an element of data visualization in the context of a linear model, particularly when we have access to a big set of comparative data. Another aspect to be considered is the aim of the analyses. If the analyses are aimed at specifying the relationships in the context of a big homogenous dataset (for instance, in order to specify the principles of valuation for the purposes of cadastral tax), then elaborating and confirming one's intuition based on regression is by all means recommendable. However, using regression in individual appraisals is not appropriate. Methods relying on exploratory data analysis (EDA), although they do not provide a definitive answer to the valuation problem, are considerably more useful. EDA consists in discovering relationships existing in an empirical dataset without referring to the parametric form of those relationships. Normally the relationships discovered between variables are not represented in the form of a function, but rather expressed descriptively. For example, we will say that properties in a given location have quite a homogenous value (it can be assumed to be constant), and in another location the value of comparative properties is split up into several levels dependent on subgroups conditioned by additional characteristics. The answer is therefore descriptive and not functional, such as that obtained in the classic approach. Examples using these methods are described in Krzykowski and Majewska (2011).

To summarise, it should be emphasized that EDA methods provide extensive analytical material that can be used to obtain structural knowledge concerning comparative properties, as well as empirical material that can be used to determine the value of the property being analysed. Carrying out these analyses, we acquire knowledge about a given situation that perhaps is different from the one we set out to obtain at the start, but is the kind of knowledge concerning the structure of comparative properties that allows for further detailed stages of property appraisal.

Comparative Approach to Valuation

The property appraisal methods and approaches used in Poland are defined in the current regulations. The comparative approach is used to define the market value understood as „the estimated amount for which an asset or liability should exchange on the valuation date between a willing buyer and a willing seller in an arm's length transaction, after proper marketing and where the parties had each acted knowledgeably, prudently and without compulsion", in keeping with the definition as stated in Blackledge (2017). The comparative approach is one of the methods of estimating the market value of property and it based on the prices obtained for similar properties in the market. This requires the valuer to gather transaction data where the object of a transaction is a property similar to the property undergoing valuation. Next, the prices of these properties should be corrected for characteristics which distinguish them from the property in question and if it is necesarry the changes of price level in time should be taken into account as well. The crux and procedura of the comparative approach is defined in International Valuation Standards (2017) and also described in relevant literature (Millington, 2000 and Blackledge, 2017).

As mentioned earlier, property appraisal involves searching for the price for which a transaction of sale of a property with certain characteristics would take place in a given market between well-informed transaction parties that act rationally. This search is carried out based on transaction data from notarial acts of property sale contracts, which in Poland are made available to property valuers. The thus collected transaction data contain information about the parties and the object of the transaction, the transaction price and date, the kind of transaction parties (e.g. property developer, individual), and the basic characteristics of the property:
-property type (undeveloped, separate premises, built-up land)
-address, or record number in case of a plot of land
-surface area in case of plots and apartments, whereas in the case of buildings that are part of built-up properties no detailed information regarding their surface area is available

Further information regarding the property, such as its purpose in the spatial layout plan, utilities provision, or technical condition are rarely stated, and only if such is the desire of the transaction parties. The information is clearly limited, and it does not contain many important pieces of data concerning the property taken into account by buyers and sellers during the transaction negotiations. The information regarding such characteristics of the property as: quality of the neighbourhood, technical condition of buildings, standard of the apartment, shape of the plot and lay of the land in case of land property, are missing. Some of these characteristics can be identified using the resources available, such as underground infrastructure maps, spatial planning maps, or by viewing the property. However, it is not possible to determine the technical condition and standard of interior finishing works. Nonetheless, by gathering additional information and relying on expert knowledge and understanding of the real estate market in the area of their professional activity, valuers are able to identify these characteristics as well.

Best Practice

When estimating the property value, understood as a market value, a property valuer seeks to answer the following question: at what price would a potential rational buyer or seller who is well-informed with regard to the real estate market, buy or sell a given property in a given moment. We can say that the valuer looks for the transaction price that would be agreed upon as a result of negotiations between the buyer and seller. A professional valuer usually follows the procedure presented below.

4.1. Identification of the object of appraisal

The object of appraisal is a market object (Kucharska-Stasiak, 2016). First, the valuer identifies the property type, which is legally and physically defined. This means that the valuer defines the rights with respect to a given property which undergoes valuation, as well as its physical characteristics, which are important for its value in a given real estate market. In the example discussed above, the

object of appraisal is ownership of the property (apartment) (art.2.2. of the Act on Ownership of Premises 2015).

Next we define physical characteristics which influence the property value, which are unambiguously interpreted, i.e. identically by all participants of the real estate market:

1) location, which is the most important physical characteristic of a property. It is an invariant characteristic that is constant in time and space. It is understood as the property's location in a given urban or rural area, within which there is a specified economic and social situation that has an important influence on the local real estate market and that determines supply and demand in this market. Moreover, a given location determines the availability of various services and its accessibility conditioned by the infrastructure and public transport available.
2) size, which determines the potential use of the property and the size of the capital associated with its price or value in a given market. At this stage of the analysis size can be defined by the number of bedrooms.

   In the case of apartments it is also possible to unambiguously define other characteristics such as:

3) location on a given floor
4) type of the building where the apartment is located

Characteristics which are not unambiguously interpreted are:

1) quality of immediate surroundings, which includes aesthetic aspects and whether the surroundings may cause disturbance
2) technical condition and standard of finishing works. This is a characteristic which can be improved upon as a result of repair works in the apartment or building, however, these entail further expenses which the buyer will have to incur in the future and which s/he will take into consideration during transaction price negotiations, but it is difficult to define what standard s/he would find satisfactory.

It is possible to consider a more extensive range of characteristics, but such an approach is not always justified, and often it does not improve the accuracy of appraisal.

Selection of comparative transactions and their analysis

Following the identification of the object of appraisal and carrying out of the analysis of the real estate market, the valuer uses their expertise and experience to define the segment of the real estate market where the potential buyers look for properties of a given kind or potential sellers try to sell properties of a given type. It should be noted that within the real estate market we can consider many segments of the market, which result both from the characteristics of the properties of a certain kind, and from their value understood as the capital which potential buyers are willing to invest in a given market. A valuer usually focuses on a concrete segment of the market, where s/he looks for a representative dataset of comparative properties, i.e. properties which have the same characteristics as the property undergoing valuation, identified beforehand.

If the object of appraisal is a residential property of a given size situated in a given location in a multi-family building erected using given technology, then we look for transactions concerning properties that are located as close as possible to the property under valuation, sharing the same characteristics, which took place at a point in time as close as possible to the moment in which the appraisal is being carried out. In other words, we look for a dataset comprising elements (properties) with the following identical characteristics, which were the object of transactions in a given period of time, when no significant price level changes took place in the real estate market:

1) type – separate premises (apartment)
2) use – residential
3) location – Żabianka district

4) size – from 1 to 4 bedrooms
5) building age and technology – buildings erected between 1970-1980, precast building technology

The thus created dataset with comparative transactions is the object of further detailed analyses. It comprises elements which still differ significantly from one another. This dataset will allow to examine tendencies in a given market and the price structure, using statistical methods which discover dependencies within the selected comparative properties.

Fig. 3: **Linear regression of price vs. time**

Source: Own study.

First of all, we examine the change of price levels in time. In the example analysed, these changes are shown in Figure 3. The above graph shows a big spread of prices, and the linear regression of this dependency is expressed by the equation: Y = 0.0389 x +3836.8. A series of diagnostic parameters show that regression is not an adequate model and does not describe the relationship of price changes and time, therefore the above equation will not allow us to update the transaction prices with respect to the date of appraisal, even if the result would fall within the expectations of those monitoring the market. Such reasoning would, however, have a low statistical value. The valuer's expertise allows them to assume that in shorter periods of time prices in the real estate market remain stable. The real estate market is characterized by big inertia, therefore in a short amount of time one can ignore the change of prices in time. Exploratory data mining methods are helpful here, allowing to determine the ranges of time when there is price stability (Krzykowski and Majewska, 2011). Hence, property valuation should be carried out based on a dataset comprising transactions which took place not long before the date of the valuation itself. The big spread of prices indicates that there are additional determinants which influence buyers' decisions. The advocates of linear regression models will assume that transaction prices and the identified characteristics of the property are in a linear relationship. The multidimensional regression model, which in this approach would be expected to describe this relationship has several defects (Wyman et al, 2013), including:

-the assumption that potentially all characteristics of the property which influence the transaction prices have been defined
-the assumption that characteristics are independent
-the assumption that relationships and phenomena which occurred in the past will repeat in the future
-the „ceteris paribus" assumption, i.e. that all variables which are not analysed, in this case the characteristics of the property, are stable
-the assumption that relationships obtained based on the global dataset are applicable to the small subset of transactions constituting the direct basis for the valuation (Samuelson at al, 2012)

By adapting different regression models, using trial and error, as well as discarding some transaction data or modifying the characteristics analysed, some valuers obtain a model which will yield a pre-determined result. Such approach does not have high quality and, what is important, can be seen as a manipulation.

A professional valuer will carry out a different logical analysis based on the assumption that, given that the object of the appraisal is a property with certain definable characteristics, one needs to check what prices are reached in a given market by properties with the same characteristics as the property in question.

Let us assume that we are looking for the value of a residential property of a given size, e.g. 3 bedrooms, and located in a given housing estate. In our example, this allowed us to obtain a dataset with three comparative data pieces with the same location and size, located in buildings of the same type.

Table 2: Selected comparative transactions

Transaction Date	Street	Area [sqm]	Price [PLN/sqm]	Floor
2016-11-08	Rybacka	53	5133,08	4
2016-04-21	Szyprów	53	6463,88	0
2016-05-06	Szyprów	53	5969,58	4

Source: Own study.

The three selected properties underwent verification with regard to conformity with the complete market information collected beforehand by the valuer. Selecting a small group of properties for direct valuation requires extensive experience and familiarity with the market. This expertise is mainly obtained by means of one's own professional practice and exchange of experience through workshops and training sessions.

Estimating the value of the property

A valuer estimates the value of the property based on a meticulously selected small group of comparative properties which have been deemed to be the most similar to the property undergoing valuation. First, the valuer views the property during a site visit (which is not possible in the case of 549 transactions) and defines characteristics, which s/he did not take into consideration beforehand, i.e. quality of the surroundings, technical condition of the buildings, and, if possible, standard of the apartment. It should be noted that regression models used in property appraisal do not identify such a wide range of property characteristics. It should be further emphasized that in the case of a big number of data used in regression this is practically impossible and almost always economically unjustified. Estimating the value of the property analysed based on a small group of selected transaction data consists in comparing each of the selected comparative properties with the property undergoing valuation. We specify the differences and estimate their influence on the differences between the transaction prices of the particular comparative properties. Next, we correct the prices with respect to the property undergoing valuation. This procedure is to a large extent based on the valuer's experience and assumptions made by her/him based on their professional expertise and intuition.

It is worth noting that this procedure allows to estimate the value of a property not only in mature markets, rich in transaction data, but also in undeveloped markets, where transaction data are scarce. When the research material is limited, automatic statistical methods are useless, while a competent professional can effectively estimate the value of the property in question.

Conclusions

The presentation of methods used in property appraisal in the comparative approach presented in this work allows to draw the following conclusions:

1) The real estate market does not generate data with a homogenous random distribution that could constitute a statistically understood population. Properties differ as far as qualitative characteristics are concerned, which are assessed differently and ambiguously by the participants in the market.

2) Using rigorous parametric models (e.g. regression models) allows to observe tendencies in the market and describe the structure of property transaction prices, however, reasoning based on automatic modelling without sufficient market information can lead to erroneous conclusions.

3) Regression methods do not reflect the behaviour of the participants in the market, therefore using them for individual appraisal is inherently erroneous. This aspect of the problem is also considered in the International Valuation Standards, which recommend using methods which are employed in a given market

4) According to the authors' opinion, the specificity of the real estate market does not hold promise for effective use of machine learning methods based on neural networks for individual appraisal. The real estate market does not generate research material extensive enough for a successful learning process.

5) The presented analysis shows that the currently widely discussed Automated Valuation Models (AVMs) based on statistical models can only be useful in large-scale valuation, e.g. for the purposes of cadastral tax.

6) In the case of individual appraisals in the comparative approach the best practices followed by professional valuers most adequately reflect the behaviour of the participants in the market, at the same time allowing for successful valuation even with limited market information.

Abstract

Description of a main objective of research. In recent years, Russia has encountered a crisis. This resulted in the low economic growth and low investment activity. In such conditions, regional authorities (including the authorities of Tambov region), face the challenge of stimulating business and developing a competitive environment. All this determines the relevance of this study. *Short description of methodology.* The study was based on official Rosstat and Tambovstat statistics and the annual social and economic research "The competitive environment in the markets for goods and services in Tambov region: current conditions and prospects for development" (in 2015-2019), commissioned by Tambov Region Administration. The authors of the study analyzed the specific features of regional entrepreneurship and assessed the competitive environment and business conditions. *Compilation of the most important research results and their significance.* The study shows that the general economic situation and the crisis processes have an impact on the business community of Tambov region, and cause changes in the competitive environment. As a result, entrepreneurs confirm that they face an increased competition, and outline the problems and basic conditions for the competitive environment. The article shows that, to a large extent, the development of the competitive environment in Tambov region is restrained by systemic and general economic processes the regional authorities can hardly influence. At the same time, due to the specifics of the regional economy, a growing crisis will have a dramatic impact on the business community of Tambov region and its competitive environment.

Keywords: Competition, Competitive Environment, Level of Competition, Economic Growth.

Introduction

Recent years have become rather problematic for the Russian economy due to a noticeable economic crisis [1]. In general, this situation can be characterized as stagnation, which is even more critical at the regional level. Thus, the volume index (GDP and GRP of Tambov region) at constant prices shows that the situation in Tambov region is more challenging than in Russia as a whole (Table 1).

Table 1: volume Index (GDP and GRP of Tambov Region) at constant prices [2, 3]

Index	2012	2013	2014	2015	2016	2017	2018
Volume Index at Constant Prices (Russia)	103,7	101,8	100,7	98,0	100,3	101,8	102,5
Volume index at constant prices (Tambov Region)	108,9	109,2	105,7	103,9	95,1	101,1	no data

[1] The article was written under the grant offered by the Administration of Tambov Region to support applied research of young scientists in 2019 ("Current conditions and prospects for the development of competition in the markets for goods and services in municipalities of Tambov region"

Moreover, the indices of the second level make the situation even clearer. For example, the analysis of investment activity demonstrates the impact of the crisis [4]. So, the dynamics of investment in fixed assets shows the following (Table. 2).

Table 2: the dynamics of fixed capital investments in the Russian Federation and Tambov region at constant prices [5]

Index	2012	2013	2014	2015	2016	2017	2018
Growth rate of fixed investment at constant prices (Russia)	**106,8**	**100,8**	**98,5**	**89,9**	**99,8**	**104,8**	**104,3**
Growth rate of fixed investment at constant prices (Tambov region)	116,7	113,6	108,0	96,1	84,0	102,7	79,2

Ultimately, this affects, not only the economy of certain regions, but it also has an impact on the regional budget balance. This problem is quite critical, since in 2018 12 regions did not receive budgetary subsidies (Tatarstan, Leningrad region, Moscow region, Samara region, Sakhalin region, Sverdlovsk region, Tyumen region, Nenets Autonomous District, Khanty-Mansiysk autonomous district, Yamalo-Nenets Autonomous District, Moscow and St. Petersburg) [4.6].

The rest districts are subsidized to some extent. However, the level of subsidization is different. Thus, the amount of the federal subsidy offered to Kaluga region was 0.27 billion rubles, while Tambov region received 9.11 billion rubles, and the Republic of Dagestan - 59.07 billion rubles. [6].

In such a situation, the quality of regional policy should be increased since it is crucial to stimulate and support the regional economies. It is vital to develop a competitive environment in the markets for goods and services of the regions of the Russian Federation [7]. Nowadays, the government does its best to contribute to the development of competition and to provide equal conditions for commodity producers, trading enterprises and consumers in all markets for goods and services, which determines the relevance of this study.

In this regard, the main goal of the study was to analyze the competitive environment in Tambov region and the corresponding problems. Thus, in future it may help to promote the effective policy aimed at improving the regional business climate.

Methods

The study was based on the logical and dialectical methods, as well as the methods of analysis and synthesis. In addition to general scientific methods, specific methods were widely applied in the research work.

In this article the authors referred to the sociological studies of entrepreneurs and the population of Tambov region devoted to the development of a competitive environment. The results of these studies were published in the Analytical Reports “The competitive environment in the markets for goods and services of Tambov Region: current conditions and prospects for development” (2016-2020) [8-12]. In the course of these sociological studies (in 2015-2019), entrepreneurs and the population of Tambov region were surveyed. An electronic questionnaire was used as a monitoring tool, and it was put on the official website of Tambov Region Administration.

In the course of the research the authors used the statistical methods, sampling methods, a method of grouping, a trend analysis and a structural analysis.

Apart from that, the authors analyzed the data related to the period of 2015-2019. On the one hand, there were certain objective restrictions on the availability of public data, and on the other hand, it is quite normal to analyze a five-year period to identify the specific trends. In some cases, the authors analyzed a three-year period as they faced some problems when carrying out a comparative assessment.

Results

Regional entrepreneurship. The regional portrait of the entrepreneur of 2015-2019 has changed dramatically. There are significant changes in the level of education of entrepreneurs (Table 3).

Table 3: the level of education of Tambov entrepreneurs [8-12]

Response options	Percentage, %				
	2019	2018	2017	2016	2015
1. Incomplete secondary education (post-primary school, vocational school, etc.)	1	1	1	1	5
2. Secondary education (secondary school, vocational school)	3	4	5	4	9,4
3. Special secondary education (technical school, medical school, pedagogical school, musical college, etc.)	19	28	32	24	36,1
4. Post-secondary education (2 years at the university)	3	2	3	4	3,4
5. Higher education	73	65	58	65	46,1
6. Academic degree	1	0	1	2	0
Total	**100**	**100**	**100**	**100**	**100**

According to the industry analysis, there are significant changes in entrepreneurship of Tambov region (Table 4).

Table 4: the sector profiles of the enterprises of Tambov region [9-12]

The sector profile	The number of respondents. %			
	2018	2017	2016	2015

Assessment of the competitive environment. According to the analytical reports "The competitive environment in the markets for goods and services of Tambov region: current conditions and prospects for development" (2016-2020), there are significant changes in the competitive environment of Tambov region (Tables 5-6). The results of assessment of competitive environment are presented in Table 5.

Table 5: assessment of competitive environment [8, 9]

Response options	Competitors, %					
	In the city / area			In the region		
	2019 г.	2018 г.	2017 г.	2019 г.	2018 г.	2017 г.
1. No	47,6	47,7	53,2	30	28,8	40,5
2. Yes, there are some	44	46,5	40,1	64,3	67,7	55,4
3. Yes, there is one	8,4	5,9	6,7	5,7	3,5	4,1
Total	**100**	**100**	**100**	**100**	**100**	**100**

The authors also analyzed the problems associated with the increase in competition.

Table 6: problems associated with the increase in competition [8.9]

Response options	Percentage, %		
	2019 г.	2018 г.	2017 г.
1. Import competition	19,2	16,6	15
2. Unfair price competition (dumping, etc.)	20,4	20,1	17,4
3. Unfair quality competition	21	22,4	22,3
4. Unfair advertising	10,4	10,7	14,7
5. Administrative barriers restricting competition	4,2	4,8	4,9
6. Government support for individual entrepreneurs	4	4,2	5,2
7. Association of business entities to increase market share and gain competitive advantages	4,2	3,6	3,4
8. No problem in this area	29,9	35,7	26,2

It should be noted that in 2019, the analytical report included the entrepreneurs' assessment of the measures aimed at the development of competition (Table 7).

Table 7: measures aimed at the development of competition (entrepreneurs' estimates, 2019) [8]

Measures for the development of competition	Share, %
Price control	40,1
Product Quality Assurance	32,6
Job creation	18,0
Creating conditions for more companies selling goods or services	17,6
Preventing companies from dictating their own terms in the market	17,3
Ensuring fair competition	16,7
Creating a system of informing the public about the services offered by various companies, consumer protection and the state of competition	12,7
Support for start-ups	12,3
Legal protection of entrepreneurs	8,8

Measures for the development of competition	Share, %
Attracting investors	7,2
Support for new directions in the economic development of the city and area	5,8
Monitoring the performance of natural monopolies, such as water supply, electricity and heat supply, railway and air transport	4,2
Providing everyone with business opportunities	3,2
Transparent procedures in municipal tendering and procurement	2,5
Reduction in the number of municipal enterprises providing services to the population due to the emergence of new commercial enterprises	1,6
Registration of citizens' complaints related to the problems of competition development	1,4

Business conditions. We should also analyze the way the business conditions in Tambov region were estimated. Thus, Tambov entrepreneurs outlined the following business factors (2017-2019) (Tables 8-10).

Table 8: business conditions (estimates of 2019) [8]

Response options	Very bad	Bad	Satisfactory	Good	Very good	No answer
1. The availability of information on the state of the markets for goods and services of the city / area	0,9	3,0	31,5	31,5	5,6	27,5
2. The goods and services are in demand and are bought by the customers	1,8	6,2	37,3	24,5	2,8	27,5
3. Relationship with other competing firms	1,1	3,5	33,3	28,9	3,3	29,9
4. An opportunity to receive a loan	2,1	3,9	26,2	31,7	6,3	29,8

9. Availability of state and municipal services	2,3	3,5	29,4	41,2	11,2	12,3
10. An opportunity to participate in tenders and competitions organized by local authorities	2,8	5,5	29,4	36,1	9,8	16,5
11. Lower barriers to business	2,8	5,6	31,6	32,8	7,2	20,0
12. No nepotism and clannishness in the bodies regulating the development of competition in the city / area	5,0	6,7	29,6	24,2	6,9	27,6

Finally, entrepreneurs claim that the most significant factors that hinder business development and competition are (Table 11):

Table 11: hindering factors in business development (estimates of 2019) [8]

Problem	Rating,% of respondents
Lack of funds	53,2
Lack of qualified personnel	36,4
Outdated equipment	24,1
Competitor pressure	10,7

Low labor productivity	7,9
Administrative barriers	7,6
Conflicts between employees and management	2,5

Unfortunately, there are estimates received only in 2019, which makes it impossible to thoroughly analyze the changes and problems associated with business development in Tambov region.

Discussions

Regional entrepreneurship. The level of education has changed most significantly (Table 3). There are a lot of entrepreneurs who have a degree and few businessmen who have only a GCSE. There are two reasons for that. Firstly, entrepreneurs tend to get a higher education. Secondly, there are more graduates who get involved in the economic life. It should be noted that at the end of the 1990s and in the early 2000s, it became clear that it was not enough for entrepreneurs to have only a GCSE to be successful in business.

According to the industry analysis, there are noticeable changes in the regional economy (Table 4). On the one hand, there was a decrease in commerce, and on the other hand, there was a dramatic increase in such sectors as agriculture, education and science. In all other sectors, the situation is quite stable. As for the negative sides, there are not enough capital-intensive industries (such as construction, mining, manufacturing and power engineering) and high-tech industries (communications, telecommunications, and information technology). It is due to the lack of large-scale production facilities in Tambov Region; in addition, there are no breakthrough projects to boost the regional economy.

All this means that in case of aggravation of crisis in Russia or all over the world, Tambov region will encounter great difficulties, since this region, in fact, does not have its own drivers of the economic growth.

On the whole, this section of economy has a significant impact on the level of competition in the region and the development of the competitive environment.

Assessment of the competitive environment. According to the entrepreneurs' estimates, the level of competition has noticeably increased over the past three years (Table 5). Moreover, when entrepreneurs assess the situation in the region, it makes us see the whole picture.

It implies that the Russian economy is in crisis (as well as Tambov regional economy). Thus, there is no increase in the income of entrepreneurs, which leads to enhancing competition. However, due to the fact that the market is stagnant, this kind of competition cannot be considered as an absolutely positive aspect.

It should be noted that the assessment of problems associated with an increase in the intensity of competition has undergone considerable changes (Table 6).

According to the estimates, the competitive environment is significantly affected by the import competition and unfair competition. In general, the role of competition between domestic and foreign companies has increased. The most competitive companies are Chinese, Turkish, German, Israeli, Polish, Korean and Belarusian.

It should also be noted that administrative barriers and insufficient government support for entrepreneurship hardly influence the competitive environment. Thus, the development of the competitive environment mainly depends on the economic factors.

The entrepreneurs' estimates of the measures aimed at the development of the competition (Table 7) made the researchers carry out a further analysis. Thus, the most effective measures to increase the competition in Tambov regional market are the following:

– price control;

– product quality assurance.

These factors are mentioned most frequently (72.7%) [8]. Apart from that, the businessmen mention such measures as:

– creating conditions for more companies selling goods or services;

– preventing companies from dictating their own terms in the market;

– ensuring fair competition;

– creating a system of informing the public about the services offered by various companies, consumer protection and the state of competition;

– offering support for start-ups.

It should be noted that the government is responsible for implementing the first two measures; however, balanced federal and regional economic policies are required.

Business conditions. The business conditions presented in Tables 8-10 are considered to be the most significant.

The following approach was used to interpret the results. If the cell value was about 70% or more, the answer option was associated with an important business condition (green cells). If the cell value was 50-70%, the answer option was associated with a condition having a moderate impact on business (yellow cells). If the cell value was 30-50%, the answer option was associated with a condition having a weak impact on business (grey cells). If the cell value was 30% or less, the answer option was associated with an insignificant business condition (the cells in the table are not highlighted). In most cases the matrix allows to unambiguously interpret the results.

Thus, all the conditions except the last two (lower barriers to business; no nepotism and clannishness in the bodies regulating the development of competition in the city / area) are believed to have either a significant or moderate impact on business. As for the last two conditions, they are not considered as the important ones since they have a weak impact on business.

There was a fairly even split between the respondents identifying the most significant business conditions, so the results reflect only an average opinion. It should also be noted that there were quite a lot of respondents who found it difficult to answer the questions. However, in general the situation related to business conditions is stable.

According to the logic of the study, the next step was to assess the competitive offers for business representatives from the standpoint of the development of competition between key suppliers. Thus, 7.7% of entrepreneurs normally work with a single supplier, 25% deal with 2-3 key suppliers, and 67.3% cooperate with four or more suppliers. In other words, most companies prefer working with different suppliers [8].

As for the level of competition between suppliers, only 1.6% of respondents consider it not to be high enough [8]. The vast majority of entrepreneurs are satisfied with the competition between suppliers.

Finally, it is crucial to analyze the way the entrepreneurs assess the problems related to business in Tambov.

In general, the identified problems are systemic in nature. Thus, more than half of entrepreneurs “complain” about the lack of financial resources. Unfortunately, it is practically impossible to solve this problem at the regional level, since the region is subsidized. The problem itself is largely associated with the ongoing monetary policy, which determines the level of interest rates and the availability of credit [13].

The second important problem is associated with the lack of qualified personnel. It is also a systemic problem, since it depends both on the demographic situation and on the education system in the country and the region. However, we should make a reservation: Tambov region borders on rather large and economically more developed regions (Saratov region, Voronezh region, Lipetsk region) and it is not far from Moscow megalopolis. In such a situation, for quite objective reasons, there is an outflow of qualified professional personnel.

The third important problem is associated with obsolete equipment. The technological systems are quite complicated. On the one hand, modernization of technologies requires financial resources. On the other hand, there is a shortage of equipment and technology produced in Russia.

However, according to entrepreneurs' estimates, the problem associated with "administrative barriers" is insignificant. They are much more concerned about the lack of financial resources, qualified personnel and equipment.

Thanks to the low level of administrative barriers, entrepreneurs have an opportunity to start up their own business in Tambov region. Over 50% of respondents do not think that there are any administrative obstacles. Only 15.5% of respondents find it hard to start up their own business. Thus, the authors of the article concluded that modern problems associated with business development and competitive environment are systemic in nature and cannot be solved by means of tactical methods. In general, one of such methods is associated with regional economic policy which is unable to influence monetary policy, education, demography, and investments. In this regard, it is obvious that the regional authorities can hardly contribute to the development of the competitive environment.

Conflict of Interests

The authors argue that the data presented in the article do not contain a conflict of interest.

Acknowledgements

This research was based on sociological studies published in the Analytical Reports "The competitive environment in the markets for goods and services of Tambov Region: current conditions and prospects for development" (2016-2020), as well as on official Rosstat and Tambovstat statistics. In addition, the authors referred to the results of their previous research works.

Abstract

The article observes the basic theoretical background of forming the "banking risk-processing" concept. Authors give its definition and identify the key areas of the banking risk-processing practical application to the regional banking system. It is settled the correlation between the risk- processing and the strategic development policy of the credit organization in the face of uncertainty. In order to activate and improve the effectiveness, the risk-management algorithm is proposed. It finds out the coherent plan of measures and actions to optimize the reserve accumulation process. The plan is designed based on "from AS IS to TO BE» model as part of the implementation of the banking risk-processing in regional bank.

Keywords: Risk-Processing; Development Strategy; Uncertainty; Bank; Risk-Management; Risk Model/

Introduction

Nowadays many financial transactions are carried out in conditions of uncertainty. This causes the need to monitor unsafe events and manage the consequences of possible threats, which is based on risk-processing. The effective functioning of any financial and credit organization, including banks, depends on the quality and efficiency of information systems, technological models applied to identifying risks.

Typically, the understanding the necessity of risk processing associated with other elements range of business activity, appears only in the implementation of major general banking projects requiring comprehensive analysis of both environmental factors and internal environment. Often goal-settings of resembling projects are aimed at the diversification of services provided, or increasing internal transparency, degree of manageability and controllability of financial organization at its different levels. In this case, the risk management is not separate from the key source of the suppositional improvements and it is involved as an essential direction and strategic development policy element of the bank, the design of which includes, on the one hand, the characteristics of the organization itself, and on the other, - regional or more global progress trends.

The relevance of the study concerning various aspects of risk-processing is proved by the escalating scientific and practical interest in this area. This is reflected in the diverse publications of domestic and foreign authors. So, S.Avdoshin and E.Pesotskaya explore the problems of applying different information technologies in the banking risk management [1]. G.Avagyan and M.Saitova analyse the characteristics of regional banking cluster [2]. E.Altuhova, V.Zotov, M.Markov develop a methodical approach to risk management in the regional commercial bank [3]. S.Vayn investigates trends and resource to optimize a modern bank [4]. V.Shumilova, A.Karataev offer information model assessment

of banking risks in different industries [5]. Among foreign scientists it is worth mentioning such authors as: J. Bessis with a study of risk management in the banking sphere [6], O. Kosta, J. Hahn and S. Levi who analyse emerging markets including the financial banking sector [7], A. Meyer, J. Armstrong and M.Zelmer who overviewed the risk management tools in Canadian banks [8].

Despite widespread scientific debate on risk management in various financial institutions, it remains poorly studied the innovative direction such as banking risk processing in the regional banking system and its correlation with strategic planning at the meso- and micro- levels. So, this direction states the research keynote within the paper submitted.

Materials and Methods (Model)

The stated purpose required to solve specific problems:

– to formulate the definition of the "banking risk-processing" concept basing on identifying the theoretical and practical prerequisites for its emergence and penetration into the practice of organizations' economic activity;

– to identify the interrelation of the banking risk-processing and Bank Strategic Policy;

– to develop an algorithm and a consistent plan of measures and actions to optimize the process of reserve accumulation based on the implementing banking risk-processing into the organization's activities in order to activate and improve the effectiveness of risk management and the bank strategic policy.

The methodology for achieving the goal, solving problems and obtaining results is based on applying system analysis approaches and using the model "from AS IS to TO BE".

Results and Discussion

To investigate the specifics of the banking risk-processing in the regional banking sector application we should start with analysing the theoretical and practical background of this innovative phenomenon and term. Such examination will give the possibility to determine the terms and terminology used, which in future will enable us to select and introduce the tools and models that are adequate to our tasks.

A. Backgrounds to define the term "banking risk-processing"

Risk management is one of the key areas of management in the banking field. The main task of risk management is to provide relevant formalized information on the expecting occurrence and the consequences of risk events, to identify and select ways and means to overcome threats, to control reactions and to detect external and internal feedback. As it is known, the process of identifying hazards is also actualized by the fact that the CBR (the Bank of Russia) withdraws licenses from banks with unsatisfactory financial condition that conduct equivocal, opaque and unbalanced operations. That is, such banks include those whose activities demonstrate a variety of unmanageable or poorly managed risks, namely: liquidity and low solvency risk, legal, reputation, operational and others. At the same time, as it can be seen from the data in Table 1, banks in different Federal Districts are exposed to varying degrees of risks, which leads to a reduction in their number in the regions. The most efficient risks overcomers are the credit and financial organizations of the South and North-West, where licenses have been withdrawn in less than 12% in three years. In the 2012-2015 period, the North Caucasus Federal District demonstrated the most complicated conditions when 53.6% of banks have lost their licenses [1].

[a.] *Compiled by the authors basing on [1] and data http://www.cbr.ru*

The choice of risk response tools depends on the risk type: functional (internal), external and financial. According to this typology, banking risks can be classified by subspecies [9].

1. Interest rate risk is associated with losses in the value of interest-bearing portfolio when interest rates change.

2. Credit risk arises from the failure to meet loan commitments and the unsustainable provisioning process.

3. Liquidity risk appears when there is insufficient funds to repay the bank's obligations.

4. Price risk is associated with losses due to changes in quotations for portfolio instruments.

5. Currency risk may cause losses due to fluctuations in the exchange rate during sales transactions.

6. Market risk is based on opportunistic changes in financial markets.

7. Investment risk is related to the activity of the bank's capital investments.

The variety and complexity of banking risks involves the working out a wide range of tools for their identification, definition, detailing, optimizing quickness and methods of feedback. Thereafter there is a need to introduce an appropriate business process to create and form easily applicable universal methods for identifying threats and overcoming their consequences. Such a process we will call "banking risk-processing". We note that multipurpose banking risk-processing is comprehensively ensured and depends directly on the means and methods of its digitization, namely: the software and automation tools used, algorithms and forms to communicate and disseminate information both inside and outside the bank.

B. Risk-processing and bank strategic policy correlation

Forming an effective strategic policy for regional bank under uncertainty is based on the analysing and processing risks and possible threats. Based on the "Risk Management Policy of the Bank of Russia" (dated March 23, 2016) [9], we should note that the risk management is aimed at setting up the formation and implementation of measures that contribute to the more efficient organization functions under uncertainty. At the same time, the financial losses reduction may not be prior, taking into account the social significance and wide range of the bank's activities. In the case of regional banks, the financial loss risk is at the heart of strategic planning, and it is advisable to analyse possible threats and dangers using banking risk-processing based on key risk management principles:

– *responsibility and authority* implies compliance with the obligations to implement risk-processing according the competence of corresponding employees;

– *the priority of the functioning objectives and the mission* distributes the benefits between the goal and the means to achieve it, i.e. to prevent possible financial losses should not prevail over the measures resolve tasks within the mission;

– *improving activities implies* a prolonged functional efficiency increase in the organization with the introducing innovative business processes, including the risk management optimization;

– *integration into business processes* is aimed at introducing risk-processing into various types of bank economic activities in order to reduce the impact of internal and external threats;

– *awareness* means conducting a preliminary identification and analytical assessment of the possible risks associated with the implementation of planned projects and passing the research results to the staff;

– *materiality and expediency*, as a principle, are realized by deciding on the necessity and mobility of a feedback to potential threats identified in banking risk-processing, taking into account the possible costs and benefits of the implementation of response measures to hazards identified;

– *prevention, identification and conflict management of internal and external interests* implies avoiding collision of different levels interests while implementing the banking risk processing;

– *the principle to provide "three lines of protection"* developed and applied directly by the Bank of Russia [10, p.6] presupposes three-level risk-processing: at the level of risk owners; in the context of divisions that fulfil methodological, controlling and monitoring functions during risk processing; at the participants performing an independent evaluation of the risk-processing system;

– basing on the possible complete information, *a transparent uncertainty demonstration* allows to assess objectively the risk degree, taking into account the likely limitations associated with the use of the analytical data obtained in a particular situation;

– *continuity* implies permanent risk-processing with the subsequent communicating the information about possible threats to the corresponding staff;

– *training and motivation* are widely used to encourage employees to risk-processing, which enables to enhance the strategic planning efficiency and the activities of the bank as a whole.

This brief overview of the risk-processing principles clearly demonstrates its close correlation with the bank strategic planning, from which the formation and improvement of relevant policies originates. However, we note that implementing every principle is aimed at increasing the efficiency of the regional bank as a whole. Though only an integrated approach is to be applied, since the principles are written down for certain business processes and types of interests: financial-economic, client, market, employees and staff motivation and stimulation; informational and methodological. It worth integrating these directions into the banking risk-process. It will ensure its positive impact on the design and implementation of the bank strategic policy, as far as it will help to actualize and compare the danger of threats, the probable losses resulting from them and the use of feedback tools to prevent them and possible benefits from implementing the appropriate measures.

C. Working out an algorithm and a consistent plan of measures and actions to optimize the reserve accumulation process basing on the model "from AS IS to TO BE»

To implement successful strategic development, the banks should introduce banking risk-processing, which may prove to be quite profitable, as it will help to level the causes and consequences of unaccounted risks.

1. High price and extremely negative consequences of errors. The risk-processing flaws are very dangerous for any bank or credit organization, as its results can be not only a significant financial loss, but, in the most negative scenario - bankruptcy.

2. High dependence on core competent employees that are high qualified in risk-processing. Each of them has a range of unique skills and abilities gained from invaluable experience in the sphere of their competencies. The firing or withdrawing such an employee entails a significant efficiency decreasing of risk management and increasing costs to restore the knowledge base lost. Therefore, there is a need to digitalize the banking risk-processing.

Thus, to introduce banking risk-processing is objectively proved. The most adaptive model is "from AS IS to TO BE". The algorithm to introduce the risk-processing into bank management is shown in Fig. 1.

Fig. 1: Banking risk-processing algorithm based on the model "from AS IS to TO BE"

Analysing the algorithm and scheme of the ASIS process makes it possible to identify two possible areas of optimization. The first of these is due to the multiple process inputs. Each of the bank unit involved (credit department, loans subdivision, middle-office, etc.) sends an e-mail to the employee participating in the implementation of a risk processing specific stage, supervising a certain client. At the same time, if there is no employee in the workplace for a good reason (sick, vacation or business trip), one’s mail remains unsorted for a long time. Simultaneously, there is a high risk of delaying the messages and information monitoring or the loss probability when sending materials to the wrong address.

Such a way to provide materials will allow them to be automatically processed and accurately sent to the employee responsible for this stage of risk-processing or supervising this client. This will utterly speed up the workflow and it will streamline the load distribution among the risk department staff, without notifying all the units involved. Those customers, for whom the corresponding employee was not selected by mistake in the subject line of the letter, would be manually processed.

The second potentially problematic area is the process exit. In the ASIS process, a professional judgments or opinions on the client arise from the papers signed and sent to the back-office. Usually in large credit organizations, the back office is centralized and geographically distant from departments

and employees carrying out the risk-processing. It stipulates the necessary to scan the relevant conclusions and documents and send them electronically.

As a result, the risk of inferior processing the documents, and even its loss, that will lead to incorrect reflection of reserves on balance sheet accounts and sanctions introduced to the financial organization by the Central Bank of the Russian Federation.

To optimize this part of the process, it is recommended to computerize the summing up conclusions and professional judgments, by providing the existing banking information system with the preliminary input of the classification parameters to encounter borrowers and clients. This will make possible to eliminate unnecessary operations in the workflow and it will significantly reduce the risk of inaccuracies. At the same time, the following action plan can be formed to implement the transition to the TOBE process (Table II).

Nevertheless, this project can take up to several years from a credit institution or a bank. Bank24.ru has recently spent 9 months for a coherent organizational and technical work, including core processes identification and its description. However, according to the representatives of the bank's management, it took much longer to change the employee's mentality including those of strategic positions, and after three years the process was not finalized.

Table 2: sequence plan of activities and operations to optimize the stocking up the reserve[a]

N	Activity	Deadline	Executor
1. Optimizing the input to the process (based on "AS IS")			
1.1	Creating a single e-mail box for the risk department	1-5 working days	IT department
1.2	Summing up and forwarding to the IT department the client list with instructions of employees who supervise them	1-5 working days	Risk department
1.3	Forming the instruction on the standard format applying to the transferring materials	5-10 working days	Risk department
1.4	Testing the information system and software for automatic distribution and sending the materials	15 working days	IT department
1.5	Distribution (intra-bank and client) of notifications on the transfer to a new format of the materials sent	1-5 working days	Risk department
2. Optimization of the output from the process (the "TO BE" plan implementation)			
2.1	Development of a technical task for the digitization of the processing expert opinions on the risks identification	up to 2 months	Risk department
2.2	Confirmation and final testing of the bank's software and information support for risk identification, taking into account the developed terms	up to and a half months	IT department
2.3	Training the risk department personnel to work with new software	up to and a half months	Risk department, IT department
2.4	Training the back-office personnel to work with new software	up to and a half months	Back-office, IT department
2.5	The transaction order issue for a new format of risk processing	1-5 working days	Risk department

[a.] *Compiled by the authors*

It seems that the integrated employment of the developed recommendations and proposals will facilitate the banking risk processing implementation and raise the efficiency of the regional bank strategic planning as a whole.

Conclusion

Based on the results of this study, the following conclusions can be summarized.

1. A definition of banking risk-processing is given, under which it is proposed to understand a permanent and prolonged business process to create and form easily applicable common methods for identifying threats and its consequences overcoming.

2. A close correlation between banking risk-processing and forming the regional bank strategic policy has been identified. It is proved that the introduction of risk processing will help to actualize and comprehend the degree of threats, the possible losses caused by them and by the implementing feedback tools to prevent them and potential benefits in case of executing the appropriate measures.

3. The developed algorithm and a consistent plan of measures and actions to optimize the reserve accumulation process based on the model "from AS IS to TO BE" allows to actually assess the existing threats and to find effective means to react.

We emphasize that the practical employing banking risk-processing by the regional banks will significantly increase the efficiency of the strategic planning and operational results of the credit institution as a whole by reducing the costs of identifying threats and choosing the appropriate means to react. This will ultimately have a beneficial effect on the competitiveness of both individual banks and on the sustainability of the regional banking system.

Abstract

The issue of financial security for Russia and for any other countries becomes one of the key in the context of economic globalization and formalization and also the existing restrictions in the movement of international financial flows. The existing problems of differentiation of regions, a serious imbalance in resource availability and sustainable development of territories were the one of the key problem of regional financial security and challenges facing the country. The relevance of the article is due to the fact that in Russian conditions the problem of ensuring financial security on the macro-and meso-level becomes systemic and chronic, covers strategies, political mechanisms, regions, economic entities, Finance, resources, etc. The article describes the theoretical and methodological issues of financial security of the region, analyzes the positions of various scientists on the issues under consideration, and formulates a methodological approach to assessment and management, justifies the need to modify approaches to assessing the financial security of the region.

Introduction

In the context of the impact of sanctions and the economic crisis, the most important task of the state became to ensure its economic security and financial in particular. The finance is the driver of any economic system. But their main drawback is the limited nature in solving a large number of equal strategic objectives of sustainable development. It is necessary to create a new powerful financial block of national security given the unstable nature of political and economic relations between Russia, the United States and the European Union. At the same time, public administration of financial security should not only be a "response to Western sanctions", but should be formed an effective mechanism of public financial management within the framework of national economic policy. This determines the relevance of the chosen research direction of financial security as the basis of national economic security.

The financial security of the state is undoubtedly linked to the sustainable economic development of all regions. Each region must adapt to new conditions and the unstable economic situation, the impact of crisis processes and to determine the vector of its development. Therefore, talking about regional financial security, it is necessary to point about the stable functioning of all elements of the territorial financial system, as well as to take into account the differentiation in the development of the regions of Russia, the unevenness of all types of resource availability and multidirectional threats to the territorial economy development.

The problem of financial security is now being discussed by regional scientists is particularly acute, but despite the large number of publications, there is no single approach to the interpretation of the essence, methodology of assessment and tools for providing both macro and meso-level. And it should also be noted that today, there is no legally fixed unified system of indicators for assessing financial security both at the Federal and at the regional level.

At the federal level, financial security is traditionally defined as the most important element of the state's economic security (V. Burtsev) [1]. At the same time, E. Rohatenyuk notes that financial security, unlike national (the protection of priority national interests) or economic (the protecting economic interests), determines the adequacy of financial resources to ensure the "normal" functioning and development of the economy in conditions of uncertainty and increased instability of the external environment. S. Klimchuk [5] draws the attention to the fact that "the goal of national financial security is the solving the problem of stable, sustainable, dynamic behavior of the economic system, which in turn will avoid imbalances in the development and functioning of the economy, taking into account the limit of available financial resources.

It should be noted that the considering this definition at the regional level, researchers are even more divided about its content. A critical analysis of the Russian scientists positions in the interpretation of the term "regional financial security" let us to reveal several basic approaches in determining its content.

Thus O. Zhalsapova, A. Korableva [4] consider the regional financial security in statics (at a certain point in time) and believe that this is substance of the economy which provides stability and sustainability of the regional economic development in the conditions of limited resources (economic, labor, social, organizational, etc.), the required standard of living, full employment etc., which compensate for the negative impact on the regional economy of the external environment. A similar approach is followed by Yu. Vorobyov, D. Poritsky [2], who consider that the financial security of the territory is a set of conditions to ensure the stability and the regional development. In contrast to them, Sh. Magomedov, L. Ivanitskaya, M. Karataev, M. Chistyakov [2,3,7] believe that the national financial security takes place if the region is able to resist destabilizing factors and improve the quality of life of the population, ensuring sustainable economic growth in the long term and saving all types of resources. P. Danilov, A. Nazarov, E. Mitrofanov [6] claim that in case of achievement of the regional financial security has an opportunity to improve the social and economic indicators that allow, in turn, to resist threats, etc. Also the regional financial security can be interpreted from organizational or administrative positions. In particular E. Kormilkin, O. Causewa, O. Fedonin [3] suggest the complex of measures which aimed at the sustainable development and the protection from internal and external stimuli.

The study of approaches and interpretations to the content of the definition "the regional financial security" allows us to formulate its content as a resource base of the regional economy, which provides stable and dynamic development of territory through the effective use of its own capacity, the neutralization of external and internal threats, as well as an integration into a global economic space.

The key objectives of regional financial security are twofold: on the one hand, ensuring sustainable economic regional growth while reducing the level of differentiation (strategic level of regional management); on the other hand as part of the national security of the Russian Federation is aimed at achieving its main priorities in the field of national defense, a quality and a standard of living, a development of science, education and health, solving environmental problems and environmental management.

Materials and Methods (Model)

The methodology of the regional financial security assessing is one of the most important tools to substantiate the directions and rates of socio-economic development of the region, as it is based on forecasting methods, identifying the correlation between the evaluation indicators, modeling of individual areas of regional development. From the point of view of the content, it allows to determine both the position of the regional economy, its potential and real financial resource availability, stability and the degree of dependence on the impact of threats and the effectiveness of

the regional authorities activities. It focuses on the refinement of the methodology for the regional financial security assessing, based on economic and mathematical methods of integrated assessment.

An integral indicator was developed to assess the level of the regional financial security. The method of its calculation is based on determining the level of impact of positive and negative factors on the resulting indicator – the regional gross product. There were 56 estimated indicators in the calculation, reflecting 5 types of regional financial security: budget, investment, banking, foreign economic, financial market. As a result, after normalization of the incoming indicators, the integral indicator was calculated based on the calculation of the average value of the assessing parameters. Calculations (on the example of the regions of the North Caucasus and Southern Federal districts) distinguish regions in which the value of the integral index tends to 1, have a higher level of financial security, and the regions with the value of the indicator close to zero – full dependence and the instability of the economy. Using of cluster analysis tools allow to distribute regions according to the level of financial security (FSA) into 4 groups: with a high level of security $0.7 \leq FSA \leq 1.0$; with an average level at $0.5 \leq FSA \leq 0.7$; with a low level $0.3 \leq FSA \leq 0.5$; with a critical level (fully dependent regions) $FSA \leq 0.3$.

Results and Discussion

The financial security of any state is determined, first of all, by its financial independence, which cannot be achieved in a simple declarative manner. It can be obtained only by a set of targeted actions to create conditions for the inflow of financial resources that ensure economic growth and a long-term supply of financial strength. At the same time, external financial sources are important, first of all, international financial organizations, transnational corporations, private foreign investments, etc. In many ways, national financial security is determined by the specifics and nature of the financial policy pursued, both within the state and beyond. And also, of course, the political situation in the country (its stability and sustainability), the organization of normal financial flows between countries, regions, industries, the expectations of the population and their well-being, the degree of development and riskiness of financial markets and the instruments used on them, etc.

Therefore, in the financial security system, it is advisable to distinguish such elements as budget, investment, monetary, stock, and foreign economic. The financial security of households can also be considered.

The specifics of any system is formed by a set of mandatory principles, the observance of which determines the effectiveness of its existence. The system of national financial security is no exception and its capabilities depend on the principles of its construction, the consistency of the elements, and the tools used.

In our opinion, the system of principles of financial security should include the following:

– legality, i.e. the activities of all economic entities should be carried out in accordance with legal standards, within their competence, and not contribute to the emergence of threats to the loss of financial independence;

– priority tasks to ensure financial security over the adoption of any managerial decisions in the socio-economic sphere;

– validity – all components of the system should be based on a clear theoretical and methodological basis);

– manageability – each element, in spite of its independence, must correspond to a certain hierarchy level, which in its entirety solves the tasks of ensuring financial security, the fulfillment of which is subject to unconditional and continuous control;

– punishability, i.e. any intentional violations leading to the threat of safe and sustainable development do not go unpunished;

– the presence of an effective and efficient law enforcement apparatus for resolving legal disputes and conflicts in the field of financial security;

– complexity and indivisibility, since no element of financial security can be compensated by another;

– balance, i.e. maintaining a balance of financial interests at the macro and micro levels;

– the mutual responsibility of all subjects of financial security at all its levels;

– closed, provides closed and limited distribution of information, taking into account the requirements of state secrets in the field of financial security;

– continuity and consistency – the formation of the system is carried out sequentially taking into account the priority of tasks, as well as existing potential and real threats;

– dynamism, i.e. take into account the constant changes in qualitative and quantitative characteristics, especially integration processes and globalization;

– alternatives in making managerial decisions aimed at achieving the desired result indicator.

The regional financial security includes the following structural elements:

1) Budget financial security. It reflects the position of the regional economy in which the region has enough of own financial resource for covering of the necessary expenses (balance of income and expenses) and ensure the socio-economic development of the territory through the effective using of financial capacity. Also budget security includes debt security which manifested in the stability of the financial system and a protect from the threats of external and internal debt, including the cost of maintenance and efficiency of using. Thus budget security characterizes the stability of the regional financial system to the impact of various financial risks, the necessary level of solvency and enough credits rating of the regional economy.

2) Investment financial security characterizes the state of the regional economy, ensuring the attraction, effective distribution and redistribution of domestic and foreign investment resources, resistance to "panic attacks" of investors, the impact of investment risks and an attractive investment climate.

3) Security of the credit and financial sector characterases the state of the regional credit system, ensuring the stability of the banking and non-banking financial institutions, the availability of credit resources for all participants, sufficient liquidity for the regional economic growth, increasing real incomes, resistance to the impact of real and potential threats.

4) Foreign economic security reflects the state of the regional economy which provides a balance in export-import operations, resistance to exposure of external risks and global "financial infections».

5) Security of the stock market characterases the optimal amount of the regional financial market capitalization (in terms of structure and level of liquidity), providing a stable financial condition of all participants and the protection from excessive volatility and “inflating stock bubbles”.

The analysis of approaches to the assessment of regional financial security presented in the researches of scientists (Sh. Magomedov, L. Ivanitskaya, M. Karataev, M. Chistyakova, I. Dolzhikova, T. Feofilova, T. Lomachenko, etc.) allowed us to form the author's system of indicators that assess comprehensively the regional financial security [4,5,7].

System of indicators for assessing regional financial security

1. Indicators of fiscal security

1.1 Revenue budget to GRP, %;

1.2 Ratio of income and expenditure of the regional budget, % (total coverage ratio);

1.3 Per capita Income to the subsistence minimum, %;

1.4 Ratio of uniformity of budgetary funds expenditure during the year;

1.5 Coverage Ratio of regional budget deficit;

1.6 Share of programme expenditures in total budget expenditures, %;

1.7 Ratio of autonomy (concentration of own funds) budget;

1.8 Ratio of the tax regional budget independence;

1.9 Share of non-tax revenues in total budget revenues, %;

1.10 Ratio of solvency of the regional budget (absolute liquidity);

1.11 Ratio of financial dependence of local budgets;

1.12 Ratio generating own revenue by region;

1.13 Ratio of tax revenues to total tax payments;

1.14 Ratio of the controllability of the budget;

1.15 Level of accounts payable of the regional budget;

1.16 Ratio of the reginal tax payments to the Federal budget to the amount of got federal transfers to the regional consolidated budget;

1.17 Level of budget risk of the territory.

2. Indicators of investment security

2.1 Index of industrial production;

2.2 Index of agricultural production;

2.3 Dimension of products produced by small enterprises to GRP, %;

2.4 Ratio of accounts payable of 2.Indicators of investment security

2.1 Index of industrial production;

2.2 the Index of agricultural production;

2.3 the Volume of products produced by small enterprises to GRP, %;

2.4 Ratio of accounts payable of enterprises to GRP, %;

2.5 Ratio of net income of enterprises to GRP;

2.6 Consumer price Index;

2.7 Ratio of economic efficiency of regional investments;

2.8 Ratio of the regional investment activity;

2.9 Investment in fixed capital per capita;

2.10 Investments in fixed assets to the value of fixed assets, %;

2.11 Dimension of investment in fixed assets to GRP, %;

2.12 Level of fixed assets depreciation, %;

2.13 Level of the regional inversion risk.

3. The security of the financial sector

3.1 Number of credit institutions in the region, units;

3.2 Ratio of funds raised by banks to GRP, %;

3.3 Ratio of invested assets to GRP, %;

3.4 Ratio of the funds attracted, %;

3.5 Level of credit risk, %;

3.6 Share of regional banks in the total number of credit institutions in the region, %;

3.7 Level of savings quota, %;

3.8 Ratio of loan debt to the economic sector to GRP, %;

3.9 Number of microfinance institutions in the region, units.

4. Indicators of foreign economic security

4.1 Growth Rate of foreign trade turnover, %;

4.2 Dimension of foreign trade turnover per capita, RUB/ person;

4.3 Share of exports per capita, RUB / person;

4.4 Share of imports per capita, RUB / person;

4.5 Ratio of the volume of regional foreign trade turnover to GRP, %;

4.6 Share of import to GDP (import quota, %);

4.7 Share of export to GDP (export quota, %);

4.9 Foreign Trade quota (%);

4.10 Share of FEC exports in total exports %);

4.11 Share of machinery exports in total exports, %;

4.12 Coverage Ratio of imports by exports;

4.13 Trade deficit to GRP, %;

4.14 International Competitiveness Index.

5. The safety performance of the stock market

5.1 Number of issuers of the region in the rating of the largest companies in Russia in terms of sales and market capitalization;

5.2 Level of capitalization of the regional stock market;

5.3 Ratio of efficiency of the regional stock market integration into the national market;

5.4 Ratio of efficiency of institutional investors ' investments;

5.5 Dimension of resources attracted to the GRP on the regional stock market.

The integral indicator reflecting the level of the financial security is calculated as the geometric mean of the 5 represented structural elements. At the same time within each group after the normalization of indicators, the group indicator is determined by a simple summation of the incoming normalized indicators.

This research allowed us to conclude from 30 to 80 % the level of the regional financial security is determined by the indicators of budgetary and investment stability, that tell about their decisive influence on the regional financial security and sustainable development of territory.

Conclusion

Thus, it is necessary to implement the following measures for determination the level of the regional financial security, its position on a country-wide scale, identification strengths and weaknesses in the stability of the territorial financial system and ensuring the capacity of the regional socio-economic development and improvement the level of competitiveness and "controllability" of regional processes:

1. To approve the methodology and to fix the list of indicators determining the level of financial security of the region. Assessment of financial security is advisable to use in the development of programs and strategies of socio-economic development of regions as an analytical block.

2. Regular monitoring of socio-economic development using the proposed indicator of the level of regional financial security allows to timely identify "failures" and "UPS" in the structure of resource availability of the territory and possible structural changes. The applied indicators of regional

financial security assessment can be modified and improved taking into account the specifics of the development of a particular region.

3. It is necessary to modify the system of assessing the effectiveness of public authorities, taking into account the identified aspects of regional financial security, and the effectiveness of their activities in solving the problems of territorial imbalances, the proportionality between the structural elements and further overcoming this imbalance.

The presented results are ambiguous, as it is necessary to continue an in-depth research of the relationship of the structural elements of the regional financial security by subjects, terms, level of imbalance, etc. However, submitted qualitative assessments allow to define the objectivity of the links and to identify the most significant features. In this case the presented approach determines the need for an integrated access to identifying the depend structure of the GRP on the regional financial system parameters in order to identify its impact to the regional financial security and national security in general.

Abstract

Both in practice and in the literature on the subject, significant trends can be observed in the change of widely understood management in the higher education sector. New trends are caused, among others, by economic, social or political changes. Currently, the higher education sector in Poland is a perfect example of that. New legal regulations impose a bigger responsibility on universities for their actions. The aim of the article is to indicate examples showing the process of creating a diversified types quality cultures at Polish universities. The methodology of research is qualitative whereas the research method is based on a case study comparative analysis of the data gained from interviews, observations and documentation. The sample is non-random and heterogenic to find examples showing the process of creating a diverse quality culture at universities in Poland. There are cases of quality culture of universities. The contribution of the article to the issue of sustainable higher education is the characteristics of the three fields of sustainable university culture development. There is a clear differentiation between public and non-public universities which introduce sustainable quality culture to their own academic culture, shaped over the years. Universities strive to create a sustainable quality culture which is possible to achieve by building it over a long period of time, taking into account quality assurance processes, academic ethos and mutual trust of stakeholders engaged in the process.

Keywords: quality culture, sustainability, sustainable quality culture, higher education sector, higher education in Poland, sustainability in education

Introduction

Both in practice and in the literature on the subject, some trends can be observed when it comes to the change of widely understood management in the higher education sector. New trends are dictated by economic, social or political changes. At present, the Polish higher education sector is a perfect example of that. The authorities superintendent over universities have introduced regulations entitled "Act 2.0", which has resulted in a number of changes in higher education. To a large extent, the new regulations have led to a transformation in the academic order. In Poland, one can observe massification of higher education, increased competition or partial commercialization of the sector. New legal regulations impose even greater responsibility on universities to take action. Universities ought to act in a transparent manner. This policy is consistent with global trends, assuming the autonomy of universities in the ways of managing their assets and in creating study programmes in which universities are required to take responsibility for the quality of the provided services (Costes et al. 2010). In the Polish system of higher education, mechanisms aimed at controlling the quality of education have been strengthened through the evaluation of educational programmes, research on the scientific development of scientific and teaching staff, evaluation of conducted classes or examination of the fate of graduates.

An important point of the changes in the Polish higher education system is the promotion of the idea of education quality assessment by external institutions among universities. In this way, Polish higher education institutions (HEIs) have a chance to create curricula consistent with international trends and based on common criteria. According to Normand, international institutions, assessing the quality of education at universities, are increasingly becoming regulators. At the same time, they create a coherent quality assessment for all universities, thus ensuring their transparency (Normand 2016). The literature on the subject devotes significant attention to the issues of methodology of university quality assessment (Banta, Palomba 2015; Harvey, Newton 2007; Martensson, Roxa, Olsson 2011) which largely depends on the region in which a given university is assessed. On the other hand, a certain universality of educational quality assessment programmes is emphasized, which makes it possible to evaluate universities according to transparent rules and criteria (Smidt 2015; EUA 2005; Yu, Mai, Tsai, Dai 2018).

Along with the growing awareness of quality assessment at universities, the number of internal units at universities, whose aim is to control and ensure proper quality of education, has also increased. These units are, in a way, a binder connecting universities with external accreditation bodies. There has been a change in the course of academic culture at universities towards internal control (Kottmann et al. 2016). Such a situation has also been observed over the last decade in Polish HEIs. In the literature on the subject there are many views on internal quality control at universities (Craft 2018; Seyfried, Ansmann 2018; Costes et al. 2010; Geven, Maricut 2015; Sułkowski, Seliga, Woźniak 2016a; Sułkowski, Seliga, Woźniak 2016b; Sułkowski, Seliga, Woźniak 2017). A common feature of all contemporary views on the issue of internal quality control in HEIs should be its specific responsibility towards the HEI stakeholders and the society itself in international and not only local terms. Such an approach is supported by the fact that universities participating in the processes of international evaluation of education become the guarantor of the quality of their diplomas which can be used all over the world. It is also important to adjust internal units and procedures of quality control at universities to international standards and requirements (Vlăsceanu, Grünberg, Pârlea 2007).

Research Aim and Questions

The issue of sustainable quality culture in the Polish higher education system is very little explored. In the Polish literature on the subject, there are no previous studies discussing and describing the issues of sustainable quality culture in the Polish higher education system. Therefore, the purpose of this study is primarily an attempt to identify and describe the activities undertaken in the Polish higher education system regarding a sustainable quality culture.

The study has been guided by the following research questions:

1. To what extent do Polish universities implement the concepts of sustainable quality culture?
   In order to obtain the answer to this question, we analyzed the internal documentation of Polish universities (strategies, administrative documentation, websites).
2. How do Polish universities implement the concepts of sustainable quality culture?

The aim of the study is to analyze sustainable quality culture at Polish universities.

Materials and Methods

The methodology of research is qualitative. The unstructured nature of the problem needs a deeper analysis, possibly with qualitative methodology. The method of the research is qualitative case study comparative analysis based on data from: interviews, observations and documentation analysis.

The comparative analysis of case studies method was used in the research process. The study was based on a targeted, heterogeneous sample of 3 case studies of Polish universities. Three Polish universities, operating in different regions of the country with different university traditions, were selected for the study. The course of the study included a number of techniques from the analysis of

internal university documentation, websites, free interviews with university employees (2 interviews at each university) as well as participant and non-participant observation. The research in the form of an interview was divided into two categories: the first - individualizing the problem of sustainable quality culture in the Polish higher education system and the second - identifying good practices in the implementation of sustainable quality culture in the Polish higher education system. The findings of this study have been critically assessed.

Sustainable Culture

The notions of "sustainability" and "sustainable development" are increasingly emerging in the science and practice of management in contemporary society, starting with business, through international development and ending up with education and politics (Huge, Waas 2013; Waas et al. 2011). Both terms are complex in nature, but "sustainable development" can be characterized as a response to the awareness of dynamic economic growth and industrialization which contribute to the degradation of the environment and, consequently, to the dramatic consequences of ecological and social changes. The literature on the subject shows a great diversity regarding the conceptualization and implementation of sustainable development in various academic disciplines (Nielsen et al.; Rametsteiner et al. 2011; Brehmer, Podoynitsyna, Langerak 2018; Geissdoerfer, Vladimirova, Evans 2018).

The first attempt to define the role of education in contributing to a more sustainable society at the global level was made in the Stockholm Declaration of 1972. In 1990, the first declaration (the Talloires Declaration) was created on the role of higher education in response to the ever-growing global environmental problems. Since then, work on sustainable development in HEIs has continued, both as a mission of universities in shaping society and as a response to the growing importance of sustainable development (Hoover, Harder 2014; Lozano et al. 2013; Wals 2014).

E. Hoover and M. Harder believe that the role of universities in shaping future members of society and potential leaders is significant. HEIs carry out these tasks by introducing innovations, conducting scientific research and shaping knowledge that contributes to the perception of a world where there can be no lack of sustainable development. It should be stated that not only activities undertaken by universities are crucial, but also the way they are conducted is important (Moore 2005; Harvey, Stensaker 2008). Changes in the educational quality processes, decision-making and organizational structure are possible to be carried out only when accompanied by a simultaneous creation of a sustainable quality culture. This is a huge challenge for the higher education sector on a global scale, requiring overcoming internal resistance on the part of academic teachers, legal and organizational barriers, as well as the interests of numerous stakeholders who often have diversified views on the possibility of making changes in the traditional academic order shaped over the years.

A quality culture can be defined in different ways. There is no single definition that clearly characterizes it. J.A. Woods defines a quality culture by combining it with a systemic approach, characterizing six fundamental values that constitute a pro-effective quality culture: 1) focus on processes, 2) learning is crucial, 3) all stakeholders work together towards the same goal, 4) there is open access to all information regarding intra-organizational processes, 5) there is open and transparent communication, 6) there are partner relationships within the organizational structure. Some definitions refer to quality management, while others define it in relation to the activity. In this approach, a quality culture of HEIs is a derivative of academic culture. Over twenty years of experience in managing institutions of the higher education sector in Poland prove that the implementation of a formalized education quality control system does not directly affect the provision of high-quality education. Therefore, the key issue seems to be the engagement of stakeholders in the process of improving quality culture in the higher education sector. Through the increasing participation of internal and external stakeholders its development is very important and brings results. Therefore, the quality culture in HEIs can be a kind of synthesis of academic culture and business methods of quality management (Sułkowski, Seliga, Wozniak 2017).

According to the definition of the European University Association, a quality culture is an organizational culture whose main objective is to continuously improve quality. It distinguishes two essential elements of quality culture: the first one has a structural and managerial nature, related to the quality improvement process whereas the second one concerns cultural and psychological aspects referring to common expectations, beliefs and values in the area of quality improvement. HEIs should manage in such a way that both of these elements support the others in synergy, thus contributing to the systematic development of the higher education sector (Bendermacher et al. 2017). The concepts of quality management and quality assurance had emerged earlier than the concept of quality culture. The latter responds to the emerging concerns of the academic community who are skeptical about the introduction of changes to the existing procedures and tools typical for quality management which do not necessarily have a positive impact on the management process of HEIs (Dzimińska, Fijalkowska, Sulkowski 2018).

HEIs should strive to create a sustainable quality culture that is achievable through a long-term development that takes into account quality assurance processes, academic ethos and mutual trust of all stakeholders engaged in this process. A sustainable quality culture can be achieved through regular evaluation and control, while balancing excessive bureaucracy. One of the barriers may be fixed financial expenditure and investment in human resources, which constitutes significant costs for universities. On the other hand, the benefits of this should be treated as a long-term investment resulting in increasing a competitive position in relation to other universities and ensuring a high quality of educational offer. The key mechanisms considered to be strategic in the context of creating a quality culture include widespread knowledge sharing, promotion of processes that foster ownership distribution and sharing. Additionally, it is necessary to involve all employees of the university, reduce barriers of change and introduce appropriate supporting mechanisms – all these elements together should contribute to the development of a quality culture of higher education (Dzimińska, Fijalkowska, Sulkowski 2018; (Harvey, Stensaker 2008).

The literature review shows that the features indicating a university with integrated sustainable development include, among others (Tilbury et al. 2005; Pinto 2017; Ferrer-Balas et al. 2008; Nidumolu, Prahalad, Rangaswami, 2009; Schaltegger, Freund, Hansen 2012):

1. integrating the concept of sustainable development into teaching and research.
2. promotional actions regarding the concept of sustainable development.
3. leadership and vision, with an emphasis on sustainable development.
4. engagement in social activities that contribute to environmental sustainability.

Universities have a high environmental impact through energy consumption and waste generation. An increasing number of universities are joining the group that has improved environmental management through their activities. Unfortunately, a full integration of sustainable development into the creation of a quality culture is progressing much slower than the “greening” of campuses along with the emergence of a “third wave of sustainability” in the learning-focused higher education sector (Wals, Blewitt, 2010).The number of universities reporting on sustainability as well as the level of sustainability reports is still far less advanced than that of corporations (Lozano, 2011; Lozano, Lozano, Mulder, Huisingh, Waas, 2013).

Case studies - three types of sustainable quality culture in the Polish higher education system

Type 1. Educational

Implementing sustainable development policy in their missions, Polish universities base themselves on social responsibility for the quality of education of future work force. Universities try to meet the expectations of stakeholders and meet the needs of business practice by adapting education programs to the needs of the labor market, taking into account environmental needs.

University of Warsaw (UW)

The university was founded in 1816 under the name of the Royal University of Warsaw. This is the largest, best and one of the oldest universities in Poland. Currently, 42,500 students are studying at the University of Warsaw. The University of Warsaw is a member of the 4EU + alliance, since 2016, the University of Warsaw has the right to use the "HR Excellence in Research" distinction, took 3rd place in Southern and Eastern Europe and 96th in the world in the ranking of rising science stars Nature Index 2016 Rising Stars.

The University of Warsaw implements the concept of sustainable development in educational programs. The University authorities have recognized the necessity of cooperation of various science disciplines for environmental protection. Therefore, the University of Warsaw established the University Center for Research on the Environment and Sustainable Development, whose mission is to provide access to knowledge about the natural environment and its role and importance for human functioning, allowing to understand the mechanisms of emerging consumer, economic and production pressure on the environment and to provide skills in solving related problems (http://test.msos.uw.edu.pl/pl/msos/jakosc-ksztalenia-2/misja-i-strategia, accessed on 5.12.2019). This center has become a place where projects combining such fields of knowledge as chemistry, physics, biology, geology and geography as well as law, philosophy, sociology, history and economics were implemented. As part of the center's activities, lectures on ecological education and support for this type of teaching are conducted in schools and regional education centers. Educational programs are organized in cooperation with significant international institutions, including the London Environment Center, European Commission for Environmental Education IUCN or Baltic University. The University Center for Research on the Environment and Sustainable Development has participated, among others in the organization of the Polish-Danish and Danish-Polish School of Environmental Protection. These activities enabled Polish and Danish students to learn about basic ecological problems in both countries.

Inter-Faculty Studies in Environmental Protection (MSOŚ) were also created at the University of Warsaw. In 2018, the University Center for Environmental Research and Sustainable Development (UCBS) and the Interfaculty Studies in Environmental Protection (MSOŚ) merged. In this way, an inter-faculty organizational unit was created: University Center for Environmental Research and Sustainable Development. It took over all tasks and rights of existing MSOŚ and UCBS sections.

The University Center for Research on the Environment and Sustainable Development (UCBS) operates at the University of Warsaw as an organizational unit with faculty rights. This unit has been operating in the structures of the University since 1989. The establishment of the center was determined by the conviction of the University of Warsaw scientific staff that environmental science is not only related to purely natural issues, but also to economic, social, legal and ethical ones. Currently, the Center for Research on the Environment and Sustainable Development brings together nine faculties: Biology, Chemistry, Geology, Geography and Regional Studies, Physics, Economic Sciences, Law and Administration, Biology, Management. As part of UCBS there are also studies in the fields of: Inter-Faculty Studies in Environmental Protection (MSOŚ), undergraduate and graduate level and Sustainable Development, in English, graduate level. In addition to educational activities, UCBS employees are also involved in scientific research and dissemination. The University Center for Research on the Environment and Sustainable Development (UCBS) implements graduate studies in the field of geoinformation in modeling and management under the Erasmus Mundus program. In addition to the University of Warsaw, four European universities cooperate as part of these studies: University of Southampton, University of Twente, Lund University and University of Iceland.

The University of Warsaw also developed the Social Responsibility Strategy, which by its assumptions is part of a cycle of changes consistent with the direction of sustainable quality culture. From 2019, the University of Warsaw has been operating the "University of Warsaw for Climate" Team, whose task is to:

- conduct and coordinate activities, including educational and practical activities, dedicated to counteracting the climate-ecological crisis and related issues related to the social responsibility of the University of Warsaw in the face of these crises;
- diagnose the needs and develop good practices related to reducing the negative impact of UW on the natural environment;
- cooperate with the scientific community, the academic community, non-governmental organizations, business and government representatives to exchange experiences, promote activities and develop joint solutions for environmental protection;
- prepare positions and recommendations for organizational units of the University of Warsaw.

Type 2. Pro-ecological orientation

Polish universities are increasingly taking part in environmental programs. Sustainable culture of the university is based primarily on the rational use of current resources, which is in accordance with respect for the natural environment. It should be noted that Polish universities are currently undergoing a phase of modernizing their campuses. These modernizations are carried out in compliance with pro-ecological principles. Old devices are replaced with new, more efficient and economical ones. The buildings of Polish universities are being modernized by replacing heat installations with ecological ones.

University of Economics in Katowice

An example of pro-ecological activities at a Polish university is the University of Economics in Katowice (https://www.ue.katowice.pl/projekty/uniademicet-spolyszne-odpowiedzialny/ekologia.html, accessed on 5.12.2019). The University of Economics in Katowice is one of the oldest universities in southern Poland, it was established in December 1936. The university provides education for nearly 10,000 students in the field of social and economic sciences. It possesses the HR Excellence in Research logo. The University of Economics in Katowice has international accreditations: AACSB, CEEMAN IQA, ACCA, CFA, CIMA, EPAS.

In the opinion of the University authorities, the functioning of the University should be based on the rational use of resources while respecting the natural environment. Taking care of ecology, the University of Economics in Katowice changes its campuses in such a way that they are as efficient as possible and that they do not harm the natural environment. Heat pumps were used at the University, thanks to which the university uses its own temperature to heat the tap water and the building. In addition, solar systems are installed, which are mainly used to heat utility water, and rainwater stored in special tanks recovered from roof and terrace drains is used in sanitary facilities and is used for watering greenery. There are also parking lots for bicycles at the university. Recently, four pro-ecological programs have been implemented at the University of Economics in Katowice: the UniEKO project, joining the "Adopt a bench" action (*Przygarnij ławkę*), participation in WWF's "Earth Hour".

The UniEKO project consisted in creating and marking a path of Polish trees, fulfilling didactic and ecological functions. This initiative was addressed not only to students of the University of Economics in Katowice but also to the inhabitants of Katowice. The aim of the project was to increase knowledge about native coniferous species and the symbol of Polish deciduous trees - pedunculate oak. The path consists of five species of Polish coniferous trees and one species of deciduous tree. The Faculties of the University took patronage over individual conifers. morphology. The University of Economics in Katowice also joined the "Przygarnij ławkę" (Adopt a bench) project organized by Park Śląski. Thanks to the University's support, the Rosarium bench located in the Park has been restored. As a result, the bench gained its former splendor without the need to replace it with a new one - which is especially important for reasons of rational resource management - the eternal problem of economics. On the bench there is also a slogan promoting a balanced lifestyle: "To be productive, you need to be rested" in two language versions: Polish and English. The University of Economics in Katowice is also a participant in the global action "Earth Hour" organized by WWF. The initiative is not so much about saving energy as demonstrating concern for the environment. Its

participants around the world turn off the light for an hour, thereby expressing support for the idea. In addition to the above-mentioned pro-ecological actions, the University of Economics in Katowice conducts full segregation of municipal waste in accordance with the guidelines of the Common Waste Sorting System (WSSO) and participates in the "Collect batteries - dispose of selectively" program. Caring for the environment, the University also uses reproduced inks and cartridges.

Type 3. Sustainable quality culture in the university's strategy

The concept of sustainable quality culture has not been clearly identified in the strategies of Polish universities. As can be seen from the analysis of documents containing the strategies of Polish universities, it can be observed that sustainable quality culture manifests itself in the form of activities in the field of sustainable development of universities.

University of Economics in Wrocław

The Higher School of Commerce in Wrocław was the precursor of the University of Economics. The university was founded in 1947. In 1974, it was transformed into the Oskar Lange University of Economics. However, in 2008 the name of the university changed to Wrocław University of Economics. Taking into account the future of its graduates, the University of Economics in Wrocław attaches great importance to the quality of study programs offered. The University has the following accreditations and domestic and foreign certificates: IQA, IEP, ACCA, EPAS, CIMA, AMBA, EMOS.

In its strategic activities the University of Economics in Wroclaw includes activities for sustainable development in a sense of social and ethical responsibility open to environmental issues. In the strategy adopted by the University of Economics in Wrocław there is a provision about: "Compliance with high ethical standards and good educational practices based on universal values and principles of education for sustainable development" (http://www.ue.wroc.pl/uczelnia/4931/strategia_rozwound_uniademicetu_ekonomowego_we_wroclawiu .html, accessed on 5.12.2019). Issues of social responsibility were also found in the vision of development of the Wrocław University of Economics. The vision of EU development in Wrocław was structured as follows: "The Wrocław University of Economics will be a modern educational and research, opinion forming and consulting unit, permanently embedded in regional, national and international space, undertaking actions for sustainable development in a sense of social and ethical responsibility, friendly to employees, students and graduates, and open to all their surroundings (http://www.ue.wroc.pl/uczelnia/5582/misja_i_wizja_uniademictu_ekonomicznych_we_wroclawiu.html, accessed on 5.12.2019). The strategic goal chosen by the University for pro-ecological activities is implemented by the Rector's Commission for Social Responsibility established within the structure of the university. The goal of the Commission is to develop a social responsibility strategy of the Wrocław University of Economics in cooperation with all university stakeholders, conduct surveys, organize meetings with business representatives, non-governmental organizations, local authorities, prepare the Code of Ethics, introduce the Diversity Charter (http: //www.ue. wroc.pl/uczelnia/17059/co_robimy.html, accessed on 5.12.2019). In 2018, the university signed an agreement with the Climate Reality Project leader regarding the transition to renewable energy on campus by 2030.

According to interviews with university executives, all managers see the need and the need for their university to implement environmental activities. As indicated by the respondents, these activities have several benefits. On the one hand, the university cares for the environment, on the other hand, such activities allow it to reduce operating costs. Some of the respondents also indicate that the university can obtain image benefit through this type of activities, which may contribute to the increase of interest in its education offer by future students.

Table 1: Comparative analysis of case studies of sustainability in 3 Polish HEI's

	Case 1 UW	Case 2 UE in Katowice	Case 3 UE in Wrocław
Main understanding of sustainability	Integrated, as processes, values and strategic objectives	Mainly pro-ecological orientation of university	Part of the strategy of HEI, more declared than implemented
Main stakeholders and their awareness	Managing staff, academic and teaching staff. High awareness of the stakeholders.	Managing staff, academic and teaching staff, local community. Very high awareness of the stakeholders.	Managing staff, academic and teaching staff. Medium awareness of the stakeholders.
Communication of sustainability	Through internal documents and resolutions.	Through internal documents and resolutions. Marketing tools are used in communication.	Through internal documents and resolutions.
Range of sustainability idea	Diversified depending on the Faculty. General principles prevailing throughout the university.	General principles prevailing throughout the university. Diverse coverage, special emphasis put on the implementation of projects.	Medium coverage. General principles prevailing throughout the university.
Limitations of sustainability idea	Financial barriers, change of organizational culture in University units.	Financial barriers, change of organizational culture in University units.	Financial barriers, change of organizational culture in University units.
Sustainability in mission, strategy and strategic management	A significant concept in development strategy.	Included in the development strategy.	A significant concept in development strategy.
Sustainability in education	High level of concept implementation in course curricula.	Medium level of concept implementation in course curricula.	Medium level of concept implementation in course curricula.
Pro-ecological orientation of HEI	High level of ecological orientation.	High level of ecological orientation.	Moderate level of ecological orientation.
Sustainability in organizational structures	Occurs as a separate organizational unit of the University.	Absent in the organizational structure.	Occurs as Rector's Commission on Social Responsibility.
Sustainability as part of organizational culture and identity	Key concept in the organizational culture and identity of the university.	Medium rooting in the organizational culture and identity of the university.	Medium rooting in the organizational culture and identity of the university.
Sustainability as part of quality culture of HEI	Highly rooted in quality culture.	Present in the quality culture.	Present in the quality culture.

Conclusions

The Polish higher education sector faces a period of transition dictated by numerous changes in the higher education law. One can see a trend showing changes in the area of university management. This is fostered by the concept of new public management, indicating management techniques and tools to direct people managing organizations towards professionalization. The literature on the

subject highlights that the analysis of changes taking place in the area of university management can be subject to the sociological and cultural analysis (Lounsbary 2007). The changes taking place in the management of universities manifest themselves in the areas of universities' administrative structures, legal regulations, missions and strategies and values, when looking at them through the change of the "university ethos" prism. It should be noted that these changes deeply interfere with the current view on the university management and its autonomy. Universities strive to create a sustainable quality culture that is achievable by building a long-term quality culture, taking into account the quality assurance processes, academic ethos and mutual trust of all stakeholders involved in this process. Obvious barriers involve constant financial expenditure and investment in human resources, which constitutes significant costs for universities. However, the resulting benefits should be seen as a long-term investment. The literature review shows an integrated sustainable university is characterized by the following features: integration of the concept of sustainable development into teaching and research, promotion of the concept of sustainable development, strategies with an emphasis on sustainable development and involvement in social activities that contribute to achieving environmental sustainability. Research shows that universities have a high environmental impact through energy consumption and waste generation. At the same time, an increasing number of universities are joining the group that improves environmental management through their activities. Unfortunately, a full integration of sustainable development into the creation of a quality culture is progressing much slower than reducing the negative impact of universities on the environment. The number of universities reporting on sustainability is still far less advanced than that of corporations. The key issue, however, is that the universities strive to achieve a sustainable quality culture by taking actions at different levels.

Formulating answers to research questions, it can be stated that in the studied universities the concept of sustainable quality culture is implemented in a diverse way. The University of Warsaw has the largest scale of implementation, it consists of a number of integrated activities ranging from formal procedures to pro-ecological and educational activities. At the other two universities, it has a much more limited range. The analysis shows that sustainable quality culture is understood and implemented in different ways depending on the type of university and how managers interpret the concept of sustainable university.

Abstract

The fourth industrial revolution fundamentally changes all spheres of economic activity, including tourism. The aim of the study was to study the key factors affecting the modification of economic activity in tourism. A statistical analysis of data on Internet access has shown that there are favorable conditions for the development of online services and the digitalization of tourism activities. The analysis of digital technologies used in tourism is carried out, their influence on the development of the tourism industry in the context of global digitalization is shown. It has been established that new digital platforms provide care from intermediaries and minimize indirect costs in tourism. The features of consumer preferences of travelers in terms of information support of tourism activities are revealed, the most popular mobile applications in tourism are considered.

Keywords: Tourism, Digital Technology, Digitalization, Tourism Economy.

Introduction

The main directions of tourism development have always been associated with technological innovation. So in the 60s of the last century, the emergence of global reservation systems fundamentally changed the entire technological process in the tourism industry, led to a significant reduction in operating costs, and increased the speed and quality of service delivery. Currently, one of the key factors in the transformation of the tourism economy is global digitalization, which was generated by the fourth industrial revolution. Along with the banking sector, the tourism industry was one of the first to apply digital technology.

Within the digital economy, the interaction of producers and consumers of tourism services is undergoing significant changes. On the one hand, information has been and remains an important factor in the interaction of all the resources that are used to form a tour product, and on the other hand, it is an important independent resource that affects the preferences of tourists and consumers of this product. Therefore, the study of the main areas of application of digital technologies in tourism, their impact on the economy of tourism systems seems to be a very relevant area of research. In the conditions of the modern digital economy, when the technologicalization of public life takes place, which entails the formation of new principles and methods for managing the tourism sector, it certainly requires an awareness of the role of digital tourism.

Methods and Materials

During the study, systematic, monographic, and statistical analysis methods were used. Based on them, the main possibilities of applying the latest digital technologies in tourism and their impact on the modification of the tourism economy were analyzed.

A study of tourism digitalization is contained in the articles of Javornik (2016), Xiang & Fesenmaier (2017), Dredge et al. (2018), Khatri (2019), Nguyen et al. (2019), Pesonen & Neidhardt (2019).

Digitalization affects the entire value chain in tourism, improves business processes and dramatically changes the economic relationships of all participants in the tourism market.

One of the factors contributing to the implementation of digitalization in the tourism sector is the availability of the Internet and the ability of the population to work in the Internet environment.

According to the International Telecommunication Union (ITU), at the end of 2019, 4.1 billion people used the Internet, i.e. 53.6% of the world's population (Fig. 1).

Built by the authors according to ITU https://www.itu.int/en/ITU-D/Statistics/Pages/stat/default.aspx

Fig. 1: The number of individual Internet users in the world (in% of the world population)

Since 2005, the number of Internet users in the world has grown from 16.8% to 53.6% of the total world population, i.e. more than 3 times. For half the world's population, the Internet has become every day and affordable tools. However, the uneven access to the Internet in different regions of the world should be noted.

Figure 2 shows a regional breakdown of the percentage of households with Internet access.

Built by the authors according to ITU http://www.itu.int/ict/statistics

Fig. 2: Percentage of households with Internet access by region

As follows from the graph, the maximum number of households with Internet access is recorded in Europe 86.5%, which is significantly higher than in the world as a whole (57%). The minimum level of household Internet access in Africa (17.8%).

In Russia, in 2018, 76.6% of households had Internet access, which is higher than the global average and slightly lower than European indicators.

The latest digital technologies that act as the basis for the digitalization of tourism activities include:

- Big data technologies (Big Data), blockchain,
- artificial Intelligence,
- Internet of Things (Internet of Things - IoT and IIoT - Industrial Internet of Things),
- mobile devices and more.

Results and Discussion

The fourth industrial revolution, which characterizes the modern stage of the development of society, is connected, first of all, with the digitalization of activity in all its fields. In terms of volume, scale and complexity, it has no analogues in all previous stages of the development of human society. The technologies that have appeared in recent years are based on completely new principles of digitalization, which are based on the use of artificial intelligence, robotics, working with big data, blockchain, the Internet of things, etc. The fastest digital technologies penetrate the banking sector, the tourism and hospitality industry. Regardless of the travel company's profile, competition is shifting to digital technology.

In tourism, dramatic changes are taking place in all business processes. The digital economy is creating fundamentally new business conditions. Its key difference is that information becomes the most important and significant resource on the basis of which new knowledge is generated.

The development of the digital economy is also addressed in the Russian tourism market, in particular, in the "Strategy for the Development of Tourism in the Russian Federation for the Period

until 2035", developed in 2019, focuses on the development of digital tourism services and digital platforms.

The digital economy is based on the digitalization of all business processes occurring at all levels and links in economic systems, with particular emphasis on the information component, which provides real-time access to information on the activities of economic systems in an integrated global network. The digital economy is creating new requirements for the information and communication environment, information systems, services, business processes. The creation of a single information space in the tourism sector should be carried out to obtain high-quality, timely and reliable information, which should be formed taking into account the needs of citizens and society. Much attention is paid to the formation of a single information space in tourism, and they have been discussed for a long time, and quite a lot has been done in this direction by the tourism authorities and the tourism community.

The tourism sector is largely consistent with the introduction of digital technology, since many business processes have already been restructured in accordance with the new paradigm of digital economy development. This is especially true for tour formation and booking systems, e-commerce technology, the use of mobile technologies, etc. This will allow in the digital economy to create new forms of tourism industry enterprises, spatially distributed network companies based on digital economy technologies.

The digitalization of business processes in tourism is especially important in terms of the formation of digital competitiveness, which is determined by the level and effectiveness of the introduction of digital technologies Morozov & Morozova (2016). The main component in the creation of tourism products is information support, which must be provided to the tourist. The result of tourist activity is again the information and impressions that the tourist receives in the process of his trip. It is not for nothing that the term "economy of impressions" is now widely used. Thus, tourism activities are associated with the process of obtaining tourist new knowledge and impressions about tourist destinations, which corresponds to an understanding of the digitalization of information.

The paradigm of the digital tourism economy is based on the collection, transmission, processing of large amounts of information, on the basis of which new knowledge is formed. In this regard, the requirements for the personnel infrastructure of the tourism business in the field of digital competencies will change. The need for a high level of staff qualification to work in the digital economy is confirmed by the following data Morozov & Morozova (2019). In Russia, the sector of information and communication technologies 74% of staff have higher education. This allows us to conclude that in the conditions of the digital tourism economy, requirements to the level of digital competencies of personnel will sharply increase.

Due to the fact that the digital economy is based on the ideology of processing large amounts of information, the digital competencies of personnel, security, reliability, and the long-term storage of large amounts of information will become especially important. High technological effectiveness of all processes of the digital tourism economy will entail the need for continuous staff development, in connection with which the so-called lifelong learning will be in demand.

In addition to the digital revolution, tourism has been greatly influenced by generational change. Now there is a formation of a new type of digital tourists who place high demands on the quality of digital services both during the preparation for the trip and during the trip itself. The main consumers of tourism services are people of generation Y (millennials) and generation Z, for whom modern digital communications are an integral attribute of everyday life. Already, 50% of requests use mobile search. The tourism needs of the new generation are changing. Tour operators must personalize their product for the client. The time from the search to the purchase of a tourist product should be minimized.

New trajectories of tourism development are closely interconnected and affect the organizational and production business processes in tourism.

Digitalization in the field of tourism leads to the formation of new economic relations between participants in the tourism market. For example, the WindingTree project, based on a blockchain platform, offers a simplified process for the interaction of economic actors in the tourism market. It excludes intermediaries from the process, thereby reducing the commission to additional intermediaries and costs. This digital platform is already in use at Lufthansa. Similar blockchain tools are used at Dubai Airport (UAE), in the transport system of Japan and South Korea, etc.

We highlight the key factors affecting the economy of the tourism industry:

- digitalization of the main business processes in tourism,
- generational change and the formation of a new type of digital tourists,
- the formation of economies of a new type of Sharing Economy, an economy of impressions,
- new technologies for the interaction of all participants in the tourism market, which provide care from intermediaries and minimize indirect costs,
- the possibility of remote access to services (online travel agencies),
- personalization of services for tourists.

An example of Sharing Economy, which dramatically changes the economic relationship between suppliers and consumers of tourism services, is the Airbnb booking system. The articles Aznar et al. (2017), Blal et al. (2018) examined the impact of Airbnb on tourism and hotel business.

In order to ensure the personalization of tourist services, it is necessary to collect and process huge amounts of information. For these purposes, Big Data technology is used. It allows you to carry out analytical studies and get complete information about tourists and their needs. Given the capabilities of artificial intelligence, you can predict and model the needs of tourists. A Booking.com study found that one-third of the world's travel audience is interested in helping artificial intelligence travel planning.

In 2018, a decentralized blockchain platform for data exchange in the TravelChain tourism industry was launched. This is an ecosystem for the tourism market, which allows you to collect customer information and use it to provide personalized offers, while users receive a reward for providing data and viewing address messages. Artificial intelligence technologies involved in processing data about tourists will allow predicting the desires and preferences of tourists, which will create tourism products that best meet the desires and needs of certain user groups and individual travelers.

The capabilities of blockchain technology with its distributed data processing system can serve as the basis for the implementation of models for the dynamic formation of tourism products and pricing, within which, according to the customer’s request, various combinations of a tourist product can be compiled in real time.

Currently, the level of monopoly in the tourism industry is quite high. The largest global reservation systems Amadeus, Saber and Travelport occupy 99% of the total market share of air transportation. For several decades, Priceline Group has received an annual 40% increase in EBITA. Blockchain projects in tourism will ensure decentralization and disintegration of the hotel reservation process with payment in the domestic cryptocurrency. The widespread adoption of blockchain technology in the tourism industry will reduce the level of monopoly in tourism.

Augmented reality technologies are used as an innovative tool in organizing and conducting tours.

Mobile devices have become an integral attribute of tourists who want to receive travel information at any time. Already, existing mobile applications can provide booking services, provide background information, thereby increasing the competitiveness of tourist destinations.The article Morozov & Morozova (2015) analyzes mobile applications used in tourism.

A study of the use of mobile applications in Russia showed that 74.7% of users use applications on vacation and while traveling, 19.3% prefer to relax even from their mobile devices. More often, women (56.4%) use applications on vacation than men (43.6%). The most active age group of users of vacation applications is people aged 25 to 35 years, their share was 32.6%. The share of pensioners was only 2.1%. The most popular are cartographic mobile applications - 59.5%. Table 1 presents mobile apps for travelers.

Table 1: Mobile applications for tourism

Group	Name of mobile application
Cartographic Services	City Guide, Redigo, MapsWithMe, Lonely Planet, Spotted by Locals, 2GIS, Around Me, MapMyRide, Waze, Pin Drop, City Guides от National Geographic, OsmAmd, ForeverMap, Pocket Earth, Galileo Offline Maps
Geoinformation Services	Google maps, City Maps 2Go, YandexMaps, NearestWiki
Guides and audio guides	TourCaster, World Explorer, Localscope, TopTripTip
Help directories with reviews and tips	TripAdvisor, Ask a Nomad - Travel Guide, Tagwhat
Booking tickets	Aviasales, Anywayanyday, Skyscanner, Kayak, Momondo, Eviterra, Flight Status, BiletyPlus, Seatguru, GateGuru, Lounge Buddy, Skyscanner–All Flights!, Smartive Travel, Corner
Hotel Reservation	Booking.com, Ostrovok.ru, Expedia, Hotel Tonight, Hotels.com, Airbnb, Roomorama, Nightswapping, Agoda, Hotellook, Hotel Tonight, Couchsurfing
Booking train tickets	Railtime Mobile
Car and taxi rental	SixT, Uber
Reference information on catering	LocalEats for iPad, Zoon, Buuuk, Foodspotting
Weather reference	GisMeteo, Swackett
Translation software	Google Translate, Word Lens, Руссо туристо, Word Lens, Lingvo
Instant messengers	WhatsApp, Viber, Couchsurfing, Skype, Postale
Travel organizers	TripIt, Tripomatic, CheapTrip, Gogobot, TouristEye, Worldmate, Flight Radar, World Airport Board, Airport (All), Flight Tracker,
Additional services	Wikitude, Roamer, Metro24, Foursquare, SmileDrive, App in the Air, mTrip Travel Guides, Triposo, Free Wi-Fi Map, Free Wi-Fi Finder

In order to increase the competitiveness of tourism enterprises and the convenience of customers, it is advisable to create your own mobile applications. In the application, it is advisable to provide for various methods of payment and prepayment of a tourist product. It is much more convenient for tourists to make payments through the mobile application. In a mobile application, it is advisable to provide search filters by cost, duration and directions, to make it possible to compare two tours. The mobile application must interact with the CRM system. It is advisable to introduce an intelligent chatbot into a mobile application that will help you choose a tour and place an application.

Conclusion

Information has become an important resource shaping consumer preferences and determining the attractiveness of both the tourist product itself and the tourist destinations that offer them. Information support of tourism acts as the most important factor in its development, which is of particular importance in recent years in the context of the development and establishment of the digital economy. Information support of the tourism business is a combination of an information

database on tourism activities and specialized information technologies designed for its processing, which ensure the effective functioning of the tourism system.

Digitalization of business processes in tourism directly depends on the availability of professional digital competencies of employees of a tourism enterprise. Currently, in all areas of economic activity there is an increased need for personnel professionally owning digital competencies. The digital economy is based on the digitalization and integration of all business processes taking place in economic systems at all levels, with particular emphasis on the information component that provides access to real-time information on the activities of economic systems in an integrated global network. In the digital economy, new requirements are being formed for the information and communication environment, information systems, services, business processes. The formation of a single information space in the tourism sector is carried out taking into account the needs of citizens and society in obtaining high-quality and reliable information. In tourism, issues of forming a single information space have been discussed for a long time, and tourism authorities have done quite a lot in this direction. The tourism sector is fully focused on the active introduction of digital technologies, many business processes have already been restructured in accordance with the new paradigm of digital economy development, including tour booking systems, e-commerce technologies, the use of mobile technologies, etc.

Abstract

The article considers the most important problem of tourism development related to the formation of tourist territories (destinations). In conditions of high competition in the tourism market, the spatial development of tourist destinations is becoming the main competitive advantage. It is proposed to use the method of cartographic taxonomy as a spatial planning method. This approach provides tools for modeling tourist clusters and destinations. Cluster binding to the territory is carried out using cartographic taxon. Each taxon is characterized by a number of parameters that make it possible to present information on tourist clusters and destinations in a formalized form. Such an idea makes it possible to plan the spatial development of the tourist area based on its model. The structure of the balance model of tourism activities is proposed, taking into account the distribution of tourist flows between tourism enterprises in the territory of the destination.

Keywords: Tourist Cluster, Tourist Destination, Spatial Development, Tourist Territory, Modeling Of Tourist Destination, Cartographic Taxon

Introduction

One of the important problems of tourism development in many countries is its competent territorial planning. The formation of the spatial development of tourist areas refers to the tasks of the state level. The key areas of development of Russian tourism in the coming years are defined in the document "Strategy for the Development of Tourism in the Russian Federation for the period until 2035". In this strategy, special attention is paid to strategic development, in particular, the spatial development of tourist areas. In this regard, the study of scientific approaches to territorial planning for the development of tourist territories is very relevant.

Methods and Materials

The theoretical and methodological basis of the article is the work of domestic and foreign scientists on spatial planning, the formation of tourist destinations and clusters, the application of the methodology of intersectoral balance for tourism.

During the study, grouping methods, comparisons, logical and economic analysis techniques, generalization and synthesis, modeling were used.

Research in tourism planning is contained in (Gunn, 2002), (Veal, 2002), (Hall, 2008), (Aminu et al., 2013) and others

Results and Discussion

Spatial development of tourism is the basis for the formation of high-quality tourist offer and sustainable tourism development. In this regard, it is necessary to consider the basic concepts associated with the territorial organization of tourism.

In the framework of solving the problems of territorial planning of economic systems, the cluster approach proposed by M. Porter at the end of the 20th century is widely known. The traditional concept of a cluster is as follows. The cluster is considered as a territory on which geographically concentrated groups of interconnected enterprises engaged in joint activities are concentrated. This joint activity can be connected by a single technological process, the creation of a certain type of product.

This approach is legitimate and is used when considering issues of territorial planning in tourism. With the spatial organization of the tourist system, it is also advisable to form tourist clusters and destinations. The initial principle of their creation is associated with those tourism resources that this territory possesses. Proper spatial organization of the tourist territory will ensure the most efficient use of tourist resources and improve the quality of tourist services.

From the point of view of the spatial organization of tourism, the concept of tourist destination should be defined, since in the scientific literature there is an ambiguous interpretation of this term.

Tourism destinations should be considered both from the point of view of the territorial approach and taking into account the needs of customers (Morozov & Morozova, 2016). In the first case, a tourist destination can be defined as a certain territory with specific tourist resources. In the second case, the key characteristic of the destination is its tourist attraction, which determines the motive of travel. The main factor generating tourist flows to the destination is its attractiveness. It is attractiveness that acts as the main motive and reason for tourists traveling to this destination. The authors propose the following definition of tourist destination.

Tourist destination is a certain territory that has tourist attractiveness for travelers and satisfies the following conditions:

- the presence of a key tourist resource, event, etc., which forms the main attraction for a tourist and the motivation for his trip,
- the presence of the necessary tourist infrastructure, including information, and a specific set of services that meets the needs and expectations of tourists.

Tourist destination can be represented as a combination of smaller structural units called clusters. Clusters provide the satisfaction of the tourist needs of a particular segment of travelers. In other words, a destination can have several tourist attractions, and only one tourist attraction is concentrated in a cluster. For example, the destination of Sochi has several tourist attractions: sea climate, summer resort, skiing, etc. At the same time, the clusters included in it are divided by type of attractiveness, for example, marine and ski clusters.

When forming a territorial tourist system, it is necessary to ensure its high-quality information support, which should contain a comprehensive description of the destination. It is necessary to describe the infrastructural support of the destination, provide comprehensive information about the tourist resources and attractions of each cluster, and describe the tourist attractiveness. Thus, the constituent elements of the destination will be clusters. They have a tourist attractiveness and are designed to satisfy the tourist demand of a certain segment of travelers (Morozov & Morozova, 2017).

To model tourist clusters and destinations, it is proposed to use the method of cartographic taxonomy, which is as follows. The geographical territory of the destination is divided into separate squares, the so-called cartographic taxa. Usually the size of a taxon is 1x1 km. Each taxon corresponds to its coordinates. The size of the taxon can be scaled depending on the accuracy of binding the

characteristics of the cluster to the terrain. Thus, the cluster consists of several taxa, and the destination includes a number of clusters. The cluster is formed by cartographic taxa that correspond to given conditions depending on the tourist needs of a particular segment of tourists.

Thus, the method of cartographic taxonomy allows a systematic and structured representation of the spatial information model of tourist destinations through a combination of clusters and cartographic taxa.

Consider the use of cartographic taxonomy in modeling the tourist destination of Krasnaya Polyana. The method of cartographic taxonomy allows us to represent the destination of Krasnaya Polyana as a collection of interconnected taxa (Figure 1).

Figure 1: Representation of the territory of Krasnaya Polyana using taxon

Each taxon has a set of parameters, including the characteristics of infrastructure, tourist resources, attractions, etc. The entire information base for taxon descriptions is structured, so it is easy to search for it according to the specified criteria and make selections using various filters. For example, you can select cartographic taxa on the basis of their belonging to the ski infrastructure. In Krasnaya Polyana, the ski infrastructure is represented by the Alpika-Service, Gazprom, and Gornaya Karusel ski lifts. Each of them is located in a specific geographical area and is tied to the corresponding cartographic taxon. In particular, ski lifts belong to the following cartographic units (taxa):

- “Alpika-Service” - for taxa A47B26, A47B27, A47B28,
- Gazprom (Laura) includes taxa A47B24, A48B24, A47B25, A48V25,
- “Mountain Carousel” refers to taxa A45B25, A46B25, A46B26, A46B27.

Figure 2 shows the binding of the Alpika-Service ski lift to the corresponding taxa.

Figure 2: Taxa modeling the Alpika-Service ski lift

Thus, each territorial unit (taxon) is described by a number of parameters, together they form an information database on the infrastructure of tourist clusters and destinations, available tourist resources, etc. Based on this information base, you can make various samples, create models of clusters and destinations depending on from various parameters, maintain up-to-date information on the destination. A formalized representation of the tourist destination will allow a complete understanding of its condition, may be the basis for the formation of spatial development plans for the territory, which is the basis for the effective management of tourist systems.

When designing the spatial development of the territory, it is necessary to take into account the degree of balance of tourist flows and tourist infrastructure. On the one hand, the production capacity of tourism infrastructure should be calculated taking into account forecasted tourist flows. On the other hand, it is necessary to form tourist flows in order not to exceed the capacity of tourist infrastructure. The quality of tourist services and the degree of satisfaction of tourists largely depend on the ratio of tourist flows and tourist infrastructure. It is also necessary to take into account the staffing of the destination (Morozov & Morozova, 2019). The phenomenon of a competitive tourism system is most fully manifested when combining individual tourism services into a single tourism product. Only in this case, the tourism industry begins to work as a holistic system. However, a prerequisite for the effectiveness of the tourism system is the degree of balance of tourist flows and its infrastructure.

One of the urgent tasks of the territorial organization of tourist activity is to ensure the balance of tourist flows and tourist infrastructure. The solution to this problem is possible through the application of a balance approach The territorial organization of tourism activities largely depends on the availability of appropriate infrastructure and its capacity. If the infrastructure capabilities of the territory significantly exceed the tourist flows received by the destination in terms of volume (capacity), there is a need for additional efforts to attract tourists. At the same time, part of the tourist infrastructure is not loaded, and tourism industry enterprises will receive less profit, i.e. will have lost profits. We can say that in the described situation the organization of tourist activities is ineffective.

With excessively large tourist flows, a full load of infrastructure facilities is observed, but at the same time, the quality of tourist services provided may decrease, which may provoke an increase in tourist dissatisfaction and subsequently lead to a decrease in tourist flow.

In the 20s of the last century, V. Leontiev developed the Input-Output Model. It is designed to assess the balance of economic systems at various levels. This model provides an analysis of intersectoral relationships at the national or regional level. The Input-Output Model allows you to calculate and evaluate the most important economic proportions in order to ensure the balance of individual sectors of the economy.

The principle of the balance approach is advisable to use when designing the spatial development of tourist areas. The relationship between supply and demand, the balance of tourism infrastructure and tourist flows can be modeled using the input-output model. This approach allows you to simulate the relationship of the tourism system with all productive sectors of the economy, as well as evaluate indirect and induced effects.

The application of the balance approach at the level of tourist destinations and clusters will allow us to correctly assess the capacity of the infrastructure and justify the spatial development of the tourist territory.

Table 1 presents the structure of the statistical balance of tourist destinations. It shows the distribution of tourist destinations flows between individual tourism industry enterprises.

Table 1: Layout of the statistical balance of tourist destinations

Total number of services		**Tourists with accommodation**	**Tourists without accommodation**	**Transit tourists**	**Local population**	**TOTAL**
Accommodation facilities (number of places)	Max = total number of tourists	H1		H2	H3	H1+…+Hn
Total:		H1/Max		H2/Max	H3/Max	(H1+…+Hn)/ Max
Catering (quantity)	Max = total number of seats	R1	R2	R3	R4	R1+…+Rn
Total:		R1/Max	R2/Max	R3/Max	R4/Max	(R1+…+Rn)/ Max
Museums (quantity)	Max = Capacity, people	M1	M2	M3	M4	M4+…+Mn
Total:		M1/Max	M2/Max	M3/Max	M4/Max	(M4+…+Mn)/Max
Transport services (quantity)	Max = Capacity, people	T1	T2	T3	T4	T1+…+Tn
Total:		T1/Max	T2/Max	T3/Max	T4/Max	(T1+…+Tn)/ Max
Other services (quantity)	Max people	S1	S2	S3	S4	S1+…+Sn
Total:		S1/Max	S2/Max	S3/Max	S4/Max	(S1+…+Sn)/ Max

According to the table, one can judge the demand for tourist services from different groups of tourist flow, as well as assess the conformity of the tourist infrastructure of destination to its tourist flow.

Conclusion

Thus, when developing projects for the development of tourist territories, it is advisable to use a modeling methodology based on the cartographic taxonomy method. It allows you to present in a formalized form all the information about tourist destinations and their tourist clusters.

The design of the spatial development of tourist areas must be carried out taking into account the principle of balanced tourist flows and tourist infrastructure. Only in this case, the tourist destination system will function efficiently, ensuring a rational loading of tourist infrastructure and an appropriate quality of tourist services. The proposed structure of the balance sheet model for assessing the conformity of tourist infrastructure and tourist flows can serve as the basis for developing managerial decisions in case of non-compliance.

The "Strategy for the Development of Tourism in the Russian Federation for the period until 2035" indicates the need to develop master plans for the development of tourist areas. They should reflect

the points of attraction (tourist attraction), the localization of collective accommodation facilities, the zone of objects of auxiliary and transport infrastructure, ensuring the development of the tourist territory and other zones. The systematic approach proposed in the article is the methodological basis for the development of master plans for territories.

Financial University under the Government of the Russian Federation, Moscow, Russia; e-mail: shchukinan@yandex.ru

Abstract

The purpose of the study is to analyze the trends in the unauthorized transactions number and volume for the funds transfer by individuals through payment cards. In the process of research, the methodology of econometric modeling was used. Econometric analysis of quarterly values unauthorized transactions number and volume for the funds transfer by individuals through payment cards during 2014-2018 allowed to trends identify. The volumes of unauthorized transactions trends in the commitment place context are separately identified: trade organizations, ATMs and CNP transactions, and also the trends types. The volumes of unauthorized transactions trends in the commitment place context are separately identified: trade organizations, ATMs and CNP transactions, and also the trends types. The analysis showed that stable pattern indicators are still being formed. Therefore, the creation and implementation of an effective strategy for the development of the banking sector, in the modern conditions, together with the traditional introduction of new, innovative approaches to risk assessment and management in its specific sphere of activity.

Keywords: the digitalization of the economy, cyber security, the risk, unauthorized operations, payment cards, express loan, the trend equation, the econometric model.

JEL Classification: C53; C15

Introduction

One of the key issues of the Information Society Development Strategy in the Russian Federation for 2017–2030 (Presidential Decree, 2017) is the formation of a national digital economy. The corresponding Program for the period 2017–2024 (Order of the Government of Russia, 2017) with an annual estimated budget of 100 billion rubles was adopted. The country's economy's transition to the digital development trajectory implies "support for the development of both existing conditions for the emergence of breakthrough and promising cross-cutting digital platforms and technologies, and the creation of conditions for the emergence of new platforms and technologies" (Order of the Government of Russia, 2017). The banking sector is one of the most important structures of a market economy, which in the context of its digitalization requires a new principle of transition from an operational response to risk management, prevention and prevention of new negative factors, risks and threats. One of the conditions for the successful implementation of this principle is the development of the skills of the digital economy, the digital education and R&D system, investment in digital infrastructure and cybersecurity (Report on the Russian economy, 2017).

The formation and implementation of an effective development strategy for the banking sector in modern conditions requires the introduction of international standards for risk assessment and management (COSO, 2017). Each country has risk management systems that take into account the

peculiarities of organizational factors for introducing risk management in small and medium enterprises. One such study at the interstate level was conducted by Henschel and Durst (2016). adjusted for the Russian market, as well as the creation and implementation of new science-based models and methods in its specific field of activity. Features of the Russian risk management system are reflected in the works of Barilenko (2016), Ankina (2017), Lanskov and Zenkovich (2017). The choice of the mathematical apparatus for modeling decision-making processes is largely determined by the degree of uncertainty of environmental factors with the strong dependence of Russian economy indicators on them.

Materials and Methods

The complexity and inconsistency of domestic and global socio-economic processes lead to the expansion of the risk zone. The evolution of banks in the emerging digital economy involves the introduction of new organizational forms. This also induces the emergence of new banking risks. Classic banking is undergoing change. Cash gives way to non-cash payments. At the same time, in terms of volume, such operations occupy 68% of the market. In general, in the first half of 2019, individuals used their cards 19.2 billion times for a total of more than 40 trillion rubles. This is primarily due to the growth of online commerce. In 2018, the turnover of online trading in Russia amounted to 1.5 trillion. rubles. Figure 1 shows the dynamics of the use of payment cards in Russia and abroad.

Fig. 1: Operations using payment cards committed in Russia and abroad

The most popular payment methods through the Robokassa platform in 2018 were bank cards, electronic money, Qiwi-wallets, mobile payments of all major operators, Internet banking, payments through Euroset and Svyaznoy salons. The distribution of payment methods for online purchases in the total volume of non-cash transactions is presented in Figure 2.

Fig. 2: The most popular payment methods

Bank cards are the leader in terms of cashless payments, which can easily be explained by their wide distribution. According to the statistics of the Bank of Russia, more than 90% of transactions on cards of Russian citizens in the first half of 2019 were made by non-cash transactions: payment for goods and services, as well as transfers from card to card / bank account / deposit. The level of provision of the population with payment infrastructure is growing every year, and as of July 1, 2019, for 1 million inhabitants, there were 21 thousand devices for receiving payment cards. The dynamics of the number and volume of transactions using payment cards in the Russian Federation is presented in Figure 3.

Fig. 3: Dynamics of transactions number and volume using payment cards in the Russian Federation

The risk of unauthorized transfers of funds by individuals using payment cards is increasing. The complexity of assessing such a risk is due to the blurring of the boundary of the operational risk category, to which it can be attributed in accordance with the agreement of the Basel Committee on Banking Supervision. In order to develop scientifically based recommendations on ways, means and methods to increase the effectiveness and efficiency of risk assessment and risk management processes, internal control and cybersecurity in the field of banking operations, it is first necessary to analyze information on the number and volumes of unauthorized money transfer operations. We take the indicators of bank reporting as a basis for this analysis.

Results

At the first stage of work, we studied the dynamics of the number and volume of unauthorized operations conducted in Russia and abroad using payment cards. The report presents quarterly data sets for the period 2014 - 2018.

In 2014, the total amount of unauthorized transactions committed using payment cards amounted to 1,581.4 million rubles (Review of unauthorized transfers of funds, 2016). In 2015, this indicator reached a value of 1,147 million rubles, which is 72.53% of its previous value. In 2016, the indicated volumes amounted to 1075.4 million rubles; in comparison with 2014, this is 68%, and compared to the previous year - 93.76%. In 2017, the emerging downward trend continued: in comparison with 2014, the volume of unauthorized transactions committed using payment cards amounted to 60.79%, and compared to the previous year - 89.39%. According to (Review of unauthorized transfers of funds, 2017), the volume of unauthorized operations using payment cards in 2017 amounted to 961.3 million rubles. The volume of all unauthorized operations committed using payment cards issued in the Russian Federation in 2018 amounted to 1384.7 million rubles, which is 44% more than the same indicator in 2017 (961.3 million rubles). The number of such operations for the reporting period in 2018 amounted to 416,933 units, which is 31.4% more than the same indicator for 2017 (317,178) (Review of unauthorized transfers of funds, 2018). The dynamics of quarterly data on the number and volumes of unauthorized payment cards operations conducted on the territory of Russia is presented in Figure 4.

Fig. 4: Unauthorized transactions number and volume using payment cards

Figures 3 and 4 show that the number of unauthorized transfers of funds by individuals is increasing against the background of an increase in the number of transactions using payment cards. An analysis was also made of the quarterly values of the volume of unauthorized transactions committed using payment cards. Its graphical interpretation is shown in Figure 5. From Figure 5 it can be seen that in

some periods the volume of unauthorized operations tends to decrease. However, in 2018, the data showed an increase in the number and volume of thefts in 2018.

Fig. 5: Unauthorized transactions volume, million rubles

According to the indicators of bank reporting, in the period 2014 - 2015 there is a slight decrease in the number of unauthorized operations. However, from the fourth quarter of 2015 to the fourth quarter of 2016, the number of these operations from 57,929 increases to 90,277 units per quarter. The first three quarters of 2017 are characterized by a decrease in the indicator to 64089 units per quarter, but in the IV quarter there is a sharp increase in the number of unauthorized transactions using payment cards to 84,559 units, which reaches the third highest value for the entire period under review. At the same time, the average amount of one unauthorized operation in 2016 amounted to 3.62 thousand rubles. The average amount of one unauthorized operation in 2018 increased by 9.6% and amounted to 3.32 thousand rubles against 3.03 thousand rubles in 2017. This increase is due not only to an increase in the number and volume of unauthorized transactions in the reporting period, but also to an increase in the number of detections of these operations in the total number of transactions completed.

It should be noted that the share of the volume of unauthorized transactions in the total volume of transactions performed using payment cards in 2018 amounted to 0.0018% compared to 0.0016% in 2017 (Fig. 6). In general, for this indicator we can observe a steady downward trend. The calculation of the coefficients of the trend equation allowed us to obtain a nonlinear equation $y_t = (4.9\ln(t) - 1.1)10^{-5}$, which shows that in 2019 we should expect a decrease in the share of the volume of unauthorized operations to 0.0013%.

Fig. 6: Share of unauthorized operations in the total transactions volume committed using payment cards, %

To estimate and obtain a forecast for 2019 of the number and volume of unauthorized transactions using payment cards conducted on the territory of Russia and outside it, we construct the trend equations. The results of the regression analysis are presented in table 1.

Table 1: Regression analysis results of the unauthorized transactions number and volume using payment cards

Indicator	Trend	Forecast values	
		I quarter 2019	II quarter 2019
Unauthorized transactions number using payment cards, units	$y_t = 41937 + 3107.7t$	107115	351,03
Unauthorized transactions volume using payment cards, million rubles	$y_t = 138.09 + 10.14t$	110218	361,17

The linear trend does not adequately describe the current dynamics in the number and volume of unauthorized transactions using payment cards conducted in Russia. For processes with a changing trend, the best forecast result is provided by adaptive models, which include, for example, the Brown model (1956), the Holt model (1957), etc. The forecasting trend approach involves extrapolating the aligned values of the dynamic time series of the predicted indicator, i.e. transferring past trends of the predicted indicator to its future development. The reliability of forecasts in this case depends on the stability of the trend of demand changes, which may be violated in the conditions of crisis development of the economy.

One of the simplest adaptive methods for short-term forecasting of irreversible processes is Brown's exponential smoothing method, the idea of which is to determine the next predicted value through the previous predicted value, adjusted by the deviation of the actual value from the predicted (Brown, 1956). The Holt-Winters model (Winters, 1960) is a modification of the Holt method (Holt,1957) and is used to predict time series in the structure of which there is an established trend and seasonality. This

model is three-parameter and takes into account the smoothed exponential series, trend and season and consists of a system of recurrence equations:

$$\begin{cases} L_t = \alpha \frac{y_t}{S_{t-s}} + (1-\alpha)(L_{t-1} - T_{t-1}), \\ T_t = \beta(L_t - L_{t-1}) + (1-\beta)T_{t-1}, \\ S_t = \gamma \frac{y_t}{L_t} + (1-\gamma)S_{t-s}, \end{cases} \quad (1)$$

where $\alpha \in [0;1]$, $\beta \in [0;1]$, $\gamma \in [0;1]$ – smoothing constants;

L_t, L_{t-1} – the smoothed values for the current and previous periods, respectively;
T_t, T_{t-1} – trend value for the current and previous periods, respectively;
S_t, S_{t-1} - seasonality for the current period and for the same period in the previous season, respectively.

