privatization provide for a realistic mechanism for regulating the relationship of the new owner (joint-stock company, partnership, private person) with environmental funds (Petrov, 2019).

The transfer of state ownership to another status without taking into account the environmental factor leads to an increase in the alienation of environmental activities from the owner of the means of production, loss of control over environmental equipment, and sometimes the refusal of the new owner from environmental funds as an additional financial burden. There is no economic mechanism to support the company's environmental activities and its bankruptcy.

Taking into account environmental requirements when privatizing national economy objects can become a serious factor in improving the environment of privatized enterprises and ensure that investors ' funds are attracted for these purposes. Some of the provisions of this environmental and economic instrument can be implemented taking into account privatization (including secondary and tertiary). Preference should be given to those investors who are committed to ensuring that the environment of privatized enterprises is restored as soon as possible. At the same time, guarantees should be taken into account and a procedure should be developed for returning to the new owners part of the funds they spent on the purchase of the enterprise, provided that the funds are used exclusively for financing environmental activities. The formation of a set of