For the first period, the exponentially smoothed series is equal to the first value of the series: $L_1 = y_1$. Seasonality in the first and second period is 1: $S_{t-s} = 1$. The trend value for the first period is 0: $T_1 = 0$. Then the forecast for p periods is

$$\hat{y}_{t+p} = (L_t + pT_t)S_{t-s+p} \ , \quad (2)$$

where S_{t-s+p} – the value of the seasonal component for the same period in the last season.

To build a forecast of the number dynamics of unauthorized operations using payment cards for the first half of 2019, as the initial value we choose the data on the number of unauthorized operations in the first quarter of 2017, for which we assume p = 1. We choose the smoothing constants $\alpha \in [0;1]$, $\beta \in [0;1]$, $\gamma \in [0;1]$ to minimize the average relative forecast error. For the initial data of the levels of the considered time series, we obtain α = 0.835, β = 0.635, γ = 0.5. The approximation error of the Holt-Winters model is $\overline{O} = \frac{1}{n}\sum \frac{|y_t - \widehat{y_t}|}{y_t} = 0.046$, which indicates the high quality of the forecast. Based on the simulation results, we obtained the following values of the number of unauthorized transactions using payment cards for the first half of 2019: in the first quarter – 123289 units, in the second quarter – 124707 units.

To build a forecast of the volume dynamics of unauthorized operations using payment cards for the first half of 2019, we choose the data on the number of unauthorized operations in the first quarter of 2017 for which we set $p = 1$. For the initial data of the levels of the considered time series, we obtain α = 0.835, β = 0.835, γ = 1. The approximation error of the Holt-Winters model is $\overline{O} = \frac{1}{n}\sum \frac{|y_t - \widehat{y_t}|}{y_t} = 0.068$, which indicates the high quality of the forecast. The result of modeling (1) and building a forecast (2) is as follows: in the first quarter of 2019, the volume of unauthorized transactions using payment cards is forecasted at 429.89 million rubles, in the second quarter – 470.09 million rubles.

The next stage of work explores the dynamics of unauthorized payment cards operations in the context of the execution place. These places are differentiated by the following groups: trade organizations, ATMs and CNP transactions (transactions performed via the Internet and mobile devices, including Internet banking). A histogram of the volumes of these operations is shown in Figure 8. In the total volume and number of unauthorized operations, the main share is made up of CNP transactions: in 2018, their share in the total volume of operations was 81.4%, which is 5.8 percentage points more than in 2017 (75.6%).

The dynamics of unauthorized operations for each group are investigated using trend highlighting. The trend hypothesis was confirmed in each group. To check the quality of the obtained nonlinear trend models, the tightness of the relationship through the correlation index was evaluated for each of them: $\rho_{ty} = \sqrt{1 - \frac{\sum_{i=1}^{n}(y_i - \widehat{y_{ti}})^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}}$ and average approximation error: $\bar{A} = \frac{1}{n}\sum_{i=1}^{n} \frac{|y_i - \widehat{y_{ti}}|}{y_i} \cdot 100\%$,

where y_i – actual row level value,
$\widehat{y_{ti}}$ – theoretical (calculated) value of the level of the series,
$\bar{y}$ – average of the actual levels of the series,
n – amount of elements.

Fig. 8: Unauthorized transactions dynamics using payment cards in the context of their terms and conditions (million rubles)

Between the 1st quarter of 2014 and the 3rd quarter of 2015, the volumes of unauthorized transactions carried out through ATMs and payment terminals are rapidly decreasing. Then, relative stability is observed, but the decline does not stop. This behavior is characteristic of both hyperbolic and logarithmic types of trend. Therefore, the standard procedure for clarifying the type of trend was carried out. Based on the results of a regression analysis for the volumes of unauthorized operations carried out through ATMs and payment terminals, the equation is obtained $y_t = 186{,}86 - 55{,}82\ln(t)$.

For volumes of unauthorized operations using payment cards committed in trade and service organizations, the linear trend equation is: $y_t = 85{,}19 - 3{,}27t$.

For the volume of transactions made through the Internet and mobile devices, the equation of the exponential trend was obtained $y_t = 123{,}13\exp(0{,}0356t)$.

It should be noted that, in contrast to the volumes of unauthorized transactions committed in trade organizations and through ATMs, the volumes of unauthorized CNP transactions tend to increase.
A feature of the consideration of the territorial distribution of unauthorized operations is their concentration on the territory of the Central Federal District. This is explained by the fact that the majority of credit organizations serving individuals are located in the Central Federal District (Table 2, Fig. 9).

Table 2: Unauthorized operations number and volume by Federal districts

Federal districts and Federal significance cities	Number of unauthorized operations, units			Unauthorized transactions volume, thousand rubles		
	2016	2017	2018	2016	2017	2018
Moscow	65 403	85 819	138 422	277 642,90	325 539,50	522 507,32
Central FD	27 224	28 572	18 858	78 924,70	56 388,81	55 717,65
Volga FD	20 496	18 810	19 952	54 131,10	40 016,48	52 008,49
Siberian FD	15 911	12 915	13 103	39 335,90	23 525,70	27 984,69
Southern FD	10 619	8 459	10 689	30 002,20	17 594,90	26 560,88
Urals FD	9 895	9 357	9 374	28 036,70	19 920,15	27 126,41
North-Western FD	9 756	10 348	9 183	27 090,20	19 724,56	17 219,57
Eastern FD	7 177	5 801	5 038	23 812,40	14 587,96	24 748,08
Saint Petersburg	6 410	5 464	6 705	27 628,80	19 471,93	61 429,02
North Caucasus FD	3 797	2 208	1 808	11 945,60	3 953,19	5 059,70

The leaders in the number and volume of unauthorized operations are Moscow and the Moscow region. In terms of the volume of unauthorized transactions using payment cards, 64% of the corresponding indicators in 2018 accounted for Moscow.

Fig. 9: Unauthorized operations number and volume by Federal districts

Unauthorized transactions committed outside the Russian Federation account for 44% of the number and 40.7% of the volume of all unauthorized transactions committed in 2018. In 2017, these indicators were 40 and 44%, respectively. In this regard, it is possible to predict the continuation of a trend in which the share of the volume and number of unauthorized operations committed in the Russian Federation in the total volume and number of all unauthorized operations is more than 50%.

Conclusion

Summarizing the results of the study, we can draw the following conclusions. A non-linear downward trend in the volume of unauthorized transactions committed using payment cards has been identified. Separately identified trends in the volume of unauthorized operations in the context of the place of their execution: trade organization, ATMs and CNP transactions. For volumes of unauthorized transactions committed through ATMs and payment terminals, a logarithmic trend is obtained. For volumes of unauthorized operations using payment cards committed in trade and service organizations, a linear trend model with a downward trend was obtained. For the volumes of transactions performed via the Internet and mobile communication devices, an equation of the exponential trend with an upward trend is obtained.

The analysis showed that for certain indicators it is difficult to obtain forecast values, since in the context of large-scale digitalization of the economy and the rapid development of information and financial technologies, stable patterns are still being formed. The results can be used by money transfer operators, as well as payment infrastructure service providers, to plan activities for risk management, internal control and information protection. Cybersecurity technologies should be prioritized.

The "Knowledge Triangle" Is A Modern Concept for Managing the Development of Education, Science and Innovation

Oleksandr BOHASHKO

Pavlo Tychyna Uman State Pedagogical University, Uman, Ukraine
bogashko@ukr.net

Abstract

The purpose of the research is to consider the modern concept of the "Knowledge Triangle" as a universal approach to higher education for the development of innovative economies of states.
The theoretical and methodological base of the research is constituted by the fundamental principles of economic theory and practice, general scientific and special methods of knowing economic reality. The main methods that were used: structural-logical; comparative, the method of detailing and synthesis. The concept of the "Knowledge Triangle" is becoming a more popular method for regulating innovation and developing state innovation policy. The article provides a conceptual analysis of various definitions of the concept and its relationships with other structures, in particular with national innovation systems. The basic elements of the concept and the possibilities of its application in the development of innovative policy of state innovation policy the state are considered. Attention is focused on a systematic approach to regulating the processes of creating scientific knowledge and innovation. The participants in the "Knowledge Triangle" are described, which include higher educational institutions, authorities and private companies. Their tasks in the development of state innovation activity are determined. It is concluded that universities perform numerous functions; therefore their functions are usually determined by the national context. The quality of educational, scientific and innovative activities of universities varies from country to country and depends on historical factors, public policy and institutional structures.

Keywords: higher education, university, science, innovation.

Introduction

The concept of the "Knowledge Triangle" formalizes the links between the traditional "basic" functions of universities – teaching, research and social activities. Under this model, universities, implementing educational programs and scientific projects, generate scientific knowledge, and multi-faceted interaction with the general public helps to create new products, processes and services.

Higher education and research systems in the public sector of developed countries are in the process of transformation. Long-term political reforms of higher education led to duplication of measures of educational, scientific and innovative policies, and sometimes to contradictions between them.

The feedback between education and the innovation sector remains poorly understood. Scientific knowledge sharing is limited to promoting individual innovations for educational purposes.

The concept of the "Knowledge Triangle" implies not only the strengthening of the educational, scientific and innovative components, but also the strengthening of the relationships between them. The concept can become an attractive basis for a policy whose task is to link the creation of scientific knowledge with innovative activity.

The theoretical basis of the "Knowledge Triangle"

The "Knowledge Triangle" is formed from the three functions of universities in educational, scientific and innovative activities. The quality, intensity and significance of each of the three activities are very different in the production of new scientific knowledge by country and region.

M. Unger and W. Polt (2017) discuss the functioning of the "Knowledge Triangle", analyse the roles of its participants, their motivation to participate in this system and possible problems. An analysis of the cases revealed that in order to implement institutional transformations in universities and other organizations, certain incentive methods are required. These include federal or regional strategies with a targeted budget, competitive programs, special measures for the distribution of state grants, etc.

The various aspects of the "Knowledge Triangle" in OECD states can be found in the studies of M. Cervantes, which address issues related to improving the effectiveness of higher education and the growth of its socio-economic significance as the main element of the innovation system. The author's work of M. Cervantes (2017) reveals the content of the model, analyzes its promotion strategies, issues of evaluating the effectiveness of educational institutions, possible contradictions in relations with other subjects of scientific knowledge production. It is concluded that there is no universal model of universities and the "Knowledge Triangle". The reason for this is the peculiarities of educational systems in different countries.

M. Raunio, N. Nordling, M. Kautonen and P. Rasanen (2018) suggest using a platform approach in which users create new value for each other, generating a network effect and a combination of digital solutions and physical innovation support centres. The authors consider this model as a source of answers to modern challenges in the development of the "Knowledge Triangle" strategies and regional development based on scientific knowledge.

The theoretical and methodological base of the research is constituted by the fundamental principles of economic theory and practice, general scientific and special methods of knowing economic reality. The main methods that were used: structural-logical (when constructing the logic and structure of the work); comparative (when considering the various participants of the "Knowledge Triangle", concepts and models of innovative development and their analysis), the method of detailing and synthesis (to study the sources of financing science and innovation).

The purpose of the research is to consider the modern concept of the "Knowledge Triangle" as a universal approach to higher education for the development of innovative economies of states. To achieve the purpose of the research, the following tasks were set: to consider the prerequisites for the emergence of this concept; analyse the definition of the "Knowledge Triangle"; to identify the basic elements of the concept and the possibility of its application in the development of innovative policy of the state; to characterize the participants of the concept and determine their tasks in the development of innovative activity of the state; point out the special role of universities in shaping the contribution of education to science and the creation of innovations.

The "Knowledge Triangle" is a concept that involves an integrated approach to politics in the field of science, education and innovation with an emphasis on the role of universities as a subject of the production of scientific knowledge. The concept intersects with other models that focus on individual participants in the innovation system, namely the "third mission", the "entrepreneurial university" and the "triple helix", whose brief characteristics are reflected in fig. 1.

Having common properties, these concepts, however, have some differences. The "Knowledge Triangle" model focuses on activities in the educational, scientific and innovative fields, while the "triple helix" considers participants in the national innovation system. The concept is a functional model that characterizes two-way communication channels between the mentioned areas of activity.

The novelty of this concept lies in the focus on the role of education in the development of science and innovation. Thus, the “Knowledge Triangle” can be defined as a combination of participants in three areas (education, science, innovation), which expands the possibilities for joint activities (Fig. 2).

Fig. 1: Conceptual models of innovation system management
Source: (OECD, 2015), (Ranga and Etzkowitz, 2013), (Unger and Polt, 2017)

Fig. 2: The "Knowledge Triangle" of science, education and innovation
Source: (Unger and Polt, 2017)

This model, which belongs to the category of "systemic innovative concepts," should not be considered as a full-fledged substitute for any of the other schemes described earlier. Some of them are already used in institutional practice, becoming part of the strategies of scientific, technological and innovation policies in a number of states.

Let us turn to a detailed examination of the activities of participants involved in the "Knowledge Triangle", problems for politics in the formation of relationships between all its components, political approaches that favour or hinder the functioning of this system. This concept can be used as a political tool, socio-economic model or strategy for the development of academic institutions.

Higher Educational Institutions

Universities as the foundation of the "Knowledge Triangle" make the main contribution to the filling of all its components. Different types of institutions do not play the same role in different countries. Diversity is found even among institutions of the same category. We mention only some key aspects: topics of scientific and educational activities, resource base, organizational structure, internal management mechanisms and relations with other stakeholders. Depending on the degree of diversification of universities, increasing the effectiveness of their participation is ensured by flexible adjustment of political measures. Based on the policy of autonomy and increasing the responsibility of universities, many states are deliberately working to strengthen their image as socially significant institutions involved in the transfer of scientific knowledge.

Universities transfer and commercialize scientific knowledge using a variety of channels. Traditional core scientific knowledge channels include (Vonortas, 2017):

- Publication of articles, monographs, proceedings of conferences, reports;
- Communication in the framework of professional conferences, informal ties, working contacts;
- Research or consulting services for companies provided by universities and state scientific organizations;

- Hiring employees in the company and student internships, the institutional basis for which can be ensured by organizing an internship, joint scientific management of graduate students;
- Development of standards defining terminology, measurement and testing procedures, interfaces;
- The founding of companies by students and recent graduates with experience in scientific research (recently this channel has received increased attention).

Less traditional ways of disseminating scientific knowledge aimed at their commercialization include (channels of the second category):

- Collaborative research, research projects carried out and sometimes funded by universities and companies on a joint basis;
- Scientific and technological partnerships, such as the creation of formal alliances with a different number of participants, for example, research corporations; conclusion of long-term research agreements;
- Contract research conducted by order of companies to solve specific problems;
- Patenting and licensing are the main functions of technology transfer centres. They do not cause much interest among universities and companies, but enjoy the great attention of state bodies.

The transfer of scientific knowledge from universities and state scientific organizations has always been carried out. It is bidirectional and through the exchange of research results and business information provides mutually beneficial cooperation. Traditional methods of transferring scientific knowledge are still relevant.

The concepts of “entrepreneurial” and “civic” universities are based on an expanded understanding of the role of universities. Nevertheless, there are contradictions between these models, since the orientation toward entrepreneurship, modernization, and the pragmatic distribution of assets from the point of view of a commercial result may not correspond to public goals, which often seem unrealizable in the short term. However, with an innovative and flexible approach, the university is able to combine “entrepreneurial” and “socially-oriented” models, gaining additional benefits through the use of creative resources to develop new solutions.

As the main participants in the “Knowledge Triangle”, universities play an important role in its formation. Their positioning in this system is determined by managerial models and financing mechanisms. The activities of universities not only contribute to strengthening the position of the region in global competition for attracting companies, but also largely determine its social, demographic and cultural appearance. The attractiveness of the region for young educated people has a positive effect on the development of its infrastructure, including schools, kindergartens, and cultural events. In addition, universities stimulate economic growth in the regions.

Public Research Institutes

The global competition for scientific leadership and the continued disregard for basic research by the business have contributed to the fact that public research institutes have become hubs of research and development (R&D). They occupy an important place in the innovative systems of countries performing unique research for the commercial sector. They carry out research in specific areas or implement strategic projects. They operate in the field between state universities and business, carry out specialized applied research, and open up career opportunities for researchers from specific areas, sometimes going beyond the university environment and not always oriented to the market.

Private Companies

Business as a subject of the “Knowledge Triangle” is guided by other interests than state institutions and developers of innovation policy. Entering into partnership with state organizations, private companies proceed from commercial rather than public or political considerations. This interaction is carried out through different channels. Particular importance is attached to the mobility of specialists with varying degrees of training, which form the basis of the innovative potential of companies, as well as research conducted by state universities or research institutes that can be converted into

innovations (Jaffe, 1986; Karlsson and Andersson, 2005). The contribution of companies to the development of education and R&D depends on the method and degree of intensity of interaction with the public sector of science and universities.

State Authorities

State innovation policy has become networked and decentralized. Politicians consider universities as suppliers of competent specialists, subjects of national and regional innovation systems. Effective communication of scientific, educational and innovative activities is a key prerequisite for responding to social challenges. State stimulation of innovations in the "Knowledge Triangle" takes various forms: tax lending to companies, conclusion of contracts with universities for the implementation of targeted R&D, the organization of postgraduate programs and student internships, the promotion of university advisory services, often financed regional authorities. Being very heterogeneous, the functions of government and administrative structures do not lend themselves to a uniform classification.

The concept of "smart specialization" is related to the coordination of the regional participants. It serves as a key paradigm for the formation of subsystems combining various components of the "triangle" in order to achieve sustainable regional development based on scientific knowledge and innovations. (European Commission, 2012; OECD, 2014a,b). In many countries, regional or other administrative units (cities, municipalities) to one degree or another participate in the formation of scientific, technological and innovative policies. Mechanisms for coordinating scientific, technological and innovation policies vary depending on the constitutional status of regions in a given country.

University management models and their financing schemes vary depending on the distribution of power between the central and regional levels.

The "Knowledge Triangle" takes on various configurations depending on the composition of participants and the areas of responsibility of the authorities. Within its framework, state structures (ministries, regional and local administrations) perform the following main functions (Mazzucato, 2013):

- determine the legal and regulatory framework for scientific, educational and innovative activities in the public sector by delegating responsibilities to relevant bodies, as well as developing norms, standards and regulations for business;
- institutes of higher education, public and private sector R&D and innovative activity are provided with resources through financing, as well as indirect incentives (provision of tax benefits, etc.);
- support innovations by generating demand for them (innovation-oriented public procurement system);
- manage the needs for highly qualified personnel and the results of scientific and innovative activities;
- establish thematic or technological priorities that serve as a long-term guideline for the distribution of financing, planning the activities of the public and private sectors.

In an attempt to coordinate activities, public authorities face many challenges. Engaging universities in the region is not an easy task for politicians. Problems arise due to differences in their teaching and educational missions. In turn, management systems and financial obligations in relation to universities, innovation policy or regional development depend on the distribution of powers between the central and regional levels.

Such a complex set of factors can lead to contradictions in the application of stimulating mechanisms. Consequently, the ability of regional structures and mechanisms for planning and implementing innovative policies to ensure the integrity of the "Knowledge Triangle" varies.

Conclusions

Thus, the "Knowledge Triangle" is not the ultimate concept, but rather a guideline that stimulates productive interaction between the educational, scientific and business sectors. Political measures based on such an approach are designed to expand the academic culture of universities, encouraging them to focus not only on scientific excellence and teaching, but also on the development of innovation and the solution of socio-economic problems. The concept was formulated to address a number of tasks: stimulate innovation; strengthening the flow of private investment in R&D; overcoming difficulties in connection with the commercialization of R&D results.

The innovative activity of business is increasingly dependent on the scientific base of universities. The latter are also the main employers for researchers in countries and serve the interests of local and national economies.

In addition, they produce public goods – from the flow of scientific knowledge, the training of qualified specialists to the scientific support of decision-making processes, and products for private consumption, including business consulting services, patented inventions, and contract research.

At the same time, in the context of decentralized financing of higher education in many countries and competition for supporting scientific projects, universities are under tremendous pressure from the state and other stakeholders. In order to meet modern requirements and satisfy the request for inclusiveness and accessibility of higher education, they need reforms.

Enhancing the social and economic importance of universities is a key task of national policy, the solution of which requires new approaches. In this regard, the relevant departments of OECD countries have high hopes for the concept of the "Knowledge Triangle", which offers tools to strengthen the links between the educational, scientific and innovative functions of universities.

Meanwhile, universities as participants are very diverse, have different missions and structure for innovation, determined by country specifics. Their various types are capable of contributing to the development of innovations, carrying out educational, scientific and other activities and collaborating with other entities.

Effective tools to support the transfer of scientific knowledge are innovative strategies adapted at the local level. The traditional concept of scientific knowledge production as a linear and sequential process is being replaced by a systematic approach to scientific, educational and innovative policies.

The logic of the concept focuses on the links between educational, scientific and innovative activities. In accordance with it, any policy measure that focuses on any of these areas automatically affects the rest. The concept includes only those measures, criteria and tools that integrate all three of its components. The "Knowledge Triangle" encompasses different levels of politics, from municipal to international. Its strategic interpretation depends on the orientation of the national or regional innovation system and approaches to the management of science, technology and innovation in a particular country.

Thus, the "Knowledge Triangle" provides support for political decision-making, showing that investments in one of its components produce positive effects not only for the other components, but also for the external context, including the modernization of the labour market, stimulating structural changes in the economy, and improving the quality of life. Therefore, it should not be perceived as a theoretical concept, but as a practical platform.

Abstract

The main objective of this paper is to characterise the Asian Monetary Fund (AMF) project as a manifestation of financial regionalism and to discuss its genesis, attributes, and challenges. The project of the Asian Monetary Fund was submitted by the Ministry of Finance of Japan in 1997; however, it has not been implemented to date. Association of Southeast Asian Nations (ASEAN) Plus Three (APT) states, led by China, Japan, and the Republic of Korea, chose the path of gradualism, establishing a regional architecture of financial cooperation on the base of the network of the swap agreements (Chiang Mai Initiative – CMI), which have since been replaced by multilateral contracts (Chiang Mai Initiative Multilateralisation - CMIM), mechanisms of policy dialogue, and macroeconomic surveillance. The authors conclude that the progress of institutionalisation under the crises episodes of 1997-98 and 2007-09 increased the probability of AMF establishment, but this is on the condition that several criteria are met, such as de-linking CMIM and the International Monetary Fund (IMF), increasing CMIM funds, enhancing the effectiveness of APT Macroeconomic Research Office (AMRO) activities, ensuring complementarity between CMIM/AMRO (AMF) and the IMF's actions to create synergy effects, expanding CMIM membership. The following research methods were used: statistical and descriptive analysis and comparative and critical studies.

Keywords: Asian Monetary Fund, financial regionalism, Chiang Mai Initiative

Introduction

The Asian Monetary Fund (AMF) project has been the subject of academic and political discussions since 1995, when the possibility of creating the Asian equivalent of the Bank for International Settlements (BIS) was considered. However, the circumstances of the Asian financial crisis of 1997-98 prompted Japan to submit a project for a new regional financial institution at the international forum. The aversion of the United States and China to the concept of an institution dominated by Japanese influences led to a premature failure of the proposal but inspired the search for a formula for financial cooperation inside the region affected by the consequences of financial turbulence from the late 1990s. The Chiang Mai Initiative (CMI) and the Economic Review and Policy Dialogue (ERPD) gave rise to closer coordination of the financial policy of the Association of Southeast Asian Nations (ASEAN) Plus Three (APT) countries at the dawn of the new century, and then the global financial crisis of 2007-09 inspired the decision to replace the CMI with a single facility, Chiang Mai Initiative Multilateralisation (CMIM), as well as the establishment of a new macroeconomic surveillance mechanism, the APT Macroeconomic Research Office (AMRO). The creation of a new regional financial institution has once again become highly likely, although a number of conditions still need to be met.

The main objective of this paper is to characterise the project of the Asian Monetary Fund as a manifestation of financial regionalism and to discuss its genesis, attributes, and challenges. The structure of the paper is as follows: a review of the literature on the AMF project and the theoretical

frameworks of financial regionalism is followed by a discussion of the characteristics of the AMF project as a framework of financial regionalism, which is followed by an overview of the major challenges facing the AMF project and, finally, the authors' conclusions. The following research methods were used: statistical and descriptive analysis and comparative and critical studies.

Literature Review

AMF Project

The AMF project has attracted the attention of many scholars over the years. Narine (2003) generated insights into the implications of the Asian financial crisis of 1997-98 for regional financial architecture, highlighting the need for the establishment of an effective system of protection against global volatilities. Lee (2006) adopted an identity approach to explain the reasoning behind the exclusion of the United States from Japan's AMF project. Grimes (2011) analysed regional liquidity arrangements established in East Asia through the prism of experiences of the global financial crisis. Kim and Yong Yang (2011) conducted research on regional financial and monetary cooperation in Asia, paying special attention to challenges resulting from the global financial crisis and global imbalances for the newly established CMIM and other financial initiatives, such as the Asian Bond Market Initiative (ABMI), the Asian Bond Fund (ABF), and regional surveillance mechanisms. Menon and Hill (2014) studied the evolution of financial safety nets in Asia, recognising the potential of CMIM as a prospective complement to the International Monetary Fund (IMF) on the condition that the total size of the facility or the de-linked IMF portion of funds and the scope of membership are increased. Kawai (2015) summarised the progress of regional financial initiatives, that is, CMIM, the ERPD, and the AMRO, pointing at key prerequisites that need to be met for AMF establishment. Bobowski (2018) contrasted the AMF project with the already established Asian Development Bank (ADB) and Asian Infrastructure Investment Bank (AIIB) through the prism of the role of Japan in the financial regionalism of East Asia in the 21st century. Hyun and Paradise (2019) conducted a comparative analysis of European and Asian financial arrangements over the years and their impacts on the financial stability of both regions.

Financial Regionalism

Although there is no single, coherent definition of financial regionalism, one can distinguish its two basic forms: a meeting or a forum for financial and (macro) economic issues and a regional financial agreement (Hamanaka 2010, 78-79). The financial forum is often a place for discussion of economic and financial issues among representatives of regional financial bodies. Regular contact and mutual understanding are conducive to closer regional financial cooperation. Meetings on economic supervision are of particular importance, usually involving the exchange of economic and financial data and continuous monitoring of the economic situation in partner countries using the mutual pressure mechanism. The second form of financial regionalism is a regional financial agreement, that is, a regional development bank or regional monetary fund, quite often involving three or more countries of the region. The signatory countries accumulate common financial resources, which they then borrow or withdraw when necessary. The region may also be covered by a network of bilateral repurchase arrangements (repos) or swap arrangements, which may be multilateralised over time; however, this does not fall under the logic of regionalism. For the purpose of securing repayment, financial arrangements are usually accompanied by an economic surveillance mechanism to monitor the stability of member states' economies or the feasibility of projects. Depending on the specificity of the regional financial agreement, the leading country used to bear specific costs in the form of contributions to the institution.

Asian Monetary Fund as a manifestation of financial regionalism

The Asian Monetary Fund project was officially announced in August 1997 by the then Deputy Minister of Finance of Japan, Eisuke Sakakibara, after nearly two years of discussions inspired by Fraser's concept regarding the Asian version of the BIS. The outline of the new regional financial institution was developed by a working team established at the Institute of Monetary Affairs,

operating under the auspices of the Ministry of Finance of Japan (Bobowski 2018, 292). The AMF project was presented during the anti-crisis meeting in Tokyo on 11 August 1997, on the occasion of arrangements for a rescue package for Thailand worth USD 1.72 billion, involving, in addition to Japan, Australia, and Brunei Darussalam, China together with Hong Kong, Indonesia, Malaysia, the Republic of Korea, Singapore, and three international organisations, that is, the ADB, the International Monetary Fund, and the World Bank (WB). The favourable circumstances of solidarity in the countries of the region during the Asian financial crisis of 1997-98 prompted the Japanese delegation to submit the AMF project at that time. The newly established institution was expected to involve Japan, Australia, Brunei Darussalam, the Philippines, Hong Kong, Indonesia, Malaysia, the Republic of Korea, Singapore, and Thailand and operate with initial capital at USD 100 billion, with Japan's contribution of USD 50 billion (Wang 2000, 207; Calder 2008, 27). The subject of the discussion at that time did not become the so-called institutional link with the IMF, which only increased the resistance of U.S. diplomacy to Japan's project.

As early as September 1997, Sakakibara initiated formal consultations with partners from Australia, China, Hong Kong, Indonesia, Malaysia, the Republic of Korea, and Singapore, gaining the official support of the 10 ASEAN member states and the Republic of Korea. Australia and Hong Kong presented a neutral position, while the U.S. Department of State and Department of the Treasury as well as high representatives of the IMF opposed the project. China was unwilling to form a new regional financial institution dominated by Japanese influences (Pempel 2012, 262).

The sources of the failure of the AMF project in 1997 can be seen not only in the attempt to exclude the United States from the new financial institution and the silent opposition of China but also in the scepticism of the Bank of Japan (BoJ), which opted for a low-profile regional institution with the option of gradual development of its structures and agenda. The AMF project can also be considered as a challenge to the concept of Asian regionalism of that time, coming down to elimination of U.S. influences in the newly established regional institutions. The result of the AMF fiasco was the New Miyazawa Initiative, which offered financial assistance to the countries of the region from a USD 30 billion fund (Grimes 2004, 193; Kawai 2006, 32). On the basis of this initiative, during the Meeting of Finance Ministers of APT in May 2000, a regional network of swap arrangements was established (CMI). By April 2009, 16 bilateral swap arrangements had been concluded, totalling USD 90 billion (Table 1).

Table 1: Bilateral swap arrangements under the Chiang Mai Initiative, April 2009 (USD billion)

From \ to	China	Japan	Republic of Korea	Indonesia	Malaysia	Philippines	Singapore	Thailand	Total
China	-	3.0[a]	4.0[a]	4.0	1.5	2.0[a]	-	2.0	16.5
Japan	3.0[a]	-	13.0[b]	12.0	1.0[c]	6.0	3.0	6.0	44.0
Republic of Korea	4.0[a]	8.0[b]	-	2.0	1.5	2.0	-	1.0	18.5
Indonesia	-	-	2.0	-	-	-	-	-	2.0

Thailand	-	3.0	1.0	-	-	-	-	-	4.0
Total	7.0	15.5	23.5	18.0	4.0	10.0	3.0	9.0	90.0[d]

[a] Arrangements were concluded in local currencies; amounts are given in USD equivalent.
[b] Bilateral swap arrangements (BSAs) between Japan and the Republic of Korea included both USD swaps (USD 10 billion from Japan to the Republic of Korea and USD 5 billion from the Republic of Korea to Japan) and swaps in local currencies (USD 3 billion equivalent from Japan to the Republic of Korea and from the Republic of Korea to Japan). In December 2008, swaps in local currencies were increased from USD 3 to USD 20 billion equivalent; this limit was maintained until the end of 2009.
[c] An additional commitment of USD 2.5 billion was made on 18 August 1999 as part of the New Miyazawa Initiative.
[d] The table does not include the ASEAN Swap Arrangements (ASAs), which amounted to USD 2 billion at the time. The ASAs were formed in 1977 among the five founding members of ASEAN; under the CMI, they were extended to all member countries. In November 2000, the value of the ASAs was increased to USD 1 billion. A decision to double the limit was made in May 2005.
Source: MoF (2016).

The favourable stance of the U.S. Department of Treasury and representatives of the IMF regarding the new liquidity support instrument was because the use of bilateral swap arrangements was accompanied by the requirement to resort to IMF programmes when applying for support exceeding 10% of the bilateral swap arrangement (BSA) limit granted. The official premise for establishing the so-called IMF link was the need to eliminate the moral hazard, associated with excessive risk, to which countries offering loans to each other, secured at the same time due to belonging to other loan institutions, would be exposed.

In parallel with the CMI, in May 2000, a new mechanism was created to promote macroeconomic and financial stability in the region, the Economic Review and Policy Dialogue, which became an integral component of the CMI five years later. The ERPD was to be a forum for the exchange of information, political discussions, and supervision to counteract future financial crises in the region. The problem was the absence of representatives of central banking and the absence of a competent secretariat that could supervise the mechanisms for monitoring the economic and financial situation of the countries in the region. The inclusion of the ERPD in the CMI was to favour the control of borrowers in the context of their economic and financial condition, political adjustments, and emerging risks during the liquidity support period. Thanks to the existence of such a structured network of financial cooperation between the countries of the region and information transmission channels and data exchange to monitor and predict market phenomena that may threaten the financial stability of East Asia, among other factors, Japan became aware of Indonesia's difficult situation in April 2009 and decided to double the financial assistance to USD 12 billion.

During the 11th Meeting of the Ministers of Finance of APT in May 2008, they agreed to multilateralise the Chiang Mai Initiative to form CMIM, which formally replaced the CMI in March 2010. At that time, the ERPD became an integral component of CMIM. In February 2009, a decision was taken to increase the size of the CMIM fund from the existing USD 80 billion to USD 120 billion to stabilise regional financial markets and restore confidence in the market. Importantly, Japan and China made an equal contribution of USD 38.4 billion, which translated into equal shares in the CMIM fund of 32%, and the Republic of Korea contributed half of this amount, which translated into the participation of the 'Plus Three' countries at the level of 80%. Meanwhile, the 10 ASEAN countries participated at the level of 20% (Bobowski 2015, 193). Hong Kong participated in the Chinese contribution, obtaining a separate multiplier and the pool of votes resulting from the contribution, although the basic votes, equal to the pool allocated to Japan and the Republic of Korea, were converted in full to mainland China.

After the changes that took effect on 17 July 2014, the CMIM fund was doubled to USD 240 billion (Table 2), and the share of the so-called IMF link was reduced to the level of 70%, which meant an increase of the limit for use by CMIM signatory countries to 30%, without the need to refer to the credit conditions of the abovementioned institution, with the prospect of a further increase to 40% in 2014 (which, however, ultimately never materialised). The CMIM fund doubled while maintaining the proportions from before 17 July 2014. In other words, the contribution of the 'Plus Three' countries

remained at 80%, while that of the 10 ASEAN countries remained at 20%, although the total distribution of votes was slightly different: the 'Plus Three' countries' share of votes declined to 71.59%, and the 10 ASEAN countries' share of votes increased to 28.41%. The maturity of the swap covered by the IMF link was extended from 90 days to a year; this also extended the so-called upholding period from two to three years, with a limit of two renewals. The maturity of the swap not covered by the IMF link was extended from 90 days to six months, and the maintenance period increased from one to two years, with a limit of three renewals (this is the so-called CMIM Stability Facility - CMIM-SF).

Table 2: Chiang Mai Initiative Multilateralisation, as per the changes enacted on 17 July 2014

	Financial contribution USD billion (%)	Lending multiplier	Maximum swap amount (USD billion)	Voting power (USD billion, %)		
				Basic votes	Votes resulting from the contribution	Total voting power, USD billion (%)
Plus Three	192.00 (80.00)	-	117.30	9.60	192.00	201.60 (71.59)
China	68.40 (28.50)	0.5	34.20	3.20	68.40	71.60 (25.43)
Hong Kong	8.40 (3.50)	2.5	6.30	0.00	8.40	8.40 (2.98)
Japan	76.80 (32.00)	0.5	38.40	3.20	76.80	80.00 (28.41)
Republic of Korea	38.40 (16.00)	1	38.40	3.20	38.40	41.60 (14.77)
ASEAN	48.00 (20.00)	-	126.20	32.0	48.00	80.00 (28.41)
Brunei Darussalam	0.06 (0.025)	5	0.30	3.20	0.06	3.26 (1.158)
Indonesia	9.104 (3.793)	2.5	22.76	3.20	9.104	12.304 (4.369)
Cambodia	0.24 (0.100)	5	1.20	3.20	0.24	3.44 (1.222)
Lao People's Democratic Republic	0.06 (0.025)	5	0.30	3.20	0.06	3.26 (1.158)
Malaysia	9.104 (3.793)	2.5	22.76	3.20	9.104	12.304 (4.369)
Myanmar	0.12 (0.050)	5	0.60	3.20	0.12	3.32 (1.179)

Singapore	9.104 (3.793)	2.5	22.76	3.20	9.104	12.304 (4.369)
Thailand	9.104 (3.793)	2.5	22.76	3.20	9.104	12.304 (4.369)
Vietnam	2.00 (0.833)	5	10.00	3.20	2.00	5.20 (1.847)
APT	240.00 (100.00)	-	243.50	41.60	240.00	281.60 (100.00)

Source: AMRO (2016b).

As part of CMIM, the CMI Precautionary Line (CMIM-PL) was also launched to provide support in the face of a crisis threat, not as a consequence. In this case, the maturity was one year for the limit

covered by the IMF link and six months for the remaining amount, with a maximum duration of up to two years. The eligibility criteria for obtaining preventive assistance covered five areas: external position and market access, fiscal policy, monetary policy, condition of the financial sector and supervision, and data adequacy. A country belonging to CMIM cannot simultaneously use the swap amount under CMIM-SF and CMIM-PL.

The CMIM-PL mechanism was introduced due to the ineffective preventive impact of the previous CMI format, a clear example of which was the mini crisis of Korean won at the end of 2008. At that time, the authorities of the Republic of Korea decided not to use the CMI network to obtain liquidity support, directing the application directly to the U.S. Federal Reserve Bank. There were at least three reasons for this. First, CMI swap arrangements were available in a crisis, not as a preventive measure. Second, due to exceeding the swap amount by 20%, the Republic of Korea would be forced to use IMF programmes, whose legitimacy since the Asian financial crisis of 1997-98 remains weak. Third, the use of bilateral swap arrangements with the Bank of Japan or the People's Bank of China would mean obtaining support at a far-reaching level of USD 3 billion and USD 4 billion, respectively, in local currency, which in the context of the lack of full convertibility of RMB to USD created additional complications.

The usefulness of CMIM-PL in the context of crisis prevention will be verified in the future, but it is undoubtedly a significant step forward in the development of regional financial cooperation. Since May 2012, representatives of the APT countries have been working on the so-called ERPD matrix, consisting of economic and financial indicators of all signatory countries. The matrix's task is to improve the qualification of signatory states for preventive support. Work continues to increase the usability of the matrix.

In May 2011, the AMRO was created in Singapore, which aimed to ‘monitor and analyse the economies of the region for early detection of threats, rapid implementation of countermeasures, and effective decision making at the CMIM level’ (Oba 2014, 65).

In April 2016, representatives of the governments of the APT countries and Hong Kong signed the Agreement Establishing ASEAN Plus Three Macroeconomic Research Office, that is, the AMRO Agreement, which transformed the existing corporation into an international organisation with full legal personality and legal capacity to implement its basic functions. The AMRO was equipped with statutory bodies, that is, the Executive Committee, composed of representatives of the ministries of finance and central banking of each of the signatory countries (with the exception of Hong Kong, which had one seat on the Committee), the director, the Advisory Panel, and staff.

The independence of the AMRO is still problematic, if only due to the link with the activities of the Executive Level Decision-Making Body (ELDMB) created by representatives of the ministries of finance and central banking of the signatory countries of CMIM, which in fact perform supervisory functions in relation to the AMRO. In other words, the AMRO's activities are controlled by the East Asian governments; thus, like CMIM, it will evolve under the influences of the intra-regional play of stakeholder states. Importantly, according to art. 13 of the AMRO Agreement, the organisation is fully financially dependent on the contributions of the members, and it cannot borrow money without the consent of the Executive Committee. In principle, the operating costs of the AMRO are borne by the government of Singapore; however, expenditures are to be the subject of regular settlements among the other signatories (AMRO 2016a). There is uncertainty regarding whether the final shape of CMIM will prefer the interests of the lenders (China, Japan, Republic of Korea) or the borrowers (ASEAN), but there is no doubt that, in the absence of a threat of dictate from either party, the proposed system guarantees relative pluralism and balance. China along with Hong Kong, Japan, and ASEAN have the same pool of votes, 28.41%, while the Republic of Korea has a smaller share, 14.77%. With the rule of a two-thirds majority, this allows each party to cast a casting vote (Pitakdumrongkit 2015). No single APT country has the ability to block joint decisions on its own; however, there is a concern regarding the ability to conciliate and cooperate in accordance with such rules in the future.

Challenges facing the Asian Monetary Fund project

The creation of the Asian Monetary Fund may be of critical importance, due to the wide spectrum of both external risks, that is, normalisation of monetary policy in the United States and deepening of the crisis in the Eurozone or outbreak of geopolitical conflict (e.g. United States versus China) and internal risks, that is, an increase in the public and private indebtedness of the region's countries, macroeconomic policy errors, the sensitivity of regional financial markets, and insufficient policy coordination of the region's countries in areas such as crisis management, economic supervision, and political dialogue.

In this context, the challenge for the APT countries is to maximise the effectiveness of regional macroeconomic supervision under the AMRO for the gradual reduction and, thus, the elimination of the IMF link so that the countries of the region can benefit from regional financial support mechanisms in both crisis and pre-crisis situations, without reference to IMF programmes. In the context of the AMRO, obtaining the status of an international organisation with legal personality and full legal capacity is undoubtedly an important step on the way to developing credit conditions independent of the IMF programmes and monitoring the economic and financial condition of the applicant countries and those already benefiting from CMIM support (in the case of activation of the stability fund).

In the context of the above, the following actions seem to be necessary (Kawai 2015, 27):

- gradual elimination of the IMF link;
- clarifying the conditions and procedures for activating CMIM-SF and CMIM-PL, in particular to avoid IMF programmes in the circumstances of local crises of small scale;
- guaranteeing the AMRO's independence for improving the quality of the regional economic supervision mechanism under the ERPD, the efficient launch of interventions under CMIM, and the formulation of adequate credit conditions independent of the IMF;
- further increasing CMIM funds and/or lending multipliers and then the financial liquidity available to signatory countries, except for Japan and China;
- supplementing CMIM with bilateral swap arrangements with countries from and outside the region, significantly increasing the available liquidity resources;
- improving the quality of economic surveillance by transitioning from the information exchange phase towards the application of mutual pressure and due diligence;
- physical contribution to CMIM in the form of capital or amounts from official foreign reserves of the countries of the region;
- CMIM extension to other ASEAN Plus Six countries, that is, Australia, India, and New Zealand.

Meeting the above conditions could pave the way for the creation of an Asian Monetary Fund equipped with the necessary financial resources, competence, organisational resources, and political mandate. The role of secretariat could be played by the AMRO. Being independent of the IMF does not mean, however, that cooperation and coordination between the AMRO/CMIM and the IMF is not necessary. Given the still limited experience and resources at the disposal of Asian financial cooperation structures and the need to coordinate activities in circumstances of a greater scale of turbulence in the financial markets of the region, it is necessary to ensure mutual complementarity and synergy of the IMF and the AMRO/CMIM (AMF) activities (Kawai 2015, 27-28). The Asian region must develop its own model of crisis management coordination.

Conclusions

Financial cooperation in the Asian region has contributed to strengthening mutual relations and increasing mutual interdependence. Therefore, there is a need to optimise the institutional architecture of the region in such critical areas as coordination of financial policy, macroeconomic supervision, and crisis management. The AMF project seemed to be a natural consequence of the difficulties experienced as a result of the crisis of the late 1990s and the growing role of the dynamically developing region in the global economy and internal integration. Japan's hegemonic ambitions were confronted with the influences of the United States, China, and the IMF in the region,

therefore taking the path of gradualism and starting with a low-profile institution turned out to be the only available option.

The AMF project can be supported by, among other factors, the co-leadership of China and Japan within CMIM (Haggard 2011, 17), providing the Republic of Korea with a proportionally larger number of votes than results from its share in the region's economy, granting the AMRO the status of an international organisation after five years, consistent efforts to increase CMIM funds, and a reduction of the link to IMF programmes.

Challenges for the future undoubtedly remain: eliminating the IMF link while ensuring consistent cooperation with this organisation, adjusting the size of the liquidity support funds available under CMIM to the needs of the borrowers, ensuring real independence and professionalism of the macroeconomic surveillance mechanism under the auspices of the AMRO, and, finally, expanding the group of members. There is no doubt that the impact of the U.S. administration on the possible success of the AMF project remains far more limited under the current circumstances than it was in the situation 20 years ago.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the 'Regional Initiative of Excellence' 2019-2022 programme, project number 015/RID/2018/19. The total funding amount is 10 721 040,00 PLN.

Abstract

The United States of America is one of the most competitive economies in the world. The country's competitive advantage is due to its specificity. Therefore, the main goal of this article is to identify the main competitive advantages of the modern U.S. economy. An analysis was conducted of the period from 1990 to 2016. This article presents the main macroeconomic indicators, including gross domestic product (GDP) growth rate, GDP per capita, consumption rate, and trade exchange. Next, the authors analysed the innovation and human capital indicators for the U.S. economy. In addition, this article presents a brief overview and evaluation of government activities. The analysis allows for identifying the strengths and weaknesses of the U.S. economy. The authors used data from World Bank, Organisation for Economic Co-operation and Development (OECD), and Global Competitiveness Index (GCI) databases.

Keywords: Competitiveness, Innovation, Human Capital, Government, U.S. Economy.

Introduction

The countries that are at the top of the competitiveness rankings differ significantly. The competitive advantage of a given country results from its characteristics. The macroeconomic indicators achieved by the country are immensely relevant in determining the country's competitiveness. Contemporary growth theories also indicate the importance of human capital and innovation as factors of economic growth. The efficiency of the functioning of the economy is significantly influenced by the institution of the state and the government's policy. A holistic analysis of the aspects shaping modern market economy systems can help to identify factors of their competitiveness. In addition, this article analyses the development conditions for the global leader, the United States, from 1990 to 2016.

The free market economy of the United States is an example of the Anglo-Saxon economic system. It is one of the largest and the most competitive in the world. Because of its history, the United States is a country that is significantly diverse in terms of culture, ethnicity, religion, and morals. The United States occupies a leading position in the global economy. It is a member of many international organisations, such as the North American Free Trade Agreement (NAFTA), the United Nations (UN), the World Trade Organisation (WTO), the Organisation for Economic Co-operation and Development (OECD), the International Monetary Fund (IMF), the Group of Eight (G8), and the Group of Twenty (G20).

The Economic Situation

The United States generates over 35% of the gross domestic product (GDP) of all the OECD countries. The economic growth rate in the United States until 2000 was higher than the OECD average. The United States has suffered from the effects of the crises of 2000 and 2008, when the GDP growth rate significantly dropped (Dobrzanski, 2009). In 2009, GDP fell by almost 4%. However, since 2010, the economy has rebounded, and the growth rate reached a value close to 1.5% in 2016.

Fig. 1 : GDP growth in the United States and OECD countries from 1990 to 2016
Source: Authors' own study based on the OECD database

Moreover, the United States is a leader in terms of GDP per capita, and this indicator is improving year by year. In 2016, the average resident generated almost 58,000 USD, exceeding the average value for the OECD countries by over 15,000 USD. The service sector generates 77% of the United States' GDP; meanwhile, the industry sector generates 22%, and agriculture generates just over 1%.

Fig. 2: GDP per capita in the United States and OECD countries from 1990 to 2016
Source: Authors' own study based on the OECD database

The consumption rate in the United States is relatively high. In the second half of the 1990s, it amounted to 4 to 5% per annum; it then remained at around 2 to 3% until the crisis in 2008. However, in subsequent years, it returned to a high level exceeding 3%. In the case of OECD countries, the trend is similar, although the growth rate is lower. Individual consumption accounts for 70% of economic activities in the United States. Therefore, the increase in consumer spending is a positive stimulus for the U.S. economy. It also ought to be noted that the United States, as a global giant, helps to develop the economies of other countries. A decline in consumption in this country exerts a negative impact on global economies, which export a large proportion of their goods to the United States.

Fig. 3: Private consumption growth in the United States and OECD countries from 1991 to 2015

Source: Authors' own study based on the World Bank database

The United States is a country that plays a key role in international trade. Due to the size of its internal market, U.S. imports far exceed exports. Both imports and exports are characterised by a positive trend and in the period from 1991 to 2015 increased more than threefold, from 414 billion USD to 1,455 billion USD.

The United States is the largest importer in the world. Imported goods are mainly passenger cars, ships, computers and electronic devices, mineral resources, fuel, sugar, fruits, tea, coffee, clothes, shoes, and wood. In terms of export value, the United States ranks third in the world. Exports mainly consist of machinery and equipment, computers, airplanes, cars, weapons, plastics, drugs, grains, and tobacco.

Fig. 4: Goods exports and imports in the United States from 1991 to 2016
Source: Authors' own study based on the World Bank database

Fig. 5 : Services exports and imports in the United States from 1991 to 2014
Source: Authors' own study based on the OECD database

Due to the high value of its imports, the United States has a negative current account balance. This value has been falling since 2009, and it reached -2.25% of GDP in 2014.

Fig. 6: Current account balance in the United States from 1991 to 2014
Source: Authors' own study based on the OECD database

The United States has a high share of trade in goods from the information and communication technology (ICT) sector. In the years between 2000 and 2015, however, this ratio dropped from 17% to 14% for imports and from 20% to 9.5% for exports.

Fig. 7: ICT exports and imports in the United States (% world imports/exports) from 2000 to 2015
Source: Authors' own study based on the World Bank database

There was a decline in the proportion of high-tech goods in U.S. exports. In 2000, exports of these goods accounted for 34% of U.S. exports. However, they accounted for only 20% in 2016.

Fig. 8: The proportion of high-tech goods in the United States' exports from 2000 to 2015
Source: Authors' own study based on the World Bank database

The level of Innovation in the Economy

In the years between 2012 and 2017, the United States of America was rated as one of the most competitive economies in the world, according to the Global Innovation Index. In 2016, it maintained third position. The United States was very highly rated in the category of indicators of increasing effectiveness, such as higher education, training, goods market efficiency, technological preparation, and market size; this is confirmed by its subindex B rating (first place among 138 researched countries).

Table 1: United States in the rankings of the Global Innovation Index 2016-2017

Global Competitiveness Index	2017-2016	
United States	Place out of 138	Score (1-7)
Global Competitiveness Index	3	5.7
Subindex A: Basic requirements	27	5.4
First pillar: Institutions	27	5
Second pillar: Infrastructure	11	5.9
Third pillar: Macroeconomic environment	17	4.6
Fourth pillar: Health and primary education	39	6.2
Subindex B: Efficiency enhancers	1	5.8
Fifth pillar: Higher education and training	8	5.9
Sixth pillar: Goods market efficiency	14	5.2
Seventh pillar: Labour market efficiency	4	5.5
Eighth pillar: Financial market development	3	5.6
Ninth pillar: Technological readiness	14	6
Tenth pillar: Market size	2	6.9
Subindex C: Innovation and sophistication factors	2	5.6

Eleventh pillar: Business sophistication	4	5.6
Twelfth pillar: Innovation	4	5.6

Rank	3/140	3/144	5/148	7/144

Source: Authors' own study based on the Global Innovation Index 2016/17

In 2016, the United States was the best-rated economy in the "Innovation Ecosystem" category. This was due to high grades that the United States received for the state of cluster development, university co-operation with the private sector in research and development (R&D) activities, and the broadly understood "culture of innovation". In addition, the United States has high-quality R&D facilities, easy access to training and research and investment financing, and intensive local competition. The percentage of the United States' workforce employed in the research sector is very high, and in this respect the United States ranks second in the world. The United States was granted the highest position of all countries for financing R&D investments.

In 2015, the total expenditure on R&D in the United States equalled 2.8% of GDP. Like in all developed economies, a significant proportion of R&D expenditure in the United States comes from the private sector.

Fig. 9: R&D expenditure in the United States from 1996 to 2015

Source: Authors' own study based on the World Bank database

Another indicator showing the level of technological development and the innovativeness of the U.S. economy is the number of patents, trademarks, and industrial designs. In this respect, the United States is a world leader, filing over 500,000 patents every year. It is worth noting that most of the patents are filed in the rapidly developing computer (11.50%) and medical (8.21%) industries. The United States is also a world leader in terms of the number of trademarks and industrial designs.

Human Resources and Human Capital

The United States is populated by over 318 million inhabitants; there has been an increase of over 36 million since 2000. According to OECD forecasts, this number is expected to increase significantly and reach 439 million by 2050. U.S. society is relatively young. In 2014, as much as 66% of the population fell within the working age. The United States has a high fertility rate, which means that, unlike in other developed economies, the share of the population falling within the pre-working age is higher than the share falling within the post-working age.

Table 3: Basic demographics – United States

	Population (million)	Population growth rate (%)	Working age population (%)	Fertility rate	Population under 15 years of age (%)	Population over 65 (%)
2000	282,16	1.12	66.21	2.06	21.36	12.43
2001	284,97	0.99	66.4	2.03	21.21	12.38
2002	287,63	0.93	66.59	2.01	21.06	12.35
2003	290,11	0.86	66.74	2.04	20.9	12.36
2004	292,81	0.93	66.92	2.05	20.71	12.36
2005	295,52	0.93	67.12	2.05	20.48	12.4
2006	298,38	0.97	67.26	2.1	20.28	12.46
2007	301,23	0.96	67.3	2.12	20.14	12.56
2008	304,09	0.95	67.22	2.08	20.03	12.75
2009	306,77	0.88	67.17	2	19.91	12.92
2010	309,33	0.83	67.13	1.93	19.79	13.09
2011	311,72	0.77	67.10	1.90	19.63	13.27
2012	314,11	0.77	66.80	1.90	19.46	13.74
2013	316,49	0.76	66.56	1.90	19.31	14.13
2014	318,86	0.75	66.35	1.90	19.15	14.50
2020	341,39	0.95	63.99	,,	19.96	16.05
2050	439,01	0.79	60.58	,,	19.25	20.17

Source: Authors' own study based on the OECD database

The phenomenon of increasing labour resources in the United States is caused by a relatively large influx of labour resources from abroad. There is a large proportion of immigrants in the total population, and this indicator is characterised by an increasing trend in the United States. In 2013, people who were born abroad constituted over 13% of the population. This value would probably be higher if the visa procedure were not so restrictive. Moreover, it is relevant that the foreign nationals who are emigrating to the United States are mainly well-educated people who fall within the working age and are proficient in foreign languages (OECD Factbook, 2013).

Fig. 12: Foreign and born population in the United States from 1995 to 2013
Source: Authors' own study based on the OECD database

In the first years of the 21st century, the United States boasted a very low unemployment rate of 4 to 6%, which is significantly lower than the OECD average. A collapse of the labour market, however, occurred in connection with the 2008 crisis, and the unemployment rate rose to 9.63% in 2010. In subsequent years, the labour market situation in the United States improved continually. It is worth noting that the unemployment rate was significantly lower than the average for OECD countries, amounted to only 6.17%, in 2014.

Fig. 13: Unemployment rate in the United States from 2000 to 2014
Source: Authors' own study based on the OECD database

The creation of national income is determined not only by the number of employees but also by the average working time. The graph below indicates that the average working time in the U.S. economy dropped from 1,844 to 1,789 hours in the period from 2000 to 2014. Despite the decline, it remains above the OECD average.

Fig. 14: Average annual hours actually worked per worker in the United States from 2000 to 2014

Source: Authors' own study based on the OECD database

Furthermore, the United States is characterised by very high work efficiency. Despite the crisis in 2008-2009, a positive annual GDP growth per employee could be observed (in most of the OECD countries, this indicator was negative during the same period). In 2016, in the United States, a working hour increased GDP by 61.9 USD; this is 22.5 USD more than the OECD average. The highest value of GDP per employee in the OECD countries was in the United States, and it equalled 121,000 USD in 2016. In this respect, the United States overtook countries such as Luxembourg and Norway. However, it ought to be remembered that this advantage is mainly caused by the greater number of working hours in the U.S. economy.

Table 4: Labour productivity in the USA from 2000 to 2016

	GDP per employee in USD	Annual GDP growth per employee (%)	GDP per hour worked in USD
2000	73 898	2.1	40.8
2001	76 294	3.2	42.6
2002	79 085	3.7	44.5
2003	82 170	3.9	46.8
2004	86 706	5.5	49.3
2005	90 941	4.9	51.9
2006	94 465	3.9	53.9

2007	97 627	3.3	55.9
2008	99 690	2.1	57.4
2009	101 410	1.7	59.5
2010	105 841	4.4	61.9
2011	109 141	3.1	63.3
2012	111 608	2.3	64.7
2013	114 181	2.3	65.8
2014	117 347	2.8	67.4
2015	120 005	2.3	68.6
2016	121 264	1.0	69.6

Source: Authors' own study based on the OECD database

The structure of education in the United States is demonstrated by its high-skilled workforce. In comparison with the OECD average, the United States has a very high proportion of people with higher education. In 2009, it was over 48%, 5% more than in the OECD countries. It is worth noting that the higher education in the United States is not financed by the government as much as in European countries. In addition, the proportion of the population with only primary education is very low, and it amounted to only 9% in 2016.

Fig. 15: Trends in educational attainment of 25- to 34-year-olds in the United States in (2000, 2005, 2010, 2015, and 2016)

The Role of The State and Direction of Economic Policy

The constitution from 1789 forms the basis of the U.S. socioeconomic system. In the case of the United States, institutional factors are perceived as a source of economic success. The principles of the inalienability of the right to freedom, private property, enrichment, and relatively unfettered economic activity are enshrined in constitutional and legal provisions that constitute the essence of U.S. solutions. Constitutional provisions and the nature of law still perfectly match modern, open realities and an increasingly global economy (Posner, 1987).

Amongst the highly developed countries, the American economy is the closest to the model of the capitalist system. However, it also represents modified capitalism, in which there is a significant role played by the state. After World War II, there was a continued growth in the size and role of the state in the U.S. economy, mainly at the federal level. Government growth was uninterrupted until the late 1970s, when the growing threat of inflation led to a reduction in spending and deregulation (Lipford & Slice, 2007).The government's activity in the U.S. economy includes public finances and, related to them, fiscal policy, monetary policy, and supervision of economic activities. At the same time, there is little government involvement in direct economic activities, and its direct control of prices and wages is also very limited (Kozłowski, 2004).

Public finance is the most visible manifestation of state activities in the United States. It is a tool that helps to realise the redistributive role of the government (it allows for correcting the distribution of income rendered by the market) and enables the creation of public goods (Neil, 2000). In 2002, public expenditure accounted for nearly 30% of the United States' GDP. In terms of federal expenditure, which amounts to nearly two-thirds of total public expenditure, the costliest item is social security: It consumes more than one-fifth of the budget and, together with medical insurance for pensioners (Medicare), more than one-third of the budget. National defence comes second (17%), and the third category (15%) is occupied by the cumulative category "income protection", which includes pensions of federal employees, disability assistance not covered by pension insurance, unemployment benefits, and housing and food assistance (CIA World Factbook, 2017).

Tax burdens situate the U.S. economy in 27th place out of 30 amongst OECD countries. There is a characteristic trend based on shifting the tax burden from big business and the richest groups of people to the average and poorer Americans. In 1950, two-thirds of federal budget revenues were derived from corporate income taxes. In 2002, corporate income taxes constituted only 17% of federal budget revenues. In the United States, the corporate income tax (CIT) is relatively high, at 35%. Among OECD countries, this is the second highest rate, after Japan (Piketty & Saez, 2007).

The main goal of monetary policy is to ensure an adequate level of activity and stability in the economy. Monetary policy is implemented by the Federal Reserve System, which is the U.S. central bank. The regulation of economic activities by the state aims at creating conditions in the economy as close as possible to the theoretical market model. The implementation of the state's functions involves the need to hire employees in various state institutions and agencies. This is the reason why the state is present in the U.S. labour market (Timberlake, 1993).

The state is also the largest U.S. employer, directly hiring approximately 16% of all employees in the civil sector; there are now more Americans employed by the government than by the entire manufacturing sector in the United States. Furthermore, the government contributes indirectly to the creation of millions of jobs. Military bases, armament factories, and large state universities stimulate economic development in the local areas. The working conditions in many fields are regulated by the public sector as well. The state's participation in production activities is low and amounts to 1.5% of the national product; however, it is possible to find public enterprises at all levels of the U.S. administration. State-owned enterprises occur mainly in the agricultural sector and public utilities (Moore, 1993).

In 2008, the subprime mortgage crisis shook the foundations of the global financial system. The first reason for the crisis was the activity of investment banks, which conducted high-risk operations in conjunction with deposit and credit banking. The second factor was speculation on financial markets, which initially concerned high-tech companies. After the collapse of the financial markets, the situation repeated itself in the real estate market. In the era of globalisation, this event exerted an impact on other countries. As a result of events in the United States, the world was plunged into the greatest financial crisis since the Great Depression; this exerted a very strong negative impact on the entire global economy. The outbreak of the global financial crisis and the strength of its spread to subsequent segments of the financial market and the real economy necessitated launching multi-billion-dollar government bailouts (Dobrzanski, 2017).

In 2014, the United States occupied 12th place in the Heritage Foundation Index of Economic Freedom rankings. In comparison with the previous year, its rating dropped marginally, mainly due to an increase in government spending, which currently amounts to slightly over 40% of GDP; meanwhile, public debt is approaching 100% of GDP. According to this measure, freedom on the labour market, freedom of business activities, freedom of trade, and the level of property rights are best evaluated.

Conclusion

The competitive advantage of a given country results from its characteristics with respect to its history, geopolitical and economic situation, state policy, and available resources. The countries that are at the top of the rankings of competitiveness differ significantly. This article examines the development conditions of a country that is a leader in many international rankings and statistics. It represents the market economy system, with a strong emphasis on economic freedom and competition. The structure of the U.S. economy can be classified as post-industrial, with a large share of its GDP generated by the service sector. This economy allocates significant resources to research and development, of which a substantial amount comes from the private sector.

Demographic predictions for the United States are favourable. According to OECD forecasts, by 2050, the population is expected to be over 40% higher than it was in 2010. Moreover, the United States has a high proportion of its population falling within the pre-working age rather than the post-working age. The reason behind the increasing labour resources in the United States is the relatively large inflow of labour from abroad. This phenomenon might support the further strengthening of the U.S. position in the future, while other economies will have to face demographic problems.

Finally, the indicators presented in this article confirm that the United States is a highly innovative economy. The high level of innovation is due to the strong co-operation of universities with the private sector and high-quality research and development facilities. The United States is also a world leader in patent applications. As the world's largest importer, the United States stimulates the economies of other countries. The average working time in the United States is high in comparison with the average working time in other researched countries; together with high labour productivity, this enables the United States to achieve its high GDP. The main manifestations of state activities in the United States are in fiscal and monetary policy and regulation and control of economic activities. In turn, the direct economic activities of the state are marginal.

Michal SIMON

Department of Industrial Engineering and Management, Faculty of Mechanical Engineering, University of West Bohemia, Pilsen, Czech Republic, simon@kpv.zcu.cz

Abstract

The first part of the paper contains the description of Industry 4.0 concept. The different views on this concept and main principles are mentioned. One of these principles is named Smart Factory. The Smart Factory concept is briefly described afterwards. The second part of the paper contains the main chapter – case study, there is described the transformation of a real industrial company into smart factory concept. The case study firstly concentrates on the current state analyses. Then Smart Factory transformation with specified technology is described. Based on the Smart Factory transformation, the realization of this solution is determined, including the implementation of elements and principles of Industry 4.0. Case study results and future plans are summarized in conclusion. Transforming into a Smart Factory and implementing Industry 4.0 technology is an extensive and long-term process. The primary purpose of the paper is to determine potential issues and obstacles faced by manufacturers during their transformation into Smart Factory.

Keywords: Industry 4.0, Smart Factory, Internal Logistics, Production, Manipulation

Introduction

The essence of Industry 4.0 is digitization, the expansion of the high-speed Internet, the development of smart technologies, communication and many other topics. Businesses that want to remain competitive and market-driven must take the first steps towards digitization today. Digitization promises lower costs, higher production quality, flexibility and efficiency. Investing in digitization is essential for the growth of all industrial companies, regardless of their size or industry. Industry and the economy are undergoing significant changes caused by the introduction of information technology, cyber-physical artificial intelligence systems into production, services and all sectors of the economy. The impact of these changes is so fundamental that they are referred to as the 4th Industrial Revolution.

The main concentration of the paper is on Industry 4.0 part named Smart Factory. The Smart Factory concept is shown in the presented case study.

Definition and main principles of the Industry 4.0 concept

According to online source Národní iniciativa Průmysl 4.0 (2015), the Industry 4.0 concept is a whole new philosophy of societal change that spans a wide range of industries, from industry to technical standardization, security, education, legal framework, science and research, to the labour market or social system. The phenomenon of today is the interconnection of the Internet of Things, Services and People, and the immense amount of data generated by it, whether machine-machine, human-machine or human-human. Basl (2017) mentions in his publication that the advent of new

technologies is changing entire value chains, creating opportunities for new business models, as well as pressure on the flexibility of modern industrial production or increased demands on cybersecurity and interdisciplinarity of access.

The comprehensive definition and description include a by Kagermann, Wahlster and Helbig (2013). Briefly, the first three industrial revolutions arose as a result of mechanization, the use of electricity and the use of computer technology. The introduction of the Internet of Things and Services into the production environment is now the fourth industrial revolution.

For example, Hofmann and Rüsch (2017), in their publication, identify four critical components of the Industry 4.0 concept, based on the revision of academic and business (industrial) publications using different publication databases to ensure objectivity. These are the key components: Cyber-Physical System, Internet of Things - IoT, Internet of Services - IoS, Smart Factory.

Other authors Rüßmann et al. (2015) mention the 9 main pillars that Industry 4.0 integrates. Many of the nine technological attributes that underlie Industry 4.0 are already being used in manufacturing. However, with the concept transforming production, insulated and optimized cells combine as a fully integrated, automated and optimized production flow, leading to greater efficiency and a change in traditional manufacturing relationships between suppliers, manufacturers and customers - as well as between humans and machine. According to Poor, Basl (2018), the main 9 pillars are autonomous robots, simulation, horizontal and vertical system integration, industrial Internet of Things, cybersecurity, cloud storage, additive manufacturing, augmented reality, big data and analysis.

Other main features of the Industry 4.0 concept are defined by Deloitte (2015). The following main characteristics of the sector show the massive capacity of industry and traditional production for change based on these assumptions:

- Vertical interconnection of intelligent manufacturing systems
- Horizontal integration through a new generation of global value chain networks
- Through-engineering throughout the value chain
- Acceleration using exponential technologies

In their publication, Weyer, Schmitt, Ohmer and Gorecky (2015) mention three main central aspects of the Industry 4.0 concept, which can be further specified using three paradigms: Smart Product, Smart Machine, Augmented Operator.

The primary characteristics of smart factories conforming to the Industry 4.0 concept can be summarized as follows, expanded from online source Národní iniciativa Průmysl 4.0 (2015) and publication by Mařík (2016):

- manufacturing processes are optimized throughout the value chain thanks to vertically and horizontally integrated IT systems,
- fully automated and interconnected production lines replace isolated production units,
- physical prototypes are replaced by virtual designs of products, means of production and production processes, and their commissioning takes place within one integrated process involving both the manufacturer and his supplier,
- flexible production processes allow efficient production of small batches tailored to individual customer requirements,

- Broum and Simon (2019) mention that interoperable robots, production equipment and products make to some extent autonomous real-time decisions, thereby increasing the flexibility and efficiency of the production process,
- the production equipment optimizes itself and configures itself according to the parameters of the processed product,
- automated logistics facilities using autonomous trucks and robots automatically adapt to production needs. The logistics background concerns more cooperative entities that are not located in a single location, and therefore the logistics chain also concerns the coordination of transport links between production entities. The same applies to coordinate the distribution process of the product itself.

Characteristics of Smart Factory

The concept of Industry 4.0 and its ideal implementation creates a so-called Smart Factory, also called Intelligent Factory, which is accessed by different authors in different forms. The technological attributes of Industry 4.0 are incorporated into this whole Smart Factory. The main views are shown in this section of the article, including an example.

There are several definitions of the meaning of "smart factory". For example, Yoon, Shin and Suh (2012) describe an intelligent factory as an innovative factory that combines ubiquitous computing as a tool to solve problems with existing components.

At Smart Factory, the products find their way independently of production processes and are easily identifiable and localized at any time, with the idea of cost-effective but highly flexible and individualized series production, as defined by Rüßmann et al. (2015).

Another definition is provided by Radziwon, Bilberg, Bogers and Madsen (2014), a smart factory is a manufacturing solution that provides flexible and adaptive manufacturing processes that solve the problems of a plant with dynamic and rapidly changing boundary conditions around the world with increasing complexity. This unique solution could, on the one hand, be associated with automation, understood as a combination of software, hardware or mechanics, which should lead to optimization of production, reducing unnecessary work and wasting resources. In a research study by Broum and Kleinová (2018), reducing waste then leads to cost reductions in the major and minor functions of the product.

Zuehlke (2010) describes the SmartFactoryKL Technology Initiative. SmartFactoryKL is an excellent concept that represents a registered non-profit association made up of SmartFactoryKL and its research, industrial and political partners. Research company SmartFactoryKL (2019) focuses on research into innovative technologies and solutions to realize the production vision of the Industry 4.0 concept. They have their hybrid production experimental equipment and can present, for example, the Plug'n'Produce modular production line, various production line modules, virtual reality training, augmented reality manual workstation, etc.

According to Valvodová (2018), another place we can talk about as Smart Factory is the EWA plant. It is a factory hall of Siemens Elektronikwerk Amberg (EWA). Machines and computers serve two-thirds of activities throughout the chain, with the rest of the work done by people. EWA is a prime example of the implementation of the Siemens Digital Enterprise (Siemens Digital Enterprise), a production environment that could become standard within a few years.

Smart Factory Components

The authors of the paper have designed the essential components listed in this chapter, and the technological aspects of Industry 4.0 can be implemented on these core components. The diagram in Figure 1 identified Smart Factory components.

Fig. 1: Smart Factory components

Of course, all components are:

- Cloud storage
- Internet of Things and Services (or Industrial Internet)

Its own information system covers each smart factory. System requirements will be increased because, in addition to the usual services (e.g. ERP), they must also include communication between components inside and outside the production system. On the physical layer of the factory, there are the following key components:

- Storage system
- Internal logistics (Micro logistics)
- Production machine and equipment
- Material handling equipment
- External logistics
- As well as employees or operators

In terms of internal logistics, we can also encounter terms such as intralogistics, micro-logistics, these are different expressions, but the meaning remains the same. The term internal logistics is used in this paper. Internal logistics deals with the material flow in companies and the accompanying information flow. These include activities such as storage, handling, supply, packaging, etc. External logistics extends beyond the scope of the enterprise between individual entities (Supply Chain Management).

Case study

In this case study, we try to put principles, available or developed technology into a real factory. The aim is to create SmartFactory concept with replacing technologies and processes of the current state. In the end, there should be a list of challenges or solutions.

Current state

In the current state, the first station is entry warehouse where is a big stock of all parts needed for production. Three vertical warehouses systems are next station (this system is called Kardex). In Kardex 1 a 2, there are small KLT boxes with small and lightweight parts like plastic or rubber seals or circles for assembling. In Kardex 3, there are different types of aluminium parts for the next processing.

The primary participant in the process is a supplier employee. This supplier has its defined routes within the factory hall. He visually checks mid-stocks in each assembly line and picks up an empty container. Then he returns with empty bins to the specific Kardexes and enters requirement for material needed. The Kardex then search material for him and pick it up. The supplier then takes full KLTs from Kardex and removes Kanban card from this bin. Then he gives this Kanban card to the warehouse worker, who records the decrease of the material and sends it to the entry warehouse. Next, the supplier refills line requirements and again looks for empty bins and the whole process is repeated.

Product Manufacturing

Company products are pipes of different shapes for the automotive industry. Currently, they have several assembly lines for individual customers. Each customer has several types of products with different manufacturing processes.

Fig. 2: Example of product

Currently, each customer has an assembly line. For assembling, there is need for shaped pipes and small parts (seals, rings). The main processes are bending and soldering. Some types of products also require some CNC manufacturing like drilling or special cutting. When these parts are ready, they are moved straight to the assembly line or back into the warehouse where they wait for use.

Assembling operations are mainly montage of seals and rings onto pipes and then covering it with rubber wrap. Assembly is done by workers at assembly workstations (FIG) After successful assembly, and there is control workstation. Some customers (Audi) requires to have their control station implemented in the system. The current state layout with material flows is also available.

Smart Factory Transformation

a) Order receive

In SmartFactory transformation, the first step is receiving of the order. For example, Customer 1 requires 500 pieces of products 1A ad 700 pieces of product 1B. The manufacturing system sends a

requirement to the last station in the process (packaging). This requirement is sent back to all previous stations and into production line itself.

b) Manufacturing line and modules

The production line should be chosen based on an occupation of other lines or the type of production it's already doing. The operator of the line should also see process request (line station, tablet or PC). Then he can send accept a command to the system and chosen line.

The line consists of modular parts. Each module presents one technology in the process. So there is need for CNC module, bending module, soldering module and possibly assembly module and control module. Currently, there is only one known assembly line. [18] This line consists of operations for creating business cards. Product and operations are straightforward, so there is a long way until specific modules will be involved in this case. For the modules to be practical, they should be able to operate several parts at once. Especially for bending, where is a requirement for a high amount of the same product. The inspiration was a publication by Slama et al. (2015).

c) RFID, parts

Publications by Hameed, Durr and Rothermel (2011) and Govindasamy and Thambidurai (2013) mention that, the parts must be identified during the whole process. Industry 4.0 counts with RFID technology. RFID tags are mostly planted right into the product in current experiments. [19] [20] So there is no need to remove RFID tags at the end of the process. However, this had been involved for just a few prototypes and for our product (pipes) there is a problem with placing and implementation of RFID tags into the product itself. With product identification, machines can do defined operations on them, so there is no need for re-programming machines each series of products. Machines also have a memory, so once specific manufacturing is programmed and recorded with its identification, machines can change to this manufacturing based on the RFID signal they get from the product.

d) Material request, delivery and storage

Depended on the order, the production line can request specific modules for the process. The Plug n Produce assembly line can be easily and fast reconfigured. Also, the production line must send requirement for material – primary pipe material and other assembly parts. The entry warehouse receives a requirement and finds the required materials. Then the manufacturing system will plan material delivery. Small boxes with lightweight parts can be delivered with the use of drones right into the assembly station. More substantial pipe parts must be delivered into carousel type of mid-storage. This storage should supply a whole manufacturing line. The material could be picked by a robotic arm, which will also orient via RFID tags. These tags should be on/in the KLT boxes so the robot can recognize what material is stored in it.

Also, the system of the main warehouse should record material type, and amount pick up. These data should be shared with the company developer so he can react fast enough for company needs.

Realization

Because with the current state of technology, it is impossible to create a smart factory transformation for this specific company directly. In this part, a list of problems and challenges will be introduced.

a) Entry warehouse

Entry warehouse can be realized with one of today standard solution where each position in the store has its identification. With this identification, we can easily search for materials with the use of manipulation techniques and also we can monitor the stock level of each type of material. This level value with planned consumption should be shared with a supplier so that he can prepare his production, as also mentioned by Sixta and Macat (2005).

b) Storage, mid-storage

The Kardex storage system can also be used in the current state. Each container should be equipped with RFID tag so his identification, content and also position can be monitored. This can navigate manipulation units. For small parts containers, they can be picked up by drones, containers with pipes should be manipulated with AGV type of unit.

According to online source Kardex Remstar (2017), vertical automated storage systems served as inspiration and source. Small versions of Kardex or carousel storage should be used at the beginning of each production line. Transport units should deliver specific identified delivery to the specific line, into specific positions in Kardex. For example, in 10 racks Kardex, each rack should have its ID (A-J), and also each ID should have several positions for store KLTs (1-10). The delivery unit will communicate with Kardex that it wants to put KLTs in the specific positions. Then following manipulation unit, which will grab material from Kardex and put it into the production line will now specific position, where required material can be found.

c) Manipulation units

As mentioned before, in this case, we could use a combination of drones and AGV transport unit. Impressive views and solutions that have been implemented are in the sources [23] and [24]. The advantage of this combination is less "collision prevent stops" when drones don't have to care about physical obstacles and AGVs. However, drones can supply only to the assembly station, where lightweight parts are used. When drones with higher carrying capacity are developed, they could pick up more containers (and reduce travelling routes count) or they could handle heavier KLTs. [25]

The production line should be supplied by AGVs trains. These trains can automatically pick up KLTs from main Kardexes and store them in the identified position in the train. Again train wagons should be identified (A-D), and each wagon should have its positions (1-5). Thanks to RFID accurate navigation, they can store the right material in the right position and also deliver the right material into the right position into production line Kardex. Here they can also pick up empty bins and deliver them back to the storage.

d) Production line

The production line is the first issue of realizing smart factory transformation. The complete production line should be assembled from modules. The idea is to create highly modular, multi-vendor production systems. [26] However, these modules are now at the experimental phase, and only CNC manufacturing could be available. But the most critical processes bending and soldering are too specific, and currently, there are no even experimental solutions for these process modules. [27] Solution with 3D metal printing also can't work, because only mass production 3D printers have such a small operation space and they are designed for small parts.

Next, and possibly the crucial, issue is with product identification. The idea of Smart factory is to monitor all products during the whole process and also after this process. This is arranged by implementing RFID tags into the product. However, RFID can't be inserted into the product at this stage of production.

Another problem is with handling. Current experimental lines are producing simple products like bottles or business cards. Our company produces a wide variety of products with different shapes which requires special handling tools. A possible solution could be creating groups of similar products and design special handling for each group. Requires more varieties of bending and soldering modules.

For production to be effective, there is also a requirement for higher quantity. That means more products should be operated at the same time, not only 1 piece. For production lines, we can only arrange challenges or requirements for possible realization.

e) Assembly

In assembly station use of robots is the highest probability. Robots like two-handed Baxter model can easily replace humans in the position of this repeated action. [28] If each product can be identified so there can be direct order to the robot. Each product should have assigned assembly workflow and parts required. The robot can determine product ID and then switch assembling the program. At the same time, the robot station should be equipped with small Kardex type of storage. This storage will communicate with the robot or with the product and can arrange the right material required. Drones supply this storage (as mentioned above). The workstation should be organized in the assembly line.

The distance between free space (caused by missing line modules) should be dealt with small AGVs, which can transport container with ready-to-assemble pipes to the assembly line. Here robot arm places part onto the conveyor. Depended on part type and ID, the robot can also set part in a specific position. Next, the part flows through the line where is assembled by the Baxter robot type. [29] [30]

The second variation of assembly is that the assembly can be one of the modules. Then there is no need for Baxter type robots. Because this type of assembly is exceptional, automated assembly in a module can be followed by human equipped with smart-glasses or another type of visualization. Based on the product ID, a smart device can project assembly workflow.

f) Control station and packaging

As mentioned in the Sawyer Intera chapter, this robot can be programmed to force use controls. In this case, it could control if products are tight enough if there are some incorrect assembly or even do some visual controls.

g) External Logistic

In this case, our product is produced in series and requires bigger transport units. This can be easily done by current truck or van delivery. However, improved unmanned our autonomous trucks bring several advantages. It is their connection to real-time data. These data can be used for algorithms that calculate the fastest track from point A to point B and should easily meet the Just-in-Time requirement.

These data should provide information about current traffic state, for example, traffic jams and their probabilities (which is currently available at Google navigations), unexpected events recording or energy renewal plans. Specific algorithms should calculate the fastest and the safest way to the customer, and it also should re-calculate tracks based on real-time data information. However, sometimes it cannot be found a way to meet the agreed date or time of delivery. The delivery unit should provide the customer with this information at the same time it finds its delay when a customer can expect required delivery and why is this delay caused. Customer can then prepare for this situation way earlier and also can save this experience for future planning.

Production System

The complete transformed system is in Figure 3. The process starts in the entry warehouse, and blue arrows present material flow within the factory. Reverse direction of material flow and starting point in the last station (packaging or export) we can imagine information flow. Detail process is described in the previous chapter.

Fig. 3: Smart Factory transformation process scheme

Case Study Results

Based on the attempt of transforming the current state factory into a smart factory concept, we have found that it is not possible with current technologies. The main reason is too specific production, where crucial issues had not been solved. The crucial problems are:

1) Product identification

Because Industry 4.0 and Smart Factory includes real-time product identification, this is the main issue in our case study. Currently, there are experiments and prototypes with straightforward products (business cards, bottles, wooden desks), and in these cases, RFID tag placement is not a problem. In our case, there is no possible way to place the RFID tag that persists the whole manufacturing process (manufacturing operations like bending, CNC machining) and post-process. Also, visual recognition algorithms can't deal with this issue because the shape of products is too complicated, and their identification requires 3D shape recognition.

This is a crucial problem because, without product identification, it cannot be tracked his position and development state. Also, all machines in the factory are dependent on product ID so they can do precisely the right operations with the individual part.

2) Production line

Another problem is the production line, where the primary material is transformed into assembling ready part. It is again caused by too specific production. And there are no available technologies (bending machines) for a modular type of production line and also no available technologies or materials for mass production 3D printing (current technologies have small operation area for this

type of product). However, current technologies allow covering processes of material storage, material delivery and handling, material assembly and external logistic. Use of these solutions brings some of the current state problems:

a) Assembly Line Replenishment

An employee now does a current check of supply state in assembly lines. During his routes around the production, he only visually checks the state of storage, and he replenishes storage when it is empty (not when it is needed). That means he picks up more material from the entry warehouse, and that leads to higher consumption of material. However, automatic replenishment requirement signal based on the order solves this problem and replenishment is also faster.

b) Material Evidence

In the current process, every time employee picks up material from main Kardex, and he has to remove cards from a material container used and give them to the employee who scans these cards and sends a record of material consumption. However, this employee is not available all the time. That means supplier employee has to wait for him for only scanning the card, and this waiting time is waste. Our solution does this evidence automatically, so there is no need for waiting or particular individual employee.

Also, the most significant advantage is coordinated overall communication between all systems and components, then flexible production lines, that can react to order deflections or changes.

The next steps in the case study will be an attempt to simulate processes and communication between components and reveal other possible issues and challenges. The current static model is in Figure 4.

Fig. 4: Base model of the transformed factory

Conclusion

The paper is concentrating on Industry 4.0 and Smart Factory concepts. Principles of these concepts were first introduced. The main chapter of the paper is a case study. There is a proposal of transforming selected production company into Smart Factory version. The case study firstly concentrates on the current state analyses. There the current processes and its weaknesses are described. Then Smart Factory transformation with specified technology is described. During the attempt of a transformation of the assembling process with current technologies, two crucial issues were found. The issues are linked with product identification during and after the process, which is one of the main principles of Industry 4.0 and Smart factory. Based on the Smart Factory transformation, the realization of this solution is determined and also issues, and obstacles are mentioned. The problem is linked with the production line - the case study products are too specific, and there is no possible solution for their manufacturing. Current production machines for Smart

factories are prototypes for straightforward products, or they can't deal with the production quantity. These two issues bring possible challenges for future progress.

The primary purpose of the article is to show the Smart Factory concept implemented. These results can help others to be inspired by Smart Factory concept implementation and to take in consideration specific issues during the implementation. The future plans linked the topic will be a simulation of specific scenarios in the created 3D model. These simulations should show communication between components within factory systems and can reveal other possible issues or challenges. Also, the model can be used for future work, and example, real-time data flow visualization etc.

Many companies still do not believe in the benefits of Industry 4.0 for their business or have difficulty finding a suitable way to apply new technologies. But many others are already introducing changes and are preparing for a future where smart devices will streamline and optimize their businesses. Companies that are suitable for robotics and automation in the automotive, electrical, plastics, machinery and equipment (engineering) sectors have the highest potential to digitize and implement Industry 4.0 elements. Industry 4.0 will also make progress in many other areas such as the aerospace and consumer industries, the mining industry.

However, Industry 4.0 also offers excellent chances for smart, digital manufacturing processes for SMEs. SMEs have a chance to become specialists with unique know-how that will play an essential role in the chain. Connecting the commercial, academic and governmental spheres is crucial.

Abstract

The growing interest in the business model (BM) as a reporting element reflects the view that it is a key starting point for analysis conducted by investors. The integrated report (IR) should answer the following question: What is the BM of the organization and how sustainable is it? (IIRC, 2013b). To this end, the International <IR> Framework provides specific guidance on how to present a high-quality BM disclosure. However, current global research clearly indicates that the method of disclosing information about the business model is very diverse, hence the purpose of the article is to discuss the practice of disclosing the business model in integrated reporting of selected Polish listed companies. The article uses literature studies, content analysis of corporate publications and observation of business practice, case studies of selected Polish companies were presented. The study was conducted in the form of a case study of some entities. Five companies were analyzed Most companies adopt their own individual solutions, only some listed companies disclose the business model in accordance with the International <IR> Framework proposed by IIRC. However, there are many reservations about the quality of disclosures in published integrated reports. The disclosures about the business model are a relatively new research area at an early stage of implementation in business practice. Our findings have important implications for confirming the role of the integrated reporting project in improving reporting on the business model.

Keywords: Business Model, Integrated Reporting, Integrated Report, Value Reporting.

Introduction

The term "business model" gained importance in reporting as discussions on the importance of non-financial information in enterprise reporting developed (ICAEW 2010).[i] As stated in The Business Model Background Paper for IR (Integrated Reporting) "business model thinking provides an interesting paradigm for developing financial reporting standards". The term "business model" was discussed in the September 2011 International Integrated Reporting Council (IIRC) discussion paper Towards Integrated Reporting – Communicating Value in the 21st Century, in which it was identified as one of the two main topics for the future orientation of organization reporting (IIRC 2013c).

The paper clearly emphasizes that despite the lack of a uniform, commonly accepted definition of the term "business model", the concept is often perceived as a process through which an organization/company strives to create and maintain value. It also indicates that reporting on the business model should be a component of the content of integrated reporting.

The aim of the article is to discuss the practice of disclosing the business model in integrated reporting of selected Polish listed companies.

The business model in IR

The business model has been identified by the International Integrated Reporting Council as the basic (key) element of integrated reporting. The International <IR> Framework (IIRC 2013a) clearly emphasizes that integrated reporting should focus on the organization's business model, its resources and the relationships it established and develops. The organization's business model has been identified as one of the key disclosures of integrated reporting. The business model is a fundamental concept allowing to understand how organizations operate and how they create value.

The International <IR> Framework emphasizes that the business model is at the heart of the organization and is based on various capitals as inputs, which through business activities, convert into outputs (products, services, by-products and waste). The organization's activities and outputs lead to outcomes in terms of impact on capitals. The ability of the business model to adapt to changes affects the long-term profitability of the organization.

Inputs include key capitals (resources) that the organization possesses. The capitals are the basis for business operations, and are significant for the ability to create value in the short, medium and long term, and the sustainability of business model (IIRC 2013b, p. 10). Business activities include core activities, i.e. planning, design, production or launching and use of specific skills, as well as activities that contribute to the long-term success of the organization, such as innovation, employee training and relationship management. The International Integrated Reporting Framework states that the company's activities are located in the very center of the business model, and by consuming and/or transforming capitals (resources) and assets (inputs) into outputs in the form of products and services, they have to generate valuable business results. The description of key business activities should include:

- characteristics distinguishing the organization on the marketplace (e.g. through product distinction, market segmentation, supply channels and marketing),
- the way the business model generates revenue,
- the organization's approach to innovation,
- how to adapt the business model to changes.

Outputs include not only the main products and services, but also by-products and waste (including emissions) that are relevant to the organization. Outcomes are defined as “the internal and external consequences for the capitals as a result of an organization’s business activities and outputs” (IIRC 2013b, p. 1). Description of the business model requires disclosure of both internal effects (e.g. employee morale, organization reputation, income and cash flows) and external effects (e.g. customer satisfaction, tax payment, brand loyalty, and social and environmental effects). The International Integrated Reporting Framework also indicates positive outcomes i.e., those that result in a net increase in the capitals and thus create value, and negative outcomes i.e., those that result in a net decrease in the capitals and thus reducing the value (see IIRC 2013a, p. 26).

The Business Model Background Paper For <IR> also lists features that can increase the efficiency and comprehensibility of the description of the business model. They include:

- explicit identification of key elements of the business model together with their presentation in the form of a simple diagram (a simple chart/diagram showing key elements, supplemented by a transparent explanation of the relevance of those elements for the organization),
- an appropriate description (narrative) that explains the conditions and circumstances in which the organization operates,
- identification of key stakeholders and other dependencies as well as important factors affecting organizations,
- description of key value drivers, value generators,

- description of the organization's position in the value chain, connection to other aspects of reporting, including reporting on the organization's strategy, opportunities and risk, and also key performance measures (IIRC 2013b, p. 13).

The International Integrated Reporting Framework also mentions organizations using diverse business models. When organizations use more business models at the same time (IIRC 2013a, p. 26), which are a reflection of, for example, different market segments in which the organization operates, it is required to separately consider and discuss each of them (if relevant) and attach a comment about the links between the business models used (the benefits of using synergies).

Reporting information on the business model is generally assigned to five categories. The aforementioned Business Model Background Paper for <IR>, preceding the publication of The International <IR> Framework, indicates elements of the description of the business model:

- company presentation – what the organization does, its structure or in which areas it conducts business,
- business strategy – key aspects of the company's strategy,
- value chain – position in the value chain and dependence on key inputs,
- financial results – how does the business model control profitability or revenue generation,
- creating value – how the company's inputs, activities and dependencies increase value and ensure desired results (IIRC 2013b, p. 13).

In order to organize the description of the business model, a map of the business model was also proposed (Figure 1).

Fig. 1: Business model disclosure map (IIRC 2013b)

The qualitative features of disclosures about the business model also include (Bini et al. 2016, pp. 87-88):

- Completeness: disclosure should offer complete identification and description of items that are aggregated in a company's business model, distinguishing them from other concepts. In this regard, research and practice indicate that the concept of business model is distinct and different from the concept of strategy (Bini, Dainelli, Giunta 2016).
- Focus: in order to be relevant, the description of the business model for external stakeholders should be focused on the contribution of the business model components to the uniqueness of the company's value creation process (Bini, Dainelli, Giunta 2016).
- Connectivity: disclosures about the business model should show the connections between key tangible and intangible factors in the process of creating value, enabling stakeholders to assess this process over time (Świderska et al. 2016).

Currently, companies disclose information about the business model in a variety of ways[ii], for example, in the form of strategy descriptions or by presenting business results or general information about the company. A more precise and transparent definition of the business model (for reporting purposes) and related guidelines can contribute to ensuring greater consistency and compliance of the procedures and methods used by companies. The results of the analysis of over 500 examples of disclosures of enterprises regarding the business model from around the world can be found in the cited Business Model Background Paper for IR. It emphasizes the impact of legal and statutory regulations, the corporate governance code and public disclosure rules on the adoption/selection of a specific reporting method on a business model.

Business Model in Selected Integrated Reports

The theoretical concepts of the business model presented earlier have been confronted with reporting practice in order to answer the question: how the business model is presented in the practice of listed companies. The study analyzed disclosures about the business model in integrated reports prepared by five capital groups: Orange, PGE, Bogdanka, Pelion and Orlen.

Key elements of the business model (IIRC 2013b) were analyzed in accordance with The International <IR> Framework, namely:

- Inputs (IIRC, 2013a, paragraph 4.14–4.15),
- Business activities (IIRC, 2013a, p paragraph 4.16–4.17),
- Outputs (IIRC, 2013a, paragraph 4.18),
- Outcomes (IIRC 2013b, paragraph 4.19–4.20).

It should be emphasized that the study is illustrative, case studies were used.

Orange Polska in its IR for 2016 revealed a business model using the approach suggested by IIRC based on 6 capitals[iii]. The company presented the business model in an integrated report in the chapter "Our business model and value creation"[iv]. In turn, the results of its business model were presented in a separate chapter "Outputs & outcomes"[v]. As part of disclosures about the business model, the company discussed key natural resources (spectrum, energy), financial (debt, equity), manufactured (network infrastructure, software, points of sale), human and intellectual (employees, innovations, customer and market knowledge) and social and relationship (brand, relations with market regulator, local authorities and the financial community, relations with business partners, social impact). The company also presented a scheme of the company's business model and provided information on the strategy of Orange Polska, which is based on network quality, convergence, improving customer experience, increasing efficiency and responsibility in operation. As part of individual sections, the company also presented sample KPIs[vi] (see: Michalak, Bek-Gaik, Karwowski 2018).

As part of financial KPIs, Orange presented adjusted revenue, revenues from mobile services, revenues from fixed-line services, other revenues, adjusted EBITDA, adjusted CAPEX, Adjusted OCF, net debt/adjusted EBITDA evolution, dividend payment. The elements of the Orange Polska business model are presented in Table 1.

Table 1: Orange business model title here

Resources	Business activities	Non-financial performance	Outcomes
Financial – debt and equity. **Manufactured** – network infrastructure, distribution network **Human and intellectual** – Orange Polska created Orange Labs to support development of new technologies and innovations. **Social and relationship** – global and widely recognized "Orange" brand **Natural** – the company manage natural resources efficiently, monitoring the consumption of energy and other resources, as well as carbon dioxide emissions related to its operations.	**Business activities** – Licenses and regulations – Network development driven by customer needs – Products and services – Sales and distribution – customer care **Social responsibility activities –** implementing a policy of corporate business responsibility in all areas of business **Environmental activities** – optimization of energy use; increase in number of recycled, re-use and refurbished devices **Activities in favor of the employees** – Volunteering programme – Training programmes	– Workforce data – Accidents at work – Environmental data – Energy consumption – CO2 emissions – Electronic and electrical waste collection	– Adjusted revenue – Adjusted EBITDA – Adjusted CAPEX – Adjusted OCF – net debt/adjusted EBITDA evolution – DPS

Subsequently, disclosures about the business model at Polska Grupa Energetyczna (PGE Group) were analyzed (Table 2). The company in its integrated report for 2016[vii] presented a business model schema - an infographic showing how the company creates value for the company, the environment and society (including the main segments: conventional energy, renewables, distribution and supply). The company revealed a business model presenting inputs, business activities and outcomes. Presenting its value creation model, the Group characterized the following issues: clients, natural environment, public affairs, investors, local communities, employees and social contribution. The Group has not precisely characterized the individual elements of the business model suggested in the IIRC IR Framework, which significantly hinders the analysis. It can therefore be said that the Group has adopted its individual way of describing the business model.

Table 2: PGE Group business model

Inputs	Outputs	Non-financial performance	Outcomes
Amount of – lignite extracted from own deposits – lignite resources – hard coal delivered – natural gas supplied – water and wind energy – biomass contracted from suppliers Capital expenditures Equity	**Energy safety**: Net electricity generation Revenues from ancillary control services Centrally Dispatched Generation Units capacity Intervention Service **Stability of supply:** Regulatory Asset Base Distribution volume Distribution grid	**Social contribution:** Taxes and fees paid to local budgets Support of sport team PGE Foundation **Environmental protection:** Operating in line with emission standards Diversified sources of energy **Services meeting expectations**	**Financial contribution:** Revenue Net profit EBITDA

The Lubelski Węgiel BOGDANKA Capital Group, when presenting the business model, applied the six-capital approach and presented the business model in accordance with the guidelines of the integrated reporting framework[viii]. The Group's business model has been described in the "About Bogdanka" and "Integrated model of creating value" chapters. The following subsections discuss business model and scale of the organization, business model and supply chain, development strategy for the upcoming years, account of the state of implementation of the strategy objectives for 2016 (presenting both the declared and the achieved level).

Disclosures about the business model focus on value creation (Table 3). Inputs are presented in detail as capitals on the basis of which the organization creates value. As part of disclosures about individual types of capital, the Group discussed key figures and cash transfers related to the capitals, risk management and relations with stakeholders. Six capitals – financial, manufactured (operating), human, intellectual, social, natural – on the basis of which the Group conducts its business activities, are presented in the chapter "Integrated model of creating value".

The individual capitals were discussed in detail. The following contents were included in each capital:

- Financial capital: shareholding structure, dividend policy, governance, governing bodies of LW Bogdanka SA, internal control and risk management in drawing up financial statements, selected financial results;
- Manufactured (operating) capital: effective business model, infrastructure and investments, integrated management system, management and corporate social responsibility, integrated enterprise risk management system;
- Human capital: social dialogue as component of the management culture, management of occupational, health and safety, ethics as a component of the organizational culture;
- Intellectual capital: technological innovation, cooperation with the academia, sector initiatives,
- Social capital: building social and community relationships, mine's economic impact, engagement in social life, mining damage;

- Natural capital: environmental management, biosphere, water management, waste management focused on effectiveness, consumption of raw and other materials, energy and emissions.

The rest of the report presents the Group's activities in terms of the abovementioned capital, while focusing on those aspects of the business that, due to the nature of the business activity, are key areas of economic, social and environmental responsibility. The company then presented financial and non-financial performance measurement indicators.

Table 3: Business model of Lubelski Węgiel BOGDANKA Group

Capitals	Activities	Outputs	Outcomes
Financial capital – total assets, equity, revenue, net profit **Manufactured (operating) capital** mining, energy and transport infrastructure, advanced IT infrastructure Examples of measures: – Non-current assets – expenditure on investment and development **Human capital** Employees' knowledge, experience and qualifications Examples of measures: – number of employees – expenditure on OHS **Intellectual capital** knowledge and innovations that constitute the Smart Mine concept Examples of measures: – hours of training courses – net book value of intangible assets **Social capital** participation in important local social initiatives and sponsorship of sport Examples of measures: – income tax – transfers: to the communities, for removing mining damage, for charity **Natural capital** – owned natural assets Examples of measures: – recovered mine water used for economic purposes – expenditure on environmental protection	**Operational activities** – extraction of commercial hard coal; – heat supply to the mine, mine's water and wastewater management operations; – delivering heat to external recipients; – waste transportation and logistics services **Social activities** – support for local social initiatives – professional cooperation with universities – charitable activities **Environmental activities** Integrated system of quality, environmental and enterprise risk management **Activities in favor of the employees** – The first study of the organizational culture and internal communication – The Code of Ethics	– extracted hard thermal coal – heat supply services – the mine's water and wastewater management operations – delivery of heat to external recipients, – repairs and refurbishments on the ground, – by-products	– Revenue – EBITDA – Net profit – EBIT margin – capital expenditure

Source: LW BOGDANKA Group Integrated Report 2016, https://www.lw.com.pl/file,106,bogdanka_raport_zintegrowany_2016.pdf [Retrieved January 25, 2018]

Another business model was presented on the example of Pelion[ix]. The company has adopted a completely different solution than other companies. In general, disclosures about the business model should be found throughout the entire report, which makes analysis much more difficult, data are dispersed and difficult to interpret. The report is divided into the chapters and each of them contains disclosures about the business model. The only aspect the company presented according to the basis of the business model is six capitals. Individual elements of the business model are contained in the following chapters:

Pelion family

- Pelion family members and their mission
- Value creation model
- Pelion's growth strategy

2016 on market and in Pelion Family

- Pelion family in 2016
- Pelion S.A. at the WSE
- Market environment

Consolidated financial performance

- Sales and financial highlights
- Consolidated statement of financial position

Business philosophy and non-financial results of operations

- Serving Patients and society at large
- Innovation and development
- Ethical business conduct and support for development

Corporate governance and risk management

- Compliance with corporate governance principles in 2016
- Risk management

Our report

Table 4 illustrates the key elements of business model of Pelion.

Table 4: Pelion business model

Capitals	Business activities	Outcomes
Financial capital – funds used to finance operations Key data: – Revenue – EBIT Objective Continued cooperation with capital market participants and lenders, receivables management **Working capital** – infrastructure, warehouse network, order picking line, distribution and logistics network, vehicle fleet, a chain of company-owned pharmacies and pharmacies working with Pelion, manufacturing plant, a hospital. Key data: – number of: pharmacies, warehouses and hospitals supplied – products sourced from manufacturers Objective ➢ development of a proprietary model for cooperation with external partners ➢ use of innovative solutions and communication channels through **Human capital –** a team of people who are open to teamwork and ready to share their ideas Key data: – number of employees – employee training hours Objective ➢ fostering a friendly work culture **Intellectual capital** –research on innovative particles, educating healthcare professionals Key data: – clinical trials of an experimental anti-atherogenic drug – combination of a medical knowledge website with the possibility of drug ordering through website and mobile Objective ➢ Willingness to create alliances and partnership with academic institutions **Social capital** Participating in treatment and protection of human health, involvement in the lives of local communities. Key data: – number of patients served – support for 35 organizations – the DOZ Marathon Łódź Objective ➢ Dialogue with local communities and NGOs **Natural capital** Helping to reduce negative environmental impact ensuring safe disposal of expired medicines. Key data: – amount of collected medical waste – collections of expired medicines from the pharmacies Objective ➢ participating in the Healthy Choice programme	Manufacture of medicines Conducting advanced clinical trials Pharmaceutical distribution CSR initiatives	Revenue EBIDTA EBIT Profitability ratios presented at individual capitals

Source: http://raport2016.pelion.eu/ [Retrieved January 25, 2018]

Polski Koncern Naftowy ORLEN S.A.[x] presented a completely individual, own approach to the presentation of its business model. The Integrated Report of the PKN ORLEN Group 2016 revealed a scheme of the business model, not referring to its individual elements. In turn, the implementation of the business model was presented by indicating the outcomes in individual business segments. The company presented other information about the business model in various parts of the report – for example, the ORLEN Group and the environment, Strategy, Financial results. Compared to 2015 (Walińska, Bek-Gaik, Gad 2015) – it can be said that the capital approach in the presentation of the business model has been abandoned. The Group has not characterized individual capitals. The section on the business model in Orlen Group integrated report lists the following key elements in detail:

1) operating segments along with specification of the products offered under each segment, i.e.
    a) upstream (crude oil, natural gas)
    b) downstream (refinery, petrochemicals, power generation)
    c) retail (petrol, diesel oil, LPG)
2) dedicated staff in each of the segments
3) key financial results in each of the operating segments
4) strategy implementation by segment in 2016, e.g.:
5) sources of competitive advantage, e.g .:
    a) implementing environmental management systems and investing in innovation,
    b) efficient logistics infrastructure,
    c) modern management culture.

Conclusions

The business model is a very important disclosure in IR. It should be emphasized that a properly articulated business model is useful in communicating organization's business for stakeholders. Good knowledge of the business model would make it possible to assess the performance of entities and the accountability or fulfillment of management tasks by the management of these entities. The concept of the business model encourages a proactive, independent way of thinking and the attitude of the persons responsible for preparing the report, its auditors and users, because it requires them to consider how the business model works, and thus – how it increases the value of the organization. In addition, accurate and reliable presentation of business model would increase the substantive relevance and reliability of financial information.

The analysis (case studies)[xi] shows that the way the business model is presented in an integrated report in the practice of the surveyed companies is very different. The companies partly apply the solutions proposed in the IIRC structure but also use their own individual solutions. In practice, we observe:

1) various forms of presentation of the business model,
2) the wide range and dispersion of topics related to the business model among various parts of the integrated report,
3) lack of interrelationships, and the value chain presentation,
4) a differentiated presentation of performance measures (indicators),
5) various business model diagrams.

Terminology is also a problem – companies use different terms for the term "business model" and some of them do not use the term, but instead use the terms "value creating model" or "business model". It can definitely be said that the surveyed companies use mixed solutions, partly using IIRC and GRI guidelines, what does not promote transparency of content related to the business model of the organization.

Preferred by IIRC so-called the six-capital approach, in line with the International <IR> Framework guidelines, was used only by Bogdanka, Orange and partly PELION. In turn, PKN Orlen and PGE applied their own individual approach to the presentation of business model. The companies that

applied the capital approach generally presented financial capital in the form of the amount of equity, liabilities and cash held. In case of production capital – companies presented data on the value of property, plant and equipment at the end of the reporting period, possibly distinguishing analytical items. In turn, intellectual capital is disclosed in the form of intangible assets, which include, among others, patents, licenses, concessions, carbon dioxide emission rights, etc. Human capital is presented in the form of a description of human resources – companies presented the number of employees, gender structure, form of employment and age structure. In turn, disclosures about social and relational capital include descriptions of ethical values, implemented codes of ethics and codes of good practice, organizational culture, awards and certificates, membership of organizations, etc. Natural capital, which is the last category of inputs, is disclosed in the form of land area owned, the area covered by mining concessions, the volume of natural resources, etc. (Michalak, Bek-Gaik, Karwowski 2018).

The second essential element of the business model – i.e. business activities – is presented in the form of a description of operational activities of companies and other selected activities, e.g. production and environmental activities, activities in favor of the employees.

The third element of the business model are the outputs, i.e. products, services, waste and other by-products, and include information on the volume of production, both value and quantitative.

As the last element of the business model consistent with the International <IR> Framework – outcomes – the companies presented both financial and non-financial KPIs. Most often, as the financial indicators they present EBITDA, investment expenditure, adjusted cash flows from operating activities, and among the non-financial indicators dominate data on employment, the number of accidents at work, carbon dioxide emissions. Describing the business model, companies also present relations with stakeholders, risks and corporate governance. The indicated conclusions are consistent with the results indicated by other authors.

It can therefore be stated that the presentations of the business model are very differentiated and chaotic. The current practice of enterprises in disclosing information about the business model is very diverse. Admittedly, the companies in their integrated reports refer to almost all elements of the business model proposed by the IIRC in the International <IR> Framework, but in very different ways. The quality and accuracy of individual disclosure categories vary widely. A major drawback are very poorly articulated links between individual elements of the business model and their impact on creating value. The size and dispersion of topics related to the business model means that some disclosures can be considered factually non-informational because they do not relate to the topic (e.g., relate to strategy, corporate governance or risk) or because they are so general that they cannot be fall into any category adopted in IIRC International <IR> Framework.

Considering the fact that the business model is a very important disclosure in the integrated report, it appears that companies should more closely follow the guidelines formulated by the IIRC and Business Model Background Paper for IR. The important barrier in disclosure about the business model is the concern of management boards against disclosing some information – in particular the disclosure of key competences, suppliers, business strategy etc.

To sum up, the business model is a very important element of reporting for investors, used to assess the organization's ability to create and maintain value over time, it is necessary to constantly update and improve the business model description form proposed in the framework structure in order to provide all stakeholders with transparent and reliable information on the way of conducting business in companies.

[i] The business model is defined differently, which is the result of looking at the "business model" from many different points of view and scientific disciplines. Most often it is referred to as a general concept representing the logic of doing business. A comprehensive overview of the business model

definition can be found, among others in: Falencikowski (2013), see also IIRC (2013b, pp. 15-19). In addition, the concept of the business model was presented in e.g.: Nogalski (2009), Osterwalder, Pigneur (2009), Richardson (2008), Rudny (2013), Michalak (2012).

[ii] When analyzing the literature on the subject, empirical research on disclosures about the business model can be divided into two main groups: the first, which deals with the problem of compliance of disclosures on the business model with the framework structure of the integrated report proposed by IIRC, e.g.: Eccles, Krzus, Ribot (2015, p. 108), Bek-Gaik, Rymkiewicz (2015a, 2015b, 2016a, 2017), Walińska et al. (2015), Michalak (2015), and a second group aimed at assessing the quality of information disclosed about the business model, e.g.: Eccles, Krzus (2014), Lai, Melloni, Stacchezzini (2013),Bagnoli, Redigolo (2015), Bini, Dainelli, Giunta (2016).

Abstract

In this paper we show the implementation of an automatic economic nowcasting and short-term forecasting procedure using MIDAS approach in gretl. We also demonstrate possibilities of gretl's interface for direct downloading macroeconomic time-series from db.nomics database. In empirical illustration we show how to predict quarterly gross domestic product using a mixture of quarterly and monthly explanatory variables. In all cases, the MIDAS generates more accurate forecasts comparing to benchmark model. Results of our study confirm that MIDAS approach may have better forecasting performance than other ADL specifications.

Keywords: short-term forecast, MIDAS models, db.nomics, gretl.

Introduction

Assessment of the current macroeconomic situation together with accurate nowcasts and short-term forecasts is an important element of effective economic, fiscal, monetary or social policy in many countries. Delivering the short-term forecasts of gross domestic product (GDP) allows the analysis of macroeconomic evaluation of state policies. However, this category is measured on a quarterly basis, while many of the explanatory processes which may drive GDP dynamics, like inflation, employment, imports and exports are measured on a monthly basis. Incoming economic signals measured monthly, weekly or daily can be used to construct quarterly GDP forecasts. The expected trends in economic development may formulate the basis for further analyses of the expected reactions of economies.

A useful tool for forecasting processes of different observation frequencies is MIDAS (MIxed DAta Sampling regressions models) described in following papers: Ghysels, Santa-Clara & Valkanov (2004), Ghysels, Sinko and Valkanov (2006), Ghysels and Wright (2009), Ghysels, Andreou and Kourtellos (2010) or Ghysels (2015).

The aim of the paper is verification of usefulness of automatic procedures for countinous forecasting of economic processes. The main research goal is implementation of an automatic short-term economic forecasting procedure using MIDAS approach in gretl scripting language. We formulate the following research question: whether combaining Open data repositories (db.nomics) with Open source econometric software (gretl) may be used as an automatic forecasting tool by both academics and practitioners?

In Section Open data we briefly describe db.nomics database with example of gretl script for automatic collecting data from db.nomics.world repository. The empirical illustration is provided for predicting quarterly gross domestic product (GDP) processes using monthly exogenous variables for

selected countries and is presented in Section Empirical results. The paper is concluded in the last Section. Additionally, we include the whole gretl script for replicattion our research in Appendix.

Forecasting macroeconomic phenomena using mixed frequencies data for U.S. real output growth was provided by Clements and Galvão (2008), while Ghysels, E., & Ozkan, N. (2015) used MIDAS for modeling U.S. current federal government expenditures and receipts. León, Nave and Rubio (2007) examined usage of MIDAS approach for risk-expected return trade-off for stock indices in European countries and found that specifying asymmetric variance parameters can improve the relationship between expected return and risk. Emre, Fendoglu and Saltoglu (2012) compare MIDAS approach to GARCH(1,1) model in out-of-sample forecasting of stock markets in ten emerging countries and obtained statistically better forecast precision.

MIDAS framework was introduced as an ideal base for extension to many different econometric models and conceptions. Foroni, Guérin and Marcellino (2015) presented an application of MIDAS approach toMarkov-switching Mixed-Frequency VAR (MSMF-VAR) models and found it useful to estimate the condition of economic activity. The proposition of single equation Markov-Switching MIDAS (MS-MIDAS) was introduced in Guérin and Marcellino (2013). Barsoum and Stankiewicz (2015) proposed solution where they allow for changing parameters according to a Markov-switching scheme and applied it to empirical U.S. GDP growth. Extension of MIDAS conception to vector autoregressive modeling (VAR) is presented in Foroni, Ghysels and Marcellino, M. (2013), while improvement to vector error correction models (VECM) was made in Seong, Ahn and Zadrozny (2013). They modeled quarterly US real GDP using monthly monthly coincident indicators. Kuzin, Marcellino and Schumacher (2011) compared MIDAS approach to mixed-frequency VAR for quarterly GDP in Euro zone countries and discovered that those methods are complementary. MIDAS gave more accurate forecasts in short-term, while MF-VAR is better in forecasting for longer horizon. Schorfheide and Song, D. (2015) used Bayesian estimation to monthly-quarterly data of vector autoregression model in state-space form. Foroni, Marcellino and Schumacher (2015) discussed of unrestricted MIDAS regression and evaluate its usability in Monte Carlo experiments and in empirical application on short-term forecasting monthly indicators in Euro area and US GDP. Bayesian methodology for mixed frequency data was used in Schorfheide, Song and Yaron (2018) to analyze annual consumption, monthly consumption and asset return data.

Schumacher (2016) compared single-equation MIDAS regression with bridge equations in modeling GDP growth for Euro area countries. Proposition of smooth transition mixed data sampling (STMIDAS) conception with application to financial time series can be found in Galvão (2013). Marcellino and Schumacher (2010) combined MIDAS methodology with modeling based on factor models, which are useful in forecasting using large data sets of macroeconomic variables. Lima, Meng and Godeiro (2019) combined MIDAS framework with quantile combination approach and applied the proposed model to the growth rate of the industrial production index. The combination of MIDAS and quantile approach gives more accurate results in terms of forecasting. Bai, Ghysels, E. and Wright (2013) performed wide comparison of MIDAS regression with Kalman filter for forecasting purposes. They examined many circumstances like: misspecifications, small samples or ideal conditions obtaining more accurate results for state space models, but with bigger computational requirements. Pettenuzzo, Timmermann, and Valkanov (2016) proposed new approach for modeling density of first and second moments with MIDAS effect and applied it to monthly growth in industrial production and inflation, gaining better performance in the volatility equations in both: out-of-sample and in-sample density predictions. Extension of standard DCC-MIDAS by employing t-student distribution is introduced in Xu, Chen, Jiang, and Yuan (2018). Results concerning Chinese banking industry showed that DCC-MIDAS-t model can be applied for measuring systematic risk or financial returns with fat-tailed distribution. The implementation of MIDAS framework for open-source and free software was accomplished in R package (see Ghysels, Kvedaras and Zemlys (2016)) or in gretl (see Cottrell & Lucchetti (2017)).

Open data - db.nomics.world

The phrases: open data, open government data open access, open algorithms, open source, open knowledge or open science indicate new paths in the development of science, research, analysis, as well as making algorithmsand software freely available as ready-made tools for their implementation. The results of these analyses (publications) should be available without any restrictions for everyone (see Ruijer, Grimmelikhuijsen & Meijer (2017)). Open data is data that is accessible to anyone, can be reused without any legal or technical restrictions and stored in a way that allows for its automatic processing.

We may use the term "open data" for data that meet the following conditions together:

1. accessible - the data are accessible to the widest possible range of users;
2. current - the data are available quick enough not to lose its value;
3. complete - individual public data sets are available with integrity;
4. machine-readable - the data are structured and can be processed automatically;
5. accessible without discrimination - the data are accessible to anyone, without the requirement to register;
6. sharing without licensing restrictions - i.e. they can be used e.g. for business purposes

It is also important that Open Data can be freely used, modified and shared by anyone for any purpose. The addresses of 140 Open Data websites with macro and micro data for economic and financial research usage are included at the page: http://www.businesseconomics.com/economic-data-links.html. Most of these addresses provide data free of charge, which can be very useful for research and empirical work. Among these addresses the db.nomics.world database is indicated and deserves more attention.

The db.nomics.world repository was established in 2018 and it is a part of the Macroeconomic Observatory project carried out by CEntre Pour la Recherche EconoMique et ses APplications (CEPREMAP) in Paris (macro.nomics.world). The aim of this project is, among other things, to develop tools and resources to support international macro-economic research by running the data repository db.nomics.world.

The db.nomics.world website satisfy all six features of Open Data and is a valuable source of information for researchers working with macro-economic data00. It provides national and international macroeconomic data from 62 providers and contains over 21,000 databases and over 602 million of series. The website contains information about downloading data via its own web interface or directly from econometric and statistical software via application programming interface (API). The 62 providers contain all major statistical offices (global, European and national) as well as global banks, among others: WB, WTO, OECD, IMF, UNDATA, ILO, ECB, FED or Eurostat.

All databases are accessed by using an uniform three element syntax (Identifier): Provider / Database / Series. For example:

Identifier: [IMF/BOP/Q.ES.BFFR_BP6_USD]
Provider: IMF - International Monetary Fund
Database: BOP - Balance of Payments
Series: Q.ES.BFFR_BP6_USD - Quarterly – Spain – Supplementary Items, Financial Account, Net, USD

For Stata, R, Phyton or gretl software, specialized tools have been developed to automatically download and update data. The gretl econometric software (Gnu Regression, Econometrics and Time-series Library) allows you to automatically download data from the db.nomics repository (Dbnomics for gretl is avaiable from 2019a version of gretl). Data collection is possible through the

graphical user interface (GUI). Additionally, one can also use an internal gretl scripting language for data acuisition. An example of a data collection script for series used in this article is as follows:

```
open dbnomics
setobs 4 1995:1 --time-series
string COUNTRY = "EU28 AT BE BG HY CY CZ DK EE FI FR GR GB IE IT LU
LV LT MT NL PL PT RO ES SE SK SI"
loop foreach KR @COUNTRY
  data   ECB/MNA/Q.N.$KR.W2.S1.S1.B.B1GQ._Z._Z._Z.EUR.V.N         --
name=$KR_GDP
endloop
```

The db.nomics repository's development team has prepared a tool for automatic update of the repository using the API interface, so the db.nomics repository is a valuable tool for all kinds of automatic short-term economic analyses. An example of such analyses is presented in Section Empirical illustration.

MIDAS In Gretl

Since most macroeconomic data are observed monthly or quarterly, there is a potential issue for forecasters related with a fact that not all time-series are sampled at the same frequency. One of the potential solution for this phenomena is to use methods for dealing with mixed frequency data. The most know approach for this kind of analysis is so-called MIDAS (Mixed Data Sampling) regression models proposed by Ghysels, Santa-Clara & Valkanov (2004), i.e. regressions that may base on time-series datasets observed at different frequencies. From a econometric point of view, in MIDAS we specify conditional expectations on lags distribution of explanatory variables sampled at some higher frequency than endogenous process. However, we have two possible ways of understanding lags in MIDAS (see Cottrell & Lucchetti (2017)):

1. high-frequency lag 0 corresponds to the first sub-period within the current low-frequency period, or
2. high-frequency lag 0 corresponds to the last sub-period in the current low-frequency period.

The very simple explanation of differences in these two approaches is that in the case of the first quarter of some year the first way of understanding lags in MIDAS assigns lag 0 to January, while the second to March. In gretl, the the first approach is used.

Following Ghysels, Santa-Clara & Valkanov (2004), let's consider autoregressive distributed lag (ADL) with high-frequency explanatory variables:

$Y_t = \alpha + \sum \beta_i L^i Y_t + \gamma \sum \Phi(k;\theta) L_{HF}^k X_t + \varepsilon_t$, where L^i is a back-shift operator such as $L^i x_t = x_{t-i}$ for any variable x_t and $\Phi(k;\theta)$ is a some polynomial which defines weights for aggregation in time. Two the most commonly used $\Phi(k;\theta)$ polynomials are:

1. beta – $\Phi(k;\theta_1,\theta_2) = \dfrac{f\left(\frac{k}{m},\theta_1,\theta_2\right)}{\sum f\left(\frac{j}{m},\theta_1,\theta_2\right)}$, where

$$f(k;\theta_1,\theta_2) = \frac{i^{\theta_1-1}(1-i)^{\theta_2-1}\Gamma(\theta_1+\theta_2)}{\Gamma(\theta_1)\Gamma(\theta_2)},$$

2. Almon – $\Phi(k;\theta_1,\theta_2)=\frac{\exp(k\theta_1+k^2\theta_2)}{\sum(j\theta_1+j^2\theta_2)}$.

In gretl, midasreg command takes one of the following five options:

1. „u-midas", unrestricted MIDAS (OLS);
2. "almonp", which stands for normalized exponential Almon (NLS);
3. "nealmon", which stands for exponential Almon; in this case, the weights of Almon polynomial sum up to 0 (NLS);
4. "beta0", which stands for normalized beta polynomial with zero last lag; in this case, there is no coefficient for the last lag (the newest high frequency observation) and the weights of beta polynomial sum up to 0 (NLS);
5. "betan", which stands for normalized beta polynomial with non-zero last lag; in this case, we have coefficients for all high frequency lags and the weights of beta polynomial sum up to 0 (NLS).

In next Section we present the results of the short-term forecasting using MIDAS approach and we evaluate the prediction accuracy in comparison to autoregressive models.

Empirical Illustration

An empirical example concerns the short-term forecasting of gross domestic product (GDP) for quarterly data for 28 EU countries. This category is measured at quarterly frequency, but many exogenous processes are measured at monthly frequency. MIDAS models are built for quarterly data using monthly exogenous processes.

The MIDAS model is described by the quarterly endogenous GDPt process (at market prices in Euro) for a given country and the monthly exogenous processes for that country: ICPt (Indices of Consumer prices), UNEPt (Standardised unemployment Rate) and CARRt (Car registration - new commercial vehicles in absolute value). The proposed exogenous processes, concerning price inflation and unemployment rates are used in the economic situation models, while the process concerning the value of registered new cars is a barometer of investment sentiment and indicates the anticipation of the economic situation.

Each monthly series has been recorded in the form of three laged processes, e.g. ICPt as ICP_m1 (January, April, July, October, etc.), ICP_m2 (February, May, August, November, etc.) and ICP_m3 (March, June, September, December, etc.).

For each country, 6 models are estimated with an AR(4) model is used as the benchmark. The next 5 models are the MIDAS regressions for 5 types of laged schedules and additionally autoregressive component with lags equals 4. All statistical data (quarterly and monthly) are taken from several data providers via the db.nomics.world repository: GDPt from the ECB (Europen Central Bank), ICPt from the ICP (Indices of Consumer Prices) database and UNEPt and CARRt from the STS (Short-Term Statistics) database. Quarterly data are available until Q3 2019, and monthly data until November 2019. Models were estimated for the period from 2000q1 to 2018q4, that is for T=76 quarters. The forecast was built for the horizon of 4 quarters of 2019. For the first 3 quarters (2019q1-2019q3, where the actual data are available) RMSE and MAPE measures are determined. The prediction for Q4 2019 (nowcasting) was based on the two-month signals (October and November 2019) coming from monthly processes.

In the Appendix Section we present the full gretl script for all EU countries, but the results presented in the paper concern 5 selected countries, namely Spain, Great Britain, Poland, Portugal and Sweden.

The selection of these countries was imposed by the limitation of the article space and the fact that empirical illustration is not the foreground aim of this paper.

All MIDAS models, which were estimated using nonlinear least squares (NLS) method, have reached the convergence criteria and fits the data at a sufficient level. The basis for evaluating the usefulness of MIDAS models for automatic short-term forecasting are the results of the forecasts and their ex post errors, which are presented in Table 1.

Table 1: Results of forecasts and ex-post errors for the AR(4) and 5 MIDAS models for the 5 countries: Spain, Great Britain, Poland, Portugal and Sweden.

RMSEs:		3649.1	**2356.5**	3198.3	3209.6	3359.8	3606.0
MAPEs:		1.963%	**1.460%**	2.001%	2.008%	2.176%	2.476%

According to the results presented in Table 1 all forecasts are close to the actual values. For all cases the MIDAS model gave more accurate predictions that benchmark AR(4) model. This means that including additional exogenous processes, which are observed at different frequency then depended variable, gives better results in terms of forecasting performance.

Conclusions

This paper presents an automatic algorithm for downloading, modeling and forecasting MIDAS datasets. Our contributed algorithm, which implements non-trivial econometric methods, can be performed automatically at any time for the most actual data available at dbnomics repository. Empirical examples show how MIDAS modeling can be easily realized in the gretl program with reasonable run-times. It's worth to mention that modeling open data in an open source software is an unique connection in this area.

Results presented in Table 1 show, that short-term GDP forecasts generated by MIDAS models have smaller errors than AR(4) specification. It seems to be encouraging, since it enables updating forecasts of quarterly GDP as new observations of monthly explanatory variables are available.

The db.nomics.world repository, with common single interface for retrieving and updating data, provides datasets from the worldwide government, banking and statistical institutions (62 providers). It is a tool that may speed up any macroeconomic analysis and may be used by either academics or practitioners.

Abstract

The regions of the Russian Federation have different economic potential, which affects their development. The economic task of typologizing the regions of the Russian Federation is determined by the need to separate the regions into homogeneous groups when conducting inter-regional comparisons, or by studying economic processes at the regional level. In this study, the differentiation of the territories of the Russian Federation refers to the establishment of qualitative relationships between groups of regions with close values of economic indicators characterizing the standard of living of the population. Homogeneous groups of regions are distinguished on the basis of a statistical (cluster) analysis of a multidimensional vector of variables. The main factors for the assessment were the share of the population with incomes below the regional living wage, the ratio of the average per capita income to the regional living wage and the ratio of the average per capita spending to the regional living wage. According to the study, the regions of Russia are divided into 7 classes according to the standard of living of the population. In the framework of the classification of regions of the Russian Federation according to the characteristics of inter-regional differentiation of the standard of living of the population, classes of regions with relatively uniform indicators of living standards are identified. The results of solving this problem can be used in further studying the regional problems of the economic and social development of Russia and developing recommendations in the field of social policy and public support.

Keywords: Clustering, Differentiation Of Regions, Standard Of Living, Poverty, Ward Linkage Method.

JEL Classification: C38; I32; P46

Introduction

The territory of the Russian Federation is vast and diverse. The structure of the Russian Federation until 2014 included 83 subjects of the Federation, and since 2014 – 85. The regions of the Russian Federation have different economic potential, which certainly affects their development. The economic task of typology of the regions of the Russian Federation is due to the necessity of dividing the various constituent entities of the Russian Federation into homogeneous groups when conducting inter-regional comparisons or studying economic processes at the regional level. A study by Violin (2018) examined various approaches to typologizing the Russian regions. The region typology basis developed by Buts et al. (2002), make up three blocks of indicators that characterize the standard of the population living, the region investment activity and the region economic potential. The study by Tikhomirova (2016) considers the classification of Russian regions according to the state and loss of health of the population.

In this study the typology of the constituent entities of the Russian Federation means the establishment of qualitative relationships between regions with close values of economic indicators characteristic of the standard of living of the population. Homogeneous groups of regions are presented solely on the basis of a statistical (cluster) analysis of multidimensional values that determine the factor of the standard of living of the population. The situation in the region for 5 years (2014–2018). Within several years, it is possible to establish the stability of the selected types, as well as the conversion between different types or between regions within the same type. Inter-regional differences in the living standards of the population provide not only the poverty level of the population, but also internal and external (from other residents of other regions) demand for goods and services in the region, inter-regional flows of cash and labor resources, social situation, inter-regional differences in price levels.

Materials and Methods

In this paper, we prefer the analysis of the aggregate data by region over several years before the analysis of annual distributions, which allows us to identify more general types of economic behavior of the regions in 2014-2018 including the dynamics of the characteristics under consideration from year to year. Analysis of the results of cluster analysis for individual years can play a supporting role and can be used to explain the belonging of a region to a certain class (type) of subjects of the Russian Federation.

Consider the main hypotheses about the allocation of possible groups of regions and the choice of indicators to characterize the standard of living of the population. In the framework of the general differentiation of the regions of the Russian Federation, we will consider the vector of indicators characterizing the interregional differentiation of the standard of living of the population: x_1 – the absolute poverty level of the region's population, characterized by the share of the population with incomes below the regional subsistence level; x_2– the relative poverty level of the region's population, characterized by the ratio of the per capita income of its population to the regional subsistence level; x_3 – ratio of average per capita expenses to the subsistence minimum by Region.

During 2014-2018, the gap in per capita income between the richest and poorest regions reached 5 times. The differentiation of living standards between individual regions of the Russian Federation remains extremely high by the standards of developed countries, as well as countries with economies in transition. The dynamics of per capita cash income of the population in the context of the Federal Districts of the Russian Federation is presented in Fig. 1.

Fig. 1: Average per capita cash income dynamics of the population by the Russian Federation federal districts (per month; rubles)

The indicators used for clustering characterizing the interregional differentiation of the standard of living of the population are heterogeneous. Therefore, we will standardize the selected three indicators by converting:

$$\tilde{x}_{i,t}^{k} = \frac{x_{i,t}^{k} - E\left(x_{i,t}\right)}{\sigma\left(x_{i,t}\right)} \tag{1}$$

$\tilde{x}_{i,t}^{k}$ – the standardized value of indicator x_i in the *k*-th country in year t, *i* = 1, 2, 3;

k – number of region, *k* = 1,…, 85;

$x_{i,t}^{k}$ – initial value of indicator x_i in the *k*-th country in year t, *i* = 1, 2, 3;

$E\left(x_{i,t}\right)$ – average of the *i*-th indicator in the year *t*;

$\sigma\left(x_{i,t}\right)$ – standard deviation value of the *i*-th indicator in the year *t*.

We classify the regions of Russia (85 regions) in the corresponding three-dimensional space according to statistical data for 2014-2018 (Rosstat, 2019) in accordance with normalized indicators by the method of hierarchical cluster analysis.

The essence of hierarchical clustering consists in sequentially combining smaller clusters into large ones or dividing large clusters into smaller ones. Hierarchical algorithms are associated with the

construction of dendrograms, which are the result of hierarchical cluster analysis. The dendrogram describes the proximity of individual points and clusters to each other, presents in graphical form the sequence of combination (separation) of clusters.

The measure of similarity is determined by the Ward method (Ward, 1963). In this method, the intragroup sum of the squared deviations, which is nothing more than the sum of the squared distances between each point (object) and the average of the cluster containing this object, is used as the objective function. At each step, two clusters are combined that lead to a minimum increase in the objective function, i.e. intragroup sum of squares. This method is aimed at combining closely spaced clusters. A measure of the distance between objects is Euclidean distances. The selected clustering method leads to the most evenly distributed classification of regions.

Results

In accordance with the Ward Linkage method and data for 2014-2018, we obtained a different number of regions in the clusters. The clustering results are presented in table 1.

Table 1: Number of Regions in clusters in 2014-2018 by Ward Linkage method

Cluster	Number of Regions in clusters				
	2014	2015	2016	2017	2018
1	11	9	1	17	2
2	5	3	7	5	5
3	2	12	8	17	4
4	25	17	18	21	13
5	14	5	15	9	21
6	11	10	7	16	9
7	3	13	14	1	16
8	4	3	3	2	1
9	8	2	3	3	2
10	0	11	9	9	3
11	0	0	0	0	9
Total number of Regions	83	85	85	85	85

A qualitative analysis of the clusters obtained for normalized indicators by the Ward Linkage method shows that clusters, from the point of view of differentiating living standards, can be assigned to several economically fairly homogeneous groups. We identified such groups on the basis of comparison and ranking of all the clusters of normalized values of the three considered indicators of living standards. Based on the results, we distinguish five groups of clusters (regions).

1. Regions with a low standard of living.
2. Regions with a high standard of living.
3. Regions with low poverty and low levels of expenditure and income.
4. Regions with low poverty, high incomes and low spending.
5. Regions with an average standard of living.

Isolation of economically homogeneous cluster groups, i.e. the reduction in the number of groups of regions with a uniform level of differentiation of life simplifies the task of dynamically classifying regions of the Russian Federation in terms of differentiation of living standards during 2014-2018. The movement of the constituent entities of the Russian Federation in 2014-2018 for the indicated groups of regions is presented in table 2.

Table 2: Movement of the Russian Federation regions by cluster groups obtained clustering with Ward Linkage method to standardized data for 2014-2018

Ulyanovsk region	5	5	5	3	3
Vladimir region	5	5	3	3	3
Volgograd region	5	5	3	3	3
Vologda region	5	5	3	3	3
Voronezh region	2	2	2	2	2
Yamalo-Nenets Autonomous Okrug	4	4	4	4	4
Yaroslavl region	5	5	5	5	5
Zabaikalsky Krai	3	1	3	3	3

The analysis of the movement of regions between these five groups of clusters indicates the presence of seven main classes of regions:

1. Regions with a consistently high standard of living. 12 regions belong to this class: Belgorod region, Krasnodar region, Lipetsk region, Moscow, Moscow oblast, Nizhny Novgorod region, Republic of Bashkortostan, Republic of Tatarstan, Saint Petersburg, Sakhalin region, Sverdlovsk region, Voronezh region.

2. Regions with low living standards. This class includes 20 regions: Altai Republic, Ingush Republic, Jewish Autonomous region, Kabardino-Balkar Republic, Karachay-Cherkess Republic, Republic of Kalmykia, Republic of Tuva, Altai territory, Chelyabinsk region, Chuvash Republic, Kaliningrad region, Kamchatka territory, Kurgan area, Penza region, Pskov region, Republic of Mari El, Republic of Sakha (Yakutia), Ryazan region, Zabaikalsky Krai, Irkutsk region.
3. Regions with a stable average standard of living. 23 regions belong to this class: Adygeya Republic, Amur region, Arkhangelsk region, Bryansk region, Kaluga region, Khabarovsk territory, Khanty-Mansi Autonomous Okrug-Yugra, Kursk region, Leningrad region, Magadan region, Novosibirsk region, Omsk region, Perm region, Primorsky Krai, Republic of Dagestan, Samara region, Stavropol territory, Tambov region, Tula region, Tyumen region, Yaroslavl region, Murmansk region, Rostov region.
4. Regions in which there is an increase in living standards. 3 regions belong to this class: Republic of Crimea, Republic of Mordovia, Sevastopol.
5. Regions in which a decline in living standards is observed. 17 regions belong to this class: Astrakhan region, Ivanovo region, Kemerovo region, Kostroma region, Krasnoyarsk region, Orel region, Republic of Chechnya, Republic of Komi, Republic of North Ossetia-Alania, Saratov region, Tomsk region, Tver region, Udmurt Republic, Ulyanovsk region, Vladimir region, Volgograd region, Vologda region.
6. Regions with an unstable situation, fluctuations in living standards from year to year without an obvious trend in one direction or another. 7 regions belong to this class: Kirov region, Novgorod region, Orenburg region, Republic of Buryatia, Republic of Karelia, Smolensk region, Republic of Khakassia.
7. Regions with low poverty, high incomes and low spending expenditures. 3 regions belong to this class: Yamalo-Nenets Autonomous Okrug, Nenets Autonomous district, Chukotka Autonomous Okrug

Table 3 presents the average values for the classes obtained.

Table 3: Average values of three characteristics of the living standard for the classes obtained

Group	The population share with incomes below the subsistence level	Ratio of average per capita income to the subsistence level	Ratio of average per capita expenses to the subsistence minimum
Regions with a consistently high living standards	9,06%	3,68	2,97
Regions with a low living standards	20,39%	2,23	1,63
Regions where the living standards increase	12,65%	2,90	2,31
Regions where the living standards is declining	17,09%	2,27	1,85
Regions with unstable situation, fluctuations in living standards from year to year without a trend	14,59%	2,58	1,97
Regions with consistently low levels of poverty, but also persistently low incomes and expenditures of the population	16,13%	2,46	2,01
Regions with low poverty, high incomes and low spending	8,27%	4,09	1,68

Regions with the unstable situation is concentrated mainly in the Central European part of Russia, Eastern Siberia and the Far East. Any uniformity of geographical distribution regions for selected classes are not observed. Subjects of the Russian Federation belonging to the regions class with stable low living standards are located in the North Caucasus and the southern part Siberia along the border of the Russian Federation.

Conclusion

It is advisable to pursue a regional policy in relation to the selected groups, taking into account the territorial differentiation of the level of socio-economic development of the regions. Each of the identified types of regions is distinguished by its own set of problems, the solution of which (taking into account the specialization of the regions) requires federal and regional authorities to apply differentiated approaches to stimulate economic activity and provide state support.

In the framework of the classification of regions of the Russian Federation according to the characteristics of inter-regional differentiation of the standard of living of the population, classes of regions with relatively uniform indicators of living standards are identified. Further research of the authors is devoted to the expansion of the feature space. The results of solving this problem can be used in further studying the regional problems of the economic and social development of Russia and developing recommendations in the field of social policy and public support. The above typology of the regions once again shows the need for a differentiated economic and social policy, depending on the region's affiliation with one or another type.

Multidimensional statistical methods among the many possible probabilistic-statistical models allow one to reasonably choose the one that best fits the initial statistical data characterizing the real behavior of the studied set of objects, to evaluate the reliability and accuracy of conclusions made on the basis of limited statistical material.

Abstract

The purpose of this paper is to identify the behaviours of contemporary consumer determined by ongoing social and technological changes. The layout of the paper is dictated by the implementation of the objective. The first part introduces the subject matter of consumer behaviour. Part two focuses on the issue of social changes as contribution to the creation of new trends in consumer behaviour, whereas part three focuses on the issues of technological changes as contribution to the creation of new trends in consumer behaviour. The paper has a theoretical character. It is based on a critical literature review.

Keywords: Consumer, Trends, Consumer Behaviour.

Introduction

Enterprises functioning in the conditions of market economy are forced to observe constantly the changes occurring in their environment and to adapt their own activity to the conditions around them. Consumers are the most important entity on the market on the demand side. Understanding consumer activities and behaviours allows a given enterprise to tailor its offer to their needs and preferences more effectively than its competition.

In times when change is a permanent element of the functioning of economic entities it is very important to observe, pay attention to changes occurring in the areas and factors determining consumer behaviour. These activities allow one to notice the changes occurring in the behaviours of individual groups of consumers quickly, to identify consumption trends and to predict changes in recipients' decisions.

In view of the above, the purpose of this paper is to identify behaviours of the contemporary consumer determined by the occurring sociological and technological changes. The paper has a theoretical character. It is based on a critical literature review. It is an introduction to pilot studies currently being prepared in terms of the impact of social and technological changes on the behaviour of the contemporary consumer.

Consumer behaviour – introduction to the subject matter

One of the fundamental roles played by a man, apart from the role of a citizen and maker, is the role of a consumer. The notion of a consumer is used in different contexts and has not been defined unambiguously. In the economic theory, the term "consumer" occurs as a symbolic notion representing entities that create demand and serving to present the theory of choice (Kieżel (ed.), 2000; Yeoman, 2011).

A slightly different approach to the notion of "consumer" is presented by disciplines related to broadly understood marketing issues. This difference has its source in the modern marketing concept in which it is the consumer who is the starting point for undertaken marketing measures. Examining consumer needs, desires and wishes becomes in this case the most important element of producers' and sellers' strategies (cf. Barmola et al., 2010; Argyriou & Melewar 2011).

In the case of a consumer, it is key to address his behaviours, which is of interest to a number of disciplines, in particular economy, sociology, psychology, anthropology and management. These fields address various aspects of the purchasing process and consumption of goods and services.

The literature lacks one single definition of the term "consumer behaviour" (Schiffman et al., 1994; Assael 2004; Perner 2007). One can assume that this is ''(…) the processes involved when individuals or groups select, purchase, use or dispose of products, services, ideas or experiences to satisfy needs and desires'' (Solomon et al., 2013, p. 5). In turn, according to other researchers, consumer behaviour includes psychological and physical activities, together with their motives and causes, carried out by persons or groups in the cycle of consumption and implementation of their goals and values, as a result of achieving satisfaction and prosperity, taking into account individual and social effects of these behaviours (Antonides & van Raaij, 2003). There are also approaches to the term "consumer behaviour" which emphasize the role of external conditions of consumer functioning on the market and in the consumption phase for example: consumption behaviour means a coherent whole of measures, activities or steps related to making choices in the process of satisfying consumption needs in specified social, cultural and economic conditions. Consumer behaviours mean steps related to the consumption process, which is composed of a market (purchasing) behaviour and behaviour during the phase of consumption of the purchased product (Kieżel (ed.), 2010).

It is worth noting that consumer behaviours are influenced by their attitudes which are shaped by their own experiences or by opinions created by the environment, including contemporary media. Consumer attitudes mean relatively permanent likelihood of positive or negative position towards the object of the attitude, which may involve a specific or abstract thing, people or events. Attitudes may also be created on the basis of emotions and convictions which in turn are an object of experiences with the object of the attitude (Stasiuk & Maison, 2014). Therefore, attitudes involve an evaluation of something or somebody, while consumer behaviour means the way he acts in all phases of satisfying physiological and psychological (emotional) needs (see more: Madichie 2012).

Consumption and consumer behaviour are determined by a number of factors dependent of the consumer himself as well as his external environment (Grzega & Kieżel, 2017). The literature features many classifications thereof. One can identify e.g. a classification into internal determinants (i.a. disposable income, professional activity, property and savings, current level and structure of consumption) and external determinants, or a broader one which classifies consumer behaviour determinants into three equal groups: economic (i.a. income, supply, prices, marketing information, free time), social-demographic (social i.a.: social groups and reference groups, family, opinion leaders, culture and subculture; demographic i.a. (cf.: Walsh & Mitchell, 2005) age, sex, (Rahman, 2012) household size, consumer's marital status) and psychological (i.a. attitudes, personality, perception and emotions), let alone the supreme role of macroeconomic determinants (Kieżel (ed.), 2000).

It needs to be emphasized that globalization of economies, social and technological changes (expansion of the use of information and communication technologies) have a specific impact on consumer behaviour in the 21st century. The consumption itself is also subject to globalization processes, which is related to the homogeneity of needs of purchasers and in consequence to mainstreaming consumption models which spread on a pan-national scale and create a global consumption culture (Bywalec, 2010).

Social changes as contribution to the emergence of new trends in consumer behavior

The issue of social changes is examined mainly in sociology. Most generally, a social change is defined as a difference between the status of a social system at a specified time and the status of the same system at a different point in time (Sztompka, 2002). It features a broad scope and refers to transformations of institutions, norms, culture and social structure, thus everything that matters for social life and development. Three main trends can be identified among the changes of social nature:

- customization of consumption,
- fragmentation,
- paradoxical juxtaposition of opposites.

Customization of consumption is the main trend of the current changes. At the moment, households are made up of increasingly fewer members while there is an increase in the number of single-person households. Numerous consumption goods, such as the radio, the telephone or the car, have become individual goods while a few decades ago they were e.g. family goods.

The observable social changes are to a large extent associated with demographic changes around the world (United Nations, 2019). The practice of taking up employment by women outside of the house is developing and fathers get involved in the life of the family in a broader scope. Spouses plan and impellent tasks jointly, they spend their leisure time together. The type of a partnership marriage is appearing more and more often and is getting stronger (Kwak, 2005). A trend among young people to enter into partnership relationships, not marital ones is also noticeable. It is also observable that not only fewer people get married, but the average age of people entering into marriage is increasingly higher – the phenomenon of "postponing marriage" , occurs, the same trend of "putting off" applies to women having their first child .

The above changes lead to i.a. customization of consumption demonstrated in independence and individual preferences while consumers strive to be seen as autonomous persons. This direction of changes is proof that expressing oneself is gaining importance for consumers, which is evidenced among others by the more and more popular personalization of products (Tiihonen & Felfernig 2017). One of its aspects involves e.g. acquiring and possessing luxury and unique products (Janoś-Kresło & Mróz, 2006). A contemporary consumer also feels like participating in taking decisions on the product's features before its final production. For this reasons, interior designers, car manufacturers and clothing companies contact consumers in order to take into consideration their private preferences for an individual product. Having higher incomes, consumers have the need to stand out on the market. This customization also steps into the sphere of services, for example before choosing a face cream, a cosmetologist will examine the customer's skin.

An individualistic attitude is a privilege today, not an obligation. People lead independent lives, create their identity, and take decisions on norms and values. Observable and progressing psychologization of life has a great impact on customization (Szlendak, 2008).

Another change in the social nature involves fragmentation. This term has a number of meanings. Fragmentation is expressed among others in market sentimentalization (consumers live the current state of soul, they live the moment) and isolated experiences. Consumers as members of their households, encouraged by numerous promotional messages, play various roles, at the same time concealing their own "self", depending on what products they are using at that given moment. They are, according to a marketing concept of a specific product, creative managers, caring mothers, resourceful hostesses.

Segment-based production, that is the so-called Kotler's "mass customization" is also an expression of fragmentation (cf.Tseng et al., 2017). A decision on buying a certain good is often made before it is produced. This process is particularly seen on the furniture market or primary car market.

Mass media are also accommodated in the discussed trend. Specialist magazines and specialized TV channels are developing on the market the aim of which is to provide exciting stimulation. Brutal murders intertwine with adverts for sweets and an erotism-rich programme is followed by religious ones. A presenter dressed in a sports t-shirt and a tuxedo at the same time does not raise eyebrows anymore.

The last example concerns another change of a social nature, namely paradoxical juxtaposition of opposites. There are no role models or a single permissible style. Quite the opposite, pluralism and tolerance to all styles are present. A shift form few styles to numerous genres is observable. New matches and juxtaposition of opposites create new forms (Mruk, 2007).

Apart from the said main trends of changes of social nature, one needs to point out to a few additional elements which also affect the creation of new trends in consumer behaviour.

For example, it needs to be noted that the contemporary man suffers from a permanent shortage of time, and his life often involves pursuit of money. In mature societies consumers more and more often flag up problems with free time which result from work overload. This situation is associated with the increase in the demand for time-saving products and services such as dishwashers, ironing washing machines as well as ready-made meals, etc. As a consequence a new trend called personal outsourcing has emerged. It is expressed in an attempt to save time through the purchase of products and using services which guarantee it. It contributes to an increase in the demand for nanny services and services of domestic workers.

The permanent shortage of time entails negative consequences – it has an impact on i.a. the decline of values and of contact with loved ones as well as on simplifying everyday life through e.g. eating out, buying ready-made meals, using advanced technologies or shopping in shopping centres (Szlendak, 2008). Therefore, it can be concluded that consumers are interested in products that may be conveniently used and easily purchased.

Another observable change occurs in terms of caring for one's health. An increase in wealth as well as knowledge and awareness of societies contributed to changes in terms of health. In this framework consumers take up various activities aiming to improve their quality of life. More and more people use goods and services contributing to caring for one's looks and health. More and more households get different types of sporting gear, home-use medical devices or spa packages. This interest is accompanied by buying the so-called safe food and non-food products or eco products (Zaharia & Zaharia 2014; Trivedi et al., 2011), by a change in eating habits or by employing professional principles of healthy eating. Interest in a healthy lifestyle is growing which is confirmed by observable evidence – a lot of people do sports, use food supplements, take up stress-reducing activities, and care for their looks and wellbeing. One can find a broad offer of many producers on the market who use natural ingredients (Schena et al., 2015). Advertisements and names of products feature such terms as: "bio", "fit", "natural" or "healthy".

Popularity of food products coming from different sides of the world is constantly growing. The search for new taste sensations for consumers also means an interest in new forms of food services – they are associated with celebrating most important life events. Particular attention is drawn at the moment to companies specialising in organising wedding parties. Restaurants compete in innovative ideas for creating value for the customer. They offer original menu items, surprising locations and arrangements.

When analysing changes occurring in social behaviour the impact of the economic downturn also needs to be mentioned. Changes in behaviour refer here mainly to money-spending tendencies, ways for taking decisions on purchases, and the types and quantities of purchased products. During the economic downturn consumers are mainly focused on shopping in smaller quantities or on decreasing purchase costs (Zalega, 2013). We may then deal with the so-called phenomenon of smart shopping (por. Mano & Elliott 1997; Atkins & Kim 2012). In a situation of demand limitation in the period of economic recession consumers protected their achieved level of consumption adjusting shopping habits to the new situation. Smart shopping activities include rational planning of the household budget by buying necessary products at a low price ("expect more, pay less") (cf. Schindler 1998).. Meeting household needs occurs as a result of increasing shopping in discount stores, purchasing store brands, searching for information from various sources about cheaper products and special offers, buying products online, more careful preparation to shopping and avoiding compulsive shopping.

To sum up, one may refer to the findings of Euromonitor International, where it was concluded that at the social level we are dealing with changes concerning four main questions (Euromonitor). Firstly, it involves an aging society – in highly developed countries the number of people aged 65 and above is going up, which involves the increase in demand for care and medical services and there is demand

for products and services relevant to persons at this age. The second question involves the phenomenon of the rich getting richer – the income of well-off persons grows, and so do disproportions between them and poor persons. The rich getting richer contributes to an intensified feeling of threat and to a rise in the demand for products and services enhancing security. Migration – movement of people between countries permanently or temporarily - was named as the third issue (Sztompka, 2005; United Nations 2019).Migration often causes a change in consumer needs or consumer choices. The fourth issue involves cocooning – also called home-focused nature of consumption. This trend involves transferring consumption form public places to one's own home (Hines, 2009). Home is becoming a place for satisfying educational or recreational needs. The cause of home-focused consumption involves on the one hand being tired of constant changes and the need to be active, and better equipment of homes which allows for spending time in an interesting way. This trend is demonstrated in reinforcing the need for products that make the time spent at home nicer. Microsoft word in bits and pieces. This will cause the figure to be distorted during formatting and production. You have to use a drawing tool and import the figure to word.

Technological changes as contribution to the emergence of new trends in consumer behavior

The turn of the 20th and 21st century was the time of intense development of new technologies which have significantly influenced the change in the functioning of economic entities, which also applies to consumers.

The changes of a technical nature include in the first place surreality of means of stimulation and communication (Mruk, 2007). A consumer can, by means of media and technical tools, create his own world and play a role in it specified by him. Examples of such situations include creating a virtual community (computer games, thematic portals or fora where the participant can be whoever he wants) or cyber space (generally available flight simulators, PlayStation games, multidimensional film shows in the cinemas).

Other changes of a technical nature include also the so-called realisation of values (Euromonitor). In post-modernist times consumption is more important than production. People define their identity through what they buy and what they use and not like earlier by what they are or what profession they have. A post-modernist man is what he buys and what he can operate.

It is also not difficult to notice now the occurrence of the phenomenon of reversing production and consumption caused by another change of a technical nature – complexity (Mruk, 2007). The consumer is able to understand the significance and values that products entail only when he starts using them. This results in the pursuit to "handle" things becoming one of the most important objectives of a contemporary consumer (Zalega, 2013). It seems that products increasingly set conditions and ways of consumption (Mruk, 2007). A consumer must act according to product instructions in order to avoid trouble and to achieve a benefit. Creating additional benefits also leads to consumers' ever greater dependence on producers because without specific instructions and in certain cases even training they cannot fully use and enjoy the purchased products. Because of that, very often buyers are not able to use all functions of high-tech products since they do not have the relevant skills.
Thus, interest in services performing supplementary functions, that is those that enhance usability of products, grows. It needs to be emphasized that using the achievements of newest technology blurs the differences between fiction and reality as it allows living the experiences in a simulated reality. Virtual reality is universally available, which gives a possibility to create one's own world and one's own role in this world. Technology-saturated products on the one hand make it easier to satisfy needs and on the other expand their scope stimulating demand for new services related to the use of equipment.

A significant role must be attributed here to the development of the Internet. It is a modern and fastest developing medium, which provides an attractive environment for various social groups. Its virtues which include i.a. (cf. B. Świecka, 2008): interactivity, global reach (without territorial or time

restrictions), speed of communication, saving time, flexibility of action, low cost, large capacity of provided information or universality – mass nature bring benefits to all its users (Bajdak, 2003). More and more enterprises around the world have recognized the Internet as a very cost-effective tool for finding new clients, obtaining products, research, sale and information supporting business activity (Smoleń, 1996). Consumers also use the Internet more and more i.a. to shop (Dennis et al., 2009), to obtain information about products and services (also to look for opinions on them) and to compare products and services in terms of their price as well as quality (Kułyk & Michałowska, 2016). Among the advantages of online shopping consumers name saving time, lower prices, choice, easy access to information about products, possibility to do shopping day or night, diversified range of products, access to unique goods or numerous special offers (Akar & Nasir 2015). One also needs to note that some consumers fear shopping in this way or are reluctant to do so. This is determined mainly by the fear of receiving a good that is different to the one ordered, the lack of possibility to inspect and evaluate the product before purchasing it, high delivery costs at a low value of the purchase. Certainly, the trend of visualisation of consumption or e-consumption is strengthened thanks to the widespread use of mobile devices and benefits of using them.

The functioning of an electronic economy is the result of the development and widespread use of technology, including a rapid development of global networks. It is also defined as a digital economy, cyber-economy, e-economy or new economy that is a new paradigm of business. It is a virtual arena in which activity is carried out, transactions are performed and values are created and exchanged. Currently it is a phenomenon with a growing economic significance that changes the essence of carrying out economic activity.

E-commerce, which is defined in various ways in the literature, is a demonstration of electronic economy. It can be understood as using internet websites and electronic mail to conclude contracts (Stosio, 2002) or as transactions done by means of electronic communications, especially the Internet (Kocot, 2004). It is worth stressing that initially e-commerce served to facilitate transactions concluded by electronic means and tools, and only with the advancement of the Internet its mass scale development occurred. The development of e-commerce contributed to the advancement of electronic means of payment (i.a. virtual payment cards, prepaid cards, instant transfers, electronic money).

The development of information and communication technology has also contributed significantly to the widespread occurrence of the so-called collaborative consumption, the so-called sharing economy (Felsona & Spaetha 1978, pp. 614–624) (that is a consumption model based on free and paid sharing, reselling, exchanging and lending goods and services, which is a new trend in consumer behaviour (Botsman & Rogers 2010; Belk 2010; Gansky 2010; Mróz, 2013), as it makes it easier to connect the supply of and demand for "available" goods and services. The increasingly popular consumers' access to the Internet or social portals and having modern mobile devices to access online payment systems allows for initiatives undertaken as part of collaborative consumption (cf. John 2013)..

In the context of shaping new trends in consumer behaviour one can then assume that as part of the observable expansive development of technology three factors play the greatest role. The first of them involves the widespread presence of the Internet, which makes it possible to access information and all types of entertainment without the need to leave the house. Today thanks to the Internet one can watch the latest movies, read a book or press. Its strength is built up along with its reach. This leads to changes in the manner of manufacturing and distributing products, changes in communicating with buyers, demand for new services and at the same time an increase in threats related to cyber space. The second factor involves the so-called media on demand, which contribute to changes in modes of distribution of offered products.

The third factor includes mobile technologies, which made mobile phones become small telecommunication centres, since apart from the calling functions they also have features such as: taking photos, browsing the web, listening to the radio, making small payments or sat nav. Next to mobile phones, smartphones and tablets also enjoy popularity. Mobile technologies contribute to easier access to information, to changes in communicating with buyers as well as to demand for new

services. Modern communication technology ensures continuous flow of information throughout the world (Euromonitor).

Conclusion

Dynamic structural changes occurring in the environment create new challenges that the entrepreneurs find more and more difficult to face. Changes in consumer behaviour are the strongest factor affecting the way contemporary enterprises operate. A true challenge for enterprises is to realise the emergence of new trends in consumer behaviour, to understand them and use as inspiration for their development in the future (see more: Shaw, 2009).

New trends in consumer behaviour are a certain response to challenges coming from the environment and at the same time a way to adjust to new circumstances. There are seven main global trends. These include the aging societies, the rich getting richer, migrations, cocooning, media on demand, widespread Internet and mobile technologies. The first four trends concern social changes while the last three technological ones.

Abstract

In-depth analysis of literature in the field diversity management does not clear answer about the nature of the relation between workforce diversity and organizational goals. The article seeks, first of all, to verify the relationship between national diversity and organizational performance and, secondly, to examine the relationship between national diversity and the results obtained by the organizations composed of women and composed of men. The research objects were European football clubs. The main results of the studies disclosed that there is a positive relationship between national diversity and clubs' performance. This positive relationship between national diversity and clubs' performance pertains to both women's and men's clubs and it is stronger in the case of women footballers. However, the national diversity in women's clubs is smaller than in the men's ones. The article presents valuable insight – it calls into question the results of previous empirical studies concerning diversity management as the studies carried out on teams composed mostly of men can be different when women are the majority in those teams (and women constitute a higher and higher percentage of those employed).

Keywords: Personnel, Workforce Diversity, Performance, Management

Introduction

What can be observed in the literature is that for a long time management scholars have been discussing and analysing mainly the positive influence diversity has on the functioning of an organisation (Tsui *et al.*, 1992; Van der Vegt 2002; Allen *et al.*, 2007; Wu *et al.*, 2010; Wziątek-Staśko, 2012). The theoretical discussions are obviously present in the empirical studies which, as will be discussed at length in the further parts of this paper, not only do not provide a unambiguous confirmation of those ponderings but they are also characterised by relatively considerable simplifications both in the way of understanding diversity as well as in the assessment of the functioning of the organisation with the use of financial measures. What can be regarded as some way of overcoming those limits was an attempt at analysing diversity in the European football clubs. In such studies, the scholars focused, on the one hand, on footballers' nationality and age and, on the other, on the position in the table occupied as a result of football games (Tworek *et al.*, 2020). The relatively readily available and objective data concerning footballers' nationality and age and the explicitly shared goal for all the teams cause the authors of this study to regard the analysis of diversity in football clubs as a promising research direction. As a result, another dimension which can be studied is the football players' gender while another research problem is the functioning of the organisation composed of the representatives of one gender in the context of diversity resulting from various nationalities. This problem refers to the long-

lasting discussion on gender differences in the workplace (Linehan, 2001; Ng, 1998; Delfgaauw *et al.*, 2013; Wang and Hsieh, 2016), the impact of those differences on interactions in the workplace (Ibarra, 1992; Andaleeb *et al.*, 2004) as well as the differences in the hierarchy of values between women and men (Buckley *et al.*, 2000; Kallar and Hampton, 2000; Giacomino and Eaton, 2003). For instance, from among the collections of values such as family security, true friendship, mature love, freedom, equality, the world at peace, social recognition, national security, the world of beauty, women show a stronger preference for the world at peace than men. However, as regards such values as health, self-respect, inner harmony, sense of accomplishment, salvation, comfortable life, wisdom, pleasure and exciting life, in comparison to men, women demonstrate a stronger preference for pleasure and the weaker one for wisdom and exciting life (Giacomino and Eaton, 2003). Thus, there arises a question about how the differences between genders translate into the results obtained by less or more diversified organisations and/or teams. This question becomes even more important particularly in the situation, in which more and more women in the world take up gainful employment and, as if, enter the areas so far controlled by men (Ortiz-Ospina and Tzvetkova, 2017).

Therefore, the article seeks, first of all, to verify the relationship between national diversity and organisational performance and, secondly, to examine the relationship between national diversity and the results of football clubs obtained by the teams composed of women and men. In the first part of this paper, the authors present an overview of the empirical studies concerning both diversity in organisations and diversity in football clubs. Then, the authors discuss the results of the empirical studies on the relationship between national diversity and the organisational performance of football clubs based on the EUFA club coefficient and the comparable results of the studies obtained for female and male clubs. The final observations and conclusions referring to both the practice of management as well as to potential avenues for further studies finish the article.

Workforce Diversity and Organisational Performance – Literature Review

What can be found in the discussion about diversity management is the view that it brings many benefits to the organisation. It supports such areas as:

- the innovation of organisational behaviours,
- the increase in organisation adaptability,
- the increase in organisational learning,
- the increase in competitive advantage,
- the reconfiguration of human resources (Allen *et al.*, 2007; Wu *et al.*, 2010; Wziątek-Staśko, 2012).

However, although less frequently, management scholars also point to several weaknesses, among which are:

- communication problems,
- supporting social divisions and interpersonal conflicts (Tsui *et al.*, 1992; Van der Vegt, 2002; Wziątek-Staśko, 2012).

Is there then a relationship between organisation members' diversity and organisational performance? The authors of this paper sought the answer to this question within the frameworks of the empirical studies which can be classified into two groups. In one of them, the intervening variable, which combines diversity with performance, is used whereas, in another, the direct relationship between the studied variables is examined.

The following facts can characterise the studies belonging to the first groups:

- Diversity is most often studied with the use of the dimensions of the so-called primary identity (age, race, gender (Joshi and Roh, 2009)). The secondary and organisational identity

dimensions such as education or the diversity of the tasks are less frequently analysed (like in the study of Wu *et al.*, 2019).

- Among the intervening variables are organisational culture (Richard *et al.*, 2004), employees' morale (Webber and Donahue, 2001), innovation (Østergaard *et al.*, 2011), strategy (Pieterse *et al.*, 2013), perceived organisational justice (Blouch and Azeem, 2019) or task complexity (Hsu and Lawler, 2019).
- The relationship between the intervening variable and organisational performance is not empirically verified but its existence is assumed on the basis of the literature review (Stahl *et al.*, 2010; Joshi and Roh 2009).

What draws attention in the less numerous studies of the second group is that:

- the personnel view personnel diversity mostly as gender diversity (Bell *et al.*, 2011; Adler and Gundersen, 2007).
- like in the first group studies, organisational performance is determined through financial indicators (Cannella *et al.*, 2008; Carter *et al.*, 2010).

Generally speaking, the results of the meta-analyses of the relationship between personnel diversity and the performance of the organisations, selected on the basis of the articles published from 2000 to 2019 by means of such keywords as "diversity" and "performance", point to the fact that it this relationship is either weak poor or does not exist (Bell *et al.*, 2011; Schneid *et al.*, 2015; Tworek *et al.*, 2020). However, there are also studies which statistically confirmed the existence of this relationship. Nonetheless, they were not included in the meta-analyses because they do not include the typical keywords. It refers mostly to the statistically significant relationship between personnel's gender diversity and financial indicators disclosed in the report prepared by the Catalyst group (2004) and by Adler and Gundersen (2007). Besides, there are also such studies which demonstrate the negative relationship between personnel diversity and organisational performance (Hogan and Huert, 2019).

Summing up, the following conclusions can be drawn:

- What dominates in the literature on diversity management is the view that it has many positively assessed effects. Its weak points are less frequently discussed.
- The empirical studies of this relationship do not allow explicitly determining its character. Most of them indicate that it is non-existent or that it is weak. However, there are such research projects, in which its occurrence was explicitly found.
- Organisational performance is typically understood in a somewhat narrow way, i.e. it is associated with financial indicators.
- The studies on the relationship discussed in this paper are dominated by American authors, which situates them in a specific cultural context (Tworek *et al.*, 2020).

Thus, it seems justified to carry out the studies which would:

- consider, on the one hand, various dimensions of diversity and, on the other hand, effectiveness indicators which are more appropriate than the financial ones;
- pertain to the organisations characterised by at least considerable diversity of their personnel but which are at the same time free from discriminatory prejudices which always hinder the analysis of the studied variables;
- encompass organisations based in many countries.

To some extent, those requirements were fulfilled by the studies conducted by some of the authors of the present paper. The objects of those studies were football clubs whose position in the final table shows the effectiveness of their activities in a given year. Moreover, they are, to a significant extent, free from the behaviours characterised by prejudices and in their management, nearly all problems related to the management of a modern organisation occur (UEFA, 2014; Bolchover and Brady, 2006).

The studies were carried out on 166 football clubs belonging to ten leagues, divided into three groups: the group of the best clubs, the group of the average clubs and the group of the weakest clubs, based on the UEFA league coefficient. However, the focus was on two groups – the best one and the average one. Five leagues with the highest number of points within each group were selected. Two primary dimensions of diversity were studied, i.e. national diversity and footballers' age diversity whereas the results were the points scored in matches by a given club in the league in the season 2016/2017 as well as the standing of the club in the final table of this season. The analysis showed no correlation between national diversity and the points of the clubs and their positions in the final table (Table 1).

Table 1: Correlation between national diversity and club performance and club market value (Spearman[1] correlation test)

National diversity		Club points	Club position
LaLiga (Spain)	Correlation coefficient	0.163	-0.163
	(Two-sided) significance	0,492	0.494
	N	20	20
Premier League (England)	Correlation coefficient	0.292	-0.266
	(Two-sided) significance	0.211	0.257
	N	20	20
Bundesliga (Germany)	Correlation coefficient	-0.182	0.165
	(Two-sided) significance	0.471	0.512
	N	18	18
Serie A (Italy)	Correlation coefficient	0.368	-0.368
	(Two-sided) significance	0.110	0.110
	N	20	20
Ligue 1 (France)	Correlation coefficient	0.138	-0.144
	(Two-sided) significance	0.562	0.546
	N	20	20
First Division (Cyprus)	Correlation coefficient	0.279	-0.279
	(Two-sided) significance	0.334	0.334
	N	14	14
Ekstraklasa (Poland)	Correlation coefficient	0.481	-0.462
	(Two-sided) significance	0.059	0.071
	N	16	16
Liga I Bergenbier (Romania)	Correlation coefficient	0.383	-0.380
	(Two-sided) significance	0.177	0.180
	N	14	14
Premyer Liquasi (Azerbaijan)	Correlation coefficient	0.143	-0.143
	(Two-sided) significance	0.736	0.736
	N	8	8
Allsvenskan (Sweden)	Correlation coefficient	0.300	-0.312
	(Two-sided) significance	0.259	0.239
	N	16	16

***Correlation which is significant at the level of 0.01 (in a two-sided way); *correlation which is significant at the level of 0.05 (in a two-sided way). Source: Tworek et al., 2020*

[1] The interpretation of the r-Spearman's coefficient: 0-0.3 means that the correlation is weak or non-existent, 0.3-0.5 means that the correlation is moderate, 0.5-0.7 means that the correlation is strong, 0.7-1.0 means that the correlation is very strong.

As a result of the univariate analysis of variance for independent groups, it was also disclosed that the best groups are essentially more diversified than the groups belonging to the average leagues (Tworek *et al.*, 2020).

What was also shown in the course of the studies is that there is no correlation between footballers' age diversity and club performance. Only for the French league, the table position positively correlates with the footballers' age diversity whereas it correlates negatively in the case of the Cypriot league (Table 2). What is also attention-grabbing is lack of no significant differences between age diversity in particular groups for all the leagues (the Kruskal-Wallis test for k independent samples).

Table 2: Correlation between age diversity and club performance (Spearman correlation test)

		Club points	Club position
LaLiga (Spain)	Correlation coefficient	0.190	-0.205
	(Two-sided) significance	0.421	0.387
	N	20	20
Premier League (England)	Correlation coefficient	0.028	-0.033
	(Two-sided) significance	0.907	0.890
	N	20	20
Bundesliga (Germany)	Correlation coefficient	0.264	-0.286
	(Two-sided) significance	0.290	0.250
	N	18	18
Serie A (Italy)	Correlation coefficient	0.035	-0.035
	(Two-sided) significance	0.885	0.885
	N	20	20
Ligue 1 (France)	Correlation coefficient	0.452*	-0.462*
	(Two-sided) significance	0.045	0.040
	N	20	20
First Division (Cyprus)	Correlation coefficient	-0.574*	0.574*
	(Two-sided) significance	0.032	0.032
	N	14	14
Ekstraklasa (Poland)	Correlation coefficient	0.071	-0.176
	(Two-sided) significance	0.794	0.513
	N	16	16

	(Two-sided) significance	0.266	0.254
	N	16	16

***Correlation which is significant at the level of 0.01 (in a two-sided way); *correlation which is significant at the level of 0.05 (in a two-sided way). Source: Tworek et al., 2020*

If the best European leagues are most diversified nationally than others, it marks the direction for further in-depth studies on the diversity of footballers and club performance. It is so since every year UEFA publishes the club ranking which takes into consideration the points obtained by the club in the Champions League and the Europa League in the last five seasons. However, it should be stressed that it does not contain many of the clubs belonging to the best leagues – those clubs which did not manage to go through to the European matches. Therefore, a question may be posed: is the national diversity

of the footballers of the ranking clubs, i.e. of the best European clubs, related to their performance (their position in the table)?[2] Such studies are also appealing for they make it possible to consider the relationship between performance and one more dimension of primary identity – gender since UEFA also publishes the ranking of the best women's clubs. Therefore, it is possible to carry out an analysis which so far has not been reported in the literature. This is the analysis of the relationship between personnel diversity and the performance of the organisations of the same type when they are composed of only women or only men.

The Results of The Empirical Studies

The interesting and ambiguous outcome of the previous empirical studies on the relationship between national diversity and organisational performance, in which the European football clubs were analysed (Tworek *et al.*, 2020) was an incentive to reflect upon the research methodology used as well as to extend the scope of the aforementioned studies. As a result, the empirical studies had two objectives.

The first objective of the studies was to verify the relationship between national diversity and organisational performance. This is the same objective which was to be achieved in the previous studies (cf. Tworek *et al.*, 2020). However, the research method of verifying the studied relationship was different. The previous studies concerned European football clubs. Based on the UEFA country coefficient for five seasons from 2013/2014 to 2017/2018, five best leagues and five average leagues (totally 166 clubs) were selected for the analysis. In the studies, national diversity was related to the points obtained by the club in the league in the season 2016/2017 and the club position in the league table in the season 2016/2017. As aforementioned, the studies showed no significant correlation between the national diversity of the clubs and the results obtained in the league. However, the beast leagues turned out to be more significantly diversified nationally than the average leagues (Tworek *et al.*, 2020). European football clubs continue to be the research object in the present study. Moreover, no changes were made to the manner of measuring national diversity whereas the method of qualifying clubs for the analysis underwent changes. Instead of the UEFA country coefficient, the UEFA club coefficient was used. It is calculated on the basis of the results of the clubs for five previous seasons of the UEFA Champions League and the UEFA Europe League. As a result, in these studies, the position of each club is examined with reference to all several hundred UEFA clubs and not with reference to a dozen or so or several dozen clubs in the league. As a consequence, the manner of measuring club performance was changed. Instead of the result obtained by a given club in the league (points or the league table position), the result of the club obtained in competition with all other UEFA clubs was adopted. The position in the UEFA ranking is not tantamount to the number of points obtained in the ranking and therefore in the course of further analyses, club performance was assessed in two ways: the points scored by the club in the EUFA club ranking for five seasons and the position in the table of the UEFA club ranking in a given season.

Moreover, the second objective of the empirical studies was formulated. It was the verification of the relationship between national diversity and organisational performance depending on organisation members' gender. Many professions are clearly feminised (e.g. office employees, service sector employees, shop assistants, welfare employees or education sector employees) or masculinised (e.g. mechanics, electricians, IT sector specialists, or construction industry workers). Therefore, what is of interest is the issue of the relationship between national diversity and the organisational performance of the typically feminine and masculine organisations. Thanks to the analysis of football clubs, it is possible to study this phenomenon in the organisations of the same type, which differ in terms of gender.

In the course of the studies, the following hypothesis was verified: the greater national diversity of men/women footballers, the better club performance. In order to measure national diversity, the author adopted the following WZN national diversity coefficient (Tworek *et al.*, 2020):

[2] In this article, women footballers' and men footballers' age diversity is not examined.

$$\forall z \quad WZN = \frac{n_z}{N_z}, \tag{1}$$

Where: z – a given club,

n_z – the number of women/men footballers in the club of a different nationality than league membership,

N_z – the number of all women/men footballers in the club (women/men footballers whose total time spent on a football pitch in the matches during the season was not shorter than 90 minutes).

The coefficient has the following values: <0;1>.

The points scored by the club in the UEFA club ranking for five seasons (from 2014/2015 to 2018/2019) as well as the position in the UEFA club ranking for the season 2018/2019 were the measures of club performance. The research sample was selected in the following way:

- It was assumed (with reference to men's clubs) that the sum of the points scored in the seasons from 2014/2015 to 2018/19 should be over ten (the best club obtained 146 points). There were 90 clubs with such numbers of points. However, in the case of three clubs, the information concerning footballers' nationality was not complete and therefore finally 87 men's clubs were subjected to the analysis (the UEFA ranking included 450 clubs in the season 2018/2019). The source of data: https://uk.soccerway.com/.
- As regards women's clubs (in the season 2018/2019, the UEFA ranking included 112 clubs), the lowest number of points allowed was five (with the best club having 100 points). 58 clubs met this condition; however, in four of them, the data concerning footballers' nationality was unavailable. For this reason, the sample consisted of 54 clubs. The source of data: https://uk.women.soccerway.com/.

Table 3 presents the descriptive statistics of the women and men footballers' national diversity variable. The Kolmogorov-Smirnov test was performed and its results indicate that it is not possible to refute the hypothesis concerning the fact that the national diversity variable was distributed normally for both subgroups. The analysis performed by means of the t-Student test for the independent samples showed that the level of national diversity in men's clubs (M = 0.55, SD = 0.17) is statistically higher than in women's clubs (M = 0.30, SD = 0.20), t(139) = -8,07; p<0,001.

Table 3: Descriptive statistics for the national diversity variable

	N	Minimum	Maximum	Average	Standard deviation
Women's clubs	54	0.00	0.85	0.30	0.20
Men's clubs	87	0.08	0.86	0.55	0.17

Source: the authors' own study

The results of the analysis of the correlation between the level of national diversity and the club's position in the EUFA ranking (season 2018/2019) and the points scored for five seasons (from 2014/2015 to 2018/2019) in the ranking are presented in the next table (Table 4).

Table 4: Correlation between national diversity and club performance (Pearson's correlation test)

National diversity		Club points (seasons: from 2014/15 to 2018/2019)	Club position (season 2018/2019)
Women's clubs	Correlation coefficient	0.356**	-0.433**
	Two-sided) significance	0.008	0.001
	N	54	54
Men's clubs	Correlation coefficient	0.233*	-0.254*
	(Two-sided) significance	0.030	0.018
	N	87	87

***Correlation which is significant at the level of 0.01 (in a two-sided way); *correlation which is significant at the level of 0.05 (in a two-sided way). Source: the authors' own study*

It is easy to observe that there is a significant, though weak, positive correlation between national diversity in men's clubs and their performance. However, as regards women's clubs, what can be noticed is the significant moderate positive correlation between the studied variables.

Observations and Conclusions

The results of the studies disclosed the following facts:

- there is a positive relationship between national diversity and clubs' performance;
- this relationship pertains to both women's and men's clubs;
- the studied relationship is stronger in the case of women footballers;
- national diversity in women's clubs is smaller than in the men's ones.

It allows adopting the hypothesis formulated at the beginning of the research procedure. It means that the differences between the results of football clubs can be accounted for by the differences between the national diversity of women and men football players. However, it seems equally justified to account for national diversity by means of the diversity of the results obtained by a club. It means that the best, and at the same time the most diversified, football clubs[3] employ the best players who come from different countries. To put it differently, the great national diversity of footballers can be the "side effect" of looking for the best footballers who, as it is today, represent different countries. It also refers to women's football (although to a smaller extent) because women's football is continually less popular. For instance, in Germany, where the largest number of footballers in the world is registered (more than seven million), eight hundred thousand are women (https://www.dfb.de/fileadmin/_dfbdam/202541-bestandserhebung.pdf).

The stronger relationship between national diversity and women's club performance can mean that the contextual variables have some impact. One of them seems to be the organisational culture which, based on the studies conducted by G. Hofstede (2011), is not likely to be the same in men's and women's clubs. What is essential in women's culture is, among others, friendly interpersonal relations, equality, solidarity and work quality whereas men's culture values such aspects as assertiveness, justice (showing tenderness and care of interpersonal relations are less significant). It would, therefore, lead to the conclusion that it is easier to implement diversity, i.e. to overcome one's anxiety about diversity,

[3] The studies carried out on 166 European football clubs revealed a significant strong correlation (0.641) between the club's market value and the points collected at the end of the season.

in women's clubs. By the same token, it is easier to build what many football managers regard as a critical factor of success – the so-called team spirit which is "(...) a combination of harmony, brotherhood with the desire for good presentation not only as regards a single individual but also as regards the whole team. It's a combination of harmony, brotherhood and a desire to do well not only for oneself but for each other. In short, it's team spirit" (Bolchover and Brady, 2006, p. 201).

However, what should be highlighted is that team spirit does not equal friendship. It is stressed by a former football player who is now a commentator - A. Hansen, who holds that: "Human nature dictates that if you have 16 players, two coaches and a manager, they won't all like each other. But that doesn't matter as long as you can rely on each other. The only way you can do that is by having a great team spirit, so that when you go on to the pitch you have a bond and unity that holds you together" (Bolchover and Brady, 2006, p. 204).

However difficult it is to develop the team spirit in men's football, it would be erroneous to refute the hypothesis concerning the occurrence of at least a weak correlation between the results obtained and this strong collective will to win. This is supported by A. Ferguson, a manager with many years of experience who was in charge of Manchester United, who stated that: "Selfishness, factionalism, clique-ishness are all death to a football team. As a manager in football, I have never been interested in simply sending out a collection of brilliant individuals. There is no substitute for talent but, on the field, talent without unity of purpose is a hopelessly devalued currency" (Bolchover and Brady, 2006, p. 202).

Thus, it is possible to formulate a hypothesis that in football, the relationship between national diversity of women (men) footballers undergoes modifications as a result of the organisational culture (Figure 1).

Fig. 1: Organisational culture as a variable modifying (moderator) the relationship between diversity and performance.

Generally speaking, the more culture is focused on the care of others and their protection, obviously apart from pressure and the will to win, the stronger the studied relationship is. Furthermore, vice versa, the weaker it is, the less important the abovementioned cultural norm is.

Can the results of the studies have any significance for business entities? However different from football clubs they are, several fundamental similarities can be pointed out (Table 5).

Table 5: Some similarities and differences between football clubs and business organisations

Similarities	Differences
Football clubs and business organisations are: • the entities which have a hierarchical construction, • socio-technical entities, • open entities, • the entities which can perfect themselves, • the organisations whose management subsystem is embedded in culture and refers mostly to people, • the organisations whose management subsystem relies on the collections of indicators used for evaluation purposes, • the organisations which bring benefits to society and which, at the same time, maintain financial fluidity.	• Football clubs are limited-size organisations, *i.e.* they are small- or medium-sized whereas business organisations can be large-sized. • The average remuneration in the best clubs is many times higher than the remuneration in efficiently functioning business organisations (*e.g.* in FC Barcelona, it amounts to EUR 10 million). • Football clubs are more transparent than business organisations.

Source: the authors' own study

It seems that the similarities which were identified justify the formulations of the following observations:

- It appears that what may play an essential role in designing a business organisation which is free from prejudice is the concept of the so-called heterogeneous culture, based on the experience of the best women's football clubs. Not only does it support the reduction of disapproving behaviours but it can also be positively correlated with organisational performance. It should be stressed that it is of hybrid character for it combines the values of women's culture (people and interpersonal relations are important) and of men's culture (success, including financial success, is what is appreciated). Moreover, it is characterised by the atmosphere of openness which in both women's and men's football clubs is a commonly occurring phenomenon but it seems to be in short supply in business.
- In the light of these considerations, it seems justified to ask the following question: do business organisations achieve better results because their personnel is nationally diversified or do they attract the best employees from foreign countries because of better results? Therefore, the relationship between the personnel's national diversity and the performance of a business organisation cannot be so simple and obvious as some supporters of diversity management seem to claim. The mechanical increase in diversity, which is known in the practice of management, does not have to yield better results.
- In the case of the better treatment of diversity in the group of women as well as in the situation of management structure change (when women constitute a higher and higher percentage of those employed), the results of the studies can point to the certain relativity of the conclusions made so far concerning diversity management. It turns out that the results of the studies carried out on teams composed mostly of men can be different when women are the majority in those teams. Obviously, it is not the first case when the theory of organisation and management changes the face of changes in organisations and their environment.
- In the article the critical factor of success is the so-called team spirit – a combination of harmony, brotherhood with the desire for good presentation not only as regards a single individual but also as regards the whole team. Obviously, it is perhaps typical for football clubs but in other organizations there are different driving forces of increasing productivity. In the context of complex organization the management of workforce diversity will be always only one of many other success factors.
- The results and conclusions of this article may be an inspiration for people who have an impact on team formation, e.g. in the area of project management. In the context of the obtained

results, a project team composed of members from different countries will function differently if we form it from women or men. Gender is therefore an important factor of demographic composition of project team. Men and women differ not only in their levels of conformity, preference of power distribution and behavioural norms, but also in the manner how they (men or women) face the diversity of other project team members.

Measurement of Training Efficiency Rationalization and operationalization

Izabela ZIEBACZ

Jan Dlugosz University, Czestochowa, Poland,
Email: i.ziebacz@ujd.edu.pl

Abstract

Developing a method for the efficient management of training process in the organization, including the process of assessing training effectiveness, is a key challenge for most organizations. The quality of the method adopted for the assessment of the effectiveness of training is of particular importance in knowledge-based organizations, where the proper selection of training determines the compatibility of employees' competence to the tasks performed. The model described in this paper puts emphasis on the responsible participation of employees in the process of planning and evaluation of training results, which, in accordance with the adopted assumptions, is to increase the effectiveness of training. The purpose of this paper is presentation of the concept and the method which allows to measure the effectiveness of training.
Design/methodology/approach: The conceptual model was tested on a research and control sample, covering 200 full-time employees employed in a public sector unit in Poland. Qualitative data was collected through group interviews, one-on-one interviews, and secondary sources.
Findings: This study analyzes the usability of information from the most popular models, which allow to predict training effectiveness. It should be emphasized that this concept has also been positively verified and scientifically reviewed as well as positively tested in one of the public administration units. **Implications**: A model and related proposals combining self and collective effectiveness with efficiency trainings, team cooperation and organizational efficiency, solutions offered in this field can support HR staff in management and measurement of training effectiveness.

Keywords: education, human resources management (HRM), training efficiency measurement, training management.

Introduction

How does the study of training effectiveness look like in most organizations? For about 80% of enterprises, this process usually ends with completing a post-training response survey, in which HR department employees or a training company asks participants, to assess the content of the training, substantive preparation of the trainer, organization of the training, etc. The opinion of participants is often the basic information material used to assess the effectiveness of training . However, employee satisfaction with the course of training is definitely not a sufficient reason to justify expenses on training and understand the benefit to the company from the employer's perspective. Expenses on training should contribute to increasing work efficiency, improving its quality, increasing the level of achievement of business goals or building a competitive advantage of the company. Therefore, it cannot be denied that the assessment of the effectiveness of training is a necessary and even critical component of an integrated human resource management system, as it allows to determine what benefits the organization has gained and whether a given training investment was justified at all. The question arises why so many companies assess the effectiveness of training in a fragmentary way, stopping at assessing employee's satisfaction, or does not deal with the profitability of training investments at all? Undoubtedly, measuring the effectiveness of training is the most important parameter of the training management process, but at the same time it is the most difficult one to quantify. The models available on the market in most cases seem to present very universal solutions, but they do not clearly present methods of operationalization of the proposed concepts and usually have a very extensive structure. In

addition, taking into account organizational restrictions (time, competence, human, financial, etc.), the systematic generation of useful information about training turns out to be a great challenge.

All managers would like the money invested in employee training to bring immediate and real benefits. However, it is not always possible to quickly determine the results of training projects (Arasanmi, 2019). Unfortunately, the organization's common experience in the area of training is the lack of desired effects. This is because they are rarely evaluated (Janowska, 2010). A critical aspect of the training effectiveness assessment process is the high level of complexity of this process. Among the reasons why training is so difficult to assess, the following arguments are most often raised:

- The goal of the management is to increase the work efficiency, and not necessarily to increase the knowledge of employees. Nevertheless, effectiveness of learning is the basis for training evaluation by trainers,
- most activities focused on measuring the effectiveness of training, focus on processes related to learning rather than results (Cassidy et al., 2005, Leimbach, 2010).
- Poor work results are almost always only partly caused by the need for training.
- Training effects are often wasted because the skills and knowledge acquired during the training are not used at work (Loomba and Karsten, 2019).
- Only 10% of the knowledge acquired during training is used by employees, which means that the transfer of knowledge to the work environment is ineffective and uncontrolled (Latif, 2012).
- Direct business effects are difficult to analyze and capturing direct economic translation is complicated (employee knowledge and skills can be quite accurately determined using the development center method, for example). Additionally there are no simple tools to conclude that after conducting a given training, the company's revenues increased e.g. by 10% (PARP, 2009).
- Obsolete methods are used to measure and evaluate training (Stolovitch, 2007), (Bates, 2004), (Griffin, 2012). Additionally tools and expertise are not available in the organization to assess the impact of training on the organization's effectiveness.
- Literature on measuring efficiency is "extensive, non-empirical, not theoretical, poorly written and boring, moreover, it is characterized by constant discussion and very few empirical examples" (Skylar et al., 2010).
- It is a complicated, difficult process and often depends on a long-term perspective to which many managers have no patience (Griffin, 2012).

Often, among those involved in training, opinions are heard that training evaluation is difficult, time-consuming, complicated and,-
\ consequently, expensive. R. Griffin (2012) describes training evaluation as: "one of the most difficult tasks of training specialists". However, despite various restrictions, companies are forced to analyze the effects of training for management purposes.

Literature Review

There are many models available on the market. The solution that is the starting point for most is the D. Kirkpatrick model, which assumes the assessment of training at four levels: reaction, learning, application (behavior) and business effects. The J.J.Phillips ROI model completes the D. Kirkpatrick model with a fifth level assessment: estimating return on investment in training (ROI) - measuring profitability. In general, the overwhelming majority of models use Kirkpatrick solutions. The table below presents an overview of the methods available to measure training effectiveness.

Table 1: Overview of the most commonly used methods to measure training effectiveness

The four-level D. Kirkpatrick model	The most popular method of assessing training effectiveness, developed in the late 1950s, includes four levels of assessment: (1) level of response - at this stage, participants are asked if they were satisfied with training, training methods, trainer, housing conditions, etc., (2) level of learning - at this stage, an appropriate knowledge test is usually used to determine whether the training has resulted in retention of training content, (3) level of behavior - at this stage the degree to which the effects of training are transferred to the work environment is determined, (4) level of effects - at this stage changes in business results as a result of training should be demonstrated / the benefits of training should be estimated, e.g. absence, staff turnover, efficiency gains and cost reduction (Kirkpatrick, 2001).
The five-level ROI model of J.J.Phillips	J. Phillips's ROI methodology is based on a five-level model. In general, Phillips supplemented the D. Kirkpatrick model with a fifth level, which is the return on investment (ROI), i.e. the question of whether the monetary value of the results exceeds the cost of the training program. To calculate ROI, you need to convert the results from the fourth level into monetary values and compare with the costs of the program, taking into account all components of costs and benefits, also irrational. So, in a sense, it is a combination of the Kirkpatrick model and BCA (benefit-cost analysis). As part of the J. J. Philips model, two basic indicators: ROI (Return on Investment) and BCR (Benefits / Costs Ratio) are calculated. These indicators allow to answer the question about how much money the company will gain in exchange for the expenses that it incurred for a given training project or other project in the area of personnel management. The ROI method obviously has pros and cons. The single numerical value obtained thanks to it combines all the basic "components" of profitability and can be used to make comparisons with other investment possibilities. However, ROI has several major disadvantages. A difficult element here is isolating the impact of training from the effects of other factors on the company's results. Model critics also point at its complexity and the fact that it is mainly used by large companies (Phillips, et al., 2009; Steensma, and Groeneveld, 2010).
Model Leslie Rea	The author systematically presents the next stages of training, from identifying the needs of the company, defining the objectives of the training and designing the appropriate program, to the preparation of individual training sessions and estimating the effects of training. The author presents many techniques and methods along with procedures for conducting trainings and training sessions (Rae, 2006).
A model for assessing the knowledge and skills of Marshall and Schriver	. This is a five-stage model in which knowledge and skills are assessed separately. At the level one, the opinions and feelings of training participants are examined. On the second level written tests checking the knowledge of trainees are employed. At the level three, the employee performs standard tasks to verify the level of acquired knowledge and skills. The fourth level concerns the transfer of skills, and the fifth - the impact of training on the economic results of the form and return on training investment (Phillips, et al., 2009).

Six sigma	Method of managing the list at Motorola in the mid-1980s by B. Galvin and B. Smith. In statistics, sigma means the standard deviation of the variable. Six sigma means the distance between the set of deviations of the measure of central tendency (e.g., arithmetic mean for normal operations) left and right. The Six Sigma method was used for the first time in a production plant. Now it is increasingly expanding to such areas as e.g. sales and HR. Six Sigma is not only a technique, but also a philosophy (Pandey, 2007; DeFeo, 2000). Six Sigma means an organization's way of thinking in which people make decisions based on data, look for the root causes of problems, try to control changes, track leading indicators of problems to allow preventive measures. (Fleming, 2005).

The literature on the subject also provides other solutions that recommend, in addition to testing of the level of satisfaction of training participants, several other contexts / levels of training assessment. At the same time, many studies confirm the low level of implementation in practice of assessments at higher levels. Therefore, the question arises: what factors influence low level of application of available training effectiveness testing models? The rest of the work will present those imperfections in the training management process (methodical and operational) that are most closely observed in training practice

Methodological dysfunctions (on the example of the Kirkpatrick and Philips model - ROI):

- The hegemony of the Kirkpatrick model occurs despite fear of its actual effectiveness - for example, the degree to which the results of one level are correlated with the results of later levels is doubtful (Berge, 2008). The results of studies carried out by G. Alliger and E. Janak (1989) show a very low correlation between reaction and learning at r = 0.07 and a correlation between reaction and behavior at r = 0.05. A slightly higher correlation was found between learning and behavior (r = 0.13); learning and effects (r = 0.40) and behavior and results (r = 0.19).
- The D. Kirkpatrick model does not provide specific solutions for use by organizations at every stage of the training program evaluation, for this reason many organizations do not use the whole model, focusing only on the first two stages, to put it simply, the model lacks practical guidelines on how to develop results at individual stages (how to generate, process and analyze data).
- The relationship between training and long-term results is unfortunately often blurred. Additionally long-term effects have many causes, and training can be just one of them.
- Although the logic of the ROI method seems uncomplicated, the assessment of the elements included in the method (inflow of returns obtained from a given investment, outflow of resources balancing these returns to carry out a given investment, course of inflow of returns and outflow of resources in each of the future periods) is quite subjective (Boudreau and Casio, 2007).
- Typical ROI calculations allow you to focus on only one investment in human resources and do not allow you to consider how these types of investments interact with each other as an investment portfolio. Training can, for example, lead to a value creation that outweighs the cost of conducting it, but wouldn't this value be even higher if combined with relevant investments in individual incentive programs correlated with training results?
- In practice, objective determination of ROI is difficult and complicated, and the assessment is totally time dependent. If the ROI model includes the collection of post-training data, the effects of the training on which the data were collected should be extracted. This "cleaned" data must then be converted into monetary values in order to calculate the return on investment and identify specific benefits. It is also important to assign a value to the costs of a given

training program, as this also affects the final return on investment. In fact, when it comes to trying to measure ROI, the calculations are very complex. In addition, to correctly determine ROI of each part of the training process, a baseline should be determined so that you can try to measure progress / development / improvement (Little, 2014).

- The clear definition of ROI is quite problematic, as it always requires a reference to hard indicators; the problem of isolating training effects also arises.

These dysfunctions should be supplemented with an opinion on the currently fashionable six sigma method in HR applications. According to W. Cascio and J. Boudreau one of the basic limitations of this measure is the fact that in reality it is not a measure that can be transferred to HR areas. This is a performance indicator that can be used to monitor overhead costs for almost any job. As a result, talent focus is not included when emphasizing performance. Paying special attention to reducing costs usually leads to the rejection of "more expensive" decision-making options, which may be often more valuable. Thus, although this measure seems attractive financially, it cannot be used to reflect the value of talent (Cascio and Boudreasu, 2011) and the added value of investment in training.

Operational Dysfunctions

- D.Kirkpatrick, J.J.Phillips models are a multi-stage evaluation of training programs. The detailed analysis means that the assessment requires both a certain amount of time and the acquisition of skills in using the assessment scheme, in other words, the models referred to require a high level of HR department involvement and line managers at the stage of planning, implementation and assessment of training, which means their application value is perceived as doubtful, moreover, too much labor-intensive use of models reduces the effectiveness of potential benefits from their use, which is why in practice the evaluation is often performed fragmentarily.
- Measuring the effects of training at level four is very complicated, even in cases where organizations have clearly indicated which long-term goals should be achieved. It is difficult to provide convincing evidence of the causal relationship between the training effect and the desired effect. Therefore, level four is often overlooked.
- Deferred assessment of the effects of a single training, without the adopted reference object, often results in the loss of objectiveness of such assessment and its exaggeration.
- Along with the popularization of the D. Kirkpatrick model, questionnaire satisfaction / response surveys of training participants, by whom the program is evaluated, the manner of conducting training and the conditions in which it took place, became widely used. An important limitation of this tool (surveys measuring the response to training) is often the faulty design of questions in the survey (excess of open questions, too many questions regarding organizational and social issues during the training), as well as the way employees approach it, which is not fully specified (e.g. high assessment does not require further explanation or tendency to transfer non-substantive assessments to assess the usefulness of training, etc.). Naturally, employee opinions can be taken into account in organizing subsequent training projects, but they are difficult to consider as a sufficient basis for assessing the value of training (Andrzejczak, 2010).
- The survey (the basic tool used in stages I-III) does not provide measurable information, as most people tend to average or overstate the ratings even when they are anonymous. The survey rating can also be misleading, among others if the last part of the training was spectacular and effective, because it is this element of the training that is usually taken into account by the assessors (training participants).
- The expectations of training participants are emphasized too strongly in the model, which is formulated as if the training was to meet only the expectations of the participant as the sole beneficiaries of the training.
- The model does not solve the problem of the low level of employee responsibility for training results and their own professional development.
- The determination of the measurement effects of training programs is often unrealistic because of the difficulties in finding the right control group and the need for a large commitment of

resources. As a result, it is often unclear whether training was needed at all (Demerouti et al., 2011). It is recommended that control group assessments are included in models, which strongly involves all stakeholders of the training. As a consequence, a large amount of materials for analysis leads to a reduction of the most important stages of assessment due to system failure, it is also worth mentioning that in practice it is rarely possible to carry out the same observations and tests involving control groups several times (Bramley, 2001).

- Another important problem in obtaining important measurement data is the usuall reluctance to disclose issues regarding knowledge of a foreign language, real skills in operating IT and operating systems, technological skills, qualifications etc. The fact is, however, that it is not enough just to watch people and talk to them to assess their learning experience, or to determine that this type of activity is consistent with the company's goals.
- Activities that lead to employee development in terms of such abilities as soft skills, are difficult to translate into monetary values. Managers really do not know what is important to measure, how to collect and analyze data and synthesize the data obtained (Abernathy, 1999).
- The problem is the lack of proper and reliable diagnosis of training needs - very often the training becomes a form of "benefit" for employees, or an element of personnel marketing, rather than satisfying actual and strategically important training needs of the organization. Employees report their own training needs, based on their often subjective feelings, which are aggregated throughout the organization. As a result, the company collects training "whims" rather than needs (Sienkiewicz, 2010).
- The top management is responsible for the relevance of the training since the expenditure for training is an investment. However, in practice, even in small companies, tasks related to the organization of the training process are delegated to employees who quite often do not have appropriate competence to organize them.

Of course, it is impossible not to mention that there are many other reasons as a result of which training expenses are wasted, such as unclear expectations of the management, little support in the workplace, no monitoring of post-training effects, resource shortages in HR departments and competence deficits to implement new skills, no incentives to apply new skills and knowledge, training discomfort related to organizational change. To sum up, the training process should also be supported by activities that take into account environmental factors, such as appropriate information mechanisms on the results achieved and employee incentives (Berge, 2008).

MTE Model

The tool has been tested in organizational conditions in a government administration unit. The testing procedure consisted of comparing the effects of two systems of training management procedures, the procedure based on the D. Kirkpatrick model and the MTE model. It is worth adding that the overall concept of the model has been scientifically verified and has received positive implementation recommendations (Ziebacz and Tychmanska, 2016). The big challenge for implementing the tool was to develop a plan that would allow to minimize disruption of the workflow caused by the MTE testing. The basic assumption, at the stage of model development, was to lower labor, cost consumption, and complexity of the process of measuring training effectiveness compared to the methods and systems available on the market. Another important assumption was to increase employees' direct responsibility for effectiveness in the area of professional development. The issue distinguishing the presented model is that the measurement of effectiveness does not refer only to a single training, but to the entire portfolio of trainings implemented in the organization. The model assumes that measuring the effectiveness of a single training is inefficient, and often impossible in practice. Attempts to measure the effectiveness of a single training require a large commitment of resources (human, financial, organizational), as a result, the boundary between the effectiveness of training activities is often lost, and the actions taken are often end with superficial (surveys, knowledge studies) which are not sufficient in the process of measuring training effectiveness. For this reason, it seems more reasonable to analyze aggregated training results and the impact of all training activities on significant organizational variables, as well as to analyze the trend of these results. In other words, the MTE model examines the ratio of the effectiveness of the entire training policy in a company to the value of strictly business indicators. This approach, first of all, improves the measurement process, secondly makes it

more effective, thirdly - makes all bills more meaningful, and fourthly, allows you to capture trends in the development of indicators and their relationships. The problem of isolating training effects can be more effectively verified (estimated) on a macro scale than on a micro scale. When conducting analysis on aggregate values, the measurement of training effectiveness should be replaced with the term - estimation of training effectiveness. The model is presented in diagram 1.

Fig. 1: The MTE method

In most of the models for training effectiveness , recognition of training needs is the first stage of the process, and the starting point for its initiation is the observed problem diagnosed in the organization (lack of knowledge, skills, qualifications). In the "MTE" model it is assumed that the starting point - the information object, constituting the reference point for identifying training needs is the TASK.

Fig. 2: The structure of information objects used at the stage of identifying the training needs of the "MTE" model.

The structure of information objects in the model results from the assumption that "training" is of a short-term nature - this is not a so-called school education (from scratch). It is assumed that the employee has a certain base of knowledge and skills as well as professional experience that allows him to actively participate in planning of the development. During the training, the employee can obtain instructions focused on the assimilation of a specific activity.

Stage I: Identification and analysis of training needs.

The process of testing training needs, according to the concept of MTE, moderates the definition of training needs in such a way that it is possible to determine the level of satisfaction of these needs after training in relation to real information objects - i.e. tasks included in action plans for individual organizational units. It is worth emphasizing that the question about training needs without reference to tasks does not generate material for verification of training results at the level of behavior change, or at the level of impact on employee work results, and, consequently, on business indicators describing company's activities. In the "MTE" model, it is assumed that not only employees but also their superiors

can have information about the competency gaps of employees (ie potential areas for the development of employees' knowledge and skills). Managers monitor employees' work on an ongoing basis, noticing unsatisfactory results of implemented tasks and competence gaps that may be their cause. Observations regarding work effects are often accompanied by reflections on insufficient skills or knowledge of employees. The on-line training database enables the introduction of currently observed information - data on employee competence gaps, and thus the objectives to be developed during training. The supervisor supplements the database using the same form as the employee, i.e. he enters the same type of data. Entries in the "database" are at the same time the material for preparing the specification of the subject and scope of the training.

The entry in the electronic sheet of the individual record of training needs begins with the selection of tasks from the scope of duties in the workplace and a description of the activities that will, according to the employee, run more efficiently, as a result of acquiring specific new skills or specific knowledge. So training needs are defined in two forms:

a) as skills - the ability to apply knowledge to perform tasks and solve problems,
b) as an area of knowledge - a set of justified judgments (descriptions of facts, theories and principles of conduct) resulting from human cognitive activity (National Qualifications System as a tool for lifelong learning, Educational Research Institute). An example was prepared for an employee of the Human Resources Department, Training, Recruitment and Development Section.

The training need has been identified in relation to the job task: *"Preparation and implementation of development programs for employees".*

Table 2: Template of the form for entering data into the database /form- Training needs study sheet

STAGE I IDENTIFICATION AND ANALYSIS OF TRAINING NEEDS			
INSTRUCTIONS FOR FIELDS			
Select a task from the drop-down list. The list includes your tasks at the workplace	**Please enter the activities for which the knowledge and skills acquired during the training will be particularly useful**	**What KNOWLEDGE do you absolutely need to EFFECTIVELY perform the indicated action → task? (complete if applicable)**	**What SKILLS do you absolutely need to EFFECTIVELY perform the indicated activity → task (complete if applicable)?**
EMPLOYEE			
TASKS AT THE WORKPLACE	**Actions**	**knowledge**	**Skills**
Preparation and implementation of development programs for employees	Development of assessing competence Assessment Center / Development Center (AC / DC)	1) learning the Assessment Center / Development Center methodology: diagnosis, describing the competences tested, creating competence models; 2) learning the rules for conducting sessions: giving instructions, keeping records	1) acquisition of skills in the preparation of AC / DC sessions: development of tasks and assessment scale, session logistics 2) acquisition of skills such as: providing feedback, analysis and evaluation of AC / DC sessions (classification of information from the records, discussion of assessors), session reporting

The method of collecting information on training needs described above is based on the following assumptions:

1) the employee has the best potential to self-diagnose the competence gaps hindering achieving the planned results of actions,
2) the employee may describe the competence gaps he / she observes in such a way as to assess the level of filling these gaps as part of the training at the stage of training assessment,
3) the employee to whom the training initiative belongs is active in the assimilation of the training objectives he or she has articulated

The following analysis is needed for training, and the result is the output structure below.

Table 3: Template of the form for entering data into the database /form-

Training needs study sheet

INSTRUCTIONS FOR FIELDS	
Define the importance of increasing the indicated knowledge / skills in the context of the results of the task	**Please select the appropriate status of your training need**
SUPERIOR	
Choose priority	**STATUS according to the supervisor's assessment:** **P - to be implemented this year** **N- to be implemented within the next 2-3 years** **O- no implementation possible**

Stage II: Specification of the development service order and implementation of the training

Information on the status of entries made by employees regarding their training needs - is available on an ongoing basis, with the option of supplementing when new tasks appear and, as a consequence, new training needs. The employee receives feedback on the opportunities for development of the skills and knowledge specified by him under the programs offered by the employer.

Stage III: Assessment of the implementation of the training service

The employee evaluates the effectiveness of the training service provided twice:

- immediately after the training (using the freshness effect: comparing the "ordered" training results with the results obtained through the training),
- after 3 months from the end of the training, during which the employee should closely monitor his or her proficiency in the knowledge and skills acquired during the training in the context of the task being carried out,

In a situation where the assessment of training effectiveness is lower than 90%, the employee fills in the electronic sheet with the field: "list of deficiencies in the training results", entering the identified elements / aspects of the training that were covered by the program (order) and which were not implemented

Table 4: Sheet for recording individual training needs

III STAGE OF TRAINING EVALUATION			
INSTRUCTIONS FOR FIELDS			
Evaluate the benefits of training. Evaluate immediately after the training (on the day of the training or 1 day after the training)		Evaluate the benefits of training. Evaluate 3 months after the training, but no later than	Indicate missing elements in the training program if identified
EMPLOYEE			
Assessment of the training result immediately after the training (0 ... 100)%	Deadline for final assessment	Final evaluation of the training result / TRAINING EFFECTIVENESS (0 ... 100)%	List of deficiencies in training results

Stage IV: Calculation of costs and benefits of training programs

The benefits and costs of training programs are not assessed at the level of a single training. The effectiveness of the implemented training policy is assessed in the context of organizational efficiency and effectiveness. The interdependencies and dynamics of changes in training cost-time indicators and general organizational indicators will be analyzed. Information entropy can be used to study these changes as a measure of information. According to E. Kolbusz in the field of management, and especially when solving specific management problems, it is necessary to operate with a synthetic definition of qualitative information features, so that each configuration of the listed features falls within the definition of this term (Kolbusz, 1993). In an information system, specific information is useful if it is used to solve a particular management problem, or more precisely, when it is an important condition for solving a given management problem (Unold, 2004). Mathematically, entropy can be expressed using the following formula (Mitzenmacher, 2009):

Formula 1.

$$H = -\sum_{i=1}^{n} p_i log(p_i)$$

where:
H- entropy
pi - probability specified on set {1, ..., n}

This formula expresses, according to the formulation of C. Shannon himself, the entropy of the probability distribution (p1, p2, p3 ... ..pn), specified on the set {1, ..., n}. It defines the amount of information in terms of value (choice, indeterminacy). From this formula it follows that H = 0 if and only if one of the probabilities equals one, i.e. when all other probabilities are zero. This is a state of certainty. The statement that from a set of events that may occur with a certain probability, one actually occurred brings uncertainty to zero, which according to Shannon's formulation qualifies H as a reasonable quantitative measure of choice or measure of information (Mitzenmacher and Upfal 2009). The goal of management is to ensure the development stability of the enterprise by skillfully controlling its functioning in the environment so that it maintains its separateness on the one hand, and maintains an optimal level of exchange with the environment on the other. Energy resources (understood as competences) embodied in the employees who make up the organization must be regulated on the one hand in such a way that no excessive clusters of them are created anywhere that can "disrupt" it from the inside (excessive concentration of similar competences), on the other so that the organization has

energy resources enabling its current functioning and development as well as effective process management, also in adverse conditions. From this perspective, management is the implementation of compensatory processes - to achieve functional balance.

Conclusion

The issue of managing the effectiveness of the training process in contemporary, modern organizations operating on the market, forces widely understood changes, where individualization of the approach becomes a necessity. Individualization is understood as the implementation of tailor-made systems. It should also be accepted that testing the effectiveness of training is continuous and long-term process. Moreover, the lasting results of investment in training are visible only after a long time, and the results of such activities can also be typically non-material. It is therefore difficult to express them in a quantified form. The main problem is therefore to clearly define the extent to which the training has contributed to the observed changes. The greater achievement is showing the trend of change. In this context, developing a method for efficient management of the training process in the organization, including the process of assessing the effectiveness of training, is a key challenge for most organizations.

In the proposed model, training effectiveness is understood as the effectiveness of training policy. The assessment of the effectiveness applies to the time period - the period of time analyzed (e.g. year) and not a single training, which gives a more favorable perspective on the analysis of the effects / benefits of training processes for organizational needs. A significant difference, that distinguish the MTE method from other methods available on the market, concerns the study of training needs. The model replaces the information object proposed by various authors: "problem" with the object "task" - "task element - activity". From the point of view of the usefulness / value of the information obtained, it is better to start the training evaluation process not with "defining the problem", but with "the description of the activity / task, which according to the employee will run more efficiently after the acquisition of specific skills and knowledge." In accordance with the model assumptions, this structural change (shifting the emphasis in the process of identifying training needs and in the process of assessing training results to the tasks of employees) should promote the effectiveness of training. An equally important element of the method is the way in which data on the training needs of employees are collected. This helps to build the responsibility of trainees for the results (learning outcomes) obtained in the training process. The MTE model allows to increase the responsibility of trained employees by defining their needs and creating opportunities to verify the quality of training (comparison of expectations for acquiring skills and verification of their mastery by the manager). This is an important transition from passive participation to active mastering of the effects of training. The goal is responsible participation of the employees in the planning and evaluation of training results. Another aspect of this approach is to eliminate the negative connotation associated with the word "problem", the use of which can inhibit the motivation to actively participate in the training process, as well as to link the results (learning outcomes) with specific occupational tasks and their components (activities). The process of collecting information in MTE provides synthetic information for the specification of the subject training order, which significantly facilitates the work process of HR cells in determining training needs when choosing training companies, and also reduces the time needed to organize training. It also provides the basis for assessing the level of implementation of ordered results (learning outcomes) of a given training process. Therefore, it is possible to evaluate the implementation of the training policy and relate its effects to company-wide indicators.

Territorial Development Capacity of Small-Towns – Evidence from Poland

Malgorzata ROGOWSKA
Wroclaw University of Economics and Business, Wroclaw, Poland,
malgorzata.rogowska@ue.wroc.pl

Abstract

The study scrutinizes the development process of small-towns in polish region, Lower Silesia. It analyses an original data set of all 56 units. Final comparison considers period 2012-2018. The conducted analysis based on taxonomic method that examines local explanatory factors towards territorial aspect of development. The evidence from the research shows that small-towns can be important link in regional settlement unit, but only those who developed specific, endogenous functions performing well and respond to changing economic patterns and economic globalization.

Keywords: Territorial Development, Territorial Capital, Small-Town

Introduction

The rapidly changing patterns of development constantly challenge the economies of cities and town, which are exposed to the turmoil of economic globalization (Kaufmann, Wittwer 2019). In the recent publication the effects of economic significance and transformation is focused on big cities (metropolises). At the same time small-town are playing important role in regional economy, but did not received the same amount of scholar attention (Servillo 2017; Meili, Mayer 2017, Kaufmann, Meili 2019). In European urban system small and medium-sized-towns is currently inhabited by 27% of population and constitutes important links in network of towns and cities form many decades (Servillo 2017).

The present paper scrutinizes the territorial aspects of development of small-towns in one of Polish regions, Lower Silesia. The aim of this paper is also to investigate chosen endogenous, embedded factors of development of small-towns in Poland and the distance between development pace of small-town and big cities in Lower Silesia.

Modern paradigm of local and regional development shifted towards territorial concept of development strongly disseminated among scientist and in real-life activities. Economics theories such as New Economic Geography or endogenous growth theories don't grow into complexity of processes that determine social and economic activity concentration in territory. Theoretical concepts that respond to factors and relations that occur in place but cannot be simply quantifiable (social capital, networking) are local development theories (Capello 2008, 2009). Local development theories focus mainly on exogenous and endogenous potential. In the second mentioned group include well-known concepts such as: industrial district theory (Becattini 1989), bottom-up development (Stör, 1990), learning region (Lundvall 1992), and territorial capital theory. Support to these concepts can be found in institutional or evolutionary economics. In institutional economy approach to local and regional development "space" become a "territory", active participant of development processes, not only a concentration of land and capital. Its essence comes to connection of physical space with cognitive and social dimensions that represent inhabitants' approach to inhabited area and mutual correlations between inhabitants. All these aspects make up for "specificity of place" (Jewtuchowicz 2017, Sokołowicz 2015).

In modern conditions of increasing mobility and connections of population, goods and information there are some institutions responsible for development process that are located in space (although we could read a lot of virtualization of certain social and economic activities). In other words, certain activities and actors are embedded in local community and shaping directions of development local

units. Another aspect stressed in literature is proximity that seems to have important implication for local scale. From economic point of view embeddedness means that certain decisions are made under net of social connections that are connected with specific territory (some of this social connection can be also virtual). As a background to further analysis territory can be understood as a system of spatially concentrated and historically shaped technical, production, institutional activities performed and coordinated in various ways by various organizations: companies, research centres, the local community, economic organizations, etc., as also human activities more or less specific depending on the activities developed locally (Jewtuchowicz 2005). Each territory is a historical product, so it has its own time, dimension, and the shared past of the local community creates its culture, material heritage and determines its identity. Another important aspect at local level is diversity that emphasizes the local nature of development (defines its specific socio-economic, cultural and natural features) and the openness of local communities and their willingness to compare problems and exchange experiences (Jewtuchowicz 2005).

Territorial Keys and Endogenous Potential

Each policy's intervention must be adjusted to specific territorial condition. It means also supporting of relationship network, pursuit of dialogue, sharing power or promoting comprehension as different forms of governance based on reciprocity (Amin 1999).

In the current development policy (in which the EU regional policy plays an important role), territories are assigned a key role in development processes, which means assigning 'places' to specific sets of features that affect local development more than other places (Barca 2009; Noworól, Noworól 2018; Markowski 2011). According to the European Commission, 'territorial cohesion means ensuring the sustainable development of all places and ensuring that all citizens enjoy the maximum benefits from the resources of their territories. This means that diversity is transformed into an asset that helps in the extensive development of the entire EU (Rogowska 2019).

Territorial potential support by EU is connected with territorial capital that is in the literature understood as several territorial keys that can be used as linking issues in conducted research (Zaucha 2014):

- accessibility (in different scale by different model of transportation and communication),
- public service (access to public service);
- territorial assets (such as specificity of local environment, local system and innovation net, renewable energy, city revitalization),
- connection inside cities net.

In contemporary condition for development, including globalized economy, turbulent milieu, global environmental changes many small-town important factor for development perceived in endogenous potential, by relying on local tradition and identity, search for newcomers (inhabitants, entrepreneur, tourists)

Small-towns have great meaning in overall social and economic processes. Recently a lot of research is directed into the spatial aspects of its development. As an example of publications focused on small-towns development aspects in Poland can be mentioned: Marszał (2009), Poczobut (2009), Korcelli (2007).

Methodology

The conducted analysis based on taxonomic method with a hypothetical pattern of development, against which taxonomic distances of the examined objects are measured. The assessment of tendency of development process of small-towns requires defining indicators characterizing the main aspects related to local development (with the special emphasis put on territorial dimensions of development), which was the first step of undertaken analysis.

In the second stage of the research selection of diagnostic variables was conducted, aimed at creating the final set of diagnostic features. Throughout the study period, formal criteria were used, which are primarily associated with access to statistical data. It was considered that the selection of variables for the model should ensure measurability of features, comparability for all facilities and study periods, completeness of data for all towns in study periods.

It needs to be mentioned that the final data matrix was dictated by final possibility to access them. Not all the data that seems to be important in the conducted analysis was available in public statistic, not all of them were comparable in longer period. That is why finial analysis considers period 2012-2018. The main source of data used in conducted research was: Central Statistic Office in Poland, Local Data Bank, information and data presented on municipalities websites.

The set of potential diagnostic variables was then verified by means of statistical procedures. The selection of diagnostic variables took into account the fact that they should not show similarities in the sense of information about objects. The coefficient of variation was used to assess spatial variability. With this procedure the features for which it reached a value lower than the arbitrarily accepted size (10%) were eliminated. The second step was to eliminate those variables that easily reach high values. The asymmetry factor was used for this purpose (Ostasiewicz 1998).

Small-town in this paper can be understood as spatial unit with ≤10.000 inhabitants. In this case study it was 56 units. Additionally, in comparison the same procedure was conducted on big cities of Lower Silesia with certain status in polish self-government system: Legnica, Jelenia Góra, Wrocław, Wałbrzych. Further on the distance in development between these two groups of cities in Lower Silesia was measured. The third group of cities are middle-sized, but they were not included into the analysis. The first stage of building a synthetic measure of development for the examined cities was the division of diagnostic variables into stimulants and destimulants, followed by the transformation of the destimulants into stimulants. The next stage of the study was to reduce the established diagnostic features to comparability, which is a necessary condition for the description of complex social, economic and spatial phenomena using selected diagnostic variables. The diversity of such defined features entails the need to use multiple measuring units, which makes it impossible to create comparisons. The next step was to receive standardize variables, by using the following formula:

$$z_{ijt} = \frac{x_{ijt} - \bar{x}_{jt}}{s_{jt}}, \quad i = 1,2,...n\ , j=1,2,..., p\ , t=1,2,..l$$

z_{ijt} *- value of j-th variable after standardization*

x_{ijt} *- value of j-th variable of the i-th object in the year t*

$\bar{x}_{jt}$ *- arithmetic average*

s_{jt} *- standard deviation*

For such described set of features development pattern with standardized coordinates was created (assuming that it is maximum value for each of the features). Further analysis is conducted on the basis of distance and Euclidean distance. This method is widely applied to measure the distance between objects and can be expressed as:

$$d_{i0t} = \sqrt{\sum_{j=1}^{m} (x_{ijt} - x_{0jt})^2}, (i = 1,2,..,n, t = 1,2,..l)$$

The more the object similar to the development pattern (the less distant from it), the higher the level of the complex phenomenon of this object. To order the results obtained and to put them in the range [0,1], where values closer to 1 indicate a higher level of development of the examined object, the

Hellwig development measure was used. The last stage of the process was therefore to determine the development measure for each object according to the formula:

$$m_{it} = 1 - \frac{d_{i0t}}{d_{0t}}, (i = 1,2,..., n, t = 1,2,..l)$$

where:

$$d_{0t} = d_{i0t} + 2s_{dt}, (i = 1,2,..., n, t = 1,2,..l)$$

s_{dt} *- standard deviation of development measure for each object*

The measures of development have been constructed in such a way that they meet the following properties (Bąk 1999):

• the higher the level of the complex phenomenon, the greater the value of the measure of development,
• the values of the development measure are included in the range [0; 1], where the measure calculated for the development pattern is 1.

Based on the results obtained, due to the level of the phenomenon under study, a ranking of communes was broken down into 4 typological groups, guided by the assumption that in group I there will be groups with the highest development rate, while in group IV the least developed communes.

Case Study. Data Description

The paper explores differences in local development conditions of small-towns in comparison to main cities of the region. Research presents Polish case based on Lower Silesia region. It is located on southwest part of country and in its history, we can observe periods where the small-towns (with industrial background) were basis for region's development. Now there is a tendency to decreasing meaning of small-towns on the map of the region. According to statistic office level of urbanization of this area reached level of around 70% in 2016 (Statistic Office in Wrocław 2016). Settlement system of the region is well developed, hierarchical, represented by a large network of various sizes cities, with an extensive network of connections, with a clearly shaped centre, which is the city of Wrocław. The largest population inhabits cities in the range from 10 to 100.000 it is almost 25% of the urban population of the region (Korenik 2009). Smallest towns (less than 5.000 inhabitants) are usually stable and long-lasting link of settlement net. Share of smallest unit in overall number of cities shaped under level 34% at the beginning of 21th Century with population 3,9% (Zaniewska 2011). In Lower Silesia at the same time the population of small-towns was around 9,4% of population of the region, and in comparison, lost 6,3% of inhabitants (between 1995 and 2008). Some small-towns lost population because the structural changes and the collapse of industrial functions. Towns that despite negative demographic tendencies during that period increase its population were units located near main city, Wrocław. Towns that showed highest drop of inhabitants were located in peripheral areas but with dominant function (touristic and resort towns).

Table 1: Main indicators included in conducted analysis

Name	Characteristic
Demographic load factor	This indicator represents social sphere of development. The ratio of the number of people in non-working age to the number of people in working age. Important especially on the background of demographic tendencies (aging society, migration of young people)
Percentage of population using the sewage system/gas installation	Strongly connected with quality of life in urban unit. Illustrate infrastructural gap
Value of contracts / decisions on co-financing projects with EU funds	Counted for 1 inhabitant. Can be perceived as a factor connected with human capital and quality of local

	authorities. Stimulant that gives us potential information of investments focus on improving quality of life in local units
Newly registered entities from professional sector	Newly registered entities from sectors: finance, insurance, real-estate, professional, science, technical activity. Illustrate economic sphere of development and level of development of non-tangible assets (knowledge, creativity)
Number of small entities	Small entities are the most important unit in local economy. Usually connected with local tradition, strongly embedded
Green areas/ Recreation zones	Surface of green areas to total areas of a city/town. Territorial asset, connected with quality of life in local unit
Newly completed dwellings	Newly completed housing areas *per capita.* Represents quality of life, the higher the number there is a possibility to increase inhabitants
Long term unemployment	Number of long term unemployed in total amount of unemployed inhabitants. Represents economic condition in local unit, is one of the factors responsible for hindering social and economic growth, lowering living standards
Women councillor in local authorities	Women councillor in local authorities to total number of councillors. Illustrate social aspects of population, can show community approach to policy making process
Water consumption in households	Water consumption in households / thousand inhabitants. Illustrate environmental aspect of development, can represent social awareness to environment protection and sustainable development
Length of bicycle paths	Length of bicycle paths in reference to total area of municipality. This indicator can represent quality of life in local unit, possible chance to develop tourism in urban unit
Road accessibility	Territorial aspect of development. Represents average time to reach local unit by car from main city of the region
Investment expenditure	Investment expenditure *per capita*. Represents economic sphere of development
Total number of entrepreneurs	Represents economic sphere of development, include small, embedded entities with less then 9 employees

Source: own elaboration.

Results from Research

Conducted research is presented in following tables. Table 1 shows the results on the differences across small-towns in terms of development capacity (with special impact place on territorial aspects) To understand better the result it is important to known certain condition that are created in each unit. For the purpose of this paper only general conclusion will be presented.

Table 2: Synthetic measure of development and position of small-towns in 2012 and 2018

Source: own calculation based on Local Data Base

General results from analysis can formulated as follows:

- Small-units in both years are located far from created ideal development pattern;
- the best results reached small-towns located in closes neighbourhood of main regional city (located in agglomeration area), where we can observed some positive aspects of development (people and location of foreign investors): Siechnice, Kąty Wrocławskie;
- second group of municipalities that have reached good results in research are small-towns that evolve some specific functions (taking into consideration regional cultural and environmental heritage in this group appeared cities such as Karpacz, Szklarska Poręba, Polanica Zdrój, well known for its spa facilities and touristic attractiveness);
- the worst results achieved municipalities without specific functions, with rural tradition and units located on periphery of the region (in mountain areas), with poor accessibility (by car or train). In this group we can point for example Międzylesie.

Table 3: Synthetic measure of development and position of big cities in 2012 and 2018

Municipality	Synthetic measure of development in 2012	Position in 2012	Municipality	Synthetic measure of development in 2018	Position in 2018
Jelenia Góra	0,9753	3	Jelenia Góra	0,9817	2
Legnica	0,9784	2	Legnica	0,9744	3
Wrocław	0,9918	1	Wrocław	0,9893	1
Wałbrzych	0,9631	4	Wałbrzych	0,9669	4

Source: own calculation based on Local Data Base

In comparison the same procedure of research was conducted to main cities in the region. All of then reached high value of synthetic measure of development in both years, with leading city Wrocław.

Conclusion

The carried-out analysis contributes to findings what are the main factors for development in small urban units (less than 10.000 inhabitants) and what are their capacities to support the development on endogenous, unique factors. Additionally, the research shows what is the distance between main, well-developed cities of the region in comparison with small units. Small-towns are important unit in development process of whole region that is also supported by European Unions regional policy. In Territorial Agenda for European Union (2011) it is strongly mentioned that new connection between different categories of cities needs to be created, mainly to overcome increasing polarisation of social and economic space.

The main findings from research showed that mainly small-towns that are located in close location to big city or inside functional areas (agglomeration areas) tend to gain good results. The data used in analysis are chosen to show new assets and phenomenon that should be important in development of modern spatial units, respond to contemporary challenges. Some small-towns of the region can be definitively described as areas in stagnation (in research period does not decrease the distance to development pattern, but opposite to that, increase it). The results can be also interesting in broader scale, especially in conditions where we should look at small units as an opportunity to spread social and economic processes outside of concentrated metropolitan areas.

Another conclusion concerns regional settlement system. Lower Silesia has a polycentric urban system with a clear dominance of the central city of Wrocław. Its basic disadvantages include significantly advanced fragmentation and enclave. Individual urban centres, especially small ones have only local significance, but they are not important in the region's economy. The settlement network itself in the region is very diverse in terms of both size and space. In recent years we can observe intensification of its transformation processes and the growing importance of the metropolitan system of Wrocław and the urbanized area of Jelenia Góra. Despite these trends, still small-towns in the region are an important element of the socio-economic space of the region. However, to maintain their position, it seems necessary to undertake diversification of the development process in the region's space.

The Author is aware that the findings generated from the analysis should be generalized with caution given do specificity of Polish conditions, but also believes that it can help to understand better the conditions for endogenous development and importance of small-towns in settlement network.

Acknowledgement

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Resumen

Este artículo analiza el efecto de los intermediarios en el establecimiento de acuerdos de cooperación para la innovación. En el estudio se analizan tres roles de intermediación (financiación, concertación y regulación) y se distinguen cuatro tipos de cooperación en función del objetivo perseguido (desarrollo de actividades de I+D; adquisición de conocimiento incorporado en maquinarias y equipos; trasferencia tecnológica y consultoría). El análisis es realizado con base en los microdatos derivados de la octava Encuesta Nacional de Innovación de Colombia (EDIT VIII), la cual recaba información sobre el comportamiento innovador de las empresas manufactureras durante el periodo 2015-2016. Los resultados muestran que el relacionamiento con actores intermediarios favorece el establecimiento de acuerdos de cooperación entre las empresas y diversos acores del sistema de innovación, y que el efecto de los mismos depende del rol de intermediación que ejerzan.

Palabras Clave: Innovación, roles de intermediación, cooperación, objetivos de cooperación

Introducción

La actividad innovadora de las empresas ha sido un campo ampliamente abordado en la literatura. Enfoques como la innovación abierta (Chesbrough, 2003) y los sistemas de innovación (Cooke & Cardiff, 1992; Lundvall, 2005; Malerba, 2005) han permitido comprender la innovación como un proceso cooperativo, por lo tanto, la actividad innovadora en la empresa se entiende como un proceso que trasciende más allá de sus capacidades y recursos internos, por lo que para innovar, se requiere de la articulación de la empresa con otros actores de su entorno.

Son varios los estudios que se han enfocado en entender los procesos de cooperación de las empresas desde diferentes puntos de vista. Barge-Gil (2010) analiza no solo los determinantes de la cooperación, sino las características de las empresas que hacen de la cooperación la principal estrategia de innovación. Weber & Heidenreich (2016), por otro lado, se han concentrado en analizar la importancia de cooperar para fortalecer capacidades internas de innovación. De igual manera, uno de los elementos clave que se han estudiado ampliamente en la literatura son las relaciones de cooperación entre actores específicos de un sistema tales como empresas, universidades, instituciones del estado, entre otras (Ranga, Mroczkowski, & Araiso, 2017; Weber & Heidenreich, 2017).

El estudio de los intermediarios y su rol en los procesos de innovación, ha generado grandes aportes en la literatura de la última década, permitiendo entender de una forma mucho más amplia la

dinámica alrededor de los procesos de cooperación para innovación. En este sentido, se han desarrollado investigaciones para entender de qué manera éstos intermediarios, facilitan el establecimiento de procesos de cooperación, eliminando o reduciendo fallas del mercado y del sistema (Shou & Intarakumnerd, 2013), e incluso deficiencias en capacidades internas de la empresa (Du, Wu, Lu, & Yu, 2013).

A pesar de que existen gran cantidad de aportes en la literatura sobre los diferentes tipos de intermediación, son muy pocos los estudios que han analizado "como la intermediación afecta el desarrollo de acuerdos de cooperación de empresas con otros actores de su entorno con miras a desarrollar procesos de innovación." Cantner, Meder, & Wolf (Cantner, Meder, & Wolf, 2011), han intentado aproximarse a dicha relación a través de la percepción sobre la importancia de los actores intermediarios..

Llegar a comprender con mayor profundidad el rol de intermediación y establecer un análisis en función de objetivos de cooperación como los ya mencionados anteriormente, constituye un aspecto sobre el cual todavía no se ha profundizado en la literatura; Y por lo tanto dicho análisis, constituye el foco de esta investigación. De esta manera el objetivo principal de este trabajo de investigación es: *analizar el impacto que tienen los intermediarios sobre el establecimiento de acuerdos de cooperación orientados a diferentes objetivos*.

Para llevar a cabo el análisis propuesto se hará uso de los daos derivados de la *Encuesta de Desarrollo e Innovación Tecnológica (EDIT)* aplicada por el *Departamento Administrativo Nacional de Estadística (DANE)* en Colombia. Esta encuesta sigue los lineamientos internacionales contenidos en el Manual de Oslo – Tercera Edición – y es similar a las aplicadas en el contexto europeo (*Community Innovation Survey*). No obstante, una particularidad del cuestionario aplicado en el contexto colombiano es que no solo indaga sobre los actores con los cuales cooperan las empresas para innovar, sino que además pregunta sobre los objetivos específicos que se persiguen con dicha cooperación (por ejemplo, desarrollo de actividades de I+D conjunta, consultoría, adquisición de conocimiento incorporado en maquinarias y equipos, etc.). Adicionalmente, la encuesta indaga sobre si las empresas han establecido relaciones con actores del Sistema Nacional de Ciencia, Tecnología e Innovación como apoyo para la realización de actividades de innovación en lo que respecta al uso de servicios de intermediación relacionados con el acceso a fuentes de financiación, la concertación, divulgación o debates acerca del estado de la Ciencia, la tecnología e innovación, o aspectos asociados a la regulación en materia de derechos de propiedad intelectual e industrial.

Se resalta entonces, la relevancia que toma la variable dependiente de este estudio dada su novedad dentro de la literatura. En este sentido no se aborda la cooperación desde un punto de vista genérico, sino desde un nivel más detallado, resaltando precisamente los objetivos de cooperación en: investigacion y desarrollo (I+D), transferencia tecnológica, consultoría, formación y adquisición de maquinaria y equipo.

Teniendo en cuenta lo anterior, este articulo busca contribuir a la literatura general sobre innovación en dos vías: en primer lugar, analiza de manera más detallada el rol de los intermediarios, destacando diferentes roles que estos actores pueden llegar a tener dentro de un sistema de innovación de acuerdo con hallazgos en este campo de literatura. En segunda instancia también se pretende contribuir, con un análisis de la variable cooperación, no desde un punto de vista general o cooperación con actores específicos como tradicionalmente se ha abordado en la literatura, sino que se centra en analizar la cooperación y su orientación hacia diferentes objetivos como: I+D, consultoría, adquisición de maquinaria y equipo, y finalmente, transferencia tecnológica y adquisición de tecnológica.

Teoría E Hipótesis

Intermediación Y Cooperación

El rol que cumplen los intermediarios es de gran importancia dado que ayudan a reducir las fallas del mercado (Agogué et al., 2017; Aquilani, Abbate, & Codini, 2017), y más recientemente fallas del sistema (Chunhavuthiyanon, 2014; Shou & Intarakumnerd, 2013). Desde el punto de vista de fallas de mercado, se encuentran dificultades para acceder a recursos de financiación para el desarrollo de actividades de innovación, o la dificultad en la provisión de infraestructura. Y por otro lado, fallas del sistema que se orientan más a la identificación de socios adecuados para cooperar y el establecimiento de acuerdos de cooperación entre las empresas y sus socios.

La literatura refleja múltiples categorías de intermediación, sin embargo esta investigación contempla los roles desde un punto de vista amplio donde se destacan tres tipos de roles: ~~E~~(e)n primer lugar, están los *intermediarios de financiamiento* (Hayter, 2016; Wang & Wang, 2017), los cuales inyectan recursos económicos a procesos de innovación especialmente en etapas precompetitivas. En segundo lugar, los *intermediarios de concertación* (Agogué et al., 2017; Dossou-Yovo & Tremblay, 2012), mayormente enfocados en la generación de espacios de discusión, dialogo y articulación en torno a procesos de innovación, facilitando la cooperación para el desarrollo de iniciativas interinstitucionales e incluso facilitan el desarrollo e implementación de políticas públicas (Chunhavuthiyanon, 2014; Wang & Wang, 2017). Adicionalmente, otro de los tipos de intermediario encontrados, son los de *regulación* (Howells, 2006), los cuales se orientan al establecimiento de parámetros de control sobre determinados procesos de innovación en las empresas. (para una facil lectura, usar la letra cursiva para resaltar los tipos de intermediarios)

Intermediarios de Financiación

Las políticas de apoyo a la innovación se han orientado tradicionalmente a corregir las fallas de mercado, estableciendo esquemas de financiación que disminuyen los riesgos asociados a los procesos de innovación. Tal rol de proveer y distribuir recursos económicos ha sido asumido por los intermediarios de financiación.

Como ya se ha mencionado, la existencia y operación de algunos intermediarios financieros~~,~~ representa un mecanismo con el que tradicionalmente muchos países han buscado superar barreras financieras estructurales en los procesos de innovación (Polzin, von Flotow, & Klerkx, 2016) en pro del desarrollo económico. Una característica que resalta en estos esquemas de financiamiento estatal es que normalmente se busca apoyar a una gran cantidad de actores en función de iniciativas que se relacionen con elementos prioritarios de política pública. De esta manera se alcanzan mejores indicadores de distribución de recursos y al mismo tiempo se fomenta la necesidad de cooperar para acceder a dichos recursos económicos. Por lo tanto, la existencia de intermediarios de financiamiento puede facilitar el establecimiento de esquemas de cooperación empresarial que dinamicen el sistema a través del fortalecimiento de procesos de innovación (Lichtenthaler, 2013).

Las actividades de financiamiento direccionadas a través de intermediarios de carácter público, pueden variar según el contexto, sin embargo, gran parte de dicha financiación se orienta en gran medida a etapas precompetitivas de los proyectos de innovación e incluso fases previas al lanzamiento de productos al mercado, donde es posible que la financiación tenga como destino actividades de investigación y desarrollo. En este panorama, el apoyo financiero se orienta a fomentar la cooperación con actores de carácter científico, como universidades, centros de investigación, parques tecnológicos etc. (Vega Jurado, Manjarrés Henríquez, Castro Martínez, & Fernández de Lucio, 2011).

> *H1: El rol de los intermediarios de financiamiento favorece la cooperación de las empresas con actores orientados al desarrollo de actividades de I+D y la transferencia tecnológica.*

Intermediarios de Concertación

Los intermediarios de concertación apoyan la creación de redes y el enlace entre una gran variedad de actores dentro de un sistema de carácter regional o sectorial. La función del intermediario se destaca en torno a la generación de posibles conexiones entre diferentes actores e incluso personas dentro de un ecosistema de innovación (Agogué et al., 2017).

Uno de los aspectos que se destaca en la literatura como factor clave para el establecimiento de acuerdos de cooperación es grado de confianza existente entre los diferentes actores del sistema (Cantner et al., 2011). Tal confianza se puede llegar a generar a partir de espacios de concertación previos, donde los posibles socios pueden llegar a interactuar, intercambiando información y generando lazos importantes, antes de iniciar procesos de cooperación.

Tal proceso de concertación y de generación de lazos de confianza es mucho más relevante cuando la cooperación se orienta: 1) al relacionamiento con actores que fortalezcan los procesos internos, a través de actividades de consultoría, 2) la adquisición de activos específicos, 3) al desarrollo de actividades que por su naturaleza comprometen el core de la empresa, o son susceptibles al comportamiento oportunista de un tercero. Ejemplo de lo anterior, son el desarrollo de actividades de I+D, o la transferencia tecnológica, donde se necesitan vínculos de confianza previos para que la cooperación misma sea dinámica y se facilite el proceso de negociación. A diferencia de otros procesos como la adquisición de maquinaria y equipo donde, en términos generales, el relacionamiento puede regularse fácilmente a través de transacciones de mercado y las salvaguardas que los contratos ofrecen en este sentido.

> *H2: Los intermediarios de concertación favorecen los procesos de cooperación orientados a la I+D, transferencia tecnológica y consultoría.*

Intermediarios De Regulación

La función de este tipo de actores es fortalecer el sistema estipulando condiciones o parámetros adecuados en las que deben gestarse cierto tipo de procesos tales como: certificaciones de funcionamiento y operación, aspectos relacionados con la propiedad industrial y derechos de autor (Bardhan, Demirkan, Kannan, Kauffman, & Sougstad, 2010; Lichtenthaler, 2013).

La literatura resalta que en la medida en que la empresa apuesta por mejores procesos de innovación, su sector puede llegar a demandar mayores estándares en función de calidad o certificaciones especiales según su sector, de tal forma que el relacionamiento con intermediarios de regulación puede llegar a tener algún tipo de importancia como una orientación de los procesos de cooperación. De la misma manera los intermediarios de regulación pueden llegar a tener un papel importante en procesos de protección de la propiedad industrial, por lo que la articulación con este tipo de actores puede llegar a fomentar procesos de cooperación orientados al desarrollo de actividades de I+D.

> *H3: Los intermediarios de regulación favorecen los procesos de cooperación enfocados especialmente a actividades dirigidas a la adquisición de maquinaria y equipo e I+D.*

Descripción del estudio Empírico

Los datos se obtuvieron de la 8va Encuesta de Desarrollo e Innovación Tecnológica (EDIT) aplicada a empresas de la industria manufacturera y recopilada por el Departamento Administrativo Nacional de Estadística (DANE) en Colombia para el período 2015-2016 (Dirección de Metodología y Producción Estadística - DIMPE 2018). El objetivo principal de la encuesta es explorar los factores que influyen en el comportamiento innovador de las empresas, es decir, las estrategias, los incentivos y las barreras a la innovación, el alcance de las diversas actividades de innovación y examinar los resultados y los efectos de la innovación. El método para recopilar datos fue un censo; se incluyeron todas las empresas que cumplen con los criterios de selección determinados por el DANE.

La base de datos de la encuesta presenta información de 7947 empresas, sin embargo, las preguntas relacionadas con la cooperación para innovar, así como el relacionamiento con actores intermediarios son respondidas únicamente por las empresas orientadas a la innovación, es decir, aquellas que realizan esfuerzos para el desarrollo de actividades de ciencia, tecnología e innovación. Lo anterior conlleva a que se disponga para el análisis solamente de 2007 registros válidos, conformados por la submuestra de empresas orientadas a la innovación. Esta selección puede generar un posible sesgo en el análisis, por lo que se hace necesario aplicar un procedimiento que permita controlar este aspecto (Heckman, 1990)

Debido a que las variables dependientes se calcularon teniendo en cuenta si la empresa ha cooperado o no con actores externos en el marco de distintos objetivos (variables dicotómicas), los modelos de selección lineal de Heckman no son adecuados para ajustarse a los datos debido a violaciones de supuestos tales como la continua variable dependiente normal y distribución de errores (J. Heckman, 1990; J. J. Heckman, 1976; Wyszynski & Marra, 2018). Bajo este escenario, los modelos de selección de *muestra de cópula* semiparamétrica son opciones para lidiar con estas restricciones teóricas. El *modelo de cópula* permite una gran flexibilidad al especificar las distribuciones conjuntas y marginales de las ecuaciones de selección y resultado, y tiene la propiedad de mantener la consistencia de los estimadores, incluso a la hora de eliminar las suposiciones distributivas. Los modelos de selección de muestras semiparamétricas utilizan técnicas de máxima verosimilitud para la estimación simultánea de todos los parámetros del modelo, asegurando estimadores consistentes,

eficientes y asintóticamente normales (Marra & Wyszynski, 2016; Wojty's, Marra, & Radice, 2016; Wyszynski & Marra, 2018)**.**

Como los modelos de selección de muestras semiparamétricas utilizan técnicas de cópula para determinar la asociación entre las ecuaciones de selección y resultado, se incluye una estimación de parámetro θ en la función de cópula para medir la dependencia entre las dos funciones de distribución acumulativa marginal. A pesar del hecho de que θ no se puede interpretar directamente, se puede transformar en el rango de τ de Kendall en el intervalo [-1, 1] produciendo una interpretación general para todas las cópulas. En la investigación presentada, las familias de cópulas implementadas en modelos de ajuste fueron normales, Joe y Ali-Mikhail-Haq (AMH). Las pruebas de selección de modelos se realizaron con los criterios de información de Akaike y Bayesian para comparar entre modelos, y las pruebas de Vuong y Clarke para comparar dos modelos de la competencia, es decir, sobre la elección de la cópula. El ajuste y la prueba del modelo se realizaron en R (R Core Team 2019) con el paquete SemiParSampleSel (Marra & Wyszynski, 2016; Wojty's et al., 2016; Wyszynski & Marra, 2018)**.**

La variable dependiente de cooperación, es abordada en la encuesta a partir de ocho variables dicotómicas (SI/NO) y reflejan diferentes objetivos de cooperación, de los cuales se analizarán aquellos que en la literatura reflejan un mayor grado de profundidad, por lo que en este trabajo solo se abordan: la cooperación para investigación y desarrollo (COOPID), cooperación para adquisición de maquinaria y equipo (COOPMAQ), cooperación para consultoría (COOPCONS), y cooperación para transferencia tecnológica (COOPTTEC).

Tabla 1: Listado de variables

DEPENDIENTE (COOPERACIÓN)		
Variable	**Descripción**	**Valores**
COOPRD	Cooperación para investigación y desarrollo	SI=1; NO=0
COOPMAC	Cooperación para adquisición de maquinaria y equipo.	SI=1; NO=0
COOPTTEC	Cooperación para Transferencia Tecnológica	SI=1; NO=0
COOPCONS	Cooperación para Consultoría	SI=1; NO=0
INDEPENDIENTE (INTERMEDIACIÓN)		
Variable	**Descripción**	**Valores**
INTFIN	Relación con intermediarios de financiamiento	SI=1; NO=0
INTREG	Relación con intermediarios de regulación	SI=1; NO=0
INTCON	Relación con intermediarios de concertación	SI=1; NO=0
CONTROL		
Variable	**Descripción**	**Valores**
PERPROCTI A	Porcentaje del personal dedicado a ACTI	%
INTRD	Intensidad en I+D	Ordinal
IMPRD	Importancia del Departamento interno de I + D	SI=1; NO=0
IMPPROD	Importancia del Departamento de producción	SI=1; NO=0
IMPSAL	Importancia del Departamento de ventas y mercadeo	SI=1; NO=0
SECT	Sector económico	Baja; Media-Baja; Media-alta; Alta
SIZELOG2	Tamaño: Total personal ocupado promedio (Cantidad de Empleados)	Logaritmo natural

Fuente: Elaboración de los autores.

Con respecto a la variable independiente de intermediación, la encuesta aborda la relación de las empresas con actores específicos, por lo cual se han construido las variables de Intermediarios de financiación (INTFIN), a partir de la agrupación de aquellos actores que son los encargados de implementar políticas o programas públicos de fomento a la innovación y que son reconocidos en el sistema principalmente por ser fuente de financiamiento para el desarrollo de proyectos de innovación , tales actores son: COLCIENCIAS, SENA, Ministerios, PROEXPORT – PROCOLOMBIA, BANCOLDEX y Cámaras de Comercio, los cuales reflejan un Cronbach's Alpha de 0,700; la variable intermediación de regulación (INTREG) está compuesta por actores que cumplen el rol de regulación de aspectos como la propiedad industrial y derechos de autor, entre otros, dichos actores son: la Superintendencia de Industria y Comercio SIC, ICONTEC y la Dirección nacional de derechos de autor, cuyo Cronbach's Alpha es de 0,530. Finalmente, para los intermediarios de concertación (INTCONS) se han agrupado actores que, por su naturaleza, fortalecen las actividades del sistema a partir de la generación de espacios de concertación y dialogo de cara al desarrollo de acuerdos de cooperación y la generación de aportes importantes para el desarrollo de políticas públicas, esta categoría está compuesta por: Centros Regionales de Productividad, Consejos Departamentales de Ciencia y Tecnología (CODECyT) y Comisiones Regionales de Competitividad presentan un Cronbach's Alpha es de 0,637.

Como variables de control se han trabajado la Intensidad en Investigación y Desarrollo (INTRD), la importancia percibida en los departamentos de I+D (IMPID), producción (IMPPROD) y ventas y mercadeo (IMPVEN), adicionalmente se abordan otras variables como: el tamaño, expresado como el logaritmo natural del número de empleados (SIZELOG2); el porcentaje del personal vinculado a actividades de ciencia, tecnología e innovación (PREPROCTIA) y la variable sector, que será analizada a partir de la distribución de los registros de actividad económica de las empresas encuestadas, según la clasificación sectorial de la Organización para la Cooperación y el Desarrollo Económicos (OCDE) que está conformado por: baja tecnología, baja y media tecnología, media y alta tecnología y alta tecnología.

En este sentido, la especificación del modelo econométrico es el siguiente:

$$COOP_i = INTFIN + INTREG + INTCON + INTRD + IMPRD + IMPPROD + IMPSAL + PERPROCTIA + SECT + SIZELOG2$$

Donde i = COOPID, COOPMAQ, COOPTTEC, COOPCONS

Resultados

La tabla 2 presenta los resultados del modelo de regresión. De forma general, los resultados muestran que el uso de intermediarios favorece los procesos de cooperación entre empresas y otros actores del sistema, lo cual es coherente con lo señalado previamente en la literatura. En el contexto analizado los intermediarios están cumpliendo con su rol de fomentar el desarrollo de acuerdos de cooperación entre las empresas y diferentes tipos de actores.

El análisis también refleja que los diferentes tipos de intermediarios ejercen un efecto distinto en función de los objetivos perseguidos en los procesos de cooperación.

En relación a la variable de intermediación de financiación, se encuentra que su importancia para el sistema es fundamental. El efecto positivo que tiene este tipo de intermediación sobre los acuerdos de cooperación orientados a objetivos como: I+D, transferencia tecnológica, consultoría, e incluso adquisición de maquinaria y equipo, es significativa. Por lo tanto, se respalda la hipótesis 1.

Con respecto a la variable de intermediación de concertación, se demuestra que existe un impacto positivo sobre los diferentes tipos de orientación de la cooperación, siendo significativos al 0.01%

sobre la cooperación orientada a la I+D, consultoría y transferencia tecnológica, Por lo tanto, se respalda la hipótesis 2.

Finalmente, la variable de intermediación de regulación refleja al igual que las otras variables independientes tener un impacto positivo sobre los objetivos a los cuales se orienta la cooperación, siendo los más significativos la consultoría y adquisición de maquinaria y equipo. De esta forma al no existir una relación significativa entre las variables de intermediación de regulación y el objetivo de I+D, y al sí existir una relación significativa entre las variables de intermediación de regulación y la adquisición de maquinaria y equipo, se respalda parcialmente la hipótesis 3.

Al observar las variables de control, se puede encontrar que la intensidad tecnológica del sector tiene efecto significativo sobre cooperación para I+D y consultoría; para el cálculo de dichos resultados se utilizó la variable de empresas de alta tecnología como variable de referencia. Sin embargo, los datos sugieren una posible relación de u invertida, que refleja que en la medida en que la intensidad tecnológica va aumentando, es más probable que se fomenten acuerdos de cooperación, pero en casos donde la intensidad tecnológica es muy alta comparado con las empresas de baja tecnología, no hay una diferencia significativa dado a que estas empresas tienen tantas capacidades internas, que no necesitan buscar tantos acuerdos de cooperación. Lo cual representa una posible explicación, que requerirá mayor análisis y que puede representar una oportunidad para profundizar de manera empírica en este foco de investigación.

Con respecto a otras de las variables de control, específicamente las que tienen que ver con la importancia que la empresa atribuye a sus diferentes departamentos como fuentes de ideas para la innovación como: investigación y desarrollo, producción, ventas y mercadeo; esta variable relaciona de cierta forma el perfil innovador de la empresa en términos del origen de sus actividades de innovación. Los hallazgos reflejan que aquellas empresas que perciben mayor importancia en fuentes internas para innovar como el departamento de I+D, se encuentran más orientados a una cooperación para I+D y consultoría, e incluso de transferencia tecnológica que refleja una significancia al 0.01%. Mientras que aquellas empresas que perciben mayor importancia en el departamento producción, reflejan una cooperación más enfocada en la compra de maquinaria y equipos, lo que posiblemente se puede atribuir a la intención de una empresa por mejorar sus procesos de producción a partir del uso de equipos y maquinaria cada vez más avanzados o de mayor capacidad de producción.

Discusión y Conclusiones

El primer hallazgo general, es que en función de la naturaleza o del rol principal de los actores intermediarios, existe un efecto positivo, pero al mismo tiempo distinto, sobre las diferentes orientaciones de cooperación.

En primer lugar, los resultados han permitido respaldar la hipótesis 1 y 2, que tienen que ver con el impacto positivo de los intermediarios de financiamiento sobre la cooperación orientados al desarrollo de actividades de I+D y la transferencia tecnológica; y el impacto positivo que los intermediarios de concertación sobre los procesos de cooperación orientados a la I+D , la transferencia tecnológica y consultoría. Por otro lado, se ha respaldado parcialmente la hipótesis 3 que expresaba un impacto positivo de los intermediarios de regulación sobre la cooperación enfocada a la I+D y la adquisición de maquinaria y equipo, sobre la cual solo se consiguió demostrar el impacto mencionado sobre la adquisición de maquinaria y equipo, pero no sobre la I+D.

Limitaciones Y Oportunidades Para Futuras Investigaciones

Este estudio representa una aproximación basado en la función o rol de los intermediarios, en este punto se han asociado cierto tipo de actores del sistema de innovación con su rol principal dentro del sistema de innovación (financiación, regulación y concertación), sin embargo, en algunos casos existen actores que pueden llegar a cumplir una o más funciones dentro del sistema y por lo tanto resultaría difícil ahondar en detalle realmente el tipo de interacción que se generó entre un intermediario específico y cada una de las empresas que suministraron información en la EDIT. En este sentido, el análisis de los actores agrupados por su rol principal y respaldado por el Alpha de Cronbach, representa una solución interesante que proporciona un elemento a fortalecer en futuras investigaciones.

La Encuesta de Desarrollo e Innovación Tecnológica (EDIT) en su mayoría es diligenciada mayormente por empresas manufactureras que desarrollaron procesos de I+D por lo que el análisis de las variables de este estudio se puede fortalecer a partir del desarrollo de una encuesta ad-hoc que desarrolle a mayor profundidad los análisis descritos en esta investigación, sin embargo, el uso de las copulas ha sido fundamental para poder llegar a generar los resultados ya proporcionados.

Es importante resaltar la importancia de profundizar aún más sobre el rol de los intermediarios, dado que la revisión de la literatura desarrollada para esta investigación refleja aún debilidades en la forma de categorizar dichos roles, dicha circunstancia parte del mismo concepto de intermediación que actualmente es concebido de diferentes formas, y que por lo tanto incide en la forma en la que se orientan las diferentes clasificaciones que actualmente existen en la literatura. En este sentido se identifican claramente dos enfoques, uno donde se perciben a los intermediarios como organizaciones de enlace entre otras organizaciones del sistema, y otro donde los intermediarios aparte de cumplir con dicho rol, también pueden cumplir con un rol de cooperación directa en términos de cooperación o en calidad de proveedores directos.

Agradecimientos

Los autores agradecen el apoyo financiero recibido por Colciencias a través del proyecto "Dinámicas de Innovación en Contextos Poco Intensivos en I + D: el caso de la Industria Manufacturera Colombiana" (121577657885), así como también el apoyo recibido en el marco de la convocatoria Colciencias-DAAD a través de la subvención 58955.

The Macroeconomic Stabilisation Pentagon as An Indicator of The Competitiveness of The Country. A New Approach to Comparative Analysis

Abstract

The main goal of this article is to assess which of the surveyed countries is the most competitive. The authors employ an innovative method similar to the Macroeconomic Stabilisation Pentagon (MSP). Analysis of basic macroeconomic indicators as sources of competitive countries can create an alternative to the existing assessment index for economies. Macroeconomic stability is reflected in five indicators: economic growth rate, unemployment rate, inflation rate, budget balance relationship to gross domestic product (GDP), and the relationship between current account balances and GDP. Such an analysis can supplement current studies, which use the method of MSP exclusively for countries undergoing transformation. In this case, the 'magic' pentagon will be applied to countries that reside at the top in terms of competitiveness rankings.

Keywords: Competitiveness, Comparative Studies Of Particular Economies, Macroeconomic Stabilisation Pentagon

Introduction

Competitiveness is one of the most important economic problems. In the literature, *competitiveness* initially referred to the microeconomic level and the performance of enterprises. However, the focus on competitiveness has not just been a microeconomic phenomenon. Today, economic literature studies competitiveness at the enterprise, regional, and country levels. *International competitiveness* denotes a complex phenomenon and is defined in various ways. It is both a relative and subjective concept (Dobrzanski 2018).

Definitions of *competitiveness* can be divided into two main groups. The first relates to the country's place in the global economy and the results achieved in foreign trade. In this case, *competitiveness* is defined as the ability to maintain and even increase market share (e.g. Dollar and Wolff 1993; Hatsopoulos et al. 1988). The second group of definitions places a much stronger emphasis on the overall or staple results achieved by the national economy (e.g. Fagerberg 1988, Porter 1990, Landau 1992, Tung 2008, Porter 2008).

Two global reports serve to assess international competitiveness. First of them, Global Competitiveness Report, published by the World Economic Forum (WEF) defines competitiveness as "the set of institutions, policies, and factors that determine the level of productivity of a country. The level of productivity, in turn, sets the sustainable level of prosperity that can be earned by an economy" (Schwab 2009). Second, World Competitiveness Yearbook, published by the International Institute for

[1] Corresponding author

Management Development's (IMD) defines competitiveness of nations as a "field of economic theory, which analyses the fact and policies that shape the ability of a nation to create and maintain an environment that sustains more value creation for its enterprises and more prosperity for its people" (Garelli 2005). Both reports indicate a huge role in improving the competitiveness of factors such as stable macroeconomic situation and the effectiveness of the state.

There is no single, generally accepted definition of *international competitiveness*. It is a dynamic, multi-faceted, and multi-dimensional category. Creating stable economic foundations is the basis for increasing competitiveness. Therefore, in further analysis, the authors define *competitiveness* as a country's ability to maintain a stable macroeconomic position. The main goal of this article is to assess which of the surveyed countries is the most competitive.

In literature there are several studies regarding MSP is applied mainly to transition economies (Misala and Bukowski 2003, Matkowski 2005, Gotz 2011, Zuchowska, 2013). In this article authors propose a new approach to comparative analysis using an innovative method similar to the Macroeconomic Stabilisation Pentagon (MSP).

MSP as an alternative measure of competitiveness

The Macroeconomic Stabilisation Pentagon (MSP) concept was popularised by Kolodko (1993). Macroeconomic stabilisation manifests itself in the following five characteristics, which secure its sustainability: gross domestic product (GDP) growth rate, unemployment rate, inflation, budget balance as a percentage of GDP, and current account as a percentage of GDP. MSP consists of five triangles. The area of the first, triangle a, called the real sphere triangle, is delimited by appropriate parameters expressing the rate of change in the real product and unemployment. The area of triangle b, which can be defined as the shortageflation (or slumpflation) triangle, is delimited by the unemployment rate and the dynamics of inflation. The area of triangle c, the budget and inflation triangle, results from the dynamics of inflation and the budget balance. The size of triangle d (financial equilibrium triangle) depends on the amount of the budget and current account balances. Finally, the area of triangle e, called the external sector triangle, is defined by the variability of the current account balance and the dynamics of the global product (Kolodko 1993).

Figure 1 depicts the GDP growth rate in Poland from 1991 to 2015.

Fig. 1: GDP growth rate in Poland (1991-2015)
Note: GDP – economic growth rate
U – unemployment rate
CPI – inflation rate (consumer price index)
G – relation of the budget balance to the gross domestic product
CA – relation of the current account balance to the gross domestic product
Source: (Kolodko 1993).

Theoretically, a country whose results were at the vertices of the MSP pentagon would have achieved full macroeconomic stabilisation. In fact, this situation is practically impossible to achieve. According to the MSP idea, the area of the pentagon would then be equal to one (MSP = 1 = 5x0.2). The total area of a pentagon can be determined by the following formula:

$$PSM = [(\Delta GDPxU) + (UxCPI) + (CPIxG) + (GxCA) + (CAx\Delta GDP)]xK,$$
$$where\ K = \frac{1}{2} sin72° \cong 0{,}475$$

The tops of the MSP are scaled such that the further away from the centre a specific point is, the better the macroeconomic situation of the country is. In the case of the axis of unemployment and inflation, the scale is decreasing because these variables are destimulants. The MSP method evaluates the area of the resulting pentagon: the larger the area is, the more favourable the macroeconomic stabilisation is.

The indicators in the MSP model are closely linked to one another. Changing the value of one of the adopted parameters leads to a change in the surface area of the two adjacent triangles. The MSP model allows for isolating internal (msp1) and external (msp2) factors. The msp1 field stands for macroeconomic stabilisation that mainly depends on internal factors. This field includes the sum of the fields of the triangles a, b, and c. Conversely, the msp2 field indicates a stabilisation situation that depends primarily on external factors. This field includes the fields of the triangles d and e. This

analysis provides the opportunity to show the progressing stabilisation or the deepening destabilisation of the country.

When conducting the analysis based on MSP, it is worth paying attention to the fact that the data received are not real. The maximum nominal field area limited by GDP and U is $(\Delta GDPxU)xK = 0{,}2$, while the real surface of triangle a can be $[(\Delta GDP^r xU^r)xK]/n$, where ΔGDP^r means the real value of the growth rate in a given year and the registered unemployment rate in a given year, and n = 5 is the number of triangles in the pentagon. This implies the need for great caution when interpreting the results. In addition, the model does not assume the existence of surpluses of unrealised production and non-marketable inventories.

Competitiveness in Accordance with The MSP Method – Empirical Analysis

The stabilisation pentagon model was used to analyse three highly developed economies: the United States, Japan, and Germany. The research period covers the years from 2000 to 2012. Research period was chosen before, during and after subprime crisis, which give information how economy is handling in different business cycle phases . Data from the International Monetary Fund (IMF) were used for the analysis.

The MSP method, as presented by Kolodko, examined countries undergoing systemic transformation. The study presented in this paper covers the most developed economies of the world. Therefore, it was necessary to introduce significant changes to the model. The research conducted by Kolodko concerned countries where hyperinflation was common. To simplify the large fluctuations in inflation, Kolodko used a logarithmic scale. In the analysis of three highly developed economies, the inflation rate is below 5%, and its changes in the analysed period are small; thus, symmetrical data axes were introduced in this study, in which the logarithmic scale on the inflation axis was abandoned. In addition, the vertices of the pentagon were scaled from -14 to 14%. This scale was chosen based on the minimum and maximum values of the indicators achieved by the analysed countries. Thanks to the introduction of the same scale, it was possible to compare three countries at the same time. Many analyses are based on a scale that is determined by the minimum and maximum values of the indicators in a given country. In the analysed case, this concept would not be correct, because in each country there are different minimum and maximum values of indicators, thus the fields of the triangles and the pentagon would be incomparable. The proposed method is innovative, as it enables comparison of many developed countries at the same time. In addition, the introduction of symmetrical axes allows for visually determining which of the pentagons is larger (better). In the original form of the MSP pentagon, the calculation of the triangle area is difficult due to the logarithmic scale for the inflation index and various quantities that are scaled in the pentagon. Under the adopted assumptions, the unemployment rate is scaled in the negative (-14; 0) and positive (0; 14) ranges. Since there is no negative unemployment rate in the economy, there are two 'blind spots' in triangles a and b on the pentagon presented here. However, this fact does not hinder the analysis; indeed, it even facilitates visual assessment of the economic situation.

The U.S. economy was analysed first.

United States

Table 1 presents the basic U.S. economic development indicators for the period from 2000 to 2012.

Table 1: Basic U.S. economic development indicators for the period from 2000 to 2012 (%)

Year	GDP growth rate	Unemployment rate	Inflation	Budget balance	Current account
2000	4.091	3.967	3.367	1.485	-4.046
2001	0.949	4.742	2.817	-0.521	-3.733
2002	1.776	5.783	1.596	-3.765	-4.169
2003	2.791	5.992	2.298	-4.730	-4.505
2004	3.798	5.542	2.668	-4.240	-5.126
2005	3.351	5.083	3.366	-3.077	-5.649
2006	2.667	4.608	3.222	-1.969	-5.762
2007	1.790	4.617	2.871	-2.659	-4.927
2008	-0.291	5.800	3.815	-6.496	-4.629
2009	-2.802	9.283	-0.320	-12.930	-2.647
2010	2.507	9.625	1.640	-10.796	-3.005
2011	1.847	8.925	3.141	-9.746	-2.947
2012	2.779	8.075	2.076	-8.340	-2.711

Source: The authors' own study based on data from the IMF.

It can be seen that in the first decade of the 21st century, U.S. GDP growth was weakened by two crises. The first occurred in 2000 and was caused by the bursting of the 'speculative bubble' on the investment market. A significant drop in GDP from 4.1% to 0.9% can be observed. Another crisis that shook the U.S. economy was the so-called subprime crisis, where the GDP fell from 1.79% in 2007 to -0.29% in 2008. The recession was also felt in 2009, as evidenced by a decline in GDP to -2.8%. The situation on the labour market deteriorated because unemployment rose steadily from 3.97% in 2000 to 8.1% in 2012. The opposite situation can be seen in the case of inflation and budget balance. The rate of change in the general price level dropped to 2.1% in 2012, whereas the inflation rate in 2000 was 3.4%. During this period, the sustainable balance of public finances improved. In terms of shaping the current account balance, the situation deteriorated as a widening deficit emerged.

Table 2 presents the values and relative importance of U.S. macroeconomic stabilisation indicators in the period from 2000 to 2012.

Table 2: Values and relative importance of U.S. macroeconomic stabilisation indicators in the period from 2000 to 2012

Source: The authors' own calculations based on data from Table 1.

Calculations of the pentagon were done on the basis of the data contained in Table 1. The obtained results confirmed the deteriorating economic situation in the United States from 2000 to 2012. The fields of the five triangles, a, b, c, d, and e, in 2000 were 0.0463, 0.0272, 0.0420, 0.0393, and 0.0459, respectively, whereas the fields of the five triangles in 2012 were 0.0253, 0.0180, 0.0172, 0.0162, and 0.0483, respectively. Remembering the interpretation according to which the larger the areas of the triangles are, the better the situation in the country is, it can be stated that in the case of the United States, the situation in fields a, b, c, and d worsened from 2000 to 2012, while the situation in field e slightly improved.

Figure 2 illustrates the MSP in the United States in 2000 and 2012.

Fig. 2: The MSP in the United States in 2000 and 2012.

Source: The authors' own study based on the data from Table 2.

Figure 2 and Table 2 indicate that from 2000 to 2003, there was a notable decrease in the values in the fields a, b, c, d, and e. The decrease in the values in these fields implies a decrease in the values in the fields msp1 (internal sphere) and msp2 (external sphere), which in turn causes the entire MSP field to drop. The highest value of the MSP indicator was recorded in 2000 and amounted to 0.208. The lowest value was recorded in 2009 and amounted to 0.701. Currently, the United States is improving its competitive position, which is demonstrated by the value of the MSP index, which has been increasing every year. In 2012, it amounted to 0.152.

Japan

Table 3 presents the basic indicators of Japan's economic development in the period from 2000 to 2012.

Table 3: Basic indicators of Japan's economic development in the period from 2000 to 2012 (%)

Year	GDP growth rate	Unemployment rate	Inflation	Budget balance	Current account
2000	2.257	4.733	-0.651	-8.034	2.528
2001	0.355	5.042	-0.804	-6.039	2.110

Source: The authors' own study based on data from the IMF.

Analysing the GDP growth rates, it can be seen that the Japanese economy is strongly dependent on the U.S. economy, achieving worse results in the same periods as the U.S. economy. This relationship is evinced in the low GDP growth rate in 2001 (0.36%) and the negative growth rate in 2008 and 2009, where decreases in the GDP growth rate can be observed. These were accompanied by budget imbalances and a widening deficit. The pace of changes in the general price level fluctuated at around 0, but deflation was often seen in the period under review. However, it is worth noting that despite the economic slowdown, the situation on the labour market in Japan was stable. The unemployment rate fell slightly and remained below 5% throughout. A similar situation can be seen in the case of the current account, which was positive. The values and relative importance of Japan's macroeconomic stabilisation indicators in the period from 2000 to 2012 are presented in Table 4.

Table 4: Values and relative importance of Japan's macroeconomic stabilisation indicators in the period from 2000 to 2012

Specification of indicators										
Year	a	b	c	a+b+c = msp 1	d	e	d+e = msp 2	msp 1+ msp 2	msp 1/(msp 1 + msp 2)	msp 2/(msp 1 + msp 2)

Source: The authors' own calculations based on data from Table 3.

The slightly worsening macroeconomic situation in Japan can also be inferred from Table 4, in which it can be seen that the fields of the five triangles, a, b, c, d, and e, in 2000 were 0.0384, 0.0346, 0.0223, 0.0252, and 0.0685, respectively, whereas the fields of the five triangles in 2012 were 0.0393, 0.0346, 0.0138, 0.0148, and 0.0611, respectively. The situation in fields c, d, and e deteriorated during the period under review, while the situation in fields a and b slightly improved.

Figure 3 depicts the MSP in Japan in 2000 and 2012.

Fig. 3: The MSP in Japan in 2000 and 2012

Source: The authors' own study based on the data from Table 4.

In the years from 2000 to 2007, Japan systematically improved its economic results. One cannot speak of very large increases here, because the crisis of the 1990s continued to make itself felt. The positive GDP growth trend continued until the 2008 subprime crisis, which, although it started in the United States, also significantly affected the negative results of the Japanese economy. These changes can be observed by analysing the data from Table 4 and Figure 3. The most significant problem faced by the Japanese economy is the phenomenon of deflation, which has plagued it since 2000 (with several periods of very low inflation). In addition, the budget balance has been upset. In the years after the subprime crisis, Japan's budget deficit oscillates at around 10% of GDP. These relationships are visible in the drawings of the pentagons of macroeconomic stabilisation, where fields c and d reach much lower values than in previous years.

In the case of Japan, the highest value of the MSP index was recorded in 2007 and amounted to 0.256. The lowest value was recorded in 2009 and amounted to 0.121. Currently, Japan is improving its competitive position, as demonstrated in the value of the MSP index, which has been growing every year. In 2012, it amounted to 0.164.

Germany

Table 5 presents the basic indicators of Germany's economic development in the period from 2000 to 2012.

Table 5. Basic indicators of Germany's economic development in the period from 2000 to 2012 (%)

Year	GDP growth rate	Unemployment rate	Inflation	Budget balance	Current account
2000	3.298	8.000	1.400	1.137	-1.732
2001	1.638	7.883	1.904	-3.076	-0.001
2002	0.030	8.700	1.355	-3.846	2.001
2003	-0.387	9.783	1.031	-4.151	1.887
2004	0.694	10.517	1.790	-3.760	4.662
2005	0.846	11.208	1.920	-3.332	5.062
2006	3.886	10.192	1.784	-1.653	6.255
2007	3.389	8.783	2.276	0.228	7.450
2008	0.807	7.600	2.754	-0.074	6.210
2009	-5.085	7.742	0.234	-3.075	5.961
2010	3.857	7.058	1.150	-4.152	6.252
2011	3.399	5.950	2.482	-0.753	6.176
2012	0.896	5.467	2.137	0.139	6.954

Source: The authors' own study based on data from the IMF.

In the first decade of the 21st century, large economic fluctuations in Germany can be observed. The GDP growth rate in 2000 was 3.3%, but in subsequent years, until 2005, it was falling and was within the range of -0.39% to 1.64%. It is also worth noting that the worse results in terms of the GDP growth rate up to 2005 contributed to the deterioration of the situation in the labour market in this period. The unemployment rate, which was 8% in 2000, increased until it reached a maximum value of 11.21% in 2006. It is worth noting, however, that subsequent years brought an improvement in the situation in the labour market, where a decreasing trend of the unemployment rate, which was only 5.46% in 2012, was observed. A fairly stable situation can be observed in the case of the public finance balance, which reached fairly stable values. The current account balance was also faring well, growing higher each year. A surplus in this account, which reached its highest value, amounting to approximately 7% of GDP, in 2012, can be seen every year from 2002 onwards. The pace of changes in the general price level remained at a similar level throughout the entire research period.

The values and relative importance of Germany's macroeconomic stabilisation indicators in the period from 2000 to 2012 are presented in Table 6.

Table 6: Values and relative importance of Germany's macroeconomic stabilisation indicators in the period from 2000 to 2012

Source: The authors' own calculations based on the data from Table 5.

The improving situation can also be inferred from Table 6, where it can be seen that the fields of the five triangles, a, b, c, d, and e, in 2000 were 0.0265, 0.0193, 0.0487, 0.0474, and 0.0558, respectively, whereas the fields of the five triangles in 2012 were 0.0324, 0.0258, 0.0428, 0.0756, and 0.0796, respectively. It can be stated that the situation in fields a, b, d, and e improved, while the situation in field c worsened.

Figure 4 illustrates the MSP in Germany in 2000 and 2012.

Fig. 4: The MSP in Germany in 2000 and 2012

Source: The authors' own study based on the data from Table 6.

The years from 2000 to 2007 can be divided into two stages. The period from 2000 to 2005 was a transitional stage in which internal indicators deteriorated strongly and external indicators slightly improved. However, the years from 2005 to 2007 brought a significant improvement in all indicators of the MSP pentagon. The positive GDP growth trend continued until the 2008 subprime crisis, which also negatively affected the results of the German economy. These changes can be observed by analysing the data from Table 6 and Figure 4. The large decreases in fields a, b, c, d, and e in the period from 2008 to 2009 demonstrate that the German economy was severely impacted by the crisis. This is due to the export factor, which plays a significant role in the German economy. Nevertheless, it should be noted that the years from 2010 to 2012 engendered a significant improvement in both internal and external factors. These relationships are visible in both the MSP drawings and Table 6.

The highest values of the MSP indicator in Germany were recorded in 2007, 2011, and 2012 and amounted to approximately 0.255 (± 0.002). These high values were caused by a very effective export policy. The lowest value was recorded in 2003 and amounted to 0.156. Currently, Germany is improving its competitive position, as demonstrated by the value of the MSP index, which has been increasing every year. In 2012, it was 0.256.

Based on the results of the Macroeconomic Stabilisation Pentagon, the author constructed a ranking of MSP competitiveness (Table 7). This ranking was constructed by awarding points from 1 to 3. A value equal to unity was given to the country with the worst result, which in this ranking means the smallest area of a pentagon. The analysis contains 13 periods, starting from 2000 and ending in 2012.

Table 7: MSP for the United States, Japan, and Germany in the period from 2000 to 2012

	United States	Japan	Germany	POINTS		
Year	**MSP**	**MSP**	**MSP**			
2001	0.174627	0.188411	0.171844	2	3	1
2002	0.156690	0.176656	0.167536	1	3	2
2003	0.149005	0.185359	0.156268	1	3	2
2004	0.153452	0.210921	0.174504	1	3	2
2005	0.153524	0.215857	0.176121	1	3	2
2006	0.159145	0.229652	0.223936	1	3	2
2007	0.159427	0.255785	0.254305	1	3	2
2008	0.120190	0.198028	0.230624	1	2	3
2009	0.070145	0.120604	0.175601	1	2	3
2010	0.097606	0.199333	0.229795	1	2	3
2011	0.103037	0.152808	0.256039	1	2	3
2012	0.125222	0.163549	0.256241	1	2	3
sum	1.622070	2.296963	2.472814	13	31	28
Rank				III	I	II

Source: The authors' own calculations based on data from tables 2, 4, and 6.

The country that took first place turned out to be Japan, which received 31 points. Second place was awarded to the German economy (28 points), and third place was awarded to the United States (13 points).

Conclusion

The presented conclusions are based on the years from 2000 to 2012. It can be observed in the analysis that economic relations between world leaders are a derivative of the state of the economies of partners. In the conducted analysis, it was observed that the poor economic condition of one country led to the worsening of the situation of the other countries. Strong trade links between the countries studied are crucial because they belong to the group of the world's largest exporters. The analysis confirmed that the phenomenon is compounded when the crisis concerns the U.S. economy. The economic crisis of 2008 to 2009 highlighted the nature of international interdependence. All analysed countries achieved the best results in the MSP model a year before or a few years before the crisis. Immediately after the subprime crisis, the MSP fields fell in all the countries studied. Despite the worse results achieved in 2008-2009, a slight improvement in the following years in the economic situation could be seen in all the countries analysed. It was also observed that in countries in the face of the crisis, the policy of state protectionism was beginning to achieve success. This fact can be observed in Tables 4 and 6, where it can be seen that internal sphere indicators in Germany and Japan strengthened.

When the values in the fields in the MSP are analysed, it can be seen that the leader of the ranking from 2000 to 2012 is Japan, which achieved such a good result thanks to a very stable and low unemployment rate. In addition, a favourable situation can be seen in the case of the current account, which took values greater than zero.

Second place in the ranking is occupied by Germany, which recorded very positive results after the subprime crisis. The German economy would occupy first place if the analysis had focused exclusively on the years after the crisis. The MSP fields for Japan and Germany in 2007 were at the same level of 0.255 (± 0.001). However, the German economy in 2012 achieved a much better result, achieving an

MSP value of 0.256, while this indicator in Japan was only 0.164. Germany achieved good results in terms of current account balance and public finances. It is also worth noting that the external sphere is dominant in the German economy.

The United States achieved the worst results and thus took last place. The analysis reveals that economic policy issues are a very important aspect in the United States. State policy should focus on the fight against high public debt and the level of unemployment. It is also worth mentioning that in recent years, the United States has stood out positively in terms of GDP growth and inflation.

To better illustrate the results of the MSP model, the charts in figures 5 and 6 are presented. An important difference that distinguishes them from the previously presented MSPs is the presentation of the three economies simultaneously on the Macroeconomic Stabilisation Pentagon chart in 2000 and 2012.

Fig. 5: The MSP in the United States, Japan, and Germany in 2000.
Source: The authors' own study based on IMF data.

Fig. 6: The MSP in the United States, Japan, and Germany in 2012.
Source: The authors' own study based on IMF data.

This study complements the existing analyses based on the MSP method, as previous case studies have mainly focused on countries undergoing systemic transformation. In this case, the 'magic' pentagon was applied to highly developed countries.

The analysis revealed similarities and differences between the studied economies. The correct interpretation of macroeconomic indicators provides a basis in today's world to achieve better results in the future. The analysis of the 'magic' pentagon can be treated as an alternative to synthetic indicators that offer insight into the overall situation of the country's economy.

Abstract

Political changes in 1989 enabled former Soviet Union satellite countries to initiate processes of political and economic transformation from a centrally planned economy to a market economy. In the early years of the 1990s, the post-communist countries adopted the Washington Consensus. It was based on three key pillars: fiscal austerity, privatisation, and liberalisation. These changes have radically changed the Polish economy. Poland had to face many challenges, which included high unemployment and hyperinflation. In addition, the accession of Poland to the European Union opened a new stage of changes in its economy. The authors focus on the main changes in the Polish economy during the past three decades. The study period begins in 1989, when Poland transformed from a centrally planned economy to a market economy. The other important period starts in 2004, when Poland become a member of the European Union. The main aim of this paper is to asses performance of Polish economy referring to main macroeconomics indicators. This article also discusses main challenges for Polish economy. Although Poland is performing rather well in the region, it still lags behind other European Union countries. The most important challenges that the authors present are the demographic trap, the average product trap, the weak institutions trap, the lack of balance trap, and the middle-income trap. Due to the complexity of the topic, the research requires the use of diverse methodological approaches. The main method is a comparative analysis using data collected from the International Monetary Fund and the Polish Statistical Office. The method employed also includes historical case studies, which are used to present the role of the Polish economy.

Keywords: Transition Economy, Capacity Building, Integration.

Introduction

Today, the capacity of the economy for growth is the most important factor in the economic success of individual countries in the long term (Samuelson and Nordhaus 2007). Economic growth occurs as a result of various factors. Over the years, the role of the individual factors of economic growth has changed. In multiplying the wealth of nations, the classical economy stressed the importance of factors other than the ones emphasised in the modern economy, especially the most recent one (Wozniak 2004). Two opposite points of view can be traced in the history of economic thought. The first is known as the catching up/convergence hypothesis. The other one is called the divergence hypothesis. According to the first theory, a developing country can make the 'jump', through which it can significantly accelerate its economic development (Jablonski 2012). Paul Romer disputes the convergence hypothesis. The main assumption in Romer's concept is a parallel increase of the economic growth rate and income, which means that developed countries grow faster than underdeveloped countries (Romer 1986).

[1] Corresponding author

In the 1990s, the concept of capacity building became an essential component in development theory and practice. New theories emphasised the importance of capacity building or capability development for achieving long-term growth. International organisations, governments, private companies, and societies have adopted the concept, especially in developing countries, which have identified capacity building as a key in the implementation of the concept of sustainable development. In accordance with the United Nations Development Programme, 'capacity building is the process through which individuals, organizations, and societies obtain, strengthen, and maintain the capabilities to set and achieve their own development objectives over time' (UNDP 2008). The World Bank introduces a similar definition: 'the proven ability of key actors in a society to achieve socioeconomic goals on their own. This is demonstrated through the functional presence of a combination of most of the following factors: viable institutions and respective organizations; commitment and vision of leadership; financial and material resources; skilled human resources' (World Bank 2006).

Capacity building has been defined as a process or activity that improves ability. Capacity building can be seen from two perspectives. In one extreme, capacity building is linked to an increase in the knowledge and skills development of individuals through training programmes. In a broader context, capacity building integrates a wide range of systems, such as policy making, management, and finance (LaFond et al. 2002).

In publications related to the subject of catching up, economic growth is a very popular concept of countries' capability. J. Fagerberg and M. Srholec (2005) identified a number of different capabilities that developing countries could potentially exploit to catch up. The set of capabilities that might be assumed to be of critical importance for catching up is presented in Figure 1.

Fig. 1 : Capabilities for economic growth

Source: Fagerberg and Srholec (2005).

History, geography, and nature are important for development, especially at an early stage. In addition, the importance of institutions, governance, and policies necessary for the efficient functioning of the economic system is generally acknowledged in the literature. The significance of education (or human capital) for the assimilation and creation of knowledge is shown as social capabilities. Technological capabilities refer to the ability to develop new goods and services and new production methods. They are closely related to the country's innovation system (Fagerberg and Srholec 2005).

Polish history as a Background of Capacity Building

To understand how the Polish economy has changed, it is important to recall how it worked in the 20th century. Poland was one of the most devastated countries after the Second World War, with human losses amounting to around 17 per cent of its population and completely damaged infrastructure. Soviet pressure forced the Polish government to reject the Marshall Plan in 1947 and to join the Soviet-Union-dominated Comecon in 1949 (Schain 2001). The communists, supported by the Soviet Army, came

into absolute power. The leading role in the state was played by the communist Polish United Workers' Party (PZPR) (Shleifer and Treisman 2014).

The economy was centrally planned: the state decided what would be produced and in what quantities, what the wages would be, and what prices would be charged in stores (Kozlowski 2011). The state owned most properties. In the 1970s and 1980s, a food-rationing system was used in Poland to keep prices under control and fight speculation with food and goods that were difficult to procure. Poland was deeply affected by the economic depression. Between 1975 and 1980, Polish debt to Western countries increased from 7.4 billion to more than 21 billion USD (Aslund 2012).

When the communist empire began to fall apart, Poland was looking for new opportunities that came with the change in 1989. Poland's new shape has been strongly affected by global trends: the development of trade and finance, changes in the supply chain, developments in technology and communications, growing international cooperation, and the mutual convergence and interdependence of states (ThinkThank and CMS 2016).

Poland was the first country in communist Europe that unshackled itself from communism. The first free elections were held in June 1989, and then in September of the same year, the first democratic government was introduced, long before the fall of the Berlin Wall. The new government under Prime Minister Tadeusz Mazowiecki introduced an ambitious programme of economic reforms to transform Poland from a centrally planned to a market-oriented economy. The commission led by Leszek Balcerowicz prepared plans for market reforms in late 1989. These reforms became known as *shock therapy*, a term coined by Jeffrey Sachs, a Polish reform adviser (Lipton et al. 1990). The main reforms indicated full openness of the market to domestic and foreign trade: the Polish zloty became convertible, prices were liberalised, subsidies for state-owned enterprises were cut, privatisation was initiated, and banking sector reform was accelerated (Balcerowicz 1995). Although the post-transition recession was much deeper than initially predicted, costing Poland almost 15 per cent of its GDP (Piatkowki 2013), four more major reforms of health, pension, and educational systems as well as regional reform had been implemented by the end of the 1990s. Those two blocks of reforms were very important for the further development of the Polish economy. The first set of reforms brought Poland back to the market economy through macroeconomic stabilisation, price liberalisation, and import liberalisation policies. These reforms released the creativity of new private and state-owned enterprises to engage in a restructuring process, that is, to modify the production process, to engage in marketing, and to reduce unproductive labour. The second large block of reforms from 1999 can be considered modernising reforms, as they transformed ineffective institutions to improve the competitiveness of the Polish economy and to ensure sustainable government finances (Lehmann 2012).

The next step for Poland was to apply for European Union (EU) membership. Not only was Poland's accession to the EU important, but the long process of adapting to the requirements of the membership was also important. This involved further reforms of the Polish economy, its justice administration, its laws, and the functioning of local government. In effect, Poland has adopted the European standards and rules of operation (ThinkThank and CMS 2016). On 1 May 2004, Poland became a member of the European Union, concluding the long process of striving to join this organisation. These efforts were initiated by the international transformations of the Autumn of Nations, which resulted in an essential redefinition of Polish foreign policy, manifested in a purely pro-Western orientation and striving towards integration with western European institutions (Kolodziejczyk 2016). In 2007, Poland joined the Schengen area. This area includes 26 European countries that have abolished passport and any other type of border control at their mutual borders (European Commission 2008). Furthermore, thanks to its accession to the European Union, Poland will continue to receive support from the EU Structural Funds. In the EU financial perspective 2014-2020, Poland is the largest beneficiary of EU funds, receiving around 106 billion euros, which in fact exceeds the value of the post-WWII Marshall Plan, which Poland missed for political reasons.

The Macroeconomic Situation of The Polish Economy

The country's macroeconomic situation is, on the one hand, its background for capacity building. On the other hand, it is also a measurable result of the increasing capacity of each country. Twenty-five years after the end of central planning, Poland has achieved remarkable economic progress. Nevertheless, the post-transition downturn in Poland was much deeper than initially predicted. This reaction is illustrated in Figure 2: in 1990 and 1991, Poland lost around 15 per cent of its GDP. However, some economists argue that the fall in GDP was actually less, as lost production also reflected goods and services that did not meet quality standards of the market economy (Orlowski 2010).

Fig. 2. GDP growth rate in Poland 1991-2018

Source: authors' own study based on International Monetary Fund (IMF) (2020).

In 1992, the Polish economy started to grow very rapidly. In 1992, Poland's GDP growth rate was 2%, but the highest value was observed in 1995 and reached 7% of GDP. Two declines can be observed after 1997. The first occurred in 2001 as a result of contractionary monetary policy, and the second occurred in 2009, after the onset of the global crisis. But despite this, it is interesting to note that GDP growth was recorded in Poland before, during, and after the subprime crisis. Over the past 10 years (2006-2018), the Polish economy has grown by almost 4% per year, which is one of the highest growth rates in the EU. Growth in Poland has been approximately 2.3% higher than that in OECD countries (Poland: 4%, OECD: 1.7%). Poland was the only country in the EU that avoided the outright recession during the global financial crisis.

There have also been positive changes in the productivity of the Polish economy. Thanks to technological changes and improvements in the production process as well as changes to and modernisation of economic structures, Poland has improved both its pure labour and structural productivity growth. However, the impact of changes in structural productivity was much more significant than the impact of changes in pure productivity, especially after the accession period (Dobrzanski and Grabowski 2019) Productivity increased in all sectors; however, the most significant rise was noted in financial intermediation and real estate, renting, and business activities. Simultaneously, employment decreased the most in agriculture, hunting, and forestry and fishing, the sector with the lowest productivity (Dobrzanski and Olszewski 2019).

Figure 3 presents GDP per capita in Poland from 1990 to 2018.

Fig. 3: GDP per capita (purchasing power parity (PPP)) in Poland (1990-2018).
Source: authors' own study based on IMF (2020).

Compared to the OECD average and the average for the 28 EU countries, Poland's performance is strong. GDP per capita in terms of purchasing power increased from $6,125 in 1990 to $31,393 in 2018. The performance is very strong, but Poland's GDP per capita is only 45% of the United States' GDP per capita.

Figure 4 depicts inflation in Poland from 1980 to 2013 and predictions for the period from 2014 to 2018.

Fig. 4: Inflation in Poland (1980-2018).
Source: authors' own study based on IMF (2019).

In 1990, prices rose rapidly in Poland. This caused higher inflation, which increased up to 853.5% in 1990. The government used contractionary monetary policy to reduce it, and interest rates grew very rapidly up to a few dozen.

Figure 5 illustrates the unemployment rate in Poland from 1980 to 2018.

Fig. 5: Unemployment rate in Poland (1980-2018).

Source: authors' own study based on IMF (2019).

Another important factor is the unemployment rate. In socialism, everybody worked, but they worked inefficiently. In the market economy, many people lost their jobs. Until 2003, employment in Poland fell precipitously to very low levels from an international perspective, while the unemployment rate was much higher for most of the period, reaching a peak of 20 per cent in 2002. Dynamic growth of the employment ratio and a steep decline in the unemployment rate, which reached the single-digit level from 2007 to 2009 for the first time since 1992, can be observed only since Poland's accession to the European Union. In addition, many people have emigrated to Germany, the United Kingdom, and other countries in the EU. This can be observed in Figure 6.

Fig. 6: Share of Polish immigrants in 2013.

Challenges for capacity building in Poland

The analysis in the second paragraph, which focuses on the main macroeconomic indicators, demonstrates that Poland has generally improved its macroeconomic indicators. The Polish economy

has been able to achieve a stable macroeconomic situation, which is a necessary background for capacity building. Capacity building is one of the main goals of the Polish government. The Ministry of Development publishes many reports regarding this topic, mainly about the main challenges for long-term growth. Figure 7 presents the main challenges identified by the Ministry of Development (MoD).

Fig. 7: Five development issues for Poland.

Source: MoD (2016).

The first challenge for the Polish economy is the demographic trap. The number of Poles who fall within the working age is declining, and society is growing older. In 1975, the Polish population was relatively young demographically. Young people accounted for a higher percentage of the total population than old people. Today, the proportion of young people has significantly decreased, while the number of older people has increased (Wilk and Pietrzak 2014). In the near future, the decline of the population will accelerate. According to the forecast of the Central Statistical Office, the Polish population will have decreased by 2 million people by 2035, from 38 to 36 million. Almost an additional 2 million people have already migrated. These trends may have serious consequences for the labour market, such as depopulation, significant shortfalls in the qualified labour force, and mismatching of skills. Reduction of the fertility rate is a global problem; however, this rate is specific for each country or region. The decrease in the fertility rate in Poland has been observed since 1950; however, during the 1960s and 1980s, the situation was more or less stable. In 1989, the fertility rate dropped below 2.1, the replacement level. Although the ageing of the Polish society is ongoing, Polish society is relatively young in the European Union: the proportion of people aged 65 or over in the population is one of the lowest in the European Union, and it is significantly below the average for EU 27 countries (OECD 2013). The Polish government is working on solutions to improve the fertility of Polish women, limiting the emigration of Poland's citizens, creating conditions for their return, and increasing the scale of labour immigration to Poland. One of the programmes aimed to boost birth-rates is Family 500+ introduced in April 2016. Under the programme parents can receive a tax-free benefit of PLN 500 (about EUR 120) per month every children until they reach the age of 18. Latest statistics shows increase in childbirth, however, it is difficult to assess the contribution of the 500+ program to this increase. There are other factors that could affect the increase in the number of births as a stable economic situation or an increase in births associated with the births among the people of the baby boom of the 80's.

The second challenge for capacity building is weak institutions. Poland lacks a comprehensive and long-term vision of public administration. The increase in the operating costs of administration has not been accompanied by an increase in its effectiveness. There is a gap in the inflow of taxes on goods,

and companies' revenue is approximately 20 billion USD. Combatting value added tax (VAT) fraud remains a major challenge for Poland. Since 2004, there have been 44 changes in the tax regulations, but those changes have not allowed for increasing tax collection. Reforms are needed to improve the effectiveness and efficiency of the Polish tax administration, as Poland's cost-of-collection ratio, that is, the administrative costs per net tax revenue collected, is the highest in the EU. Moreover, compared with most EU member states, Poland still has low online interactions between public authorities and citizens (European Commission 2016). Poland was one of countries with the highest level of non-compliance and non-collection of VAT till 2016, when the VAT gap was reported at the level of approximately 20 %. In recent years it has decreased at a rate not observed in other EU countries (to approx. 9-10 % in 2019), due to i.a. VAT regulations introduced already in September 2015 and gradually (in years 2016-2018) embracing companies of various sizes.

The third issue is the average product trap. According to the rankings and reports of the international institutions, Poland's economy is not innovative. Another EU report (European Commission 2014) reveals a very low evaluation of Polish innovative capabilities: Poland is the fourth least innovative country in the European Union. Expenditures on research and development (R&D) are less than 1% of GDP, and only 5% of exports are high-tech products. In the EU scoreboard, Poland is presented as 'a moderate innovator'. This report emphasises low investment in innovations. This indicator has slightly improved since 2006, but it has been deteriorating compared to the EU average, which has been increasing much faster. Most indicators for Poland are below the European Union average, the worst of them being a small number of PhDs from outside the EU, a small number of patent applications concerning social challenges, and low income from Polish licenses and patents abroad. The Europe Strategy 2020 (European Commission 2010) clearly shows the way and the percentage of its GDP that Poland should spend on research and development. Many Polish companies are delivering basic products at the lowest price to build their competitiveness. Poland's product specialisation is biased towards low- or medium-low-technology goods. Furthermore, Poland's product specialisation has been relatively static, with little progress towards a higher share of medium- or high-technology goods (Bogumil and Wieladek 2014). In this case, to improve the quality and variety of goods, the Polish state must collaborate with the business sector and the academic environment and also must itself become a technologically demanding customer through its public procurement system.

The fourth challenge is the lack of balance trap. Since its economic transition and integration into the EU, Poland has received a significant amount of capital inflows, which have supported the catching-up process in the region. Today, the Polish economy is mainly built on foreign capital. The presence of foreign capital in Poland is desirable and important, since it allows for increasing GDP and contributes to technology transfer. This fact was magnified after Poland's accession to the EU in 2004. Capital inflows to Poland have concentrated in the manufacturing and services sectors, supporting the development of the tradable sector. Each year, approximately 25 billion USD flows out to foreign investors. In addition, 50% of industrial output originates from foreign companies. Moreover, 66% of Polish exports originate from foreign companies (Bogumil 2014). Nevertheless, to maintain healthy economic growth, it is necessary to maintain an appropriate balance between domestic and foreign capital. In this case, besides foreign investors, domestic capital needs to be strengthened on a larger scale to ensure Poland's future and a stable path of development.

The final issue presented in this article is the middle-income trap. The middle-income trap occurs when after several years of relatively high rates of growth, a country's growth rate becomes low, and eventually the country stagnates after reaching middle income levels (Garrett 2004). The middle-income trap refers to a country that has already used the advantages of cheap labour and other resources and now is unable to offer better quality and more technologically advanced products. As a result, such countries become stuck between richer countries, which compete using their innovations, and poorer countries, which compete by means of low prices (Pruchnik and Toborowicz 2014). Although GDP per capita in Poland is growing rapidly, some weaknesses can still be observed. The alarming fact is that approximately 50% of working people earn a net income of less than 650 USD, to compare Poland's GDP per capita amounts only to 45% of the United States. This fact is evinced in the large social inequalities. While short-term economic growth forecasts for Poland are positive, long-term projections support the thesis that Poland might lose its dynamic drive. According to the Organisation

for Economic Co-operation and Development (OECD), Poland's economic growth in the next few years will reach around 3.0 to 3.5% of GDP. However, the long-term forecasts predict that in the next 50 years, the Polish economy's growth rate will be among the lowest in OECD countries (OECD 2014). If Poland wants to avoid becoming stuck in the group of countries with middle income, Poland needs to find new drivers of growth because low labour costs have run out. This goal can be achieved by building global specialisations of the Polish economy. Economic growth must be accompanied by the growth of salaries.

Poland has reached a stage of economic development where efficiency gains and sustained growth are more difficult to achieve. Although the Polish economy has made steady progress over the past two decades, continuing to close the income gap with the EU average is becoming more difficult (European Commission 2016). The abovementioned challenges and the depletion of existing growth factors require action from Poland to boost its socioeconomic development. In 2016, the Council of Ministers adopted the Responsible Development Plan. This plan is a set of tools to make the development of Poland more dynamic. These are actions that will result in a positive and high-quality expansion of the Polish economy. The Responsible Development Plan is based on five pillars: reindustrialisation; the development of innovative companies; capital for development; foreign expansion; and sustainable social and regional development. Sustainable social and regional development means an emphasis on inclusion in the development process, not only in large urban areas but also in smaller towns and rural areas (Pinkas 2016)

Conclusion

Catching up with the West is a marathon, not a sprint. Poland has a very difficult history. More than 50 years in the Soviet Bloc caused economic delay in Polish development. Today, Poland, as a member of the North Atlantic Treaty Organisation (NATO) and the European Union, is experiencing the best years in its history, but this new Golden Age has only just begun. To maintain positive economic and social growth, Poland must work on its capacity-building challenges.

With a population of around 38 million, Poland is the largest economy in Central Europe. Since its accession to the European Union, Poland has achieved very positive results in terms of its economic performance so far. However, if Poland wants to catch up with the core of the European Union and other developed countries, which are in the third stage of development in terms of economic growth and standard of living, then it must improve cooperation between business and science at the micro and macroeconomic level. Such improvement could be achieved by creating business and innovation ecosystems using triple-helix concept. The Polish economy also needs more investment and higher innovation expenditures. Such actions would exert a positive impact on its innovation capacity. Increase budget revenues from the seal of the tax system will definitely help in achieving this objective. Human capital is one of Poland's most significant advantages, but its ageing society will be a huge problem in the future. Poland needs to use a coherent set of policies to respond to long-term challenges and opportunities in an effort to maintain balance between working society and population. Especially further assessment is necessary for Family 500+ program. In addition, Poland needs to further reform its institutions in an effort to make them more efficient. State institutions are creating a background for effective public and private activity. Poland should retain foreign capital and encourage foreign companies to make further investments through preferential lending and tax incentives

Poland's economic performance over the past 30 years has been remarkable, and this has been translated into significant welfare gains across the entire income distribution. In this case, it would be useful to emphasise that Poland had a very high absorption of European Union funds. During the 2007–13 programming period, a large percentage of the European Union funds were directed towards hard infrastructure assets. The period from 2014 to 2020 has seen a shift of funds from hard infrastructure to funds that will create and promote competitiveness, innovation, and entrepreneurship.

The growth prospects for the Polish economy are strong. Poland needs to improve in many areas, such as infrastructure, labour, high-tech industry development, productivity, and business environment. In

addition, Poland should take advantage of its central geographical location in Europe. If Poland addresses its problems, it can become one of the most powerful engines of the EU.

Abstract

The competence literature uses a set of terms whose definitions have a high degree of ambiguity and intersection. This situation causes difficulties when applying competence frameworks for describing the content of jobs and planning the evolution of competences, both at an individual and organizational level. This work focuses on the competence construct, reviewing related concepts and identifying relationships between them. The authors provide a structure for the competence construct, which integrates and articulates the concepts of knowledge, skill, ability, capacity, posture, disposition and behaviour. The structure supports the proposal of a mechanism for mapping the internal competences of an organization. The mapping may assist the organization to compare its current set of competences with the desired competence blueprint. Underlying this mechanism is the assumption that individuals working in an organizational environment are the source of competences for the organization. The mechanism may also assist an individual to set a course for professional development. To illustrate the application of the mapping mechanism a scenario informed by an Information Systems and Technology framework is used.

Keywords: competence, information systems, information systems and technology competences, competence mapping

Introduction

The central theme in this paper – competence – has been the subject of many scientific discussions and investigations. However, despite the number of works that have been published (exceeding 8,000 in 2019 according to the Web Science and more than 14,000 based on Scopus), additional research is required, as some concepts related to competence are considered synonyms by some authors or overlap in their meanings in the view of others. The existing mix of conflicting views may raise doubts regarding the approaches adopted by works on professional competences. To mitigate the drawbacks of that situation, this study promoted searches and analysis in several dictionaries and frameworks in order to better organize concepts and, subsequently, to identify relationships between them and influences they exert on each other. The starting point of the study were several competence frameworks, lately complemented by the analysis of additional references and dictionaries.

The literature review suggested an absence of criteria to make sense of the terms associated to competence, hindering the development of a conceptual structure capable of defining a profession. This state of affairs was recognized in spite of the existence of explanations for the meanings of career, function, job, work, and even profession. The absence of criteria may also interfere with the design of training programs or graduate and postgraduate programs, as these programs need to focus on learning objectives that take into account the professional profile required by the labour market. Hence, we argue for the need of conducting research studies on competence-related concepts and on their relationships.

In order to produce a structure for the competence construct, we compared, grouped and contrasted the definitions of related concepts found in the literature reviewed. Then, we advanced revised definitions

for the concepts so there was no overlapping and incompatibility in the proposed structure for the competence construct. This made possible a visual display to show how concepts relate and to trace the path an individual may take to evolve in his/her professional field.

Building on the structure for the competence construct, in this paper we propose a mechanism for mapping competences. This mechanism assists in diagnosing existing competences, suggesting paths to develop individual competences and defining requirements to meet organization's competence demands.

Following this introduction, we briefly describe competence frameworks. These frameworks include various concepts present in the proposed mechanism for competence mapping. In the subsequent section we present definitions for the concepts, based on competence frameworks and other references, such as scientific articles and dictionaries. The section includes a display of how the concepts relate at an individual level of analysis. The next section presents a competence measurement mechanism and shows how it can be used to map an organization's competences. Afterwards, representations are provided to exemplify some applications of the mechanism, based on a scenario, for both measurement and mapping purposes. For the sake of illustration, the example provided uses a framework from the Information Systems and Technology (IST) domain. The proposed mechanism allows the use of other frameworks for the purpose of competence measurement that the user of the mechanism (an individual, a group or an organization) considers appropriate. In the final sections of the paper, the authors draw conclusions and propose future work.

Competence Frameworks

Different competence-based approaches have been developed, serving as guidance in diverse professional areas. A well-known framework is the European Competence Framework (ECF), which in 2016 was recognized as a European Standard, aiming to standardize an approach to competences, skills, knowledge and proficiency levels (European Union, 2016), for the IST area, and providing descriptions for typical professional role profiles. Its architecture divides competence into four dimensions. Dimension 1 refers to the purpose of the competence. Dimension 2 includes the name and a generic description for the competence. Dimension 3 covers proficiency levels for the competence and its equivalence with the European Qualification Framework (EQF). Dimension 4 covers two fundamental concepts for competence, namely knowledge and skill. The framework includes examples of skills and knowledge for each competence, although recognizing that competence is not limited to the examples provided and may involve other skills and knowledge not mentioned in the framework.

In addition to the ECF, there are other frameworks that aim to standardize the approach of competences, such as the Skills Framework for the Information Age (SFIA) (SFIA Foundation, 2015, 2018) and the i-Competency Dictionary (i-CD) (Hayashiguchi et al., 2018), both in the IST ares. SFIA divides Skills into categories and subcategories, with each skill having specific levels of responsibility, which include descriptions about the practical application of the skill. Focusing on skills, i-CD provides more than 2,200 task items and 10,000 knowledge items.

Other frameworks are transversal to professional areas of activities. The framework used in the United States of America, O*NET (National Center for O*NET, 2008), represents an approach to competences, in which the professional occupations that an individual may have during his/her active professional life are the central theme. Another approach focusing attention on the scope of job specificities and proficiencies is ROME (ETALAB, 2020), maintained by the French government. This framework covers synonyms for jobs, i.e., occupations that have different names, but that in practice are equivalent. Similar approaches are found in other countries. For example, the Brazilian Catalogue of Occupations (CBO) provides an extremely simplified structure, targeting the profession/occupation that an individual will perform, classified in a base group, which, per se, belongs to a subgroup. The CBO, as well as the Portuguese Catalogue of Professions (CPP), pay attention to the profession, offering no support that indicates the path an individual may follow to reach that position.

These frameworks, as well as several dictionaries, do not always attribute the same meaning to the concepts addressed and, although they do not enter into irremediable disagreement, there is a need for more attention in the application of the concepts, at least to prevent an uncritical and generic use. Hence, taking into account the different approaches adopted by each framework, it is advisable to highlight the specificities associated to each concept employed in this work – Competence, Ability, Proficiency, Skill, Knowledge, Posture, Disposition and Behaviour – and to advance revised definitions for each of them.

Main Concepts

The motivation for this paper resulted from the difficulty to depict ways for an individual to acquire professional competences. The first phase of this study took advantage of a set of definitions that made use of other concepts in a coherent way, allowing the authors to formulate a competence structure. ECF, for example, portrays competence as "demonstrated ability to apply knowledge, skills, and attitudes for achieving observable results".

Frameworks such as O*NET, ROME, CBO and CPP do not directly portray the term competence, but refer, as a central theme, to occupation or profession, containing descriptions that complement the ECF's approach, having competences as the central theme. SFIA places skill as a central theme and considers the levels of responsibility as the specifics of the skill, which are grouped into categories and subcategories.

The i-CD uses the concept of competence as a central theme and considers that its origin is placed in the human resource, which is the source of the organization's capability since it provides the needed competence for the business execution. Fleury and Fleury (2001) corroborate this view, indicating that competence refers to the stock of resources that the individual holds. However, McClelland (1973) draws attention to the fact that competence can be observed in the performance of a position exercised by the individual, provided that the individual has skills, knowledge, behaviors, attitude, ability and necessary dispositions corresponding to the individual's professional occupation. Nordhaug and Gr⊘nhaug (1994) advocate that the elements that make up competence are knowledge, skill, and ability related to the work performed by the person. The work of these authors provides important support for the definition proposed in this study for the concept of competence.

Looking to the ECF framework, it makes sense to say that competence relates to a professional area where individuals employ their abilities, such as Programming and Software Development, Network Systems, Quality Assurance, among others. The proposed definition of ability by the Cambridge Dictionary (Cambridge, 2012) indicates ability as an occurrence that enables someone to be able to do something, supported by the Oxford Dictionary that complements the explanation of the concept, referring to ability as the capacity to do something, physically, mentally, legally, morally, etc. (Oxford, 2020).

Taking into account these delineations, we define competence as a combination of the individual's abilities and postures to attend to a certain task at a specific moment. The definition emphasizes the temporality of the occurrence of the competence, as it is not something permanent or static, but an event that occurs at the right time and involving appropriate people to accomplish a task.

Among the cited frameworks, only O*NET mentions the concept of abilities. However, its context of use does not match the one addressed in this paper. This is justified by the fact that the authors of the present work consider that competences have different specificities. For example, in a particular area of professional activity it is possible for different professionals to work together and collaborate in a project, with the specificities of competence being responsible for different groups of tasks. In the case of ECF, which articulates skills, knowledge, and attitudes as elements of competence, the specificity of competences is taken into account and reflected in the level of abilities. ECF establishes a relationship between the concepts of knowledge and skills, so that different combinations of knowledge and skills imply varying levels of proficiency related to ability in the context of a competence.

In what concerns abilities in O*NET, the framework treats it as the natural resources of the individual. However, the authors of this paper consider the need to separate what is natural from what is acquired. Abilities have a broader view and include natural resources, which are defined as aptitude, being a factor that influences positively or negatively on the variables that indicate the level of abilities of the individual, corresponding to the natural talent possessed by the professional. The APA Dictionary (APA, 2018) defines aptitude as a potential in a particular area, while the Cambridge Dictionary (Cambridge, 2020) refers to a natural skill or ability. In addition to the facility in some aptitude or some ability, the Business Dictionary (Business Dictionary, 2020) complements by indicating that the individual's interest in some task or responsibility is also a factor that will influence professional performance when putting his/her ability into practice, which will also enable the occurrence of fitness improvements resultant from practice. Therefore, practice is one of the ways to improve competence, that is, it refers to the possibility of someone doing a task in a more efficient way than he/she already does, through experience. The other way to improve competence is to look for training or qualifications that promote professional development, whether through the acquisition of knowledge or the practice of new skills.

Knowledge, considered here as one of the ways that leads to obtaining abilities, is what can be acquired through training courses and education, which, according to IT2017 (IT2017, 2017), must appear in the official documents of the training programs. In the context of EQF (European Communities, 2008), knowledge is referred to as the result of the assimilation of information through learning, which may come from facts, principles, theories, and practices that are related to a field of work or study. Grant (1996) emphasizes that the creation of knowledge is an individual activity and that knowledge is the primary source of value and may be the factor that will differentiate one organization from another, due to the amount of knowledge it might have. Takeuchi and Shibata (2006) emphasize the division of knowledge into two categories, corresponding to tacit and explicit. They refer to the knowledge that can be expressed in words or numbers and that can be shared as explicit knowledge. However, the authors refer to the existence of knowledge that cannot be easily perceived and expressed, called tacit knowledge. This category of knowledge is deeply rooted in an individual's actions and experiences, as well as in its ideals, beliefs, values or emotions.

Another way to support and acquire the ability at the individual level is the skill of the individual. The skill is the knowledge put into practice, considering the possession of the means for such an occurrence. The EQF refers to the skill as the possession of the means to apply knowledge and use know-how to complete tasks and solve problems (European Communities, 2008).

There is a close relationship between the concepts of knowledge and skill since some skills are dependent on the existence of knowledge for their realization. In this relationship, some skills refer to the application of one or more acquired knowledge or natural knowledge. Regarding skill, the fact of "thinking analytically", for example, supports the execution of skills acquired through experience, which can also refer to the execution of skills that reflect the application of knowledge acquired through training courses. The "thinking analytically" skill may be understood as a natural skill, once it is not acquired from graduate or undergraduate courses.

However, the possession of knowledge and skills, which form the ability, is not a unique condition for competence, since the ability holder needs to put it into practice in the service of something. The abilities are fundamental for the execution of tasks inherent to the professional; however, the practice of the abilities implies the maintenance of an adequate posture, supported by dispositions, which will lead him/her to have appropriate and expected behaviors. Personal factors have great relevance to make the skills hold by the professional generate concrete results. The relationship between the concepts, on a personal level, originates from the observed professional posture, which includes dispositions for certain behaviors to be performed (Collins Dictionary, 2020). Thus, posture is defined as a classifier of recurrent behavior in the individual, that is, the moment when the individual responds to a received stimulus. It is necessary to mention that the answer may simply be "non-action".

What sustains the relationship between stimulus and response is the disposition of the professional, considered as an exclusive inclination or tendency of the individual (OXFORD, 2020) to choose an

alternative over others, basically supported by individual preferences (Strickland, 2001). The result, therefore, is the behaviour, conditioned to the environment in which it is located. According to Fonseca (2016), the behaviour is directly influenced by experience, and Peppard and Ward (2004) note that the behaviour of the individual is the result of organizational demands, social demands, and personal demands.

Figure 1 represents the relationships between concepts related to the construct individual competence.

Fig. 1: Relationship between concepts related to individual knowledge

Through Figure 1, it is possible to see that the competence construct, at the individual level, is supported by two main concepts, which are the practitioner's ability [E6] and posture [E3]. The formation of the ability occurs through the combination of knowledge [E1] and skill [E2], and this formation allows even greater possibility to measure the ability and indicate their different levels of proficiency. The posture is dependent on the existence of disposition [E4], which will lead the person to perform different behaviors [E5]. Professional ability can be more easily practiced or improved when there is an individual's aptitude, which is considered a natural ability for an area of professional activity. The arrows in the picture indicate the points where there is a relationship between the concepts, when one considers the dependencies between them, being:

D1: Dependence of skills related to the acquisition of knowledge;

D2: After the possession of the means to perform an action, there is a dependence on the professional posture to effective action;

D3: Dependence on the disposition so that the posture is maintained by the professional;

D4: Behaviors that will result from the disposition;

D5: The behavior of the individual leads to the acquisition of new abilities or leads to the application of abilities already possessed;

D6: Considering knowledge as the basis of skills, there is the possibility of being improved precisely through professional posture and behavior arising from the posture. The fact that occurred at this moment is the acquisition of experience, which influences the attitude of the professional.

Although the relationship between the concepts is clarified in Figure 1, it must be acknowledge that an organization is formed by different people with different backgrounds and experiences. In the next section, it will be discussed the proposal of a generic mechanism that enables the mapping and identification of competences and the indication of a path for improvement, according to measures defined by the organization itself.

Proposal of a Measurement Mechanism

An organization is made up of people, who, at their different hierarchical levels, will have different experiences, although the professional path followed by some individuals may be equivalent. The training may be similar, as well as the professional experiences, but the way of interpreting them will be unique, referring to the beliefs and inclinations hold by the professional, which influence its behavior for the application of its ability.

Considering the different professional profiles present in the organizational environment, it is relevant to monitor the resources that the organization has, which may provide support to identify possibilities for improvement and situations in which the organization's potential is being underutilized. It is also possible to define internal action plans, like offer of seminars, workshops, training, reformulation of the team regarding the projects in execution, to meet gaps related to the identified needs.

Figure 2 is a representation that has eight different points of analysis, related to the concepts covered in the previous section. It is arranged in a way that makes it possible to position the organization at a specific point that corresponds to the relationship proposed, contemplating the training of professionals and their experience in their area of professional activity. This relationship is a proposal that addresses two parameters but that does not define measurement scales. The definition of measures for the parameters should be defined by the organization, eventually by making use of external references, such as widely used competence frameworks or specific references for some area of knowledge. In any case, a document that can assist in the definition of the measurement scale can be the plan of the organization, considering that it contemplates the area of human resources and is in communication with the other sectors of the organization, which will present the demands related to the professionals necessary for the continuity of the organization.

Fig. 2: Evolution of Competence

To facilitate the understanding of the representation in Figure 2, Table 1 provides a legend for the symbols used in the picture.

Table 1: Representations about Competence evolution

ID	Symbol	Meaning
(1)		Evolutionary line of competence
(2)		Aptitude
(3)		Capacity (acquiring Knowledge / Skill)
(4)		Gaining experience
(5)		Ability expansion
(6)		Demonstrated ability
(7)		Posture
(8)		Natural limitations (lack of aptitude)

The first sign, corresponding to *(1)*, represents how competence should evolve. According to the example, the evolution of a professional is measured in terms of experience and capacity, corresponding to the training of the organization's professionals. The second sign *(2)* is the influence of the natural talent, which serves as a facilitator for the evolution of the level of ability. In the representation of phases, the evolution of competence is based on two variables, one vertically and the other horizontally. The vertical renders the moment when knowledge and skills are acquired *(3)*, either through internal training, hiring employees, etc., while the horizontal reflects the moment when the acquired knowledge and skill are placed in practice *(4)* and experience is gained, serving as an influence on the evolution of ability. The sign equivalent to (5) represents the moments when there is an expansion of the ability, motivated by participation in training or qualifications that meet the metrics defined by the organization. In the sequence, *(6)* corresponds to the improvement of the results in the context of professional practice, that is, what the professional can do considering his/her ability. The evolution of ability occurs through the posture of the professional, which leads to the acquisition of knowledge and skill, as well as when faced with a specific scenario, he/she sees the opportunity to apply the ability he/she possesses, being represented by *(7)*, which is the line that is directly related to all the elements of the representation. The *(8)* corresponds to the limitations that a professional may have when exercising his profession, depending on the level of proficiency of his ability.

The Mechanism in Practice

In order to illustrate the application of the mechanism, the following scenario is considered: An organization has 100 employees, 80 of which have an undergraduate degree, 15 have a master's degree and 5 have a PhD degree. The average time of experience of the Bachelors is 1 year and 8 months, while the Masters have 5 years and 7 months of experience and the PhDs have an average of 5 years of experience. Using the proposed mechanism to perform the organization's competences mapping, the result would be as shown in Figure 3. Figure 4 also uses the proposed mechanism; however, it presents greater refinement, referring to the existence of groups of professionals with equivalent values. This representation indicates the existence of different profiles in the staff. To this end, the proposal allows the definition of action plans, to meet the organization's objectives of seeking to level the abilities and experiences of its employees.

Thus, using the concept related to the evolutionary line of competence, proposed in this work, it is supposed that the organization seeks professionals who have more experience in their area of expertise, making possible the leveraging of its employees' competence.

Fig. 3: Competence Mapping

Fig. 4: Group of Competences

Table 2: BPMM Maturity Levels
Based on Object Management Group (2008)

Maturity Level	Description
1-Initial	The processes are performed in inconsistent, sometimes *ad hoc* ways. Results are difficult to predict.
2-Managed	The management stabilizes the work within local work units to ensure that it can be repeatable. However, work units performing similar tasks may use different procedures.
3-Standardized	Standard processes are synthetized from best practices identified in the work groups, providing an economy of scale and a foundation for learning from common measures and experience
4-Predictable	Capabilities enabled by standard processes are exploited and provided back into the work units. Process performance is managed statistically. The process outcomes can be predicted from intermediate states.
5-Innovating	Both proactive and opportunistic improvement actions seek innovations that can close gaps between the organization's current capability and the capability required to achieve its business objectives.

The scope of the proposed mechanism is illustrated in Figure 5. This representation involves the application of the Business Process Maturity Model (BPMM), proposed by the Object Management

Group (OMG) (Object Management Group, 2008). The OMG considers that the adoption of a maturity model provides a way to implement vital practices in one or more domains of the organizational process. This model consists of five levels, which evolve from an organization that has no maturity in the process, with an inconsistent or *ad hoc* process and results that are difficult to predict, to an innovative, proactive organization.

Table 3: Knowledge & Skills for each BPMM Maturity Level Based on Object Management Group (2008)

Maturity Level	Knowledge	Skill
1-Initial	K1- Individualized Methods	
2-Managed	K2 - Planning and management process; K3 - Requirements control; K4 - Costs, schedules, renting	S1 - Develop, prepare, deploy, operate and support products and services; S2 - Follow plans, processes, and procedures
3-Standardized	K5 - Work process; K6 - Support process; K7 - Management people; K8 - Input; K9 - Standards and procedures; K10 - Work activities; K11 - Verification mechanisms; K12 - Results; K13 - Output criteria;	S3 - Develop, prepare, deploy, operate and support products and services across the organization; S4 - Record lessons learned
4-Predictable	K14 - Methods and measures for managing work; K15 - Regression graphs; K16 – Histograms	S5 - Establish and manage assets; S6 - Integrate processes from different disciplines; S7 - Establish processes and plans; S8 - Establish and maintain organization's capability data S9 - Manage job performance and variation; S10 - Manage achieve quantitative performance and quality goals
5-Innovating	K17 - Business goals; K18 - Business implications; K19 - Improvements in defect and problem prevention; K20 - Continuous improvement	S11 - Analyse cause-effect; S12 - Implement corrective actions; S13 - Identify continuous improvement

Table 2 represents the maturity levels of the model proposed by OMG, with the respective description of the scenario and Table 3 contains the Knowledge and Skills corresponding to each maturity level.

Through this representation, following the example of using a maturity model with a relevant contribution for professionals in the IST area, it is possible to align it with managers in decision-making processes that involve the context of available human resources.

In a punctual analysis, the professional can also make use of this mechanism by him/herself. Considering that the professional holds a set of knowledge and skills, these can be put to the test at some point of its professional career, for example, to get a certification. To this end, the mechanism proposed for the mapping of competences may define, in the vertical axis of attitude (7), the values corresponding to the metrics that will be required for getting the certification, as well as depicting, in the horizontal axis of attitude (7), the length of professional experience working in a given position.

The scope of the proposed mechanism, based on the relationship between the concepts related to competence, allows its application in different scenarios since the measures can be defined by the user of the mechanism who, after mapping, may resort to the guidance provided by the concepts covered in this work.

Fig. 5: Competence mapping for BPMM Maturity Levels

Conclusions

During the study of the concepts coved in this work, it was found that measuring competences was also noted as being difficult. Thus, the search for a mechanism that would assist in the mapping of competences began to be defined, emphasizing the importance of meeting different demands, be at an individual or organizational level. Parameters used to measure will certainly be different from one organization to another, as demands are different, as well as the specifics of any given environment. At the individual level, the proposed mechanism also makes it possible to define measures in a generic way, since a professional should be able to identify the appropriate measurement units by using some reference or benchmark in its professional field.

Although the aim of this study is comprehensive and not restricted to particular contexts, exhaustive application of the mechanism is necessary, both as a diagnosis tool and as a tool for monitoring and following up competences and to prove its effectiveness in supporting decisions related to competences.

Future Work

In addition to the definition of a mechanism for managing and monitoring competences, the central theme of this study requires greater attention in situations involving the relationship among competences at different levels of the organizational hierarchy, such as on the individual, group, and organization level. Further studies could focus on portraying the interaction among those levels and finding out how to achieve mutual benefits for improving global competences of organization. In view of the existence of incongruences between the frameworks that used the concepts related to competences, we suggest carrying out work aiming at specifying the components of competences in specific contexts of professional practice and thus contributing to minimize certain misunderstandings, perhaps caused by the lack of criteria for defining those concepts.

Considering the concepts covered in this paper and their relationships, an additional research goal is to develop a set of rules for classifying items related to the competence construct that are currently being used in an *ad hoc* manner, strengthening the scientific research on competences. The purpose of this planned work is to make it possible to pay attention to problems instead of, for example, paying attention to the framework of a profession and the composition of its elements. It is our belief that communication between practitioners and academics will facilitate the structuring of professional careers. Academic institutions would also benefit, insofar as they can better understand the relationship between companies' needs for professionals and training requirements.

Abstract

The aim of the paper is to analyse the life cycle of the enterprises in the Slovak creative industries according to the various determinants such as the economic development and clusters. Creative industries tend to localise mainly around large and medium sized cities forming creative local clusters. The study provides a first empirical evidence of the forces behind clustering of creative industries influencing the success of the creative industries' entities as well as the length of the life cycle. The analysis has been performed for Slovakia. The results show different patterns of clustering of creative employment in Slovakia. The average size of creative industries, the productive diversity and the concentration of human capital and creative class have been found as common aspects of clustering in Slovakia. Our findings provide empirical evidence of the small positive role of historical and cultural endowments as influences of clustering. We make suitable recommendations required to conclude that the length of the entities' life cycle in the creative industries is influenced by the several factors linked mainly to culture, economic progress, modernization and local clusters. The paper contains just the partial results of our research.

Keywords: Creative industry, life cycle, clusters, economic development, Slovakia.

Introduction

The question of how the life cycle model should be implemented to the research of organizations is still an open debate. There have been several attempts to define an organic approach to progress and growth. Many of the previous researches on the lifecycle of small firms have concentrated on its growth path. Key researchers in the field (Miller & Friesen, 1984; Quinn & Cameron, 1983; Rayna & Striukova, 2016) have examined stages of small business progress from beginning to maturity and in so moving, they analysed the formation of a business, their reply to growth and external demands. Overall, they break down to agree on one model. Notwithstanding, they get to the opinion that the failure to determine and integrate business systems and processes can generate a production crisis and stops progress for small firms. In summary, these scientists provide useful templates to reinforce the expansion of small business. Using the manual prepared by Churchill and Lewis (1983), we are prepared to record what could be expected as the first "fruits of success".

The Life Cycle Model of Creative Businesses

For owners and executives of small firms, such an understanding of the business life cycle can assist in evaluating current challenges (de Jong & den Hartog, 2010; Pellikka & Malinen, 2014). As an example, we mention the demand to boost an existing computer system or to employ and train second-level managers to provide planned growth. It can aid in preparing for the key needs at various stages – for example the unconscionable time engagement for owners during the first stage (start-up period) and the need for organization and shifts in their managerial roles when enterprises develop into larger and more complex.

Figure 1 below displays the five stages of small business progress - from birth to resource maturity. In stage 1 – which is the birth stage of the business, the most significant business choices for the future are proposed. Some of these decisions consist of the market capacity for the product, the start-up finances, the extension of production and the capability of the employees. However, as crucial as these activities are, they simply become significant when the small business turns into the survival stage - stage 2. At this stage, the business requires to prove that it is a working entity with clients who are satisfied with its products. The turnover of sales can generate sufficient cash to breakeven. Breaking even and turning to the next stage which is success - stage 3 means a major change because the business owners - they may prefer to stay at the survival stage - maintains supervision over the firm and only they have to decide on the firm's future paths.

Figure 1: Five stages of a business life cycle

Source: Churchill and Lewis, (1983)

Creative business owners manage to hold back at this stage there by threatening the progression towards resource capability (stage 5).This is because the resolution to move to the following stage (stage 3-D) requires plentiful liquidity, above average profitability and effective financial management with proper production systems (Figure 2). The owner is also supposed to totally or partially withdraw from the firm (Mota et al., 2020). This fear of carrying out these modifications in a healthful manner leaves a number of owners holding back at the value of the increase of the business. In breaking stage 3 into stages of success, Churchill and Lewis (1983) demonstrated that small businesses are located in a continuity from which it can go forward or last the same. It is frequent to encounter that the condition of disengagement by owners of creative business is painful and turn into the seed of its eventual breakdown.

Figure 2: Development of the ownership throughout the business life cycle

Source: Churchill and Lewis, (1983)

The modern theories in industrial dynamics present a way to explain the spatial expansion of industries as a transformative process (Lazzeretti et al., 2019). Using data on the access and quit of companies, the additional information on the location of enterprises provides one with an expanding spatial placement of entities in the creative industries. One can suggest the question to what extent an expansion in spatial concentration derives from differential spinoff rates (considering that spinoffs locate in the same province as their parent enterprise) as well as to what extent spatial concentration influences the survival percentages of new enterprises through agglomeration effects (Rodrigues & Franco, 2020; Zhou & Verburg, 2020).

The rest of our paper is structured as follows. Section two presents data and the methodology used, section three provides results and discussion related to our research, while the last section concludes the results of the research.

Data and Methodology

The aim of the paper is to analyse the life cycle of the enterprises in the Slovak creative industries according to the various determinants such as the economic development and clusters located in Slovakia. Creative industries tend to localise mainly around large and medium sized cities forming creative local clusters. The study provides a first empirical evidence of the forces behind clustering of creative industries influencing the success of the creative industries' entities as well as the length of the life cycle.

The industrial geography literature generally describes the clustering by place-specific elements and agglomeration economies. This approach covers interests that can be utilized by companies that are settled in a region. It is trivial to separate between localization and urbanization economies. Such local assets entail better infrastructure and a larger diversification in local industries and relevant technologies. The research questions were following:

- **Research question no. 1** - Are the biggest creative industries' clusters of the by the number of businesses located in the regions with the highest GDP?
- **Research question no. 2** - Are the birth of the enterprises in the creative industries influenced by the economic situation of the country?

The data used in the research were provided by the Eurostat Database and the Finstat Database. The Finstat Database provides various data about business entities located in Slovakia. The most important data sources processed in the mentioned database are Business Journal, Business Register, The Trade

Register of the Slovak Republic, Register of Financial Statements, Bankruptcy Register, lists of debtors from insurance companies, lists of financial administration and court decisions (Finstat, 2020).

Our research sample consists of 3 978 businesses in the Slovak creative industries and we have selected the following four specific activities included in the creative industries:

- Other professional scientific and technical activities (SK NACE 74.900),
- Organization of congresses and business exhibitions (SK NACE 82.300),
- Providing the artistic education (SK NACE 85.520),
- and Supporting activities related to performing arts (SK NACE 90.020).

Results and Discussion

The economic development of the country can be measured by the various indicators. We chose the GDP as the most relevant economic indicator for our research. Figure 3 shows the development of the GDP reached by the regions in Slovakia (in mil. EUR).

Figure 3: Development of Regional GDP in the Slovak Republic (2000-2017)

Source: own processing, data extracted from Eurostat database.

The economic conditions in clusters may radically influence the first stage of the creative business life cycle. In another words, clusters represent the density of the creative industries' entities. Creative industries contribute to cluster in specific places and the reasons of this aspect can be due to a plenty of factors related mainly to culture, creativity, innovation and local development (Vitálišová, Vaňová & Borseková, 2015). Five concepts have been examined: the reasons of creative clustering linked to the existence of historical and cultural heritage and the relations of this method to cultural cluster and region, the influence of agglomeration economies and the organization of the industry, the approach of "related variety" and its contribution to the clustering of creative projects, a fourth approach deals with the role of human capital in clustering and the fifth relies on the creative class. The interpretation of the process of clustering of creative industries has been mainly concentrated from a descriptive and conceptual point of view rather than modelled or mathematically determined. According to the research provided by Baculáková (2018), Slovakia has four clusters. Cluster 1 is presented by the Bratislava Region with the highest density of creative industries' entities, Cluster 2 consists of following regions: Trnava, Žilina, Banská Bystrica and Prešov; Cluster 3 covers the Trenčín and the Košice Region; and the Nitra Region represents Cluster 4. Cluster 1 with the highest number of creative industries' businesses is located in the Bratislava Region. Western Slovakia (the Trenčín, Nitra and Žilina Region) has reached the highest GDP, but the biggest clusters in the number of businesses are not situated there. The research assumption that the biggest cluster is situated in the region with the highest GDP was false.

Figure 4: Regional Clusters of Creative Industries in Slovakia

Source: Baculáková, 2018.

Figure 5 illustrates the development of the GDP in Slovakia from 1995 till 2018. The data for year 2019 are not available yet. Real GDP growth rate data in Slovakia are available from 1995 to 2018, with an average rate of 4.3 % (Eurostat, 2020). The data reached an all-time high of 13.9 % in Q4 2007 and a record low of -5.9 % in Q1 2009. The decrease of the GDP growth rate was caused by the global financial crisis which started in 2008. One can see the constant growth of the GDP excluding the beginning of the financial crisis.

Figure 5: Development of GDP in Slovakia (1995-2018) in current prices (mil. EUR)

Source: own processing, data extracted from Eurostat database.

As we mentioned above, the significant growth has been reported in the group of enterprises providing other professional scientific and technical activities (SK NACE 74.900). In overall view, we may confirm that the development of enterprises providing other professional scientific and technical activities is related to the economic development in Slovakia. On the other hand, the enterprises organizing the congresses and business exhibitions (SK NACE 82.300) are stagnating (Figure 6).

Figure 6: Development of enterprises providing other professional scientific and technical activities and organization of congresses and business exhibitions (1989-2019)

Source: own processing, data extracted from Finstat database.

Figure 7 illustrates the development of enterprises providing the artistic education (SK NACE 85.520) and enterprises focused on supporting activities related to performing arts (SK NACE 90.020) from 1989 till 2019. The progress of enterprises providing the artistic education is opposite to the development of the Slovak GDP. In this case, we have to reject the assumption that the number of the enterprise's birth is influenced by the economic development. For the group of enterprises focused on supporting activities related to performing arts (SK NACE 90.020), the research assumption is confirmed.

Figure 7: Development of enterprises providing the artistic education and enterprises focused on supporting activities related to performing arts (1989-2019)

Source: own processing, data extracted from Finstat database.

Conclusion

As the literature review in the first part of this paper proved scientists in East Central Europe followed the academic discussion on creative economy after the beginning of the new millennium. This was partially related to the prosperous economic restructuring of these regions and the increasing role of creative industries, and partially the intrusion of EU policy measures and programmes. Results of global comparative research projects, as well statistical reports focusing on the macroeconomic position and local pattern of creative economy in different countries became commonly distributed. Our paper fits to the second group of studies, as we analysed the varying geographical pattern of creative economy in Slovakia, based on statistical data.

A firm's development stage affects the managerial considerations that must be dealt with. Realizing its development stage and subsequent plans enables managers, owners, business partners and investors to make more knowledgeable decisions and to strengthen themselves and their enterprises for later challenges. While each company is special in many ways, all deal with similar issues and all are subject to considerable changes.

Cluster 1 with the highest number of creative industries' businesses is located in the Bratislava Region (the second highest GDP in Slovakia). Western Slovakia consisting of the Trenčín, the Nitra and the Žilina Region) has reached the highest GDP, but the biggest clusters in the number of businesses are not situated in these regions. The research assumption that the biggest cluster is situated in the region with the highest GDP was rejected.

The progress of enterprises providing the artistic education and the enterprises organizing the congresses and business exhibitions is opposite to the development of the Slovak GDP. In these two cases, we have to reject the assumption that the number of the enterprise's birth is influenced by the economic development. For the group of enterprises providing other professional scientific and technical activities and enterprises focused on supporting activities related to performing arts, the research assumption is confirmed.

Acknowledgments

The presented research paper is the output of the scientific grant VEGA n. 1/0340/19 "The Entrepreneurial Dimension of Creative industries in the Context of Innovation and Smart Growth" (50 %) and the internal grant project of the University of Economics in Bratislava (Faculty of Business Management) no. I-20-101-00 called "Research of Creative Industry Enterprises with regard to Their Life Cycle in the Slovak Republic" (50 %).

Abstract

The number of mobile phones and mobile phone subscriptions has grown significantly in the last years. More and more powerful phones are launched in the market. This has driven the development of various mobile applications for different fields of activity, one of them being the education area. Also, the cloud in mobile solutions is increasingly present, having the role of enriching the user experience by boosting the capabilities of the mobile devices through increased processing power and increased storage capability. The goal of our paper is to analyse the impact of cloud in mobile solutions for educational systems. Our methodological approach in this paper is to obtain statistical data about the usage of mobile devices, the cloud services and educational applications in order to analyze the role of cloud in mobile solutions and its impact for the educational systems. In our research we observed an increasing usage of mobile devices and a preference of those devices over desktop computers. Also cloud mobile data traffic increased in recent years compared to non-cloud mobile data traffic. Given the fact that the educational systems require more computational power and more storage capability, cloud is a natural option for those. Also, the number of mobile solutions in educational systems has increased in the last years, fact that changed the way an individual can learn and manage activities in schools.
From our results of the analysis we've concluded that cloud mobile solutions already have a high impact in the educational systems and will continue to change the schools for the upcoming years, by offering easier access to learning resources. The impact will be more felt in the developing countries which currently have difficulties in accessing decent learning resources.

Keywords: Mobile Applications, Education System, Cloud, M-Learning

Introduction

In the last years the number of mobile phones users has grown significantly, which has led to a continuous improvement of the phones capabilities over the years (Kemp, 2020). The rapid development of phones has resulted in the emergence of various mobile applications for different fields of activity, one of them being *education*. In the last years worldwide there have been created various mobile applications that help students in their learning processes.

The best mobile phones in the world come from the most important manufacturers, including Apple, Samsung, Huawei or Sony, but also new companies such as OnePlus or Xiaomi (Jessica, 2020). In the last 10 years many features of the phones have changed enormously, most of them for good, since they are really true mini-computers. If we were to think of a few minuses, the biggest one is that the top models are extremely expensive, other minus is that the batteries rarely last for more than one day of use, and another negative aspect is that the phones weight, most of them can be considered as heavy (Jessica, 2020).

More and more advanced technologies have strongly penetrated in the field of education (Raja & Nagasubramani, 2018). There have been created various mobile applications around the world that help students in their learning process like Smart Vocabulary, Zoom, Edmodo, Kahoot!, Socrative Student, Quizlet, Evernote, Google Classroom, Google Earth, Duolingo and many others (Group, 2020). More software and hardware resources are included in the process of developing the educational applications

and by that are offered courses and teaching materials with rich educational content, supporting learning and assessment to those interested.

Cloud computing technologies have become increasingly popular in recent years. Cloud computing allows to store data and applications and provides very powerful computing services. A big attraction of the cloud is the fact that it reduces the cost to build your own infrastructure. The increasing capacity of the networks to transmit data over long distances, cheaper high performance computers and mobile devices and also the low cost storage units have increased the popularity of the cloud. (Kushida, et al., September 2011)

Mobile technologies in the cloud environment face an increasing interest nowadays by bringing richer computing resources for the users of mobile devices. Although mobile devices are becoming better and better in terms of resources and computing power, they are still considered limited. Our current technological evolution is leading to an increase in the volume of data, which calls for more demanding programs to process it. In this case, Mobile Cloud Computing attacks the limitations of mobile devices such as: processing capacity and storage capacity, delegating these requirements to other systems with better performance and richer resources. (Akherfi, et al., 2018) (Noor, et al., 2018)

In this paper our methodological approach is to obtain statistical data about the usage of mobile devices, the cloud services and educational applications in order to analyze the role of cloud in mobile solutions and its impact for the educational systems.

This paper is structured in 4 chapters, an introduction in which we make a general presentation about mobile devices, education and cloud computing. After that we have 2 chapters for the literature review and the analysis of the mobile solutions for the education sector. At the end of the paper we have the conclusions chapter in which we draw a line and conclude about the impact of the cloud for mobile solutions in education.

Literature Review

In the last years the number of mobile phones users has grown significantly from 2.5 billion users in 2016 to over 3.2 billion in 2019 and it is forecasted that in 2021 there will be 3.8 billion mobile users **(Holst, 2019)**. This has resulted in a continuous improvement of the phones over the years, as shown in figure 1.

Fig. 1: Number of smartphone users worldwide from 2016 to 2019 and the forecast for 2020 and 2021 (Holst, 2019)

Also recently, the usage of mobile devices has outgrown the usage of desktop/laptop devices (StatCounter, 2016). Being easier to carry from place to place, mobile devices are the preferred choice for accessing information at anytime from anywhere.

A research from Statista made last year that present the findings of Mary Meeker, published in the annual Internet Trend report suggests that smartphones consume about a quarter of our day for an individual (Anon., 2019). Although, we can see from the chart in figure 2 that in 2018 from the total of 6.3 hours per day in a digital environment, people from U.S. spend 4 hours in front of their phones, a significant larger time than the time spend in front of desktops or laptops and this is emphasized by the stronger networks to which mobile devices are connected, especially due to the last jump in mobile network connectivity, 5G (Anon., 2019).

Fig. 2: Daily hours spent with digital media in the U.S. per adult user ***(Anon., 2019)***

Mobile devices, although more powerful in terms of resources, which allow them to run more demanding applications, are still limited. They are currently on the same level in terms of processing power with some laptops but their highest limitation is the battery lifetime which doesn't last long. So, running demanding applications, although being possible with the current processing capacity of the mobile devices is not recommended, because this will shorten the battery lifespan.

In order to preserve the battery and limit the calculations made by mobile devices, the answer is mobile application offloading. With offloading, the mobile application and the device become just a client, tasking a server with the processing, increasing the efficiency of the device and thus extending the battery life. Cloud services are perfect for this task, they are already being used to host applications that run in the cloud. Also, the cloud has another benefit for mobile devices, such as extending the storage of the device. This is particularly important for educational platforms, which require large storage and processing power.

Fig. 3: Distribution of global cloud and non-cloud mobile data traffic from 2014 to 2019 ***(Anon., 2015)***

Mobile devices and the cloud work well together, the cloud being able to reduce the deficits of mobile devices, processing power which drains the battery and storage limitations. This is also shown in a survey made by Cisco Systems in 2014 which was released in February 2015 and published also on Statista. This survey indicates, as shown in figure 3, that in 2014 cloud traffic for mobile devices was already 81% of the total traffic globally with 19% being non-cloud traffic. They also made a forecast for the next years up to 2019 that shows a growth in cloud traffic and a decrease in non-cloud traffic (Anon., 2015).

Analysis of mobile solutions for the education sector

In the context of the current technological development, the educational area is facing more and more challenges in adapting to the ever-changing needs of the students (Litvinov, et al., 2018). The increasingly diversified expectations and the presence of mobile phones in everyday life has led to the emergence of a new method of learning, learning through mobile devices (m-learning), attracting the interest of more and more researchers (European Students' Union (ESU), n.d.). Conventional methods of learning can now be joined by other non-conventional methods, more adaptable to rapid progress, one of these methods being represented by the notion of learning by electronic devices (e-learning).

In the last fifteen years, e-learning has become a real viable alternative to the traditional educational practices, being implemented in more and more institutions. The concept of electronic learning can be defined as a form of formal or non-formal education with established learning objectives, where the interaction between participants is facilitated by computer or communication technologies (European Students' Union (ESU), n.d.).

Over time mobile learning has become an important tool for education, preferred due to the flexible and personalized approach of learning (Ally & Prieto-Blazquez, 2014). Also, the interest in mobile learning grown because the students spend a lot of time using their mobile devices. When using mobile devices students can access online platforms, attend online courses, read books, contact teachers or take exams as they would do in the formal education (Ally & Prieto-Blazquez, 2014). The notion of mobile learning comes as a natural extension of the broader concept of electronic learning. The main difference is due to the higher degree of availability and accessibility that can be achieved using a

mobile learning environment. The implementation of this notion brings substantial benefits to the quality of education within the whole community (teachers, students or parents). There are also opinions in the literature that, in addition to support for the learning component, mobile learning also includes all the interactions that take place between teachers, students or other members who can be part in the learning process (Andrews & Haythornthwaite, 2007). In a simplistic approach, the m-learning can be defined as "the ability to access educational resources, tools or other materials at any time, from any location, using a mobile device" (Development Fund, 2010).

The mobile market experienced an accelerated growth rate from $2936 million in 2014 to $3522 million in 2017 (Technologies, 2017). Moreover, within the Apple app store, education applications were among the top three most used apps in the May 2019 (Technologies, 2017).

A survey published by J. Clement, based on more than 10,900 mobile devices, from September 2019 shows that worldwide the mobile educational applications are present in almost 29% of the mobile devices, while almost all of the devices have tools, communication, travel and local, social, music and audio mobile applications (Clement, 2019).

Fig. 4: Popular Android app categories worldwide, September 2019 (Clement, 2019)

All this research and improvement of mobile cloud solutions has led to the emergence of the mobile educational solutions. Worldwide can be found thousands of mobile educational solutions. A very good example is Mobitti, which is an application that provides mobile services and applications for universities and colleges. The main features of the solution are Android & IOS support, exams, grades, timetable, check student attendance, push notifications, social capabilities, private mobile messaging service for students and faculty, in-campus navigation, links to social networks, high security and many more (Mobitti, 2020). Other example is Creatrix Campus, which is a company founded in 2006 that has clients in 18 countries, with more than 150 clients, more than 12 years of mobile and web development and has developed more than 250 web and mobile projects. Creatrix Campus is a campus management system that helps colleges or universities to align their core academic and administrative processes with the current technologies and gives them the ability to compete in today's market. Creatrix Campus offers an automated scheduling software, online evaluations and assessments, learning management system, curriculum management, chat bots, and many others services (Creatrix Campus, 2020).

Fig. *5*: Mobitti and Creatrix Campus mobile cloud based applications (Mobitti, 2020) (APKPure, 2019)

The Creatrix Campus mobile application improves the collaboration and engagement between the faculty, teachers, administrators, students and parents. The users can easily get access to information related to profile, attendance, assignments, grades, fee payments, events, etc. Also, they can track all their activities and schedules in real time such as grades, transport, attendance to courses, news, events and more. The application can be used to store and retrieve files and documents such as assignments and assessments without syncing to the mobile service. We can say that the Creatrix Campus application is an important tool for education, preferred due to the flexible and personalized approach of learning (Sriram, 2015).

Conclusions

Our research resulted that the number of educational solutions for e-learning is increasing. Also, these solutions are becoming more and more complex and are helping more in the educational processes, like organizing classes project and exams, take quizzes give grades and share educational resources. M-learning is more present with the increased usage of mobile devices, which is a consequence of the increasing number of these type of devices. From our research we have seen that the majority of the traffic for mobile devices is cloud traffic and with the benefits of the cloud we are convinced that the cloud is having a big impact in improving the mobile solutions for education.

The biggest impact will be encountered in the developing countries, like the countries in Africa. The fact that the costs with mobile devices are not high and those devices are more and more available will convince the authorities to buy them in favour of desktop PCs. Mobile devices are a better choice especially because they are easier to be deployed in schools and are easier to be moved from unit to unit, depending of the needs of each unit and the changing number of children learning in those.

The cloud will be also be a big game changer by allowing the schools, especially those in developing countries to use an existing infrastructure without the need to build one in house. This will save costs and time in developing a hardware and software architecture that might fail as a project, if the people involved don't have the right skills. Also this will take the need for administration for such a system which would take considerable resources in man power to keep this kind of system alive.

There are already many educational resources available on the market, which are ready to use, further reducing the cost and time for development. Those solutions will need the cloud infrastructure because of the demanding computing power required and large storage needed. Those systems could be used not just for storing courses for students, but also manage teachers, students and gradebooks. Also, complex educational systems can be used for managing exams and allowing children to take tests on mobile devices connected to the cloud, further enriching the educational experience.

In conclusion, we can say that the mobile solutions in cloud have currently a strong impact in the education system and can change the future for education worldwide.

Further research is required on this subject and a future direction in this research will be a case study for the schools that adopted e-learning solutions based on the cloud and the analysis of the changes that these solutions bring to the conventional methods of learning in these schools.

The Impact of State Reforms on The Russian Federation's Agriculture Development

Irina V. SOKOLNIKOVA

PhD in Economics, Associate Professor, Department of Financial Management,
Plekhanov Russian University of Economics,
Address: 36 Stremyanny Lane, Moscow, 117997, Russia
Email: irinasokolnikova@yandex.ru

Abstract

The article outlines the main stages of Russia's agricultural development in the wake of state reforms since the beginning of the 90s until the present time. It studies the agrarian reform of the 90s, which formed private ownership and created interest in getting profit from economic operations. At the same time poor legislation, severing of economic ties, the lack of due support of farmers undermined large-scale agrarian companies, reduced agrarian lands and led to a significant dependence of the country on food imports. The article focuses on a priority national project of agriculture development fulfilled in 2006-2007, its contribution to the recovery of agriculture, and stresses insufficient elaboration of support measures for companies of various sizes, the weakness of financial support channels. Special attention was paid to a state agriculture support progamme of 2013-2020.The article assesses the effectiveness of the state measures with the help of financial indicators of agricultural companies. Our critical approach demonstrates that further modernization of Russia's farming is only possible, if there is long-term financial stability in the segment. At the same time the technologies producing high-quality local seeds and modern equipment should become the priority directions for investment. A state import substitution programme had a significant positive effect on the investment attractiveness of agriculture.

Keywords*:* Agricultural Companies, Agro-Industrial Complex, State Reforms, Development.

Introduction

The share of agricultural products in Russia's GDP is growing thanks to an agriculture programme adopted by the Russian Federation government in 2012. The share rose from 4.64% in 2012 to 5.4% in 2019. The GDP is to grow by 0.3% and the current trend of expanding food exports will persist until 2024 (Deloitte, 2019). This demonstrates that agriculture accounts for a significant share of the Russian economy and the share increases. At the same time, we should note that the share of agriculture in GDP fell both in developing and developed states in the last decade. The question arises: is this change good for the national economy's competitive advantages? The positive factors include higher independence of the Russian economy on all types of food imports, creation of jobs at farms and agricultural organizations, a better food quality, the launch of innovative technologies in plant growing and cattle breeding. The positive effect from agriculture exports support spreads to transport, wholesale, construction, machines and equipment. There are also negative factors – for instance, plant growing greatly depends on the weather, while cattle breeding can be prone to the loss of livestock from epidemics. There are also difficulties in forecasting the agricultural market trends, which translates into fluctuations of the financial result. This is why to assess the effectiveness of farming on the whole, we have to assess financial indicators of Russian agricultural companies in the wake of the government's supportive measures.

Literature Review

The Russian agriculture has undergone large-scale reforms in the last three decades. First, the agrarian reform of the 90s, which introduced a sea change to all the farming processes. D. Sedik, Z. Lerman, N. Shagaida, V. Uzun, R. Yanbykh analyzed the results of Russia's agrarian reform from1990 to 2015 (Sedik, Lerman, Shagaida, Uzun, & Yanbykh, 2018). Privatization, forming of

private ownership in agriculture, the appearance of interest in the financial result and the possibility of reinvestment in development made this industry attractive for dozens of thousands companies, hundreds of thousand farmers and millions of independent farms. Simultaneously, the unwise policies of the 90s led to a lower turnover of land used for agricultural purposes from 214 mln ha in 1990 to 195 mln ha in 2002, or 8.8%. It was only thanks to a new developing and preserving concept of agriculture in the new millennium and implementation of a 2014–2020 federal target programme Development of Russian Agricultural Land Reclamation, which produced positive signs (Brooks, K., & Lerman, Z, 1994). However, the situation is far from ideal, because not all agricultural land is used for that purpose.

Priority national project Agriculture Development implemented in 2006-2007 (Barsukova, 2007) is the proof the necessity and good reason behind state support for the achievement of state strategic purposes. It is worth mentioning that it was one of the four projects launched by the Russian Federation government in that period. The agribusiness, of course, is one of the country's priorities capable of ensuring long-term strategic security.

The key development vectors under the priority national project were faster development of cattle breeding, incentives for the spread of small farms, provision of young farmers with housing in the rural settlements. Initially, the programme amounted to 35 bln rbls, but the priority national project was replaced with a 2008-2012 State Program for the Development of Agriculture and Regulation of Markets for Agricultural Products, Raw Materials and Food in 2008 (Svatoš, Smutka, Ishchukova, 2014).

A wholly new state programme was developed in 2012 until 2013-2020 (State Program, 2019). This programme has attractive conditions for boosting investment in agriculture as one of the key goals. This programme ensures comprehensive development of agriculture, all-encompassing initiatives both in cattle breeding and plant growing, it counts 11 subprogrammes, which ensure comprehensive agriculture development and support to hi-tech innovative solutions.

Concept Headings

The negative factors of the 90s were so strong that by 1998 agricultural production volumes amounted to just 56% of the 1990 levels in comparable prices. In fact, farmers found themselves in very tough conditions in the 90s due to the collapse of old and the absence of new effective development mechanisms, pauperization of households, the end consumers of food, multiple price growth for materials and resources compared with agricultural goods and the overall collapse of parity in interindustry relations (Barsukova, 2017). To be fair, we should note that no country has agriculture functioning totally on market principles. Subsidies exist both in the developed and developing states neutralizing the risks immanent in agriculture because of the impossibility of creation of full protection from drought, floods, hurricanes and simply harsh weather. Of course, financial provision for this activity created in the Soviet times ceased to exist, while new instruments did not work, the crediting system failed to create conditions for production and promotion of food. Besides, the integration links between agriculture, the producers of agricultural equipment, the processing industry and retail were severed. Such business conditions explain the low attractiveness for investors, falling investment, a critical level of fixed assets deterioration. There was no prestige in being a farmer in the 90s, and even if some industries did produce a margin, it was much lower than the one in production and exports of raw materials (oil, timber, metals, etc) or creation of financial pyramids.

The Russian companies received a positive impulse for development in 1998 after ruble devaluation and as a result better competitiveness of local products thanks to low prices. However, the scale of the agricultural crisis was so vast that the 1990 production level was only achieved in 2004. The ensuing international oil price growth prevented long-term development of agriculture thanks to the1998 ruble devaluation. The farming margins shrank fast compared with other industries because of price growth for fuel and other resources (Barsukova, 2007). This means that agriculture cannot be effective without state support and bring the margins comparable with other businesses.

Under the priority national project Agriculture Development in 2006-2007, the following measures to develop cattle breeding were chosen – subsidies for commercial credits with duration of up to 8 years with targeted use for construction, reconstruction and modernization of cattle breeding farms; the purchase and leasing of highly-productive pedigree cattle as well as machines and equipment for cattle breeding farms. The method of financial support was seriously discussed before the launch of the project – whether they should be direct subsidies or interest subsidies. It became Russia's first programme, which did not provide for direct investment in agriculture. It was consistent with the decisions adopted in the last decade of the XXth century, and on the whole financing of farmers on the basis of subsidized crediting proved to be good for market relations and is still applied taking the accumulated experience into account. It is important to note that the subsidized crediting system under the project did not mean state credits, the credits were issued by commercial banks, which set the interest rate. It was up to the government to decide who receives a long-term credit and how large the subsidy from the federal and local budget will be. For instance, in a credit at 14.5% annual, its cost for the borrower amounted to 3% as a result of a subsidy from the federal budget (2/3 of the refinancing rate) and local budget (up to 1/3 of the refinancing rate of 11.5% in 2006). However, the project was of a narrow nature, it focused on cattle breeding and small farms, while the volumes and variety of financial resources were insufficient to upgrade fixed assets and launch innovative technological solutions.

1. Crediting volumes under the project exceeded the government plan significantly, which testifies to the high popularity of the mechanism. The choice of cattle breeding as a driver project can be explained by the fact that the country in 2006 only produced about 50% of meat produced in 1990. Import dependence was critical bordering on a threat to the national security. Small private farms accounted for the bulk of cattle and poultry output in 2005 - 52.7%, agricultural organizations accounted for 45.8%, farmers for 2.5%. This is why small private farms had no restrictions in raising credit, while for the others it was conditioned against development of cattle breeding.
2. The leasing programme of the project changed the leasing structure significantly– previously machines and equipment prevailed, while the project increased the share of pedigree cattle in accordance with the goal of upgrading the livestock and increasing its productiveness. The advance payment on the leasing amounted to 7% and although the interest rates were higher compared to debt, it was this form that helped develop the farms lacking credit collaterals. The project also ensured a 8.1 bln rbl financing of the chains of agricultural consumer cooperatives for procurement, supply and sale of products of small private farms and farmers. However, the project had no clear scale and performance indicators for the cooperatives, only their number, while the land and mortgage lending received insignificant resources. Also, only a handful of agricultural producers can boast of land ownership, necessary for this type of crediting. The third point of the project -- to provide young specialists with housing had a very modest budget (4 bln rbls), but thanks to mutual financing federal budget money is augmented with regional budgets' funds and outbudget sources of municipalities, employers and employees.
3. The project prevented reduction of cattle livestock, increased cow productivity to a milk yield of higher than in the best years of the Soviet era (in 2006 – 3,600 kg, compared with the Soviet peak of 2,800 kg (Barsukova, 2007). Despite criticism of the project, on the whole it introduced positive changes and created conditions for the recovery of Russian agriculture. But we would like to point again to the fact that the project did not create conditions for all the agriculture directions with cattle breeding being the priority; not all types of operations were covered, small private farms had priority; the financial support channels were not diversified, the main method of financial support under the programme was subsidizing of the interest rate.

Let's discuss a wholly new agriculture programme adopted by the government in 2012.

It has many types of financial support forms for agriculture, including the following instruments:

1. Subsidizing. Subsidies can be received to compensate for direct costs of creation and modernization of agricultural facilities, for production of equipment for the agricultural producers as well as for its purchase.

2. Compensation of part of an interest rate to increase credit affordability for agricultural producers.
3. Grants for young farmers, development of family cattle breeding farms, etc.
4. Measures to develop country infrastructure, including to improve housing, development of roads, gasification and water supply.
5. State support to insurance for a harvest loss of 20% and more.

The key goals of the programme are presented in figure 1.

State support, a balanced and comprehensive development of Russian agro-industrial complex helped increase investment indicators. Investors became interested, agriculture can now be profit making and generate stable financial incomes despite its specific risks of the epizootic situation and the weather.

Figure 1: The key directions of the State Programme for Agriculture Development and Regulation of Agricultural Goods, Raw Materials and Food Market for 2013 - 2020 (created by the author on the basis of (State Program, 2019))

Investment in fixed capital of plant growing, cattle breeding and hunting companies increased from 492.5 bln rbls in 2014 to 707.7 bln rbls, demonstrating an average annual growth of 7.5% and outstripping annual inflation of 7.2% for the period (Russia in figures, 2019). Agricultural margins between 2014 and 2018 exceed the average by 7.5% and amounted to 15.6% on average. It is important to note that in 2013 agricultural organizations' margin amounted to only 6.3%, while the average indicator for all types of activities stood at 7.7%. According to rating agency Expert Online (https://expert.ru/expert/), Russia's top agricultural companies are Miratorg and Cherkizovo. Let's calculate the financial coefficients for their cattle breeding subsidiaries.

Table1: Financial coefficients of Miratorg–Belgorod

Indicators	2012	2013	2014	2015	2016	2017	2018
Total Asset Turnover Ratio (TAT)	0.38	0.52	0.72	0.67	0.65	0.51	0.62
Gross Profit Margin (GPM)	0.47	0.23	0.51	0.44	0.43	0.47	0.50
EBIT margin	0.42	0.20	0.49	0.41	0.41	0.45	0.48
Net Profit Margin (NPM)	0.45	0.35	0.40	0.38	0.35	0.39	0.40
Return on Equity (ROE)	0.69	0.50	0.72	0.59	0.43	0.33	0.36
Debt – to – Equity Ratio (D/E)	0.47	0.81	0.73	1.12	1.41	2.51	2.67

Own calculations based on financial statements from the Internet resource: https://www.audit-it.ru/
As follows from table1, comparison of the indicators for 2013 and 2018 demonstrates higher profitability ratios: the Gross Profit Margin (by 27%), the EBIT margin (by 28%), the Net Profit

Margin (by 5%). The fall of Return on Equity is due to a significant increase of capital, although this increase has failed to curb financial leverage growth by 230%.

Table 2: Financial coefficients Cherkizovo – Pig Breeding

Indicators	2013	2014	2015	2016	2017	2018
Total Asset Turnover Ratio (TAT)	0.34	0.49	0.34	0.51	0.65	0.72
Gross Profit Margin (GPM)	0.03	0.46	0.40	0.24	0.29	0.35
EBIT margin	-0.04	0.41	0.33	0.18	0.23	0.30
Net Profit Margin (NPM)	-0.03	0.40	0.30	0.09	0.13	0.23
Return on Equity (ROE)	0.00	0.31	0.25	0.14	0.25	0.51
Debt – to – Equity Ratio (D/E)	2.192	1.90	0.57	0.56	0.71	0.41

Own calculations based on financial statements from the Internet resource: https://www.audit-it.ru/
Using table 2, we can conclude that the profitability ratios increased significantly in 2018 compared with 2013. At the same time the dynamics is negative in the middle of the period. We should also note that sanctions against the Russian economy prompted Cherkizovo to delist from the London Stock Exchange. The shares of the company are traded in Russia. At the same time the following indicators grow: Total Asset Turnover Ratio and Return on Equity, dependence on creditors decreased (Morozova, Akhmadeev, Bykanova, & Philippova, 2019).

Positive results were also achieved in imports substitution. According to table 3, meat sales rose by 12.9%; milk by 5.8%; vegetables and cucurbits by 3.1%. Grain production is significantly higher than self-sufficiency. At the same time self-sufficiency in fruit and berries falls behind the plan significantly.

Table 3: Russian Federation's food self-sufficiency (Agriculture in Russia, 2019) and (Decree, 2020)

	2000	2014	2015	2016	2017	2018	target
Grain	102.5	153.8	149.1	160.0	170.6	147.2	>95%
Meat	67.0	82.8	88.7	90.6	93.5	95.7	>85%
Milk	88.3	78.1	79.9	80.7	82.3	83.9	>90%
Potatoes	99.6	98.0	102.1	93.2	91.1	95.3	>95%
Vegetables and cucurbits	85.6	84.1	86.8	87.4	87.6	87.2	>90%
Fruit and berries	55.7	32.5	32.5	36.5	33.1	38.8	>60%

In the new Russia's Food Safety Doctrine adopted in January 2020 (Decree, 2020), there appeared an item devoted to the level of self-sufficiency in the seeds of the key agricultural crops of local selection with a target of no less than 75%. Unfortunately, experts say that the target is very far away as Russian companies now strongly depend on foreign seed suppliers.

Discussion

First, further development of Russian agriculture should ensure, on the one hand, security of the national economy and the absence of its dependence on the key foods imports.

Second, export potential of the Russian agriculture should be boosted further. The programme should logically be extended not only to ensure high food production indicators in Russia, but also export development and as a result inclusion in 2017 in the priority project Export of Agricultural Products. Russian agricultural products exports grew between 2014 and 2018 by 5.6% annual on average. At the same time we should note that the growth was uneven-- for instance, in 2015 agricultural products

exports fell by 15% compared to 2014, while in 2018 the exports rose by 20% to the previous period. Nevertheless, the trend of the last few years encouraged optimism about the exports. For example, wider grain sales helped increase its production by 40%, meat and subproducts by 26%, fish and crustacean by 23% in 2018. (Deloitte, 2019). The countries importers of Russian food are diversified. Exports to China and the Asian region on the whole increased strongly. At the same time the volume of exports increases not only under the existing contracts, -- Russia obtained the right to sell various types of meat products to Egypt, Iran, Jordan, Iraq, of dairy products to the UAE and Iraq, fish products to Serbia, Iran and Brazil, honey to Serbia, and collagen to the E.C. states from 2016.

Third, new projects to boost food export are needed. Under the federal project Agricultural Products Export, the Russian food exports should rise to 45 bln rbls by 2024, growth should amount to 80.6% as compared with 2018. This means that we should not only continue to increase the food exports, where Russia leads the market (wheat, sunflower oil, corn, etc), but continue working to promote Russian regional subbrands like internationally known products with a clear geographical reference. We all know that subbrand has a different goal than just increasing the product line of a brand. A subbrand aim sat strategically important goals, primarily at widening the consumer group by forming a new target group. Subbrands become a wonderful solution, when the master brand creates a poorly attractive image to motivate a purchase. Subbrands are also meant to ensure image support to the master brand. The following registered and legally protected Russian brands have a promising future – Vologda Butter, Tula Gingerbread, Mozhaisk Milk, Astrakhan Watermelons, Astrakhan Tomatoes, Belyov Pastila, Altai Honey, Lukhovitsy Cucumber, etc. Regional subbrands should become the drivers of the national products promotion as ecologically safe, high quality and diverse food and form an attractive image on the foreign markets. It will be a quantum leap in Russian agricultural exports structure, which mainly consists of raw materials -- cereals, fish and sea food, vegetable oil. The products we suggest will help achieve a good added value and increase investment attractiveness of agriculture. The Russian Export Center takes an active part in the promotion of the umbrella brand Made in Russia.

Results

Our analysis of the reforms' impact on Russian agriculture between 1990 and 2020 helps us conclude that despite several existing problems, agricultural companies demonstrate positive financial dynamics. As tables 1 and 2 and official statistics demonstrate agriculture's investment attractiveness grows as their margins grow despite their significant volatility. Thus, investment in farming under the new conditions can become attractive despite the natural conditions and epizootic epidemics.

National security of all countries depends on agriculture. We can note significant achievements in self-sufficiency in the key food types, although there are areas requiring systematic and responsible work.

Agriculture needs all-encompassing financial support measures from the government aimed at introduction of new innovative technologies, especially for the creation of a seed basis of our own and a pedigree cattle livestock as well as for the development of agricultural machine-building, ensuring stable profitability targets for agricultural companies. This is why the inclusion of the Russian companies' seeds self-sufficiency target into the Food Security Doctrine in 2020 became very timely.

Future belongs to the products with a high added value. Exports of such food will help create sustainable competitive advantages for the economy, which calls for the development of regional subbrands and cementing of the Made in Russia umbrella brand.

The efficiency of state programmes will depend on the speed and degree of innovative solutions penetration into the farmers' operations to ensure higher labour productivity, low energy, materials and funds consumption. Agriculture needs new technologies, modern equipment and advanced environmental standards.

Abstract

The research aims at identifying the current situation regarding the migration of the Romanian rural population, as well as the causes of migration due to the country's accession to the European Union in 2007. The analysis also relies on data provided by the European Commission about the destination of the Romanian rural population, which chose to expand their professional horizons outside the borders of Romania. In order to statistically reflect the latest trends, the methodology included an analysis of the following indicators: the population by place of permanent residence; the change of permanent residence from rural or urban areas and the dynamics of urban and rural migration caused by moving house. During the period of time analysed, the highest domestic migration from both rural and urban areas nationwide was seen in 2017, when approximately 380,202 people decided to change their permanent residence. This study is a first step in designing a strategy for repopulating rural areas in Romania, and entrepreneurship is considered a major factor of economic growth, related to population migration.

Keywords: Migration, Population, Rural, Urban

Introduction

Following the fall of the communist regime (in December 1989), Romania engaged in a democratisation process and in the transition towards a market economy, applying numerous reforms in all the major social sectors and in all the economic sectors. During the last two decades there appeared temporary (circular and seasonal) forms of migration of the labour force which developed at a more accelerated pace than permanent migration (own contribution). With more than 15% of the population outside its borders, Romania is among the countries with the highest emigration rate within the European Union. Romania's emigrant population comprises an equal number of men and women and it is relatively young, 65% of it being between the ages of 18 and 39, Italy (43%) and Spain (30%) are the main countries of destination, also accounting for the highest concentration of Romanians working abroad (according to the European Commission).

As for domestic migration, between 1970 and 1990 its main flow was from the rural areas to the urban ones. Starting with 1992, the number of people who moved from the rural areas (villages) to the urban ones (cities) began to decrease, while the mobility in the opposite direction (from urban to rural areas) went up, which was mostly due to the economic transition and the decrease of work opportunities in cities. After 1997, the migration from urban to rural areas surpassed the number of people who moved from villages to urban centres, which is only partially due to the suburbanisation phenomenon (own contribution based on statistical data from National Institute for Statistics).

Emigration and domestic migration are phenomena which emerged within the previously existing framework of acute disparities between the level of economic development of the different regions of the country, as well as between the urban and rural areas, The Romanian regions characterised by a high loss owing to domestic migration are also regions of origin for considerable emigration flows. The

top three regions with the highest net population loss due to migration are the North-East, South-East and South. These are predominantly rural regions with high rates of employment in the agricultural sector, relatively high poverty rates (including of people who are in employment), which are faced with the danger of the rapidly aging population, with a generally low development of the infrastructure and managing to produce a GDP per capita which is much lower than the country average level (50-60%) according to the European Commission.

Migration and socio-economic transformation have been central topics for both scientists and members of the general public since the collapse of the former Eastern bloc. Romania is one of the countries affected in a special manner by these processes from which the country has to suffer particularly hard (Wilfried H.). Basically, Romania still is in a process of modernization and adaptation to European requirements.

Results and Discussion

From the social perspective, a phenomenon which is impacting the evolution of the rural area is the high number of people who chose to leave their birth place in search for other opportunities in urban areas or in other European Member States. In order to have a statistics overview of the last 30 years, we will consider indicators such as: population by permanent residence, change of permanent residence situated in the rural area or the urban area and the dynamics of the gross domestic rural and urban migration due to the change of permanent residence.

A, Analysis of the rural population by permanent residence

The density of the rural population is an important aspect that is taken into consideration by the entrepreneurs who intend to start a business in this area. Our analysis will cover the current situation of each of the eight development regions in Romania, by gender. As for the methodology used to obtain this indicator at country level, we have taken into account the total natural population growth and the total permanent international migration. The analysis by region took into consideration the different administrative situation, which is calculated based on the total natural population growth, the total permanent international migration and the total domestic migration (change of permanent residence).

Table 1: Rural population by development region, between 2013-2018

Gender	Development region	Year				
		2013	2014	2015	2016	2017
		UM: Number of people				
Male	**TOTAL**	**3,281,183**	**3,295,220**	**3,303,202**	**3,362,847**	**3,378,015**

-	WEST	213,645	213,740	213,450	218,588	218,800

Source: Processed data from the National Institute for Statistics

The male population reached its maximum level in 2013, in the North-East region, with 719,506 people, while the minimum number was in the Bucharest-Ilfov region, with 69,118 people. As for the female population, the highest value was also in the North-East region, where it stood at 580,775 people, the minimum being 62,714, in the Bucharest-Ilfov region. During the 2013-2017 time interval there were some fluctuations in the number of both males and females at local level. In the South-Muntenia region, although the male population experienced a decrease in 2015 in comparison with 2013, there was an upward trend, while in the South-West Oltenia region the numbers went down as well, but in two consecutive years, 2014 and 2015.

The female population also saw a regional fluctuation, but different as compared to the males. At the same time, in 2015, in the South-East region, there was an insignificant decrease in the female population, but in the South-Muntenia and South-West Oltenia regions there was the same pattern as for the male population between 2014-2015.

Likewise, the county with the highest density of rural population is Iasi, accounting for 23.3% of the total regional value (according to Appendix 1). The same situation is true for the female population, where the same two regions (North-East and Bucharest-Ilfov) have the most extreme values (according to Appendix 2).

B, Moving out of rural areas

The migration of the population from the rural area in the period 2013-2017 is a topical problem faced by the entrepreneurs operating in this area. As a consequence, the analysis will focus on the current situation of each development region in Romania. From the methodological point of view, this indicator will be determined without taking into account the changes of residence within the same locality, from one street to another or from one village to another, within the same commune. The change of residence is considered effective the moment the police has written the change of residence in the identity card and the respective citizen has received it back.

Table 2: People moving out of rural areas between 2013-2017

Development region	Year				
	2013	2014	2015	2016	2017
	UM: Number of people				
NORTH-WEST	17,575	18,328	18,405	19,308	19,400
CENTRE	13,708	14,505	14,179	15,171	15,545
NORTH-EAST	30,573	33,290	33,106	35,474	34,770

SOUTH-EAST	19,170	20,659	20,779	22,025	22,095
SOUTH-MUNTENIA	26,574	28,727	28,196	30,225	30,095
BUCHAREST-ILFOV	2,584	3,165	3,397	3,770	4,099
SOUTH-WEST OLTENIA	17,847	18,643	18,654	20,041	19,551
WEST	11,445	12,157	12,428	13,537	13,652
TOTAL	**139,476**	**149,474**	**149,144**	**159,551**	**159,207**

Source: Processed data from the National Institute for Statistics

The lowest number of people moved house from rural areas in 2013, when 2,584 people were recorded in the Bucharest-Ilfov region, while the highest value was in the North-East region. During the analysed period, the maximum number of people who moved out of the urban area was also in the North East region, when 35,474 people decided to move dwelling in 2016 in search for a better paid job. On a positive note, we can notice that in 2017 this migration flow experienced a downward trend, Likewise, at national level, several fluctuations can be observed due to the manner of reporting the moving of residence out of the rural areas, which resulted in an upward trend of the migration rate in the North-East, South-East and Bucharest-Ilfov regions, while in the Centre, North-East, South-Muntenia and South-West Oltenia the situation differed from one year to another.

C, Moving dwelling out of urban areas

The migration of the population from urban areas between 2013-2017 was indicated separately for each of the eight development regions and it was calculated without including the people who moved within the same locality, from one street to another or from one village to another, within the same commune. Also, the change of residence was considered effective as of the date when the police entered the change of residence on the identity card.

Table 3: Moving out of urban areas between 2013-2017

Development region	Year				
	2013	**2014**	**2015**	**2016**	**2017**
	UM: Number of people				
NORTH-WEST	19,411	21,276	20,800	22,880	21,988
CENTRE	20,681	21,538	21,174	22,733	22,278
NORTH-EAST	29,051	31,606	29,401	31,460	30,458
SOUTH-EAST	23,675	25,523	25,493	27,157	26,639
SOUTH-MUNTENIA	22,499	23,569	23,240	25,853	24,422
BUCHAREST-ILFOV	58,281	58,733	51,397	54,665	52,985
SOUTH-WEST OLTENIA	18,072	19,286	19,396	22,091	19,491
WEST	19,410	20,672	21,038	22,983	22,734
TOTAL	**211,080**	**222,203**	**211,939**	**229,822**	**220,995**

Source: Processed data from the National Institute for Statistics

During the baseline year, the minimum number of people who moved dwelling out of urban areas was in the South-West Oltenia region, while the Bucharest-Ilfov region accounted for the maximum number of 58,281 people. It was also in the latter region that the highest number of people moved out in 2014,

when approximately 58,733 people made the decision to leave the capital city. The main social categories were young university and/or master graduates who returned to their places of origin or went abroad for internships or to various workplaces, retired people who decided to move to the countryside in order to enjoy the beauty of this environment or employees, especially of big corporations, who were requested to temporarily change their residence (based on a Gfk study made in 2017). Another important aspect is the fact that all the development regions in Romania experienced a fluctuation of the migration from urban areas.

D. Dynamics of urban and rural domestic migration due to change of permanent residence

Domestic migration from both urban and rural areas between 2013 and 2017 is represented in Table 4 in terms of number of people and per mil, and it is broken down into four migration variables: from rural to urban areas, from urban to urban areas, from rural to rural areas and from urban to rural areas. The methodology used to obtain this indicator consists in a calculation basis which does not include the changes of residence within the same locality, from one street to another or from one village to another within the same commune. Also, the change of residence was considered effective as of the date when the police entered the change of residence on the identity card.

Table 4: Structure of urban and rural domestic migration flows due to change of permanent residence between 2013-2017

Domestic migration flows	Year									
	2013		2014		2015		2016		2017	
	UM: Number of people, per mil inhabitants									
	Number of prople	Per mil	Number of prople	Per mil	Number of prople	Per mil	Number of prople	Per mil	Number of prople	Per mil
Total	**350,556**	**15.7**	**371,677**	**16.7**	**361,083**	**16.2**	**389,373**	**17.5**	**380,202**	**17.1**
From rural to urban areas	74,023	5.9	78,411	6.2	77,878	6.2	82,612	6.6	87,097	7

Source: Processed data from the National Institute for Statistics

At national level, the maximum value of the domestic migration to and out of the rural and urban areas was recorded in 2017, when approximately 380,202 people made the decision to move dwelling. The maximum number of people moving from rural to urban areas was reached in 2017, while the migration from urban to rural areas peaked in 2016, when it stood at 120,950 people. This aspect is due to government programmes which offer various subsidies for moving back into rural areas, as well as to the National Rural Development Programme offering various facilities to the current and future entrepreneurs who can bring added value and innovation to the rural areas. In addition to the above

mentioned aspects, people who are 65 and above move to rural areas because they want to remain active and enjoy the beautiful landscapes of rural Romania.

The indicator analyzed in this section is very common in the analyzes of the European Commission at national level, but less at the regional level, as based on this research I have tried to show that there is not always a symmetry between the migration of the population from the urban area to the rural zone in all regions of a country.

Conclusions

Regarding the migration of the Romanian population, the study has found that, at national level, the maximum value of domestic migration from and to urban and rural areas was in 2017, when approximately 380,202 people decided to change their permanent residence.

The complexity of the factors related to the migration of the rural population of Romania is an issue of general interest and a concern for the decision makers. The topic tends to gain political importance during periods of time marked by economic difficulties. The need to support entrepreneurship comes from an understanding of the fact that profitable and highly adaptable businesses can thus be created and that they represent the main pillar of the repopulation of the rural areas.

To conclude, we consider this research to be a first step towards a strategy for the repopulation of the Romanian rural areas, where entrepreneurship is a major factor of economic growth, innovation, competitiveness, employment and social integration. As such, it has enjoyed support at European level for a long time. At the moment, the promotion and development of entrepreneurship is one of the main directions of the Europe 2020 Strategy, aiming at creating work places and ensuring a decent living to the population within the community space.

Abstract

The current development of economic sectors cannot be imagined without the using of information technology. An increasing number of countries around the world are developing government programs aimed at digitalization and robotization of various spheres of economic activity, where industrial production occupies one of the leading positions. Today, an increasing number of industrial enterprises are clustering, which allow companies to significantly better withstand the risks that arise in the market, reduce costs, receive higher rates of profit, and produce goods with significant competitive advantages. In the context of the Fourth Industrial Revolution (Industry 4.0), the active using of ICT tools, which underlie the system-forming innovative-active industrial clusters operating on digital platforms, has become especially urgent. In this regard, consideration of issues related to the assessment of digital potential and the creation of a mechanism for its effective management are particular importance. The authors conducted studies to substantiate assessment methods, develop a conceptual approach and methodology for assessing the cluster's digital potential, and create an organizational and economic mechanism for managing the digital potential of a system-forming innovative-active industrial cluster.

Keywords: Digital Economy, System-Forming Innovative-Active Industrial Cluster, Digital Potential, Organizational and Economic Mechanism.

Introduction

The modern economic development of industrial sectors is inextricably linked with the processes of the active introduction of advanced digital technologies that allow enterprises to be more efficient, reduce costs, receive a high rate of return, producing goods with higher added value. In the scientific articles by Anokhin et al (2019), Babkin et al (2013, 2016, 2019) digital transformation issues are becoming even more relevant in the context of actively forming and developing integration industrial structures - clusters. In a research study by Babkin and Tashenova (2019) industrial enterprises realized the necessity and advantages of such interaction, and with the active introduction of information

technologies, industrial structures began to take a new form - a more complex one, which is characterized by the active using of various innovative systems operating on digital platforms, and therefore a new form of association of industrial enterprises, called the "system-forming innovative-active industrial cluster" (hereinafter - SFIAIC) as the authors Babkin and Tashenova (2017, 2019) suggest, the characteristic features of which are presented in Figure 1.

The analysis of the sources showed that in the modern scientific literature insufficient attention is given to the study of the concept of "digital potential (hereinafter - DP)". For 2015-2019, the authors conducted an analysis of literary sources using the Scopus, Clarivate Analytics and RSCI databases, which showed that the number of scientific works on digital potential over the past 5 years is small.

Fig. 1: Characteristic features of system-forming innovative-active industrial clusters
Note - the figure is developed by the authors.

At the same time, about 95-98% of all published articles are mainly devoted to studying not "digital potential", but such branches of knowledge as: Du et al (2020) consider in the framework of digital twins, Sanasi et al (2020), Viriyasitavat et al (2019), Wu (2020) and Dudin (2020) within the digital economy, Barry (2019), Roblek et al (2020) and Jacob et al (2019) in the structure of digitalization of the public sector, Dneprovskaya et al (2019), Tien (2019), Kwok et al (2019), Guillemot and Privat (2019) within the digitalization of economic sectors, Jin et al (2019), Sturgeon (2019), Ojanpera et al (2019) like the digital transformation and Foa (2019), Lebedeva (2019), Pearce et al (2020), Khodaiemehr and Kiani (2020) in the course of digital communication, the effectiveness of Internet technologies and etc. In essence, works that fully and comprehensively reflect the authors did not find the essence and component composition of digital potential of the industrial clusters. More and more often, scientists in their scientific works consider innovative potential, sometimes identifying it with a digital one. Today, the question of what, nevertheless, is appropriate to understand by the innovative potential of an industrial enterprise, given the capacity of the concept, also remains open and not fully understood. The issue of identifying the concepts of "innovative" and "digital" potentials, as a rule, is associated with the fact that "digitalization" is a new phenomenon, which has been reflected in scientific publications relatively recently.

It should also be noted, that innovative and digital potentials are not equivalent in size or scale to the economic potential of the industrial cluster (Figure 2).

2. Innovative enterprises / innovative industrial clusters
3. Innovative-active enterprises / innovative-active industrial clusters
4. Digital enterprises / System-forming innovative-active industrial clusters

Fig. 2: The essence of the digital potential

Note - the figure is developed by the authors.

In general, on the basis of the analysis, we believe that the "digital potential of a system-forming innovative-active industrial cluster" should be understood as a combination of various sub-potentials (material-technical, scientific, organizational and managerial, infrastructural, financial and economic, personnel and information and communication), which should reflect two aspects of the enterprise / cluster: opportunities and its abilities; the difference between them is the efficient using of cluster resources with the active implementation of various ICT tools and without them (or with their partial presence).

In this regard, the question arises of substantiating effective approaches to assessing the digital potential of system-forming innovation-active industrial clusters. It should be noted, that the analysis of literary sources also did not reveal works on the issues of assessing digital potential, therefore, we believe that in the context of poorly studied issues related to assessing the digital potential of a system-forming innovative-active industrial cluster, the existing uncertainty in the choice of methods, it is most expedient to highlight the following *generalized assessment approaches:*

1. Resource - based on the using in the evaluation of indicators of economic activity of industrial enterprises included in the cluster, as well as indicators directly related to digital infrastructure.
2. Result - based on the search for possible effects that an industrial cluster can receive from the implementation of active innovation and the active introduction of digital technologies in all the processes of its activity.
3. Integrated - this approach is represented by a combination of both resource and result approaches, which are considered in combination to obtain the most optimal and complete integrated assessment of the digital potential of a system-forming innovative-active industrial cluster.

This approach is considered detailed in Figure 3.

Fig. 3: Characteristic and advantages of an integrated approach for assessing the digital potential of the system-forming innovative-active industrial cluster

Note - the figure is developed by the authors.

The advantages in assessing the digital potential of the system-forming innovative-active industrial cluster using an integrated approach are obvious:

1. this approach is represented by a combination of a resource and result approach, which makes it possible to use in the analysis a set of factors characterizing the level and efficiency of the cluster's economic activity, as well as factors forming its direct digital infrastructure and the so-called "digital capital";
2. allows us to take into account the specifics of assessing digital potential, which is an integral part of economic and innovative potentials;
3. leads to a complete and systematic understanding of the essence of digital potential and the directions of its development based on the results of the assessment.

Carrying out an effective assessment of the digital potential level of a system-forming innovative-active industrial cluster using the considered approach and the methods indicated below allows developing an organizational and economic mechanism for managing digital potential, the main purpose of which is to increase the industrial cluster's digital potential through the using of organizational and economic levers.

Methods

Speaking about methods for assessing the digital potential of the system-forming innovative-active industrial cluster, it can be divided into 3 key groups:

1. *quantitative,* including analytical, statistical and graphical methods that allow structural and more detailed analysis of the digital potential of an industrial cluster;
2. *qualitative methods* presented by the method of expert evaluations, "Delphi", in-depth interviews, and other methods that allow us to study the nature of the data obtained;
3. *mixed methods* include both quantitative and qualitative assessment methods.

At the same time, speaking about the using of certain groups of methods, it should be noted, that the using of quantitative methods for analyzing the digital potential of a system-forming innovative-active industrial cluster is due to the fact that quantitative estimates are a universal way to obtain final results, prove or refute hypotheses put forward during analysis, while the conditionality of the choice of qualitative methods is the complexity of the study, the inability to give answers of the "yes" or "no" format, as well as a wide scope of their application.

Table 1 presents, according to the authors, the most effective methods for assessing the digital potential of a system-forming innovative-active industrial cluster, which form the basis of the author's methodology, which is included and mediates the organizational and economic mechanism, the development of which is the aim of the study conducted in this scientific article.

Table 1: Research methods used to assess the digital potential of the system-forming innovative-active industrial cluster

The features of the task	Type of the method	The feature of using the method within the selected section (s) / direction of the research
Studying the theoretical aspects of the formation and development of the system-forming innovative-active industrial clusters in the context of digital transformation	Analytical: methods of tabular analysis, link analysis, cross-tabular analysis, cartographic method	Tabular and cross-tabular analysis methods can be used to build tables characterizing the e-commerce market and the development of IoT; in the study of the main approaches to the concept of a cluster and the allocation of its types; as part of the study of clustering in the regions of the world; when studying leaders in the ranking of innovative companies in the world, as well as analyzing the current state of the digital economies of the world. The cartographic method can be reflected in the study of cluster initiatives in the regions of the world.
	Statistical: scaling and cluster analysis	The scaling method can be used to build scales for assessing the level of digital activity of an industrial cluster. The cluster analysis method can be used, for example, to differentiate the regions of a country according to the level of development of industrial production.
	Graphic: building 2M and 2M-categorized graphs	The graphical method is usually widely used to display statistical information using linear, bar and other types of categorized and uncategorized graphs.
Development of tools for assessing the digital potential of the system-forming innovative-active industrial cluster	Analytical: methods of tabular analysis, link analysis, cross-tabular analysis	Tabular methods of data analysis are widely used to display the structural components of the digital potential and the parameters, which are characterized them.
	Statistical: correlation analysis method, scoring method	The correlation method can be used to isolate from a variety of parameters precisely those that maximally satisfy the requirements in the framework of the research.

	Graphic: building categorized figures and algorithms	The widespread using of the graphical method is usually dictated by the need to clearly display parameters that include representatives of the scientific community in assessing the digital potential. In addition, this method is used in the development of the author's stages and an algorithm for assessing the digital potential of a system-forming innovative-active industrial cluster.
Development of an organizational and economic mechanism for managing the digital potential of the system-forming innovative-active industrial cluster	Analytical: methods of tabular analysis, link analysis, cross-tabular analysis, flow analysis method	In the research of the economic activity of the system-forming innovative-active industrial cluster is often used the method of flows.
	Statistical: correlation-regression and factor analysis	The methods of correlation-regression and factor analysis are widely used in the process of business analysis of an industrial cluster and the identification of factors that have the greatest influence on the development of its digital potential.
	Graphic: building structured figures with highlighting groups and components	The graphical method is used for building the model and developing the structure of the organizational and economic mechanism for managing the digital potential of the system-forming innovative-active industrial cluster.
	Qualitative analysis methods: expert interview and content analysis method	These techniques are used to analyze the economic activity of the system-forming innovative-active industrial clusters (using specific examples) and to correlate the results of their digital potential development with the certain values within the framework of the selected scale.
Note - the table is compiled by the authors.		

Thus, to assess the digital potential of the system-forming innovative-active industrial cluster, a wide range of both qualitative and quantitative methods and the mixed methods can be used.

The most important step in assessing the digital potential of the SFIAIC is the development of a methodology for its assessment, which includes the following components: allocation of subpotentials, determination of a set of factors within each of the subpotentials, expert survey, calculations to determine the reliability of the obtained expert estimates, final determination of the set of factors, reduction of the obtained values to a unified measurement system, determination of weighting coefficients, calculation of the integral estimate for each of the subpotentials, as well as the final estimate SFIAIC digital capacity allocation received value to a certain level of the DP, according to Harrington scale (Figure 4).

Fig. 4: Methodology for assessing the digital potential of the system-forming innovative-active industrial cluster

Note - the figure is developed by the authors.

The methodology presented by the authors is comprehensive and allows a clear range of estimates to be obtained with the digital potential of the system-forming innovative-active industrial clusters.

It is important to note that after the development of a methodology for assessing the digital potential of a system-forming innovative-active industrial cluster is advisable to develop an organizational and economic mechanism.

Results

Based on the developed methodology and the methods studied, which may be most applicable for assessing the digital potential, it seems possible to develop an organizational and economic mechanism for managing the digital potential of a system-forming innovative and active industrial cluster, the main purpose of which is increasing the efficiency of the using of digital potential by all cluster members, and also the increasing the level of digital potential based on the right combination of resources awns and abilities of the industrial integrated structure under consideration (Figure 5).

The presented organizational and economic mechanism reflects in detail the SFIAIC structure, the distinctive features and characteristics of which are shown in Figure 1, as well as the subjects and objects of management. The subjects are state authorities implementing cluster policy in the country, cluster development centers (for example, the Cluster Development Center of St. Petersburg, created as a structural unit of JSC Technopark of St. Petersburg), cluster observatories (for example, the Russian Cluster Observatory, opened in 2012 in the structure of the Institute for Statistical Studies and Economics of Knowledge of the National Research University "Higher School of Economics"), as well as directly the management of the companies included in the SFIAIC. The management object in the presented scheme is innovation potential. As levers, we distinguish:

1. **economic**, including targeted financing of SFIAIC to provide ICT with the necessary funds, for example, through existing government programs aimed at implementing initiatives in the field of the digital economy, preferential taxation and lending, as well as a flexible investment policy;
2. **organizational**, which, according to the authors, it is advisable to divide into two groups:

– *external*:

1. compliance of the SFIAIC production process with existing state and industrial standards and norms;
2. continuous accounting of enterprises and industrial clusters involved in the active implementation and using of ICT technologies, including for the creation and effective functioning of digital platforms on which they should be based; compliance of SFIAIC activities with all legal norms and rules adopted both in the territory of the state where the cluster operates (in the case of a geographically allocated cluster with a limited territory) and beyond (if the industrial cluster is international, in which the territorial borders are, in fact, conditional);

– *enternal*:

1. collection, processing and analysis of scientific, technical and management information; building an effective management system using business models adapted to the needs of industrial clusters and enterprises operating and communicating on digital platforms;
2. presence of a mechanism for the commercialization of innovative SFIAIC's products;
3. using of an effective automated resource allocation system, as well as the formation and widespread using of the system for creating and managing human resources that are necessary to implement the strategy and achieve the target indicators in the field of digitalization.

In addition, it is important to understand that such mechanism should be based on certain principles (among which the principle of continuity, adaptability, stability, efficiency, compatibility, scientific validity, planning, motivation and democratization of management), functions (planning, organization, motivation and control) and management standards; the implementation of the measures presented in the mechanism is possible only when assessing the level of digital potential of the SFIAIC on the basis of an integrated approach using the methodology presented above.

The most important point in the effectiveness of using this kind of a mechanism is the continuous monitoring of activities, as it will allow in the intermediate stages to identify inaccuracies and make appropriate adjustments to all aspects of the organizational and production activities of the SFIAIC.

Fig. 5: Organizational and economic mechanism for managing the digital potential of the system-forming innovative-active industrial cluster

Note - the figure is developed by the authors

The result of the using of the organizational and economic mechanism for managing the digital potential of a system-forming innovative-active industrial cluster is either an increase the DP in the SFIAIC or an intensification of the work of all cluster members (both first and second levels - Figure 5) on the implementation and widespread using of existing digital information and communication technologies, as well as Industry 4.0 tools:

– *Big Data* - a set of methods and approaches for processing structured and unstructured a large volume of data and the different types;

– *Industrial Internet of Things* - equipping a variety of physical objects and systems with IT technologies to reduce their interaction with humans in the process of industrial production;

– *Blockchain* - a continuous system of blocks containing information built according to certain

algorithms that can establish relationships with decentralized databases;

– *Cyberphysical Systems* - the processes of interaction of sensors installed at different objects of the production process, equipment of the industrial cluster and information systems (including digital platforms) for forecasting, self-tuning and adaptation to changes in production in the shortest possible time.

In the case of the successful implementation of these types of activities, it is possible to talk about the stable functioning of the SFIAIC in the conditions of the Fourth Industrial Revolution, which will undoubtedly provide significant competitive advantages to all enterprises that are part of the industrial cluster.

Within the framework of this section, it is advisable to consider further directions of the authors' research: in the near future, the researchers will study the economic activity of the innovative-active industrial clusters in St. Petersburg (Russia) and Karaganda (Kazakhstan), as well as the development of practical proposals for the development of organizational -economic mechanism for managing the digital potential of these clusters.

Conclusions

Based on the research conducted by the authors, the following conclusions can be made:

– in the conditions of modern economic development and the active introduction of digital technologies in almost all spheres of human life, including in industrial production, the study of the essence of digital potential and its structure is particular importance, but this is especially true for integrated industrial entities, for example, represented by industrial clusters; on the whole, the analysis shows that publications devoted to assessing the digital potential of system-forming innovative-active industrial clusters (functioning, as a rule, on digital platforms) are small, since the economic phenomenon considered by the authors is a new, so far poorly studied economic category, which , in turn, once again emphasizes the need for research of this kind, taking into account the fact that now an increasing number of industrial enterprises have realized the role and importance of integration, as well as the introduction of modern information technologies at all levels of their activity - from production and organizational to communication;

– in the developing the organizational and economic mechanism for managing the digital potential of the SFIAIC, it is necessary, first of all, to determine the existing level of the cluster's DP based on an integrated approach, using the developed methodology, only after that it is advisable to shift the key aspects of the mechanism under consideration to the DP management process;

– the implementation of the organizational and economic mechanism is aimed at obtaining a certain result; in our case, it means raising the level of the DP of the SFIAIC, or activating of all cluster members in introducing and using various digitalization tools, which, in turn, will contribute to the sustainable functioning of SFIAIC in the conditions of Industry 4.0;

– the most important aspect in the development of such a mechanism is to take into account existing principles, functions and management standards, without which the effective functioning of the mechanism is not possible.

Abstract

The article defines the essence and content of the state management of the tourism industry. It is proved that the state should provide in its policy mechanisms that would inhibit the spontaneous development of the industry and guide its evolution in this direction in order to preserve the natural and cultural environment for future generations. The main areas of state support for the implementation of the strategy for the development of public administration in the tourism industry, based on the direct participation of the state in the implementation of special programs of the target appointments by appropriate funding for all components of a comprehensive public tourism policy.

Keywords: Tourism, Travel Industry, Travel Policy, Governance.

Introduction

Currently, tourism has developed considerably and became a massive socio-economic phenomenon of international scope, since it is among the leading sectors of the global economic complex. The expansion of the interstate political, economic, scientific and cultural relations contributes to the spread of intensive tourism. It should be noted that the tourism industry is closely linked with a number of components as a service industry and the production sector of the economy, which calls for effective implementation of appropriate governance arrangements.

Based on this, there is every reason to believe that the development of the tourism industry requires regulation and government support. The need to influence government agencies to promote tourism proven international practice. Most countries in the world do not use centralized tourism management methods, but do not rely entirely on market self-regulation of the industry. It is believed that it is impossible to fully market tourism and develop it without harming the natural and cultural values of a country or region.

It is up to the State to provide in its policy mechanisms that would inhibit the spontaneous development of the industry and direct its evolution in such a direction as to preserve the natural and cultural environment for future generations.

A variety of factors affecting the development of domestic tourism, as well as the complexity and contradictory nature of its constituent processes require mining multilevel mechanism of state regulation of tourism in Russia, aimed at creating an enabling legal and administrative, organizational and economic condition of the tourist activity of economic entities.

Methodology

Methodology of scientific research in this article is based on the theory of tourism (tourismology, turizmovedenii, tourist logistics), whose main goal is the systemic reflection of the phenomenon of tourism in the context of its impact on the socio-economic development of the territory. Dialectical method of research was used to organize and generalize scientific approaches to the organization of state regulation of tourism development; analysis and synthesis, induction and deduction - for the detail of the study; a systematic approach is to justify the definition of a comprehensive public policy in the tourism sector.

Results

For Russia, the role of tourism is important not only in terms of ensuring the constitutional right of citizens to rest, but also to increase the amount of state budget revenues from the results of tourism business activities. The development of tourism business has a positive impact on the state of the labor market, contributes to the reduction of unemployment due to the increase in employment in this area (Bespartochny, Cherkashin, 2010).

Based on this, the tourism business can be rightly considered as a key at the current stage based on the fact that he is now developing dynamically and is the most profitable of all the service sector in the economy. The development of the tourism business directly affects the competitiveness of a region, its attractiveness (Spitsina, Cherkashin, 2015, p. 221). With regard to socio-cultural and historical aspects, tourism allows you to demonstrate the features of a unique Russian mentality.

Based on the above, the role of tourism is a priority in the formation of cultural communications in Russia and its well-being in modern conditions.

Thus, the development of the tourism sector creates favorable conditions for increasing state budget revenues, generating new jobs, developing the infrastructure of the economic sector, protecting and restoring monuments of historical and cultural significance, and protecting the environment, which, accordingly, contributes to the active development of the tourism industry.

In the most general form, the tourism industry can be defined as a set of organizational forms of business that provide accommodation, transportation, food in the process of organizing knowledge and entertainment, recreation, business activities, sports and other tourism-oriented events. If you turn to the scientific literature, you should pay attention to the point of view of scientists V. I. Zorin and V. O. Kvartalnov, who affirm that the tourism industry, in addition to enterprises that provide accommodation and food, should also include tourism infrastructure of tour-rating, transport, entertainment, cultural, religious, communicative, informational, educational, scientific, medical, and commercial orientation (Zorin, 2003, p. 86). Based on this, it can be assumed that the tourism industry is a complex of inter-sectorial nature, which combines various components of the sphere of material production and services of the national economy to ensure the consumption of goods and services for tourist purposes. Because of the functioning of this cross-industry complex, it is possible to obtain a comprehensive tourist product.

The necessity for state management of the tourism industry is a consequence of scientific reasons for this need in all spheres of public life, as well as due to the specifics of the tourism industry itself. In fact, the main goal of state management of the tourism industry can be considered to be the formation of favorable conditions for the functioning and development of the tourism sector and related areas and industries related to material production and services of the national economy.

One of the curiosities of public administration research is that in many languages there is no significant difference between the terms used to describe politics and public policy (Hall & Jenkins, 1995). This means that in many studies, including in the field of tourism, the terms politics, public policy, and public administration are often used interchangeably (Hall & Campos, 2014).

One of the central concepts in the tourism industry is the concept of tourism policy. It is the basis for the management of tourism services at the national, regional and local levels. Therefore, before proceeding to the consideration of methodological issues of regulation of the tourism sector, it is necessary to determine what constitutes a tourist policy.

The concept of "tourism policy" originates from the time when tourism has become a mass socio-economic phenomenon and has become an important role in the economy of many countries, including Russia. By its etymological origin, it is associated with the Greek word "polis", which in ancient Greece defined the space where different interests collide, and, accordingly, require urgent solutions to the problem of regulating certain social relations. In our time, this concept refers to purposeful actions to develop rules for the functioning of individual social groups and the state as a whole. However, despite its significance and prominent place among other basic concepts of tourism science and practice, the definition of "tourist policy" does not have a generalized interpretation in specialized information sources, which causes its different meaningful interpretations.

Thus, I.T. Balabanov and A.I. Balabanov define tourism policy exclusively as "the state's activities for the development of the tourism industry and the subjects of the tourist market (tour operators, travel agents), improving the forms of tourist services for citizens and changing their political, economic and social potential on their basis (Balabanov, 2000, p. 40). Kvartalnov V. A., exploring the essence of tourism policy, focuses exclusively on its goals (Kvartalnov, 1999). In particular, he defines that tourism policy pursues both economic and non-economic goals. In his opinion, to the economical aims we can regard a promotion of some types consumption by increasing the production in the specific sectors of the economy, in the specific geographical zones, control of export trade, employment and economic growth. To the non-economic aims we can regard : freedom of peoples movement ,revival of the natural and cultural heritage.

An objective necessity in the tourist policy has emerged and grow in a result of statement of an important role of the tourism in a societys life. This happened in certain historical moment, when a real possibility of self-regulation of a tourist development exhausted.

Considering a level of processes in the hierarchical structure » tourism policy» we can highlight the next its types: an international, tourism policy, state, regional and the tourism policy of the separate company.

The tourism policy has the characteristic features of the common policy of a government. Along with that there are some specific factors under influence which it forms : natural conditions of country , development of the transport connections ,the social factors(conditions of peoples life, the vacation system).Factors is associated with a creature of the economical base for development of a tourism (stable monetary and financial ,foreign economic relations)and legal factors is associated with creating and functioning of the tourist legislation.

The important component of the state tourism policy are its target landmarks. They are defined by a subject of the regulatory actions, they are submitted by the common state or international policy and

depends on concrete economical and historical conditions of the development of the country and degree of a maturity of the tourism policy itself.

The state regulation in a sphere of the tourism is one of the fundamental factors of a management and development of an industry (Potapova,2016). With absence of an effective mechanism of public administration the industry can render a recessive influence on a socio-economic development of a territory. Most widespread problems which mostly arise as a result of an uncontrolled (massive) tourist flows are:

-In a social aspect is an outflow of the labour resources to a tourism industry from others industry of the economy, especially of the agricultural industry; of an occurrence of an excessive irritation between a tourist and local population; a gain of a criminogenic situation; an excessive consumption by tourists an alcohol and tobacco;

- In an economic aspect is a high decree of a dependence from the tourism; an excessive export of currency due to a predominance of volumes of a offsite tourism; a shadowed of the intrepreneurial activity due to an absence of the effective mechanisms of the tracking fact of a provision of a tourist service; an outflow of the investment capital from others industries an economy to the tourism such a highly profitable;

- In an environmental aspect are an occurrence of the environmental problems through a recreational digression (a negative influence of the tourists on the natural environment, an excessive tourist-recreational load on the territory);

- In a cultural aspect is a device of the local and national features to the tourists interests; the destraction of objects have the historical and architectural value due to an excessive tourist recreational load;

- In an educational aspect is a mastering by tourists the foreign cultures and customs , a lifestyle due to a predominance of the host country in a socio-economic development , a stimulation of the excessive of the migration mobility;

- In a globalization aspect is a leveling of the cultural differences, the language barriers, the ethical standards through a periodical stay of persons on a territory of the foreign countries in a tourists status.

In our days, an understanding grows that the role of the government says more than never important in a tourism. Perhaps, increasingly than before considering the reactions on the recent financial crises and the natural disasters. There are again the researches in an area of the state policy in a sphere of the tourism reflects more widely shifts in a thinking about a role and a character of the public administration (Jenkins and Hall, 2014).

The negative influences of the tourism industry is conditioned by the emergency sensitivity of the tourism to the factors of the external sphere (meso (direct interaction) and macro setting (an indirect interaction) , which in turn itself are characterized of the range of the indicators which play the role of basis for a forming the strategic directions of the implementation of the functions of the public administration. By the exogenous factors of meso-setting performs: subjects of the tourist activity, intermediaries on the market of the tourist services , consumers of the tourist services, public authorities, public companies, scientific companies, educational institutions. To the exogenous factors of the macro setting belongs the natural, socio-economic, demographic, socio-cultural, political-legal, environmental, scientific, technical and international factors.

Thus, state management of the tourism industry should be directed not only to achieve a positive effect from the implementation of tourism functions and eliminate possible threats from the influence of the

industry, but also to assess the level of influence of the relevant environmental factors, which together should create favorable conditions for the development of tourism in the relevant territory.

State management of the tourism industry should be understood as a type of state activity that involves purposeful influence on the industry or its individual components through an effective mechanism of state management in order to achieve certain strategic objectives.

State regulation of the tourism industry is a set of methods of influence of management entities on the tourism industry as an object that have a practical nature and functional focus on achieving certain goals. A feature of state regulation that distinguishes it from management is the consideration of market laws in the course of implementing management functions. In other words, public administration is the theoretical shell and conceptual basis for the implementation of the relevant mechanism, and state regulation is reflected in the practical dimension with the mandatory inclusion of current market processes and their forecasts.

Taking into consideration that the state management of the tourism industry is carried out through the appropriate state policy in the field of tourism and resorts, its priority areas for tourism activities are:

- improvement of legal norms of state management of the tourism industry;

- promoting the development of tourism as a highly profitable part of the service sector of the national economy of Russia; attracting domestic and foreign investors to enhance the development of the tourism industry, creating new jobs;

- promotion of rural and green tourism, inbound and domestic tourism;

- development of international cooperation, integration of Russia into the world tourism market;

- creating favorable conditions for the development of the tourism industry by simplifying and harmonizing such areas of state regulation as: tax, currency, customs, border;

- ensuring the availability of tourist and recreational services for children, young people, the elderly, the disabled and low-income segments of the population through the introduction of a preferential system for these categories of persons.

Based on the national policy in the field of tourism and resorts, local tourism authorities determine the appropriate regional goals that can be achieved by relying on the local potential of the tourism sector. In accordance with these goals, local authorities form tourism development programs that set specific goals. Such tourism development programs at the local level may include the following provisions:

- promoting the conservation and rational use of natural, historical and cultural resources of a tourist nature;

- attracting domestic and foreign investment in the development of the tourism industry;

- determining the procedure for standardization, certification and licensing in the tourism industry;

- introduction of statistical reporting of tourism market entities;

- identification of the status of certain tourist centers;

- creating a system of scientific support for the tourism industry and promoting its development;

- organization of training, retraining and advanced training of personnel;

- creating favorable conditions for increasing tourism activity in Russia.

In General, state management of the tourism industry is necessary because of the need to develop a framework for planning the activities of the tourism sector from strategic positions, in particular, such as:

- ensuring the development of the entire existing potential of tourist areas in General and the needs of the leisure infrastructure in particular;

- conducting research in a specialized field;

- design and placement of tourist facilities;

- control of environmental pollution;

- assessment of the potential use of tourist territories and calculation of their permissible maximum capacity to receive tourists, avoiding excessive load on territorial ecosystems;

- justification of the feasibility of placing tourist destinations from an economic point of view.

The importance and scope of tourism show its belonging to the strategic sectors of our country's economy. The economic effects tourism activities are not limited to direct financial results. They go far outside the framework of tourism sector, influencing whole economic body of the country. Thus, the tourism sector requires direct State regulation in order to provide proportional development both territorial and branches of economic complexes, as well as inform employment policy, supporting growth of budget revenues and management the whole state's balance of payment (Trukhachev, Varivoda, 2014, pp. 155-160).

Conclusions

The content of state regulation of tourism development is determined by the goals, faced by the government bodies, as well as the tools, which the state has for the implementation policy. In the most common form, the government policy's strategical goal of the tourism development can be defined as follows: formation of a competitive tourism complex, meeting citizens' requirements in tourism services and contribution to the country's economic development. Effectiveness of the government policy in the tourism development should be evaluated according to the goal based on the following criteria: economic and social effectiveness, environmental implications of implementing the targeted programmes and activities.

At the same time, the government control in the tourism industry should not allow negative impact on tourist areas, as well as encourage the implementation of tourist functions, which, in turn, allow getting comprehensive socio-economic effect.

Resumen

El concepto de innovación abierta ha cobrado especial relevancia no sólo como objeto de estudio en el ámbito académico, sino también como marco para el desarrollo de nuevos modelos de gestión empresarial. Este artículo explora los determinantes de una de las dimensiones de la innovación abierta asociada con el uso del conocimiento externo para el desarrollo de l os procesos de innovación empresarial. El análisis es realizado con base en los microdatos de la Encuesta de Desarrollo e Innovación Tecnológica EDIT 2015 – 2016 realizada por la agencia estadística en Colombia (DANE). Para ello se introduce una medida que captura el grado de apertura de la empresa con relación al uso de fuentes externas de información para el desarrollo de actividades de innovación. Como posibles determinantes se tienen en cuenta variables relacionados con las capacidades tecnológicas de la empresa, las barreras para innovar y la estrategia de apropiabilidad.

Palabras clave*:* Innovación abierta; fuentes de información; I+D; Estrategias de apropiabilidad

Introducción

La importancia de las fuentes externas de conocimiento en los procesos de innovación empresarial ha sido destacada ampliamente en la literatura reciente. En esta línea, ha cobrado particular relevancia el enfoque de la innovación abierta catalogado por algunos autores como el nuevo paradigma en la gestión de la innovación. Chesbrough (2003) define la innovación abierta como un enfoque que asume que las empresas pueden y deben utilizar durante el desarrollo de sus procesos de innovación, no sólo ideas internas, sino también el conocimiento existente en su entorno. De igual forma, destaca que las empresas pueden emplear diversos caminos para explotar eficientemente sus capacidades tecnológicas e introducir productos y/o procesos nuevos en el mercado.

En términos generales, el enfoque de la innovación abierta permite integrar numerosos estudios enfocados en la importancia de conocimiento externo para el proceso innovador de la empresa. Pero no sólo se queda allí, el enfoque es mucho más amplio en la medida en que incluye estrategias de apertura no sólo entrantes (inbound), sino también salientes (outbound) (Dahlander & Gahn, 2010; Saebi & Foss, 2015).

A pesar de la distinción antes señalada, lo cierto es que el mayor interés desde el punto de vista académico se ha centrado en el estudio de los procesos de entrada, es decir, en analizar cómo la empresa

accede y explota el conocimiento externo en sus procesos de innovación. La atención sobre esta dimensión en particular se encuentra justificada por la complejidad actual de los procesos de innovación y la necesidad de las organizaciones de apalancar sus recursos y capacidades internas con el conocimiento disponible en el mercado (West et al. 2014).

El presente artículo tiene como objetivo explorar los determinantes del grado de apertura empresarial para el desarrollo de actividades de innovación en el contexto de la industria manufacturera Colombiana. Este análisis es interesante si se tiene en cuenta que la mayor parte de las investigaciones realizadas hasta la fecha han sido abordadas a partir de la consideración de sectores intensivos en tecnología en países desarrollados (Greco et al. 2015; Ghisetti et al. 2015) y poco se ha hecho en contextos tecnológicamente menos dinámicos. Además, si se tiene en cuenta que en estos contextos las empresas tienen una mayor necesidad de recurrir a las fuentes externas de conocimiento debido a sus debilidades tecnológicas internas, identificar los factores que inciden en el grado de apertura constituye un tema de especial importancia desde el punto de vista de la gestión empresarial.

El análisis realizado en el presente artículo emplea como fuente de información los datos derivados de la encuesta nacional de innovación, realizada por el DANE en Colombia. Esta encuesta, al seguir las directrices del Manual de Oslo, es similar a los cuestionarios empleados por los países europeos en el marco de la Community Innovation Survey, lo cual facilita la comparación de los resultados obtenidos con aquellos encontrados en contextos más desarrollados.

La estructura del presente documento está compuesta por tres secciones adicionales a la presente introducción. A continuación se presenta la revisión de literatura del concepto de innovación abierta, explorando cómo ha evolucionado y los factores que se han analizado en la literatura como posibles determinantes del mismo. En el capítulo siguiente, se describe la metodología utilizada en el estudio empírico, describiendo los datos, las variables y el método de estimación empleado. Posteriormente se presentan los resultados y finalmente se destacan las conclusiones más relevantes derivadas el estudio.

Revisión de la Literatura

En las últimas décadas ha emergido una literatura que establece que la empresa no puede innovar en solitario y que esta actividad depende de la interacción con otros actores que le permita a la empresa no sólo compartir costos y disminuir riesgos, sino más importante aún compartir recursos complementarios. Uno de los enfoques que ha destacado de forma especial los aspectos antes mencionados y que ha tenido un amplio grado de difusión es el de la innovación abierta. Chesbrough (2003) definió la innovación abierta como un paradigma que establece que las empresas pueden y deben emplear fuentes de conocimiento externo para avanzar tecnológicamente.

La literatura ha abordado el paradigma de la innovación abierta desde múltiples perspectivas y unidades de análisis tales como el individuo, la empresa, el sector o incluso el sistema nacional de innovación (Saebi & Foss, 2015). Dahlander & Gahn, (2010), a partir de una extensa revisión de más de 150 artículos, concluyeron que los investigadores han empleado múltiples definiciones y enfoques para sus estudios, lo cual genera dificultades en la construcción de un marco analítico uniforme. En función de lo anterior, estos autores identificaron que el proceso de apertura puede comprender un flujo de información entrante o saliente, y que este a su vez puede ser una interacción pecuniaria y no pecuniaria.

Usualmente el concepto de innovación abierta es contrastado con innovación cerrada, es decir, prácticas en donde las empresas realizan las actividades de generación de ideas, construcción de mercados, distribución, servicios y finanzas de manera independiente y solitaria. Sin embargo, en la realidad, no muchas empresas siguen una estrategia completamente cerrada, el constante desarrollo por fuera de la organización hace necesario procesos más abiertos (Laursen & Salter, 2006). En este sentido, más que la distinción entre innovación abierta y cerrada, la apertura empresarial debería entenderse como un proceso continuo de interacción en el cual las empresas pueden implementar diferentes niveles de apertura en función del grado de importancia que tengan las fuentes externas de conocimiento para el desarrollo de las innovaciones.

Como se mencionó anteriormente, la falta de un marco analítico uniforme ha dado origen a la puesta en operación de diferentes constructos que conciben el concepto de innovación abierta de diferentes formas. Una práctica empleada recientemente ha sido abordar el análisis de esta temática empleando

los datos derivados de las encuestas de innovación aplicadas en muchos contextos nacionales y basadas en las directrices planteadas en el Manual de Oslo (OECD, 2005). En esta línea se destacan los aportes realizados por Laursen & Salter (2006), los cuales emplearon la información derivada de la Encuesta Nacional de innovación en el Reino unido. En este trabajo, los autores se aproximaron al estudio de la apertura empresarial a través del análisis de las fuentes externas de conocimiento empleadas por las empresas británicas en sus procesos de innovación, distinguiendo entre dos constructos clave: amplitud (número de fuentes externas usadas) y profundidad (número de fuentes externas consideradas de alta importancia para los procesos de innovación). Los resultados mostraron que existe una alta correlación entre la búsqueda amplia y profunda a través de diversos canales y la captura de ideas que generan retornos a la empresa por medio de la explotación de innovaciones.

En la literatura existen diversos trabajos que han explorado los factores, tanto a nivel de firma como a nivel de sector, que influyen en la adopción por parte de la empresa, en mayor o menor grado, de una estrategia abierta para el desarrollo de sus actividades de innovación.

En lo que respecta a los factores empresariales, los aspectos más analizados han sido el tamaño y los esfuerzos en la realización de actividades internas de I+D. En términos generales, la literatura no es concluyente con respecto al efecto de estos dos factores. Con relación al tamaño, por ejemplo, algunos estudios sostienen la idea de que la apertura es más relevante para las grandes empresas, teniendo en cuenta la mayor disponibilidad de recursos y capacidades complementarias que estas poseen y que, por lo tanto, le facilitan la búsqueda de socios y la gestión de los convenios de colaboración (Veugelers, 1998). No obstante, existen otros estudios que argumentan que, debido a la falta de recursos internos, las pequeñas empresas tienen una mayor necesidad de estar abiertas al medio ambiente para desarrollar sus actividades de innovación (Nieto & Santamaría, 2010). Para estas empresas el uso del conocimiento externo constituye un elemento estratégico debido a que no disponen de las capacidades necesarias para afrontar proyectos de manera solitaria y son más vulnerables a aspectos como la incertidumbre de los proyectos de innovación y la alta probabilidad de fracaso asociado a los mismos (Bayona et al. 2001).

Con respecto a los esfuerzos empresariales en I+D, existen también visiones contradictorias. Uno de los argumentos más extendidos, especialmente desde que Cohen y Levinthal propusieron el concepto de capacidad de absorción, es el que establece una relación positiva entre los esfuerzos internos en I+D y el grado de apertura empresarial. Atendiendo al concepto de capacidad de absorción (Cohen & Levinthal, 1990), se ha establecido que la I+D interna no sólo contribuye de manera directa al desarrollo de nuevos productos y procesos, sino que, además, le permite a la empresa desarrollar capacidades internas que le facilitan el acceso a fuentes externas de conocimiento y su explotación económica en términos de innovaciones. Sin embargo, algunos autores sostienen que desde la perspectiva del enfoque de los recursos y las capacidades, las empresas con las capacidades de I+D altamente desarrollados pueden beneficiarse de economías de escala internas por lo que les resulta menos necesaria la participación de los socios externos en sus procesos de I+D (Cassiman & Valentini, 2009).

Tal como se observa en los párrafos anteriores, la lógica detrás de la innovación abierta recae en la posibilidad que esta estrategia tiene para acceder a recursos externos complementarios. Estos recursos pueden ser recursos de conocimiento, pero también recursos financieros. El uso de fuentes externas de información o la colaboración con actores externos, puede ser relevante para disminuir los costos de los procesos de innovación, al permitir a la empresa acceder a un mercado de conocimiento y tecnología en condiciones económicas más ventajosas en comparación con el desarrollo interno (Chesbrough & Bogers, 2014; West & Bogers, 2014). Igualmente, la innovación abierta puede contribuir a disminuir las barreras asociadas con la incertidumbre de los procesos de innovación, derivada de los cambios potenciales en el entorno en cuanto al mercado y la tecnología. La incertidumbre del mercado se refiere a las fluctuaciones y a la imprevisibilidad de la demanda, mientras que la incertidumbre tecnológica está relacionada con la incapacidad de la organización para predecir acertadamente los requerimientos tecnológicos (Robertson & Gatignon, 1998). Algunos autores señalan que si bien la incertidumbre puede incrementar los costos del desarrollo externo, la flexibilidad que otorga la cooperación o la adquisición externa de tecnología puede compensar dicho incremento (Klein et al. 1990). Así, por ejemplo, la incertidumbre que se genera como producto de la rapidez del cambio tecnológico puede hacer que la empresa encuentre el desarrollo interno una estrategia menos atractiva para el desarrollo

de sus innovaciones, dada la alta probabilidad de que las capacidades internas se queden obsoletas. Para las empresas que afrontan una alta incertidumbre tecnológica, la cooperación con agentes externos y el uso de fuentes externas de conocimiento puede convertirse en un mecanismo importante para acceder a recursos y conocimientos complementarios que le ayudaran a introducir productos en el mercado con una mayor rapidez (Steensma et al. 2000)

Adicional a los aspectos anteriores, otro factor que ha sido relacionado con el grado de apertura es el relacionado con la estrategia de apropiabilidad que implementa la empresa. Dicha estrategia está asociada con la capacidad de las empresas para capturar los beneficios derivados de sus esfuerzos en innovación, disminuyendo lo máximo posible las filtraciones de información y conocimiento hacia otros actores del mercado (Teece, 1986). En la literatura actual de innovación abierta no existe un consenso acerca de la relación entre la apropiabilidad y el nivel de apertura empresarial. Por una parte se señala que cuanto mayor es la importancia que la empresa atribuye a las condiciones de apropiabilidad dentro de la estrategia empresarial, menor será su nivel de apertura (Laursen & Salter, 2014). En este sentido se ha indicado que las firmas que sobreprotegen su base de conocimiento son más propensas a perder oportunidades para intercambiar conocimiento valioso con diferentes actores (Bessen & Maskin, 2009). Por otro lado, algunos autores argumentan que el grado de apropiabilidad existente en una industria puede favorecer el nivel de apertura de una organización (Chesbrough, 2006). La existencia de fuertes mecanismos legales de protección, por ejemplo, aumenta la confianza de los gestores empresariales para la adopción de mecanismos de transferencia de conocimiento con agentes externos. En estos casos, la existencia y uso de fuertes mecanismos de protección le aseguran a la empresa la posibilidad de capturar el mayor valor posible de la innovación realizada y, por ende, en ausencia de estos, los incentivos a usar fuentes externas de conocimiento son menores.

Además de las características empresariales antes mencionadas, en la literatura se han analizado una serie de factores asociados con las dinámicas sectoriales como posibles determinantes del grado de apertura empresarial. Entre estos factores se destaca la intensidad tecnológica del sector en el que opera la empresa. En este sentido, algunos autores señalan los beneficios que tiene el implementar una estrategia de innovación abierta en sectores catalogados como de alta tecnología (Tödtling et al. 2006). Lo anterior debido a que en estos sectores existe, por lo general, un mayor nivel de oportunidades tecnológicas que incentiva a las empresas a realizar una búsqueda más amplia y profunda con el fin de obtener acceso a recursos que son críticos para el desarrollo de procesos de innovación (Laursen & Salter, 2006). Sin embargo, algunos autores (Tether, 2002).

Metodología

Datos Y Variables

Para el análisis empírico se tomaron los datos de la Encuesta de Desarrollo e Innovación Tecnológica (EDIT) de la industria manufacturera de Colombia entre los años 2015 y 2016, realizada por del Departamento Administrativo Nacional de Estadística (DANE). La EDIT tiene como propósito investigar sobre las actividades de desarrollo e innovación tecnológica adelantadas por las empresas industriales en Colombia con personal mayor o igual a 10 personas.

La encuesta recoge datos de 7947 empresas, sin embargo, el detalle de la encuesta en preguntas relacionadas a aspectos de innovación, condiciona la posibilidad de responder la totalidad de las preguntas para empresas que no se consideran *innovadoras*, o que aún no tengan clara tal dinámica. Por lo tanto, este trabajo se centra en 2237 registros de empresas manufactureras que cuentan con la totalidad de los registros necesarios para abordar este análisis, por lo que el análisis de datos censurados requirió implementar un enfoque de para evitar el sesgo de selección de la muestra.

En la tabla 1 se presentan las definiciones de las variables utilizadas en los modelos econométricos. La variable dependiente en el estudio es el grado de apertura empresarial. Siguiendo la estrategia empleada en investigaciones previas (Laursen y Salter, 2014; Huang et al., 2014), esta variable se ha definido teniendo en cuenta el uso de agentes externos como fuente de información para el desarrollo de los procesos de innovación empresarial. En la EDIT indaga en total por el uso de 15 actores como fuentes externas de conocimiento e información, entre los que se encuentran gentes industriales (clientes, proveedores, competidores, etc.) como agentes institucionales (universidades, Centros de Desarrollo Tecnológico, parques tecnológicos, etc.).

Tabla 1: Definición de las variables y estadísticos descriptivos

Variables	Descripción
GRAPER	Mide el grado de apertura de la empresa en el periodo 2015-2016. Es una variable de conteo que toma valores enteros positivos de 0 a 15.
INTID	Es una medida de intensidad del esfuerzo interno de la empresa para investigación y desarrollo. Representa la inversión en I+D sobre el total invertido en actividades de innovación en el año 2015.
TAM	Número de empleados de la empresa en el año 2015.
SECT	Clasificación sectorial acorde a la clasificación de intensidad tecnológica empleada por EUROSTAT. SECT0(sectores de intensidad tecnológica baja) SECT1(sectores de intensidad tecnológica media) SECT2(sectores de intensidad tecnológica media-alta) SECT3(sectores de intensidad tecnológica alta)
BAR_COS	Valoración de una serie de factores como obstáculos para el desarrollo de actividades de innovación. Se calculó un indicador compuesto teniendo en cuenta los siguientes factores: Escasez de recursos propios; dificultades para acceder a financiamiento externo. Alpha de Cronbrach 0,71
BAR_CON	Valoración de una serie de factores como obstáculos para el desarrollo de actividades de innovación. Se calculó un indicador compuesto teniendo en cuenta los siguientes factores: falta de personal cualificado, escasa información sobre mercados, escasa información sobre tecnología. Alpha de Cronbrach 0,79
BAR_INC	Valoración de una serie de factores como obstáculos para el desarrollo de actividades de innovación. Se calculó un indicador compuesto teniendo en cuenta los siguientes factores: Incertidumbre frente a la demanda de bienes y servicios; incertidumbre frente a la ejecución técnica del proyecto. Alpha de Cronbrach 0,79

Método De Estimación

Para el análisis econométrico se empleó un Heckman (1979) en dos etapas. La necesidad de este modelo se sustenta en el hecho que existe un sesgo de selección muestral, al tomar sólo las empresas activas en innovación, es decir, aquellas que realizaron inversiones en actividades orientadas al desarrollo de procesos de innovación. De estimarse directamente el modelo principal la inferencia seria errada, ya que los estimadores de la ecuación objetivo serían inconsistentes.

En este orden de ideas, la ecuación de selección corresponde a un modelo que mide la probabilidad de estar en la muestra, en este caso de haber realizado inversiones en actividades de innovación. A partir de dicha estimación, se obtiene la razón inversa de Mills que captura la magnitud del sesgo. Posteriormente, se incorpora en el modelo de regresión principal, que en este caso obedece a un modelo de regresión binomial negativa debido a las características de la variable dependiente (datos de conteo que toma valores enteros no negativos).

Resultados Y Discusión

La tabla 2 presenta los resultados del modelo principal con la inclusión del inverso de Mills para controlar por el posible sesgo de selección. Con respecto a las características empresariales, los resultados muestran (ver tabla 2) que el tamaño ejerce un efecto significativo y positivo sobre el grado de apertura de la empresa. Este resultado es consistente con los argumentos planteados en estudios previos que señalan que las empresas grandes, debido a su mayor disponibilidad de recursos, pueden implementar una estrategia más abierta en lo que respecta al uso de fuentes externas de conocimiento.

Por otra parte, la variable que refleja los esfuerzos en I+D interna (INTID) no presenta efecto significativo. A pesar de ello hay que destacar que la variable que mide la intensidad tecnológica del sector en el que opera la empresa sí juega un papel determinante en la definición de su grado de apertura, aunque hasta cierto nivel. Comparado con los sectores intensivos de baja tecnología (categoría empleada como referencia), los sectores de media baja (SECT 1) y media alta (SECT2) son más propensos a emplear un mayor número de fuentes externas de conocimiento en sus procesos de innovación. No obstante, pertenecer a un sector catalogado como de alta tecnología (SECT3) no muestra un efecto significativo. En parte, este resultado está en línea con lo señalado en diversos estudios previos en los que se ha asociado una mayor intensidad tecnológica del sector con un mayor uso de fuentes externas de conocimiento, pero al mismo tiempo señala que para el caso de los sectores más avanzados es posible que las empresas tengan menos necesidad de buscar externamente conocimiento o que tengan mayor dificultad para encontrar fuentes que le ofrezcan recursos complementarias, por lo que su grado de apertura resulta menor en comparación con sectores de menor intensidad tecnológica.

Los resultados anteriores pueden también entenderse a la luz de lo propuesto por Barge-Gil (2011) en su estudio sobre el caso español. Esta autor, a través de la distinción de tres niveles de apertura (abierta, semi-abierta y cerrado) señaló que el efecto del tamaño y de la intensidad en I+D sobre el grado de apertura empresarial se encuentra determinado por dos aspectos: la capacidad de absorción y la necesidad de conocimiento. De esta forma las empresas muy pequeñas y poco intensivas en I+D si bien tienen una gran necesidad de conocimiento externo, carecen de la capacidad de absorción necesaria para beneficiarse de un acuerdo de colaboración con agentes externos. En este caso, las empresas optan por una estrategia cerrada. Por el contrario, las empresas grandes y con una alta intensidad en I+D, tienen una gran capacidad de absorción pero una necesidad menor de recurrir a fuentes externas. Estas empresas, por lo tanto, recurren a una estrategia semi-abierta, en la cual si bien captan cierta información del entorno siguen basando sus procesos de innovación en sus capacidades tecnológicas internas. Finalmente, son las empresas con una intensidad media en I+D que - en nuestro caso podría asociarse con la pertenencia a sectores de intensidad tecnológica media y media alta - las que tienen a basar sus procesos de innovación en el uso de fuentes externas de conocimiento (estrategia abierta) debido a que en ellas se conjugan dos factores clave: poseen un nivel de capacidad de absorción que le permite explotar el conocimiento que tienen otros agentes y, además, tienen la necesidad de recurrir a fuentes externas debido a que no poseen capacidades tecnológicas suficientes para adelantar procesos de innovación por sí solas.

Co relación a las variables asociadas a las barreras para la innovación, los resultados muestran que las barreras de incertidumbre (BAR_INC) y las barreras de conocimiento (BAR_CON) tienen un efecto significativo y positivo sobre el grado de apertura, mientras que las barreras de costos (BAR_COST) resultó ser no significativa. Este resultado sugiere que, en el contexto analizado, el grado de apertura en los procesos de innovación está más asociado con la posibilidad de acceder a conocimientos e información complementaria que disminuya las barreras derivadas de la falta de conocimiento propio o la incertidumbre (tanto de mercado como tecnológica), que con el hecho de disminuir el costo de la innovación.

Fuente: cálculo de los autores

En lo que concierne a la estrategia de apropiabilidad de la empresa, dos variables presentan un efecto significativo y positivo: el uso de registro de marcas (RMS) y el uso de mecanismos de protección estratégicos (MEST). En general, estos resultados ponen de manifiesto que las empresas que implementan estrategias para proteger los resultados de sus esfuerzos en innovación y apropiarse en la mayor parte posible de los beneficios derivados de los mismos, tienen a abrirse más al uso de fuentes externas. En este sentido, el uso de las estrategias de apropiabilidad pueden disminuir los riesgos asociados a un "derrame" involuntario de conocimiento en los procesos de relacionamiento con actores externos, dando mayor tranquilidad a las empresas para interactuar con otros actores. Las variables asociadas con el uso de patentes (PAT) y derechos de autor (DA) aunque tienen coeficientes positivos, son no significativas, pero esto podría estar relacionado con el hecho que estas estrategias son muy poco habituales en el contexto analizado.

Conclusiones

La innovación abierta se ha convertido en un enfoque relevante para el análisis de los procesos de innovación empresarial. Su importancia es, si cabe, mucho mayor en el contexto de los países en desarrollo donde las empresas poseen pocas capacidades internas y difícilmente pueden adelantar actividades de innovación sin recurrir a la colaboración con agentes externos o al uso del conocimiento disponible en su entorno. En este sentido, el análisis de los factores que influyen en la adopción por parte de la empresa de una estrategia de innovación abierta constituye un aspecto de interés no sólo desde el punto de vista académico, sino también en el ámbito de la gestión empresarial.

Este artículo ha explorado este fenómeno tomando como caso de estudio la industria manufacturera de Colombia y empleando como fuente de información los datos derivados de la Encuesta nacional de Desarrollo Industrial y Tecnológico (EDIT), realizada por el DANE.

En el estudio, dentro del conjunto de posibles determinantes del grado de apertura, se han considerado factores internos de la empresa como también características del sector en el que opera la empresa. En general, los resultados muestran que el tamaño influye de forma significativa en el grado de apertura de la empresa. En este sentido, si bien las pequeñas y medianas empresas pueden tener un beneficio marginal mayor al abrir su estrategia de innovación, es probable que sus recursos limitados les impidan buscar y acceder a una mayor diversidad de fuentes de información. Asimismo, los resultados sugieren

que, en el contexto analizado, las empresas implementan una estrategia de innovación abierta para subsanar las debilidades internas en materia de conocimiento o las barreras asociadas a la incertidumbre de los procesos de innovación, pero no con el fin de solventar los problemas relacionados con los costos de dichos procesos. En otras palabras, la apertura es vista fundamentalmente como un proceso para acceder a recursos de conocimiento, bien sea para el desarrollo en sí de la innovación o la validación tecnológica y comercial de la misma, pero no tanto como una estrategia para la disminución de costos.

Finalmente, los resultados ponen de manifiesto que en la medida que las empresas perciben que existen escasas posibilidades de imitación de terceros, éstas tienden a emplear un mayor número de fuentes externas de conocimiento. Por el contrario, cuando sea difícil proteger sus resultados, la compañía tiende a recurrir menos a agentes externos, quizá con el objetivo de evitar fugas involuntarias de información o que terceros entren en contacto con un conocimiento relevante.

Agradecimientos

Los autores agradecen el apoyo financiero recibido por Colciencias a través del proyecto "Dinámicas de Innovación en Contextos Poco Intensivos en I + D: el caso de la Industria Manufacturera Colombiana" (121577657885), así como también el apoyo recibido en el marco de la convocatoria Colciencias-DAAD a través de la subvención 58955.

Consumer Ethnocentrism and The Consequences for Marketing in The Countries of East-Central Europe

Robert JADACH

Wroclaw University of Economics and Business, Wroclaw, Poland,
robert.jadach@ue.wroc.pl

Abstract

The fall of the Soviet Union and the accession of Poland, the Czech Republic, Slovakia, Hungary and the Baltic States to the European Union deepened the progress of globalization and with it the liberalization of trade in Central and Eastern Europe. Although tariff restrictions have decreased significantly over the past few decades, the recent economic crisis, Brexit, Russian-Ukrainian crisis and trade wars are raising the discussion about the importance of non-tariff barriers and new subtle forms of protectionism again. These events (although they are not the only ones) seem to activate national identity and strengthen consumer ethnocentrism. Based on the review of literature, the author discusses the phenomenon of consumer ethnocentrism in selected Central and Eastern European countries and formulates its marketing consequences. The results presented may help managers, who can use this phenomenon to optimise their marketing strategies or to segment buyers in the context of their attitudes towards domestic and foreign products.

Keywords: Consumer Ethnocentrism, Consumer Behavior, Product Origin.

Introduction

Based on the review of literature, the author discusses the phenomenon of consumer ethnocentrism in selected Central and Eastern European countries and formulates its marketing consequences. The results presented may help managers, who can use this phenomenon to optimise their marketing strategies or to segment buyers in the context of their attitudes towards domestic and foreign products. The concept of consumer ethnocentrism was first defined in 1987 by Shimp and Sharma (1987), who suggested that from the perspective of ethnocentric consumers buying foreign products is inappropriate as it leads to negative changes in the domestic economy, resulting in job losses (Shimp and Sharma, 1987). Shimp and Sharma (1987) created the CETSCALE research tool for this purpose, which was later tested successfully in many countries, including France, USA, and Japan (Netemeyer, Durvasula and Lichtenstein, 1991).

Buying domestic products allows consumers to express their attachment to the country where they live and is an expression of support for the local community. As suggested by (Siamagka and Balabanis, 2015), the source of consumer ethnocentrism is also the pro-community attitude of individuals and the desire to care for the welfare of others. Ethnocentric tendencies in the purchasing process are also a manifestation of consumers' openness to other cultures; this openness is acquired through travelling abroad a lot. On the other hand, a better knowledge of foreign cultures leads to weaker ethnocentrism (Shankarmahesh, 2006).

Consumer Ethnocentrism in Central and Eastern European Countries

The first research on consumer ethnocentrism in Central and Eastern European countries was conducted as late as after 1989, when the post-communist countries gaining their sovereignty started the extended process aimed at building free markets, and consumers were given the full freedom to choose products and services according to their own needs. The long-standing neglect during the

communist times led to a delay in the technological development of the region. Research conducted in the '90s showed that the level of consumer ethnocentrism in countries such as Poland, Czech Republic and Estonia was low (Vida and Fairhurst, 1999). The main reason for this was the distrust in domestic goods, which were of lower quality compared to imported products. Over time, the post-communist countries carried out a number of activities including promoting export, building a positive image of the country and technological investments, and their main goal was to become competitive and quickly adjust production quality standards in the single European market. Research conducted in Russia and Poland shows that Western products were preferred in the early stages of the political transformation, as a sign of looking for better quality and product novelties. However, as the economy goes through successive phases of transition, consumer ethnocentrism increases (Good and Huddleston, 1995).

According to research conducted in 2012 by Maison (2014), 86% of Poles agreed, more or less strongly, that domestic companies should be supported by buying domestic products, and 84% of respondents declared that they often buy Polish products. Research conducted in the Czech Republic (an individualistic country) suggests that the ethnocentrism of Czech consumers is the result of a sense of superiority and domination of the Czech nation (Balabanis et al., 2001). It should be added that the level of consumer ethnocentrism varies across product categories. Czech consumers believe that domestic products are of high quality and, as in many Central and Eastern European countries, consumer ethnocentrism is strongest in the food category (Kreckova, Odehnalova and Reardon, 2012). As observed by Minta (2015), the market of regional products attracts an increasing interest as consumers look for unique, healthy, organic, and traditionally manufactured products (Minta, 2015). Moreover, among Slovak consumers, consumer ethnocentrism is positively correlated with age (Petrovicova, 2014). It can be concluded that with further economic development of Central and Eastern European countries, the level of consumer ethnocentrism will increase. This may be important for marketing managers, especially while making decisions related to how to shape the image of foreign brands operating in this region. Due to the fact that consumer ethnocentrism is strongest in the food category, retail chains should adjust their product range with products from the consumer's country and cooperate with local suppliers. Consumer ethnocentrism can also be useful in managing own brand portfolios of retail chains. In the categories where this phenomenon is strong (bakery products, dairy products, alcoholic and non-alcoholic beverages), newly created brands should relate to national motives of the buyer's country.

Macroeconomic Factors Affecting Household Indebtedness

Zuzana STOLICNA
Department of Economy and Finance, Faculty of Management Comenius University, Bratislava, Slovakia, zuzana.stolicna@fm.uniba.sk

Adam GROZAK,
Department of Economy and Finance, Faculty of Management Comenius University, Bratislava, Slovakia, adam.grozak@fm.uniba.sk

Abstract

The financial sector is considered stable when it performs its core functions even with negative phenomena in the external and domestic financial environment. The aim of the article will be to describe the state of the economy of the state, which contributes to the greater indebtedness of the population, which may ultimately pose a risk that will appear on the domestic market. The indebtedness of the Slovak population and businesses in relation to GDP has been growing almost continuously since 2012 and exceeds the average of Central and Eastern European countries. The development of the credit market is the result of low interest rates and stable economic growth. The Slovak Republic records the highest year-on-year growth in loans to the entire European Union. In 2018, the volume of loans almost doubled. Also, income growth and increasing credit availability have fueled debt. Continuing pressure on low interest rates and indebtedness of NBS principles has taken many measures to adjust the limits for credit scandals. These changes in lending conditions should mitigate the risk of excessive debt growth. The aim of this article is to bring readers closer to these financial market restrictions.

Keywords: Debt, GDP Growth, Credit Market, Financial Stability

Introduction

The main scope of this article is to introduce to the readers the current economic situation of Slovakia and how the indebtedness of the Slovak population develops and its possible impact on the country's financial stability. In Slovakia, indebtedness receives great attention from the National Bank of Slovakia, but also from the media. Household funding is a topic that is currently affecting a large number of people across Europe, and this topic is becoming more and more prominent in Slovakia. Increasing household indebtedness affects not only the lives of the people themselves, but also affects the country's financial stability. The current trend in Europe, and especially in the Slovak Republic, is increasingly borrowing for housing as well as for the normal functioning of households. Slovakia is on the top of the European Union in the indebtedness of the population. Given the fact that this topic is currently up to date, we have decided to analyze the situation.

Despite a number of consolidation measures and the intervention of the National Bank of Slovakia, the borrowing rate in Slovakia is still at a high level, which may cause major problems for the economy of our country in the coming years, given that our economy may not be ready for the expected economic cycles.

In this article we will focus on defining the indebtedness of Slovak households and the current economic situation of the household. First, we will focus on the development of GDP, inflation, minimum wage, average wage and unemployment in Slovakia, which have a significant impact on the country's economic situation. Then we define the household and its needs, we will focus on consumption and income of Slovak households and an overview of their total financial income and expenditure. In the last part of the article, we will deal with the situation on the financial market, loans

and mortgages, as a source of housing finance and consolidation measures of the National Bank of Slovakia, which was forced to tighten the conditions for providing loans and mortgages to households, in response to the very rapid pace of indebtedness of Slovak households.

Household Consumption in Slovakia

Net financial expenses for Slovakia are expenditure on food and non-alcoholic beverages, alcoholic beverages and tobacco, clothing and footwear, housing, furniture, hotels, education and other net expenditure. The main net financial expenditure for the Slovak household is the housing item, which is due to the need for households to acquire their own housing.

Fig. 1 : Final household consumption, own data processing, source: Eurostat

From this graph we can see that household expenditures in the monitored period from 2006 to 2018 can be divided into three main periods.

The first period is a period of steep growth since 2006-2008. In this time period, consumption increased, also due to the attractiveness of Slovakia as an investment site, which was given by several factors. In addition to being incorporated into the European Union (2004) and the geographical location (proximity and accessibility of the central part of the EU, especially the western part of the SR), it also included cheap labor. These factors also contributed to increased household consumption growth.

The second period has been recorded since 2008-2013, which can be called post-crisis convalescence, as the Slovak economy was hit by the financial crisis in 2008-2009, but its impact was not as much as that of other EU economies. In the period under review, we have seen growth beyond 2009 and the period between 2012 and 2013, which is likely to be attributed to high unemployment rates.

The third monitored period is the period between 2014-2018, where we see a steady increase in the main macroeconomic indicators, which is also reflected in the final household consumption, which recorded an average year-on-year increase of 2.7%. Based on the data, we can say that household consumption also reflects to some extent the development of net financial income of households.

Fig. 5: Gross disposable income, own data processing, source: National Bank of Slovakia

It can be deduced from the above graphs that the Slovak household does not have much room for saving in the future. It is best to see the phenomenon visible in the disposable income curve, which grows very much like the household consumption curve, which can be dangerous, in a badly evolving economy and in debt repayment problems, despite the fact that the Slovak economy is not following a very favorable global trend in the saving-to-debt ratio, which is one of the worst in the EU for Slovak households. However, a few facts need to be considered when interpreting these economic indicators. The net financial position does not take into account non-financial assets, which are mainly real estate and therefore need to be careful when interpreting.[1] Slovak households have one of the highest property ownership rates they live in. It is very likely that the relative lack of savings of Slovak households is probably directly related to their non-financial assets, ie. j. with apartments and houses. Therefore, it is not necessary to be under the illusion that Slovak households are poorer, only property is represented in their property to a greater extent.

Loan as a foreign source of property coverage

In this chapter of our work we will devote to specific loans that Slovak households receive. In the first chapter we proved that the Slovak economy is in good condition and this fact supports the growth of loans. Slovak households most often receive a mortgage loan or a consumer loan.

[1] Vilčeková, L. Mucha, B. Peráček, T. and Strážovská, L. (2018) 'Selected issues of family business in selected countries with emphasis on the Slovak Republic 2020, Milan Italy

Fig. 6 Gross disposable income, own data processing, source: Eurostat

The weak spot of Slovak households is still high credit debt. Demand for loans has increased since 2010 in Slovaks more than the average in the region. Last year, our debts increased by 10.3%, each Slovak owed an average of € 6,792, while the region's average is € 4,564. On the above chart, there is a visible up to 5% year-on-year increase in property owners who are burdened by mortgages or loans.

Fig. 7 : Total volume of loans, own data processing, source: National Bank of Slovakia

Slovak households' financial assets grew by only 5.5% last year, which is almost half compared to the previous year (9.8%). In particular, this may be due to deposits in banks, where Slovaks accumulate up to 60% of their savings and have only increased by 4.2%. Neither securities, insurance and pension assets, which recorded double-digit growth, helped. In the wealth list, Slovaks with savings of 6,190 euros per person rank up to 40th out of 53 countries. The average in the region is significantly higher, reaching EUR 10,381. In the region, all other countries outperformed us, with the exception of Romanians (4521 euros), when, for example, Czechs have saved more than double, namely 15 291 euros, Hungarians 13 404 euros, Poles 8 273 euros and the average Bulgarian has savings EUR 7 678.

The richest nation is traditionally Swiss with savings of almost 174,000 euros, in close ties with the US, where households have savings of 169,000 euros. Thanks to the strong euro, the old continent was doing well last year - up to 12 European countries in the first 20 richest countries.[2]

Tightening Of The Measures For Mortgage Market

Maximum Debt (DTI- debt to income)

Gradually, the proportion of loans that would unduly debt clients in comparison with their income will be reduced. These are loans where the total debt (including the new loan) exceeds 8 times the net annual income of the loan applicants (Debt to Income, DTI).

A new and substantial change in the assessment of the ability to repay the loan and the provision of loans to individuals and households should, according to the recommendation of the NBS, introduce a condition of maximum acceptable indebtedness. The maximum indebtedness is set at 8 times the net annual wage. Total overdrafts on current accounts, credit cards, leasing, consumer loans and mortgage loans will be included in the total maximum indebtedness.

Over time, this step can be signed by a gradual reduction in housing prices. However, it should be noted that there will still be a possibility to provide some of the loans above this value, similar to LTV. This share will only gradually decrease. From 1 July 2018, up to 20% of new loans will be able to exceed this value.

Determination and compliance with the internal limit on the client's ability to repay the loan

The indicator of the consumer's ability to repay a housing loan (hereafter the ability to repay) is calculated as the proportion of the total amount of expenditure on the consumer's monetary obligations under paragraph 3 to the total consumer income under paragraph 4, reduced by the total cost to ensure the necessary conditions to meet basic living needs consumer under paragraph 5.

Fixed living minimum is € 199.48 per month. The mandatory reserve (the amount that cannot be borne by the repayment of a loan product) will increase to 20% of the net wage net of wages and loan product repayments from July 2018 (currently, this provision is set at 15% of the net wage net of the subsistence minimum) credit products).

Cash liabilities represent the monthly cost of credit products. Thus, for a net salary of € 800 a month, a living minimum of € 199.48 is to be deducted for an individual and a 20% reserve is deducted from the rest of € 600.52, ie. 120,104 €. The total installment space will therefore be € 480.416 for a € 800 net salary (which represents a mortgage of about € 135,000 under current conditions). This example is valid provided that the client does not use other credit products.

Keeping the limit on the client's ability to repay the loan even under adverse conditions

The Bank is advised to ensure in the provision of retail credit that in the case of loans for which the interest rate is not fixed throughout the loan repayment period, the limit on the client's ability to repay credit under Art. Also retained in paragraph 1, provided that the same retail loan would be granted at an interest rate of at least 2 percentage points higher than the rate provided and its maturity would be at the level of the longest recommended maturity referred to in Art. VIII paragraph 1, taking due account of the assumption of a decrease in income if the client's retirement age is reached.

---

[2] ALLIANZSP.SK (2018). *Slováci sú rekordéri v zadlžovaní. Bohatstvo však máme rozdelené najrovnomernejšie* Available at: https://www.allianzsp.sk/slovaci-su-rekorderi Accessed: 27 May 2019

This recommendation applies mainly to mortgage loans because the maturity of mortgage loans is in most cases 30 years, with interest rate fixation in most cases agreed for 3 or 5 years (minimum fixation period is 1 year and maximum 10 years). In practice this means that if the bank approves interest of 1.69%, for example, the bank will have to find out if you would be able to repay the same loan with a 2% surcharge, as at 3.69%. A client with a net salary of € 800 will receive a loan of up to € 104,000 after deducting the subsistence minimum, the mandatory reserve and taking into account the increased rate.

Loan to Value (LTV)

The loan may not exceed 90% of the value of the property. This limit may exceed a maximum of 10% of new loans, but these loans may not exceed 100% of the property price. In addition, the share of new loans in excess of 80% of the property price can be up to 40%.

Loan to Value (LTV) is the ratio of the funded amount over the loan product to the value of the property. 100% financing mortgages are no longer practical. At the moment, it is realistic to fund a mortgage with a maximum of 90% funding. But in the near future, it is more reasonable to assume that the bank will provide you with a maximum of 70-80% funding for the value of the property. The remainder must be financed through another credit product or paid for by own savings, bearing in mind that loan product repayments must not exceed those limits.

Conclusion

In this article, we looked at the indebtedness of the country's population in relation to the country's financial stability. At the beginning, we have readers read about the current economic situation in Slovakia. On the basis of current data from Eurostat, the National Bank of Slovakia and the Statistical Office of the Slovak Republic, we can say that the Slovak economy has gained a rising trend after joining the European Monetary Union and all macroeconomic indicators show favorable values. Indicators such as inflation and registered unemployment are at historically lowest levels, which is good for the economy. On the other hand, household incomes and their expenditures are in very similar values, which means that there is no greater space for households to generate savings. Therefore, several households opt for consumer loans or mortgages as a source of financing their own property. This fact is also aided by a low base rate and low interest rates on house purchase loans, which have been below 2% for the past 3 years. With high employment, favorable inflation, rising GDP and low interest rates, households are not afraid of debt.

Precisely because of the rapid growth rate of the indebtedness of Slovak households, the National Bank of Slovakia has opted for consolidation measures and tightened the conditions for providing loans and mortgages. Especially the two principles of Loan to Value (LTV) and Debt to Income (DTI) are very effective measures. The future for Slovak households is certainly the savings that are being made more difficult in the current situation, but the highest savings and the lowest possible debts will be crucial for the forthcoming economic cycles that are waiting for the Eurozone in the coming years.

Power, Leadership & Organizational Politcs

Zuzana STOLIČNÁ
Department of Economy and Finance, Faculty of Management Comenius University, Bratislava, Slovakia, zuzana.stolicna@fm.uniba.sk

Loretta Pinke
Department of Economy and Finance, Faculty of Management Comenius University, Bratislava, Slovakia, loretta.pinke@fm.uniba.sk

Abstract

The aim of this work is to examine the meanings of power, leadership and organizational politics in the managerial environment. This article also aims to outline the differences in the field of power, leadership and organizational politics.

Keywords: Power, Leadership, Manager, Employer, Employee, Organization

Introduction

Management is one of the most important tools an organization has. It has an interdisciplinary character and has an immediate effect on the performance of a community.
Therefore, the leaders, managers, power-holding persons should be aware of the vast impact their decisions may have on the others. Once we have clearly set our vision and mission, we shall start thinking about how we want to accomplish those goals. The main resources an organization has are its employees. Their knowledge and experiences present an endless option of opportunities for growth. Related to the communication and motivation of employees, it is really important for an employer to know what kind of leader he/she wants to be and how he/she is willing to put on with his/her power to reach the expected outcomes. The aim of this article is to clarify the various types of approaches a power-holding, decision-making person can have.

Methodology

In the first part of this article we are going to focus on power and its five types we identify. After making understandable each type, we continue to understand and deepen our knowledge in the field of leadership. On the top of the twelve leadership types we recognize, we will briefly outline and distinguish the difference between power and leadership.

In the third part we will focus on the organizational politics and its four types, using a graph which bases on two axis – x,y. The X axis stands for source of power, and the Y axis declares the level of political activeness within an organization.

Power

The word power is being explained by the Cambridge Dictionary as „the ability to control people or events. “ [1] The singe meaning of the word gives us already a great insight what and how do people use power. Obviously, there are plenty of explanations of the meaning of the word. Another one, published by the Merriam-Webster Dictionary states, that is can be „a legal or official authority, capacity or right. My personal favorite one is the statement, that power is a mixture of „possession of control, authority, or influence over others.” [2]

All the above-mentioned words are kind of synonyms, yet there are some major differences in their understanding.

Power can be explained as the ability to influence others. Meanwhile the word influence in a process of conscious affecting of thoughts, behavior and feelings of others.

The authority, does all of the mentioned patterns of behavior and approaches, only the authority holds the legal right to do so.

In a great comparison it was stated that:

“- Authority has the right to influence others, but power is the ability to influence the others.
- Authority is legitimate while power is not.
- Authority confers legitimacy to power, but power itself need not to be legitimate.”[3]

When talking about power, all of us have dealt with or have observed situations, where the attitude of the power holding person and their way of leadership were the direction showing and approach changing points. Mostly, the person who holds the power it is the moment, when the subordinates and co-workers are being faces with the manners of the upcoming coworking relationship.
Power has more forms and types. Therefore, it is necessarily to know and distinguish them.

Coercive Power

When referring to the usage of this power, it comes with a lot of negativity and fear. Using this power in an working environment means, that the power holding authority is threatening the employees with some kind of unpleasant outcomes in case of not performing as wished. The performing employees are threatened by being fired, financial loses, demotion.

Reward Power

This approach bets on the motivation of employees with rewards. Those rewards can be monetary, tangible or as well intangible. It depends on the management and the style they choose how to enhance the performance of the workers.

[1] POWER | meaning in the Cambridge English Dictionary. In *Dictionary.cambridge.org*. [online]. [Cited 2020-01-31]. Available from Internet: <https://dictionary.cambridge.org/dictionary/english/power>
[2] Definition of POWER. In *Merriam-webster.com*. [online]. [Cited 2020-01-31]. Available from Internet: <https://www.merriam-webster.com/dictionary/power>
[3] Definition of power. In *Ebrary.net*. [online]. [Cited 2020-01-31]. Available from Internet: <https://ebrary.net/2986/management/definition_power>

Legitimate Power

This kind of power comes from the position the order giving person has in the hierarchy of a company. This power gives the right to a superior to give orders to his/her subordinates in the company. The power-holding persons power reaches only to a certain point, which is being defined by the role and position held by this person.

Referent Power

Referent power doesn't really come from a strictly stated power position within a company. It refers more to the sympathy a person and his or her ability to influence people around them. This power has more and interpersonal character, as the liking of the one is base on the fact, that more people can identify themselves with his/her actions and lifestyle.

Expert Power

This power that comes from the fact that, positions requires an expertise and knowledge in a certain specific field. For example, the word – power of knowledge, is a really helpful explanation, as this Expert power, doesn't come from the hierarchical position in a company. This power is the one where the knowledge in a specific, hard-reachable area of demesne is demonstrated. [4]

The last form of power, which is not officially stated, we could count the power which comes by being part or a member of a powerful entity. By the word powerful entity, we mean members of royal families and other relationship-based affiliation to a powerhouse which can be inherited or gained by marriage and birth.

When writing about the power and all the functions and forms it has we are coming to a point, where we are asking ourselves, where and what are the main differences between the power and leadership. As we already have stated, power is the ability to control some other individual's actions and activities. While leadership is the ability to influence individuals to perform voluntarily our instructions without havening to use any source of force.

The traditional view on power is, that is has evolved from leadership. But in real life, we can witness that having the power leads us to leadership traits. Because of the fact that these two are closely interrelated, it may be hard to distinguish and understand the difference. The one thing we have to keep in our mind is, that a good leader has power. Leadership comes with having end executing power.

Leadership

„A leader is an effective individual who creates a vision, motivates people to work towards achieving the vision, coaches and builds the team that will pioneer the completion of the vision and manages the end delivery of the vision. " [5]

When it comes to leadership, we have found out and determined 12 different styles of leadership.

[4] MSGManagement Study Guide. In *Managementstudyguide.com*. [online]. [Cited 2020-01-31]. Available from Internet: <https://www.managementstudyguide.com/types-of-power.htm>

[5] Difference Between Power and Leadership. In *Differencebetween.net*. [online]. [Cited 2020-01-31]. Available from Internet: <http://www.differencebetween.net/business/difference-between-power-and-leadership/>

1. Autocratic leadership

This leadership styles is centered on one decision making body, who mostly is the so called boss, CEO or the owner. The responsibility and decision are being held by the same person and is being not consulted by any subordinates. The flow of information is downwards and the coworkers are taken as the implementation making employees.

2. Democratic leadership

Unlike the previous leadership style, democratic one involves the employees in the decision-making process but the responsibility is still in the hand of the democratic leader. The communication flows both sides through the hierarchy of a firm.

3. Strategic leadership style

This style of leadership involves more individuals at different levels of the organization. The responsibility doesn't necessarily have to be at the top management level of the organization. This leadership style demands strategic thinking, with a view on the long-term goals of the group or corporate, and having the ability to react quickly to the present challenges of the environment.

4. Transformational leadership

Unlike other leaderships, this boosts constant changes in working groups. This approach expects the working team to set challenging goals and to improve themselves and keep gaining new work-related knowledge. The responsibility is mainly held by the leader and the leader are empowering the subordinates to make decision, and by doing so, part of the responsibility is being carried over the subordinates.

5. Team leadership

This approach is creating a positive picture of the group's future, using their beliefs and enthusiasm about the issue to create a more efficient working collaboration. The responsibility and the flow of information is shared within the groupmates.

6. Cross-Cultural leadership

This leadership style is being used the most in the globalized world of huge concerns all around the world. By this approach the managers are making sure that are well aware of the diversity of different cultures and their backgrounds. The main positive side of this approach is that, by demonstrating this approach it enhances the possibility to an individual to outshine in a certain field, which is typical for the region/country the ones come from.

7. Facilitative leadership

The outcomes are the measurement tool of the effectiveness of a group. If the group is highly effective and shows good functioning, the need for a facilitative leadership is low.

On the other hand, if the group is lacking in performance, the facilitative manager will give more command orders, to help the group to stay on track with the set goals.

8. Laissez-faire leadership

The main characteristics of this leadership style is that the power over is giver over to the subordinate. The employee makes the decision, either he/she wants to participate and to what level of interest.

9. Transactional leadership

Having the employees performing the roles they are given in a correct way, leads the leaders with transactional leadership style to the point of rewards their subordinates with tangible or monetary rewards as a immediate reaction to their well performed actions.

10. Coaching leadership

The tenth leadership style is based on teaching, mentoring, coaching the subordinates, which helps them to improve their skills and knowledge right in the field and with their hands-on work.

11. Charismatic leadership

This type of leadership affects the belief system and core values of a follower. The charismatic leader manifest strong personal power and positive conduct performance to which a lot of people can relate to, therefore charismatic leaders are well spoken about and are well known for their big follower basis.

12. Visionary leadership

Visionary leadership style performers are keeping in their minds the big picture and are not being stopped or bogged down by technical issues. These leaders know, that their visions can be implemented to the reality, if the processes and strategies are well executed within the company in the cooperation with its biggest assets – employees. [6]

Outlining the precise differences between the Leadership and Power[7]

Organizational Politics

„Organizational politics are informal, unofficial, and sometimes behind-the-scenes efforts to sell ideas, influence an organization, increase power, or achieve other targeted objectives. "[8]

Referring to organizational power, we are coming to the point, where we admit the need for a leader in an organizational environment holding tight power in his/her arms with the goal in their minds to meet strategically set targets using the core values and beliefs of an organization. Having the ability to manage and be more politically aware of the power within organization helps the governing person to execute the necessary steps to meet organization's goals.

The use of organizational power doesn't necessarily has to be in the hand of a superior one. The need and occurrence of organizational politics power in a great variety comes from bad time management, or with the need to meet goals in a short time and under a lot of pressure. An other motivation for working with organizational politics are the fact, that some inequalities can be managed better and the reverse side of the politics is, that it can be misused for personal beneficial outcomes and motivations. To be able to change and react to certain changes and challenges in the working environment, it is necessary to be able to work with 4 so called fields, with different set of rules and norms.

1. The weeds
2. The rocks
3. The high ground
4. The woods

This dimension differs on 2 levels, on both X and Y axis.
On the X axis we track the source of power. It can be informal or formal.
On Y axis we follow the levels of source of political activity. It can be either on a lower level – individual level, or on a higher level – organizational level.

---

[6] 12 Different Types of Leadership Styles. In *WiseToast*. [online]. [Cited 2020-01-31]. Available from Internet: <https://wisetoast.com/types-of-leadership-styles/>

[7] Difference Between Power and Leadership. In *Differencebetween.net*. [online]. [Cited 2020-01-31]. Available from Internet: <http://www.differencebetween.net/business/difference-between-power-and-leadership/>

[8] Brandon, R., & Seldman, M. (2004). *Survival of the savvy: High-integrity political tactics for career and company success*. New York: Free Press; Hochwarter, W. A., Witt, L. A., & Kacmar, K. M. (2000).

The four types of organizational politics

1. THE WEEDS

The first quadrant belongs to weeds, it is a mixture of the lower levels of the two axis. This mixture combines the individual level of an individual and informal source of power within the organization.

2. THE ROCK

In this dimension, the point on the X axis is higher, which demonstrates a higher level of the source of power. It is a combination of formal source of power on a level of individual interaction. In these cases, we can see that a formal role in an organization and a superiors single interest could differ from the attitude of the rest of the group.

3. THE WOODS

It is a combination of informal source of power on an organizational level. By the word “woods\l we often refer to the hidden and unspoken attitudes and routines in an organization. The woods can create a great space for cover and safety for single ones. On the other hand, it can be a place, where fresh and new ideas can get easily burned down.

4. THE HIGH GROUND

Combines formal power on organizational level. This type of organizational politics gives space for rules, strictly set structures and guidelines. This type of organization uses the written rules, and in case

of any variance, are not afraid to use sanctions or other forms of threat to keep the organization in compliance. [9]

Conclusion

All things considered, the above-mentioned definitions and statements are interlinked on multiple grounds. What all of them have in common is, that there is always a target that someone wants to reach. And by reaching the wished goals, they need to allocate the required actions within others (subordinates, co-workers) in order for achievement. By allocating the work, we can see the leadership methods and how the power held by authorities are being used. In the organizational politics we could monitor how all the power and leadership are being used and shaped based on the form of the organization and the rules, terms and policies governing within.

Resumen

La Resiliencia Organizacional (RO) se considera un proceso sistémico orientado a identificar y promover los recursos personales y colectivos de una organización para mitigar los efectos adversos que conllevan las amenazas y las crisis internas o externas presentes en el devenir de las empresas. El objetivo principal fu comprender cómo emerge la RO desde las propias concepciones, significados y experiencias de los funcionarios de la clínica. Se empleó la metodología de estudio de caso único, con el análisis de múltiples dimensiones de la categoría central; participaron 24 colaboradores entre personal administrativo, médicos y paramédicos, en entrevistas a profundidad y grupos focales, a partir de lo cual emergieron narrativas resilientes que permitieron configurar una matriz de categorías y dimensiones. Los resultados evidencian la confluencia de factores protectores como relaciones positivas e introspección; recursos y practicas saludables como trabajo en equipo y compromiso; de la resiliencia colectiva como capacidad de aprendizaje y adaptación del empleado entre otros rasgos positivos de la organización que atenúan factores de riesgo como la escasez de recursos físicos y económicos, adversidades que se han podido afrontar y han permitido posicionar a la clínica por la prestación de servicios gineco-obstreticos oportunos y de calidad que ofrece a comunidades en condiciones de vulnerabilidad social . Se espera con los resultados, visibilizar la importancia de la promoción de los recursos personales y colectivos para mejorar el clima laboral, la autoeficacia en el trabajo y la productividad del sector empresarial.

Palabras clave: Resiliencia, Organizaciones, Recursos, Adversidad

Introducción

La clínica de maternidad Rafael Calvo, es una institución de carácter público prestadora de servicios en salud, referente en el departamento de Bolívar-Colombia por su portafolio de servicios variado, centrado en la prevención, diagnóstico y tratamiento de enfermedades gineco-obstetricas; especialmente atiende con un alto sentido social y de manera oportuna, a comunidades que viven en condiciones de vulnerabilidad social para así garantizarles el derecho a una salud digna. El logro de este propósito es amenazado por la presencia de algunos factores de riesgo como su situación de iliquidez, cambios en la dirección, escasa dotación y falta de una política de bienestar del personal. Frente a estos riesgos, la empresa realiza esfuerzos por mejorar los procesos administrativos, financieros y de capacitación de su capital humano, como factor clave en el éxito de la organización.

Meneghel, Salanova y Mª Mart (2013), definen la RO como procesos que ayudan a las organizaciones a mantener los recursos de una forma suficientemente flexible, sostenible en el tiempo, almacenable, convertible y maleable como para evitar las tendencias menos adaptativas y hacer frente de manera positiva a lo inesperado. Al analizar el concepto de RO, se pudo encontrar un marco de referencia pertinente para fundamentar el estudio de un caso como el de la Clínica Rafael Calvo, desde la perspectiva de sus procesos resilientes, de sus potenciales capacidades para enfrentar sus amenazas, crisis y adversidades, aprender de ellas, sobrevivir y salir adelante en un entorno competitivo como el de las empresas prestadores de servicios en salud.

Cada día las organizaciones buscan prever las fallas que puedan afectar el logro de sus objetivos, el poder identificar la resiliencia dentro del sistema organizacional es fundamental para la toma de decisiones y para planear nuevas estrategias en la recuperación de posibles fallas y eventos inesperados. Para Blanco y Caicedo (2016), la viabilidad y la sostenibilidad de las organizaciones depende de la manera como ellas afrontan las incertidumbres de un mundo cambiante y por lo tanto deben ser capaces de emplear estrategias novedosas, ajustadas a sus necesidades y también recurriendo a prácticas saludables y exitosas que, en el pasado, les permitieron afrontar y superar la adversidad con la recursividad del equipo de colaboradores.

En los estudios que se han realizado sobre RO se nota el interés de las empresas por descubrir el rol de algunas variables positivas como la identidad colectiva para superar las crisis (Angarita, 2015); las ventajas competitivas de la RO (González, Delgado y Jordán, 2009) y la correlación positiva que existe entre resiliencia y la percepción de autorrealización en el trabajo con lo cual se previene el desgaste emocional del empleado (Sánchez, 2015). Del análisis de estos referentes se evidencia el impacto positivo de los factores protectores sobre la sostenibilidad de una empresa, como potenciador de las competencias del personal para sobrepasar las dificultades y mejorar sus resultados.

La realización de este estudio generará una fuente de información esencial para apoyar los procesos de mejora continua (capital intelectual, financiero, tecnológico, etc.) en los cuales siempre permanece la empresa, y así describir y comprender sus características resilientes, sus factores de riesgo o adversidades vividas como dimensiones a tener en cuenta por las directivas y funcionarios para la toma de decisiones en los ámbitos administrativos, académicos y especialmente del capital humano como factor clave en el desarrollo de toda organización.

Para la Clínica Rafael Calvo y para su cuerpo directivo fue interesante realizar este proceso investigativo desde la auto observación y auto reflexión de los directamente involucrados e interesados en el crecimiento y desarrollo de la empresa y por ello se procedió a la realización de un estudio de caso, sin pretensiones de generalización, pero sí de profundizar en la dinámica compleja del quehacer profesional y laboral de un colectivo de administrativos y personal médico y paramédico que de manera articulada buscan un mismo propósito de servir, cuidar y proteger la salud sexual y reproductiva de la mujer en la región norte del caribe colombiano. La pregunta central que orientó el estudio fue: ¿Cómo se comprende el proceso de la Resiliencia Organizacional (RO) en la ESE Clínica de Maternidad Rafael Calvo desde la perspectiva de las personas y los grupos que conforman la organización?

Método

Estrategia metodológica

El estudio se llevó a cabo bajo la estructura del estudio de caso único que consiste en una descripción detallada de un sistema, individuo, institución, comunidad o grupo, a partir de la recolección de datos desde diferentes fuentes como entrevistas, grupos focales observaciones y documentos institucionales (Creswell, 2013). A través de esta estrategia se describen y analizan sentires, pensamientos, experiencias buscando su sentido a la luz del contexto teórico y practico donde ocurren los hechos en un lugar y espacio particular (González, 2013) empleando la subjetividad e intersubjetividad como herramienta para la interpretación de los datos o relatos de los participantes (Barrera, Tonon y Salgado, 2012).

Participantes

El tipo de muestreo para los estudios cualitativos es intencional por cuanto va a depender del criterio del investigador que se orienta por una teoría para escoger a aquellas personas que representen una diversidad de perspectivas, que conozcan en profundidad el fenómeno a estudiar y que estén dispuestos a participar en la investigación (Creswell, 2013).

Se escogieron varios funcionarios, nuevos, antiguos de distintas dependencias y en distintas posiciones jerárquicas. La decisión sobre el número de casos no estuvo predeterminada por cuanto dependió de la calidad y cantidad de información recogida, hasta saturar las categorías de análisis. Para la realización de este proyecto se trabajó con veinticuatro personas (Ver tabla 1).

Fuente: elaboración propia

Técnicas de Recolección de Datos

Se utilizó la entrevista cualitativa definida como una reunión para conversar e intercambiar información entre una persona (el entrevistador) y otra (el entrevistado), a partir de la formulación de preguntas evocadoras, abiertas y neutras que permiten conocer de la manera más exacta posible, la realidad construida desde otro que la ha vivido, puede narrarla y reelaborarla (Sandoval, 2002). Se realizaron veinte entrevistas en profundidad, con una duración de 45 a 90 minutos cada una.

Se realizaron tres grupos focales que consisten en una reunión de grupos pequeños o medianos (3 a 10 personas), en las cuales los participantes conversan a profundidad en torno a uno o varios temas bajo la conducción del equipo investigador (Hernández, Fernandez & Baptista, 2014). Más allá de hacer la misma pregunta a varios participantes, su objetivo es generar y analizar la interacción ente ellos y cómo se construyen grupalmente significados.

También la observación sirvió como fuente de recogida de datos, la cual consiste en observar conductas, reacciones, gestos, posturas corporales, entre otros rasgos visibles de los participantes, simultáneamente al desarrollo de las entrevistas y de los grupos focales. La información que surge de la observación sirve para complementar el proceso de recolección de datos que se deja por escrito en un protocolo de observación (Aguiar, 2015).

Finlamente los documentos de la clinica referidos a la historia, enfoque y politicas de la empresa fueron utiles para contextualizar el problema de investigación, seleccionar a la clinica como un caso especial e identificar los momentos, crisis y desafios de la organización desde la ultima decada.

Procesamiento y Análisis de los Datos

Para el procesamiento de los datos, inicialmente se utilizó el programa Nvivo versión 12, para la codificación abierta de las narraciones, luego se agruparon los códigos que apuntan a una misma etiqueta o categoría, iniciando un proceso de clasificación y agrupamiento en categorías y dimensiones para su posterior relacionamiento. Finalmente se hicieron asociaciones entre categorías que emergieron en los relatos de los sujetos (Domínguez y Aleán, 2020).

Para validar el análisis de los datos se llevó a cabo un proceso denominado saturación de la información, que consiste en agotar el análisis cuando al hacer comparaciones constantes entre los datos, las categorías y dimensiones no surgen nuevas categorías (San Martín, 2014). También se hizo triangulación que consiste en seleccionar aquellas categorías coincidentes que surgen tanto en los grupos focales, las entrevistas y las observaciones.

Resultados

Los resultados se muestran en tres partes, la primera (figura 1), muestra una codificación selectiva que integra en una red las categorías, dimensiones, sus relaciones y condicionantes y representa como está conformada en general RO en la clínica Rafael Calvo; la segunda parte, detalla todas las categorías y dimensiones encontradas, se fueron denominando con relación a las convergencias y divergencias encontradas al darle el sentido a los relatos en función de los objetivos de la investigación (tabla 2).

Figura 1: ***Integración de categorías y dimensiones***

Las categorías y dimensiones que aparecen en las matrices de resultados, con sus respectivos códigos que las soportan, se fueron denominando con relación a las convergencias y divergencias encontradas al darle el sentido a los relatos en función de los objetivos de la investigación. Aparecen unas nomenclaturas al final de cada relato que, permiten identificar el autor del texto y el total de menciones al terminar cada dimensión, para visibilizar la recurrencia de las evidencias.

El análisis e interpretación de los relatos de los participantes permitió que los resultados pudieran organizarse en 5 categorías principales y sus dimensiones que hablan acerca de la RO, a saber:

1. **Factores protectores,** con 8 dimensiones: autoestima, iniciativa, introspección, moralidad, fe y religiosidad, relaciones personales positivas, emociones positivas y autoeficacia.
2. **Resiliencia organizacional**, con cuatro dimensiones liderazgo, capacidad de aprendizaje, adaptación del empleado y apoyo social (de compañeros y de la empresa).

3. **Factores de riesgos:** pocos recursos económicos, pocos recursos físicos y humanos, dificultades en las relaciones personales, emociones negativas, dificultad en la comunicación, individualismo y múltiples ocupaciones de la mujer.

4. **Recursos y prácticas saludables** con sus respectivas dimensiones que se componen por comunicación organizacional, trabajo en equipo, optimismo, compromiso, satisfacción laboral, eficacia colectiva y servicio a la gente; siendo la última una dimensión emergente de los relatos de los profesionales

5. **Resultados saludables** y se divide en dos dimensiones, las cuales son: relación positiva de la organización con el entorno y calidad y desempeño.

La siguiente figura recoge la codificación selectiva que integra en una red las categorías, dimensiones, sus relaciones y condicionantes y representa como está conformada la RO en la clínica Rafael Calvo:

Por asuntos de espacio, solo se muestran las evidencias de una de las categorías, con sus respectivas dimensiones y códigos representativos de la RO (Ver **Tabla 2).**

Tabla 2: Factores de RO

Categoría	Dimensiones	Códigos
Resiliencia organizacional Minolli (2000) la define como aquellas empresas capaces de absorber cambios y rupturas, tanto internos como externos, sin que por ello se vea afectada su rentabilidad y que incluso desarrollan una flexibilidad tal que, a través de procesos de rápida adaptación, logran obtener beneficios extras, sean estos pecuniarios o intangibles, derivados de circunstancias adversas y/o imprevistas (citado en Hoffman, 2014).	Liderazgo De acuerdo al planteamiento de Robbins (2015), el liderazgo implica la habilidad para influir en un grupo y dirigirlo hacia el logro de un objetivo o conjunto de metas (citado en Finol, 2019).	*- "… yo llegué ahí y organicé la cuestión, porque las comidas con los pacientes no eran las adecuadas. Pero ya hasta el momento mejoró…" E5* *- "… para lo que yo encontré yo he ido ajustando con mi equipo pues cosas que desde mi experiencia encaminado a corregir cosas que no se hacían de cierta manera…" E6 GF P1* *- "… Trato de resolver todos los inconvenientes que se presenten dentro del día a día aquí en cirugía…" E14* TOTAL MENCIONES: 10
	Capacidad de aprendizaje Esta capacidad es entendida como la habilidad que tienen las personas de aprender de las experiencias para desarrollar formas nuevas de conocimiento. Así mismo, describe la habilidad de una comunidad para contribuir a la adaptación como resultado de un desastre (Cretney, 2016 citado en Casado, Muñiz y Milanés, 2019).	*- "… de aprender mucho más, o sea he aprendido muchas cosas que cuando llegué aquí no las sabía, y sí, me he superado aquí poquito a poco…"E5* *- "… cada día que uno vive aquí, que uno trabaja aquí es una experiencia, cada día uno ve un caso nuevo que uno cree que es relevante y vamos a ver que viene otro día y… también es relevante…" E9* *- "… me han ido ascendiendo porque yo trato de brindar todo lo humanamente posible y de resolver todos los inconvenientes que se nos presentan…" E14* *- "… No se puede uno ni desesperar, ni estar de mal humor, ni responder de mala manera, además que todo esto es un aprendizaje para lo que a futuro venga… Saber esperar y tratar de darle soluciones a las cosas…" E17* TOTAL MENCIONES: 29
	Adaptación del empleado Se refiere a la habilidad para restablecerse en el entorno (Chakravarthy, 1982 citado en Romero y Rivero, 2017).	*- "…a pesar de las dificultades económicas le presto más atención a la parte asistencias, y trato de olvidar ese tema…"E19* *- "… el cambio fue como un poco abrupto porque llegar a un sitio donde hay personas que llevan*

		mucho tiempo trabajando acá… como cuando tu llegas eres como nuevo…" E15 *- "… Estamos en ese proceso… armando nuevos teclados, nuevos equipos sobre todo pues, para que las personas puedan trabajar bien en ellos…"E15* *- "… así nadie sepa hay que investigar, hay que tratar de solucionar para poder resolver la situación que se presente…" E15* TOTAL MENCIONES: 15
	Apoyo social Provisiones instrumentales o expresivas, reales o percibidas, dadas por la comunidad, redes sociales y amigos íntimos (Lin, Dean y Ensel, 1986 citado en Romero, 2017).	*- "... Me dieron de pronto la oportunidad de un puesto que no tenía mucha idea y pues pensé que iba a ser difícil, pero me desenvolví y me fue excelentemente bien..."E1* *- "… Siempre la administración pues, nos está capacitando para que en la clínica siga, siga adelante…" E4* *- "… nos ayuda a investigar dentro de la clínica, estamos a la vanguardia de muchos temas… estamos innovando cosas…" E19* *- "... Se han portado muy bien conmigo, me han brindado una buena acogida..."E2* *- "...siento que somos, digamos que nos ayudamos un poco, si tu no entiendes algo yo te lo explico, o si tú de pronto no puedes hacer algo yo te ayudo, y así..."E2* *- "…las personas son muy amables, el ambiente laboral en general es bueno, hay compañerismo…" E16* TOTAL MENCIONES: 22

Discusión y Conclusiones

Teniendo en cuenta el discurso de los participantes, respecto a sus fortalezas personales y a las de la organización, referidas a las características de la Clínica, se puede notar la emergencia de una resiliencia organizacional que incluye una diversidad de factores protectores personales y relacionales, entre los que se destacan por su mayor recurrencia: la autoestima (15 menciones), las emociones positivas (21 menciones) y las relaciones personales positivas (22 menciones).

Dentro de esos factores, estudios recientes han dejado en claro que la autoestima está estrechamente asociada a la resiliencia, ya que una alta autoestima y una buena dosis de eficacia personal hacen más probable el éxito en la superación de las dificultades (Salami, 2010; Fuentes, 2018).

De la misma manera Estrada y Martínez (2014), apuntan a que las emociones positivas optimizan la salud, el bienestar subjetivo y la resiliencia psicológica, favoreciendo un razonamiento eficiente, flexible y creativo. Un razonamiento de este tipo es clave para el desarrollo de un aprendizaje significativo. Así es como las emociones positivas ayudan a otorgar sentido y significado positivo a las

circunstancias cambiantes y adversas. Así mismo, se pudo observar en los relatos cómo las emociones positivas influyen directamente en que se den relaciones personales positivas en la organización. Como expone Vecina (2006), las emociones positivas son parte de la naturaleza humana y se han convertido en una clave indiscutible para la consecución de las relaciones sociales.

Por el contrario, existen algunos factores de riesgo que pueden influir en la ejecución del trabajo de los empleados dentro de la empresa, entre estos se encuentran la falta de recursos económicos (31 menciones), físicos y/o humanos (14 menciones) que traen consigo dificultades en las relaciones interpersonales (10 menciones), generan emociones negativas (14 menciones) y poca motivación hacía el trabajo.

Un factor de riesgo hace referencia a situaciones contextuales o personales que incrementan la probabilidad de desarrollar problemas emocionales, conductuales o de salud (Villanueva, 2015). Fernández (2004) señala que identificar y reconocer los riesgos de un individuo, grupo o comunidad significa poder estimar la probabilidad de que se produzcan daños (Fuentes, Medina, van Barneveld y Escobar, 2012).

Uno de los principales problemas en la organización es el atraso en los pagos, esto de acuerdo con los relatos les genera a ellos desmotivación, porque aunque se identifican con su trabajo y lo realizan de la mejor manera, les hace falta el incentivo económico. Por lo tanto, clasificamos al factor económico como un factor de riesgo para la satisfacción laboral de los empleados.

Cabe destacar que los diferentes factores protectores, al igual que los de riesgo, no actúan de manera aislada sino ejerciendo un efecto de conjunto, donde se establecen complejas relaciones funcionales que traen como resultado la atenuación de los efectos de las circunstancias adversas y los eventos estresantes (Fuentes, Medina, van Barneveld y Escobar, 2012).

Por lo anterior, se considera que una de las virtudes del concepto de resiliencia radica en la observación o tendencia de que una persona por el hecho de vivir en un ambiente exiguo y en condiciones de extrema necesidad, adversidad o desigualdad, no implica que esa persona esté abocada al fracaso social, personal o de salud. Lo que demuestra la investigación empírica es, que a pesar de las adversidades una persona resiliente es capaz de superar y aprender de las adversidades (García del Castillo, García del Castillo, L., López y Días, 2016). Con relación a la resiliencia organizacional se destacaron diferentes aspectos de acuerdo con los relatos de los participantes, entre esos están: la capacidad de aprendizaje (29 menciones), el apoyo social (22 menciones) y la adaptabilidad del empleado (15 menciones). Estas dimensiones coinciden con las planteadas en el Modelo Hero (Salanova, Llorens, Martinez, & Cifre, 2012), que hace referencia a una organización saludable y resiliente.

Se define como una organización que tiene un modelo HERO como aquella que lleva a cabo acciones sistemáticas, planificadas y proactivas para mejorar los procesos y resultados tanto de los empleados como de la organización como un todo. Además, son resilientes porque mantienen un ajuste positivo bajo circunstancias retadoras, se fortalecen ante situaciones adversas y bajo presión son capaces de mantener su funcionamiento y sus resultados (Salanova, Llorens y Martínez, 2016).

En las intervenciones positivas del Modelo Hero se destaca la palabra 'resilear', como el desarrollo de la capacidad para adaptarnos de manera positiva en contextos de gran adversidad donde se pongan en marcha mecanismos de afrontamiento de la situación amenazante donde los cambios se perciban como una oportunidad y no como un peligro(Salanova, Llorens y Martínez, 2016). Así mismo, García-Vesga y Domínguez (2013) consideran a la resiliencia como una adaptación positiva que supera las exposiciones de riesgo o la vulnerabilidad.

Con relación a lo anterior, en los relatos de los participantes encontramos una conexión entre adaptación y aprendizaje. Siguiendo a Cumming, Olson and Chapin (2013) y Beichler et al. (2014), la generación de conocimiento y el aprendizaje social contribuyen al desarrollo de la capacidad adaptativa, y por tanto, de la resiliencia (Casado, Muñiz y Milanés, 2019).

Además, desde la resiliencia organizacional nace una teoría de aprendizaje organizacional que pone el acento en la capacidad de aprendizaje como la fuente de supervivencia a largo plazo de las

organizaciones. El aprendizaje se considera un mecanismo fundamental por el cual las organizaciones, como sistemas abiertos, interactúan con su entorno, procesan información, y se adaptan a las cambiantes condiciones externas e internas (Meneghel, Salanova y Mª Mart, 2013).

Desde la perspectiva del modelo HERO también se destaca el liderazgo transformacional, considerado uno de los principales recursos sociales, que tiene un efecto positivo en los niveles de autoeficacia y el compromiso de los trabajadores tanto individual como colectivo, incrementando sus niveles de confianza organizacional (Salanova, Llorens y Martínez, 2016).

Así mismo, del Modelo Hero surgieron en la investigación dos componentes que lo conforman: los recursos y prácticas organizacionales saludables y los resultados organizacionales saludables. En la primera parte se destacan las dimensiones de: trabajo en equipo (44 menciones), optimismo (26 menciones), satisfacción laboral (22 menciones) y servicio a la gente (29 menciones), esta última surgió como dimensión emergente.

Se ha demostrado en investigaciones anteriores que los recursos laborales, definidos como aquellas condiciones del trabajo de tipo físico, social y/u organizacional que favorecen la consecución de las metas en cuanto estimulan el crecimiento y el desarrollo personal y profesional (Bakker y Demerouti, 2007), tienen un efecto positivo en el clima de apoyo social y coordinación, y la resiliencia grupal (Meneghel, Salanova y Mª Mart, 2013).

Eso es debido a que las relaciones positivas y de calidad entre compañeros de equipo (demostradas a través de un buen clima de apoyo social y de un alto nivel de coordinación) facilitan el compartimiento de informaciones, los procesos de aprendizaje y el desarrollo de soluciones adaptativas para los problemas que se presentan, influyendo por tanto en el incremento de la resiliencia (Meneghel, Salanova y Mª Mart, 2013).

Así mismo, de la propuesta de Horne y Orr (1998) de las siete pautas dentro de una organización, en la investigación surgieron cuatro: conexiones (que en este caso sería apoyo social), compromiso, comunicación y coordinación. Los autores recomiendan que estas pautas deben ser evaluadas a nivel general, ya que conjuntamente ayudan a la organización a cumplir sus objetivos en tiempos de crisis. Eso porque, a nivel organizacional, tales pautas conducen a resultados favorables a través de la facilitación del procesamiento de la información en condiciones de estrés (Meneghel, Salanova y Mª Mart, 2013).

También es importante destacar el papel del optimismo que resulta en los relatos de los participantes. Fredrickson (2009) afirma que el optimismo constituye uno de los factores más importantes para crear las condiciones de satisfacción y de felicidad. Incluye las expectativas de control sobre los resultados de las propias acciones, las expectativas sobre la posibilidad de alcanzar resultados positivos en el futuro, así como un cierto componente de eficacia personal (Fuentes y Medina, 2012).

El segundo componente, son los resultados saludables. De acuerdo a los relatos se destacan: la relación positiva de la organización con el entorno, la calidad y desempeño. En la relación positiva de la organización con el entorno, se destaca el agradecimiento por parte de los pacientes que asisten a la clínica, debido a que los profesionales atienden a todo paciente (independientemente de dónde venga o con qué recursos cuente) y a su vez, lo hacen de una manera eficiente y profesional.

Las organizaciones saludables cuidan no sólo de las relaciones entre los empleados y dirección dentro de la propia organización, sino también de las relaciones de la organización como un todo con su ambiente extra-organizacional, con la comunidad cercana y la sociedad en general. Uno de los objetivos de estas organizaciones es tener un impacto positivo en el ambiente local externo a la organización, así como ofrecer una imagen positiva y saludable de la empresa hacia el exterior (Montilla, 2014).

Para finalizar, es pertinente decir que la organización estudiada, muestra de acuerdo a los relatos de los empleados que cuenta con rasgos que la distinguen de otras clínicas y que así mismo cuentan con una actitud propositiva. Son capaces de adaptarse y atender a todo paciente que llegue a la clínica, sin importar sus recursos o la procedencia, y así mismo todo el personal cuenta con diferentes capacidades

para cada atención. Esto último se debe a que la clínica tiene una característica de rotación de personal y de realización de capacitaciones para los empleados.

La resiliencia organizacional toma un papel muy importante en las organizaciones, ya que con los recursos personales y colectivos de los empleados se superan los momentos de crisis, y con las capacidades de aprendizaje y adaptación se logra salir renovado ante las dificultades. También es importante que desde el Modelo Hero se empleen todos los recursos y prácticas como un conjunto para lograr así que las organizaciones logren sus objetivos.

Por todo lo anterior, se considera que los empleados de la ESE Clínica de Maternidad Rafael Calvo cuentan con diversos factores protectores, recursos y prácticas saludables para poder superar las crisis económicas que se presenten a futuro.

Así mismo, dando cumplimiento al compromiso adquirido con la clínica al inicio de este proyecto se devolverán los resultados para la validación por parte de los participantes y hacer recomendaciones.

Internet in purchase processes of Polish SMEs

Ewa PRAŁAT

Faculty of Computer Science and Management, Wroclaw University of Science and Technology, 50-370 Wrocław, Wybrzeże Wyspiańskiego 27 Poland, ewa.pralat@pwr.edu.pl

Abstract

Growing popularity of information and communication technologies has a significant impact on the way how enterprises are conducting their purchase processes and make them less time and resource consuming, as well as environmentally aware due to the paperless communication. For quite a long period of time, mostly big enterprises have benefited from these solutions and attention of most researchers has been focused on them. The aim of this paper is to examine how small and medium-sized enterprises use Internet in their purchase processes (12 actions itemized in the purchase process were analysed). The available Internet tools included homepages of suppliers, company blogs, social networks, B2B e-commerce websites, B2B e-marketplaces, e-catalogues, e-requests, etc. The matter of the sources of information about suppliers was also raised. The author conducted a survey among 126 small and medium-sized enterprises from the Lower Silesia Region. It was aimed at learning their preferences as to how to use the Internet in the purchasing process, at evaluating the usage rate of individual solutions and at identifying the types of products bought via the Internet.
Results of the research proved that Polish SMEs are familiarized with Internet tools that can be applied in the purchasing process, although these solutions are not very common, especially in small enterprises. A further research should be based on the interviews to identify deeply the reasons that prevent enterprises from using available solutions. Moreover, the author would like to verify whether there are some industries less amenable to using the new opportunities.

Keywords: SME, purchase process, Internet tools

Introduction

Use of the information and communication technology (ICT) in purchasing process is not a new idea born during the recent years only. As early as 50 years ago, Electronic Data Interchange (EDI) was applied, the solution that made it possible to exchange business documents between various computer systems with use of established message formats. However, the traditional EDI was an expensive solution and, in consequence, was used mostly by large, well-funded companies having many suppliers. Emergence of the World Wide Web and a drop in prices of personal computers resulted in common and comprehensive application of the ICT in enterprises. Nowadays, it strongly influences many aspects of a company operation and one of the processes clearly modified by these changes is the procurement process. The Web offers numerous solutions that facilitate and speed-up the actions related to purchases in the enterprises. It makes it possible not only to search for potential suppliers, establishing contacts with them, exchange of information and also, more and more often, execution of the purchase itself and making the payment.

Small and medium-sized enterprises significantly affect economies of many countries (Sila & Dobni, 2012). They significantly contribute to the GDP, generate the majority of employment (Morais et al., 2011) and influence economic growth not only at the local or regional levels, but at the national level as well. The SMEs appreciate importance of the supply management in the enterprise and are aware of the relation between correct execution of the purchasing process and the results reached by the company. However, because of numerous restrictions present in this size companies, they are often described as “normative” or “conservative” buyers. This concerns also adoption of the solutions related to using the ICT in purchases – many publications indicate that SMEs are lagging in implementing modern solutions in their businesses.

The issues related to using the Internet at purchasing process in the SMEs do not take too much place in the literature. Attention of most researchers is focused on big enterprises, which usually apply modern solutions supporting the procurement processes. This publication concerns employment of the Internet in purchasing process by SMEs, is aimed at determination of goals and the application level, as well as at identification of possible differences occurring in this area by enterprises of individual sizes.

Therefore, the goal the author set for this article is: firstly, to identify the available Internet tools, that can be appropriable in purchasing process of SMEs, both as a source of information and as place of transaction, and secondly, to explore the ways they are used. These included the homepages of suppliers, company blogs, social networks, B2B e-commerce websites, B2B e-marketplaces, e-catalogues, e-requests, etc. The author conducted a survey among 126 small and medium-sized enterprises from the Lower Silesia Region. It aimed at learning their preferences as to how to use particular tools in purchasing process and the usage rate of individual solutions.

Review of the subject literature

Clear differences are observed between the SMEs and large companies as regards the levels of using the ICT solutions (Eurostat Statistics Explained, 2019). Researchers indicate several types of barriers hampering acceptation of these solutions by the enterprises (Levy & Powell, 2005). These barriers can be divided to the external ones (related e.g. to legal, cultural or technological aspects) and the internal ones (having their sources in the organisation itself). In the case of the SME companies, the latter is above all limited level of financial and human resources and also insufficient knowledge about available possibilities and missing support from the management (resulting from insufficient time and underestimation of the opportunities offered by these solutions (Cox et al., 2001), (Kapurubandara & Lawson, 2006).

These factors affect also adoption and use of the e-commerce solutions by the SME companies (Morais et al., 2011). However, it is worth to note that some aspects of operation of this size enterprises can next contribute to easier implementation of the e-commerce related solutions. They include, first of all, closer contacts with customers, better skills to adapt to new situations and ability to implement changes faster.

Companies use the e-commerce solutions to different degrees. Sila and Dobni (Sila & Dobni, 2012) distinguished three usage patterns of e-commerce in SME: E-Limiteds, E-Leaders, and E-Laggards, taking into consideration the following three groups of factors: technological, organizational, as well as inter-organizational and environmental factors.

Because of limited resources and sometimes insufficient knowledge about purchasing and supply management, the SMEs less often treat this activity as a strategic one (Ellegaard, 2006]) Results of Paik (Paik et al., 2009) show however that the persons making purchases realize a strong influence of the purchased products and services on the company results. They also believe that market position of their company is highly dependent on the way, how their procurement is executed. The companies emphasized also the problems of finding new suppliers to replace those currently collaborating, which can mean that they may have insufficient purchasing leverage.

Even if there are no significant differences in the access level to the Web between different-size enterprises, there are differences between them in their way of using the Internet in purchases. However, the profits identified in researches are similar and the following can be mentioned among them: quick access to information, easier communication with the current suppliers, its lower cost, less paper work, easier and faster searching for new suppliers (Moon, 2005), (Stankovska, 2016). Sometimes, financial benefits connected with lower purchase costs are mentioned (Stratopoulos & Dehning, 2000), but the authors claim that the advantage is rather short-lasting, since the competing companies usually implement a similar technology in a few years.

The e-procurement is the process that, according to van Weele (2010) "..includes web technology-based purchasing solutions aimed at simplifying commercial transactions within and between organizations and information technology solutions for ordering, logistics and handling systems as well as for payment systems". Even if elements of this process are more and more often executed by companies, they are not so common in the SME sector as among large companies. Chan and Lee (2003) developed a model of behaviour of small and medium-sized companies connected with adoption of the electronic procurement solutions. They found that the factors like the value of e-procurement adoption, power of the e-procurement, trust on a supplier, trust on the IT and power of suppliers, decisively affect adoption of these solutions. The same authors pay attention to the role of intermediary institutions (like B2B e- marketplaces) in promoting the purchasing solutions using the Internet and in building confidence to this type solutions. In addition, the government institutions should conduct a wide-scale educative action and implement the necessary legal regulations (Chan & Lee, 2003), (Prałat, 2017).

The sector of micro, small and medium-sized enterprises represents the prevailing majority of enterprises in Poland – as many as 99.8% of them (according to 2018 data of Polish Agency for Enterprise Development). The most numerous group, 96.5%, are 2 million of microenterprises. The fractions in the structure of Polish companies are: 2.6% (53.8 thousands) for small enterprises and 0.7% (15.3 thousands) for medium-sized enterprises (PARP, 2019). Moreover, in 2017, the SME sector made nearly a half (49.8%) of the GDP and was the workplace for 68.3% of total employees in the business sector.

The high importance attached by the SMEs to the purchase area is confirmed by the results obtained in 2012 by Dorożyński and Urbaniak (2013), who examined the factors that facilitate or hamper running a business on a sample of 171 small and medium-sized enterprises from the Lodz Metropolitan Area. In the opinion of the companies, "cooperation with suppliers and subcontractors" appeared the most significant factor from among 30 of those examined and was rated 5.5 in the 7-degree scale (standard deviation 1.43 and coefficient of variability 26%) (Dorożyński & Urbaniak, 2013).

Procurement is also indicated as the most important area of the knowledge partnership on the grounds of results of the examinations carried-out within 2010-2012 on the sample of 247 SMEs representing both the regional, national and international ranges (Adamik & Flaszewska, 2013). The actions aimed at the knowledge partnership in the procurement area are carried-out by 69.7% of the companies operating in the regional market and by 56.9% of those with the national range. The examined enterprises gathered the knowledge about their closer and further environment utilizing mostly professional press/literature and the Internet (61.8% and 52.2%, respectively).

Supply purchasing in the enterprises

According to Lysons and Farrington (2005), the term "supply purchasing" means the function responsible for "acquisition of equipment, materials, components (semi-products), parts and services by buying, leasing or in another legal way in order to use them for production or to resale them".

Purchases in the enterprise market are made in the three situations: new purchase, renewed purchase and modified one. Each of these options is connected with a different way of action and, in consequence, emphasis is put on the other ones from the described below stages of the purchasing process. The purchasing process of an enterprise can be divided to several stages, whose description and number is different depending on the source. The most often quoted one is the Buy-Phases model, presented by Robinson (Robinson et al., 1967), comprising of the following eight decision stages:

1. Need recognition – awareness of the problem, need or a potential benefit gives a pulse to begin the purchasing process;
2. General need description – determination of the features that the product or service identified at the previous stage should have and the approximate demand;

3. Definition of technical and qualitative specification – the need is precisely described and the request for quotation can be prepared;
4. Supplier search – on the grounds of own market analyses and possible external opinions, the enterprise can identify the manufacturers, which should be considered at sending-out the requests for quotation;
5. Proposal solicitation – requests for quotation are sent to the selected suppliers, their answers are analysed and possible counter proposals are prepared;
6. Evaluation of proposals and selection of suppliers – final quotations are evaluated considering the previously elaborated evaluation criteria. Finally, one or a number of proposals is selected and, possibly, negotiations with the suppliers are carried-out. The stage is finalized with conclusion of a contract.
7. Specification of the order routine – detailed conditions of the transaction are agreed (qualitative parameters, delivery terms, warrantees, claim procedures, etc.);
8. Performance evaluation and feedback – the purchased products are verified from the viewpoint of fulfilling the previously determined need. Information on cooperation with the supplier are also collected to be used for its future evaluation.

Internet as the information source and place of purchases

The problems related to incomplete information or its insufficient reliability are the elements most often (36.9% and 32.2% of indications) mentioned by the B2B buyers in 2018, as causes of delays in accomplishment of their purchases (ShowPad Report, 2018). At the same time, nearly 60% of the buyers admit that they often experienced the situation when they did not receive any response to the question related to the purchase (Time Trade Report, 2018). The more and more common use of Internet and various types of ICT tools contributes to increasing accessibility of electronic information sources in companies and to their increasing importance. The greatest advantages of using the Internet in the supply market search are: access to comprehensive data resources not restricted by spatial and temporal barriers, saving of time, convenience and low cost of data acquisition [Sobczyk].

The Internet is also the place of searching the information about the suppliers for possible collaboration and their products. This enables the buyer to collect the most important information quickly and independently, as well as to be better prepared for negotiations with sales representatives of the potential supplier or even for the purchase. Among new information sources, the following can be distinguished:

- The B2B e-commerce websites They are online stores acting on the B2B market, whose offer is designed only for the logged-in customers. Here, it is possible that the products can be searched not in the standard way only, by their names, but also in the advanced way by bar codes, manufacturers' names or their attributes (in some sectors, the offered products are described by numerous technical parameters). The service can also include the information about substitutes, as well as photographs and engineering drawings. A useful function can be a comparison website considering numerous criteria that makes it possible to select the product best fitted to the customer's needs.
- The B2B e-marketplaces. These solutions present the offers of numerous suppliers and were created in order to automate the purchase and sale process. They make it possible to find the required products, as well as to conclude the transaction and to settle it. These services are also a perfect place for searching the information about potential suppliers of goods or services, entering into communication with them and being informed about details of co-operation with individual suppliers (delivery and payment terms). This is provided by catalogues containing current offers and by advanced searching and communicating tools (Radzikowska, 2014).
- Company blogs. In addition to the product information, the suppliers' websites more and more often include the sections named "blog" or "knowledge base", where reports, webinars, case studies, novelties, customers' opinions and experts' advices concerning the offered products or services are placed. These contents are oriented to the potential customers and are aimed at increasing reliability of the company, creating its image as an expert in its field and at distinguishing it against the competitors (Szamrowski & Pawlewicz, 2013). An additional advantage is the possibility to reach the

future customers for free, the more that publishing the blog gives higher position of the company website in the Google browser results.

- Answers to the inquiries sent-out by the customer. There are three basic kinds of these inquiries: Request for information (RFI), Request for proposal (RFP) and Request for quotation (RFQ). Selection of a specific inquiry or the sequence of using the inquiries depends on the knowledge that the potential buyer has about the product and the suppliers' market. In the case of the RFI, the buyer needs a general information and expects from the suppliers the information about their market position, financial position, products and their parameters. In reply to the RFP, the customer expects that the potential supplier suggests how to solve the specific problems. A reply to the RFQ should include a declaration whether the exactly specified requirements can be met (in order to compare offers coming from many suppliers). The inquiries (in particular the RFI) can be the preliminary steps in preparation of purchase auctions or be used to obtain some knowledge about the market. They are more and more often sent in the electronic form by e-mail or via trading platforms that usually make it possible to assess the responses automatically on the grounds of the previously defined criteria.
- Social networks. To search products and suppliers or to seek an opinion, the buyers in the B2B markets more and more often use various social networks. Both in the LinkedIn and in the Facebook thematic groups, one can search for information about solutions and recommendations, exchange experiences or verify reliability of potential suppliers (Sitarska, 2019).

Employees of purchase departments more and more often expect obtaining, through the Web and with no necessity to contact a sale agent, not only general marketing data, but also comprehensive information about products and purchase terms (e.g. technical details or legal aspects), that is the knowledge necessary at the final stage of the purchase process. This approach is well-grounded the more that many B2B products and services can be acknowledged as standard solutions. If the buyers' information needs can be completely fulfilled thanks to the information presented in the electronic form, this can suggest that implementation of a trading platform should be considered in order to utilize its advantages (including lower selling costs and savings of the salesmen time to utilize them where the personal contact is really necessary). It should be stressed that the buyers in the B2B market readily transfer their habits, experiences and inclinations from the private life to the professional area and as many as 75% of them think that using B2B e-commerce websites is more convenient than purchases at the trade representatives (Bielobradek, 2018).

However, this does not mean complete withdrawal from contacts with the seller's agent – lack of such need was indicated by merely 30% the surveyed B2B buyers. As many as 70% of them still need an agent's help at some purchase stage or when it concerns complex and complicated products, of that 38% higher appreciate contacts with the sale rep than independent searching the information and 32% prefer a combination of these two information sources (ShowPad Report, 2018).

Information sources in the purchase process

The actions aimed at a supplier selection can be classified to the tactical ones, however, the selection alone and its consequences are of a great meaning for the company. Staff of the departments responsible for purchases can have insufficient knowledge and understanding of the market (especially regarding a new purchase), so they should search for many various sources of information about the potential suppliers. Monczka (Monczka et al., 2011) indicates both traditional and modern sources of this information:

- personal contacts,
- participation in fairs, exhibitions and other specialised events,
- professional papers, catalogues and brochures,
- opinions and advices obtained from independent experts or institutions (e.g. from chambers of commerce or commercial counsellors),
- opinions issued by other companies (recommendations concerning a specific supplier or their absence),
- Internet,

- catalogues (databases) available in electronic version.

Polish authors additionally indicate the following sources of the knowledge about potential suppliers and their offers: suppliers' offers sent independently or in reply to the requests sent-out or published in periodicals, websites of companies, stock exchange news, experience acquired by buyers, tenders and telephone directories (like Panorama Firm) (Urbaniak, 2013).

It results from the research carried-out by Urbaniak (2013) on a group of over 130 Polish small and medium-sized enterprises that the most common source of information about suppliers were fairs and exhibitions, suppliers' websites, recommendations of other companies and commercial representatives (Fig. 1). Each of these sources was used by 67.4% to 71.2% of the examined companies. The lowest interest (18.2%) was shown to chambers of commerce or chambers of commerce and industry. However, when small and medium-sized enterprises are analysed separately, the results are different. This is especially visible for small enterprises, where most popular appear recommendation of other companies (77.6%) and then the suppliers' websites and fairs or exhibitions (67.2% each). As relates to medium-sized enterprises searching for information about suppliers, they used most frequently fairs and exhibitions (74.3%) and then the information obtained from commercial representatives and websites (73.0% and 71.6%, respectively).

Fig. 1: Sources of information about suppliers used by small and medium-sized enterprises
Own presentation based on (Urbaniak, 2013)

Research Methodology

In order to evaluate the use of Internet as a source of information in purchasing process, a study was conducted among small and medium enterprises from the Lower Silesia Region. This research was a part of more extensive research works carried-out by the author, related to purchases in small and medium-sized Polish enterprises. The research tool was the questionnaire form and the CAWI survey technic was used. Discussed will be that part of the questionnaire only, whose results are used in this paper. The main hypothesis was

- to identify the sources used by the enterprises searching for suppliers;
- to ascertain, whether the SME companies use the Internet in the purchasing process;
- to determine the level of using the Internet on individual stages of the purchasing process;
- to identify the type of products that are frequently bought via the Internet;
- to examine possible differences in actions between small and medium-sized enterprises.

The mentioned part of a questionnaire consisted of seven questions, most of them close-ended, with nominal or ordinal scale. Moreover, the respondent's particulars part included five questions concerning the enterprise size (like in the previously discussed research, the only division criterion was number of employees: small enterprises employed 10 to 49 persons and medium-sized ones employed 50 to 249 persons), industry, business line, etc. After verifying the questionnaire in a pilot survey and introducing necessary changes, the main survey was conducted. 144 questionnaires were obtained, of which 126 really concerned small and medium-sized enterprises and were correctly completed.

Discussion and Results

90 small and 36 medium-sized enterprises took part in the research. They conducted trading, manufacturing and service activities (more than one answer was often indicated). Small enterprises operated first of all in local and regional markets, and medium ones – in regional and national markets. The enterprises that operated in the market longer than for five years represented nearly three-fourths of medium-sized enterprises (72.3%) and over a half of small enterprises (52.3%).

In the question concerning sources on information about suppliers, the cafeteria of responses was significantly extended in relation to the proposal of Monczka (Monczka et al., 2011). First of all, new sources related to use of the Internet in this area were added. When searching for suppliers, the examined companies use various sources, what is shown in Fig. 2. The source most often used by the examined enterprises appeared their sale services, traditional recommendations of other companies, as well as fairs and exhibitions. Results are different depending on size of a company. Small enterprises use mostly recommendations (63.3%), sale services (53.3%), fairs and exhibitions (44.4%), but medium-sized enterprises search for information in sale services (72.2%), in fairs and exhibitions (69.4%), in electronic trade catalogues (58.3%), but use also recommendations of other companies and information from commercial representatives (55.6% each). Among the analysed companies, the lowest interest was shown to the information coming from chambers of commerce and industry. Sending-out requests for offers by traditional post was rarely practised and offers were also rarely obtained this way. Small enterprises sporadically (5.6%) searched for information on trade B2B platforms and every fifth medium-sized enterprise searched for information this way.

Fig. 2: Extensive sources of information about suppliers used by small and medium-sized enterprises

Source: own work

All the companies taking part in the survey confirmed use of the Internet in the purchasing process. In the questions related to purchases, the previously described stages of the Robinson's Buy-Phases model were used. The actions executed just after the purchase were also added, namely payment, exchange of trade documents, warranty and complaint handling, as well as keeping contacts with the suppliers. The examined companies used the Internet in all their actions related to purchases, which is shown in Fig. 3. In individual actions being subjects of questions, over a half (at least 54.5%) of the examined companies used the Internet often or very often. Most often, it was used at payments and at the initial stage of the purchasing process, that is at searching for the product. In both these actions, the Internet was used often or very often by over 90% of the examined companies (93.9% and 90.9%, respectively). The actions most rarely executed with use of the Internet was searching for opinions about the specific supplier and establishing conditions of the contract. It results from discussions with representatives of purchase departments that the contract negotiation is the action carried out (depending on the contract) usually during a telephone call or a personal talk and still confirmed by paper documents. Almost each of the actions was more often performed with use of the Internet by medium-sized enterprises and the only exception was searching for opinions about suppliers. The reason can be less widespread contacts of small enterprises and their smaller market research abilities.

As for searching for an opinion, there are no services strictly designed for the supplier evaluation in the B2B market, especially in the case of direct purchases (related to production). The buyers can possibly ask for opinions about suppliers or warn against collaboration with some of them by means of social networks.

Fig. 3: Frequency of using the Internet at individual stages of procurement process by small and medium-sized enterprises

Source: own work

Depending on sizes of the examined companies, there are differences between levels of using the Internet in individual actions related to purchasing. For small and medium-sized companies, average scores showing frequency of using the Internet for each of the actions were calculated (0 points were attributed to the answer "never" and 4 points were attributed to the answer "very often"). The results shown in Fig. 4 indicate that small enterprises less frequently use the Internet in 11 of 12 analysed actions. The largest difference in results between small and medium-sized enterprises appeared in the case of "placing orders" and was equal to 0.91 points. An advantage of medium-sized enterprises was also big in the case of the final stage of the purchasing process, i.e. searching the product and establishing contacts with the supplier. In both cases, the difference was equal to 0.75 points.

In the actions related to execution of the purchasing process, all the examined companies use the e-mail, the Web browser and the online banking. In the case of online shopping, B2B e-commerce websites are mostly used, where 84.2% of medium-sized and 47.4% of small enterprises do their purchases. The B2B e-marketplaces are used much less frequently, by 19.4% of medium-sized and 1.1% of small enterprises only. Use of these platforms is generally payable, so it may be the reason, moreover companies can be afraid of their insufficient skills or have no knowledge about the benefits that can be reached by use of such a solution.

A significant part of the examined companies buys also products (first of all indirect ones) on open trading platforms like Allegro.pl, Amazon or AliExpress. This concerns mostly small enterprises (53.4%), but also a part (23.7%) of those medium-sized. This markets make it possible to recognise product prices and to find new suppliers for cooperation also outside the platform. A small percentage of the companies purchased also in online shops.

Among the products bought by small and medium-sized enterprises through the Web, there are first of all: equipment and appliances related to the business operation, office supplies and computer hardware (Fig. 5). The differences appear in popularity of these purchases. Most of medium-sized companies buy this way their business-related equipment/appliances and office supplies (83.3% each), as well as computer hardware (72.2%). In the case of small companies, nearly the same part

buys online computer hardware (71.1%), but the other results are much lower at 53.3% for business-related equipment/appliances and 46.7% for office supplies.

Fig. 4: Differences in using the Internet at individual stages of procurement process between small and medium-sized enterprises

Source: own work

Small and medium-sized enterprises were significantly different with regard to the range of goods purchased through the Internet. Percentage of medium-sized enterprises that clearly more often bought office supplies, business-related equipment and appliances, as well as groceries, was at least 30% higher than for small enterprises. This can result from small volume of purchases, which does not stimulate them to resign usage of traditional wholesalers.

Fig. 5: Percentages of small and medium-sized enterprises using the Internet in purchases of individual product types

Source: own work

The following aspects were indicated as the greatest advantage of online shopping: convenience (72.7%), possibility to reach a great number of suppliers (66.7%) and possibility to obtain lower prices for goods and services (61.2%).

Results of the questionnaire survey showed that they more and more often searched for information about suppliers by means of ICT solutions. The most popular were B2B e-commerce websites of individual suppliers and e-catalogues. Percentages of the enterprises using individual solutions were different between small and medium-sized organizations. In comparison to the Urbaniak results, increasing interest in using the information that can be obtained by Internet is visible. However, the examined companies use modern solutions not in place but in addition to those traditional and do not resign the information acquired during fairs and exhibitions, from commercial representatives or by advertisements in professional press (that is also more and more often in electronic form).

Conclusion

Low purchase costs of computer hardware and open access to the Internet (in 2018, 95.6% of Polish companies used the Internet) compose one of two most important causes of growth of electronic purchases in enterprises. The other cause is popularization of the idea of electronic purchases in companies, which became possible due to common knowledge of online shops and auction services acting on B2C market. In spite of indisputable advantages of online purchases (convenience, promptness of reaching the seller, savings resulting from both usually lower price and the transaction costs themselves), there exists a great discrepancy in using this type solutions by different size enterprises. According to the data published by the Statistics Poland, in 2017 percentage of Polish enterprises placing orders by the Web was 33.6%. Even if these actions concerned 2/3 of big enterprises, the percentages among small and medium-sized enterprises were much smaller, amounting to ca. 43.6% for medium-sized enterprises and ca. 29.8% only for small ones (Statistics Poland, 2018). Central Office of Statistics publishes two values: percentage of the companies purchasing through websites and mobile applications and percentage of the companies purchasing with use of Electronic Data Interchange (EDI). However, these numbers can not be totalled, since the two groups are not disjoint sets.

This paper concerns using the Internet non only in execution of purchases, but in the entire process connected with purchases of small and medium-sized enterprises – starting from market researches (searching for both the products meeting specific requirements and, in the next step, their suppliers), establishing contacts with the suppliers by acquiring their offers, negotiations and concluding contracts, up to making payments for completed deliveries. Another question raised in the work is analysis of sources of information about suppliers, used by companies from the SME sector, with the special emphasis on application of online sources.

This study is focused on the impact of Internet tools on purchasing process of small and medium-sized enterprises. The information sources used by these enterprises were examined, with a particular emphasis to various types of online sources. Moreover, it was determined, how often the analysed organisations use the Internet in individual actions connected with execution of the purchasing process. Results of the questionnaire survey carried out among 126 small and medium-sized enterprises show that Polish SMEs are familiar with Internet tools that can be applied in purchasing process, however, these solutions are not very common. Moreover there is a noticeable difference between small and medium enterprises. The conclusion arising from the research is the enterprises should aim at more and more comprehensive usage of the possibilities offered by ICT, by improving their supply management routines. By using these solutions and proper performing the tasks in the sourcing and procurement areas, they can increase their ability to compete with bigger market players, as well as improve their performance and efficiency.

Further research could identify the reasons that prevent enterprises from using the available solutions. Moreover, the author would like to verify whether there are some industries less amenable to the new opportunities and conduct the interviews in depth in such companies.

The Situation of Capital Markets in The Current Context

Andreea ANTON

PhD student, Faculty of Economic Sciences and Public Administration
"Stefan cel Mare" University of Suceava, Romania, e-mail: anton.andreea20@yahoo.com

Abstract

The outlook for 2020 depends on the balance between political risks and fiscal and monetary policy responses. This will create two possible outcomes: either the slowdown observed at the end of 2018 will be stopped and a moderate recovery will occur, or the economy will go into recession. The trends of inflation and the interest rate also depend on this policy combination. Continued over-confidence in monetary policy is likely to keep yields and inflation expectations low, as monetary policy approaches its limitations. Other policy levers, such as fiscal incentives, would boost economic growth and returns.

Keywords: Capital Markets, Fiscal Policy, Recession, Investors.

JEL code: G11, G12, G15.

Introduction

The capital market can be defined as the place where financial instruments are sold and bought (see https://www.financialmarket.ro). This covers the markets of various financial instruments, as well as the financial institutions that activate and are involved in its proper functioning (https://admiralmarkets.com).

In other words, the capital market consists of a set of economic relationships and associated mechanisms with which investors who have capital surplus and want to make use of it come in contact with the issuers of securities (financial instruments), that is, those in need of investment. Thus, the exchange of money funds takes place through securities or financial instruments. Therefore, the capital available from the economy reaches those who need it for the development of economic activities. The most well-known forms of the capital market are the stock exchanges, the shares and bond markets, but also the currency markets. Most capital markets are found in large financial centres, including New York, London, Frankfurt, Hong Kong, Tokyo.

The purpose of capital markets is to improve the efficiency of transactions. In order to achieve this objective it is necessary to refer to a longer period of time, i.e. those investments that block capital for periods longer than one year (see https://ing.ro).

The Troubles of 2020

2020 is marked by uncertainties, which is why we have pointed out a few questions that will probably bother us during the year.

1. Will global expansion continue in 2020?
2. Will we escape political uncertainty in 2020?
3. Will inflation return in 2020?
4. Will fiscal policy help?
5. What could cause the next recession?
6. How is Romania in this context?

The answers we can offer at the moment are based on the decisions taken last year and the context in which we find ourselves, so we can state that at the moment, the risks associated with the US-China trade war and Brexit have diminished considerably, but the global political situation is a volatile one if we refer to the US-Iran conflict.

Political uncertainty is fueled by power imbalances in the economic and political system, the fundamental indicators that support it remain present.

Regarding inflation, for now we can say that it will not increase soon, the role of central banks is to temper the expectations of markets regarding the inflation and to stabilize the level of unemployment.

Fiscal policy may be supportive, but for the moment, it faces many constraints, such as very low interest rates and inflation.

Political uncertainty can discourage company investments and increase productivity (see https://beleggingsvisie.ingbank.nl).

The Current Context

The challenges facing the global economy have increased in 2019. If we refer to the political situation, we can say that tensions related to global trade have continued to wane over time, threatening Brexit without agreement has diminished, however, nevertheless remaining a challenge for European financial markets.

Social unrest has increased throughout the world, fuelled by rising income inequality, but also by the on-going uncertainty of climate change. As a result of these factors, we noticed a decrease in the risk appetite of investors, this fact reducing the yields of the government bonds in the developed markets (https://www.zf.ro/burse-fonduri-mutuale). Investor appetite has recently improved due to the reduction of political risks and the stabilization of macroeconomic indicators. The evolution of markets in 2019 shows how difficult it is to identify a solid anchor in an uncertain world.

2020 brings a global economy approaching a crossroads. The challenges generated by the political uncertainty we are in continue to influence financial markets. Bond yields and inflation expectations have been pushed down due to excessive confidence in monetary policy. However, we can mention that the fiscal stimulus measures have increased the confidence in the business environment and consumers, thus boosting the economic growth. Meanwhile, the US and China have reached a preliminary trade agreement, and the uproar caused by Brexit is reaching a stable resolution.

In terms of asset performance, 2019 proved to be an exceptional one, given that both low-risk asset classes (government bonds) and high-risk assets (equities) recorded solid performances, as table no. 1 reflects. The main global stock indices registered increases of 15%-25% in 2019, a notable evolution, considering the tendency of the global economy to slow down compared to 2018. At the same time, investors in government bonds were rewarded with consistent yields, taking into consideration that the cost of borrowing for the major developed states ended the year at lower levels than at the end of 2018 (see https://www.nnip.com).

Table 1: The performance of the main classes of global assets in 2019 and in the last 5 years

Asset classes	Index	Performance 31 Dec 2018-31 Dec 2019	Performance 31 Dec 2014-31 Dec 2019
Emerging market shares	MSCI Emerging Markets	15.42%	16.56%
American markets shares	S&P 500	28.88%	56.92%
European markets shares	Stoxx Europe 600	23.16%	21.40%
US Government Bonds	Bloomberg Barclays US	6.86%	12.35%

	Treasury Total Return		
Government bonds in emerging markets	JPM EMBI Global Diversified	15.04%	35.34%
European government bonds	Bloomberg Baclays EU Govt All Bonds	6.76%	13.30%
European high risk bonds	Bloomberg European Ccy High Yield	12.29%	26.04%
Raw materials	Bloomberg Commodity	5.44%	-22.47%
Oil	Crude Oil Brent	22.68%	15.12%
Real estate US	Dow Jones US	22.34%	60.12%

Source: Bloomberg

In 2019, there was a paradox in which markets ticked increases both on the background of positive macroeconomic news and on the news regarding the deterioration of economic data. In other words, when the economic data indicated an economic slowdown, analysts interpreted this as an argument for the continuation of the monetary stimulus, therefore a strong impulse for the markets. At the same time, if subsequent data signalled the recovery of the economy, the effect on investor sentiment was also positive. Taking into account all the aspects presented, we can state that the year 2019 has been a positive one, for both the prudent investors and those with a higher risk appetite.

With regard to the outlook for 2020, it is possible that solid performances similar to 2019 may be more difficult to repeat.

The United States is experiencing one of the longest stages of growth in the economy, which may increase the risk of an economic slowdown, according to several analysts. In the meantime, Europe is facing structural growth problems. Monetary policies have pretty much exhausted their arsenal, and any additional measures appear to have little chance of making a truly material impact. As far as fiscal policies are concerned, the second main economic stimulus channel, for 2020 analysts do not expect fiscal aid in any of the big economies. At this time, the price of the main categories of assets is already high, thus investors could also opt for global shares in 2020, at the expense of those with fixed income, given that their current levels leave little room for compressing yields, especially in Europe (see https://nnip.com).

Local Developments

At the end of 2019, Romania faced negative economic data. First, the data on economic growth in the third quarter of the year fell behind the expectations of analysts, indicating a slowdown at 3% compared to the third trimester of 2018, when in the second trimester of 2019, the economy grew by 4.4%. Annual inflation for November 2019 accelerated to 3.8% from 3.4% in October 2019. This level is outside the central bank's inflation target range of 1.5% -3.5%.

Romania ended 2019 with a budget deficit with 1% of GDP higher than the initial target of 3%. From a fiscal point of view, the year 2020 remains a difficult one for the current Government in the challenge of keeping the electoral commitments eluded by the previous government and at the same time keeping the budget under control. An example in this regard is the pension law adopted last year which provides for large pension increases in the public system (40%).

In this context, the national currency began to depreciate. The EURO/RON rate recorded at the end of 2019 had a 2.5% lower level than the end of 2018. During the whole of 2019, the RON had a constant tendency of depreciation, a situation that is easy to explain, if we look at the general vulnerability of the economic situation during the year (see https://www.bursa.ro).

In early December, the rating agency Standard & Poor's announced the change in Romania's rating outlook, from stable to negative. They justified their decision against the background of increased risks regarding fiscal and economic stability. They also stated that Romania is at the lower limit of the rating

range recommended for investments, which means that a future rating change will have an impact on investors' appetite for Romanian bonds.

However, despite the announcement of Standard & Poor's agency, the level of the Romanian bonds did not react significantly to this announcement. The level of the Romanian government bonds reflects the risks regarding the fiscal situation and Romania had to pay significantly more to investors compared to other countries with a similar rating over the last year. However, delaying the correction of imbalances can have consequences on financing costs, and the rating agencies will have to be convinced that the economy is kept under control (see https://www.conso.ro).

Chart 1: Market share of local funds

Source: own representation based on informations retrived from ***http://www.aaf.ro***

The graph above shows the structure of mutual funds invested in 2019. We can note that most of the subscriptions were in bonds, followed by other funds and shares.

Table no. 2 structures the situation of the investments made in 2019 in Romania, a situation that demonstrates that the investors were not discouraged by the current context of the country, continuing to trade on the basis of the previously obtained returns.

Table 2: The situation of the investment funda traded in Romania in 2019

Name	No funds	Net assets	Subscriptions	Redemptions	Net subscriptions	No investors
Local shares	21	1526.6	51,3	23,60	27,70	14463
Foreign shares	46	291,9	30,10	32.9	-2,8	0
Other local funds	9	3862,9	178,6	140,8	37,9	43983
Other foreign funds	2	0,1	0	0	0	0
Guaranteed/protected local capital	2	277,3	1,9	12,5	-10,6	3261
Local multi-shares	37	1297,7	57,9	28,3	29,6	64190

Foreign multi-shares	11	486,4	31,1	5,8	25,3	0
Local bonds	20	17606,2	578,2	420,1	158,1	215199

Chart no. 2 surprises the evolution of local funds in the year 2019. If at the beginning of the year the net subscriptions exceeded the subscriptions, which means that the investments still recovered the losses recorded in 2018, we can see that by the end of the year they had yields that fuelled the investors' desire to continue to subscribe important amounts.

Chart 2: The evolution of local subscriptions in the last 12 months

Conclusions

The challenges facing the global economy increased in 2019. Tensions related to global trade continued to grow throughout the year, and Brexit will bring major changes in the capital market. At the end of 2019, investors' appetite improved due to the reduction of political risks and the stabilization of macroeconomic indicators. However, the year 2020 is a crossroads in economic growth. New political uncertainties can influence financial markets. Thus, the year 2020 depends on the balance between

political risks and fiscal and monetary policy responses. We can talk about two possible scenarios, namely: either to stop the slowdown observed at the end of 2018, or the economy will go into recession. In this context, for an optimistic scenario of 2020, policy makers are crucial. To stop the slowdown in economic growth, governments will need to implement measures that complement monetary policies and support the confidence of the business environment and consumers.

As far as the banking sector is concerned, in a prolonged slowdown in economic growth, credit spreads will not increase significantly, continuing to benefit from considerable protection from the yield search. As a result, bank financing costs should remain relatively low. On the assets side of the balance sheet of the banks, the rate of non-performing loans should not increase substantially. This should prevent a considerable narrowing of the credit offer. In the event of a recession, things will be very different, and the narrowing of the loan offer will harm the labour market even more.

Assessing the risk of recession is very difficult, being near impossible in the present circumstances, which are practically unprecedented in modern economic history. It thus becomes difficult to draw conclusions based on past experiences. First, the usual cyclical economic imbalances are largely absent, inflation remains subdued and may even be too low. In addition, there is no sign of over-indebtedness or over-investment. However, there are more structural imbalances such as adverse demographic developments, rising inequality and increased concentration in different sectors, all fuelling secular stagnation.

The essence of these forces lies in the low willingness to take risks, both in the real economy and in the financial sphere. Since the engine of capitalism is clearly the ability and willingness to take risks, it becomes a big problem. From a cyclical perspective, increasing secular stagnation forces makes the economy more vulnerable to shocks, as it reduces real balance rates and thus increases the risk of bank rates reaching level zero.

Provisions and Reserves in Banking Sector Under Conditions Of Excess Liquidity Exemplified by Selected Banks Operating in Poland

Ewa LOSIEWICZ-DNIESTRZANSKA

Wroclaw University of Economics and Business, Wroclaw, Poland
ewa.losiewicz@ue.wroc.pl

Abstract

Excess liquidity of banking sector implies that banks hold too much free funds instead of investing them, thus an undesired or even detrimental phenomenon occurs. Nevertheless, excess liquidity has also some strong points when we look at it as a "tool" supporting a bank's safety and stability. Under uncertainty conditions, prudential regulations become more restrictive and result in more reserves and further security buffers in addition to basic capital requirements. The paper aims at researching the significance of bank's excess liquidity for the creation of loan loss provisions and capital adequacy ratio as well as the contribution of an individual bank to liquidity of the whole sector. The research was conducted with financial data from selected banks listed on the Warsaw Stock Exchange.

Keywords: Banking Sector, Provisions and Reserves, Capital Adequacy Ratio, Excess Liquidity

Introduction

Excess liquidity has been for many years characteristic of many banking sectors worldwide. The last global financial crisis motivated banks to accumulate funds in precautionary intentions and most banks do hold considerable surpluses. However, banking sector comprises different banks and some of them have got no excess liquidity. Baldo et al. (2017) examined liquidity distribution in the euro zone and show the countries with excess liquidity and with deficits of liquidity. In this context, the strength of banking sector is noticeable, as excess liquidity from one country can be transferred to those in need. A similar case happens within domestic banking sector, where such transfers are accomplished by means of an interbank market. But when a bank experiences serious financial trouble, its ability to borrow funds is lost, and this can spell trouble for the whole sector. In this situation, excess liquidity is appreciated for its safeguarding value, as provisions and other reserves can be created, if financial condition of the bank deteriorates in future.

The main goal of the paper is to examine the significance of a bank's excess liquidity in the creation of loan loss provisions and the capital adequacy ratio, as well as the role played by an individual bank in the shaping of liquidity of the entire sector.

Section one of the paper characterizes the phenomenon of excess liquidity in banks, indicating its weaknesses and strong points. Based on the analyzed literature, examples of distinguishing two portions of excess liquidity are given: precautionary excess liquidity and involuntary excess liquidity, emphasizing advantages of the former one. Section two of the paper deals with the creation of loan loss provisions and loan loss reserves, with special attention drawn to a problem of dynamic reserves model. Section three of the paper presents the phenomenon of excess liquidity of banking sector in Poland. Based on financial data from selected banks which are listed on the Warsaw Stock Exchange, an examination of the dependency between excess liquidity of banks, levels of reserves and capital adequacy ratio was attempted.

Excess liquidity of Banking Sector

The start of financial crisis in 2008 revised banks' approach to a liquidity problem and they began accumulating considerable amounts of excess financial means on their accounts with central bank, as reported by Baldo et al. (2017).

In Polish banking sector, excess liquidity measured by the issuance of NBP money bills and standing facilities has been occurring since 2004, i.e. since the beginning of stabilization process as a result of transition to a market economy. In 2009 a considerable increase of excess liquidity occurred due to adoption of prudential policies in banking sector and this situation has been continuing with a slight decline of excess liquidity, as discussed by Losiewicz-Dniestrzanska (2019).

A huge excess liquidity of banking sector is assessed as negative for every banking system, as emphasized by Barik Bathaluddin et al (2012). The surplus of free funds in the interbank market results in a decline of the price of money, whereas almost zero or negative interest rates impede the effectiveness of monetary policy transmission, do not encourage the economic growth, obstruct inflation control, as well as instigate speculative bubbles, e.g. in real estate market. It is also a serious obstacle for central banks and brings about difficulties in accomplishment of monetary policy targets. However, an excess of liquidity is not a burden for banks or an impediment to effective transmission mechanism of monetary policy as a whole. Bathaluddin et al (2012) divide the excess liquidity into two portions: precautionary excess liquidity and involuntary excess liquidity. In its first portion, the excess liquidity is useful as a buffer against the threats of withdrawal of funds by customers and of volatile currency rates as well as it influences bank capital. The other part of the excess liquidity is unnecessary and may negatively influence the effectiveness of monetary policy.

Agénor and El Aynaoui (2008) argue that bank excess liquidity may increase because of "precautionary" motivation when banks decide that lending in a volatile environment is too risky.

Provisions and reserves in a bank

Banks create reserves first of all for the purpose of safeguarding financial security and protecting against consequences of uncertainty and bank risk. Isa et al (2015) and Wang et al (2019) classify reserves into two categories: loan loss provisions and loan loss reserves. Provisions can be created when a banks sets aside a certain amount of money to fund an expected liability resulting from past events. They are created when the expected liability was recognized and the loss will be incurred, e.g. provisions for nonperforming / outstanding loans, for depreciation. Another category of safeguarding is represented by reserves that can be defined as a separated portion of bank's profit set aside to be used in future for any needs, such as increasing assets or compensating for unexpected losses. The category of loan loss reserves accomplishes tasks of prudential concept in regulatory and supervisory functions.

Olszak (2014) emphasizes popularity of dynamic reserves as an accounting tool of managing banks' ability to survive under adverse external conditions, e.g. during recession. She notices a problem of incoherent definition of this model, because according to one interpretation it can be associated with increase of general reserves during economic expansion, it generates surpluses which can be used to back possible loan losses incurred by banks during recession. Another definition states that it is a model of reserves equal to expected loan loss at the moment of extending a loan. However, irrespectively of the nature of dynamic reserves applied in different countries, the function they perform is similar. The main purpose of those reserves is to reduce procyclicality of banks' lending activity, by means of limiting the amplitude of variation of loan growth rate, with respect to GDP. Reaching this objective can be possible due to equipping banks with additional reserves for general risk. These reserves should be increasing during expansion when banks show less prudence in examining borrowers and assessing their creditworthiness. During recession, these reserves should slowly decrease, as a result of absorbing losses which were incurred because of bad loans extended during the credit boom. A similar opinion on dynamic reserves is presented by Ozili and Outa (2017) and by Wang et al (2019), who notice that a dynamic model of bank reserves is aimed at increasing safety and stability of banks by means of

higher levels of loan loss provisions (or reserves) set aside in time of expansion so as to be able to cover losses incurred during economic downturn.

Haan and Van Oordt express their criticism in the discussion about models of reserves applied by banks. Based on own research they infer that most of examples in banks under study about models of loan loss reserves are mainly retrospective and procyclical. Previously, formal model of incurred losses, implemented according to International Accounting Standards 39 (IAS 39) did not allow to create reserves for bad loans before loss event occurred. After the global financial crisis, the Basel Committee on Banking Supervision replaced the incurred loss model by expected loss model and now, in accordance with International Financial Reporting Standard 9 (IFRS 9) banks are required to create loan loss reserve for past losses which already occurred, but also for loans which are expected in future.

Level of provisions in banks in Poland

A high level of excess liquidity observed in Poland indicates banks' prudence while expanding their investment activity due to concerns about worsening financial condition. New regulations obligate banks to hold more liquid assets and to exhibit a higher Capital Adequacy Ratio, thus limiting liquidity in banks. However, one should emphasize the difference between liquidity of banking sector and liquidity of individual banks. On one hand, liquidity risk of the whole banking sector can be smaller than of a particular bank separately, on the other though individual positions of banks can be extremely different. For many years, banks in Poland have been dynamically engaged in lending activity characterized by diverse profiles of credit risk. The quality of loan portfolio in 2018 remained stable according to the report on banking sector condition (Sytuacja sektora (2019)), but the introduction of IFRS 9 in January 2018 resulted, among other things, in new rules of presentation, classification and valuation of financial instruments, including recognition and calculation of their impairment. The consequences of new accounting standards can be experiences in the following years. Some banks holding loan portfolios of worse quality, mostly because of lending in foreign currency, will be forced to increase their reserves in view of failure to repay loans or judicial sentences unfavorable to banks in court cases concerning the abrogation of loan contracts.

Banks operating in Poland are obliged to comply with Polish legal regulations corresponding with European Union regulations. The fundamental principles regulating the formation of reserves for general risk are written in the Banking Act, which stipulates that reserves belong to prudential regulations and aim at mitigating risk. The principal objectives of banks' reserves according to the act of law are: to ensure financial security for banks, to protect from consequences of uncertainty and bank risk, to recognize authentic financial profit or loss and to protect interest of banks' owners. The amount of annual write-off to create a reserve for general risk equals at the most 1.5 percent of unpaid loans and advances reduced by the sum of loans and advances classified 'loss', in accordance with separate regulations, as of the end of previous financial year.

In accordance with the *Regulation of the Minister of Finance of* 2019 *on the principles of creating special provisions for risk associated with the activities of banks* allowances for loan losses are created on the basis of the assessment of individual risk generated by a given exposure. The provision is equal, at the least, to a required level of reserves and write-offs that represents the following percentages of the basis to create special provisions and write-offs adjusting receivables associated with credit exposures:

1) 1.5 percent – for credit exposures classified "special mention";
2) 20 percent – for credit exposures classified "substandard";
3) 50 percent – for credit exposures classified "doubtful";
4) 100 percent – for credit exposures classified "loss".

The research into relationship between excess liquidity of banking sector in Poland and levels of loan loss provisions (LLP) conducted with data from different periods between 2006 and 2019 did not confirm the dependency. However, in some periods, as presented in figure 1, and in determined levels

of correlation measured by the Pearson correlation coefficient, the results may indicate the existence of dependency. It was the motivation to examine mentioned relationships in particular banks.

Figure 1: Over liquidity and provisions in banking sector in Poland, 2010-2018

Source: own elaboration based on data from NBP, https://www.nbp.pl/homen.aspx?f=/en/publikacje/instruments/instruments.html&navid=5508

The research was carried out with data from 13 banks listed on the Warsaw Stock Exchange (GPW) in the period between 2000 and 2019 (Notoria database), but due to lacking data some time series are shorter. A relationship between excess liquidity in individual banks and levels of loan loss provisions (LLP) and capital adequacy ratio (CAR). Excess liquidity was measured by an item from bank's balance sheet: cash and operations with central bank, i.e. a sum of cash in treasury and funds on current account.

Measurements for LLP and CAR were sourced from Notoria database. A sample of banks under study was quite diversified, hence they were grouped by the value of their assets (table 1). Besides, two banks were rejected, because after the merger with one of the largest banks in Poland they terminated own operations.

Table 1: Statistical dependency of bank's excess liquidity on loan loss provisions (LLP) and capital adequacy ratio (CAR)

Bank	Statistical dependency	
	Loan loss provisions	Capital adequacy ratio
A1	-0,355	0,566
A2	0,661	0,157
A3	0,217	-0,254
A4	0,669	0,685
B1	0,644	0,136
B2	-0,508	0,064
B3	0,519	-0,147
B4	-0,496	0,686

C1	0,511	-0,346
C2	0,337	-0,272
C3	-0,501	-0,727
X1	-	-
X2	-	-

Source: own elaboration based on data from Notoria database - Program Minigranty (project number 015/RID/2018/19).

Levels of correlation between excess liquidity and LLP or CAR presented in table 1 do not actually confirm the existence of such dependency. Banks from group A are characterized by very high levels of cash and central bank balances, as a result, their sensitivity to increased levels of LLP is lower (fig. 2).

Fig. 2: Levels of loan loss provisions (LLP) during high excess liquidity of banks A1, A2, A4
Source: own elaboration based on data from Notoria database.

Banks in group A were able to "invest" in their financial safety by means of increased reserves. In addition to high levels of LLP, they also exhibit very high levels of CAR (from 16 percent to 20 percent), as illustrated in figure 3.

Fig. 3: Capital adequacy ratio against excess liquidity of bank's A1, A2, A4
Source: own elaboration Source: own elaboration based on data from Notoria database.

Group C contains financially troubled banks experiencing problems with liquidity and consequently, they were covered by remedial actions. Increased levels of LLP in these banks mainly correspond with increased threats to repayment of loans and advances by customers.

Liquidity position of banks C1 and C2 in 2018 reached low levels as a result of the need to increase the level of LLP (fig. 4) and withdrawal of funds from deposit accounts by banks' customers. A low level of liquidity in bank C3 was predominantly caused by the increase of the LLP level.

Fig. 4: Increasing levels of LLP in banks C1, C2, C3 with low levels of liquidity
Source: own elaboration based on data from Notoria database.

In 2018, levels of CAR decreased significantly following the Ordinance of the Minister of Development and Finance (2017). This ordinance imposed higher risk weighting equal 150 percent for credit

exposures secured by mortgages on residential properties, whose repayment depend on exchange rate of currency different from the currency of borrower's earnings.

Fig. 5: Capital adequacy ratio (CAR) in banks C1, C2, C3 with low levels of liquidity
Source: own elaboration based on data from Notoria database.

The ordinance forces the increase of CAR at the cost of liquidity or when liquidity was not available – CAR was decreased below a required level. CAR levels of banks in group C are presented in figure 5.

Presented examples demonstrate smaller sensitivity to changes in levels of liquidity in those banks which have got large excess liquidity, accompanied by holding sufficiently high levels of assets. Bawazira (2018) notes that Implementation of Basel III framework may result in reduced excess liquidity following more severe capital requirements, but also in reduced funds available to finance the growth.

Summary

Banking sector in Poland has been characteristic for many years for its high excess liquidity and also very much diversified in regard to individual liquidity and levels of safety built by respective banks. Completely different is the situation of banks with largest assets, as they also present high liquidity and create reserves with add-ons. The in-between state is presented by banks from the 'middle' of the banking sector, exhibiting some surpluses along with compliance regarding basic regulatory requirements to create safeguarding reserves. A worse situation is characteristic for banks from the weakest group; they made imprudent investments, got into financial trouble and were covered by remedial actions. The funds held by these banks (often insufficient) were directed to the creation of loan loss provisions at the cost of the capital adequacy ratio.

The examined correlations of excess liquidity with LLP or CAR do not actually confirm the existence of those dependencies, but the analysis in a short accounting period clearly indicates the response of banks to more severe prudential regulations by means of decreased excess liquidity with respect to the levels of loan loss provisions and capital adequacy ratio.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN

Abstract

The technical and organisational knowledge of the manufacturing methods is recorded in the literature and technical documentation. However, much of the technical knowledge is contained in the practical skills and qualifications resulting from the laborious acquisition of professional experience. Technical progress, as a fundamental factor in the growth of production, is made by inventions, i.e. the discovery of new knowledge and innovation, i.e. the application of new knowledge in the production process. This article presents the essence and sources of innovation processes in the company. Five generations of innovation models have been characterised. The analysis of the qualitative aspect of the inclusion of innovations in the selected competition of sub-measures from the source of financing the innovative economy and the European Union was carried out.

Keywords: Innovation, Process, Enterprise, Competition, Quality, System

Introduction

Technical and organisational knowledge of the manufacturing methods is indicated in the literature and technical documentation. It can be said that technical knowledge is included in practical skills and qualifications which are the result of gaining specific professional experience. Technical progress, as a fundamental factor in the growth of production, is made by inventions, i.e. the discovery of new knowledge and innovation, i.e. the application of new knowledge in the production process.

The essence and sources of innovation processes in an enterprise indicate the characteristics of innovation models. Here, the analysis was carried out in the qualitative aspect of the inclusion of innovations in a selected competition of sub-measures from the source of financing the innovative economy and the European Union.

The Essence and Sources of Innovation Processes in An Enterprise

There are many definitions of the term referring to innovation in the literature. It is worth mentioning that they are synonymous with new ways of satisfying specific needs, which can be applied to all aspects of human activity J.A. Schumpeter was one of the first to define the role of innovation in the economy and defined it as the introduction of a new product, the introduction of a new or

significantly modernised production method, the opening of a new outlet or the entry of a new type of organisation (Schumpeter, 2000, pp. 51-75).

The authors of this study indicate that innovation in a company is therefore associated with the introduction of innovations in production or organization. Schumpeter's approach corresponds to a static approach to innovation. This means that then the result of innovative processes undertaken in the company may be a new product, a new production method, a new market or a new type of organisation. The process understanding of innovation is much broader and includes not only the result, but the whole of the activities preceding its creation. In this case, we are talking about an innovation process that includes idea creation, R&D, design, implementation and dissemination. This process is a sequence of time-based activities necessary to make a specific innovative concept come true and turn it into a new state of affairs. The innovation process is closed from the first concept to the first implementation. In this sense, the innovation process means material and immaterial changes of elements in an enterprise. The basic event in such a process is the implementation of a new product or solution in practice (Lazzarotti, Dalfovo, Hoffmann, 2011, pp. 121-135).

However, it should be stressed that each innovation process has its own specific features, depending on the size of the company or the type of activity, where each case requires an individual research approach. In the process of innovation, it is fundamental to identify the sources of innovation. P.F. Drucker considers the most important sources of innovation to be: unexpected events, incompatibility between reality and imagination, the need to introduce a new process, changes in the structure of industry or market, demography, changes in perceptions, moods and values, new knowledge. The source of innovation can be anything that creates an environment that stimulates change processes. It is important for the company to pay attention to knowledge resources and information from different sources (Drucker, 1996, pp. 1-9).

The primary objective of innovation is to develop the company. The company, striving to achieve this goal, pursues a number of intermediate objectives, which are: adapting the company to changes in the environment, achieving a higher quality of products, increasing competitiveness, modernizing manufacturing processes, increasing efficiency and quality of work, expanding the market of customers, developing marketing activities, increasing the prestige of the company, increasing the overall efficiency and effectiveness of operations, or improving the conditions and safety of specific work (Miciuła, I. 2015). The basic classification of innovations includes product and process innovations in manufacturing and production technologies. Product innovation is any kind of change in a product or service that is an improvement or extension of a new range or service. They involve the use of new technologies, new applications of existing technologies or new knowledge. Process innovations are changes in the production methods used, as well as in the ways in which products or services reach customers. An example of process innovation can also be the change of office procedures for a service. Usually these types of innovation occur simultaneously, as many product innovations could not exist without process innovations. However, process innovation differs from product innovation in that product innovation is more sensitive to market factors (Chesbrough, H. 2004).

In the course of developing the theory of innovation, 5 generations of innovation models have emerged. The characteristics of these models are presented in Table 1.

Table 1: Characteristics of innovation models

Generation	Name	Features
1	technology pus	The increase in innovation depends on the expenditure on B+R
2	market pull	Research directions and innovative processes reflect market needs.
3	coupled model	A link between the needs and technological possibilities, where the intensity of R&D and marketing is balanced.
4	integrated parallel model	Innovations are the result of close cooperation and cooperation with suppliers, leading customers and between teams. Integrated development and emphasis on close links between the research sector and producers.
5	integrated network model	Innovations are the result of integrated parallel development and application of expert systems, simulation modeling, cooperation and other links with edge customers and suppliers in research and marketing.

Source: Jasiński A.H, Technical innovations and marketing activities. Higher School of Enterprise and Management, Warsaw 1998, p. 13-14

The innovation models presented in Table 1 differ in their degree of complexity. The first two are simplest and linear. In these models, the innovation is the result of needs reported by the market or R&D activities. The third model is a juxtaposition of the previous two. The last two models are based on inter-organisational cooperation. The network of connections then facilitates the process of creation and introduction of innovations to the market, naturally assuming certain quality (Smith, K. H. 2005).

Qualitative Inclusion of Innovations in The Sub-Measure Competition 1.6.3

The owners of individual business entities could learn about the financial perspective of the European Union for the years 2014-2020 for entrepreneurs, current possibilities of obtaining support for the development of business activity in the form of grants and preferentially interest-bearing repayable instruments, regional and national EU programmes offering support for entrepreneurship. The meeting was organized by the Main Information Point of European Funds in specific cities throughout Poland (Pavitt, K. 2005).

The competitions implemented by information projects, the European Union and other entities aim to improve the quality of innovation processes, including management aspects.

Innovative solution, i.e. it is a product, process, marketing or organization which can be a result of the company's own research and development activity, cooperation with other companies and institutions and can be a result of purchase of knowledge in an intangible form, i.e. patents, licences, software, know-how, services of technical, marketing, organizational, training, etc. or material character, i.e. machines and devices with increased parameters (Smith, K. H., 2005). Figure 1. below presents data concerning the ROP sub-measures 1.6.2.

Fig.1: What is the sub-measure competition about RPO 1.6.2.

Source: research presentation and diversification of the offer created by the Main Information Point of European Funds in Bydgoszcz by Marcin Kościelna. Internet (1/6/2 INNOVATIONS) access (01.12.2019. Slide 4 Polish version, different colors have been adopted.

The competition of the above sub-measure indicates legal protection in terms of a patent, utility model, idea and R&D works and implementation in industry.

The concept of INNOVATION is best reflected in the definitions contained in the *Proposed Guidelines for Collecting and Interpreting Technological Innovation Data* - Oslo Manual*, which* distinguishes product, process, marketing, organisational and eco-innovation (Sundbo, J. 1998).

Calculation data indicate that at least one technological innovation is usually mandatory and innovations should be optional and sometimes additionally scored (Smith, K. H. 2005).

A product innovation is the implementation of a product or service that is new or substantially improved in terms of its functional characteristics or the intended use. This includes, in particular, improvements to the technical characteristics, components and materials used and the software that is an integral part of the product, as well as improvements to facilitate user use. This is basically user-friendly.
Improvements may include technical characteristics, components, materials, embedded software, more user-friendly operation and other functional features (Goffin, Keith, and Rick Mitchell. 2010).

The Scale of Process Innovation

A process innovation is the implementation of a new or significantly improved production or logistics method. This includes in particular significant changes in the techniques, equipment and software used. Process innovations are introduced by companies with a view to reducing unit production costs, increasing quality and implementing the production of new or significantly improved products (Verspagen, B. 2005).

Process innovations also include new or significantly improved methods of creating and providing services (Miciuła, I. 2018). This may involve substantial changes to the equipment and software used in service companies and changes in procedures and techniques used to provide services.

Marketing innovation - it means the implementation of a new marketing method that includes significant changes in the scope:

- design and packaging;
- promotion and advertising of products and services;
- methods (strategies) for pricing products and services.
A marketing innovation can relate to both new and old, already implemented products of a company (Chesbrough, H., Vanhaverbeke, W., & West, J. 2006).

Organizational innovation - this is the implementation of a new organizational method in terms of business practices, workplace organization or relations with the external environment (Smith, K. H. 2005).

The aim of its implementation is to increase a firm's performance by reducing administrative and/or transaction costs, improving employee satisfaction with the way the workplace is organised and consequently increasing its efficiency, gaining access to assets not subject to sale, such as uncodified external knowledge, and reducing the cost of supply delivery (Miles, I. 1995).

This is one of the most frequent so-called borderline cases, i.e. cases where a change introduced by an enterprise contains features of more than one type of innovation (Sundbo, J. 1998).

Breakthrough innovation - called radical innovation refers to the effects of innovation and not to the novelty aspect. It may result, among other things, in a change in the structure of the market, the creation of new markets or a situation where existing products become obsolete. Innovations that change the course of development are very risky, as the information needed for new investments is often lacking (Nelson, Richard, R. 1993).

A breakthrough innovation is obligatory in several R&D competitions for entrepreneurs, e.g. *POIR 4.1.4 Application projects* (Mahayan, V. 2010).

Eco-innovation - are innovations that directly or indirectly contribute to the reduction of various environmental burdens. They may manifest themselves, e.g. by reducing the negative impact on the environment, increasing the resistance to environmental stress or achieving a more efficient and responsible use of natural resources (Bruns, T., & Stalker, G. M. 1961).
An example of eco-innovation is the 4R principle:

Fig. 2: Example of eco-innovation principle 4R

Source: Own study

Fig. 3: Redearch comprtitions od contests for the diversification on the offer

Source: Own study

Example of RPO application documentation

In the ROP 1.6.2 application documentation, the issues of innovation should be addressed in points:
a) application for funding:

C.3 Compliance of the project with the objective of the measure/sub-measure of the ROP JPC for 2014-2020

The compliance of the project with the objective of the measure/submeasure indicated in the MPC ROP for 2014-2020 should be demonstrated.

-> Increased use of innovation in SMEs
(b) Business Plan:

B.2 Compatibility of the project with the types of projects supported under the competition*
B.3 Project innovation, including eco-innovation

C.1.1 - Support for implementation of objectives specified for Sub-measure 1.6.2, including project innovativeness

Has the applicant submitted an analysis of innovation confirming
that the undertaking which it intends to implement fits into the definition of innovation, at least on a regional scale, applied for less than 3 years?

-> it is not necessary to reattach the same documents that were
submitted with the preselection application

How do "Project Selection Criteria" score innovation, in the relevant application
for dof.?

C.1.2 - Implementation of R&D results

- The subject of the implementation has been developed by the applicant itself
and activities on legal protection are conducted - 15 points;
- The subject of implementation was developed by the applicant himself, but was not applied for in
the Patent Office - 10 points;
- The subject of the implementation was developed at the request of the applicant -5 pt.
How do "Project Selection Criteria" score innovation, in the relevant application
for dof.?

C.2.3 - Promoting eco-innovation

Does the applicant assume, within the framework of the planned project, the implementation of eco-innovation, including modern solutions enabling the reduction of operating costs through the reduction of energy consumption or more effective - 0/3 point.

How do "Project Selection Criteria" score innovation, in the relevant application
for dof.?

C.2.4 - Level of project innovation

Whether the project includes innovative product or process solutions:
- nationwide (applicable less than 3 years) - 5 points.
- worldwide (used less than 3 years) - 7 points.
No points will be allocated for non-technological innovation

How do "Project Selection Criteria" score innovation, in the relevant application
for dof.?

C.2.9 - Sustainable innovation links

It shall be assessed whether the applicant has established or maintained a relationship with the scientific body within the last 3 years:
- carried out the R&D project together with the scientific unit;
- has taken on an internship or hired highly qualified personnel.

The applicant should identify and justify the type/type of innovation and its scale.
The criteria suggest necessity:

(a) validation of innovative solutions by means of, inter alia

- of the opinion on innovation;
- an inventory of basiss/data sources on the basis of which the degree of innovative solutions applied in the project was determined (with indication of the source).
-> the basis for the statement of innovativeness cannot be based only on general advertising and writing texts. Links to unknown sites, articles from newspapers, non-technical magazines, etc.) also seem unreliable.

(b) justification of innovation by means of, inter alia
- information on which elements of the project are innovative and which are complementary;

- an analysis of what the innovation is about;
- comparison of the new offer with similar products on the market.

The applicant should identify and justify the type/type of innovation and its scale.
Is there an opinion about innovation?
It is an independent expert opinion on a given technology that the entrepreneur wants to implement in his company. Such an opinion, as required by the Ministry of Development, is proof of the application of process or product innovation in the planned investment.

The applicant should identify and justify the type/type of innovation and its scale.
Is there an opinion about innovation?

The opinion prepared includes, among others:

- the characteristics of the technology to be implemented by the company;
- determines the time it is applied in the region, in Poland
or in the world;
- declaration of impartiality and confidentiality.
The applicant should identify and justify the type/type of innovation and its scale.
Who "should" give an opinion on innovation?
- scientific unit within the meaning of Article 2, point 9, excluding letter g of the Act of 8 October 2004 on the principles of financing science (Journal of Laws of 2008 No. 169, item 1049), i.e.:
scientific unit - conducting continuous scientific research or development work, such as:
a) basic organisational units of higher education institutions within the meaning of their statutes,
(b) scientific institutions of the Polish Academy of Sciences,
(c) research and development units,
(d) international scientific institutes established under separate regulations,
(e) organisational units having the status of research and development unit,
(f) the Polish Academy of Arts and Sciences,
The applicant should identify and justify the type and type of innovation and its scale.
Who should give an opinion on innovation?
...or
- research and development centre within the meaning of the Act of 29 July 2005 on certain forms of support for innovative activity (Journal of Laws No. 179, item 1484);

- a nationwide scientific and technical association or an industrial chamber of commerce whose scope of activity is related to the investment subject to the application, which are not related to the applicant.

Conclusions

The sources and the essence of innovation make it possible to clearly outline information about the direct application of certain activities aimed at creating something new - in fact, something that will be considered new.

Many factors need to be taken into account and observed.

Innovation models have different degrees of complexity, which has a positive impact on their scope of operation. Innovation is the result of needs reported by the market or R&D activities. The models are also based on inter-organisational cooperation. In principle, the network facilitates the process of creating and introducing innovations to the market with the assumption of a certain quality, which is the basis in this particular example of operation.

In the financial perspective of the European Union for entrepreneurs, the current possibilities of obtaining support for the development of business activity in the form of grants and preferentially

interest-bearing repayable instruments, regional and national EU programmes offering support for the entrepreneurship of individual business entities.

The competitions implemented by information projects, the European Union and other entities aim to improve the quality of innovation processes, including management aspects.

Abstract

The considerations contained in the article concern project management issues with particular emphasis on the functions of the control process. The aim of the article is to diagnose control in EU project management, systematize theories constituting the genesis of control as a management function, and to synthesize the concept of control in project management. The research hypothesis is: control procedures are the factor that determines the efficiency of project management by establishing rules of operation and the implementation of corrective actions. The research method used in the research was the analysis of existing data, the so-called desk-research.

Keywords: Management, Control, EU Projects.

JEL Classification: A13, E21, G18, H23, H71, J11.

Introduction

The term control is a term that has its origin in the French and British traditions. It is derived from the words contra, meaning 'against', and roles, meaning 'role'. Initially, the name explained the activities that consisted of verification and assessment of the correctness of legal acts. Over time, both the concept and scope of control have been used more broadly and deeply.

The concept of control in the literature has many meanings and definitions, which are characterized by quite a wide variety (Gołębiewski, 2001, p. 97). It should be emphasized that the control concerns many organized forms of human activity, regardless of whether their organizer is an entity located in the structures of public administration, an economic entity or a citizen who is a private person (Kirsch, 1996, pp. 1-21)

In management sciences, controlling is one of the key management processes in an organization, in addition to planning, organizing and managing (Hejduk, 2016, pp. 33-34). Control, which is a management function, consists of checking and correcting the organization's activities to ensure that the tasks undertaken are carried out and plans are developed so that these tasks are carried out correctly. In the simplified version of the management cycle, control is its final stage. It should also be noted that control is increasingly becoming an indispensable source of information in the processes of making the right decisions at individual management stages (Bisbe, Otley, 2006, p. 710).

As a function, it closes the management cycle, while as a process it permeates and binds together all management functions (Abdel-Kader, Luther,2006, p.230). An audit is necessary to verify that the development of the organization is proceeding in a set direction, whether the organization achieves its intended goals, undertaking realistic tasks. It also allows the identification and verification of any adverse trends and changes in the organization's activities, providing the knowledge necessary for day-to-day management of the organization.

The paper deals with control, audit and controlling. Those terms are very important and similar, not identic. In the literature on the subject a control is always comparison between actual situation (as it is) and plan or internal standards or should be.

Audit compares actual situation (as it is) with widely (international) accepted standards, norms, rules (as accounting standards, auditing standards).

Controlling is more than control, it is management support system and it includes minimum of goals settings, planning, control and reporting.

The article was prepared on the basis of literature studies in the field of management, organization, planning and control of EU projects, national and European documents in this subject area. The aim of the presented work is to diagnose control in EU project management, systematize the theories constituting the genesis of control as a management function, and to synthesize the concept of control in project management.

Literature Review

The concept of control in the literature has many meanings and definitions, which are characterized by quite a wide variety (Gołębiewski, 2001, p. 97). K. Winiarska writes that "along with the formation of statehood, there was a need to exercise control over the state (Plato 427-347 B.C.) about politics (Aristotle 384-322 B.C.). The necessity of control was also noticed by the rulers citing censors or auditors, knowing that the authorities' attributes are control activities. Every power administrator must have an executive apparatus to check that his decisions are correctly made. It was realized that without control over the execution of orders, power became ineffective over time. Trusted subordinates informed the rulers about threats to sustainability and security" (Winiarska, 2010, p. 16).

Control is a process characteristic of each area of human life. It usually means comparing the actual state with the required state and determining possible deviations; checking whether something complies with applicable regulations, but also the person or institution performing the control (Morris, Jamieson, 2005, p. 5).

When analyzing the views of authors dealing with this issue, one should recall the extensive literature on the very definition of the concept of control in management. Control is a process that makes it possible to ensure compliance of real operations with those previously planned. Proper, it is extremely important and necessary for efficient operation (Snell, 199, pp. 292-327). Generally speaking, the control consists in comparing the actual state with the planned standard and it should answer the question: where are the deviations and what are their nature (Kirsch, 1996, pp. 1-21). In contrast, P. Szczepankowski claims that control is a comparison of information about what actually occurs during the implementation of the plan with estimates, budgets, programs, as well as patterns that were developed during the planning process (Szczepanowski, 2000, p. 200). Table 1 presents selected control definitions that relate to management sciences.

Table 1: Selected control definitions

AUTHOR	DEFINITION OF CONTROL
M. Ward	it consists of constantly checking to what extent the plan corresponds to reality and immediately neutralizing adversity; goal plan is usually divided into small segments, making it easier to control
J. Penc	is the function that closes the complete management process and determines the effectiveness of the organization
T. Grzeszczyk	is a routine verification operation carried out at random and irregularly to determine the actual state of the project, compare it with the intentions and plans, detect the cause of the non-compliance of the actual state with the required state, and indicate the way to repair the resulting irregularities
R. W. Griffin	is the regulation of the organization's activities. helping the organization achieve its goals more easily and making it easier to manage
K. Adamiecki	it is checking if the performance is in line with the plan, i.e. the pattern
J. Zieleniewski	is a comparison of implementations with an appropriate pattern

Generally speaking, control is a process of assessment, comparison of the actual state with the state that is required, i.e. with the pattern. Standards are norms that regulate specific activities, i.e. legal, financial, organizational, technical norms, but also limits, plans, board decisions and all determinants that are the benchmark when assessing specific phenomena, such as planned data or data means of the period taken for analysis (Osmanagić BN, Lalovac B, 2007). In the absence of such standards, the benchmark in control assessments is the specific experience and results of other entities, similar in nature and type of activity to the entities that were included in the audit. It should be remembered that in general assessments should be measurable (Sveiby, 2017). The audit process consists of the following activities (Boć, 2000, p. 364):

- checking the compliance of the status as it exists in relation to the postulated status,
- determine the scope and causes of non-compliance,,
- forwarding the results of this determination, and sometimes resulting instructions, to the controlled entity and the superior organization.

S. Kałużny notes that "the essence of control always comes down to the act of determining the existing state, comparing it with appropriate models, assessing and formulating post-control conclusions, in other words, it is an action consisting in examining the existing state of affairs, comparing facts with this, what should be and draw conclusions. Thus, the starting point for defining the concept of control - in praxeological terms, in terms of organization and management sciences - are two basic elements of human activity:

- designations - e.g. legal norms, ethical norms, procedures, so-called good practices - indicate what the activity should be like, determine the current status, being models of real activity, are also a criterion for its assessment;
- performance - in contrast to designations, the actual actions of individual persons or teams, which may constitute complete or partial implementation of designations, may also be partly or completely inconsistent with the designations; the purpose of the audit is therefore to compare performances with designations to determine their compliance and to explain the reasons for the differences found between performances and designations "(Kałużny, 2008, p. 21).

The element connecting the above definitions of control is the aspect of checking and comparing the existing state with what is actually required. The ideal of control is self-control aimed at revealing deviations from the standards, even before they arise, or in the shortest possible time, to allow correction of actions taken before they are completed (Miciuła, 2015, p. 314). To sum up, the presented review of the interpretation of the concept of control is probably not exhaustive, because this concept can be considered on many levels and from many perspectives. The purpose of the comparison can be assumed that this concept functions in three aspects of meaning (Martan, 2002, p.11):

- in a general - broad sense - as management, e.g. "such and such government exercises control over the situation in one territory or another",
- in a technical sense - narrower than the previous one - as an examination of facts, e.g. "control of river water level"
- in the organizational and legal sense - the narrowest - as a study of model and real behaviors of people, devices and causes that have been identified in terms of deviations.

Management is to a large extent controlling, i.e. setting standards for given processes and activities and constant supervision over their course (Engwall, 2003), as well as undertaking interventions when the control reveals deviations from the assumed norms (Kirsch, 1996, pp. 1-21). Control which is a management function is definitely also a source of information for the management, used to assess the actions taken by employees employed in the organization and subordinate organizational structures (Morris, Jamieson, 2005, p. 5). However, one cannot ignore the fact that it is only a supplement to the information system, whose key task is, however, to provide the management with full, reliable and accessible information enabling assessment of the current situation in the organization.

It should be clearly stated that there are no significant differences in substance between the audit and control, such as definition, purpose, authority, location, methodology of operation. This applies to both internal and external aspects. All opinions expressing statements about the significant differences between audit and control - sometimes even statements that they are opposite - are unjustified and unauthorized. As the in-depth analysis of these issues has shown, audit and control are two different words that mean one action. All the cited differences relate to secondary and tertiary issues, and therefore irrelevant.

Results of the research and analyses

The Marshal's Office The control, which is a specific type of process, aims at comparing the actual state with the postulated and determining all irregularities and passing the results in the form of conclusions and recommendations to the authorized body (Zysińska, 2007: 226). Control is a routine verification activity, carried out in a fragmented and irregular manner, but aimed at determining the actual state of a given project, comparing it with the intentions and plans, identifying the reason for the incompatibility of the existing state with the state that is required, indicating possible corrective actions, to repair existing irregularities (Meredith, 2002). The audit is usually concise and applies to representative areas, for example expenses incurred. Inspection of a representative research area allows inferences to be made regarding the population of data covered by the study (Rydzewska-Włodarczyk, 2011: 296-305). An important element of an effective project control system is how changes are made. The project is not properly managed if uncontrolled changes occur during its implementation. This situation ultimately introduces chaos, as a result of which the entire project is destabilized (Webb, 2008, p. 124). Stabryła proposed to include the organization of the control system in the following aspects (Stabryła, 2006, p. 122):

- identification of control fields,
- establishment of controlling entities,
- developing procedures with control instruments.

The areas of control are various types of objects and processes subject to examination and assessment. The basic fields include:

- "economic and financial condition of the enterprise,
- human resources management,
- manufacturing technique,
- market and marketing,
- financial policy,
- organization of the project management process "- which is the subject of this study's interest.

As mentioned earlier, the control system requires control entities (figure 1) that exercise this control based on the commercial code, statutes, organizational regulations and instructions. The control system may take an extensive form, and then precise delegation of powers becomes necessary. The system is characterized by (Stabryła, 2006, p. 123):

1) "strict division of tasks and rights among individual entities,
2) instance, treated as a subordinate of controlling entities, established in connection with a specific mode of performing research and evaluation activities,
3) mutual complementarity of control areas "

Fig. 1: Controlling entities in the control system

On the other hand, the procedures and control instruments at individual stages measure parameters, determine the deviations between the actual and planned state, possibly postulated, as well as analyze and evaluate the degree of implementation of projects that were previously assumed (Snell, 1992, pp. 292-327). In addition to the typical control, as part of the control process itself, mention should also be made of controlling, whose primary goal is to make corrections and supervise the business of the enterprise, regardless of the field in which it operates. In this process, coordination, information, planning and control activities are consolidated (Wojtaszek, Miciuła, 2019). If controlling is developed, then controlling task teams are created, which include coordinators, planners and controllers of various specialties (Stabryła, 2006, p. 125). Based on the above, the overarching task of controlling is the concentration of detached control activities into a coherent whole, which distinguishes them from control processes that are often performed by independent units of the

organization and relate to a limited area of its operation (Ostapenko et. al, 2016, p. 106). The basic differences between control and controlling are presented in figure 2.

Fig. 2: Basic differences between control and controlling

In addition, when considering the concept of control in project management, it is worth extending this aspect to the type of control that is exercised in the management of European projects. The legal foundations of the operation of management and control systems for the spending of European funds can be found both in EU and Polish legislation. One of the key Polish documents that regulate the main rules for controlling the spending of EU funds are "National guidelines for the eligibility of expenditure under the Structural Funds and the Cohesion Fund in the 2007-2013 programming period". Regulations relevant from the point of view of project audits are included in the "Guidelines on the audit process as part of the responsibilities of the Operational Program Managing Authority". This document indicates the control procedures implemented by the managing authorities of a specific operational program (European Union, 2012). Considering the concept of control, taking into account EU projects, noteworthy are also such controls as: financial control, on-the-spot check or sample check. Referring to the first of the above, it is constituted by mechanisms and measures that ensure the proper operation of the process of collecting and managing European Union funds (Nowakowska-Grunt, Kabus, 2014, p. 192). It should be noted that this control also includes management control and audit. Financial control is most often carried out with an audit. The controllers' interest is primarily the contribution intended for the project implementation, taking into account the correct spending of public funds and the products and / or effects produced under it (Trocki, 2013, p. 231).

In the case of an audit, its main purpose is "to establish legal and financial regularity in the spending of European Union funds, always in relation to the functioning of a specific institution (e.g. managing, intermediate, implementing or final beneficiary. This audit process it is carried out in a group of projects in a comprehensive, regular and irregular manner, as opposed to control carried out on a random basis and covering only certain areas of the project. Audit can be carried out both during the project implementation and after its completion, i.e. up to 5-10 years after the end of the project implementation period, and the subject of his interest are "products (results), legality and economy in spending the European Union funds by a given institution". The scope of the audit covers the entire project is carried out in the institution, in which project was or is being implemented, and in the center of his interest are products (results), legality and economy in spending European Union funds by a given organization, as mentioned in the Public Finance Act. The unit being audited may be subject to internal control, which is carried out in English by internal audit, which is carried out by the organization's own employees or, which occurs more often, by external auditors. External audit, always based on formalized recommendations and standards. External auditors, i.e. auditors, have the

power to issue certificates that relate to the proper use of European Union funds. The audit is carried out in the following areas (Rydzewska-Włodarczyk, 2011):

- system audit directed towards implemented management and control systems,
- financial audit directed towards the eligibility of expenditure,
- systems and finance audit - an integrated approach that includes examining both previous aspects at the same time.

Another type of control is the so-called on-site control, which focuses on funded operations and management systems, and as the name implies, is performed at the place of project implementation. The decision on undertaking such control is made by the final Beneficiary or managing authority (Zysińska, 2007, p. 226). This control includes, among others, verification of compliance of the project implementation with its assumptions and the project co-financing agreement, in particular taking into account (Nasalski, 2014, p. 110):

- correctness of financial settlements,
- the way final beneficiaries are recruited,
- the way data about project participants are acquired, stored and processed,
- compliance of the data that is provided in the payment application in the part related to physical progress with the documentation regarding project implementation,
- the correctness of awarding public contracts, if they take place in the project,
- correctness of granting public aid,
- the way promotional activities are carried out,
- the way project documentation is kept and archived.

Another type of control is sampling, carried out on a representative group of projects approved for implementation. In the case of projects co-financed from EU funds, the key role is played by inspections carried out by the Managing Authority (MA). They take the form of systemic control and expenditure verification (figure 3).

Fig 3. System control and expenditure verification

The system audit is aimed at assessing the efficiency of the management system as well as the functioning of the specific operational program. The purpose of this check is to check the correctness of the control procedures and activities of the institution in terms of their compliance with the law and intended results. The expenditure review is directed towards checking the correctness of project implementation and takes the form of verification and certification. The verification covers:

- supplies of goods and services that are co-financed under projects,
- compliance of spending with Community and national rules.

Due to the fact that the Polish system has a large number of institutions participating in the implementation of EU programs, expenditure verification is delegated to lower levels of management (Miciuła, 2016). In this regard, it is the managing authority that formulates the conditions for carrying out expenditure verification as well as allocates responsibilities under the management and control system.

In addition to system audits and verification of expenditure under audits of projects co-financed from EU funds, other types of audits take place, namely cross-checks and ad-hoc audits. The main purpose of cross-checking is to eliminate double financing of expenses. Ad-hoc controls are carried out in situations where there is a suspicion of occurrence (Kirsch, 1996, pp. 1-21):

- a key institution that is involved in the implementation system - this refers to system audits,
- serious irregularities in the spending of funds by the Beneficiary - this refers to the verification of expenditure.

Reconciliation of the facts is an extremely important task of the audit procedure. It is equally important to carefully document and evaluate the audited activities. To sum up, control is a routine activity involving familiarizing yourself with the project plan, checking the current stage of project implementation, and then drawing and comparing conclusions from both observations. The main purpose of the control is to block the derailment of the project by constantly supervising its progress. Effective control is the ability to read relevant information about the implementation of the project in specific situations and conditions, and developing a management efficiency methodology will allow identifying areas of change in EU projects in relation to control as one of the management functions.
The delay in the implementation of a task identified during the audit allows the manager to make early decisions about the location of resources in the right areas to make up for lost time (Farme, 2001, p. 150). Control in the project also creates the possibility of supervision over the quality of tasks and the project budget.

Summary

One of the overarching goals of proper management of EU projects is to create mechanisms to control spending that effectively reduces the scale of errors or irregularities. With regard to funds from both EU funds, the highest degree of responsibility, related to project control issues, is attributed to EU Member States, and above all to institutions responsible for implementing programs and initiatives subsidized from EU funds. It is the responsibility of each Member State to develop appropriate project control procedures that will not only allow effective identification of irregularities before making payments from public funds, but will also provide assistance to Beneficiaries in implementing projects. In connection with the above, in order to counteract undesirable actions on the part of beneficiaries, many regulations were introduced in the scope of project control, allowing to minimize the level of fraud and irregularities. The research conducted by the authors of the dissertation shows that the control process is an indispensable element of management and implementation of the rich offer of EU projects. Completed studies, based on theoretical analysis, emphasize in particular the importance of conducting systematic audits of EU projects so that the audit process is efficient and effective, while contributing to the improvement of the position of controlling institutions.

Abstract

Worker retention is one of the challenges faced by firms in any industry. Since the performance of any business unit depends on its employees, the ability to retain qualified labour contributes significantly to the success of the business. This study explores how job satisfaction influences workers' turnover and retention in firms operating in the Information, Communication and Electronic Technologies (ICET) sector. This research is relevant because mobility and the difficulty in retaining employees in the ICET sector is a reality. A descriptive approach was adopted, and data were collected from firms in a technological cluster in Aveiro, Portugal, using a structured survey, sent by email. A total of 100 respondents were included in this study. The results reveal that workers seem to be not very satisfied with the financial rewards, which may have an impact on employee retention and turnover. Moreover, women are generally more satisfied compared to men, in their current jobs.

Keywords: Job Satisfaction, Worker Retention, Employee Turnover, ICET sector.

Introduction

Human resources management would be much easier if everyone were the same. However, each individual is very different due to personal characteristics and their background (the way in which they were brought up). Some people also consider gender, race or disability as factors that affect people's behaviour at workplace, although holding this view readily leads to discrimination. In addition, there will be differences in ability, intelligence and personality (Armstrong and Taylor, 2014; Krabel and Flöther, 2014).

Employee turnover may be defined as the rate at which people leave an organization (Armstrong and Taylor, 2014). Worker turnover has been one of the most widely investigated organizational phenomenon (Hom, Griffeth and Sellaro, 1984). The turnover of a talented employee constitutes the loss of a valued resource and has implications on firm costs such as recruitment, training and general administration that subsequently hinder companies' growth and success (Agyeman and Ponniah, 2014).

Numerous studies addressing the workforce in the field of Information Technology (IT) have looked at intentions to turnover as a result of job satisfaction (Carayon et al., 2006). Job satisfaction may be defined as the attitudes and feelings that people have towards their work (Armstrong and Taylor, 2014).

Some research points out that micro, small and medium-sized enterprises (MSMEs) have been an essential instrument for growth and economic development in developed and developing economies.

However, labour turnover has had a greater impact on the survival of firms on those dimensions (Agyeman and Ponniah, 2014). Notably, employee retention and commitment in Information, Communication and Electronic Technologies (ICET) MSMEs must be a matter of concern for employers because "employee mobility" is very common in this sector (Scholarios *et al.*, 2008).

Various studies (Holbeche, 1998; Anitha, 2014) on the factors that help the retention and motivation of highly qualified workers include providing career development opportunities, challenges and achievements, mentors, self-assessment and realistic feedback.

Technology employees are among the most sought-after professionals in the world, which causes high turnover. The study by Booz (2018) shows that the problem of retaining talent in technology is the high demand of these workers and the increase in remunerations in the sector, because as employers and offers become more competitive and attractive, the main talents would want to seize new opportunities.

This study aims to contribute to understand the perception of workers in the ICET sector regarding the satisfaction they feel in their current jobs and the impact it has on the willingness of quitting their jobs (possibility of turnover). To this end the study explores the answers to the questions: "How satisfied are you with your current job?", "How often do you think about quitting your job?" and "How many jobs have you had in the past 5 years?". In addition, the study is relevant because it identifies the factors that human resources management should improve and give more attention so that they are able to increase the retention of their employees and reduce the turnover of labour in the firms of this sector.

Literature Review

A literature Review was conducted as a preliminary step to support the empirical study aiming to identify variables that have identified in previous studies as being determinants for employee turnover.

Upfront, a set of demographic characteristics are often mentioned, according to the literature review, including gender, age, qualification (Agyeman and Ponniah, 2014), district (Biagi et al., 2018), and type of occupation (SamGnanakkan, 2010). These were mentioned in past research as the ones with stronger impacts on retention and turnover of employees.

Proxy Variables for Job Satisfaction

Satisfaction has been advanced as the major determinant of employees' turnover (Freeman, 1978; Mudor and Tooksoon, 2011) the variables adopted for the purpose of this study were:

Table 1 : Proxy Variables for Job Satisfaction

1. Financial and non-financial rewards	• Compensation (Financial rewards) • Benefits (Financial rewards) • Work-life balance (Non-financial rewards) • Performance management and recognition (Non-financial rewards) • Development and career opportunities (Non-financial rewards)
2. Organizational related variables	• Corporate image • Role of the organization in society
3. Working Conditions	• Work environment • Flexible working • Possibility to combine work with issues related to health • Functional flexibility • Remote working • Equal treatment in the organization

4. Management System	• Management skills to communicate and lead • Performance evaluation system • Supervision support (mentoring)
5. Motivation	• Education and training • Working methods • Internal communication • Challenge • Teamwork
6. Supporting infrastructures	• Pub • Job infrastructure • Canteen

Financial and Non-Financial Rewards

Financial rewards are a job-based pay, which provides pay related to the value of the job, and person-based pay, so it is reward that recognize the individual's contribution. They may also include employee benefits and pensions and financial recognition schemes (Armstrong and Taylor, 2014). Bussin and Brigman (2019) consider compensation and benefits as variables of financial rewards.

Non-financial rewards: focus on the needs people have for different types of recognition, achievement, personal growth and acceptable working conditions. They include the non-financial recognition of achievements, the design of fulfilling jobs, giving people the scope to develop their skills and careers and offering a work environment that provides a high quality of working life and an appropriate relationship between work and private life (work–life balance). Non-financial rewards can be extrinsic, such as praise or recognition, or intrinsic, associated with job challenge and interest and feelings that the work is worthwhile (Armstrong and Taylor, 2014). Bussin and Brigman (2019) account the following variables of non-financial rewards: work-life balance, performance management and recognition and development and career opportunities.

Organizational Related Variables

Corporate image is the immediate mental picture that audiences have of an organization (Gray and Balmer, 1998). Riordan, Gatewood and Bill (1997) found that employee's perceptions of corporate image can positively influence job satisfaction, and negatively influence turnover and turnover intentions through strengthening their identification with the organization.

Role of the organization in society: Wood (1991:695) stated that 'The basic idea of corporate social responsibility is that business and society are interwoven rather than distinct entities; therefore, society has certain expectations for appropriate business behaviour and outcomes.'

Working Conditions

Work environment: Increasing organizational engagement through the work environment means developing a culture that encourages positive attitudes to work, promoting interest and excitement in the jobs people do, reducing stress and recognizing the importance of social interaction (Armstrong and Taylor, 2014). Whilst some workers might be happy to accept a poor working environment in exchange for higher pay, the reality is that this choice is not binary and poor working environments rarely result in higher wage (Taylor et al., 2017).

The work environment comprises the design of jobs, working conditions and the ways in which people are treated at work by their managers and co-workers as well as the work system. Work design is closely associated with organization and job design in that the latter is conducted within the context of the system of work and the work environment (Armstrong and Taylor, 2014).

Flexible working: is a pattern of working practice or working hours that deviates from the standard or normal arrangement. The aim is to provide for greater operational flexibility, improve the use of employees' skills and capacities, increase productivity and reduce employment costs. Flexible working has become increasingly important as a means of enhancing operational effectiveness. Flexible working means reconsidering traditional employment patterns. This could include operational flexibility, multiskilling, the use of subcontracting and outsourcing, or introducing working arrangements such as flexible hours, job sharing and remote working (Armstrong & Taylor, 2014; Carayon et al., 2006).

Possibility to combine work with issues related to health: while having employment is itself vital to people's health and well-being, the quality of people's work is also a major factor in helping people to stay healthy and happy, something which benefits them and serves the wider public interest (Taylor *et al.*, 2017).

Functional flexibility: so that employees can be redeployed quickly and smoothly between activities and tasks. It may require multiskilling – workers who possess and can apply a number of skills, for example, both mechanical and electrical engineering, or multitasking – workers who carry out a number of different tasks in a work team (Armstrong and Taylor, 2014; Van der Heijde *et al.*, 2018).

Remote working: allows employees to work from home or away from their normal workplace on an occasional basis (Armstrong and Taylor, 2014). The study of Fonner and Roloff (2010) provides initial evidence that teleworking the majority of the time allows employees to filter out some of the distracting and stressful aspects of the workplace and in turn experience greater job satisfaction.

Management System

Management skills to communicate and lead: Communication is the process by which information is transmitted from one person to another and it is also the way of relating to other people through ideas, facts and values. Communication is the process that brings people together to share feelings and knowledge, and that includes transactions between them (Chiavenato, 2009). Leadership is the capacity to inspire individuals to give of their best to achieve results and to maintain effective relationships with people and the team (Armstrong & Taylor, 2014).

Performance evaluation system: Performance management processes can be used to define individual goals and responsibilities, offer feedback on performance and provide the basis for developing skills and planning career development. Although the organization can create a performance management system, its effectiveness will depend on the interest and competence of line managers (SamGnanakkan, 2010; Armstrong and Taylor, 2014).

Supervision support (mentoring)**:** Organizations largely function by means of managers and supervisors who exercise leadership in order to get their teams into action and ensure that they achieve the results expected of them (Armstrong and Taylor, 2014; Taylor *et al.*, 2017). Supervisory support is positively related to employee engagement as is involvement in decision making and day-to-day control over tasks and schedules (Hakanen, Bakker and Schaufeli, 2006; Agyeman and Ponniah, 2014).

Motivation

Motivation is enhanced by leadership, which sets the direction, encourages and stimulates achievement and provides support to employees in their efforts to reach goals and improve their performance generally (Armstrong and Taylor, 2014). IT professionals are knowledge workers who may have personal knowledge transformed by the firms into shared social knowledge. The knowledge workers, described by the motivation and capacity to co-create new insights and capability to communicate, coach and facilitate new ideas, are seen as less loyal to their current employers (Korsakienė et al., 2014).

Education and training**:** As stated by Ehrenberg and Smith (2012: 278) human capital theory indicates that: 'The knowledge and skills a worker has – which comes from education and training, including the training that experience brings – generate productive capital'.

Teamwork: The ability to work cooperatively and flexibly with other members of the team with a full understanding of the role to be played as a team member (Armstrong and Taylor, 2014). The work team, especially at the informal level, has great significance for feelings of satisfaction, and the dynamics of such teams have a powerful effect on the behaviour of their members (Armstrong and Taylor, 2014; Hassan, Juhdi and Ali, 2019).

Working methods: A self-managing team enlarges individual jobs to include a wider range of operative skills (multiskilling); decides on methods of work and the planning, scheduling and control of work; distributes tasks itself among its members; and monitors its own performance, taking corrective action when required (Armstrong and Taylor, 2014)**.**

Internal communication: The communications processes used in organizations have a marked effect on how it functions, especially if they take place through the network. E-mails encourage the instant flow of information (and sometimes produce information overload) but may inhibit face-to-face interactions, which are often the best ways of doing things (SamGnanakkan, 2010; Agyeman and Ponniah, 2014; Armstrong and Taylor, 2014).

Challenge: takes place when the scope of jobs is broad, job responsibility is high and there is a high workload. It enhances engagement because it creates potential for accomplishment and personal growth (Calisir, Gumussoy and Iskin, 2011; Armstrong and Taylor, 2014).

Supporting Infrastructures

Job infrastructure: workplace arrangements that equip workers with the proper abilities to do their jobs, provide them with the means to do their jobs, and give them the motivation to do their jobs. These practices must be combined to produce their proper effects (Armstrong and Taylor, 2014; Biagi *et al.*, 2018).

Employee welfare facilities in the organization has impact on the behavior of the employees as well as on the productivity of the organization. The management should provide required good facilities to all employees, as canteen and pub, in such way that employees become satisfied and they work harder and more efficiently and more effectively (Srinivas, 2013).

Methodology and Data

The study builds on data collected from companies in the ICET sector belonging to a technological cluster in the region of Aveiro, Portugal, using a structured questionnaire online and sent by email to 75 executive managers, requesting that they ask employees to fill it. To measure job satisfaction, respondents were asked to classify their degree of satisfaction towards the following aspects in their organization: financial and non-financial rewards, organization, working conditions, management system, motivation and, finally, support infrastructure. The unipolar Likert scale of 5 points was used: 1 - not at all satisfied, 2 - slightly satisfied, 3 - moderately satisfied, 4 - very satisfied and 5 - extremely satisfied. The question "How often do you think about quitting your job" had the scale 1 (never), 2 (rarely), 3 (sometimes), 4 (often) and 5 (always) (Vagias, 2006).

In order to investigate if there is a significant difference in the preferences of ICET sector workers to remain in the organization based on the number of years working for the respective company, two questions in the survey were asked, as Bussin and Brigman (2019): "How long have you been working for this company?" and "How long do you plan to keep working at this company?". To measure turnover in the last 5 years, respondents are asked: "How many jobs did you have before the current one, in the same area? (consider the last 5 years)".

Our research follows Calisir, Gumussoy and Iskin (2011) hypothesis: 'Job satisfaction will negatively influence the intention to leave among Information Technology professionals'. Two questions in the survey will allow it: “How satisfied are you overall with your current job?” and “How often do you think about quitting your current job?”.

The data were analysed trough descriptive statistics, comparisons between groups considering demographic factors of the individuals and a Pearson correlation. Version 26 of the Statistical Package for the Social Sciences (SPSS) IT software was used to meet the necessary requests regarding data analysis.

Descriptive Data Analysis

The 40 managers of ICET companies associated with the Aveiro technological cluster were contacted by email to send the survey to their employees (about 2000 workers from 40 companies). The collected sample consists of 100 workers from companies in the ICET sector, of which 69 are men and 31 are women. Most respondents are between 25 and 44 years old. 92% of respondents live in the district of Aveiro. From the total 58% of workers have 5 years of service or less and 42% have more than 5 years. Most respondents have a degree (68%), 7% are senior technicians (post-secondary education) and 25% have no degree (figure 1).

Figure 1 : Characteristics of the Respondents (N=100)

In our sample there are workers from firms of very different dimensions: 40% of workers work in large companies, 28% work in small companies and with smaller percentages are workers in small and medium-sized companies (19% and 13% respectively). Regarding the age of firms 45% of the workers work in companies over 22 years old, 21% work in companies aged between 7 and 14 years old (Table 3). It should be noted that most of the companies contacted are small size (<50 workers).

Table 2: Classification of companies where employees perform their work

	Labels	%
Size of enterprises	Micro enterprise (< 10 company employees)	19
	Small enterprise (<50 company employees)	28
	Medium enterprise (<250 company employees)	13
	Great enterprise (>250 company employees)	40
Age of enterprises	< 7 years	15
	7 – 14 years	21
	15 – 22 years	19
	> 22 years	45

Results and Discussion

Gender and Job Satisfaction

Overall, respondents reveal that they are more satisfied with non-financial rewards (work-life balance, performance recognition and development and career opportunities) than with financial rewards (remuneration and benefits). There are differences in responses between the two genders: women are more satisfied, on average, with all aspects of financial and non-financial rewards (figure 2).

Figure 2 : Gender and financial and non-financial rewards

On average, respondents are satisfied with the corporate image and the role of the organization in society, however, it is evident in figure 3 that this satisfaction is higher in the female gender.

Figure 3 : Gender and characteristics of the organization

The female gender classifies better all aspects related to working conditions, that is, they are satisfied with remote work (M = 3.88), functional flexibility (M = 3.90), equal treatment in the organization (M = 3.84), work environment (M = 4.23), flexible schedules (M = 4.29) and the possibility of combining work with issues health-related (M = 4.48). Men are not very satisfied with remote work (M = 2.86) (figure 4).

Figure 4 : Gender and working conditions

As exhibited in figure 5, male respondents expressed low satisfaction with the performance evaluation system (M = 2.90) compared to the female (M = 3.27), that is, they are not satisfied with the way they are assessed, being this an aspect that deserves special attention by firms in the future. On average, respondents are satisfied with management's ability to communicate and lead and with the support of supervision.

Figure 5 : Gender and management system

The work team is the aspect recognized by the of ICET workers, with the best degree of satisfaction, contributing to the motivation felt in companies. Men are more satisfied with the challenge of their tasks (M = 3.40) than women (M = 3.34). In figure 6, a great difference between genders is visible in two aspects: Education/Training and working methods, Men seem to be less satisfied than women, therefore, these aspects must be improved in order to increase satisfaction and, therefore, retention on male workers.

Figure 6: Gender and motivation

Finally, women are more satisfied with the support infrastructures, that is, with the job infrastructure (M = 4.10), canteen (M = 4.17) and pub (4.10). These infrastructures are relevant to the well-being of workers (figure 7).

Figure 7: Gender and supporting infrastructures

Qualification and Job Satisfaction

It is visible in figure 8 that non-graduates are more satisfied (M=3,54) with their current job than graduates/post-graduates (M=3,26), higher technicians (M=3,14) and masters/doctorates (M=3,31).

Figure 8 : Job Satisfaction and Qualification of workers

Years of service in the firm and Intention of quitting their job

Figure 9 shows that workers with 3 to 9 years of service in current companies think more often about leaving their jobs than workers with less than 2 years of service (M = 2.07) or with more than 10 years of service (M = 2.10) that rarely think about this.

Figure 9: Years of service in the company and Intention of quitting of the job

Age and Turnover of the employees in the last 5 years

To the question "How many jobs did you have before the current one, in the same area? (consider the last 5 years) "the graph in figure 10 shows that the most mobile group is the one that is over 55 years old (they had, on average, 1.33 jobs in the last 5 years, in the same area) and the less mobile is the one who is less than 25 years old (they had, on average, 0.17 jobs in the last 5 years, in the same area). There is also a growing tendency for mobility to increase with age.

Figure 10 : Age and Turnover in the last 5 years

Significant Correlations

Concerning the appreciation of the current job, two different parameters were evaluated - "Satisfaction with current job" and "How often do you think about quitting your job". A Pearson correlation test was performed to measure the existence of a linear correlation between these two parameters (table 3). Through this correlation, we have the intensity of a linear relationship between two datasets (Pallant, 2007).

There is a significant negative correlation that indicates a moderate correlation between these two variables, that is, if job satisfaction increases, then the intention to quit a company decreases (r = 0.543) which is in accordance with the literature and the sense common.

Table 3 : Correlations between job satisfaction and thinking about quitting your job

Correlations			
		Job satisfaction	Think about quitting your job
Job satisfaction	Pearson Correlation	1	-.543**
	Sig. (2-tailed)		.000
	N	100	100
**. *Correlation is significant at the 0.01 level (2-tailed).*			

Conclusions

The review of the literature identified that Human Resource (HR) practices are the most important and valuable means for employee retention in any organization. The retention factors are strongly associated to different demographic characteristics of gender, age, qualification, and years of service.

The sample of this study showed that both men and women seem to be not very satisfied with the financial rewards: wage and benefits/premiums. In this way, workers may be tempted to take advantage of better paid employment opportunities. Managers must act quickly. On the other hand, respondents are moderately satisfied with the non-financial rewards.

In relation to the satisfaction of other aspects: organization, motivation, working conditions, management system and support infrastructures, the women revealed to be more satisfied that men, except for the challenge variable and men seem to feel challenged in their jobs.

Non-graduates in the sample are more satisfied with their current jobs than graduates. Highly qualified workers tend to be more demanding and managers must find strategies to retain them, improving for example the rewards that have proved low for these individuals. On average, workers with 3 to 9 years of service often think about quitting their jobs.

HR managers struggle to retain their qualified ICET employees due to a general shortage of brilliant candidates. According to the findings of the current study, HR executives and ICET executives must work together to build more supportive organizational climate in order to foster retention and recruitment. Thus, reducing ICET professionals' turnover intentions is very crucial for key employee retention as a strategic human resource management activity.

Limitations and Recommendations for Future Research

This study had the limitation of some employers thinking that the questionnaire would make workers reflect on mobility and turnover and could lead them to a future departure from companies and, therefore, they did not share it with their employees. The request made by email to employers to share the questionnaire link with their workers proved to be an inefficient method. There was a low response rate (5%) on the part of the employees of the member companies of the technological cluster.

Increasing the number of responses is a challenge to make the study results more valid. A method that seems to be more efficient than email is a face-to-face visit to firms and their workers, explaining the aim of the study.

Acknowledgment

We thank Inova-Ria (technological cluster of the Aveiro Region, Portugal) for the provision of an internship that supported the conduction of surveys made to workers of companies in the ICET sector which allowed to carry out this investigation.

Abstract

Currently, Peruvian manufacturing companies have had an increase of 3.7% over the previous year, that is, 16.5% of the national GDP, whereas manufacturing SMEs have been reduced by 8.4% so far this year. Thus, we proposed a logistics enterprise architecture model aimed at reducing the supplier lead time through a multi-criteria decision-making (MCDM) method for supplier selection. This helps to make strategic decisions together with the suppliers and thus provides a better service to the end customer. We validated the model in a real case where we achieved a reduction of 48.8% in the total supplier lead time and an increase of 27.47% in perfect order fulfillment according to the specifications.

Keywords: Logistics, Manufacturing, Suppliers, Delivery Delay

Introduction

Today's business environment is increasingly influenced by international competitors, demanding customers, rapid technological change, and shorter product life cycles. Thus, several companies have decided to focus on their core competencies and outsource to suppliers, such that the supplier's value-added share has increased from 50% to 70% in several industries. However, 7 out of 10 companies choose to carefully evaluate and select their suppliers, which then become strategic suppliers. Additionally, some companies have begun to strategically enhance their suppliers' capabilities and, thereby, their supply base competitiveness through knowledge transfer or buyer involvement (García, 2013) (Gil, 2018) (Concha, 2000).

Purchasing plays an important role in process development and/or improvement in manufacturing companies and, to a lesser extent, in manufacturing organizations. Several authors agree that strategic suppliers enable organizations to work more effectively and efficiently. Suppliers help companies to improve product quality, decrease product development costs, and provide valuable information about their product design. However, poor supplier performance can cause losses in a company; thus, companies must analyze the current understanding of supplier development strategies and buyer–supplier relationship approaches for improvement. Furthermore, there is an increased need for buyers and suppliers to strategically collaborate to build a stronger long-term relationship (Concha, 2000)

(Torres, 2012) (Paul, 2011). Some authors and many case studies on supplier selection have focused on long-term supplier-customer operations.

However, because of the large number of suppliers and limited resources for supplier development, not all suppliers in the supply base can be improved; this generates a problem in supplier selection and development. Thus, we propose a logistics management model that addresses the sales and supplier departments based on supplier selection using a MCDM method. In addition, the 5W2H tool is proposed for the analysis of problems in the luminaire company under study. This method consists of asking seven questions about a problem to determine its root cause. Its name comes from the initials of each English word corresponding to the questions "What," "Why," "When," "Where," "Who," "How," and "How much." It is a comprehensive tool intended to determine all the aspects of a problem to have a broader view thereof and improve our actions.

State of the Art

Supplier Selection

Many of the scientific articles on supplier selection discuss the problems faced by companies; thus, they seek to improve supplier development to achieve more effective communication with suppliers. Furthermore, these suppliers present better potential for establishing a supplier–buyer relationship and aligning with the buyer's development and cordiality efforts in the post-selection stage (Amin, 2015) (Vieri, 2018). However, Fernandez (2011) argue that effective supplier development positively impacts the buyer–supplier relationship, improving long-term cooperation. Finally, the Grey relational analysis method is used to develop a decision-making process that, unlike in other models, needs simple linguistic scales as input for comparison to generate possibility values in numerical figures regarding the organizational decision-making process.

Multi-Criteria Decision-Making Methodology

All the reviewed methods and procedures focus on selecting the best suppliers based on average data and supplier eligibility, using criteria such as preference, value, and efficiency among other measures to rank suppliers and decision-making. Chen (2012) and Chang (2011) include processes such as the analytic hierarchy process, analytic network process, and the Technique for order preference by similarity to ideal solution in their research methods to manage the total logistics costs, which include price, warehousing, and transport cost. The data envelopment analysis model is used to improve and compare supplier performance through a data analysis that describes a multi-attribute theory to establish optimal purchasing strategies for procurement (Kahraman, 2003) (Beikkhakhian, 2015).

To evaluate suppliers with a mixture of historical quantitative data and qualitative judgments, the causal relationship of the suppliers' factors is calculated, without any requirement for large amounts of data. Researchers have implemented these methods in industrial engineering, particularly in SCM, for decision-making in supplier selection (Junior, 2014) (Junior, 2017).

Contribution

Proposed Model

The proposed model contributes through the implementation of the 5W2H methodology to the analysis and management of logistics area planning. Likewise, a MCDM method called weighted point rating system will be applied for supplier selection, contributing to the novelty of this model. As shown in Figure 1, the model consists of three components, namely, the problem diagnosis (through the 5W2H method), the improvement proposal, and the MCDM method. Each of them is briefly explained below:

5W2H: This component results from the analysis of the company's current state where the problem is identified through seven dimensions: what, why, when, where, who, how, and how much. This information is based on processes, policies, and supplier relationship management, among other components.

Improvement proposal: In this stage, the purchasing area is restructured; policies, structure, and roles are implemented; and a multifunctional management is proposed. This must be approached based on the three fundamental pillars that will be seen later.

MCDM method: This method explicitly evaluates multiple conflicting criteria in decision-making such as cost or price, which is usually one of the main criteria. At this stage, the MCDM weighted point rating system is carried out.

Fig. 1: Suppliers selection proposed model

Proposed Method

Figure 2 shows the implementation steps of the 5W2H method, the improvement proposal, and the MCDM method.

Fig. 2: 5W2H applied to the problem

Indicators

The indicators used before and after the implementation of the methodology are shown and explained below:

Delayed deliveries (Dd): Refers to the percentage of orders with late delivery over the total number of orders sent to the selected suppliers. It is calculated as follows.

$$Dd = \frac{Number\ of\ delayed\ orders}{Total\ number\ of\ orders} \times 100 \quad (1)$$

If the volume of losses found is less than 10%, it is an optimal result; 10% to 20% is a matter of concern; and more than 20% is a critical stage.

Perfect order (Pf): This indicator refers to the percentage of orders that meet all the specifications stipulated in the purchase order.

$$Pf = \frac{Toyota\ perfect\ orders\ delivered}{Total\ number\ of\ oarers} \times 100 \quad (2)$$

If the number of orders that meet specifications is greater than 95%, it is an optimal result; 70% to 95% is a matter of concern; and less than 70% is a critical stage.

Lead time (Lt): Refers to the percentage of orders with late delivery over the total number of orders sent to the selected suppliers. It is calculated as follows.

$$IRA = delivery\ due\ date - request\ date \quad (3)$$

If the number of calendar days is less than five, it is an optimal result; five to ten days is a matter of concern; and more than ten days is a critical stage.

Validation

Case Study

The supplier selection method was implemented in the Peruvian company ABC, part of the luminaire manufacturing sector. This company is dedicated to the design, manufacture, commercial management, technical advice, and after-sales service of lighting systems. However, to manufacture the products, it needs suppliers of parts for assembly or different key products. Most of its suppliers are from the Asian continent; thus, export is a key process in its logistics.

Current State

The main problems faced by the company ABC are supplier lead time delays, the lack of planning by the company's purchasing department, and the reduced supplier portfolio. Thus, they often fail to comply with commercial agreements such as order specifications, payments, and shipping time. Because of these problems, the company has experienced a significant reduction in its sales and loss of market share. Table 2 shows the initial indicator values during August 2019, which is compared to that of the case study.

Table 1: Initial Diagnosis

Indicator	Initial result
Delayed orders	57%
Perfect order fulfillment	68%
Lead time	90 days

Application of the model in case study

Phase 1: Analysis of the current state: The company's manager was made to understand that to solve the latent problem of delivery delays on the part of suppliers, a plan using the 5W2H tool must be set up. First, a meeting with the logistics area team took place, where some relevant data for implementation, validation, and control was provided. Then, the 5W2H method and the tools were developed, and we proceeded with the first part of the improvement.

Problem analysis: Problem analysis using the 5W2H method.

Fig. 3: 5W2H applied to the problem

5W2H: We studied supplier lead time delays using the 5W2H method by which all perspectives can be analyzed to find the root cause and to address it. Graph 5 shows that this problem begins when the sales area requests for orders and the purchase area notifies that there is no stock because of late delivery; thus, it turns out that the situation is due to the lack of suppliers

Phase 2: Implementation of the improvement proposal:
Three-pillar model: All regulations explained previously in phase 2 should be aligned to the three-pillar model.

Purchasing policy: Although these new policies are designed to improve the purchasing area, they must be aligned and must work in conjunction with the general organizational policies.

Restructuring processes in the purchasing area: The recommended purchasing process specifically focuses on the time of sending the order to the suppliers abroad and ends when the product is in ABC Company's offices.

Roles and responsibilities: We redefine the roles and responsibilities of the area's personnel to optimize work and avoid task repetition

Logistics area structure:. We build a solid structure for the area so that having established roles, there is an order and knowledge of who to report to and who to supervise

Phase 3: MCDM method: The steps of the MCDM method were as follows:

Kraljic matrix was proposed to inform the suppliers about the products that would be assessed (strategic products).

The supplier portfolio was defined through internal company information and a search for catalogs was brought in from the company's trade fairs.

The abovementioned suppliers were evaluated, taking into account the criteria and weights that our model suggests. Table 8 shows supplier evaluation.

We selected the suppliers that were in the range of 3–4 points.

Initial and post-implementation indicators

Below, we present variations in the indicators' values after the implementation of the supplier selection method through the MCDM in the luminaire company ABC SAC during August 2019.

Table 2: Kraljic Matrix Applied to the Case Study

Leveraged Items	***Strategic Items***
Classic lightbulbs	Luminaire lamp parts
Non-critical Items	***Bottleneck Items***
Office supplies	90 days

Table 3: Results Obtained from MCDM Method Applied to Suppliers

Luminaire supplier									
Criteria	***Weight***	***Supplier 1 VANMOLD***		***Supplier 2: ALDER***		***Supplier 3: VENEZINA***		***Supplier 4: MINHOU***	
		Score	***Total***	***Score***	***Total***	***Score***	***Total***	***Score***	***Total***
Price	20%	3	0.60	3	0.60	1	0.20	2	0.40
Quality	15%	4	0.60	4	0.60	3	0.45	3	0.45
Leat time	20%	3	0.60	4	0.80	3	0.60	3	0.60
Terms & conditions	15%	3	0.45	4	0.60	2	0.30	2	0.30
Supply capacity	15%	3	0.45	4	0.60	2	0.30	2	0.30
Flexibility	15%	3	0.45	4	0.60	2	0.30	2	0.30
Total	100%	19	3.15	23	3.8	13	2.15	14	2.35

Table 4: Initial Indicators vs After implementation Results

Indicators	**July 2019**	**September 2019**
Delayed deliveries (%)	57.00%	12.06%
Perfect order fulfillment (%)	68.00%	95.47%
Lead time (days)	90	46.00

As can be seen, the indicators have improved significantly. The volume of delayed deliveries decreased by 44.94%, the perfect order fulfillment increased by more than 27%, and the lead time was greatly reduced.

Conclusions

This study has led to the improvement of supplier performance in terms of the main variable: time. We identified the following conclusions.

Delayed deliveries were reduced by about 44.94%, while the lead time was reduced by more than 50% because of the correct implementation of supplier evaluation using the MCDM method.

This model contributes to the restructuring of the purchasing area to later implement supplier selection. This improvement proposal can be adapted to any company that has problems in this area.

The alternative of the MCDM method in supplier selection can be applied in any type of company because of its simplicity and flexibility; it guarantees sustainable competitive advantages over time.

Paradoxes of Degressively Proportional Allocations

janusz.lyko@ue.wroc.pl

Abstract

The crucial problem in the theory of integer proportional divisions is how to find the allocation that is both a sequence of integers and also the best approximation of the sequence of quotas of such division, i.e. a not necessarily integer sequence determined by the exact proportions. It turns out that very intuitive and natural solutions in this area lead to quite unexpected properties called paradoxes. The best-known and widely researched in the literature are the population paradox, the Alabama paradox and the new state paradox. It was proved that there is no repeatable algorithmic way to solve this problem and free from all defects. One of the streams of theoretical analysis of degressively proportional divisions relates to the methods applied in proportional allocation. As a result, one can consider the problem of existence of similar paradoxes in this case. The paper demonstrates that there exist the circumstances when any degressively proportional integer approximation leads to the occurrence of all basic paradoxes.

Keywords: Degressive Proportionality, Paradoxes of Fair Division

Introduction

The best known and most widely spread rule of allocating gains and burdens is the principle of proportional allocation stemming from Aristotle. According to this rule, all agents participating in division are either allocated some amount or a number of goods or charged with burdens proportionally to the quotient of their values to the total value of all agents. The value of one agent can be explained in a number of ways. For example, when dividing profits of companies it is the number of shares held by an agent, when assigning investment costs it is a degree to which individual investors benefit from investment, and when determining the parliamentary representation it is the population of a given election district. The problem tackles both the division of gains and burdens, but for the sake of clarity in the remainder we shall deal with the division of goods.

Formally speaking, the division $a=(a_1,a_2,...,a_n)$ of total amount $A=a_1+a_2+...+a_n$ of goods among n agents whose values are represented by the sequence $v=(v_1,v_2,...,v_n)$ is consistent with the principle of proportionality if and only if $a_i=A\cdot(v_i/V)$, where $V=v_1+v_2+...+v_n$. In a special case, when the sequence v is constant, applying the principle of proportionality results in a equal division, i.e. one with $a_1=a_2=...=a_n=A/n$.

Proportional allocation is a perfect solution of the task of goods division in the case of insignificant differences in values of the sequence v. Otherwise, its application results in the marginalization of roles played by the agents with the smallest values. This is especially noticeable when divisions are integer. It can happen specifically that the value of the quotient $a_i=A\cdot(v_i/V)$ is so small, that when integer representation is elected, the respective agent will not be allocated the divided good at all. In

many cases this solution is not viable because of other significant reasons. For example, the investment should be accomplished with the contribution of all agents or else common interest if not solidarity of all agents do not allow to exclude anyone.

In such circumstances one can attempt another solution of the allocation problem, i.e. the principle of degressive proportionality. This principle was put forward as a rule of apportionment of the seats in the European Parliament. The reason of this decision was a significant dissimilarity of populations in member states, particularly in Malta and in Germany, i.e. the least and the most populated countries in the European Union. If the sequence of populations in all countries in the community were assumed as the sequence of values v , Malta would have practically no representation in the assembly. Its calculated share is smaller than one, therefore it is allocated just one seat in the European Parliament. Aiming at the suitable position of every state in the European Union the Lisbon Treaty decided to abandon the classic rule of Aristotle with respect to degressive proportionality.

Degressively proportional allocation is a solution that reduces the right of agents with greater values to possess the goods to the benefit of agents with smaller values. The reduction is obviously in comparison with the allocations generated by the exact proportions of agents' values to the total of all values, i.e. by the quotients v_i/V . More precisely, a nondecreasing sequence $a=(a_1,a_2,...,a_n)$ is a degressively proportional allocation with respect to a nondecreasing sequence of values $v=(v_1,v_2,...,v_n)$, if and only if

$$(1) \quad \frac{a_i}{v_i} \geq \frac{a_{i+1}}{v_{i+1}} .$$

Therefore, the degressive proportionality can be interpreted as a transfer of entitlements to obtain goods expressed by the sequence v from entities with greater values to those with smaller values. The boundary of such operation is the complete equalization of entitlements and consequently, reaching the equal division.

Hence, the principle of degressively proportional division can be satisfied by many sequences a and this is the significant difference from the principle of proportional allocation. In this regard, one seeks additional conditions so as to be able to select one particular solution in practical applications. Furthermore, one also often introduces the so-called boundary conditions which define minimal and maximal values of the sequence a (Dniestrzański, Łyko, 2014a, Łyko, 2013). The boundary conditions significantly reduce the set of all possible solutions, but do not remove ambiguity of solutions.

The problem of degressively proportional integer allocation is central in the context of apportioning the seats in the European Parliament, i.e. all the terms in the sequence a are integers. Two major research streams emerged in the theoretical analysis of the problem. First, the principle is approached literally, i.e. the inequality (1) must be satisfied by the terms of the sequence a (Dniestrzański, Łyko, 2014b, Łyko, Rudek, 2013). This approach is called RDP (rounded degressive proportionality). The methods applied here include numerical methods, combinatorics and relations theory. A general idea of these methods involves finding a solution that is optimal with respect to a given additional criterion. The criterion can be specified by conditions of the order type (Cegiełka et al, 2017) or metric type (Cegiełka, Łyko, 2014). The second stream deals with the condition of degressive proportionality in its weaker variant. The inequality (1) must be satisfied before finding the integer representation. This approach is called UDP (unrounded degressive proportionality).Thus, a sequence of real numbers is indicated that is degressively proportional with respect to the given sequence of values v, and then its integer representation that does not have to satisfy the condition (1) (Cegiełka et al, 2018). The methods applied here are sourced from the theory of integer proportional divisions where a proportional allocation $a_i = A\cdot(v_i/V)$ that is not necessarily integer is approximated in a specific way by the sequence with integer terms (Cegiełka et al, 2017, Grimmett et al, 2017, Słomczyński, Życzkowski, 2012).
The choice of a specific approximation method is a major difficulty when solving proportional division problems. It turns out that the most natural and intuitive solutions involve some paradoxes.

What is more, one may prove that there is no solution to this problem that would be flawless. The choice of one particular approximation is always a compromise that agrees to some flaws and paradoxes while avoiding others. The paper proves that this problem becomes completely different in the area of degressively proportional divisions. Some examples are shown proving that when selecting an integer representation of a degressively proportional sequence, it is not possible to avoid any of basic paradoxes. Therefore, what is most important for proportional divisions, i.e. finding a concrete allocation with integer terms based on any sequence that satisfies the rule of division, is marginalized and completely insignificant in practice, since there are some cases when, regardless of the method applied, one is not able to avoid all disadvantages resulting from the occurrence of paradoxes.

Formulation of the Problem

Theoretical analyses of integer proportional divisions started in the 18th century. The interest in this problem was motivated by the event of voting for parliamentary representation. Researches were conducted at the same time in the US and in Europe (Young, 1994). In spite of different ways of reaching the conclusions by means of various methods, the inference turned out to be similar. The most important conclusions, unfortunately negative, state that there is no a method indicating, based on a sequence of quotas, an integer allocation free from unexpected and undesired features.

Formally approached, the question was about indicating an integer sequence a, which could be regarded as approximation of the so-called sequence of quotas $q_i = A \cdot (v_i / V)$, i.e. the sequence that expresses the exact proportions of shares in the allocated good. The first and most natural proposal consists in a suitable downward-rounding of the quotas and allocation of obtained numbers of goods to agents in the first step of division. If the total number of goods distributed in this way equals A, the stage concludes the allocation. Otherwise, the next stage is performed, and remaining goods are allocated by one piece to each agent, in the order of decreasing fractional parts of quotas, until the entire pool is depleted. The method is called Hamilton method or the largest remainder method.

When Hamilton method was a legally binding rule adopted to apportion the U.S. House of Representatives, it was discovered that the method is not resistant to the so-called **Alabama paradox**. The Alabama paradox refers to any case when increasing the total number of goods to be allocated, with unchanged entitlements of agents, would decrease one of the shares, compared to the case with smaller pool of available goods. The paradox was called after discovering in 1880 that for a House size of 299, Alabama would receive eight Representatives, but if the House increased to 300, Alabama's delegation would have dropped to seven. The Hamilton method is also vulnerable to the **new states paradox**. It refers to any case when increasing the number of agents entitled to goods may result in increasing the number of goods allocated to one of the old agents, compared to the case before a new agent emerged, given the same total number of goods and the same entitlements of agents.

Vulnerability of Hamilton method to paradoxes was one of the reasons why the so-called divisor methods became more popular; their authors were Jefferson, Webster, Hill, Adams and Dean. All divisor methods put forward by these authors are similarly structured as one-step procedures. Given the number of goods A and the sequence of entitlements $v = (v_1, v_2, ..., v_n)$, one seeks a coefficient a in the function of proportional allocation of the form $f(x) = ax$, with $\sum_{i=1}^{n} [f(v_i)]_r = A$, where $[\ \ ]_r$ is one of the five types of rounding adjusted to a given method. Afterward, each agent i is allocated the number of goods equal to the appropriate rounding of the value of $f(v_i)$ to the integer. The values $f(v_i)$ are called modified quotas. The term "divisor methods" originates from the algorithm that generates the allocation, as put forward by the authors of these concepts. They proposed to find a number d called a divisor and a modified quota of each agent, i.e. the quotient of the entitlements v_i and the divisor d in such a way that, after a suitable rounding of modified quotas, all available amount A of goods is allocated. Divisor methods are free of the Alabama paradox and new states paradox, nevertheless it turned out that they are flawed in such a way that generated

divisions do not satisfy the quota rule. A division is said to **satisfy the quota rule** when no agent is allocated more than its upper quota or less than its lower quota.

A requirement to satisfy the quota rule is quite natural when approximating the exact proportions represented by a sequence of quotas. It turns out however that possibly seeking additional methods of proportional allocation, different than divisor methods, which might satisfy the quota rule, does not solve the problem of paradoxes bias, since all the allocations found on the basis of meeting the quota rule are significantly flawed by vulnerability to the so-called **population paradox**. This paradox occurs when an agent whose entitlement decreased gains an extra good at the cost of an agent whose entitlement increased.

The known methods of integer approximation of quotas characterizing strictly proportional divisions are flawed by paradoxes, so one of the consequences is plenty of solutions to this problem applied in electoral systems worldwide. They reflect an approval of some flaws in favor of avoiding other shortcomings. It turns out that similar problems, to a greater degree, accompany degressively proportional allocations.

Results

Degressive proportionality is exposed to all above-mentioned paradoxes: Alabama, new states and population paradox. Moreover, in this case, in contrast to proportional allocations, there is no choice available, because regardless of possible additional restrictions imposed on the method leading to a degressively proportional allocation, a risk of flaws is unavoidable.

Example 1 (Alabama paradox for degressive proportionality)

If the entitlements of three agents have values $v_1 = 10$, $v_2 = 11$, $v_3 = 40$, then, given the total amount of the good $A = 5$, a single degressively proportional allocation is given by $a_1 = 1$, $a_2 = 1$, $a_3 = 3$. If we now increase the total number of goods by one, there is also just one degressively proportional division, given by values $v_1 = 2$, $v_2 = 2$, $v_3 = 2$. Therefore, increasing the number of goods by one unit decreases the number of goods allocated to agent 3 by one unit. Since in both cases, given $A = 5$ and $A = 6$, the set of all degressively proportional allocations includes one element, thus irrespective of adopted method to generate the allocations, the Alabama paradox is unavoidable. The values of entitlements and allocations generating the Alabama paradox are presented in table 1.

Table 1: Alabama paradox for degressive proportionality

Entitlements v_i	**Division DP for** $A = 5$	**Division DP for** $A = 6$
10	1	2
11	1	2
40	3	2

Source: own elaboration.

Example 2 (New states paradox for degressive proportionality)

Let $A = 10$ be the total amount of goods to be distributed among four agents with entitlements $v_1 = 10$, $v_2 = 30$, $v_3 = 40$, $v_4 = 40$. In that case, a single degressively proportional allocation is given by $a_1 = 1$, $a_2 = 3$, $a_3 = 3$, $a_4 = 3$. If a new agent entitled by $v_5 = 60$ joins the group, then the only degressively proportional allocation will be $a_1 = 2$, $a_2 = 2$, $a_3 = 2$, $a_4 = 2$, $a_5 = 2$. Increasing the number of agents, with the same total number of goods to be allocated, increases the number of goods allocated to the first agent compared to the previous case of four agents. Thus we deal with the new states paradox for degressively proportional allocation. The values of entitlements and allocations generating the new states paradox are presented in table 2.

Table 2: New states paradox for degressive proportionality

Entitlements v_i	Division DP for $A=10$	Entitlements v_i	Division DP for $A=10$
10	1	10	2
30	3	30	2
40	3	40	2
50	3	50	2
		60	2

Source: own elaboration.

Example 3 (Population paradox for degressive proportionality)

A total number $A=11$ of goods is to be allocated among three agents with entitlements $v_1=20$, $p_2=40$, $p_3=50$. A single degressively proportional allocation is $a_1=2$, $a_2=4$, $a_3=5$. If now the entitlements of agents increase and equal $v_1^{'}=15$, $v_2^{'}=70$, $v_3^{'}=80$, then the only degressively proportional allocation will be $a_1^{'}=3$, $a_2^{'}=4$, $a_3^{'}=5$. Agent 3 whose entitlements increased from $v_3=50$ to $v_3^{'}=80$ loses one unit of the good for the benefit of agent 1 whose entitlements decreased from $v_1=20$ to $v_1^{'}=15$. Consequently we deal with the population paradox for degressively proportional allocation. The values of entitlements and divisions generating the population paradox are presented in table 3.

Table 3: Population paradox for degressive proportionality

Entitlements v_i	Division DP for $A=11$	Entitlements $v_i^{'}$	Division DP for $A=11$
10	1	15	2
20	3	70	2
40	3	80	2

Source: own elaboration.

Conclusions

The practical applications of proportional allocation, among other difficulties, involve the choice of integer representation of the sequence of quotas. Natural schemes leading to suitable rounding may generate the mentioned paradoxes. As a consequence, adopting some solution is always a compromise that consists in avoiding some flaws at the cost of tolerating other shortcomings.

The problem looks differently in case of the rule of degressive proportionality. First, there is no uniquely determined equivalent of the sequence of quotas here, and therefore considering the allocations which satisfy the quota rule is not possible. Second, the listed paradoxes may occur independently from the rule that generates the integer representation of any degressively proportional sequence. The presented examples demonstrate such cases when every integer allocation generates all described paradoxes.

The practical consequence follows that a choice of integer approximation of a degressively proportional sequence is actually arbitrary, as every method of its creation is at risk of paradoxes. One might therefore postulate the most natural choice that was proposed as the first one in the area of proportional divisions, consisting in minimization, in standard metrics, of the distance from the sequence of quotas, i.e. the method based on the idea of Hamilton. The Hamilton method, rejected in case of proportional divisions because of the Alabama paradox, is flawed by risk of paradoxes similarly as any other method applied to degressively proportional divisions, but its intuitiveness in terms of metric properties is its remarkable strong point. This point of view is different than for

example in the proposition called Cambridge Compromise. The authors of this idea proposed rounding down as a method of integer approximation. There is no explanation of such choice in literature, so the proposition of applying Hamilton's method is in our opinion better. Our further research will focus on the problem of the importance of particular boundary conditions for the existence of paradoxes. We will try to figure out conditions such that for the set of all feasible degresivelly proportional allocations the paradoxes do not exist.

Problems of Healthcare System in Poland And A Platform for Remote Consultation Between Primary Care Physicians and Specialist Doctors in The Light of a Qualitative Research[1]

Marcin HABERLA

Wroclaw University of Economics and Business, Wroclaw, Poland,
marcin.haberla@ue.wroc.pl

Abstract

The aim of this paper is to present problems of healthcare system in Poland. The subject of the analysis is Polish healthcare system, and in particular the possibility of using remote consultation platform that will improve cooperation/communication between primary care physicians and specialist doctors. Qualitative research methodology was used to acquire the knowledge and determine organizational solutions to improve cooperation and communication between primary care physicians and medical specialists, as well as to improve patient service processes, and public healthcare system.

Keywords: Healthcare, Healthcare System, Cooperation Barriers

Introduction

Primary healthcare (PHC) addresses the majority of a human's health needs throughout their lifetime. This includes physical, mental and social well-being, it is people-centred. PHC is a whole-of-society approach that includes health promotion, disease prevention, treatment, rehabilitation and palliative care. Primary healthcare approach includes three major components: meeting people's health needs, taking care of a broader range of determinants of health through multi-sectoral policies and activities and empowering people to take charge of their own health (World Health Organization 2020). According to World Health Organization (2020) "all people, everywhere, deserve the right care, right in their community. This is the fundamental premise of primary healthcare".

According to Polish regulations "basic healthcare are preventive, diagnostic, therapeutic, rehabilitation and nursing health services in the field of general, family and pediatric medicine, provided as a part of an outpatient healthcare" (Ustawa z dnia 27 sierpnia 2004).

The basic healthcare is a part of the healthcare system, granting access for all people entitled to benefits, residing/staying on the territory of Poland, of comprehensive and coordinated healthcare services at the place of residence. The benefits can be provided both on an outpatient basis (in an office, an outpatient clinic) and in medically justified cases, also at the patient's home (also at a social welfare home). The services also include preventive activities, i.e. child and youth care by a nurse/hygienist in a teaching and education environment (Narodowy Fundusz Zdrowia 2017).

It should also be emphasized that a necessary condition for the functioning of the healthcare system is a fact that: "the public health is the most important component of a national wealth; and a concern for

[1] "The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN".

achieving positive health standards is a responsibility of a state, local governments, NGOs, public and private organizations, as well as every citizen" (Nosko 2005).

In the recent decades, the basic healthcare has started to play an increasingly important role in healthcare systems across Europe (Mackenbach and McKee 2013). The effective primary care system requires a consciously conducted and a well-defined policy, includes a division of roles between individual levels of care, therapeutic and preventive services on the primary care level, coordination of functions in the healthcare system and incentives for the healthcare providers (European Observatory 2016).

The exchange of experience and knowledge between the primary care physician and the specialist in a given field is crucial for the best possible treatment of patients. The primary care physicians often feel uninformed. They think they are not qualified enough to make a diagnosis, change the dosage of a drug or treatment method.

The aim of this research was to characterize pro-quality activities and organizational solutions in the healthcare system facilitating access to inexpensive, durable and high-quality health services in healthcare units. In addition, interviews served to acquire the knowledge and identify organizational solutions to improve cooperation and communication of primary care physicians and specialist doctors.

Research Methodology

According to the American Marketing Association „marketing research is the function that links the consumer, customer, and public to the marketer through information – information used to identify and define marketing opportunities and problems; generate, refine, and evaluate marketing actions; monitor marketing performance; and improve understanding of marketing as a process. Research specifies the information required to address these issues, designs the method for collecting information, manages and implements the data collection process, analyses the results, and communicates the findings and their implications" (American Marketing Association 2018).

Another definition of research comes from UK Market Research Society „…one of the most useful tools in business, any business. It is the way in which organisations find out what their customers or potential customers need, want and care about" (Bredley, 2013, p. 7).

According to G.A. Churchill (2002, p.15) „marketing research is diagnosis of information needs of the company (organization), variable's selection and collection, analysis and interpretation of data used to make marketing decisions."

According to K. Mazurek-Łopacińska (2016), "research includes the diagnosis of information needs of an enterprise (institution), a selection of variables, and a collection, analysis and interpretation of data that are the basis for making decisions".

The main task of this research is to provide information necessary to improve decision-making processes. Three research goals can be identified (Mazurek-Łopacińska 2016):

- obtaining the necessary knowledge about the phenomena and the processes on the market and factors that shape them,
- support for decision-making processes,
- verification of the effectiveness of a decision.

The type of research methodology used, was a qualitative research. An individual in-depth interview (IDI) technique was used, whereby a researcher conducts an individual interview with a respondent, selected because of his/her relation to the subject of the study. In the IDI research, the researcher has the opportunity to ask the respondent about issues that seem particularly valuable for achieving research goals, which further increases the quality and value of the obtained research material. The in-depth

individual interview is more detailed than other data collection techniques, thus increases the value of the study, and is also a solid basis for formulating conclusions and practical recommendations.

Qualitative research is primarily about understanding reality, not measuring it. The results are not generalized to the population, the method of interpretation is more flexible, subjective, but it answers the questions which in the case of quantitative research are not discussed. Qualitative research is aimed at a closer look at the analyzed topics and a description, interpretation and even explanation of some behavior (Gibbs, 2011).

W.G. Zikmund, B.J. Babin (2010, p. 97) claim that "qualitative research can be performed in many ways using many techniques. Orientations to qualitative research are very much influenced by the different fields of study involved in research. These orientations are each associated with a category of qualitative research".

The most popular methods of collecting primary data in qualitative research are individual in-depth interviews and focus group interviews. These methods are most often carried out in the form of a free discussion between the respondent or a group of respondents with the moderator. Without a rigid "sticking" of questions as in the case of a questionnaire, and with the help of a topic guide only, the moderator gradually deepens those areas that are most important from the point of view of the purpose of the research.

Individual in-depth interview (IDI), depending on the level of formalization of the intelligence structure (the freedom to ask questions), can take the form from a free interview to a fully structured interview. However, the most popular used is a semi-structured interview, that is, such in which „the researcher uses the list of problems that should be raised during the interview: a list of questions to be asked, in the form recognized by the researcher as appropriate and in any order (…)This type of interview gives the researcher more flexibility during its execution, and at the same time allows a certain unification of data that is obtained in interviews on the same subject" (Sztumski 1995, p. 121). Questions in the IDI interview are not standardized, and the respondents have full freedom in their answers. During an individual in-depth interview, exploratory research questions, attempts to explain or understand motivation, attitudes or behaviors are undertaken. Its results allow to specify the created service, and at the same time can be used to verify the results obtained in the quantitative study.

An individual in-depth interview is a very useful method in planning services. It is used when there is a need for more in-depth knowledge and information that cannot be obtained with the help of data analysis. The argument for using this tool is the ability to capture essence of the problem, its flexibility and the ability to deepen the received information about the attitudes or motivations of the respondents. However, its disadvantage is subjectivity.

It should also be noted that the in-depth interviews minimize the risk of omitting issues relevant to the study. In addition, the interviews were conducted adequately to the needs and capabilities of the respondents. The research using the IDI technique was performed in medical facilities of primary care physicians and specialist doctors. A total number of 16 interviews were conducted:

- 6 IDI with primary care physicians,
- 10 IDI with specialist doctors.

The final effect of the research was the preparation of conclusions and recommendations on the cooperation of primary care physicians and specialists. The survey was conducted in November/December 2018.

Current diagnosis of the healthcare system and its problems

Nowadays technological innovations influence service delivery advancements. Despite a number of improvements, the processes have just began and patients have just started to experience the changes. The process of the computerization still faces some problems. The medical field currently faces four main challenges: service integration, service quality, Internet connected medical device security and publicly sustainable pharmaceutical pricing. While innovations promise to change healthcare service delivery forever, it will take some time before the advancements reach their full potential.

According to the report issued by the PwC Health Research Institute, patients have an access to innovations available due to recent healthcare reform and technological innovation, resulting in service delivery when and where patients want and need it. The advancements come in a moment when patients need particular information to manage complex and increased caregiving expenses. This process results in rethinking and improving management of retirement funds by many clients. This prudence will likely carry over into other fields connected to healthcare service delivery (Managed Healthcare Executive 2020).

While these changes are significant, they will take place at a moderate pace. Caregiving organizations want some empirical evidence that each innovation will provide returns, and while a unified patient database moves toward fruition, conflict over information rights slows the progress substantially. Finally, legislative wrangling over healthcare delivery policies additionally slows down the advancement in the medical field (Managed Healthcare Executive 2020).

In 2019, during the The HealthCare Executive Group (HCEG) Annual Forum, more than 100 C-suite and director-level executives were asked to pick the top 10 critical challenges, issues, and opportunities they expect to face in the year 2020. The executives were given a list of 25 topics to choose from. The final list included among others the following challenges, issues, and opportunities (Managed Healthcare Executive 2020):

1. Costs and transparency. Implementation of strategies and tactics to address growth of medical and pharmaceutical costs and impacts to access and quality of care.

2. Consumer experience. Understanding, addressing, and assuring that all consumer interactions and outcomes are easy, convenient and timely.

3. Delivery system transformation. Operationalizing and scaling coordination and delivery system transformation of medical and non-medical services via collaborations between healthcare and community-based organizations to overcome barriers.

4. Data and analytics. Leveraging advanced analytics and new sources of disparate, non-standard, unstructured, highly variable data to improve health outcomes, reduce administrative burdens, and support transition from volume to value and facilitate effectiveness.

5. Interoperability/consumer data access. Integrating and improving the exchange of member, payer, patient, data provider, and workflows to bring value of aggregated data and systems on a near real-time and cost-effective basis to all stakeholders equitably.

6. Holistic individual health. Identifying, addressing, and improving the member/patient's overall medical, lifestyle/behavioral, socioeconomic, cultural, financial, educational, geographic, and environmental well-being for a frictionless and connected healthcare experience.

At the beginning of the interview, the respondents were asked to evaluate the current healthcare system and its organization. In their opinion, positive changes in the current healthcare system are certainly the increasing use of technology (electronic medical records, e-prescriptions and e-sick leave) and modern treatments as well as greater access of patients to medicines. In the opinion of one the respondents: "(...)

It is better, first of all when it comes to technology and modern methods of treatment. Than when it comes to patients' access to medicines, to modern methods, to better educated people, to better hospitals (...) ".

On the other hand, the weaknesses are low expenditure on healthcare. According to WHO, this should be 6.8% of GDP. The level of expenditure on healthcare in Poland is one of the lowest in the European Union. Poland occupies one of the last places both in nominal terms and in relation to GDP. According to the data published by Eurostat, Poland is in the tail of the EU rate when it comes to the level of expenditure on healthcare (in all entities of this sector). According to the latest available data, the nominal level of expenditure on this purpose per capita in Poland in 2016 was EUR 731. Among the EU countries, only Bulgaria (EUR 556) and Romania (EUR 432) had lower results. Luxembourg, Sweden and Denmark are at the other extreme with amounts above EUR 5000. Even more is allocated to healthcare in Switzerland and Norway (Banker 2019).

The contact with the patients is also negatively evaluated. There is no continuity of care and the patients are often lost in the current system (concerning data gathering), sometimes the same tests are repeated several times, because the specialist doctors are not aware of the fact that the patient has already had the ordered tests. This may be a result of a lack of referral cards from specialist doctors. There is a poor flow of information between primary care physicians - patients - specialist doctors.

One of the basic problems in the respondents' opinion is the shortage of doctors, medical personnel of all categories/specializations. The organization and pricing of services, contracting are issues that also need to be improved. Another problem of the system is the lack of stabilization of legal system in the area of health protection. There is chaos and misinformation. „(…) A lot of things need improvement. Shortage of doctors and medical staff is the first basic problem. The organization of services, contracting, these are all things that need improvement. Financing new equipment for many entities. What worries the most is the lack of doctors - all of the specializations. There is emigration, but I would not suspect that this causes such shortcomings. These are many years of negligence in the educational system, in the number of trained doctors (…)" – sums up one of the respondents.

The next extremely important problem are long queues to specialists. In the mentality of the patients, primary care physicians still do not get much trust, and in principle, patients do not know what competences these doctors have. There is a widespread attachment to visits to specialist doctors. The system's second problem is the lack of preparation of patients for visits and the lack of cancellation of previously planned visits.

Computerization is a chance for the healthcare system, however, this raises concerns among the older generation of doctors and may increase readiness to leave if electronic documentation is introduced. „(…) Now technical innovations are introduced to improve the functioning of the system. But the doctors who have been working for many years in the profession, just like me, see this as a certain burden, because we are used to work "on paper". We are definitely more skilled at working with paper documentation than working with a computer. For young people who communicate and do most things on computer (30-year-old generation) in 20 years there will be no problem. Introducing it at the moment, i.e. what is happening now through e-prescriptions, sick leave forms, e-referrals is a challenge for older doctors. Many doctors who have already finished their work, e.g. 65-year-olds - for many of them it is tantamount to leave the profession. This is very bad for the system because there are very few doctors. Any experienced physician who leaves the system is a waste. Young people who have just started to work in the profession do not have experience in action, practice, knowledge of procedures. Although their theoretical knowledge is better, more timely than those who leave (…)" - states one of the respondents.

The table below sums up problems in primary healthcare in Poland.

Table 1: Strenghts and weaknesses of PHC

Strengths of PHC	Weaknesses of PHC
The use of modern technologies (electronic medical records, e-prescriptions and e-releases)	Shortage of doctors, medical personnel of all categories/specializations
New treatments	Low expenditures on healthcare
Greater patient access to medicines	Organization and valuation of services, contracting
	Lack of stabilization of the legal system in the area of health protection. There is chaos and misinformation
	Queues to specialists, long waiting time for visits to specialist doctors
	Poor contact with the patient, there is no continuity of care

Source: Authors' own study

The respondents were also asked to assess how currently functioning system affects organizational solutions in their facility. In the respondents' opinion, organizational solutions in healthcare facilities are influenced by legal regulations, infrastructure and competences of employees, as well as the procedures performed by primary care physicians. Regulations come from the central level, through law, financing, the level of relationship between a service provider and the patient, the level of quality of services and patient safety.

In addition, the complex contracting system is a hindrance, which is constantly modified and still does not work, which is associated with procedures for first-time, multiple-time visits, complicated reporting to the National Health Fund.

Respondents say that the system often forces referrals for examinations to specialists in order to obtain a referral for diagnostic tests that are not on the list of primary care physicians. In the opinion of the respondents, there is also a problem in the lack of an update of regulations. There are situations when new guidelines, new procedure cards, new requirements are introduced, especially before the medical procedures, although the old ones are still in force, which causes confusion and a waste of time for bureaucracy. Some activities are done only to make an effect visible quickly, e.g. e-sick leaves were introduced without cooperation with the doctors and their comments were not taken into account. „(…) There is a change in regulations that requires something from us, but the old regulations are not withdrawn. There are more and more regulations. Something new is coming, and at the same time there are regulations from the fifties that shouldn't exist anymore but we continue to do them (…)". "(…) There are new guidelines, new procedure cards, new requirements, especially before the treatments. Often in my field these are unnecessary things. There is no rollback or documentation update. Whatever they introduce, we must comply, if the control comes they won't pay (...) " – emphasizes one of the respondents. Another surveyed adds "(...) Now e-sick leaves have been introduced, the system freezes – we were informing about it before. This is all done to make an effect, and cooperation with us and our comments are not taken into account. You could sit in a panel, work on it. We are not against computerization, but it must be done wisely - on the first day the system was inefficient (...)".

The current system enforces record keeping, which, with such a huge number of responsibilities, is a big problem. There is a time limit for an appointment, which means that primary care physician cannot do what he/she has full competence and education for. "(...) There are too many papers. We keep records, nobody analyzes them. A part of what we write goes to the National Health Fund, on the basis of which they divide money (I do not know exactly how it is). In our specialization there is too much of it, it is troublesome, there is no time for it, there are no medical secretaries and this is a system error (...) "- notes one of the respondents.

The respondents were also asked whether they perceive the possibility of improving this state of affairs and what actions could improve the situation. In their opinion, the system would improve, if the path of patient care was visible – to what specialists did the patient go, what tests he performed, doctors must have information on how the system works. It is natural that the system could be improved through adequate financial outlays. The cooperation of doctors would also facilitate the work, so they would not have to duplicate diagnostic tests.

The respondents claim that to enhance the effectiveness of the healthcare system, business environment organizations, agreements, employers' unions, various types of hospital unions and all other significant organizations that bring together members who are responsible for implementing legislative solutions in practice, should be involved.

The respondents say that business environment organizations, agreements, employers' associations, various types of hospital unions, all significant organizations that bring together members who are generally those who are responsible for implementing legislative solutions should be involved in increasing the efficiency of healthcare system activities in practice. "(...) All organizations must cooperate. There must be business environment organizations, employers' associations, various types of hospital unions, all those large organizations that bring together members who are generally, those people who do what politicians come up with. The cooperation of these organizations and the joint determination of activities, tools, at a specific time, schedule, acceptable to all parties, is the solution. This should not work on the principle that an idea is being created and needs to be implemented the next day. It must go from bottom to top, as it is done in the other countries. Due to political turmoil, the role of SDC (Social Dialogue Council) diminished, due to the fact that some organizations operate in a chaotic manner. This means that for now the partner for the government is unstructured, but there are more and more strong institutions that know what they want, that cooperate with each other. Listening to the other side, considering your own arguments, is important as it is in the West. If this is not done, conflicts arise or projects fail (...) ´points out one of the respondents.

The respondents also note that often corrective actions are carried out at the level of the entity that tries to compensate for system errors through more effective organizational activities, e.g. through good communication with the patient. In addition, the system would be streamlined with easy-to-use, intuitive equipment that will not slow down the process but will speed it up. In the opinion of the respondents, a medical assistant could be a solution to the problem of documentation and data entry.

The cooperation platform between primary care physicians and specialist doctors

One of the major problems of the current healthcare system is also the lack of cooperation and communication between primary care physicians and specialist doctors. The basic problem noticed by the specialist doctors surveyed is not enough information on referrals, which results from the lack of time of primary care physicians.

Respondents (specialist physicians) believe that communication problems are not present to such exstand if they occur directly, within one unit. It is definitely harder to cooperate if doctors work in various medical entities. Often, for example, there is no feedback after a patient's visit to a specialist.

A potential solution to the current state of affairs could be a platform for remote consultations, which should improve the cooperation/communication between primary care physicians and specialist doctors. In the course of qualitative research, both primary care physicians and specialist doctors were asked to evaluate the concept of such a platform and the possibility of using it in their current work.

Most of the surveyed think that this is a good idea. A consultation at the right time is well received by each party. There are doctors who could only help in this way. The consultation would require real interest in the patient. „(...) I like this idea very much, it is an important element that needs to be developed, just like all the telemedicine and teleconsils, the possibility of using modern communication media. To solve

the patient's problem in a short way, consultation can be obtained electronically. We use an electronic sending of information on an ongoing basis. We are computerized (...)" - states one of the respondents.

„(...) I think it is a good idea, though I don't know if it works yet. The question remains who will pay the doctors for their time? This time will be taken away from the patient (…)" – another respondent notes.

The respondents believe that such a consultation would allow a more informed approach to the patient, would allow to find out what routine specialist disease management looks like, which will speed up the diagnosis and avoid repetitive visits. „(...) That's what I've heard. I think it is a good idea because every day such an action is also needed. A direct access to specialists is difficult. We contact them through referrals. Phone or mail - there is no custom or tradition. However, very often there are questions that I would like to ask when something happens, and it is not an urgent matter (…)" – says one of the respondents.

However, there are doubts about payment and time, due to staff shortages and workload - there is a suggestion of consultation in the afternoon/evening, after work. Computerization may also be a barrier, which older doctors refrain from.

Further reservations relate the trust in the information received on the platform as well as medical confidentiality and discussing specific cases, without detailed personal data. The opinions about consultations appear as an introduction to further action, not as a basis to make a final diagnosis. "(…) This is a good solution. I think that I would use it. This can be used to suspect the occurrence of a disease, but not to diagnose it, because it cannot be done without examination of the patient. This may be an introduction to further proceedings (...) "- notes one of the respondents.

In the next question, the respondents were asked if they had already had the opportunity to familiarize themselves with the remote consultation platform and whether such solutions in their opinion improves communication. The respondents were asked if anything requires improvement, and in what other way cooperation/communication between primary care physicians and specialist doctors could be improved?

Only a small group of respondents had the opportunity to familiarize themselves with the platform for remote consultation at a test meeting. They assess this tool well as an additional possibility of contact, and sometimes as the only contact with specialists.

Respondents suggested that a standard question protocol should be prepared that would guide the diagnostic path so that the primary care physician would not waste time writing questions. Such questions could be asked first by the nurse, the coordinator, who would direct the question to a specialist if necessary. „(...) This should be the simplest possible protocol of questions, to help guide the patient to the appropriate diagnostic path. The point is that the primary care physician would not waste time asking questions, e-mailing, but would simply ask questions with "yes/no" answers. On the other hand there will be a coordinator, or a nurse (not a specialist) who determines who to direct the questions to (based on the check list), or requests being given a referral (...)" – one of the respondents noticed.

The telemedicine and the teleconsils are seen as a way to improve communication, but require improvement. "(...) There are now a number of ideas - you can consult by phone, telemedicine – but it requires medical assistants who will watch over it, who will prepare the environment, the room. So the telemedicine needs improvements (...). "- claims one of the respondents.

Summary

The healthcare industry nowadays is facing many changes that pose new challenges to healthcare organizations in many countries in the world. In particular, the fast-evolving government regulations, technological innovations, and patient expectations create a new environment in which running a medical practice isn't just about treating patients anymore.

Even though, the healthcare system has undergone many changes in the recent decades, it still remains not as effective as it could be. There are many problems connected with the system, starting from financing, through staffing and infrastructure shortages to the cooperation and coordination of activities between medical entities and on the line of cooperation between primary care physicians and specialist doctors.

A faulty information flow system does not guarantee the physician an access to comprehensive information about the patient's state of health. There is a lack of a lot of relevant medical information about patients, and the data that exists is often inconsistent and incomplete. This significantly limits the possibility of making decisions.

As the results of the research indicate, the problems of the healthcare system are, among others:

- the ineffective flow of information about the treatment process and its effects (e.g. in connection with the insufficient development of modern electronic information circulation systems),
- the low expenditure on the healthcare,
- the shortage of doctors, medical personnel of all categories/specializations,
- the organization and pricing of services, contracting that need improvement,
- the lack of stabilization of the legal system in the area of health protection,
- the long queues to specialists, because in the mentality of patients, primary care physicians still are not trusted, and in principle, patients do not know what competences these doctors have,
- the increase of patients' expectations regarding medical care,
- the failure to prepare patients for visits and the lack of cancellation of previously planned visits,
- sending the patient to various medical entities (for specialist examinations), which in turn negatively affects the quality of medical services.

The positive changes in the current healthcare system are certainly the increasing use of technology (electronic medical records, e-prescriptions and e-sick leave) and modern treatments, as well as greater access of patients to medicines. For sure, computerization is a chance for the healthcare system, which, however, raises concerns among the older generation because it may contribute to the retirement of a group of doctors.

An important role in the effectiveness of this system is also played by the cooperation between the primary care physician and a specialist doctor, and thus a frequent problem with the incorrect flow of information about the treatment process and its effects. That is why understanding the role of this cooperation and improving communication include using the platform for remote consultations between primary care physicians and specialist doctors, which is one of the most important elements of improving the healthcare system in Poland.

Abstract

This research study proposes an agile inventory management model, implementing cycle counting and 5S methodology, in order to increase inventory accuracy rate by more than 90% in a glass, aluminum, and hardware trading enterprise. The initial scenario showed a 30% inventory accuracy rate for the Class A glass family group. We proposed a cycle count program that improved this rate so that in the first audit it grew to 35% and went up to 95% in the fifth audit. Finally, the results of the study show that the integration of Lean concepts and inventory management methodologies in an agile framework improves the state of an enterprise that faces an inventory inaccuracy problem.

Keywords: Agile model, Scrum, 5S´s, Inventory Record Accuracy.

Introduction

The global trade sector has been experiencing slower growth because of different trade disputes between various emerging markets. However, a 2.6% growth is forecast by the end of 2019 (Banco Mundial, 2019). China, the world's largest exporter of goods (16.2%), has increased its export value by 17% (World Trade Organization - WTO, 2019). The hardware business is considered to be one of the country's most dynamic industries. Besides, large enterprises are not the ones with the largest market share as they only represent 12% and barely had a four-percentage-point growth in the last 4 years. Rather, it is the small- and medium-sized enterprises (SMEs) that represent 88% and exceeded the 20-percentage-point-growth mark in the same period (INEI, 2019).

This sector comprises various product trading enterprises, and most of them face inventory inaccuracy depending on the business: those who market small products have higher inventory inaccuracy, and conversely, those with large products have less inaccuracy. In either case, this problem generates two detrimental situations for the enterprise: selling something that is not in physical inventory or stopping the provision of any product that is physically in the warehouse. This is related to the enterprise's poor management and control, which is the key to long-term sustainable sales (Norazira et al, 2018). In addition, the elimination of inventory record inaccuracy can improve the match between supply and demand and reduce inventory costs and transaction costs for shipping wrong items to customers (Norazira et al, 2018) (Ismail et al, 2018) (Chen et al, 2015).

This research work studies inventory record inaccuracy that is based on the following causes: poor warehouse distribution; the lack of controls and policies; the lack of training in service areas; and the lack of induction for dispatch area employees. In addition, the study focuses on SMEs that do not have the high purchasing power to invest in technology solutions, such as the plastic supplier in a case where a model for the assessment of radio frequency identification (RFID) technology's impact on the inventory accuracy is proposed (Hellström et al, 2010).

The following research is aimed at improving inventory record accuracy and at the same time reducing the number of invoices cancelled because of inventory inaccuracy in hardware and construction enterprises. Another goal is to increase scientific evidence regarding inventory accuracy improvement through both quantitative and qualitative research as there is no evidence until now of any study focused on integrating 5S tools and cycle counting into an agile framework such as Scrum in a retail sector. The products to be audited will be classified using the activity-based costing (ABC) method in cycle counting to prioritize the most profitable products.

State of the Art

Cycle Counting Inventory Management

We aimed at reaching total inventory improvement by implementing, in conjunction with the above, the cycle counting method, an inventory auditing procedure that comprises physically counting inventory items and comparing them with the quantities recorded in the system (Aghazadeh, 2001). Similarly, other studies concluded on the effectiveness of this method in controlling inventory and maintaining control actions. In addition, this technique was associated with ABC analysis so as to prioritize the selection of products to be audited (Jugraj, 2017) (Norazira et al, 2018). Furthermore, both authors reach similar conclusions, i.e., cycle counting should not only be performed once at year-end but also periodically. This is much more reasonable when it comes to trading enterprises in terms of achieving results (Harrington et al, 1990). In addition, they argue that to be effective, cycle counting must be based on order and cleanliness (Harrington et al, 1990) (Norazira et al, 2018).

Agile Approach to Inventory Management

The agile approach proposed in this work of research, Scrum, is considered to be an agile framework, and to date, there is very little evidence regarding the implementation of this tool outside of an IT project context. Likewise, studies agree that Scrum leads to the development of successful projects because of its flexibility vis-à-vis the unforeseen requirements that arise in each project in addition to integrating all the employees involved. Moreover, another author argues that team size and project duration have an effect on the results that its implementation can provide. In sum, both authors conclude that enterprises should be aware of Scrum implementation as the choice should be based on the context, practical needs, and project resources (Jugraj, 2017) (Qing, 2015).

Contribution

Proposed Model

The proposed model (Fig. 1) is aimed at complying with the guidelines so that an enterprise with a context that is similar to the one under study may implement an inventory management model that is based on cycle counting and 5S methodology along with Scrum tools in order to reduce inventory inaccuracy.

Fig. 1: Proposed Model

Proposed Method

This view details the sequences of activities to implement the proposed model. Further, we reconsider whether certain activities should be implemented so that the model can be adapted to different organizational contexts. (Fig. 2).

Fig 2: Proposed Method

Indicators

The ratios that will be analysed to measure the impact of the contribution proposed in this research are the following:

Inventory record accuracy (IRA): This shows how accurate the physical quantities are when compared with the quantities recorded in the system. The calculation formula is as follows:

$$IRA = \frac{Number\ of\ successful\ counts}{Number\ of\ counts\ performed} \times 100 \quad (1)$$

Equation (1) yields a percentage number, i.e., the accuracy level that exists between the physical and logical (system) inventory. That is to say, the higher the IRA the greater the accuracy between the two factors.

Order fulfillment (OF): This calculates the average time taken by a worker in the dispatch area to fulfill an order. The calculation formula is as follows:

$$OF = \frac{60\ minutes}{Number\ of\ orders\ dispatched} \tag{2}$$

Equation (2) shows a number that is equivalent to the average time taken by a worker to dispatch per hour. The exiting amount is assumed to be uniform for the remainder of the hours worked.

Index of products not reentered into the system: This shows the index of commercially-sized scraps (larger than 30 cm × 30cm) that are not reentered into the system for sale. The calculation formula is as follows:

$$\frac{Total\ leftover\ products\ with\ trade\ sizes}{Total\ worked\ products} \tag{3}$$

The index yielded by Equation (3) is interpreted as the percentage of commercially-sized glass that could be reentered into the system.

Index of improperly cut products: This shows the percentage of improperly cut glass out of the total glass worked during the day/week/month depending on the analysis. The calculation formula is as follows:

$$\frac{Total\ improperly\ cut\ products}{Total\ worked\ products} \tag{4}$$

This ratio shows how much glass out of the total glass worked per day/week/month was cut outside of customer specifications and subsequently discarded.

Table 1: Initial Diagnosis

Ratios	Current state
IRA	30%
Average order fulfillment time glass	9 minutes
Glass scraps not re-entered into the system	72%
Improperly cut glass	28%

Validation

Enterprise Presentation

This case study was implemented in a Peruvian enterprise that sells glass, aluminum, and accessories. The enterprise also performs aftersales work at the client's request, such as glass and aluminum cuts, and has 43 employees. The model will be implemented in the services area and in the accessories and aluminum warehouse, located on the third level, and the glass warehouse, located on the first level.

Initial Diagnosis

On the basis of the main problem, we analysed the causes, i.e., the lack of warehouse distribution, lack of controls and policies, lack of service area training, and lack of dispatch area induction. Table 4 shows the results of the initial diagnosis carried out in the enterprise under study.

Implementation of the Proposed Model

The model is based on Scrum, an agile project management methodology. The tools and events presented above were adapted to the enterprise's context.

We classified the staff involved and the responsibilities in the process as shown below:

Scrum: Sprint retrospective meetings, As the enterprise had no history of improvement project implementation, we validated the work and whether the implementation was working. At the end of each deliverable, accompanied by work appreciation and in order to document the lessons learned, a form was completed with the following questions: (1) What worked well? (2) What can be improved? (3) How can we improve it?

Prioritization and audit: In this implementation stage, 5S audits used an employee questionnaire to identify the area in which this methodology will be implemented and found warehouse and service areas to be critical in terms of 5S. Subsequently, we performed an ABC analysis to identify the products that represent higher sales revenue in the enterprise. Table 2 below shows the analysis:

Table 2: ABC Analysis

Product family	% Accumulated Profit	Criteria
Glass	78.03%	A
Aluminium	12.02%	B
Accessories	9.95%	C

Alignments: We implemented the first 3S (Sort, Set in Order, and Shine). In the second stage, we redesigned the warehouse material flow on the basis of ABC analysis of product distribution order by glass area. Both contribute to the reduction of order fulfillment times. Fig. 3 shows the warehouse design implemented for glass.

Fig. 3: Material flow design in glass warehouse

Control and Continuous: Furthermore, we proposed the implementation of a Kanban system to maintain control over this process and show the products that will be re-entered to reduce the IRA ratio. Fig.4 shows the proposed Kanban board and cards.

Fig. 4: Kanban board and cards implementation

Results

The following Table shows the final state after proposal implementation versus the initial state, thus highlighting an optimistic variation compared to the initial ratio.

Table 3: Ratio Results

Ratios	Initial	Final	Variation
IRA	30%	95%	217%
Average lead time or glass order fulfillment	9	2	7
Index of products not re-entered into the system	72%	37%	-49%
Index of improperly cut products	28%	18%	-36%

After total 5S implementation, a second audit was carried out to show how many improvements were made and above all that the enterprise has a sense of continuous improvement about its workplace. Fig.5 shows the results obtained with respect to the critical areas, services, and warehouses.

Fig. 5: Kanban board and cards implementation

The above Fig. 5 shows a considerable change in the 5S audit scores, which varied from 10 to 21 and 20 points, respectively, in glass services and warehouses.

Finally, there was a decrease in the number of invoices canceled because of inventory inaccuracy. The following figure shows that the trend of canceled invoices in 2019 is decreasing when compared with the previous year, thereby accounting for a drastic variation, from 188 invoices canceled due to inventory inaccuracy in December 2018 to only 21 invoices in December 2019.

Fig. 6: Percentage comparison of invoices canceled because on inventory inaccuracy in 2018 and 2019

Conclusions

This study shows that the integration of Lean concepts, an agile framework, and inventory management methodologies is effective in improving the state of an enterprise that faces an inventory inaccuracy problem.

We raised the hypothesis of achieving more than 90% for the IRA ratio; however, 95% was accomplished. Thus, we conclude that the 5S methodology, cycle counting, and layout are aligned in the implementation area and complement each other in audits because order and hygiene improve product identification.

The proposed model is intended to be adapted to other marketing enterprises. Similarly, it provides flexible implementation in SMEs with a small work team.

The proposed model helped to reduce lead time from 9 minutes (initial state) to 2 minutes, i.e., an index variation of 7 points. As for the index of products not reentered into the system, there was a negative variation of 49%, from 72% (initial state) to 37%. Finally, the index of improperly cut products went from 28% to 18%, i.e., signifying a 36% decrease.

carlos.raymundo@upc.edu.pe

Abstract

Peruvian micro and small enterprises (MSEs) constitute 99.08% of Peru's business density and have the highest rate of problems in performing and managing their operations. This precedent is reflected in the high expenses and costs incurred, creating low profitability in their activities. Peruvian MSEs have found an extremely difficult bridge to gap in order to improve the main areas and become more competitive in the market. One of the main problems of the enterprises in this sector is warehouse management; it is known that 49.9% of the companies in the country have warehouses and that, out of this total, 41.9% have some type of problem when storing their products. This article has selected an MSE from the textile sector as a case study, and this is where the Warehouse Management Model based on DMAIC methodology is applied. This method seeks to improve processes in the area and achieve its objective, continuous improvement, and cost reductions. To implement the model, the various techniques and tools used were grouped into five phases of the DMAIC methodology, and then, they were divided into 3 pillars: purchases, indicators, and location and storage. These are the ones most relevant for organizations with the aforementioned characteristics.

Keywords: DMAIC, Warehouse, Purchase KPIs, 5s.

Introduction

Among the organizations in Peru, microenterprises represent 94.6%, while small businesses constitute 4.4% and medium and large enterprises together—including public administration—represent 1% (INEI, 2015). Considering the aforementioned data, we can conclude that 99% of the enterprises in the country are MSEs. Furthermore, the business density represented by MSEs amounts to 99.08%. It is known that MSEs constitute 85% of the country's enterprises (Agencia Andina, 2018). In contrast, textile is one of the most important sectors in Peru, contributing 5.873 million to the country's total GDP: 1.3% to the national GDP and 8.9% to the manufacturing GDP. In 2015, 37,112 micro, small, and medium enterprises provided 411331 jobs through the employment assistance program in Peru (Ministerio de la Producción, 2015). As mentioned earlier, the textile sector is a main sector, providing income and work to the country, and thus, the efficiency level of its operations must be considered, as most SMEs in the sector are failing to meet the objectives raised in their different areas. The enterprises, regardless of the business segment they belong to, are disputing over how to meet the customers' needs and become more efficient in their operations. A main problem of these companies is supply change management where findings obtained were divided into the following four pillars: lack of automation, difficulty in finding trained personnel, improvement opportunities for SCM, and the opportunity to outsource services (PAD, 2015).

Enterprises have several problems when conducting their operations and offering their products and/or services, as shown in the study conducted by the National Institute of Statistics and Information Technology (INEI), which sets out the importance that warehouses have for enterprises.

INEI reports that 49.9% of the companies in Peru store their products, and from this total, it is known that 57.7% use some type of model for their inventories. Moreover, it was identified that out of the total number of companies that store their products, 41.9% indicated having some type of problem in their warehouses (INEI, 2015).

To solve the warehouse problems, a management model is proposed to reduce the shrinkage costs in the purchasing and storage processes. The DMAIC methodology consisting of the five phases that form the acronym will be used, and the tools were selected to be used in each of the five steps. The model to be implemented in the case study uses the following tools: Selection and Supplier Evaluation, 5S, value-stream mapping, Kardex, and ABC distribution of inventories.

State of the Art

Lean Philosophy

To reduce waste that does not generate value for the company, the Lean principle suggests eliminating the 3Ms (i.e., Muda, Mura, and Muri). The objective of the implementation is to increase productivity and reduce costs. The benefits of implementing the Lean philosophy in warehouses are increased efficiency and flexibility, continuous improvement, and adjustments to the requirements of suppliers and customers (Oey et al, 2018) (Reis et al, 2017). The Lean tool seeks process optimization, reduction of worthless activities, efficiency improvement, and cost reduction (Baeza, 2015) (Ben et al, 2019). The Lean philosophy has several variants such as the "lean office," which is used for handling computerized data, and ensures that by implementing this approach, benefits may be obtained in the management and administration of databases and files. The goal remains the same, which is to eliminate waste by reprocessing and ensuring that activities add value (Monteiro, 2017).

The main results of the Lean philosophy in warehouses are the restructuring of scope space, increasing the layout, and reducing costs and times in operations (Oey et al, 2018) (Reis et al, 2017). Moreover, the reduction in operating time and significant economic savings for companies were obtained as a result (Baeza, 2015) (Ben et al, 2019). Implementing Lean office results in processing time and sending information and feedback (Monteiro, 2017).

ABC Inventory Classification

ABC inventory classification is a method focused on material inventory storage, using various criteria such as inventory value, annual demand, and average cost. This analysis can be performed according to various criteria such as cost, requirement, and affinity, with an aim of process optimization (Li et al, 2016) (Li et al, 2017). Furthermore, good inventory and warehouse management is of vital importance to organizations, and thus, the priority of the warehouse is to manage materials efficiently, as this is the link between the purchases and sales of a company (Sathish et al, 2019) (Arunyanart et al, 2019).

The results of correctly implementing the ABC inventory method are a reduction of runs being made and less time in operations carried out (Li et al, 2016) (Li et al, 2017). By implementing the method correctly, benefits are achieved such as the time taken to dispose materials, leading to 59.46% stock reduction and 13.73% storage increase (Sathish et al, 2019) (Arunyanart et al, 2019).

Contribution

Proposed Model

This model is divided into three areas: suppliers, warehouse and inventories, and processes and indicators. The DMAIC methodology is taken as a framework and is focused on process and continuous improvement. DMAIC is an acronym composed of five words: define, measure, analyze, improve, and monitor. For each of the phases, techniques, tools, and methods belonging to the Lean

philosophy and the ABC inventory method will be selected to solve the main problems of textile MSEs.

Fig 1. Proposed Model

Area 1 - Suppliers: In this stage, the supplier selection and evaluation processes will be presented. The objective is to implement a method that ensures the supplying of the materials required to perform the operations. By implementing this model, it is possible to have suppliers with the flexibility and possibility to fulfill the orders requested.

Area 2 – Warehouse and Inventory: In this stage, the distribution and control processes of materials in the warehouse will be shown. The objective of this area is to control the receipt and issue of material, reduce shrinkage in processes and material, and take advantage of the space in the warehouse.

Area 3 – Processes and Indicators: This stage will present the purchasing and inventory end-to-end processes of materials. The objective is to implement a process map that covers activities and to implement measurement indicators for operation control.

The proposed process for the model is based on DMAIC methodology, which serves as a framework to implement methods, techniques, and tools in each of its five steps. It seeks to implement various tools that achieve synergy between them to bring a solution to a common objective, which is to improve supplier selection and evaluation and efficiently manage the inventories and warehouse.

For each of the areas, methods will be selected to help meet the objective of each step; the methods will be distributed in the phases of the DMAIC methodology to focus the proposed model on continuous improvement. The benefits obtained will be costs reduction; process, operations, and management improvement; supplier control; control in materials receipt and materials issue; traceability; waste reduction; waiting times; and production downtime. Figure 2 presents the process that will follow the proposed warehouse management model.

Fig. 2: Purchases improved proposed process

Indicators

The indicators used to control the model are as follows: purchase quantity per month, non-conforming purchases, damaged material deliveries in purchases, raw material shrinkage, inventory turnover, and compliance with the monthly production plan.

Purchase quantity per month: The objective of this indicator is to measure the purchase quantity—supplier interactions—that are made per period. The indicator is based on measuring how the number of purchases varies per month and if the purchasing planning and inventory control was conducted correctly. The indicator will be compared with the results of previous periods to identify if a good purchasing plan exists.

$$\frac{Purchase\ Quantity}{Number\ of\ Months} \tag{1}$$

If there are many purchases, the indicator will be compared with the results of previous periods to identify if a good purchasing plan exists.

Non-compliant purchases: The purpose of this formula is to measure supplier compliance in relation to the requirements made by the organization. Supplier compliance relating to the issue of purchase orders will be controlled. Whether the supplier meets the purchase orders made will be checked.

As the result approaches 100%, this shows a poor requirement fulfillment by suppliers. The closer the result is to 0%, the better the supplier performance will be.

$$\frac{Non\text{-}conforming\ purchase}{Total\ purchases\ issued} \times 100 \tag{2}$$

Results will show worse fulfillment of requirement by suppliers when the result is closer to 100%. The closer the result is to 0%, the better the performance of the suppliers.

Damaged material deliveries in purchases: The measurement of deliveries of damaged material by suppliers seeks to identify supplier performance and the quality used in its products and services.

$$\frac{Total\ purchasing\ cost}{Damaged\ material} \times 100 \tag{3}$$

As the result approaches 100%, it will show a low compliance for damaged materials. The closer the result is to 0%, the better the supplier performance will be concerning material delivery. The level of raw material shrinkage will be measured to be able to quantify what the percentage of loss is owing to raw material waste.

Raw material shrinkage: The level of raw material shrinkage will be measured to be able to quantify what the percentage of loss is due to raw material waste.

$$\frac{Cost\ of\ raw\ material\ loss}{Warehouse\ products\ total\ cost} \times 100 \tag{4}$$

As the result approaches 100%, it will show a high level of raw material shrinkage. When the result is closer to 0%, there will be less raw material shrinkage.

Inventory turnover: The indicator is used to measure raw material input use ratio in relation to the raw material total cost held by the organization.

$$\frac{Warehouse\ material\ issue}{Current\ input\ quantity} \tag{5}$$

As the result approaches 100%, it will show a high level of inventory turnover. When the result is closer to 0%, the raw material inventory turnover will be worse.

Production plan compliance: The percentage of production downtime in a given period, caused due to a poor inventory, and purchase management is measured.

$$\frac{Real\ production}{Planned\ production} \tag{6}$$

As the result approaches 100%, the real production increases, showing a low warehouse performance. If the result is close to 0%, a good inventory and purchase management will be ensured.

Validation

Model Implementation

To show the proposed model behavior in relation to the main problems encountered in the case study, the model presented will be followed. This is divided into three areas, as shown below.

Define, measure and analyze:

These stages were included in the situational analysis of the organization to provide solutions for the main warehouse problems. The process to perform these activities is described below.

- The first activity carried out was the definition of the main problems that happen at the warehouses.
- An internal audit was carried out to identify the cause of poor performance operations and gather information as the basis of the analysis.
- The information was analyzed using the Ishikawa tool and prioritization matrix to identify the causes and root causes and to weight them for identifying their importance.

Improve:

Area 1 - Suppliers: The first activity carried out was the implementation of a supplier evaluation criteria matrix. To implement this matrix, information was collected from the ISO 9001 guide (Yadav et al, 2018) and from scientific articles (Gupta et al, 2017). The most relevant criteria for the context wherein the organization is developed were identified and the following seven were chosen: purchase requirement fulfillment, delivery time, coordination with supplier, order capacity, replacement or return guarantee, price and payments. The measurement criteria were divided into “very good,” “good,” “regular,” and “bad,” and according to these, the respective specification belonging to the quadrant is described.

The evaluation criteria will provide a clear criteria that a supplier must have to attend to a need. Thus, the supplier aligning with the objectives and needs of the organization will be assured
After this, a supplier evaluation chart is prepared, which uses the criteria that were shown. The objective is to measure the fulfillment of the enterprises to cover any organizational need. The format requires specific information from the supplier and contact person and shows the most relevant criteria. Moreover, it shows the evaluation chart where the evaluation is carried out, and according to the result, it is identified whether the organization evaluated can be considered as a supplier. The re-evaluation date according to the score obtained is shown at the bottom of the document.

The implementation function is to have a control method that ensures that the chosen supplier can meet a need with the required specifications in cost, time, quality, and service.

A supplier list box was created to identify the data required for contact. This implementation cannot be shown owing to the suppliers’ request and legal restrictions.

Finally, an inspection box for supplies was introduced, where all interactions (purchases) and their correct fulfillment are monitored.

Area 2 – Warehouse and inventory: The Area 2 implementation was carried out in the fabric warehouse, as the company to which the case study was made imposed this limitation. This point is divided into 3 tools, which will be shown below:
5S:

- Classify: At this stage, the materials and objects that were in the warehouse were selected. All materials were classified to eliminate the unusable ones; the walkways were delimited and the materials that interrupted the walkway were removed. Those were classified according to their specifications.
- Sort: Fabrics were sorted in the warehouse, so that they are easy to identify. Conversely, materials and tools not belonging to the area were removed.
- Clean: At this stage, the overall area (shelves, passageways, etc.) was cleaned, an analysis of the requirement functionalities such as light and connectors was made. Finally, a cleaning plan was made consisting of specific activities per day.
- Standardize: Formats for monitoring activities and daily controls were implemented.
- Discipline: For this stage, monthly training meetings and discussions of the results were proposed. Moreover, reports on problems and non-compliances will be made.

ABC: Inventory classification. After this, the implementation of the ABC inventory distribution is carried out. Codes were used in the stage to classify the 5S for input identification.

Kardex: Finally, Kardex warehouse of the materials belonging to Warehouse 1 was implemented. Codes in the setep were used to classify the 5S for input identification.

Area 3 – Processes and indicators:
Processes: The first activity for conducting the value flow mapping was to gather the information of all activities, including the implementations made. The flow of activities along with the functions creating the greatest value for the processes and the organization were identified.

Indicators: Finally, the implementation measurement was performed using the indicators shown in previous sections. The obtained results are shown in Table 1.

Table 1: Implementation Control

Indicator	Value after model implementation
Purchase quantity per month	7.00
Non-conforming purchases	28.57%
Damaged material deliveries in purchases	6.40%
Raw material shrinkage	6.63%
Inventory turnover	32.77%
Monthly production plan compliance	76.92%

Control:

The variation of results before and after the implementation are shown in Table 2.

Table 2: Comparison Results

Indicator	Value before model implementation	Value after model implementation	Savings from the model
Purchase quantity per month	18.00	7.00	PEN 283.54
Non-conforming purchases	38.89%	28.57%	PEN 438.45
Damaged material deliveries in purchases	11.02%	6.40%	PEN 593.13
Raw material shrinkage	14.34%	6.63%	PEN 627.65
Inventory turnover	19.63%	32.77%	PEN 408.88
Monthly production plan compliance	73.87%	76.92%	PEN 1,902.30

Following are the results obtained when implementing the warehouse management model in the Central Uniforms EIRL enterprise.

- The proposed model managed to improve warehouse operations, reduce costs, and improve quality.
- Total monthly costs were reduced by 9.24%, in comparison to the average monthly costs of the previous year.
- Total monthly savings was 4253.95 soles compared with the monthly average of the previous ones.

Results

The proposed model was implemented in other warehouses of the organization and another textile MYPE, to validate the viability of the proposal. The results obtained are presented below (The case study is warehouse 2).

Table 3: Implementation of the model in other warehouses

	MP 1 warehouse		MP 3 warehouse		MP 4 warehouse	
Indicator	Value before model implementation	Value after model implementation	Value before model implementation	Value after model implementation	Value before model implementation	Value after model implementation
Purchase quantity per month	16	12	20	12	17	11
Non-conforming purchases	31.83%	24.77%	22.65%	16.98%	27.16%	21.45%
Damaged material deliveries in purchases	12.84%	10.22%	10.99%	9.77%	11.02%	10.76%
Raw material shrinkage	13.11%	11.47%	13.98%	12.87%	17.55%	13.19%
Inventory turnover	29.45%	35.55%	31.65%	36.66%	38.56%	42.14%
Monthly production plan compliance	71.83%	72.91%	75.21%	77.11%	79.76%	82.76%

Conclusions

The proposed model meets the objective of improving the results of the warehouse area.

The model considerably improves supplier selection and evaluation operations and inventory control, reducing time in operations and reprocessing.

The average of deliveries of material damaged by purchases decreased by 18.94%.

When comparing the results of the 4 implementations, it is observed that the average losses were reduced by 24.76%.

The inventory turnover level was increased by 28.18%.

The model achieved that compliance with the production plan increased by 2.98%.

Abstract

Approximately 16.9% of Peruvian manufacturing companies experience losses and damaged product issues in their production processes. In the face of our current digital era, which has impacted all business areas, markets in general have become more competitive. Moreover, the digital printing industry now represents approximately US$ 5 million of the Peruvian production sector and exhibits further growth opportunities. Within this context, a continuous improvement model was developed to increase productivity in a flexographic printing press through process optimization and implementation of an appropriate work environment using Lean and Ergonomics tools. The application of these tools was not only aimed at increasing process productivity but also the working condition and workstation design. The results herein achieved an 88% reduction in waste and 90% in defective products.

Keywords: Waste, Non-conforming Products, Continuous Improvement, Lean Manufacturing.

Introduction

The paper and printing industry accounts for 11.6% of the Peruvian production sector (INEI, 2017). Moreover, this industry represented 8.61% of the 2018 production GDP (INEI, 2018), being one of the primary non-primary manufacturing contributors.

The graphic arts industry is experiencing significant growth, which is partially fueled by the 20% rise in the use of digital technology expected for 2020 (Diario Gestión, 2015). Prior to this digital growth, this study seeks to assess other printing techniques that continue to be relevant in Peru. In this light, the initial case study assessment revealed that the main issues currently faced by this industry are non-compliant products, losses, absenteeism, unprocessed orders, and work-related accidents. Furthermore, this assessment identified that non-conforming products and losses represented 90% of the company's expenses owing to internal failures (Villarreal, 2019).

Therefore, this study proposed the implementation of a continuous improvement model, coupled with the application of 5S, Poka-Yoke, and Ergonomics tools, to increase ink-tinting productivity and reduce non-conforming products and losses. Similarly, this process will be standardized through the creation of control indicators. Finally, the authors wish to share the learnings during model implementation within other areas to create a feedback environment and establish joint goals that will lead to the successful achievement of company objectives.

This paper is organized as follows: the State of the Art section reviews the existing literature on the subject matter and states the research problem. The subsequent section describes the expected contribution from this work, followed by the model validation section, wherein the improvements implemented are validated. Similarly, this section also reveals our results and findings from the research study. Finally, the conclusions section discusses our conclusions, constraints, and recommendations for future studies based on our assessment herein.

State of the Art

Application of Lean Manufacturing in the Production Sector

When reviewing the Lean model literature, there is an evident demand from organizations for effectively removing non-value-added operations to reduce costs and foster continuous process improvement. Lean is used in multiple sectors and there are several definitions and perspectives as per different authors (Bhamu, 2014). For example, Hallgren et al (2009) define Lean as a main objective approach seeking to increase operations efficiency, identify value and waste, develop knowledge, and create a continuous improvement culture at work to promote process operations and business management sustainability. Therefore, reducing reprocesses will increase the employee awareness regarding organizational sustainability. On the other hand, Mostafa et al. (2013) argue that a successful Lean initiative must be well structured, designed, and sufficiently comprehensive so that it can be completely understood by all staff, without neglecting human and technical factors. Therefore, Lean can be defined as a main objective approach aimed at obtaining benefits through tool implementation, eliminating waste, fostering knowledge development, and promoting organizational culture. As for the application of Lean, Mathur et al. (2012) suggest that small and medium-sized companies should only implement simple and affordable Lean practices. In addition, Chaplin et al. (2016) recommend small and medium-sized enterprises to implement a “Lean Lite” approach (limited number of Lean practices) owing to their limited financial and knowledge resources. Therefore, instead of adopting Lean in all its dimensions, small and medium-sized businesses must select specific Lean practices within the reach of their operations.

One of these Lean tools is the 5S, which focuses on organizing, cleaning, and establishing the workplace environment in order. Further, Gajdzik (2009) states that the 5S method contributes to creating and maintaining an organized, clean, efficient, and an optimal quality workplace. In addition, Pepper and Spedding (2010) consider that the 5S helps to organize, classify, clean, standardize, and improve processes to foster their systematization and standardization within organizations so that they may become the norm and routine followed there. Another Lean tool is

Poka-Yoke, which focuses on error prevention. As stated by Stewart et al. (2001), Poka-Yoke uses processes or design features to prevent errors or their negative impact. On the other hand, Middleton (2001) defines Poka-Yoke as the systematic practice of eradicating errors by determining their root cause. Finally, Plonka (1997) considers that a Poka-Yoke is a mechanism for detecting, eliminating, and correcting errors at their source, prior to them being identified by the client.

Manufacturing companies have benefited from implementing the 5S principles as it is a basic practice for improving the use of space by cleaning and organizing workplaces, thereby obtaining higher levels of quality, better delivery times, and improved cost reduction. For example, Alves et al. (2012) implemented the 5S methodology to facilitate deliveries of raw materials and tools to minimize travel time and downtimes. On the other hand, Agrahari et al. (2015) implemented the 5S methodology in a small-scale industry to improve cleanliness and productivity. Furthermore, to sustain the improvement, they encouraged staff feedback through questionnaires, which allowed them to get feedback and identify process improvement opportunities.

Regarding Poka-Yoke implementation in production companies, Sundaramali et al. (2018) focus on minimizing rejection rates at piston manufacturing lines and guaranteeing maximum rejected material recovery through the tool. Once the tool had been implemented, they were able to inspect the transformed raw material before it was transferred to the assembly line, thereby identifying defective components and avoiding unnecessary assembly. In addition, the recovery of defective components helped to minimize waste, generating savings in terms of money, resources, time, and labor.

Application of Ergonomic Assessments in the Production Sector

As evidenced by the several ergonomics application cases reported, companies must effectively account for ergonomics in their processes and facilities to reduce musculoskeletal disorders affecting their staff. Furthermore, this problem has been assessed from various perspectives. For instance, Muntaner et al. (2016) assert that guaranteeing safe working conditions is a key factor in workforce empowerment. Demirel et al. (2016) further argue that we must first completely comprehend the relationship and synergy between improving working conditions and the quality of manufacturing processes, which can be achieved through the proactive implementation of improvement measures in the field of ergonomics. In addition, Cadavid et al. (2015) conclude that companies that invest resources in improving ergonomic conditions at their facilities achieve a more favorable external projection. Similarly, some certifications allow companies to prove that they are interested in providing health care to their employees, which identifies them as a great place to work. Consequently, these initiatives generate greater integration between employees and the company's vision, which reduces turnover rates and improves organizational development.

In the manufacturing industry, the application of ergonomic assessments ultimately reduces expenses related to disabilities, overtime, medical care, and penalties (Chang, 2016). For example, Munguía et al. (2017) discuss ergonomics opportunities that facilitate sustainability in the manufacturing industry. Through the implementation of Rapid Entire Body Assessments, Rapíd Upper Limb Assessments, and a worker perception survey, they confirmed that ergonomics is an effective means to cultivate higher levels of sustainability in the manufacturing industry. In this sense, daily exercise sessions or active breaks also contributed to reduce stress among participating employees, consequently, stimulating productivity through the development of new activities at the facilities under study.

On the other hand, Brandl et al. (2016) performs a comprehensive ergonomic assessment of employee postures using the Ovako Working posture Analysis System (OWAS) with an

individual sampling strategy in the semi-trailer assembly industry to implement corrective measures and improve uncomfortable work postures. This study reported that the 11 most frequent work postures defined by OWAS had a relative frequency of more than 90%. In the assembly of semi-trailers, work postures such as kneeling, lying down, or squatting could be almost completely avoided through a better ergonomic design at the workplace.

Contribution

Proposed Model

Based on our research, as well as our previous literature review, this study proposed the implementation of a continuous improvement model based on Lean Manufacturing and Ergonomics for reducing non-conforming products and losses in the flexographic printing industry. As denoted in Figure 1, this model encompasses the following five phases: identify opportunities for improvement, assess defects at a qualitative level, implement improvements, control processes, and share knowledge.

Fig. 1: Proposed continuous improvement model for reducing defective products and losses.

Identify Opportunities for Improvement: Subsequent to assessing the current situation of the company, opportunities for improvement are identified with respect to defective products and losses related to the ink-tinting process. This phase seeks to evaluate the company in terms of the 5S to completely map all current processes and measure their performance to prepare an improvement proposal

Assess Defects: This phase provides an in-depth assessment of the defects presented during the ink-tinting process through the Ishikawa and Failure Mode Effect Analysis tools to determine the impact exerted by these failures.

Implement Improvements: During this stage, a 5S implementation method is developed as per its five steps: sort, set in order, shine, standardize, and self-discipline. In addition, a Poka-Yoke system is also designed and implemented to detect and remove process errors, and subsequently

provide employee training sessions on its application. Finally, ergonomic assessments aligned with the improvements needs of the company are conducted.

Control Processes: Once the improvement implementation stage has been completed, processes must be subsequently controlled through KPI's and by taking preventive and corrective.

Proposed Method

Figure 2 depicts the implementation steps for the continuous improvement model in the ink-tinting process.

Fig. 2: Breakdown of the proposed model for implementation

The following figures display a specific view for each tool implemented in Phase 3.

Fig. 3: Specific 5S´s implementation view

Fig. 4: Specific *Poka-Yoke* implementation view

Fig. 5: Specific ergonomic assessment implementation view

Indicators

The indicators measured prior and subsequent to the model implementation are listed and explained below:

Non-conforming product rate: Measures the number of non-conforming labels delivered against the total number of labels delivered (in thousands).

$$IpNc = \frac{Non\text{-}conforming\ labels}{Labels\ delivered} \quad (1)$$

Traffic Light Indicator		
Optimal	***Regular***	***Deficient***
Less than 0.7	Between 0.7 and 1.5	Over 1.5

Loss rate: Measures the total number of labels lost during the production process against the total number of labels produced (in thousands).

$$Im = \frac{Labels\ lost}{Labels\ produced} \quad (2)$$

Traffic Light Indicator		
Optimal	***Regular***	***Deficient***
Less than 0.3	Between 0.3 and 0.7	Over 0.7

Validation

Case Study – Simulation

This paper focuses on the case study of a printing press. The company produces prime label packages and coding, representing 89% and 11% of its annual sales, respectively. Therefore, this research exclusively focuses on the prime label production and its corresponding problems.

Initial Assessment

The main probable causes for the problems reported (non-conforming products and losses) were identified as variations in ink shades and excessive physical efforts from workers while performing the ink-tinting process.

The following are the initial indicators for the ink-tinting area:

Table 1: Initial indicators

Non-conforming labels owing to the colour shade	98,000 per month
Losses owing to colour shade	125,000 per month

Next, the authors performed a representation of the current ink-tinting process, observing two process reprocesses. The first was the ink testing with a 20% probability and the second was the tinting validation with a 35% probability (Fig. 6).

Fig. 6: Current system representation

Proposed Model Application

Subsequent to the proposed scenario being implemented, reprocesses were eliminated and tinting times decreased by 20% from the initial times.

Proposed Model Application

A simulation of the current ink-tinting process was performed, with a confidence level of 95% and a margin of error of 10%, with the following results:

The results from the proposed model are (Table 2 and Table 3)

Table 2: Simulation Indicators

Factor	Current	Proposed	Results
Processing times	112 min	89 min	Decreases
Older queue	12 units	9 units	Decreases
Incoming orders	15 units	17 units	Increases
Resource	0.98	0.86	Decreases
Orders fulfilled	9 units	17 units	Increases

Table 3: Control Indicators

Indicator	Current	Proposed
Non-conforming labels due to colour shade	98,000 per month	10,000 per month
Losses due to colour shade	125,000 per month	15,000 per month

Conclusions

In this case study, an 84% integration rate was reported for Lean tools and Ergonomic Assessments.

By integrating Lean tools and Ergonomic Assessments, the proposed model can be adapted for any other company production area.

Subsequent to the implementation of the proposed model, the number of non-compliant products owing to the color shade was reduced by 90%.

Furthermore, the total number of losses owing to the color shade was reduced by 88%.

Abstract

The present research focuses on the importance of forecasting outdoor advertising effectiveness in the placement of advertising items in the public thoroughfare, especially in the implementation of billboards, as every damage entails a percentage decrease in the investment in Latin America compared with the previous year. The inexistent effectiveness measurement and a process lacking structure have caused loss of service in trade marketing companies because customers prefer a more expensive service such as digital advertising, which has an effectiveness measurement system. To solve this problem, we developed a placement process flow and used a linear regression model to demonstrate the placement time influence on sales of 40 stores, in two scenarios: 2018 and 2019. Thus, placement time was reduced by approximately 74.35% and sales increased by 145%.

Keywords: Advertising, public road, effectiveness, POS.

Introduction

Advertising is the means by which companies in the mass consumption sector communicate with the final consumer by providing information, promotions, and product launches. Hence, companies make a significant investment in the area or company engaged in the placement of advertising items. According to Zenith, in the Global Intelligence report of March 2018, advertising spending in America stands at 8.2 % as opposed to Europe and Asia (Sainsbury et al, 2017). This shows America's opportunity for growth. The same magazine mentions the average annual growth in terms of advertising, where we find outdoor advertising (2.7%) as opposed to the average of digital advertising (12.7%) (Sainsbury et al, 2017), although there has been a decrease in outdoor advertising investment and an increase in digital advertising owing to technological trends in recent years. Similarly, in Peru, according to the Peruvian Advertisers Association (ANDA), investment in advertising has increased considerably from 2017 to 2018, owing to sports and political events (Hutter, 2014). However, these events are seasonal, as they

occur every four years. Without these events, investment in advertising would have continued to decline. According to the Peruvian Superintendence of Customs and Tax Administration (SUNAT), the payment made by advertising media from 2015 to 2018 shows a decrease in public advertising investment with a share of only 4%, as opposed to previous analyses, owing to an 8% increase in digital advertising (Shvetsov, 2010).

The previous research showed an opportunity for improvement, as companies must prepare themselves to offer results in the reach of their investment. Thus, companies, especially small ones, must have a structured process to meet requests and counteract existing problems. Optimal process implementation to improve quality, costs, and productivity levels requires firm discipline, work ethic, and culture, seeking customer satisfaction.

We propose a process aimed at boosting investment in the visibility element implementation through an effectiveness forecast model applying enterprise architecture and continuous improvement. The model aims to create added value and, in this case, to determine a scope of investment. For this research, we propose the use of enterprise architecture and, in each phase, to use service optimization tools, such as continuous improvement and key performance indicators (KPIs) focused on measuring advertising scope on the public road. These tools are implemented for the improvement of the problem faced by small enterprises or marketing and advertising areas.

State of the Art

Model of Outdoor Advertising Effectiveness in Small Enterprises

Some authors argue that the forecast of outdoor advertising effectiveness has not been sufficiently studied; thus, they researched on different outdoor advertising means, such as transportation, trains, and buses, in static and moving billboards placed in different areas and of large dimensions. However, not all outdoor advertising media have the same variables, due to different case studies (Henningsen et al, 2011) (Perlich et al, 2014) (Browning, 2009) (Ross et al, 2004) (Kumar et al, 2016). The authors state that outdoor advertising has a greater reach than digital media such as television, radio, and social networks, but that there is no way to quantify it. Therefore, they used data processing tools, element recognition surveys, forecasts, and variable measurement (Henningsen et al, 2011) (Perlich et al, 2014) (Browning, 2009).

Enterprise Architecture

The authors summarize that overall enterprise architecture encompasses the entire business life cycle: from business process reengineering to continuous process improvement to streamline high-priority activities. However, in reality, the small businesses' processes are not structured from the beginning of their operation because their only goal is to subsist (Scheer et al, 2000) (Winter et al, 2007) (Laroche et al, 2001) (Rosset et al, 2006). Other authors disagree and choose to develop enterprise architecture based on a workflow to reduce the bottleneck activity in a company, as it generates a delay in business execution (Scheer et al, 2000) (Kong et al, 2002) (Lee et al, 2010).

Outdoor Advertising Effectiveness Forecasting Model Applying Enterprise Architecture

The authors agree that small enterprises must take advantage of the changing climate to maximize their profits and achieve an effectiveness model in outdoor advertising. They are currently in a constant search to define and improve their processes, through workflow and continuous improvement (Sainsbury et al, 2017) (Shvetsov, 2010) (Kumar et al, 2016). Small businesses lacking a well-defined process structure

generate bottlenecks that affect the flow time. Therefore, the goal of enterprise architecture (EA) is to organize the flow and increase outdoor advertising effectiveness, which is reflected in sales; because the lesser the installation time, the longer the advertisement will be exposed to consumers (Sainsbury et al, 2017) (Shvetsov, 2010).

Contribution

Proposed Model

Phase 1: Plan :Companies must achieve commitment from the sales executive and the staff involved in the task and, conversely, must have access to the prior-year investment data regarding the placement of elements in the chosen campaign and the consequently achieved sales. The case study consisted of a Pareto chart of the point-of-sale tops and the panel element, followed by an analysis of KPIs.

Phase 2: Do: Based on the study conducted, we created a process applying EA, involving phases, stakeholders, database, and decisions, to improve process activity control. Staff is trained in requesting legal permissions and in the process flow, and the company places the process on a website using business intelligence to achieve better results.

Phase 3: Check: The third phase consists of checking the control of advertisement placement and trainings. On the other hand, activities are followed up during the process, i.e., response time, checks, and decisions are controlled in the activities.

Phase 4: Act: In improvement actions, the process carried out must be addressed to continuously improve their performance. If any defect, error, or waste is found, the Plan-Do-Check-Act model should be applied to solve it as shown in Fig. 1.

Fig. 1: Proposed Model

Indicators

Indicator 1: Item placement process time (PT).
Objective: To achieve a level greater than 90% in placement time.

$$\frac{Optimal\ Placement\ Time}{Average\ Placement\ Time} \times 100 \quad (1)$$

Interpretation: If the result is higher than 85%, it is optimal; if the result ranges between 60% and 84%, it is regular; and finally, if the result of the indicator is lower than 59%, it is poor.

Indicator 2: Response time per stakeholder (RT).
Objective: Achieve a higher level of 90% in response time per stakeholder in the placement process.

$$\frac{Optimal\ Placement\ Time \times Phase}{Average\ Placement\ Time \times Stakeholder} \times 100 \quad (2)$$

Interpretation: If the result is higher than 85%, it is optimal; if the result ranges between 60% and 84%, it is regular; and finally, if the result of the indicator is lower than 59%, it is poor.

Indicator 3: Placement Efficiency (PI)
Objective: Achieve 95% placement efficiency.

$$\frac{Number\ of\ Efficiently\ Placed\ Elements}{Total\ Number\ of\ Placed\ Elements} \times 100 \quad (3)$$

Interpretation: If the result is greater than 95%, it is optimal; if the result ranges between 70% and 94%, it is regular; and finally, if the result of the indicator is less than 69%, it is poor.

Indicator 4: Goal Achievement (GA)
Objective: Achieve 90% of goals.

$$\frac{Number\ of\ Item\ Placed}{Total\ Forecast\ of\ Items\ to\ be\ Placed} \times 100 \quad (4)$$

Interpretation: If the result is higher than 85%, it is optimal, if the result ranges between 60% and 84%, it is regular; and finally, if the result of the indicator is lower than 59%, it is poor.

Validation

Case Study

The validation will be performed for the company Reyplast SAC, identified with tax identification No. 20125508716; this company is engaged in the production, processing, and distribution of plastic products for industrial and household use.

Initial Diagnosis

The diagnosis made in the case study is shown in Figure 2 (Year 2018).

Fig. 2: Sales figures according to placement time

First, the PT indicator showed that 66% of the item placement process time is regular. Second, the RT indicator is divided into process phases and all are at a poor level, except for phase 5, which is at a regular level. Third, the PE indicator was 75, which means that placement efficiency was regular and the AO of 80% means that goal achievement (GA) was regular.

Contribution Development in the Scenario

Plan: We classified the staff involved and the responsibilities in the process as shown in Tab. 1.

Table 1: Duties According to the Staff Involved

Process Role	Position in the Organization	Duties
Customer	Sales executive	• Enter advertising request • Approve photomontage • Draft letter of approval
Service	Controller	• Assess POS and forecast the required amount • Manage route and photomontage • Budget investment amount • Communicate budget disapproval and photomontage • Receive approvals • Enter proformas • Cancel request • Monitor item placement process • Generate final photo report • Approve advertising placement
Customer	Sales Supervisor	• Approve request • Fill out the application
Customer	Marketing Manager	• Approve budget • Generate approval • Validate advertising placement

Customer	Procurement Manager	• Approve correct *pro forma* • Generate purchase order

Do: The regression equation is used to forecast sales according to the time it takes to place the advertising element.

$$b = \frac{N\sum xy - \sum x \sum y}{N\sum X^2 - (\sum X)^2} = -1{,}006.22 \quad (5)$$

$$a = \frac{\sum y - b\sum x}{N} = 10{,}703.20 \quad (6)$$

$$Y = a + bx \quad (7)$$

$$Y = 10{,}703.20 - 1{,}006.22x \quad (8)$$

According to the process flow, activities are established according to their phases and the time required by each one. Thus, the number of days spent by each defined process is shown.

Table 2: Estimated Time per Phase

Year	**2019**
Phase 1: Request Collection	
Activity	***Estimated Time***
Enter advertising request	2
Phase 2: Justification for Request	
Evaluate POS and forecast required amount	4
Fill out the application	3
Phase 3: Application Specifications	
Manage route	4
Generate photomontage	4
Budget investment amount	2
Generate approval	2
Phase 4: Request Approval	
Generate approval letter	4
Communicate budget disapproval	1
Receive approvals	1
Phase 5: Processing and execution	
Start processing	19
Finish processing	19
Execute placement	15
Enter 3 proformas	1
Approve proformas	0.5
Generate purchase order	1
Phase 6: Verification and quality control	
Monitor advertising placement	1
Generate final report	1
Validate advertising placement	2.5
Total days	87

Check:

Table 3: Regression Statistics

Multiple Correlation Coefficient	94.4%
R-Squared Coefficient of Determination	89.2%
Adjusted R-Squared	88.9%
Standard Error	241.9
Comments	40

Table 2 and 3 show the high influence between time and sales (94.4%).

The shorter the time, the greater the sales, as advertising will be found from the beginning of the campaign and not days later as shown in Table 4.

Table 4: Sales Forecast According to Advertising Placement Time

***Y* = 10703.20–1006.22 x**	
Sale (PEN)	***Time (Months)***
6,678.34	4
5,672.12	5
4,665.91	6
3,659.69	7

With increase in the placement time of an advertising item, sales will decrease. Therefore, the model is aimed at reducing placement time.

Act

Table 5: Indicators

Year	**2018**	**2019**
PT	66%	75%
	50%	100%
	58%	100%
RT	43%	75%
	30%	50%
	88%	97%
	22%	44%
PE	75%	87.50%
GA	80%	88.80%

First, the PT indicator increased to 75%, but remains at a regular level over the time the item placement process is regular. Second, the RT indicator shows the change in level from regular to optimal in phases 1 and 2 (100%). Phase 3 increased to 75%, from a poor level to a regular level. Phase 4 increased to 5%, but remained at a poor level. Phase 5 went up to 97%, remaining at an optimal level. Phase 6 increased to

44%, but remains at a poor level. Third, PE stood at 87.5%, improving from its regular level to an optimal level. Fourth, the GA indicator amounted to 88.8%, remaining at an optimal level.

Conclusions

We applied the model in three additional scenarios to implementation. With respect to indicator 1, the result in scenario 0 (75%) is not far from the average analyzed in the four scenarios (68%). This analysis shows that the model used to measure outdoor advertising placement effectiveness can be applied to any advertising item. However, we recommend the collection of process information with other items to adjust total time to a future final process.

Indicator 2 (78%) is not far from the average analyzed in the four scenarios (71%); the analysis shows that the model used to measure the effectiveness of outdoor advertising placement can be applied to any advertising item, since the proposed phase time has been determined with maximum placement times.

The analysis of indicator 3 shows that the average of the four scenarios is 100%, which, when compared with the application scenario—scenario 0—indicates a significant difference, as this result was 79% getting a result or so optimal considering another type of item in work effectiveness. Thus, we believe we did not measure some external factors that generate this variant with respect to scenarios.

Indicator 4, which refers to GA, shows that according to the analysis, the average is below the required target of 72%, and the result obtained from scenario 0 was 75%, which is also not far from average. This analysis shows that the effectiveness measurement model complies with the measure of GA ultimately reflected in sales.

Abstract

Currently, the chemical sector continues to consolidate itself as one of the key business sectors of the Peruvian economy, especially as its products are on high demand as essential components used by other industries, such as construction, mining, and textile. This reflects the great responsibility that chemical companies have regarding efficiently managing their material and human resources, which includes assessing productivity in terms of growth rates and levels. Within this context, Lean Manufacturing tools are used to measure these indicators and propose improvements and/or solutions that may generate added value to the company. However, Peru does not report a wide variety of research that focuses on the chemical industry productivity. In this light, this study proposes using the abovementioned tools to assess the current situation and determine opportunities for improving production processes in this industry. However, the literature review also reveals that Lean projects may sometimes not be successful owing to implementation issues. Therefore, this proposal will be developed using an agile approach to quickly make decisions in the event of any problem. This model was validated through a pilot run at a small Peruvian chemical company, which reported low productivity issues owing to idle operator times, non-conformities with production requirements, reprocesses, and poor purchasing planning. The pilot implementation was conducted for a month and the results were assessed through a simulation, which reflected an increase in productivity coupled with a decrease in reprocesses and service levels.

Keywords: Agile, Lean Manufacturing, Chemical-sector, Scrum

Introduction

In 2017, the chemical industry contributed $1.1 trillion to the global GDP, effectively becoming the fifth largest production sector in the world. (ICCA, 2019) Moreover, the chemical industry has recently played a key role in Peruvian exports, ranking third among the economic sectors in 2017.

(Posada, 2018) According to a recent study, there are 3,744 small and medium-sized chemical companies in Peru, accounting for 86% of all companies operating within the sector, and all of these companies largely depend on increasing their product exports. (SUNAT, 2017) However, their growth rate is often affected by deficits caused by low process productivity. Therefore, the lack of technological advancement and innovation must be offset through the application of new development trends aimed at streamlining and optimizing production processes and avoiding unnecessary expenses that could decrease their profits. (Posada, 2018)

Given the importance of guaranteeing competitiveness for the chemical industry, the operational plan for the chemical sector proposes the following eight objectives: (i) to adapt legal and technical standards for the needs of the sector, (ii) to promote research and associativity within the chemical sector, (iii) to train highly qualified human resources, (iv) to foster the development of petrochemical complexes, (v) to increase value-added product exports in the chemical sector, (vi) to endorse specialization in products with export potential, (vii) to develop an efficient business intelligence system, and (viii) to encourage new products and exporters. These objectives are embodied in specific action items assigned to individual owners and employees. (MINCETUR, 2016)

Lean Manufacturing is effective in achieving desired results for any organization. Moreover, several authors confirm that the selection of Lean Manufacturing as the system of choice for improvement is quite unanimous. (MINCETUR, 2016) (PRODUCE, 2015) The transformation capabilities of Lean Manufacturing do not depend on the size of the organization. Therefore, the proposed model is aimed at improving the operational productivity in small and medium-sized chemical businesses. The pilot implementation will be performed at a Peruvian company that produces adhesives and their accessories and has reported low productivity issues owing to operator downtimes, non-conformities with production requirements, reprocesses, and poor purchasing planning. The development of the Lean model will also be grounded on the Scrum agile development approach, which is easy to understand and will follow Lean action plans to ensure quick responses to any market changes that may arise.

This paper is structured as follows: state of the art (correlation between the results from previous research studies), contribution (methods and tools), validation (results) and conclusions.

State of the art

Production Management in the Chemical Sector

Acquiring knowledge on advanced production management systems (Materials Requirements Planning (MRP), JIT, OPT, TOC, and others) can help improve customer service, result in greater inventory control, and leverage other benefits related to production costs and quality. (Matias, 2013)

Renowned authors have used Lean tools and managed to implement an 18%–25% reduction in downtimes as well as reported an 8%–12% increase in productivity. (Xavier, 2015) (Hai, 2012) Some authors are committed to the development of a production management strategy in which market demands and manufacturing capacities are utilized for observing problems arising during the purchase and sale analysis. These authors assess the company and discuss the technological improvements that could be beneficial for it, concluding by providing feedback and repeating the cycle to determine opportunities for improvement. (Saravanan, 2017) (Marmolejo, 2016)

Lean Tools used in the Chemical Sector

Lean tools improve the production capabilities of manufacturing companies through a group of tools and measures adapted for different crises that the company could face. (Szwejczewski, 2016) Currently, renowned authors of scientific papers have reached different conclusions regarding the use of these tools within the sector. Many of them argue that the application of Lean tools such as VSM, 5S, and KAIZEN may help decrease the downtimes, improving company productivity. (Feldman, 2013) (Silva, 2014) However, other authors state that implementing Lean in the chemical sector increases profitability, reduces costs, increases customer satisfaction, provides greater environmental protection, and improves skills, morale, and job satisfaction among workers. (Amrina, 2017) (Fredj, 2016)

On the other hand, the benefits from standardized work include the documentation of changes to current processes, decreased variability, easier training of new operators, less number of injuries and stress, and a baseline for improvement activities. (Muganyi, 2018) (Szwejczewski, 2016) This tool could also facilitate problem solving (Cournoyer, 2013). Similarly, through work standardization, other authors have been able to reduce the cycle times by over 20% when removing non-value-added activities from the final product, thereby increasing their productivity by approximately 10%. (Pereira, 2016) (Wigglesworth, 2012). However, despite being an extremely useful tool, its use is usually neglected either because of outdated methods or lack of training; therefore, there must be an update plan for each tool that is implemented. (Miroslava, 2016)

Agile Approach in the Chemical Sector

The agile approach is not only based on Continuous Improvement but also seeks to redesign project development approaches, allowing simultaneous execution in project cycles. (Nallusamy, 2016) Moreover, as it is an adaptive process, the Scrum agile methodology can manage projects in a more efficient manner. (Mor, 2016)

Although Scrum was designed primarily for software development, it can also be used for managing non-technological projects as evidenced by authors who have used Scrum to improve project development in terms of problem solving and assigning tasks to stakeholders. Furthermore, the limited studies wherein this methodology has been applied to the production sector have reported good results; however, no other studies that specifically focus on the chemical industry have been found. (Angappa, 2018) (Hu, 2009) Implementing the agile approach in a small company may have certain limitations owing to external interruptions. As these companies usually have limited number of employees, each one often plays more than one role in the organization. Therefore, project stakeholders are usually interrupted by issues related to other projects. (Omer, 2018)

Lean Production Management in the Chemical Sector Using Agile Approaches

Production management implementation involves determining certain functions such as MRP, Warehouse Management, Manufacturing Equipment Management, Workshop Management, Documentation Management, and Knowledge Management. (Matías, 2013) Supporting Lean Manufacturing principles with an agile approach can achieve productivity gains and improvements in customer satisfaction as well as develop capabilities for providing quick responses to market changes. (PRODUCE, 2015) (Paasivaara, 2016) During the actual application, adapting an agile or Lean environment can generate opportunities for improving profits up to 12%, considering low-variation demands and small production batches. (Breno, 2015) An essential project monitoring

component is the integration of Kanban boards or monitoring programs, like Trello, which can be used in any type of planning or organization. This application, in addition to supporting Scrum processes, has a number of advantages, including making progress visible to the entire team and adding details to each task (for example, comments, checklists, due dates, and attachments). (Sunil, 2015)

Contribution

Rationale

In this section, three typologies previously used will be analyzed, as well as the model used and the results obtained (Table 1).

Table 1: Rationale Summary

Typology	Production Management in the Chemical Sector Model	Lean Tools used in the Chemical Sector	Agile Approach in the Chemical Sector
Model	Strategy Implementation in a Manufacturing Network	Lean Model for Cost Reduction	Scrum Model for Project Development
Results	Increased production plant efficiency	Higher profitability and lower costs. Higher customer satisfaction.	Problem Resolution and Task Assignment

Regarding the first production management typology in the chemical sector, we found a paper that implements a manufacturing network strategy. This strategy aimed to increase the production plant efficiency and has proven to be replicable in most manufacturing industries, including the chemical sector. On the other hand, we have the typology of Lean tools that have previously been used in chemical companies. In this branch, there is a Lean model for cost reduction that increased profitability and in turn reduced costs by improving customer satisfaction.

Proposed Model

Fig. 1: Lean Manufacturing model using an agile approach

Model Components

- Stage 1: To start with the implementation of an Agile model, a team comprising a project owner, a Scrum master, and project members must be formed.
- Stage 2: Subsequent to establishing a team, the project or product owner will be responsible for providing the objective to be achieved and its corresponding requirements. These requirements are broken down into stories, where a priority order will be established for tasks required for completing the said requirement, in addition to determining the work cycle length.
- Stage 3: Depending on the task priority, the team starts rating the tasks based on a pivot activity, which is a simple task that everyone can perform. The score is given through the SCRUM POKER prior to the team selecting who would perform each activity based on the number of work hours required and how much the team members are able to work during the sprint.
- Stage 4: Once the tasks to be executed during the cycle have been planned, Lean Manufacturing tools are used to diagnose the current process status. At the end of the cycle, the progress made by the team will be communicated to the stakeholders, the Scrum Master, and the Project Owner, so that they can provide feedback and incorporate the necessary changes to the project and/or the product.
- Stage 5: The previous step is repeated for a maximum of four times, wherein the tangible and intangible results of the project may be observed.
- Stage 6: Finally, the completed project is presented to the project owner.

Proposed Method

The proposed flowchart is shown in Figure 2.

Fig. 2: Design flowchart

Indicator

To measure and monitor the improvements implemented as a part of this study, proposal indicators were established. The results are divided into three colours as shown in Table 2 and Table 3.

Table 2: Colour meanings

Within Control	Moderately within control	Outside of Control. Critical

Table 3: Traffic light indicator

Indicator	Formula	Results		
		Optimal	**Regular**	**Dangerous**
Downtimes	$\frac{Downtime}{Operation\ Time} x\ 100$	<=10%	<=15%	>15%
Defective Containers	$\frac{No. Defective\ Containers}{Total\ Number\ of\ Containers} x\ 100$	<=2%	<=4%	>4%
Product Reprocesses	$\frac{No. of\ Batches\ Reprocessed}{No. of\ Batches\ Requested} x\ 100$	<=1%	<=3%	>3%
Internal Audit Progress	Audit Score	>=50	>=40	<40
Shortage of Production Containers	$\frac{Times\ containers\ are\ missing}{No. of\ containers\ required} x\ 100$	<=5%	<=10%	>10%
Conformity with Product Requirements	$\frac{Units\ Addressed}{Units\ Requested} x\ 100$	>=90%	>=75%	<75
Productivity	$\frac{Units\ Produced\ (kg)}{Time\ Dedicated\ (hr)} x\ 100$	>=60 kg/hh	>=50 kg/hh	<50 kg/hh

Validation

The proposed improvement was validated both through a pilot implementation and an Arena software simulation.

Validation Through Pilot Implementation

To validate the expected results, a work standardization pilot was implemented using the three tools proposed in section III: the 5S, PA, and MRP. The traffic light indicators are presented below, wherein the original values recorded prior to the improvement are compared against the expected values and the results from implementing the tools proposed in Table 4.

Table 4: Validation of traffic light

Indicator	Current Value	Expected Value	Actual Value
Downtimes	25%	10%	12.54%
Defective Containers	5%	2%	4%
Product Reprocesses	5%	1%	2%
Internal Audit Progress	17	40	45
Shortage of Production Containers	25%	5%	10%
Conformity with Product Requirements	73%	90%	84%
Productivity	**53 kg/hh**	**60 kg/hh**	**57.8 kg/hh**

As observed in the indicators, operator downtimes decreased from 25% to 15%, thereby placing them within the (yellow) range as the study expected to obtain downtimes of 10%. As for the number of defective containers received, it was possible to detect 4% of abnormalities in the batch that supplied the plant. Regarding the audit score, there is an improvement in the implementation of the 5S, yielding a 50% increase between the final score as compared with the original score.

ARENA Software Simulation

To chart the proposals and obtain results from the changes implemented, AS IS and TO BE simulations were executed to compare times. For these purposes, process times were considered as variables.

The results subsequent to the simulation and exhibited in Table 5 and Table 6 revealed a notable reduction in downtimes and an increase in value-added times.

Table 5: Statistical analysis by scenario and indicator

Time	
VA time 1	Average
Entity 1	776.90
Wait Time	Average
Entity 1	16464.71

Table 6: Statistical analysis by scenario and indicator

Time	
VA time 1	Average
Entity 1	799.01
Wait Time	Average
Entity 1	3294.84

A 3% increase was reported for value-added times, whereas non-value-added times decreased by 80%.

This implementation expected to achieve the green levels that have been established in the traffic light indicators. For these purposes, the indicators obtained both from the pilot implementation and the simulations were measured. The results are denoted below.

Conclusions

This study addressed the low productivity issues reported by companies operating within the chemical industry. Based on this context, a case study of a small producer of adhesives and their accessories was assessed, including an in-depth analysis of the causes responsible for low-operational productivity. Similarly, subsequent to reviewing the existing literature, the implementation of a production management model supported by Lean tools was proposed owing to its numerous success stories reported worldwide.

Abstract

The most important determinant for future labour market trends is technological change. Although the evolution of digital technologies has already gained momentum, the main impacts of this new era of technological change remain largely in front of us. Given this, it is essential to understand what are the impacts caused by digitalisation in the labour market. The purpose of this work is to conduct a systematic review of the literature of how the emerging digital technologies may influence the gaps of the labour market. This understanding may allow an assessment of the spread of skills and the persistence of unemployment, and if these situations are absent, slowed down or intensified by digitization. Evaluate the relevance of digitization for structural issues in the labour market, focusing on topics such as recruitment difficulties and skills shortages, persistent unemployment and changes in forms of employment. The relevant drivers of the identified structural issues can serve as a basis for the development of a region that is facing structural problems in the labour market caused by digitalisation. In addition, it can assist a region that needs highly qualified human resources and is aware of the type of workers it wants to attract, as this identification helps to predict skill gaps and develop training. The conclusions can be used to align companies' strategies and public policies to generate greater efficiency and success in the search for sustainable growth solutions in a regional economy.

Keywords: Digitalisation, Impact of Digitalisation on the Labour Market, Problems of Digitalisation on the Labour Market.

Introduction

The future of work depends on several factors, such as the long term and demographic development (Walwei, 2016). Currently one of the key drivers of competitiveness are the technological changes associated with the digitization, notably the adoption of digital logic circuits and their derived technologies, including computers, intelligent automation and information technology (IT). These changes will lead to considerable changes in the employment structure, for example, in what concerns the characteristics of production, professions and relevant skills (Walwei, 2016). Thus, the economic development of countries depends directly on the consequences of digitalisation processes, and the answers to its emerging demands (Plutova, Lagutina and Sadkova, 2019).

A country's readiness for the digital economy is largely determined by the network's readiness index, the Information and Communication Technologies (ICT) development index, the cybersecurity index, the digital compatibility index and the digital evolution index (Plutova, Lagutina and Sadkova, 2019).

According to Acemoglu *et al.* (2018), automation succeeds trough the replacement of human labour. This type of substitution has a direct displacement effect, reducing the demand for labour. According to the same author, if the effect of this displacement is not counterbalanced by other economic forces,

it will reduce the demand for labour, wages and employment (Agrawal, Gans and Goldfarb, 2019). However it has been acknowledged that with the development of the digital economy, people management functions are not minimized, but on the contrary, they acquire greater importance (Plutova, Lagutina and Sadkova, 2019).

Increased productivity due to new technological changes affects processes, products and prices. More efficient processes tend to cause reductions in rationalization and work, while the emergence of new products is often associated with new jobs (Shkodinsky *et al.*, 2019). Price reductions due to technological changes have the potential to create new demand in two ways. First, due to lower prices, economic agents can spend money elsewhere, which can generate demands in other areas of the economy. Second, depending on the elasticity of demand, a price reduction for a given product can have adverse impacts. Therefore, digital technologies have been considered an advantage with important future gains in productivity (Shkodinsky *et al.*, 2019). This nullifies the threat of massive technological unemployment due to digitization. However, the obsolescence of (technological) skills can be a much more realistic challenge for companies and the labour market (Walwei, 2016).

In this context, the regional labour market is subject to positive and negative changes, which are a response to the economic and political phenomena that occur in the country (Astafurova, Borisova and Kulagina, 2019).

In a recent study by Astafurova (2019), addressing the digitalisation process of the labour market in the Volgograd region in Russia, the author emphasises that the need for staff with digital skills exceeds the volumes available in the labour market. Furthermore, the author proves that the successful adaptation of the labour market to the technological changes that have occurred in the economy of the Volgograd region are associated with socially responsible restructuring. Advanced recycling of workers' skills and continuing professional education were the most important aspects of such restructuring (Astafurova, 2019).

In this context, companies increasingly report that the limited availability of skills imposes a barrier to corporate investment. Skill constraints can negatively affect labour productivity and hinder the ability to innovate and adopt technological developments (Zhuravleva, Grigoryan and Riet, 2019). Lack of the right skills can limit prospects for employability and access to quality jobs. In general, persistent skills gaps and incompatibilities have economic and social costs (Dodel and Mesch, 2020).

On the other hand, Kolokytha *et al*. (2018) argues that despite the concern about the fact that automation may result in job losses, in many countries there is a serious problem of labour shortages. This means that digitization can really be a solution to the problems of the labour market and instead of a social and economic problem (Kolokytha, Kolokythas and Perdiki, 2018).

The mismatch of skills at the macro level refers to the gap between supply (aggregate) and demand for skills. This usually refers to a specific geographical unit (region, country or group of countries) and to the fact of the correspondence between available workers, jobs offered by companies in terms of skills and / or qualifications are not ideal. Skills mismatch at the micro level occurs when workers have a different skill level than necessary for the job (Walwei, 2016). Skill shortages arise when employers are unable to recruit employees with the necessary skills in the affordable labour market and with the continuous rate of pay and skill surpluses occur when the supply of certain skills exceeds demand (Pulkka, 2019).

For Acemoglu *et al.* (2018), in the traditional view, workers with good skills are protected in the automation process. This happens since according to the author, they are retained by the system because they are more able to qualify for more complex tasks that require human judgment, problem solving, analytical and personal skills.

If, in addition, the change in the structure of labour supply by skill level is considered, we should expect an increasing share of academics in the working age population. For this reason, long-term projections

reveal likely bottlenecks, especially with regard to occupations that require medium skill levels (Walwei, 2016).

As the digitization of the economy will affect the quality and composition of jobs, changes in priorities for professions, necessary skills and inequalities must be the subject of debates in the processes of digitization of the economy. In this way, the government plays a necessary supporting role (Astafurova, Borisova and Kulagina, 2019).

Considering the previously mentioned, this study offers a contribution for the understanding of the impacts of the implementation of digitalisation in the labour market. The study tries to highlight the most important trends, building on asystematic review of the recent literature on topics discussed about the future of work.

An up-to-date survey on digitalisation and the labour market

This study employs a method of systematic literature review. Literature reviews depend on a systematic process to identify and develop an interpretation of contributions from previous research. The purpose of this type of study is to provide a summary of the existing literature, identifying patterns and themes, thus contributing to the development of the theory and the identification of lines of research. This work used an inductive approach to synthesize existing research on the impacts of digitization on the labour market to extract knowledge about the impact of the implementation of new digital technologies.

The selection of articles was based on the following criteria. Firstly, research was carried out using the keywords: "problems of digitalisation on the labour market" and "impacts of digitalisation on the labour market", "automation impacts on the labour market", "impacts of industry 4.0 on the labour market", "impacts of digital transformation on the labour market". For the search, the following databases were used: Scopus, ISI Web of Knowledge and academic research at Google. Next, we examine the bibliographic references of the identified articles to find additional works that the previous research was unable to capture. Then a screening was carried out to remove duplicate articles or articles considered not applicable.

The selection and refinement process lead to a final sample of 50 works published in the last 3 years (2018 to 2020), that addressed issues related to the digitization process and the labour market. Of these 50 works, eight were published in 2018, thirty-two in 2019 and ten in 2020. In addition, we selected the digitalisation impacts used in these 50 research outputs and performed a word frequency analysis of the abstracts works to find out dominant impact topics. For better visualization of this analysis a word cloud was created. The word cloud was built through the pro word cloud, which is a Windows extension for the office package. This method was chosen because it allows, through graphic resources, to perceive through the size of the words what is their frequency in bulky hypertexts.

The results reveal the mastery of words, which are shown in figure 1. From these words, we selected the 4 main impact themes related with digitalisation on the labour market: demand for new competences and skills, employment, inequality and wages.

Fig. 1: Word cloud of the dominant words

After the analysis of the main keywords, the works were again analysed to identify which works debate which theme, in order to help this and future research (Appendix 1). The classification in figure 2 allows the comparison between the main impact topics/ themes find with most frequency in research outputs. The employment (45%) and demand for new competences and skills (37%) are the most explored impacts of digitalisation on the labour market, followed by wages (11%) and inequalities (7%).

Fig. 2: Distribution of the most frequent topics/themes across the 50 works

Furthermore, the main themes identified were crossed with the countries in table1. This table allows for a better understanding about the prevalence of the main themes relating to digitalisation on the labour market, by country. The results suggest a particular prevalence of words referring to Russia investigating the impacts of digitalisation on the labour market. This suggests that Russia gives a special attention to the process of implementing digitalisation in the economy. Regarding the impacts, we can see that employment and demand for new competences and skills received greater prominence. This can be a path on which countries must dedicate themselves when going through the digitisation process.

Table 1: Cross tabulation main impact themes and countries

Impact / Country	**Employment**	**Demand for new competences and skills**	**Inequality**	**Wages**	Total
Bulgaria	1	1	0	0	2
Canada	0	1	0	0	1
China	3	0	0	1	4
Czech Republic	0	1	0	0	1
Denmark	1	1	0	0	2
Finland	2	1	0	0	3
France	3	0	0	0	3
Germany	2	1	1	1	5
Greece	1	1	0	0	2

Total	37	30	6	9	82

Employment

The available labour market scenarios show several trends in relation to the future and the development of employment. According to Palier (2019), employment in services and employment in manufacturing increase. The same authors also state that there are indications that, in relation to employment levels, particularly management-oriented services and the health sector will gain importance. Likewise, the demand for specific occupations (for example, doctors, nurses, management consultants) in these sectors will also increase (Palier, 2019)

According to Rogulenko *et al.* (2019), the future of the labour market under digital economy conditions is influenced by two factors. First, demographic trends in the socio-economic system, which determine the structure of digital personnel, their accessibility and level of digital skills mastery. And the second factor is the automation of production and distribution processes, which leads to a reduction in the demand for digital personnel in the labour market due to the competition between intelligent machines and digital personnel (Rogulenko, Ponomavera and Krishtaleva, 2019).

The introduction of the digital economy and modern innovative technologies brings the need for professional readiness of graduates from educational institutions to work according to information

skills, which will lead to a more efficient use of work resources and, as a result, to increase labour productivity in all sectors of the economy. Improving the quality of work and achieving a balance between supply and demand for the regional labour market will be facilitated by a timely response to changes in its quantitative and qualitative composition (Astafurova, Borisova and Kulagina, 2019; Pulkka, 2019).

Dobel and Mesch (2020), in his work on "Perceptions about the impact of automation in the workplace", indicate that individuals employed in jobs involving manual or physical tasks had more negative perceptions regarding the impact of technology on their careers, whereas those involved in managerial and data analysis tasks reported more positive views. Young employees with higher incomes and more education, who use the Internet almost constantly, expressed more positive views of technology's impact on their jobs. Nonetheless, technological unemployment and under-employment were associated with age, income, race and negative perceptions regarding the intrusion of new digital technologies on the workplace.

The introduction of digital technologies contributes to the formation of a class of workers with partial or temporary employment and transforms the working process itself into a set of small operations that make up the skills of the new professions. This brings about changes in the relationship between workers, employee and employer (Astafurova, Zapryagaylo and Kulagina, 2019; Basu, 2019; Zhuravleva, Grigoryan and Riet, 2019).

It is important to identify all structural changes caused by the labour market, especially at the regional level. For this assessment, the demand model in a regional labour market must contain at least three main components: parameters of compliance of the skills required with the digital technologies introduced in the region; built-in mechanism for analysing indicators of territory development and personnel compliance; a temporary matrix to generate new skills, taking into account all educational systems (Zhuravleva, Grigoryan and Riet, 2019; Xu, Chin and Cao, 2020).

Expected changes can also lead to additional demand for highly skilled workers (academics), slightly less demand for workers with medium skills (graduates) and considerably less demand for workers with low skills (Basu, 2019).

The study by author Houngbonon and Liang (2018) on France on the impacts of broadband Internet on employment showed that the direct effect is job destruction. But this job destruction occurs in manufacturing activities, unlike the service sector with the adoption of broadband on the Internet creates jobs, which in the end does not affect the unemployment rate (Hounbonon and Liang, 2018).

An interesting question about the impacts of technologies on the labour market is the analysis of who will be affected in the substitution of work by digitalisation processes. The authors Zhou *et al.* (2020) make this approach of substitution by occupation in the Chinese labour market. The results of this study show that artificial intelligence is more likely to be substituted in jobs performed by women, workers with advanced age, low education and low income (Ito, 2019; Zhou *et al.*, 2020).

The approach on the subject of replacing workers by occupation is also made by the author Fedyaeva (2019). For these authors, robots and bots can replace routine production work, but all creative and innovative activities will never be automated. The massive introduction of robots and computers allows the labour market to reach a new level, and domestic workers can meet international criteria and standards through retraining and additional training (Fedyaeva, 2019).

In the substitution of labour, we can also see that at the regional level, it is clear that urban service centres and some rural areas have a much smaller share of employees working in a highly substitutable occupation compared to manufacturing regions (Dengler, 2019). This difference in the ratio of the impact of labour substitution between regions can be corrected. Close monitoring of future labour market developments and (further) education are of great importance in meeting the challenges of the digital transformation (Dengler, 2019).

The implementation of technology in the labour market not only causes the effect of job substitution, according to the authors Fossen and Sorgner (2019), there is also the transformative effect. Transforming digitalisation for these authors alters the content of occupations without necessarily replacing human workers (Fossen and Sorgner, 2019).

A study conducted in Switzerland by the authors Balsmeier and Woerter (2019), points out the increase in investment in digitization is associated with an increase in the employment of high-skilled workers and a reduction in the employment of low-skilled workers, with a slightly positive net effect. This evidence improves the understanding of the possible economic implications of the digitization process, where digital technologies constantly change production methods and generate new products and services. The advancement of machine-based digital technologies requires a better technological infrastructure (faster Internet connections, ubiquitous Internet access, cloud technologies, etc.) and this knowledge develops technologies and workers sufficiently skilled to use them effectively (Aghion, Antonin and Bunel, 2019; Balsmeier and Woerter, 2019; Cijan *et al.*, 2019).

Different skill levels and digital technologies affect the demand for work and the speed of scanning. This can cause not only the destruction and transformation of jobs as already mentioned, but can also bring about new forms of work (freelance, remote employment), as an impact we have on the breakdown of organizations and the active use of outsourcing, which can cause job insecurity (Bannykh, 2020). In this sense the government role in the field of education, skills and jobs is necessary to balance the labour market and create digital capital (Bannykh, 2020).

Another point about the implications of technology at work is related to productivity (Acemoglu and Restrepo, 2019a). New technologies not only increase the productivity of capital and labour in the tasks they currently perform, but also affect the allocation of tasks to these production factors - what we call the content of the production task. Changes in the content of the production task can have important effects on how the demand for labour changes and also on productivity (Acemoglu and Restrepo, 2019a; Ismail, 2019).

Shkodinsky (2019) points out that human resources are responsible for the sustainability of digitalisation. They have the potential to stimulate the development of labour and entrepreneurship, which can ensure that the increase in the standard of living of the population accelerates the rate of economic growth.

Demand for new competences and skills

The relationship between technology and employment is mediated by the organisation of work, the reconstruction of professionals, skills and learning, human resources management, social dialogue, economic and social processes of diffusion and the adoption of innovations. Technology is just one of the factors that shape the future of employment (Lebedeva, 2019).

The digital transformation is not just about implementing new technologies. Digital tools are one of the edges of this transformation that must be accompanied by a digital mindset by people who use technology daily. If they are not compromised, digital transformation will not have a strong impact on the organisation and the economy (Astafurova, Borisova and Kulagina, 2019; Habanik, Grencikova and Krajco, 2019). When talking about digital skills, we refer to the ability to use technological knowledge and skills to optimize processes and make them increasingly efficient (Astafurova, Borisova and Kulagina, 2019).

These changes will have a major impact on the required qualifications and the job market in general, considering the social aspects of these impacts (Skoludová and Cerovská, 2018).

Specifically, investment in human capital is the necessary mechanism to face technological progress. New skills are needed, especially light skills, some basic skills that must be developed to facilitate learning or faster knowledge acquisition: content skills such as active learning, oral expressions, reading comprehension, written expression. As well, literacy and ICT process skills such as active

listening, critical thinking, self-monitoring and interdisciplinary skills are also very important (Walker, Bowkett and Duchaine, 2018; Maimina *et al.*, 2019).

Pulkka (2018), in his study on future prospects for the Finnish digital labour market, points out that younger generations have a more optimistic view of the labour market. The same survey pointed out that workers believe that educational reforms with acquisition of new skills are decisive to combat technological unemployment (Pulkka, 2019).

Minimising the negative impacts of digitisation on the labour market as technological unemployment in Sweden should also be tackled by acquiring new skills according to Ismail (2019). These authors state that there is an emerging need to reform the structure and content of the educational system to provide the skills and competencies needed to compete in a world of digitalisation. This concerns both the role of higher education and secondary education, as well as discussions about new structures for adult education to facilitate career development and lifelong or continuing learning (Ismail, 2019).

An interesting approach to the acquisition of digital skills is the one advanced by Joseph (2020) in the study on the impact of digitalisation on the professional performance of employees. The study states that younger people are more adaptable and with a positive approach towards learning and digitalisation when compared with more experienced employees. This shows the positive sign that young people are showing a willingness to know and study modern tools and prepare for the digital future (Joseph, 2020).

Lladós-Masllorens (2019) states that there is a biased technological change, which requires professionals with a complex set of skills. Digital technologies are inciting a task-oriented technological change, decreasing the demand for workers who perform routine tasks (Lladós-Masllorens, 2019).

Horbach and Ramer (2020) in their work on labour shortage and innovation claim that a shortage in the supply of qualified labour can, therefore, prevent innovation activities, resulting in lower productivity gains. Innovative companies are likely to be subject to skills shortages and skills shortages lead to the cancellation of innovation projects. The effects are strongest in the lack of labour related to professional occupations and less in academic qualifications (Horbach and Rammer, 2020).

There is an urgent need for substantial spending on human resources to take steps to ensure the timely digital transformation of the labour market (Astafurova, Zapryagaylo and Kulagina, 2019). Close monitoring of future labour market needs and (additional) education appear to be of particular importance in addressing the challenges of digital transformation (Cirillo *et al.*, 2019; Habanik, Grencikova and Krajco, 2019; Kutsuri *et al.*, 2019).

The ideal scenario understood by Astafurova *et al*. (2019), has several aspects, among them, maximum provision of the labour market with qualified personnel, maximum acquisition of digital skills, minimization of unemployment, minimization of labour migration (Astafurova Olga, Borisova Anna and Kulagina Irina, 2019).

Inequality

Digitization, artificial intelligence and automation have the potential to change the nature of production processes, increase productivity and reshape labour markets. On the other hand, because they occur at a time of low real wage growth and a drop in labour participation in national income, technology can generate insecurity and doubts. As with most periods of technological interruption in the past, this trade-off between income gains and distribution costs should pose significant challenges (Mönnig, Maier and Gerd Zika, 2019).

Digitization can exacerbate the problem of income distribution and the main problem is that the potential increase in the prosperity of the use of robots is not distributed fairly, since it benefits only a portion of the population (Krämer, 2019). Ownership of capital is already highly concentrated today,

if the main beneficiaries of robotization are a small number of capital owners, the vast majority of workers do not participate in wealth and this further exacerbates economic inequality (Krämer, 2019).

The increase in wage inequality is already implemented due to structural and demographic changes (Genz, Janser and Lehmer, 2019). The digital transformation reinforces the impact of structural changes on wage inequality, especially in the long term, as the growing demand for highly qualified employees is reflected in the increase in wage inequality (Genz, Janser and Lehmer, 2019). However, the relatively low impact of digitization on low-skilled employees prevents a further increase in wage inequality (Gurova, Laas and I, 2018; Krämer, 2019; Mönnig, Maier and Gerd Zika, 2019).

For the author Nafchi and Mohelská (2018), the industry 4.0 is particularly useful in very developed countries with regard to competitive advantage because wages are high in such countries. In developing countries like Iran, wages are low, there are relatively high levels of unemployment, and substantial developments are required in other basic but vital infrastructures. Automation surges the unemployment rate with no regards for how well a country is developed. The mere difference is how large is the magnitude of the impact of this change on the economy of the country, and whether or not that country is able to cope with the consequences of such a change (Nafchi and Mohelská, 2018).

To manage the negatively impact or potentially increase performance in the labour market, governments must balance or encourage the qualification and requalification of their human resources (Maimina *et al.*, 2019; Zhuravleva, Grigoryan and Riet, 2019). Labour reforms, investments in digital infrastructure and economic integration can facilitate technological diffusion and efficient resource allocation (Mönnig, Maier and Gerd Zika, 2019).

Meanwhile, labour policies and safety nets can benefit workers. Tax and benefit systems can help ensure that growth is distributed (Korneeva *et al.*, 2020). Education has the main potential to meet the demand for more flexible skills and lifelong learning, especially for negatively affected professionals (Astafurova Olga, Borisova Anna and Kulagina Irina, 2019; Astafurova, Zapryagaylo and Kulagina, 2019; Kelchevskaya and Shirinkina, 2019).

To deal with this, it is necessary to understand the role of technology in transforming new processes of production, productivity and relations in the labour market. However, data on the participation of the digital economy in national accounts and labour market statistics is incomplete, so it is necessary to create new measures of productivity and monitor structural changes, such as new forms of work organized around new digital technologies (Acemoglu and Restrepo, 2019b).

Wages

The sharp increase in digitisation, automation, machine learning and other new digital related technologies leads to an intense debate about their social impacts. How occupation transitions and effects on labour demand and workers' weights are still open questions (Genz, Janser and Lehmer, 2019).

The creation of new tasks and other technologies that increase the labour intensity of production and labour force participation are vital for the continuous growth of wages, proportional to productivity growth (Acemoglu and Restrepo, 2019a).

Acemoglu (2018) in his work on the implementation of automation in the labour market, developed a task-based model in which workers of high and low skills compete against machines in the production and tasks. For the same author, the low-skill automation corresponds to tasks performed by low-skill labour being taken over by capital. Automation displaces the type of labour it directly affects, depressing its wage. Through ripple effects, automation also affects the real wage of other workers. Counteracting these forces, automation creates a positive productivity effect, pushing up the price of all factors. As capital adjusts to keep the interest rate constant, the productivity effect dominates the real wage. While low-skill automation reduces wage inequality, high-skill automation increases wage inequality (Acemoglu, 2018).

Wages increase significantly for highly qualified professions, but wage gains for medium and low-skilled workers do not point to a further deepening of wage polarization. This implies that there are also losses of compensation after the introduction of robots in industries (Nafchi and Mohelská, 2018).

In the work of Genz *et al.* 2019, the results of the estimates of fixed effects at the individual level suggest that investments in new digital technologies at the establishment level positively affect the salaries of the establishment workers. For the authors, investments in new digital technologies increase wages in knowledge-intensive production establishments and knowledge-intensive services. The effects of the salary increase of employees in digital pioneer establishments in relation to the specific reference group of workers in late digital establishments are more pronounced for low and medium skilled workers (Genz, Janser and Lehmer, 2019).

In a paper that seeks to understand some key patterns in the rise of digitalisation in Chinese industry, author Cheng *et al.* (2019) explains that one of the drivers of robotization is the rising cost of labour. Due to the increase in wages and labour costs that generate a high cost for the employer, robotization becomes more attractive (Cheng *et al.*, 2019).

Bessen *et al*. (2019) also conducted a study on the impacts of automation on individual workers in the Netherlands and had the negative impact on wages as a result. Automation at the firm increases the probability of workers separating from their employers and decreases days worked, leading to a 5-year cumulative wage income loss of about 8% of one year's earnings for incumbent workers (Bessen *et al.*, 2019).

To minimize the social risks related to digital transformation in the area of work it is necessary to establish arrangements that support the expected digital development. Actions should be aimed at minimizing the global polarization of the labour market leading to the definitive displacement of the standard form of employment with its atypical forms, such as remote work and outsourcing. Conduct that prevents high technological unemployment related to the rejection of human resources in favor of intelligent robots and further decline in the wage level of remaining human workers (Popova *et al.*, 2020; Putilo, Volkova and Antonova, 2020).

Conclusion

A huge amount of literature has emerged in recent years, in the context of future work. This topic is also the subject of political discussions that determine how the future of work is changing and how we can shape it. The labour market will undergo major changes, but there is still no universal definition of exactly how this will happen. This work offers a systematic view of the topics discussed on the impact themes of digitization on the labour market, highlighting the most important trends.

We can see that the global effects on the quality of employment, working conditions, ways of working are difficult to accurately assess. There seems to be an emerging consensus on the growth of new skills and professions that must demand the sustainability of digital transformation.

The literature shows that the skill set required in old and new occupations will change in most sectors and transform where and how people work. Average wage jobs are expected to be at greater risk of being replaced by smart machines. Digitization presents enormous opportunities, challenges and risks. Managing the challenges and risks of digitization is a joint responsibility of all stakeholders.

Sustainable development is a process of change that aims to ensure that today's needs are met. Without compromising the ability of future generations to meet their own needs. This can be achieved by ensuring that the exploitation of resources, the direction of investment, the orientation of technological development and institutional changes are in harmony and increase the current and future potential to meet human needs and aspirations,. Job creation policies should focus on the final stages of the production chain, characterized by high intellectual performance and high levels of income. Therefore,

the educational system must reflect these trends in order to prepare the young generation for changes in the labour market (Habanik, Grencikova and Krajco, 2019).

Acknowledgments

This study contributes to the Aveiro STEAM City project. The project "Aveiro STEAM City" is led by the Municipality of Aveiro and has the following investing partners: University of Aveiro, Altice Labs, Institute of Telecommunications, INOVARIA and CEDES. This project is co-financed by the Regional Development Fund - ERDF through the "Urban Innovative Actions" program and has a global investment of € 6,115,915, with ERDF support of € 4,892,732.

This work has been in part financially supported by the Research Unit on Governance, Competitiveness and Public Policy - GOVCOPP (project POCI-01-0145-FEDER-008540), funded by FEDER funds through COMPETE2020 - Programa Operacional Competitividade e Internacionalização (POCI) – and by national funds through FCT - Fundação para a Ciência e a Tecnologia. Stablecoins – Potential New Money and Potential New Problems for Regulators

Robert HUTERSKI

Nicolaus Copernicus University in Torun, Torun, Poland
robhuski@umk.pl

Abstract

Cryptocurrencies with a stabilised value called stablecoins are supposed to become the solution to the problem of a significant variability of the value of cryptocurrencies against fiat money. Despite their imperfection, stablecoins are developing dynamically. The aim of the article is to indicate substantial problems of international character that regulators and supervisors of the financial market need to face in the context of developing stablecoins in every country with the access to the internet.
On the basis of the information included in the four main parts of the article, a doubt may arise whether the cooperation of supervisory national and international institutions itself in the style practised so far is enough. It raises the question concerning the necessity and possibility to institutionalise and centralise international cooperation of regulators and supervisors of by its very nature global market of cryptocurrencies and stablecoins.

Keywords: Stablecoins, Cryptocurrencies, Bigtech, Financial Regulation

Introduction

The development of globalisation and the internet has brought about changes in many aspects of our life, and since the first Bitcoin cryptocurrency appeared in 2009, it has also influenced the realm of money and accounts.

The volatility of their price expressed in money issued by the public authorities constitutes a significant problem of cryptocurrencies, which does not let them perform a few important functions typical for money – a store of value, a means of payment and unit of account.

On 16th December 2017, Bitcoin cost USD 19296, exactly one year later, on 16th December 2018, only USD 3271, and another year later, on 16th December 2019, much more, USD 7164. It means that the value of Bitcoin in USD first fell by six times within 12 months, and then doubled its value during the next year (CoinMarketCap, 2020a).

Cryptocurrencies with a stabilised value called stablecoins are supposed to become the solution to the problem of such a significant variability of the value of cryptocurrencies against fiat money. However, the value of key stablecoins functioning currently, though they reduce the volatility of their value against fiat money, is not fully stable yet. As Bullman et al. (2019) calculated, averaging the annualised, standardised seven-day rolling averages from 27 December 2017 to 28 July 2019, the price volatility for Tether USDT amounted to 10%, and for Dai as much as 28%.

Despite their imperfection, stablecoins are developing dynamically. Even Christine Lagarde, the Governor of the European Central Bank and former Managing Director of the International Monetary Fund admitted that significant demand for cryptocurrencies and stablecoins existed, and regulators and supervisors of the financial market should not neglect it (Lagarde, 2019a; Lagarde, 2019b).

The aim of the article is to indicate substantial problems of international character that regulators and supervisors of the financial market need to face in the context of developing stablecoins in every country with the access to the internet.

The first part of the article presents the problem of defining stablecoins, which intends to prove the validity of the question whether building one stable and internationally accepted definition of stablecoins is possible taking into consideration their volatility and dynamic development.

The second part presents an outline of problems appearing when stablecoins need to be classified, which is naturally connected with the problem of their defining, therefore also in the context of the question concerning arrangement and coordination of regulatory and supervisory activities internationally.

The third part includes the key features of the most important stablecoin functioning on the cryptocurrency market, that is Tether. The objective is to show the importance of institutional and transaction connections between entities issuing classical cryptocurrencies and those issuing stablecoins and cryptocurrency exchanges and other intermediaries. Additionally, the aspect of using transnational networks of companies with non-transparent capital links appears. This raises a question concerning the effectiveness of individual national regulatory and supervisory actions in the field of cryptocurrencies, stablecoins in particular, even with quite advanced exchange of information between financial authorities of different countries, but without a strong centre coordinating activities on the global level.

The fourth part concerns controversies surrounding the Libra stablecoin, which, though not existing at the time of writing the article, stirs emotions as does the whole project strongly promoted by social media giant Facebook. An obvious issue how to regulate and supervise combining their basic activity with financial activities (starting with payment services) by BigTech global companies appears alongside Libra. However, a question can also be asked what factors encouraged a global BigTech company like Facebook to promote an unprepared (and certainly not disclosed) in detail venture consisting in creating an alternative global payment system, in fact ignoring financial regulators and supervisors in different countries at the stage of its designing. What are national financial authorities for business giants?

The article is not able to indicate a set of solutions for the described problems or to answer the questions comprehensively. It rather indicates in the author's opinion important directions of financial regulators and supervisors' work, and lines of research which could support socially and financially safe development of stablecoins and the cryptocurrency market.

Taking into account the character of the discussed issue, the descriptive method was chosen. Official publications of institutions regulating and supervising financial markets, particularly in the USA (Fed) and in the euro zone (ECB) were mainly used, as were scientific articles by authors affiliated with those institutions. Recognised websites specialising in the subject matter of stablecoins like CoinMarketCap (2020b), press agencies like Reuters and official publications of companies issuing stablecoins (Tether) or planning their issuance (Libra) were used when presenting the situation on the cryptocurrency market.

What stablecoins are (and are not)

In defining stablecoins, it is commonly agreed that it is a cryptocurrency designed to minimalize the variation in its price (Blockchain, 2019; Blockdata, 2019). However, definitions not underlining the cryptographic character of stablecoins can be found, like for example Bullman et al. (2019) giving them a wider name as "digital units of value". Further on, differences in in relation to what this volatility is to be reduced, or otherwise, to what a stablecoin is supposed to be stabilised. Numerous definitions emphasise the stability of parity of stablecoin exchange into the national currency (fiat currency), into the USA dollar in particular, or alternatively into euro (Bullmann et al., 2019; Blockchain, 2019). Together with the market development, various stablecoin constructions appeared, which intended to

build their international popularity thanks to the exchange rate stability not against one currency, but a basket of many currencies or even based on the prices of raw materials and/or securities. It was reflected in different definitions of stablecoins; however, disagreements appear with reference to the distinction of formulations indicating what the reference point, the anchor for the purchasing power of a given stablecoin should be (BIS, 2019) from the formulations indicating by means of what the convertibility of a given stablecoin is achieved and stabilised (Blockdata, 2019). This problem is also reflected in the ways of classifying the types of stablecoins, which is discussed in the further part of the article.

Therefore, it is not possible to define the essence of stablecoins in one short sentence. Almost each attempt to define stablecoins involves elements of their classification and together with the development of those digital instruments, their new categories appear. For this reason, the following attempt to define the essence of stablecoins reflects the state of affairs at the end of 2019 and may soon require a revision in certain details.

For the purpose of the article, stablecoins can be defined as digital units of value, which are supposed to perform functions possibly similar to those of the current money, mostly using solutions typical for cryptocurrencies and normally based on distributed ledger technology (DLT), blockchain in particular. Stablecoins are supposed to maintain possibly stable purchasing power as regards selected assets when compared to regular cryptocurrencies and other crypto-assets with a high variability of value. Different assets, such as national currency, a basket of national currencies, other financial assets such as securities or monetary gold, non-financial assets such as raw materials (e.g. gold), other cryptocurrencies and other connected algorithms or a basket of the groups of those assets, are the reference point for the stability of stablecoin purchasing power (an imitated unit of value, an anchor) and resources allowing achieving the assumed stability of value (a tool).

In the above attempt to present the essence of digital constructions named stablecoins synthetically, it is not clarified whether they can be categorised as crypto-assets or electronic money (e-money). In relation to the definition of crypto-assets accepted by ECB Crypto-Assets Task Force (2019), those stablecoins which have an identified issuer and in specific conditions can be categorised as e-money under some national legislation should be excluded from it. As a result of such a situation, it is not possible to define clearly whether stablecoins as a category are (or rather can become) money from a formal and legal point of view or are not, since it turns out to depend on the institutional side of their emission and possible other conditions taking into account the specificity of a given country. By its nature, the creators and issuers of stablecoins want them to be considered money and used like it by their purchasers, which is reflected in the suggested working definition of stablecoins.

Types of stablecoins

When the Libra project (mentioned in the introduction) appeared, defining the concept of stablecoin became more complicated. The distinction between the projects with a so far limited international importance for payment systems preceding Libra (together with the two most important functioning stablecoins, that is Tether i Maker/Dai) and by definition a global payment concept of Libra (and possible further initiatives of big tech firms or large financial firms with similarly international scope like Facebook) has become important particularly for central banks and other regulators (Ehrentraud et al., 2020; FSB, 2019). The name ”global stablecoins”, which currently cannot be attributed to any existing cryptocurrency, was created. Equally promising character is manifested by the distinction made by the G7 Working Group on Stablecoins (BIS, 2019) between *retail or general purpose stablecoins that could be used by anyone and wholesale stablecoins used only by a limited set of actors, i.e. financial institutions or selected clients of financial institutions*. There is however a substantial likelihood that, apart from retail and general purpose, a third example of type of stablecoins, business-to-business (or institutional) stablecoin will be created. It will be a stablecoin called JPM Coin “representing a fiat currency” that is USD, announced 14th February 2019 by JP Morgan, one of the biggest financial holdings in the world JP Morgan (JP Morgan, 2019).
However, the types of stablecoins are the most often classified according to the kind of collateral of their value stability. Those collaterals are commonly divided into the following kinds:

1. Traditional collateral (called off-chain – outside blockchain technology)
    1.1. Asset- or commodity-backed
        (gold, securities – e.g. DGX, OneGram, HelloGold, SendGold)
    1.2. Fiat-backed
        (currencies issued by the central banks: USD, EUR, etc. – e.g. Tether, USD Coin, Gemini dollar, TrustToken)
    1.3. Asset-and-Fiat-Backed
        (mix of gold or other precious metals, securities and fiat currencies – e.g. Libra?)
    1.4. E-money
        (becoming an EU electronic money institution – e.g. Monerium)
2. Crypto Collateral (called on-chain – with blockchain technology)
    2.1. Cryptoasset-Backed
        (Ethereum – e.g. Dai, Huobi, Steem, Alchemint)
    2.2. Crypto-and-Fiat-Backed
        (Ethereum and USD – e.g. Money on Chain)
3. Algorithmic (no collateral assets as such – e.g. karbo, Terra, Ampleforth, Element Zero)
    3.1. Algorithmic-Backed
    3.2. Fee-backed
    3.3. Seigniorage Share

Blockchain (2019) and Blockdata (2019) were the main sources for creating the above classification.

While the basic tripartition is common, the subgroups in the above classification are partly copied and partly changed in different classifications. The assignment of the exemplary stablecoins to a category can also be debatable with regard to more and more frequent use of combinations of collaterals and corrections of constructions introduced by issuers of stablecoins and of regular cryptocurrencies.

On the basis of the above classification, it is peculiar that FINMA, a Swiss financial regulator, adopted a seemingly simple classification, dividing stablecoins into four categories: linked to currencies, commodities, real estate and securities. The classification grows however to eight categories taking into account two variants of stablecoins based on a single type of assets in a given category or a basket of assets, and two types of users' claims on the issuer, independent of and dependent on price movements. Detailed categories with their supervisory classification can be found in the table below.

Table 1: Typology of stablecoins according to the Swiss Financial Market Supervisory Authority FINMA

Categories	**Indicative supervisory classification (in addition to anti-money laundering legislation)**
1. Linked to *fiat currency / cryptocurrency* with fixed redemption claim	Deposit under banking law
2. Linked to basket of *fiat currencies / cryptocurrencies* with redemption claim dependent on price development	Management of the currency basket and risk-bearing: – for the account of the issuer: deposit under banking law3/4 – for the account of the token holder: collective investment scheme
3. Linked to *commodity* (incl. "bank precious metals") with contractual claim	Bank precious metals: deposit under banking law Commodity: security and possibly derivative
4. Linked to basket of *commodities* (incl. "bank precious metals") with redemption claim dependent on price development	Collective investment scheme

5. Linked to *commodities* (incl. "bank precious metals") with ownership rights	No prudential licensing requirement
6. Linked to *real estate* with redemption claim dependent on price development	Collective investment scheme
Linked to specific *security* with contractual claim	Security and possibly derivative
Linked to basket of *securities* with redemption claim dependent on price development	Collective investment scheme

Source: FINMA (2019), Supplement to the guidelines for enquiries regarding the regulatory framework for initial coin offerings. [Online] [Retrieved January 11, 2020], https://www.finma.ch/en/~/media/finma/dokumente/dokumentencenter/myfinma/1bewilligung/fintech/wegleitung-stable-coins.pdf?la=en

FINMA underlines however that the whole classification is purely for indicative purposes (FINMA, 2019). From a supervisor's and a financial regulator's point of view, it is crucial how the stablecoin typology is organised. Otherwise, it will be difficult to develop appropriate and flexible enough legal regulations, within the framework of which issuers can create stablecoins, and financial authorities can supervise issuers and market intermediaries.The assets by means of which a stablecoin issuer secures the stability of their value and/or with whose value links the value of his stablecoin unit, may but do not have to be and often are not assets to which an issuer guarantees the exchange of his stablecoins. For instance, accepting USD as a reference currency, securing stability by means of assets denominated in USD does not imply exchangeability of a given stablecoin on USD guaranteed by an issuer. Together with new issuances of stablecoins on the market and an increase of their popularity, a proper recognition of this construction differentiation of stablecoins can cause considerable problems not only for their users but even for financial regulators (FSB, 2019; FCA, 2019; EU, 2019; ECB, 2019). As the German central bank rightly notes, stablecoins are therefore not payment tokens which have an inherently stable value (in their respective reference fiat currency). It results from the fact that the price of a stablecoin is additionally determined by fluctuations in supply and demand on digital trading platforms (Deutsche Bundesbank, 2019).

The problem of the transparency of stablecoins functioning illustrated with the example of Tether

Tether in its version stabilised to USD, hence its code USDT, is the best known stablecoin functioning on the cryptocurrency market. Also Tether CNHT is being developed, and it is stabilised to the Chinese currency renminbi, better known as yuan (CNH abbreviation for yuan traded in Hongkong corresponds to CNY in the ISO standard, used also in the SWIFT payment system – see ISO, 2020). USDT market cap amounts to USD 4.64 billion on 28th January 2020. It gives Tether the sixth position among all cryptocurrencies according to CoinMarketCap (2020c). Bitcoin BTC takes the first position with the market cap of USD 164.9 billion.

The principles of Tether functioning described in its Whitepaper seem to present the mechanisms of issuance and safeguarding stability against USD reliably and in details (Tether, 2016). The indicated technological connections between Tether and Bitcoin, also the location of the Tether Ltd company as an issuer in Hongkong belonging to the Tether Holdings Ltd company from British Virgin Islands (BVI Business Company), are open to public.

However, it was Tether in connection with Bitcoin that made regulators of financial market sensitive to uncertainties in the mechanisms of stablecoins issuance, stabilisations of their listings and trading. The mentioned USDT market cap is questioned due to manifestations of wash trading, which means manipulating the market by simultaneous selling and buying the same assets by the same investor, which overstates the actual volume of trading of these assets (Bullman et al., 2019). Apart from that, in 2019 doubts arose and resulted in legal actions regarding the actual amount of cash and its equivalents to back USDT and correlation between USDT issuance by its parent company and growths in the prices of Bitcoin. A class-action lawsuit was filed against Tether and associated entities in connection with suspicion of unfair practices (IFRS, 2019). It is noteworthy that in connection with the case of disappearance of USD 850 million of Tether collateral from the Bitfinex cryptocurrency

exchange, connecting the threads of Tether and Bitcoin cases, the New York Attorney General experienced certain problems with finding the domicile of the exchange. The report made in 2018 indicated Taiwan (Underwood, 2018), and in May 2019 it was established that the actual domicile of the Bitfinex exchange was in Hongkong, just like of the iFinex Inc. company, which was the actual operator of the exchange and also the owner of the Tether Ltd company (Hougan et al., 2019; Larson et al., 2019; Igna, 2019).

The above events made regulators pay a close attention to the most significant functioning cryptocurrency and connected stablecoin, as soon as it became clear that the cryptocurrency market can demonstrate irregularities significantly similar to those of a classical financial market. Particularly with reference to cryptocurrencies of the stablecoin type, the mechanisms of connections between stablecoin resources and national currency resources and transformations of those resources in both directions constitute an important issue for regulators. A national currency is exchanged into cryptocurrencies by their purchasers and taken over by cryptocurrency issuers. Some cryptocurrencies can also be bought with other cryptocurrencies, like for instance purchasing Dai with Ethereum (The Maker Team, 2017), but a national currency is always a reference point at the beginning of a transaction chain. A considerable differentiation of solutions securing the stability of the purchasing power of individual stablecoins must be remembered as it was indicated in the part of this article discussing the kinds of stablecoins.

In those circumstances, it is natural that the appearance of the Libra stablecoin project endorsed by Facebook has caused distrust of the financial market regulators, not only in the USA, since the very beginning. Although central banks and other public regulators of the financial market in principle shape this market in the best interest of society and constitute a part of a complex network of institutional connections within the structures of a given country, the transparency of their activities is not fully guaranteed (Krivoluzky & Kim, 2019). All the more private entities issuing cryptocurrencies are able to use transnational organisational structures, the global character of the internet and resulting limitations in the efficiency of control of national jurisdictions, and even international organisations.

Stablecoin Libra and its path to conflict with financial regulators

Facebook, which is the worldwide leader among all online social media and social networking services, on 18th June 2019 announced the Libra project and specified it as a "modern, low-friction, high-security payment network". However, the cryptocurrency based on the blockchain technology called Libra (like the whole project), constitutes the essence of this payment network and it will be stabilized to reserve assets (Libra, 2020). For this reason, the concept of the Libra currency is frequently called global stablecoin (Cœuré, 2019; Claeys & Demertzis, 2019). There are almost 3,000 cryptocurrencies in circulation, most of which basing on blockchain (CoinMarketCap, 2020c), but none of them has such a widely recognised promoter. According to an internal report, in September 2019 Facebook had on average 1.62 billion active users daily and 2.45 billion active users monthly on 30th September 2019 (Facebook, 2019). For this reason, the Libra project was exposed to fierce criticism of the regulators of the financial markets in the USA, the European Union and other countries. As a result, in the first half of October 2019, a few important companies like Visa, Mastercard, eBay, Stripe, PayPal and a less known Mercado Pago withdrew from the Libra project (De & Dale, 2019). However, this did not prevent the remaining 21 charter members from signing the statute of The Libra Association on 15th October 2019 as an independent, not-for-profit membership organization, headquartered in Geneva, Switzerland and establishing its management structures. It was also announced that over 1,500 entities had indicated interest in joining the Libra project, and approximately 180 entities had met the preliminary membership criteria required by libra.org (Libra, 2019). However, the basic institutional structure of the Libra project was not changed despite the financial regulators' serious doubts concerning the control mechanisms within the consortium of companies belonging to the Libra Association and the actual influence of Facebook on the whole entrepreneurship. Yves Mersch, Member of the Executive Board of the European Central Bank, at the ESCB Legal Conference in Frankfurt am Main on 2nd September 2019 said that "Libra's ecosystem is not only complex, it is actually cartel-like" (Mersch, 2019).

Less than a month later, on 12th November 2019, a press release announced another payment system – Facebook Pay, which is supposed to constitute an addition to the existing payment system for national cryptocurrencies. Facebook Pay is to consist in adding an appropriate integrated payment functionality to the existing applications, firstly to Facebook, Messenger, Instagram and WhatsApp. Therefore, it does not mean giving up on the Libra project, which is confirmed by the mentioned Facebook's press release: "Facebook Pay is built on the existing financial infrastructure and partnerships, and is separate from the Calibra wallet which will run on the Libra network" (Liu, 2019).

The unstable and unclear presentation of the financial principles of Libra cryptocurrency functioning mechanisms stands in contrast to the consistency in institutional organizing of the Libra project manifested by Facebook. In an official document presenting the Libra project principles (Libra, 2020), it was claimed that the Libra currency would be neither backed by gold nor pegged to a single currency. It will be backed by a collection of low-volatility assets, such as bank deposits and short-term government securities in currencies from stable and reputable central banks.

A few days after the meeting of Facebook and JP Morgan with the representatives of the key world central banks (16th September 2019), Facebook announced the percentage composition of the currency basket of global importance (23rd September 2019), which would constitute an anchor of the stable value of the Libra currency (Mayer, 2019). The basket was supposed to include US dollar (50%), euro (18%), the yen (14%), the British pound (11%) and the Singapore dollar (7%). However, on 20th October 2019, Facebook Inc informed the media that the initiative could use cryptocurrencies based on national currencies such as the dollar, instead of the synthetic ones it initially proposed. David Marcus, the project leader in the name of Facebook said that "… we could have a series of stablecoins, a dollar stablecoin, a euro stablecoin, a sterling pound stable coin, etc.". He added that "having a multitude of stablecoins that represent national currencies in a tokenized digital form" (Shalal, 2019) was one of the options. It was considered an answer to the adverse criticism of the original version of the Libra project by the world financial regulators (Palmer, 2019a).

On 6th November 2019, Libra co-creator Christian Catalini said that the Libra Association will be able to expand its founding member set. Consequently, he added that the initial breakdown of the Libra basket was just a proposal, and that the final composition of the basket would be decided by the final members of the association (Sarkar, 2019).

All the confusion in connection with the Libra construction was briefly concluded by the Governor of the US Federal Reserve Lael Brainard during his speech in Germany (18th December 2019): "What would set Facebook's Libra apart, if it were to proceed, is the combination of an active-user network representing more than a third of the global population with the issuance of a private digital currency opaquely tied to a basket of sovereign currencies". He expressed additional reservations considering the transparency of the Libra project saying that "it is not even clear how much price risk consumers will face since they do not appear to have rights to the stablecoin's underlying assets." (Brainard, 2019; Palmer, 2019b).

Another version of the Libra Whitepaper of 29th January 2020 does not include any changes in the financial construction of the project when compared with the version of May 2019 criticised by the financial regulators in numerous countries. The new version does not answer any questions concerning the details of the Libra Association functioning and Facebook's position, the Libra cryptocurrency issuance principles, establishing and stabilising its value or the mechanisms of the reserve assets management (Libra, 2020).

In conclusion, as at the end of January 2020, the Libra stablecoin project is continued by the consortium led by Facebook according to the original principles, despite justified reservations of the key financial regulators regarding the transparency, stability and safety of the Libra cryptocurrency construction and its ecosystem.

Summary

Quoting the statement of the Governor of the European Central Bank, Christine Lagarde, which she made during the Hearing at the Committee on Economic and Monetary Affairs of the European Parliament on the 2nd of December 2019 seems an adequate summary of the above considerations: *Innovations – including stablecoins – will only be beneficial if the associated risks are mitigated through effective regulation and oversight. So I believe we should follow the golden rule of supervision: "same business, same risk, same rules"* (Lagarde, 2019a).

At the same time, Governor Legarde mentioned the global context of stablecoins on numerous occasions referring to the works of the international forum G7 Working Group on Stablecoins and to the cooperation with other central banks.

On the basis of the information included in the four main parts of the article, a doubt may arise whether the cooperation of supervisory national and international institutions itself in the style practised so far is enough to "*ensure that stablecoins do not compromise the safety and efficiency of the payment system or the soundness and stability of the financial and monetary system*" (Lagarde, 2019a).

The problems the regulators and supervisors of financial systems face in connection with the development of stablecoins are of various character. It was not possible to indicate all of them in this article. A uniform definition and classification of stablecoins is necessary for the international cooperation of financial regulators and supervisors in the issues concerning stablecoins to be effective. It is not however possible without arranging the whole network of interrelated concepts, e.g. in connection with blockchain and cryptocurrencies.

However, creating international mechanisms for controlling institutional connections between stablecoin issuers and cryptocurrency exchanges and other intermediary companies may prove to be much more difficult. Differences between countries in the forms and principles of registration of economic activity with limited extension of national jurisdictions create opportunities for such entities to form non-transparent organisational and financial links, like in the case of Tether.

The issue of an actual authority of national regulatory and supervisory powers in the light of the activities of global BigTech companies is of a different character, as it was illustrated with the example of the Libra project. Building the credibility of financial authorities cannot however be limited to bans paralysing any initiatives problematic from the regulatory and supervisory point of view.

The above comments raise the question concerning the necessity and possibility to institutionalise and centralise international cooperation of regulators and supervisors of by its very nature global market of cryptocurrencies and stablecoins. How to design such a global regulator and supervisor and also the possible scenarios when such an institution is not created constitute an interesting research problem.

In the author's opinion, there is a danger that over-strict regulations introduced by public authorities of different countries may block, or at least significantly slow down the evolution of stablecoins into a useful and safe financial instrument. However, without an appropriate regulatory framework, stablecoins will not gain both the approval of authorities and wider acceptance by business participants. This situation may continue as long as the potential benefits of using stablecoins are overshadowed by the high risks involved.

Animal Spirits and the Business Cycle – the case of Poland

Monika WYRZYKOWSKA-ANTKIEWICZ

WSB University in Torun, Torun, Poland
monika.wyrzykowska@wsb.torun.pl

Abstract

The paper integrates the 'animal spirits' hypothesis and business cycle in the new environment i.e. emerging market of bonds with non-residents as the investors in Poland. The main aim of it is to show the investments and investors from a different perspective. The paper will prove that according to macroeconomics factors, non-residents should buy bonds, but they behave irrationally.

Keywords: animal spirits, behavioral macroeconomics, business cycle, bonds.

Introduction

The efficient market hypothesis says that it is impossible to beat the market. This hypothesis assumes that people buying and selling stock rationally process the information that they have about the stocks' underlying value. But there is a long tradition suggesting that the fluctuations on the stock market are psychological. In 1930s, economist John Maynard Keynes suggested that assets markets are driven by the "animal spirits" of investors – irrational waves of optimism and pessimism. In Keynes's 1936 publication, 'The General Theory of Employment, Interest, and Money', he speaks of animal spirits as the human emotions that affect consumer confidence.

In 2009 the term animal spirits returned to popularity when two economists: Akerlof and Shiller published their book, 'Animal Spirits: How Human Psychology Drives the Economy, and Why it Matters for Global Capitalism'. The authors argue that although animal spirits are important, it is equally important that the government actively intervene to control them via economic policymaking when necessary. Otherwise, the authors postulate, the spirits might follow their own devices—that is, capitalism could get out of hand, and result in the kind of overindulgence that we saw in the 2008 financial crisis.

The main idea of this paper is to show the different kind of investments and investors from different perspectives. The paper concentrates on the market of bonds in Poland. The paper discusses according to different research papers, the correlation between the Real Business Cycle model and the Animal Spirit Hypothesis. The Real Business Cycle model assumes rational expectations in contrast to the animal spirit hypothesis where people prefer to follow trends and behave with irrational expectations. However, the main idea of this paper is to check if the animal spirit hypothesis can be the answer if the business cycle fluctuation depends on the investors' mood.

Animal spirits and the business cycle – the review of literature, methodology and empirical research

'According to the real business cycle theory, there is nothing the government can do to eliminate business cycle fluctuations. According to Farmer and Guo, in contrast, governments may be able to design policies to moderate economic fluctuations.' (see Espinosa-Vega and Guo (2001)).

Do business cycle represent optimal responses by rational agent to erratic changes in technology, or are they also influenced by the 'animal spirit' of investors? (see Farmer and Guo (1994)). They

observed that politicians should not care about allocations, when the economy is Pareto Optimal. This means that when the supply of random products embody business fluctuations, appears as Arrow-Debreu models. Moreover, they discuss economic activities and how it impacts the reduction of fluctuations and the increase of economic welfare based on decisions made by the policy marker. In the beginning, the term of 'animal spirit' was the way that people explained the Keynesian concept of recession. Then people began to doubt it due to the influence of many new results on the subject, which was the basis of economic fluctuations. Furthermore, people created theories about animal spirits, which told us that the animal sprit was not related to real business cycles. For that reason, they started that the animal spirit was letter as *'sunspots' or* '*self-fulfilling prophecies'* (see Azariadis (1981)).

The literature extended by Farmer and Guo (1994) disagreed that it is impossible to calibrate the business cycle model to the same level as the real business cycle (RBC) model. Therefore, they conducted their own surveys, which were based on the first moments of time series data to prove their point of view. However, rational expectations are self- fulfilling prophecies for that reason macroeconomics variables such as: output, consumption, employment and investment transfer as erratic fluctuations. They wanted to show that a simultaneous correlation between the macroeconomics variable mentioned above in US time series in the context of real business cycle model existed and they thought that it would be a better explanation of the dynamics of US data.

Hall's observation (1989) was the starting point on the discussion of animal spirits, which was based on the Solow residual that it is not correlated between any variable with productivity - under competition, constant return-to-scale and Solow residual might be unbiased estimates. Hall tried to prove that there is a positive correlation in U.S. post-war data – with Solow residual and various instrument. Moreover, he observed that we possibly could not understand economic fluctuations through monopolistic competition and increasing returns-to-scale. In some period of time, Hall's observation was the reason that more people started to investigate that US data can be explained by technology under increasing return- to-scale.

Papers of Caballero and Lyons (1989), and Bexter and King (1995) were the next step of discussion of the paper of Famer and Guo. Caballero and Lyons discusses evidence about the proof of external effect in production functions whereas Bexter and King focused on increasing return-to-scale technology in the real business cycle. Moreover, they wanted to show that a demand driven model could obtain correlation by supply disturbance under the assumption of increasing returns. Then Benhabib and Farmer (1994) have estimated that increasing returns' assumption had potentially more radical implications.

When shock to the technology does not occur, we can say that two-dimensional dynamical system around a stationary state that is the saddle point in the standard real business cycle model. When the standard assumptions are not familiar with Benhabib and Farmer observations, then appearing an indeterminate steady state – self-fulfilling beliefs and the increasing return-to-scale by population technology described as instability of the steady state.

Farmer and Guo in their paper created three kinds of economics model, which were the main tools of their research. The first model was presented as a real business cycle model with Hansen. The next two models represent monopolistic competition and increasing returns. The next step was calibrating those three models based on the first moments of the US time series data. They keyed theoretical constructs with accounting data by elasticity in calibration. However, in the case of monopoly power, uncertainty in the US economy appeared, and they assumed that it could be due to the distinct feature of the average mark-up of price over marginal cost. Their assumption lends to the comparison of two models, repressed monopoly competition and increasing returns. Farmer and Guo thought that this elasticity is in a position to explain the difference between model 2 and model 3. The second model obtains 0.63 for labour share and 0.3 for the price-cost-margin – a determinate saddle point in steady state. The third model obtained 0.7 for labour's share and 0.42 for the price-cost-margin - an indeterminate a drop in steady state.

There are many alternative approaches to modelling animal spirits. For example, De Grauwe presents (2008) in his papers that the notions of "animal spirits" and rational expectations do not mix well. However in contrast the author underlines the role of the animal spirits hypothesis developed by Keynes based on the fact that individuals only understand small parts of the total information set, and they are not capable of describing the statistical distribution of economic shocks. This limitation of individuals has been documented by psychologists and brain scientists (e.g. Kanhnemman and Thaler (2006), Della Vigna (2007). De Grauwe and Yuemei (2016, 2017) continued a test of "animal spirits" in two countries where the synchronization of the business cycle is produced endogenously.

These are the limits of the De Grauwe models because they are applicable only to the closed economy. The development of this model for the open economy was made by writer Tae-Seok (2019).

The research in the presented areas concentrated mainly on the instruments role of monetary policy, not exactly on the instruments of the fiscal policy (see De Grauwe and Foresti (2018). This paper shows that fiscal policy is also very important for the decisions that drive investors.

The Animal Spirits Hypothesis and The Market of Bonds in Poland

Over the last few decades, the demand for government bonds increased significantly. This demonstrated that the proper direction of public debt management determined the future government debt price level. In other words, bond yields are depended on interest rates and price, bond yields are defined as the expected profit from the purchase of bonds. The price increase when yields, interest rate and payment discount decrease (see Andritzky (2012)). There is a link between the investor base and bond yields.

The number of non-residents investing increased due to lower yields. More broadly, the question is of the risk to the global financial market by non-residents in a local market. The empirical evidence has motivated the hypothesis that the expansion of non-residents investors should be limited through diversified investor base (see Arslanalp and Tsuda (2014)). It is possible to distinguish three main categories of bonds: treasury, municipal and corporate. In my research I am concentrated on the category of treasury bonds.

The regression model in this paper is presented as the main result for the empirical question of this paper: which macroeconomic factors have an influence on the share of non-residents in the market of bonds in Poland. The macroeconomic situation of Poland in recent years has been stable according to the Standards and Poor rating which is at the level of BBB+.

Poland's gross domestic product has changed during the years 2006-2018. The data shows that the GDP annual growth rate could be at the level of 7% as in 2007, as well as at, above 1% like in 2013. Since 2017 has been around 5%.

Fig. 1: GDP Annual Growth Rate of in Poland during the years 2006-2018 in %
Source: Central Statistical Office of Poland.

Another macroeconomic factor that influenced the pessimistic or optimistic decisions of inventors on the market of bonds is general government deficit.

Fig 2: General government deficit in Poland as the % of GDP during the years 2006-2018
Source: Central Statistical Office of Poland.

Even though the deficit decreased as a level of debt as the % of GDP is still at the very high level – 48 % of the polish GDP.

Fig. 3: Debt as the % of GDP of Poland during the years 2006-2018 in %
Source: Central Statistical Office of Poland.

One of the ways to finance public debt is the issue of bonds, as well as for home (residents) and foreign investors (non-residents).

The Polish Ministry of Finance has been issued bond' shares and foreign debt to non-residents investors since 2004/2005. In mid-2007 the yields on Treasury bond were decreased significantly in Poland and the largest boom was during 2009-2011. Comparing the difference between 2007 and 2014, the nominal value of foreign debt increased from PLN 558 828 to 1251 028. In 2016, the foreign debt reached 1403 997. At the end of 2014, half of the Polish debt was held by foreign investors - profitability level decreased.

Foreign debt determines longer payment terms than domestic debt. For instance, in 2014, the average foreign debt payment was 7 years and the national debt was 4 years. At the end of 2014, Poland occupies t eleventh place in the European Union in terms of the share of non-residents in public debt. In 2014 the ten-year bond yields were 3,5%, in contract to 2008 - 6,1%. Foreign investors / non-residents generate an increase in foreign currency in the State Treasury debt.

During the full analyzed period the total value of external debt increased. This was caused mainly by the debt of residents. The participation of non-residents in external debts during the last 3 years has decreased. This was probably caused by the level of the 10Y bond yield which has been decreasing year by year since 2016 – 3,6%, 2017, - 3,3% 2018 – 2,8%, 2019 – 1,9% (Trading Economics).

Fig. 4: Gross External Debt Position by Sector in Poland during the years 2006-2019 in mln PLN

Source: Ministry of Finance in Poland

The results show that GDP growth does not have any impact, in contrast to the cross-section model. Public debt and deficit are negatively significant, so a lower level of public debt and deficit increase the share of non-resident. It is logic assumption and it was expected to be met. Investors are not likely to invest when a government spends more money than it takes in (expenditure exceeds its revenues). When a country's ability to make future payments on its affected it is exactly what the results of estimations shows.

Table 1: Results of cross section regression model for Poland

	coefficient	standard deviation	t-sudent	p value
const	-55,7828	33,9958	-1,6410	0,1352
GDPannualgrowthra	1,1821	1,3004	0,9090	0,3870
DeficitasofGDP	3,9387	0,7342	5,3650	0,005**
DebtGDP	0,8384	0,5897	1,4220	0,1888

Source: based on the own calculations using Gretl.

The results of the estimations show that the highest influence on the GDP growth rate, is public debts, not the deficit. When the growth rate increases the investor's mood should be much more optimistic and they should want to buy bonds. But in Poland we see that rather residents want to buy bonds since 2016. For non-residents a much more important factors can be public debt, and the deficit.

For instance, examining the reaction of the ratio between public debt held by non-residents, the result shows "better fiscal positions increase the share of non-residents held debt" and "crisis since 2009 flags the reduction of the share of non-residents held debt (see Afonso and Silva, (2017)). However, the regression model provided a similar outcome. Mainly with non-residents investors, a fiscal position has significant effect or decreasing public debt. While decreasing the share of non-residents may have contributed to the financial crisis - less stable financial situation on the market and ("public debt"). Therefore, the improvement of financial positions and stress and financial volatility has an impact for

higher shares of non-residents holding debt. However, this paper is not focused on provided the evidence of policy actions and any regulation reform for non-residents (see Jalles (2018)).

Conclusions

The main aim of this this paper was to show the different kind of investments and investors from different perspectives. The paper shows that there is a lot of factors that influenced on the decisions of investors. The case of Poland proved that investors, especially non-residents, didn't buy bonds even annual growth rate of GDP suggested the effective annual yield. In other words, they are like 'animal spirits', because maybe they have some instinct or intuition what can happened on the financial markets. The paper is a prove that there is the negative correlation between the Real Business Cycle model and the Animal Spirit Hypothesis in case of the polish economy. It causes that Poland should create the special policy for non-residents investors of bonds. They behave in opposite way in comparison with the residents. This conclusion is the main contribution of this research. This paper steps away from investigating how the share of non-residents held debt influences on the yields. However, have provided evidences reduction of non-resident holdings debt decreasing the yields.

This paper just wants to show how non-residents react in the stable and in an unstable economic situation, only in Poland.

However, these kinds of problems could be provided more wide analysis of non-residents and residents behavior on the financial market for many countries from different region of world.

Ontological Approach Toward Security Knowledge Management for Secure Software Engineering

Sarra LASMAR and Henda Hajjemi BEN GHEZALA

RIADI Laboratory, National School of Computer Sciences ENSI, Manouba University, Manouba, Tunisia
Lasmar.sarra@gmail.com, Henda.benghezala@ensi.rnu.tn

Abstract

Secure software engineering involves very complex and unconventional development processes; that require a great deal of security knowledge that is continuously evolving and hard to discern. This significant bulk of knowledge is currently scattered, unstructured and difficult to be reused in a specific application domain and in every software development phase (specification, design and implementation) by security inexperienced software developers. In order to manage this knowledge in a formal and widely shareable representation, this paper presents an ontological approach which aims security knowledge management (security knowledge and security experiences) to support the engineering of secure software product. Firstly, we propose a literature survey, analysis and classification of some existing security ontologies that are candidates for full use in secure software development processes. Based on this survey, we propose an ontological approach for modeling, capitalization and sharing of security knowledge covering both dimensions of software: product and project and taking into consideration the context of the application domain and the risk analysis and deals with the different phases of software development process.

Keywords: Security Ontology; Secure Software; Security Knowledge; Knowledge Management.

Introduction

Nowadays, it is universally accepted that, proactive and ongoing security assessment and treatments are the only ways that could guarantee security assurance of software product (Standard 27034, 2011). However, adopting these ways still quite limited and software security is not always ensured or guaranteed because of the considerable effort they generate, the skills required and, in particular, the developer's lack of experience. The selection of required security features and mechanisms often presents serious challenges for the system owners and application developers (Karyda, 2006). Whilst significant efforts (processes, methods, models, standards, security tools, etc.) have been undertaken to improve software security, they have clearly proved to be insufficient. Recent statistics show that security problems still persist even in the recently developed software for many reasons, namely: the widespread deployment of the Internet, the emergence of new application domains and technologies e.g. the spread of smart cities with new weaknesses which introduce new possibilities of attacks that could affect even human lives, the well-known attacks are still frequent, the exploits of old (déjà vu) vulnerabilities, and the propagation of hacking tools making the task of hacker much easier. According to the security reports such as the National Vulnerability Database (NVD), 22% of vulnerabilities in 2016 are rated as critical and the software product is the privileged target in security attacks. This is mainly due to the ever evolving number and forms of attacks (e.g. zero day attacks), to the continually rising of new threats and risks, hence new mitigating actions have been devised. Likewise this is due to the limited proposals that aim at the intersection of both disciplines: the secure software engineering and the knowledge management.

Therefore, the discipline of secure software engineering requires even more than the improvement of the development processes. These later require additional knowledge about the product which is related to its security. According to McGraw (2005), knowledge constitutes one of the main pillars to

guarantee the development of secure software product. However, Security knowledge is not easy or obvious to be defined for a specific domain and to be precisely integrated in the development cycle. This knowledge often results from past experiences, historical incidents and in-depth analysis of experts. Thus, it is scattered, scalable and dependent on several factors associated to software products.

Considering these facts, it becomes clear that the current secure software engineering practices are not reliable and relevant enough and there is a growing need for an efficient management of security knowledge and experience that address every phase of the software development process (specification, design and implementation) and every application domain. For that purpose, this paper focuses on the representation of the security knowledge management approach. Our method, exploits three disciplines namely (knowledge management, ontological engineering and secure software engineering). In this context, ontology seems to be a promising tool to formally represent and manage security knowledge compared to other methodologies. They are mainly used as a means to model information, they have reasoning and high-level decision-making mechanisms (Wang, 2009; Souag, 2012b), they are more structured and provide better computational inference (Blanco, 2008) facilitating hence the secure software engineering.

The rest of the paper is structured as follows: Section 2 describes the software security issues. In section 3, we present a deep and comparative study of the existing literature on ontological engineering applied to the security field. We propose in section 4 an ontological approach for security knowledge management required for the development of secure software. Finally, section 6 presents our overall conclusions and future work for the evolution of our approach.

Secure Software Engineering

Secure software aims to ensure dependable software in order to prevent any malicious act (unauthorized access, manipulation or attack) that could affect security services and criteria (confidentiality, integrity and availability). The discipline of secure software engineering has provided several proposals to improve the quality of software products, while they are mainly concentrated on improving the development processes. Nevertheless, these processes require more additional knowledge about the product which is related to its security. The resort to a knowledge base to serve as complementary information about secure software product has been suggested in some works as catalogue, security patterns, security knowledge repositories, taxonomies, models, so forth (Carl, 1994; McGraw, 2005; Tsipenyuk, 2005; Dritsas, 2006; Essafi, 2006; Young, 2014; Munawar, 2012). However, the proposals found in the literature do not adequately reflect the developer's needs and do not provide sufficient support to be used throughout the development process and serve in the different phases.

We identify five key factors contributing to define adequately the required software security knowledge: (1) The application domain factor serves in formulating security requirements which correspond to a specific domain (e.g. nuclear energy, social media or e-commerce). (2) The Activity sectors of the same application domain are a key factor contributing to provide different security knowledge. For instance, in the health field, the impact on the data integrity of the surgical operations (activity sector) is more important and higher than on the availability and the confidentiality, while the latter is the most crucial and critical in psychiatry sector. (3) The security properties priority provides the most important security properties that should be taken into consideration for a specific domain. In fact, risks in the health field affect the confidentiality of patients' private data. However integrity and availability are actually the cause of the most serious security problems, since information technologies were integrated into the daily practice of doctors with computerized medical records, telemedicine and appointment management software and connected biomedical devices. (4) The environment of software product (e.g. web-oriented, desktop software, etc.) contributes to the determination of security level and objectives. For instance, a medical software product running on a single isolated workstation in a doctor's office will have very different security requirements from those in a similar web-based software product or from the ones in a public space in a hospital. (5) The software development life cycle factor aims at integrating security in the

different phases (principal phases) of software life cycle namely specification, design and implementation to mitigate the vulnerabilities risks.

Consequently, in order to manage and exploit this bulk of constantly evolving security knowledge in the different phases of software life cycle, we are particularly interested in the ontological engineering. In this context, many research studies exposed the importance of using ontologies to represent and manage information security knowledge (Ekelhart, 2007; Souag, 2012a). We will demonstrate thereafter the ability of these ontologies to ensure a secure software product by the study of the existing proposals in ontological engineering applied to security.

Security Ontologies Survey

Based on the literature, there are three main surveys that focus on security ontologies; each one of them targets a different objective. Blanco (2008) was based on manual evaluation security ontologies modeling criteria (number of concepts, instances, taxonomic relations, etc.) using a comparison framework of basic elements (Ontometric framework). The study of Souag (2012b) concerns security requirements engineering in Information Systems. It is based on the analysis and classification of security ontologies that could be used to support the requirements engineering process. Singh et al (2014) focuses mainly on semantic representation of security issues and countermeasure in cloud computing. They provide a critical study of security ontologies to ensure the implementation of cloud computing security using the appropriate and complete security knowledge specific to this field. Our work aims at providing an overview and a new classification of security ontologies -as illustrated in (figure 1)- compared to the one proposed in (Singh et al, 2014). First, we have extended the classification of security ontologies proposed in (Souag, 2012b) which presents among other two limited categories to a basic taxonomies "Beginning security ontologies » and « Security taxonomies". Our update in (figure 1) aims mainly at adding two other categories (secure network and source code) providing hence five categorization criteria (development phase, typology, network, risk analysis and web oriented security). Then, we have presented a brief outline of the most relevant proposals to ensure their efficient analysis and to identify the security ontologies that could be able to ensure a secure software product.

Fig.1: Classification of security ontologies

a- *Web-oriented security ontologies (*Maamar*, 2006;* Vorobiev*, 2006;* Garcia et al, 2011): The proposals described in this category focus mainly on developing distributed defensive mechanisms for web service-based systems; and on providing context reconciliation between web services in order to avoid heterogeneity and security vulnerabilities that threaten their integrity.

b- *Security ontologies by phase*

- *Security requirements ontologies (*Lasheras*, 2009; Vasquez, 2012; Souag, 2015):* This category presents the proposals that contribute to the security requirements specification derived from risk analysis or from application domain or based on the use of security requirements patterns in order to mitigate the effect of the lack of security engineering expertise, to ensure formal security requirements representation and to improve thus the information system's security.

- *Modeling security ontologies (*Massacci, 2011)*:* This category mostly describes security modeling using ontology, similar to misuse-case, abuse-case and I* approaches.

- *Code source security ontologies (Herzog, 2007;* Al-Qahtani, 2017)*:* This category describes the different vulnerabilities and errors of the source code a developer could avoid during the programming phase likewise the best secure coding practices such as black-box testing, threat modeling, bug tracking system and static analysis.

c- Security ontologies by typology

- *General security ontologies (Herzog, 2007; Fenz, 2010; Ramanauskaitė, 2013):* This category includes mainly the general proposals which cover (IS, network, software, infrastructure, organization, etc.) and their corresponding concepts. It includes generic concepts and technical detailed ones independent of all application domains.

- *Specific security ontologies(*Dritsas, 2006; *Karyda, 2006;* Geneiatakis, 2007 ; Wang, 2009; Lekhchine, 2009)*:* Specific security ontologies refer to the specific area e.g. E-health, mobile agent technology or to the specific concept on which the ontology is developed e.g. the security vulnerabilities of the Session Initiation Protocol (SIP) used by VoIP, threat ontology to discover new system requirements.

*d- Risk based security ontologies (*Ekelhart, 2007; Assali, 2008)*:* Risk analysis forms a paramount factor to success the development of secure software product (Essafi, 2006). This category contributes to define exactly the security requirements based on the impact and the type and level of risk in order to ovoid bad decisions and to improve quantitative risks analysis of organizations.

e- *Network security ontologies (*Liu, 2007)*:* aims to manage the network security risks and controls. The proposed ontology based on security standard 27001 as well as good practices BS7799 in order to ensure a reliable and full exchange with a minimum acceptable risk.

Although interesting proposals have been made for the definition of security ontology, these latter are not prepared for reusing and extending (Salini, 2012). The literature study carried out allows us to identify relevant criteria which are presented in table I in order to answer the problem of the security knowledge management.

Table 1: Comparative study of security ontologies

	Criteria				
	Domain	***Development phase***	***Covers Core Security Concepts****	***Ontology***	***Standards***
Alqahtani 2017	traceability of source code vulnerabilities found in APIs	Source Code Analysis	No	Security Vulnerability Onto (SEVONT) + Software Evolution Onto (SEON) + Software Build Systems Onto (SBSON)	No
Souag 2013	Security requirements for IS	Requirements engineering	Yes	Security onto + domain onto	No
Vasquez 2012	Security requirements for IS (based on risks analysis)	Risk analysis + security requirements identification	No	Risk Onto + security requirement onto	Yes

	Criteria				
	Domain	***Development phase***	***Covers Core Security Concepts****	***Ontology***	***Standards***
Fenz 2010	IT security metrics for organization	–	No	Security Onto	Yes
Herzog 2007	Information security	–	No	Security Onto	No
Karyda 2006	E-government applications	Security requirements identification	No	Security Onto	No
Ramanauskaite 2013	Adaptive mapping of security standards	–	No	Security Onto	Yes
Lekhchine 2009	Mobile agent security	–	No	Security Onto	No
Massacci 2011	Security requirements for organization	Modeling security requirements	No	Security modeling Onto	No
Lasheras 2009	Security requirements for IS (based on risks analysis)	Requirements engineering	No	Risk analysis onto + requirement onto	Yes
Wang et al 2010	System security	Assessment (Risk analysis)	No	Vulnerability management Onto (OVM)	Yes
Tsoumas et al 2006	Security management of IS	–	No	Security Onto	Yes
Leo Obrst 2012	Cyber security	–	No	Cyber Security Onto	No
Salini 2012	E-Voting System	Security Requirements engineering	No	Security requirement onto	No
Salinesi et al 2008	Banking Sector	Requirement elicitation	No	Threats Onto (RITA)	No
Daramola et al 2012	Security Requirements Specification process	Security Requirements Specification	No	Basic Threat Onto (BTO)	No
Dobson and Sawyer (2006)	Semantic Web	Dependability Requirements engineering	No	Dependability Onto + Requirements Onto	No
Geneiatakis 2007	VoIP) services based on the Session Initiation Protocol (SIP)	–	No	SIP Vulnerability	No
Abou assali 2008	Industrial Risk Analysis	Risk Analysis	No	Risk Analysis Onto	No
Dritsas et al (2006)	E-health applications	security requirements identification	No	Security Onto	No
Liu and Lee (2007)	Enterprise information network security risk management	–	No	Three sub-onto: domain, task, and problem-solving	Yes
Ángel García-Crespo (2009)	Semantic web	Security requirements identification (access control)	No	SecurOnto for access control	No
Parkin (2009)	Human security behaviour within organization	Security requirements identification	No	Security Onto	Yes
Lee et al (2006)	Information Systems Certification and Accreditation	Certification and Accreditation security requirements	No	Problem Domain Onto (PDO)	Yes

	Criteria				
	Domain	***Development phase***	***Covers Core Security Concepts****	***Ontology***	***Standards***
Maamar (2006)	Web service	–	No	Secure Context Onto	No
Vorobiev (2006)	Web service	–	No	Security Attack Onto	No
Ekelhart (2007)	Improving Quantitative Risk analysis for organization	Risk Analysis	No	Security Onto	No

As shown in Table I, the proposals present significant results in terms of formal and consensual representation of security knowledge. However, they are still far from the expectation in the field of secure software engineering because of their restriction to certain concepts, development phases or specific application areas with a limited set of security properties and their negligence to risks analysis and security standards. Besides, we have observed that the greatest part of security ontologies do not specify which vulnerabilities correspond to each phase and the associated security requirements and countermeasures. Hence, once a software is deployed it will be difficult for the developer to specify the source of vulnerability and to address it, especially those specific to the architecture and design phase. In order to improve the software security, developers have to be aware about the different types of vulnerabilities a threat can exploit based on theirs classification (a flaw in the specification, a defect in the design phase and a bug in the implementation).

Ontological Approach for Software Security Knowledge Management

Due to the amount and dynamic nature of security knowledge, we propose the required knowledge that should be used during the development process to avoid security failures in software products. Therefore, as illustrated in (figure 2), our approach is mainly composed of two views for secure software engineering, the "project" view and the "secure software" view which cover the dimensions describing a secure software product, namely:

- The "secure software" dimension: provide the product security knowledge required throughout the development cycle such as its requirements, specification, documentation, environment, etc. We distinguished two main classes of product knowledge to manage:
    - A wide knowledge typology used during the development of secure software product (based on standards, guideline, knowledge base, etc.)
    - The previous projects experiences as security artifacts depicting undertaken security decisions in a particular situation.
- The "project" dimension: explicitly presents knowledge about the process, i.e. secure software engineering context in the form of process, engineering activities, resources, and engineering artifacts. It describes how to develop a software product (process, procedure, etc.) and helps to identify the strategies and tasks to be performed.

Fig.2: Security knowledge typology in the different view of software product

This research study focuses mainly on the "secure software" dimension to manage the product knowledge (Theoretical and Experience). The security experiences (cases of previous projects) that result from the software development process could enrich security knowledge.

Our approach encompasses the three pillars of knowledge management namely: (modeling, capitalization and sharing) to provide a vocabulary of discovered security issues and their resolutions needed for the engineering of secure software. A high-level schematic overview of our approach is presented in (Figure.3). It guides in fact, the discovery and the utilization of security knowledge using an ontological framework and the classification and reuse of previous projects experiences in a specific domain, phase and context. In the following section, each component of the approach will be described in details.

Fig.3: Ontological approach for software security knowledge management

a- Explicit and Consensual Modeling of Domain Security Knowledge for Secure Software Engineering:

We have identified three main facets characterizing the security knowledge management: application domain, risk analysis and secure software product. The modeling of these facets relies on the ontological engineering as it supports browsing and search semantic contents and on the ontology alignment process in order to retrieve and provide the main security concepts and risks in different application domains. In this context, we propose a generic domain security ontological framework for secure software engineering (DSOF-SSE) depicted in (figure 4), encompassing three ontologies representing the identified facets respectively. This generic framework presents domain security knowledge in a formal and structured way. It could be used in the different software development methodologies (Agile or traditional process) as it provides security knowledge by phase and objective (security functionality). The security functionalities (e.g. access control, authentication, cryptography, etc.) could be integrated into the Agile development process particularly in the Scrum methodology (ex. described in user stories and implemented in sprints). This will allow us to avoid the vulnerabilities that could emerge due to the accelerated development process and to reduce the time and effort required to solve security issues, preserving therefore the characteristics of Agile methods (in terms of time and size). Likewise, DSOF-SSE framework acts as a semantic foundation for security experiences management.

Fig.4: Domain Security Ontological Framework for Secure Software Engineering (DSOF-SSE)

The originality of the proposed generic ontological framework lies in the use of the application domain context and the risk analysis to derive the required security requirements that deal with full life cycle of software product development. Likewise, it provides all the relevant security concepts based on the software security standard (ISO 27034) and the reasoning services about security concerns to make software developers aware of the main security risks, vulnerabilities and countermeasures in a given domain. The DSOF-SSE would reduce the required effort to design and implement secure software product for any domain.

b- Capitalization and Sharing of Security Experiences:

Experience management is a special kind of knowledge management. It aims at the acquisition and spread of specific knowledge emerged and generated during a particular problem-resolution situation in previous projects. The security experience management (SEM) method adopted in our approach relies on the case-based reasoning (CBR) which exploits the ontological framework proposed

previously. This latter plays an important role in capitalizing, describing and sharing security artifacts that present decisional and contextual dimensions of security knowledge. In fact, security artifacts are an important source of knowledge. They incorporate specific security knowledge situated in a particular problem-solving context and can be reused in the development of similar future projects. These artifacts are a powerful tool for three reasons: First, they help in indicating the best method to integrate security during the development of software and to choose the appropriate technology depending on application domain and process. Second, they facilitate the exploitation of the know-how emerged during the development process by software developer. Third, they help in reusing tested and validated previous experiences to improve the resolution of current problems. In this case, we propose security experience management to support an easy development of secure software by integrating approved security solutions during the different phases of the software development (misuse case, abuse case, threats model, specific security ontology, secure source code in a specific programming language, etc.). Our goal is to provide software developers with real and similar cases that deal with full life cycle in order to adapt and reuse them to the considered case. We propose two models to manage security experiences: capitalization model and sharing model.

c- Enrichment of security ontologies

With the current state of technology constantly evolving, we guarantee the enrichment of the proposed ontologies to address the emerging security problems. In fact, the knowledge represented in security artifacts populates and extends in return our ontological framework. Accordingly, this latter has the ability to evolve over time.

Conclusion and Perspectives

This study has shown the significant role of ontology in ensuring the knowledge management for secure software engineering. We presented a classification and analysis of existent security ontologies based on relevant criteria (domain, context, risk analysis, phase, security standards, etc.) identified for secure software. The survey has demonstrated the lack of security ontology that covers all the required criteria for the development of secure software. Accordingly, we have described an ontological approach for security knowledge management and security experience management, specific to software product. We have also proposed Domain Security Ontological Framework for the modelling of security knowledge which would be more suitable for secure software engineering and which would support the capitalization and sharing of security experiences from previous projects. We believe that the proposed approach can substantially help the developer to search, retrieve and reuse domain security knowledge. Moreover, it addresses software security related issues in every phase without the need of a high level of security expertise in the required domain. Regarding future work, we envisage the development of the proposed framework and provide a case study to test the effectiveness of our contribution. We plan to make this ontological framework a fundamental base for the management of security experiences and to associate security knowledge with security artifacts produced in the development of software.

Abstract

The purpose of the study was to understand if the hotel, being the bond between real experiences in the destination and the guest, would increase their satisfaction and possible loyalty. Based on the internship carried out in the Guest Relations department of one Hotel in Oporto, a qualitative and quantitative analysis was carried out on the comments left by guests on Booking, Tripadvisor and Google, the main online tourist platforms for the unit - best current way in order to be aware of the customer's needs and preferences. From the analysis carried out, we can conclude that although there is a great importance with the main services that a hotel can offer, namely the room, it is the intangible aspects that are most important. Currently, tourists need to add value to the tangible through experiences that make them evaluate the service in a positive way. With the evolution of technology, and the fact that information available is increasingly quickly, it is necessary to be constantly analyzing the preferences and wishes of the guests, as this knowledge is an advantage for the units and therefore it would be advantageous to cover this study to other units in order to achieve a better objective - increasing all the Portuguese hotel service.

Keywords: Experiences Marketing, Hospitality, Loyalty, Satisfaction

Introduction

As a result of the exponential increase in tourism, all areas were forced to develop and evolve in order to be able to sustain themselves in the market. Hospitality was no exception, and so, these days, it is not just about offering an accommodation service, or a restaurant service, but a memorable experience that the guest will not be able to forget.

Guests demand for a higher quality of service is increasing and the great trend in recent years is the offer experiences (entertainment, aesthetics, escapism and education), (Sipe & Testa, 2018). The customer is no longer looking for just an accommodation service or a catering service, but to live an experience that remains in his memory, the moment he lived or passed through. Nowadays, this reality is already common knowledge and is already beginning to be applied in the hotel units, however, very little is known about how they can influence the satisfaction of a tourist or guest and establish practices of what to do. Thus, experience marketing emerged and took shape, and this involves "providing customers with unique and memorable experiences to establish a positive relationship between the customer and the brand has become one of the main challenges for brand managers." (Wiedmann, Labenz , Haase, & Hennigs, 2018, p. 103).

In an era in which more and more information is available and it reaches people in a short time, the needs and preferences of the individual, more specifically of a tourist, has been changing and thus, we are witnessing a transformation in this economic sector. All the information that future customers receive can influence them before they use the unit. According to Malheiro, Sousa & Ferreira (2019) the information given by tourism blogs can be considered an attempt to express tourism consumption, that is, the user reveals their experiences throughout the trip from boarding to destination as well as accommodation, meals and its final impression of the trip.

Therefore, we try to understand with this study if this type of marketing that has grown in relevance in the last few times, can influence and increase customer satisfaction in relation to a hotel and, consequently, allow customer loyalty to the brand. It is intended to develop a project in the area of experience marketing, more specifically, to understand whether the offer of experiences to guests that involve them in the local community leads to a greater degree of satisfaction and even to their loyalty to the hotel.

Taking into account this last factor and the fact that little is known about how to "design multisensory experiences that lead to a high and sustainable brand strength and offer customers a high perceived value" (Wiedmann *et al*., 2018, p. 121) , the objective of this project was to understand whether a possible relationship between the hotel unit and the local community in order to offer unique experiences, adapted to the destination so that the tourist lives and witnesses the true customs of the local population, raises their satisfaction and possible loyalty. According to Sipe & Testa (2018) "Destinations provide a combination of products and services." (p. 181). Thus, the goal is to create programs of activities or experiences to awaken the 5 senses in order to create a life experience for guests, realizing if the degree of satisfaction achieved in this can be such that it leads to their loyalty to the hotel unit / group. With that goals in mind, the starting question was: How can the relationship between the hotel and the local community influence customer satisfaction? For this, the comments of guests left on the online platforms were analyzed, as we considered that this was the most effective way of knowing their feedback.

Literature Review

One of the tourism composites is the hotel industry and, at this moment, it occupies a central and essential place in this economic sector. According to Melik & Ingram (2002) these activities take on enormous importance not only for visitors, but also for society, in terms of being adapted for business transactions, meetings and conferences. In addition to the specific workforce of the hotels, we also have as examples the collaborators that are needed, such as decorators, civil construction, material suppliers. All these dynamics contributes to the economy and hotels are an important instrument for society itself. In recent years what we have seen is an exponential increase in tourism, worldwide, but mainly in Portugal. A radical change, not only at an economic level, but also at a professional level, in cultures, in the rehabilitation of cities, all because of this activity. If we consider all Europe, in turn, in the same year, remains the most visited continent in the world. "Once again, the strong economic performance of the tourism sector proves its power as a tool for governments to generate prosperity while creating jobs around the world." Gloria Guevara Manzo, President & CEO of WTTC, in 2019 (p.2).

Now moving to Portugal, and according to the WTTC, in 2018, tourism grew more than the world result by around 8% and the main source market remains the United Kingdom.

Several authors claim that the internet was a determining factor in the evolution of the hotel industry. In addition to a greater booking and online purchase of different tourist services, it appears that tourists are more informed and, consequently, more demanding.

Therefore, internet means more information and more information implies an evolution in the motivations of consumers that have led to new forms of hospitality. Due to the high existing competition, the differentiation is found on the experiences offered. Igreja, Silva & Sousa (2020) defend that the quality of service has proved to be one of the key elements to obtain a sustainable competitive advantage in the market. A tourist is no longer looking for just a room, a meal, he is

looking for an experience "as a whole", that is, that encompasses all these elements and remains in his memory - unique, authentic, memorable experiences, complementary to the offer, such as resorts, charming hotels, design hotels, thematic hotels. Ferreira & Sousa (2020) defend that tourist activity is performed for leisure purposes, although there is also tourism for business reasons and other reasons, and more and more tourism is conceived for playful moments and escapades to the routine. And this is where a Guest Relations comes in. One of the tasks or the major task of a Guest Relations is to understand and get to know the guest in order to encounter their needs and exceed their expectations. Already in 2015, they warned that with the changes that we have been observing in this area, we cannot forget the essentials - always keep in mind that hospitality is the "art of welcoming" and that the so-called "human warmth" is what it turns a mere stay into an experience to repeat and recommend (Costa & Sousa). There are other resources equally important and taken into account when you talk about the relation with customers, and through activity on their social media pages, hotels are able to provide feedback on how their strategy is developing. (Malheiro, Sousa & Ferreira, 2019)

Marketing in Hospitality

Everyday problems appear, difficulties and needs arise that need to be sought and found a solution. Consequently, Marketing emerged to give some answers. Marketing can vary from company to company, but it is then used to solve customer problems with the ultimate goal of maximizing results. This area emerged in the 1920s (the production era) and the emphasis was on products. Producing as much as possible, at low costs, was the objective at the time, but a stage was reached when it was difficult to sell so much product, thus entering the era of sales. In the 20s and 30s, companies realized that the starting point must be the market and, therefore, the emphasis is on the customer. In the 1950s (the era of marketing), it was when it started to effectively speak and develop marketing strategies in order to satisfy the needs of the market. With a view to satisfying customers, promotions began to be created, for example, "take 2 pay 1".

Today, we are in the age of relationship marketing that is related to customer loyalty and with the objective of establishing a long relationship with the consumer, it allows to give the service to the respective consumer.

In hospitality, for most hotel units it was only in the mid-1980s that marketing evolved from the act of just selling. (O'Fallon & Rutherford, 2011). According to O'Fallon & Rutherford (2011) Hotel marketing has its own characteristics and is defined as a "global attitude of the company in the continuous search for excellence in customer satisfaction to win and retain its market share, in search of changes in the market and new solutions to satisfy customers with different requirements, and exceed your expectations, and finally in the search for the best possible profitability" (p. 21). Costa and Sousa (2015) point out as characteristics of the hotel service that must be met:

• Intangibility: the reminder of the service after it has already been used, hence the importance of creating, for example, objects that not only create value for the customer, but also create a souvenir;

• Simultaneity: the hotel as a whole, including employees and management who work together not only to serve one, but several customers at the same time; these are the interactions that are established between the hotel and each client between clients, as a necessary condition for the existence of the service itself;

• Heterogeneity: each service depends on the client that is presented, the number of clients, nationalities, and the worker who is providing the service;

• Perishability: the hotel service is limited to selling rooms mostly, and these cannot be stored, hence the famous phrase, "a room not sold today, will never be again". (Costa & Sousa, 2015, pp. 19-22).

Therefore, it is clear that the hotel industry has several aggravating factors and characteristics that require their own strategies - hotel marketing strategies.

Marketing services vs. Product Marketing vs. Experience Marketing

Product marketing was the first type of marketing to be analyzed and for which they began to outline marketing strategies and plans. With the emergence of service marketing, the focus turned to the customer, on what the company could, in addition to the product, have at its disposal in order to add value, such as delivery, packaging and tracking. If, on the one hand, a product is predominantly physical and tangible, a service is the result of the application of human

efforts to people or objects. And last state is considered the type most complete marketing and is characterized by being all that is received by an exchange process, all that can be offered to a market for acquisition, attention, use, or consumption and that can satisfy a desire or need, a set of tangible and intangible attributes, including functional, social psychological benefits or utilities. It can be an idea, a service, a good, a place, a person or combination of several and includes support services –

facilities, guarantees, information, among others. Arises from the fact that services are becoming increasingly common and repeated and, in this case, factors such as price, category, location and brand in the hotel industry already not sufficient to differentiate themselves from the competition. Most units offer the same kind of services and, therefore, it is necessary to create additional value - experiences that make the customer forget the routine and stress daily. It happens when "a company intentionally uses services as a stage and products as supports to attract consumers in a way that creates a memorable event " (Beni, 2004, p. 303).

Perfect examples of experience savings are: (1) the Walt Disney theme park and (2) the Hard Rock Cafe´, where you can see the use of its products as entertainment and food as a means of entertainment. Developing and triggering real experiences is the secret and also the great challenge, considering that two people cannot have the same experience. The experience to have the desired effect has to be adapted to each client and will always depend on the interaction between the event and the person's mood at the time.

In a study carried out in 2014, determining the contribution of sensory marketing to the marketing of experience, the authors concluded that it is a trend, mainly in rural tourism, that one begins to practice in order to awaken positive emotions, enhancing a high level of satisfaction and loyalty. It is a type of marketing that appeals to the five senses of the human being - sight, smell, taste, touch and hearing - and leads to the processing of sensory stimulation and initiates the process of perceiving the tourist experience. That is why it is so important to adapt the experiences in order to trigger positive reactions. (Agapito *et al*).

On the other hand, already in 2004, it was stated that the best environment to trigger a good reaction is the harmony between destiny and what it has to offer and what it expects to experience, that is, to have the perception of what the tourist seeks, desires and needs (Beni). The total assimilation of the meaning of cultural heritage, knowledge, tradition is a key to this reaction and it always depends, in the case of tourism, on the interaction between residents, visitors and tourists. The author even believes that by entertaining tourists from the big cosmopolitan centers and taking them to places with great patrimonial value, where they can really absorb the moment and away from the temptation of consumption, this will lead to the satisfaction of the experience and the creation of memories. Authenticity is the key and can only be transmitted by the local community. A study, carried out in 2020, by Ferreira & Sousa, contributes to this theory demonstrating that an activity as typical and traditional as handicrafts and its craftsmen, in the target city of the study being used as a marketing strategy, contributes to the experience of tourists and your decision making in that same destination. Thus, experiential marketing begins to gain prominence today, following the preference of consumers.

In a hotel unit, several are authors who can contribute to the guest having a true experience , from the receptionist who, for example, in the city of Oporto, welcomes the client with the well-known northern hospitality, to the floor maid who contributed to the comfort and cleanliness (feeling at home), to the barman, who can either serve an Oporto Wine when telling the story of the wine, or giving recommendations and suggestions.

Today, a hotel employee is not limited to his function, there is a synergy of functions that contributed to the true experience. The role, in the various tourist developments, that contributed most and that can help in carrying out the experiences has several designations depending on its location in the world: Concierge, Guest Relations, Guest Service Collaborator, among others.

Social Responsibility and Perception (Impact of tourism on local development)

With experiences more authentic and more real, we give to tourists the opportunity to know how the locals really live in the destination tourist and what are the true traditions.

They are not limited to passing through the so-called "most touristic" places, if possible, even avoiding them, but taking them to see characteristic places with authentic details, buildings and history, places that make them feel that they have returned to their homes, truly knowing the area they are visited and their people and traditions. This communication between tourists and destination, can and should be done through the hotel not only because it is the place where guests ask for more advice and clarify their doubts about visits and tours, such as the hotel employees themselves being citizens in the destination, have the knowledge of what is really true in the city and know how to advise the guest.

This interpersonal relationship is fundamental when we talk about the hotel service, which involves the customer, the service recipient and the employee, the service provider. Only if there is a relationship between these two parts can there be an economic development.

Satisfaction and Loyalty

The main purpose for which the hotels are in constant change and try to adapt to the client and meet their needs is to get their satisfaction and loyalty to his unit and, therefore, already Costa in 2008, explain the importance of offering a service of quality.

In addition to a service with quality, we are in an era of experiences and the administrators in order to raise the satisfaction most invest in improving the various services of the hotel or improve the perception of customers in relation to their experiences lived. The latter is the best and least expensive method. (Sturman *et al,* 2011).

Regarding the guiding guests ' experiences, the goal is to reinforce the customer's attention to the positive aspects of their experiences and avoid focusing on the negative aspects. One way to guide experiences is to pay attention to guests ' feelings. And how can we act? Raising the awareness of guests, involving them in sensations and leading them to think. The guests emotionally involved are those that most enhance the "word of mouth" and the promotion of unity than merely satisfied and are these that we have to work. Consequently, it is necessary to apply strategies that meet the needs and preferences of the guests and satisfy them and create this emotional link. (Sukhu Choi, Bujisic, & Bilgihan, 2019). With the importance of the internet and social networks, sharing experiences on online channels started to be a concern for hotel managers. Today, these help in making decisions and the definition of strategies marketing as they help to understand what generates satisfaction and what are the new preferences. (Ahani *et al*, 2019). In 2019, Malheiro *et al*, concluded that the biggest advantage they bring is their help in publicizing the hotel, promoting it, facilitating the brand exposure as well as interacting with customers quickly, creating an impact and thus arousing a desire and consequent action. However, these must be implemented with due care and rigor and, if so, their influence should be immediate. On the other hand, the budget for them is very low because hotels still do not feel the need to invest in their online promotion and this leads to a decrease in possible effects such as attracting users and leads to a need to create value for the brand. Therefore, the intention of this study was to evaluate the online platforms where guests share their comments more, since 2017, in order to answer the question previously mentioned.

Methodology

In order to answer the question "*Can, the relationship between the hotel and the local community in offering real experiences, influence customer satisfaction*?" an analysis of all online reviews since 2017 was carried out on the Tripadvisor, Booking and Google channels. These three platforms were analyzed because the unit in study considers the most important, and focus the attention when it comes to advising customers to leave their message, those that are subject to evaluation by the Guest Relations department, which evaluates and responds (100% response rate) and which contribute to the company's annual goal.

According to official hotel figures, the average annual occupancy rate is around 62%. Thus, considering that the hotel has a capacity of 107 rooms, we can conclude that the hotel establishment has an average number of rooms nights sold of approximately 24.214 per year. Also considering that until the mentioned dates, the combination of comments from both Booking , Tripadvisor and Google was 3.064 and considering that the occupancy rate of groups is around 54% (guests who already come with a defined program of what to visit and therefore, there is no margin for contact with the hotel services and everything they visit and experience is defined by the guides), the rate of sharing of comments is around 10%, with a greater adhesion by the guests who make reservations through Booking with a rate of 39.65%, on Tripadvisor 36.29% and on Google 24.05%.

The sample was the subject of a longitudinal study, that is, in a first phase the sample was analyzed, which is the adherence over the years and its contribution to the position of the hotel online, and in a second phase, the comments were analyzed, which were the guests' needs, what kind of experience influenced their satisfaction in order to increase their satisfaction and led to a possible return of the customer. The data collected were analyzed between the dates of sixteen and twenty-one of September. Comparing the three, we find that 2018 was the year with the most affluence, in which the top two categories lead the table, however, at the same time last year, the number of comments was lower in about 118 shares and therefore , it is estimated that this year the shares will be more, keeping the number in the categories of 4 and 5 stars, but observing a substantial increase in the two lower categories. So, to conclude, the unit on both platforms is in an excellent position, remaining in the TOP 10 of the Oporto region. On the other hand, there seems to be a decline mainly on Tripadvisor for comments and a greater appearance of negative comments. So, as a response, the hotel should try to analyze these negative comments and understand what happened so that they are specific events and in order to improve the service for future customers, and on the other hand, they must find strategies to encourage guests who express their satisfaction in sharing their comments on online platforms in order to increase their annual volume.

Results Analysis

First, a qualitative analysis divided into several categories (based on the monthly analysis table for online comments) and classifications, and then a quantitative analysis to determine the weight of each category in scores and guest satisfaction; and finally.

In short, making a division between satisfied guests (ratings of 4 and 5 stars or from 7 to 9 and more than 9 points on Booking) and dissatisfied (ratings 1, 2, 3 or from 1 to 3, from 3 to 5 and from 5 to 7 points, respectively), we can formulate the following conclusions:

- There are categories common to all scores, namely the room, service, breakfast, spa, cleaning service and facilities, and thus, it can be said by referring to the marketing concepts, these are the main "products" of the Hotel;

- Especially in the lower scores, not obtaining satisfaction with the main products, the reference only goes through these aspects and in which point they had an experience with them, not to mention other categories;

- In the higher scores, the positive rating dominates the negative while in the lower scores, the opposite occurs;

- In the lower scores, more specifically in the 2 and 3 stars (1 to 3 and 3 to 5 points), although the same categories have both positive and negative expressions, in the lower one, breakfast is more criticized and in the upper one, the cleaning service is more congratulated, the service and the room more criticized;

- The categories mentioned above, as main products, are therefore the target of the highest criticism in the lower scores, and it is in these that the hotel has to evaluate and analyze what can be improved in order to achieve global satisfaction;

- In the higher scores, with their satisfaction already achieved through the main products, the criticisms focus more on intangible aspects and on those that can add value to the "product". In the score 3, there is also a marked negative percentage in the concierge service and, therefore, the function of recommending, suggesting, influencing the customer experience, wi-fi, maintenance of facilities, security, parking and air conditioning are targets also for analysis and that matters to guests and that when improved can lead to an increase in their satisfaction or full;

- Adding the two highest categories, most guests leave the hotel willing to recommend or return the next time and about 39% mentioned the concierge actions, such as surprises in the room, welcome amenities, city recommendations, among others. The services of this department appear in these two as a well-mentioned positive point, and thus, we conclude that it is aspects like these that make the difference and distinguish higher from lower scores. In this way, we can conclude that in the unit of analysis the so-called "main product", despite failing, in the majority is very well achieved; and with the type of price it charges, guests expect more and, therefore, the biggest concerns focus on adding value and extra services and that customers "demand" quality. However, it is necessary to maintain regular control over essential services and invest in improvement in order to reach a state of full satisfaction that reaches everyone.

Based on the above, satisfaction can only be achieved when a hotel bets on improving its services, or when strategies are developed to appeal to the 5 basic senses of its guests and shifting the focus to the positive points of their experience , of what you can enjoy and help the client to "stop" and live real and memorable experiences, deep down, escape from your daily life. Thus, in Tables 1 and 2, a set of actions is developed for both scoring fields (satisfied and dissatisfied), for the main and most mentioned categories and based on the referred strategies.

Table 1: Actions to increase satisfaction in higher categories

Category Fields	Actions	
	Improvement of services	Sensory and experiential awareness
Satisfied	**Spa**	Put on the turndown service (bedding), robe, slippers, candles, blindfold for example, in order to refer the client's awareness to the spa part of the hotel and to help him relax on the premises;
	Increased space;	
	Space renovation;	
	Knowledgeable, professional and friendly service, that is, hiring a permanent person who knows the space and relax the guests you receive;	
	Personal Trainer service to accompany guests;	Creation of references and actions with a view to the relationship between the guest and social networks, such as a hashtag specific to the hotel, of a specific space in the unit designated for guests to take pictures in order to promote sharing and draw attention to the service of internet;
	Regular maintenance check;	
	Wi-fi	
	Enlargement and strengthening for the total area of the hotel;	
	Maintenance	Promotion of the hotel's history and the originality of its façade with references throughout the unit, for example, in elevators, corridors etc; A way to awaken vision and touch, inviting guests to touch Portuguese stone for example;
	Hiring an own hotel team and not an outsourcing service;	
	Regular control of the condition of the facilities;	
	Long-term maintenance plan;	
	Parking	Insist on a professional service, awakening the sense of smell and exceeding expectations by placing, for example, a source of smell in the car, for the guest to go with the memory of their trip home, a farewell message and water for the trip;
	It is not possible to own parking, investment in a permanent vallet service.	

Table 2: Actions to increase satisfaction in the lower categories

Category Fields	Actions	
	Improvement of services	Sensory and experiential awareness
Dissatisfied	**Service**	Impeccable presentation, according to company standards - awakens the vision;
	Continuous training and new employees with a view to improving cordiality, keeping in mind the company's philosophy, going beyond what is expected to serve the customer;	Knowledge of the hotel, its history, the city, warmth, friendliness and a focus on going further to satisfy guests' needs, is the focus and that elevates an experience - making customers feel they can count on them;
	Creation of a network of restaurants, taxi services, tours, etc. reliable and safe to recommend to guests;	Betting on local, Portuguese decoration that promotes tranquility - vision and a sense of refuge; placement of show-cookings to increase the sense of smell and empower the client;
	Breakfast	
	Opening the breakfast area for greater capacity;	Promote smell, with a typical incense left when cleaning the rooms;
	Differentiated, local, quality products, varied every day;	
	Definition of a more competitive price;	Creation of a relationship between the customer and the cleaning team with the placement of a card with the name of the employee who performed the cleaning and with space for the customer to be able to say what they want in their cleaning in the coming days;
	Facilities	
	Redefining the organization, practicality and design of the facilities;	
	Housekeeping Service	Betting on a constant presence, on the part of the concierge, in the customer experience and accompanying him on his visit to the city and showing the best places according to his requirements and thus awakening all the senses feeling that they are with a security person and that you can count on it;
	Correct formation of good cleaning, and chain standards;	
	More control by the floor housekeepers;	
	Motivation and assurance of human resources;	
	Concierge	
	Regular attendance indicating your presence at the hotel;	
	Portfolio of reliable partners and differentiated knowledge of the city.	

Conclusion

For the eighth consecutive year, tourism is the economic sector that has registered a greater increase than the world economy. In this way, the President and CEO of WTTC draws attention to the fact that governments begin to see this development as a "lever" for the improvement of national economies. Despite the economy showing signs of slowing down, tourism is expected to remain resilient and constantly changing.

The majority of the responsibility attributed to this change is the internet. The technology and quick information available being increasingly present in our daily lives, the tendency to leave an online comment about your stay in a hotel seems to be fading, however, on some platforms more than others, the estimate in 2019 it seems to follow the 2018 numbers.

Stress and pressure also seem to dominate our routine and that is why it is imperative to think of ways to escape from everyday life and create memorable and real programs. If, on the one hand, tourists are looking for the best experience at the best price, on the other, hotels and destinations want more and more tourists, to spend more and more and be satisfied in order to be able to return and recommend to others. Loyalty and *wom* are fundamental for business loyalty and sustainability.

Marketing appears as a response to the needs of consumers and, consequently, in hospitality, the marketing of experiences begins to gain a prominent place. Unique experiences, adapted to each person, according to their preferences and needs and memorable. On the other hand, in response to this new trend and high competition, the challenge for hotel units is to create something with different added value, at the best price, in order to create satisfaction.

Thus, it was important to understand if these were really affirming needs, what kind of experiences they were looking for, and if the hotel, by creating a relationship between these two agents, could bring advantages such as possible satisfaction, or an increase in this (as a way of adding value) and possible loyalty.

A study was carried out, first qualitative based on the attribution of categories and classifications, and in a second phase, a quantitative analysis was performed in Excel file, to determine its weight. Responding to the proposed objectives, it is concluded that although there is a need for something more on the part of the visitors, the basic needs of sleeping, eating and cleaning, remain their biggest concern. In view of the above, it can be concluded that a hotel unit can and has the need to be a link between the destination and the guest, taking advantage of the role of Concierges/ Guest Relations, to create a close relationship with the guest. It is essential that he feels that he can always count on someone to help him and provide the best experience, that he has a vast knowledge of the sights and secrets of the city and thus, complementing with basic services, reach a level of maximum satisfaction and possible loyalty to the enterprise.

Thus, a set of actions and practices were developed based on the comments analyzed and based on the strategies referred to in the literature review (strategies that the authors defend are the secret to increase consumer satisfaction), in order to achieve the greatest objective of a tourist enterprise that is the greatest satisfaction with a greater profitability.

Abstract

In the presented paper, the authors deal with the topical issues of e-tutoring in the context of (learning) organizations and attempt to describe the factors which can be important from the aspect of its application's success within an organization. The purpose of the paper is to highlight the benefits of e-tutoring as a cost-saving and effective solution for working individuals as well as organizations. For the elaboration of the topic, traditional desk research methods together with the methods of analysis, synthesis, description, comparison, generalisation, and idealisation were used.

Based on the results of the literature review, it can be assumed that for the so-called learning organizations promoting their personnel's learning activities - which on one hand, are willing to invest in their education, but on the other hand, want to reduce its costs in order to use their resources effectively - e-tutoring is the optimal solution. E-tutoring with its openness, flexibility and accessibility brings benefits for individuals as well; and the experience indicates that it could be suitable both for organizations and the majority of their personnel.

Key words: E-Tutoring, Learning Organizations, Learning, Personnel

Introduction

The ongoing process of implementation of digital technologies into organizations and business communication brings radical changes into companies. Innovations and technologies are being introduced with the aim to make people's lives and work easier but, to make their usage meaningful, purposeful and efficient, certain changes in organizations' structure and functioning, as well as in human resources management must be carried out.

Using technologies and working online have become a commonplace in our times – both at traditional and virtual (digital) workplaces. Moreover, the current trends indicate a further enormous development of digital technologies and an increasing tendency of working in the digital environment, which, under certain circumstances, can lead to higher efficiency of employees' activities. In this context, Faith (2015) highlights the opportunities which more than 2,000 emerging sophisticated technologies under development can bring.

Based on the above, companies must face the challenge of making changes in their cultures and adapt to the newest trends (Snow et al., 2017). They must recognize that digital space promotes collaboration, but at the same time, several threats and difficulties, as well as new opportunities can occur.

With the implementation of new trends and modern technologies, competition in the labour market increases and new needs and requirements occur. In organizations, personnel must be prepared in order to cope successfully with challenging situations and therefore, companies should invest into the

education of their employees – whether they offer learning opportunities at the workplace or support their personnel in their individual learning activities outside the organization. It means that they should provide them with sufficient opportunities for their professional and personal development and so, create favourable conditions increasing their job satisfaction. Organizations must recognize the fact that learning is among the factors that help individuals adapt quickly and easily to the changing reality both in their private and professional lives. In this context, e-learning and e-tutoring with their benefits for both employers and employees appear to be the most suitable option.

Learning Organizations

Organizations paying sufficient attention to the education and training of their personnel have an undeniable advantage in the labour market, as opportunities for further education and promoting personnel's learning activities have the potential to accelerate the processes inside organizations and increase the efficiency and the quality of their services provided to their customers (Barna, 2019). Moreover, learning opportunities and sufficient space for professional and personal development of personnel increase their job satisfaction and it is employees' job satisfaction which can be the decisive factor from the aspect of an organization's success on the market (Krásna, 2015).

Promoting learning activities forms an integral part of most successful organizations' personnel management policy as they have realized that investment in human capital can be considered among the best investments (see Matúšová, 2015; Hužovičová and Jakúbek, 2014; Oberuč et al, 2016) in the current era of high expectations placed on organizations. Also managers are well aware of the fact that if they want to develop and expand, they must create such working environments, which enable their personnel's adaptation to new conditions and expectations quickly and easily. It means preparing them for permanently changing conditions and circumstances, teaching them how to behave in unexpected situations, to be creative and to apply critical thinking. This is only possible by means of education (Tamášová et al., 2018).

As indicated above, available research results suggest that employees' knowledge and learning activities have an impact on the success and productivity of an organization on one hand and on the other hand, they increase their job satisfaction (Krásna, 2016). But for organizations, there is a wider range of benefits which can be used in argumentation for supporting their personnel's learning activities - e.g. better developed skills and competencies, increased effectiveness of workforce, up-to-date knowledge and information about the latest development in their segment, increased competitiveness in the market, higher profit, etc. It is undeniable that for every organization, personnel's involvement in educational activities has many positive aspects.

Learning organizations go even further than traditional organizations, they do not only support their personnel in their learning activities - promotion of education has become a part of their culture. They recognize the importance of up-to-date knowledge and information, and well-developed skills in the context of their functioning. They know that for rapid progress, they need to undergo certain changes. The shift from a traditional organization into a learning one is a complex process. Truneček (2004) draws attention to four basic requirements which must be fulfilled:

1. Creation of a favourable climate which motivates individuals to learn and to develop their skills and abilities voluntarily.
2. Spreading the culture of learning outside the organization - to suppliers, customers, partners, etc.
3. Application of a specific strategy for human resources development and including the processes of individual learning into that strategy.
4. Continuous transformation of the organization based on the results of individual and collective learning.

In learning organizations, development is a systematic process. They do not promote isolated activities; the emphasis is on personnel's continuous improvement. Senge (1990) defines learning organizations as those paying special attention to increasing their personnel's ability to achieve the expected results

and to their involvement in joint learning activities aiming to teach them how to participate in creating and improving the reality. In these organizations, high quality personnel management and charismatic leadership have a big role to play.

Pokorná and Ivanová (2010) characterize learning organizations as follows:

1. They have a clear vision. The direction of personnel education and training is given - the organization's goal in this fields is explicitly formulated and individual, collective, and whole-organizational systematic activities are targeted at achieving it. A special emphasis is placed on the importance of learning and particular attention is paid to its forms, methods, and the overall context of educational activities.
2. The overall concept of learning organizations is based on high-quality human resources and personnel management activities. They pay increased attention to human resources, creation of favourable working conditions, and make efforts to provide their employees with a range of opportunities to learn.
3. They work on changing their personnel's way of thinking, which is a very long and complicated process, and focus on their overall development. Such an approach must be first adopted by the leaders in the organization - changes start from the management. Managers are charismatic leaders who apply positive thinking and openness in communication. These factors can be considered among the basic preconditions for success. Managers' task is to become role models for other personnel in the entire organization.
4. In learning organizations, team work is applied and the importance of open communication is emphasized. They form an inevitable part of an organization's system of work which should be adopted by every employee. In practice, real team work is very difficult to achieve and the possibility of its full and flawless functioning within the entire organization is questionable.
5. Strict rules apply to handling information produced, gathered, and used by employees.
6. Within learning organizations, untraditional forms and methods of learning are often used. They see learning in its broadest sense and are open to "experiments" in order to achieve the best possible results.

From the point of view of a learning organization's success, the choice of a suitable strategy is decisive. It is very important to motivate employees to learn and to find appropriate forms and methods of personnel training which meet the needs of both the organization and individuals working in it. They must be meaningful, purposeful, attractive and diverse as especially adult learners must face various problems in the process of learning. They often complain about a lack of motivation or opportunities. For them, it is also difficult to find time for learning as it is demanding to synchronize their work, family life, friends, and hobbies with their studies. Therefore, such forms and methods of learning must be found for them, which are accessible and affordable (Barnová and Krásna, 2018a).

For dynamically developing organizations, traditional forms of education - e.g. learning from textbooks or school based learning - are not suitable anymore (Pokorná and Ivanová, 2010). In learning organizations, the offered educational opportunities are flexible, learners' preferences and interests are taken into account and formal learning is partially replaced by non-formal learning activities. Traditional learning environments are often changed for learning online as with the working population, highly individualized forms of learning appear to be the most effective.

(E-)Tutoring in Learning Organizations

In the last two decades, it has come to radical changes in the educational needs and requirements of individuals, organizations, as well as the whole society. Especially employees and organizations must deal with a range of new and demanding situations on a daily basis (Lajčin et al., 2014), which is mirrored in their strong need for replacing traditional forms of education by those more corresponding with the current needs. The methods of individualized instruction have become very popular, which, compared with the traditional ones, can be characterized as more open and flexible. This is an important issue for learning organizations, which want to find the most efficient way of education and training for their personnel.

Based on the above, it can be assumed that currently, highly individualized, tailor-made forms of education are frequently opted for among employees because they can be adjusted to every learner's needs, requirements, and expectations. For the same reasons and because of time restrains, individual learning is becoming more popular than learning in groups or on the organizational level. At workplaces, the virtual learning environment is often used for the purposes of both self-directed learning and guided learning - including tutoring.

Tutoring can be defined as a process based on the relationship of a tutor and a tutee of any age in the process of personal or professional development (What is tutoring?). Tutors are experienced and competent professionals who provide their tutees with guidance, counselling or supervision.

It is often wrongly assumed that tutors exclusively work with school children or university students. Not only children and adolescents but also adults often need someone who can guide them through their learning, professional advancement or personal growth and adult-to-adult guidance with its advantages appears to be an effective form of adult education (Barnová and Krásna, 2019b). Besides mentoring and coaching - which are based on different types of relationships - tutoring is the option frequently applied in working environments.

The purpose of tutoring in the context of organizations is to prepare independent workers, to show them how to handle various situations, how to find answers without their tutor's help. Tutors do not offer ready-to-use solutions, they lead their tutees towards knowledge and help them develop skills, knowledge, competencies, and abilities they need for their personal and professional growth.

E-tutoring is the innovative form of tutoring realized online, i.e. in the virtual environment, which occurred with the development of new technologies. It can make use of the advantages of a recent phenomenon - permanent connectedness. Connectedness has a significant impact on the way people access, publish and share information, but also on the way they learn. In learning, it must be taken into account that the ability to actively deal with digital information and media and to communicate with others in the virtual environment (OECD, 2012) are important. One of the advantages that connectedness brings is that it helps creating communities and changes the character of social interaction and relationships - connectedness changes communication to interaction (Barnová and Krásna, 2018b, 2019a).

E-tutoring can be considered the optimal solution in contexts, in which regular face-to-face communication is difficult. For organizations, it is among the suitable form of workplace training as it is flexible, open, accessible at any time and from everywhere, and highly efficient. Its advantage for the learner is that the development of social networks has made "here and now" real-time communication between the tutor and the tutee possible.

The history of online tutoring started with the implementation of digital technologies into the educational practice. Online tutoring emerged with e-mail communication, which provides learners with the opportunity to submit their tutor questions anytime a problem occurs, they needed help or a question arises, and, subsequently, they receive answers online. The problem of this form of contact lies in the time gap between sending a question and receiving a respond - students cannot expect immediate answers. This kind of asynchronous online tutoring has several benefits as well - e.g. it gives the tutor time to think about the answer, to search additional information and formulate the answer carefully. E-mail tutoring is especially suitable for reviewing writings or evaluation of written assignments.

With the ongoing rapid development of technology, the synchronous form of online tutoring was introduced. Both the learner and the tutor are online and they can chat on social networks or in the applied virtual learning environment in real time - they can interact simultaneously.

E-tutoring is undoubtedly an effective form of learning combining several benefits for both the organization and the learner. It completely eliminates travelling costs as there is no need to commute

and the relationship between the tutor and the tutee is not limited by distance. It is also time saving as it is available 24/7 and it is accessible any time and from anywhere with no time restrictions, which means that it reduces stress from being absent at the workplace and saves time for tutees to be with their families and for leisure time activities. E-tutoring enables self-paced personalized learning where, if needed, the same topic can be discussed several times, the entire communication can be recorded and learning can be enhanced by using individualized tools.

Is e-tutoring for everyone?

Even though both face-to-face and online tutoring presuppose self-motivated and independent learners, if we compare traditional tutoring and e-tutoring, e-tutoring is a more open and convenient form of education for those who not only possess the motivation, sufficient competences, skills, and abilities to use digital technologies for learning, but also positive attitudes towards learning online are important.

As e-tutoring is most frequently used with new personnel who need guidance and advice in the initial stages of their careers, it is usually (but not exclusively) applied with the younger generation, i.e. the "Digital Natives". It is broadly accepted that the young generation tend to use digital technologies for educational purposes more than their older colleagues as they have been born into the digital era and technologies represent an inevitable part of their existence - they cannot even imagine their lives without them. But in available resources, they are often wrongly considered a homogenous group. In fact, not all of them are digital learners, many of them prefer face-to-face communication or more traditional forms of learning, which should be taken into account when planning to introduce changes in organizations. Digital technologies can make a difference only if its users have the appropriate set of competences, skills, and attitudes - e.g. their inability to fully evaluate the validity of information can represent a barrier in their learning. In this context, the extent to which the "Digital Natives'" expectations have changed is questionable and it is not clear whether all of them want to transform the more or less traditional forms and methods of learning. Therefore, e-tutoring should be an option, not the only choice for employees.

Conclusion

Organization, if they want to maintain their competitiveness in the labour market and increase their productivity, must pay sufficient attention to creating a favourable learning environment for their personnel. Nowadays, it is not a matter of questioning whether the creation of such conditions and application of newest knowledge from the field of pedagogy brings any benefits (Várkoly et al., 2015) for organizations and learners. Providing learning opportunities as a part of personnel management policy generates skilled and educated personnel, which possess up-to-date information and know what the current trends in their segment are.

For organizations promoting their personnel's learning activities - on one hand, they are willing to invest in their education, but on the other hand, want to reduce its costs in order to use their resources effectively - highly individualized forms of learning are the optimal solution. Digital technologies and connectedness offer new opportunities for online learning which is open for everyone, flexible and accessible at any time and from everywhere - they make learning possible even for those adults, which, for any reason, cannot be involved in traditional education. E-tutoring combines the advantages of highly individualized forms of leaning and learning online and so, represents an attractive and effective option for both the organizations and their personnel.

Abstract

This research includes the analysis of the current state of the information environment of Kazakhstan, assessment of the effectiveness of regulatory activities of government agencies in this area of information environment, the analysis of the need for permits, identification of promising areas for the development of entrepreneurship in the Internet industry. The article also focuses on the formation of value chain structure for Internet projects in Kazakhstan. Justification for value chain development is based on the experience of developers and experts of this research in the development of the information environment in Kazakhstan.

Keywords: Kazakhstan, economics, digitalization, value added, internet projects, information technology, budget investments

JEL Classification: L86, H11, H54, O14,

Introduction

An essential part of the new information society is its global nature. Today's large-scale transformation around the world is driven by the rapid development of information and communications technologies. The Charter of the Global Information Society states that "information and communication technologies are one of the most important factors influencing the shaping of the twenty-first century society. Their revolutionary impact concerns lifestyles, education and work, as well as the organization of interaction between government and civil society. Information and communications technologies are rapidly becoming a vital driver of the world economy".

Information has an immeasurable potential for impact, both positive (creative) and negative (destructive). It is obvious that the global information network Internet is the largest and most massive source for the world information space. Information in the global network has become a key

strategic resource of any state, and the scale and methods of use of information are actively used in political processes in many countries, on a par with traditional resources.

The information space in Kazakhstan is undergoing significant changes due to both political developments in the world and the rapid development and wide spread of new social and media Internet technologies. Businesses in Kazakhstan have started to actively use online resources to promote their products and services on the global Internet. The impact of the information environment on the business community of the country and the economy of Kazakhstan has increased and requires a separate study on this topic.

The global informatization and development of Kaznet on the one hand, and the unpreparedness of the state and business on the other hand, have led to the fact that the country's information and communication infrastructure and national information resources have become the most vulnerable objects of influence from hostile states, terrorist organizations, criminal groups, individual attackers and special compromising material created. The threat of international information terrorism and information wars have become important geopolitical factors.

Development of the information environment of Kazakhstan in the Internet space is an intersectoral, interdepartmental and state task requiring coordination of actions of many participants of this process. Such coordination is possible only on the basis of complex assessment of information environment in the Internet space of Kazakhstan and assessment of its impact on the business community of the country.

In this regard, the issues of development of information environment and assessment of its impact on the business community of Kazakhstan become particularly important. It becomes obvious that in modern conditions Kazakhstan concedes its own information environment to external influence of business companies from Eurasian Economic Union countries.

The purpose of this research is to identify the potential for entrepreneurship development in the Internet industry and to improve the system of its support based on the review of the current state of the information environment and the Internet in Kazakhstan, assessment of the impact of the information environment on the business community of Kazakhstan, making suggestions and recommendations for further development and promotion of Kazakhstani products in the world, assessment of risks and possible negative consequences on the business community of the country in the current economic conditions.

The materials of the article are the result of the research on the development of information environment, assessment of its impact on the business community of the Republic of Kazakhstan and development of recommendations on promotion of Kazakhstani manufacturers in the Internet space.

The objects of research, analysis and evaluation are the information environment of Kazakhstan and participants of the business community working in it.

The research methodology provides an integrated approach to the analysis and evaluation of the information obtained. The following works were carried out to collect, analyze information and develop recommendations:

- collection of relevant statistical information in the information environment;
- primary processing of information on the current state of the information environment;
- inventory of permit documents, obtaining of which is necessary for business activity in the information environment;
- working meetings with representatives of associations of the information environment - identification of problem questions of the information environment;
- primary analysis of the level of development of the information environment;
- conducting surveys, interviews with representatives of the business community;
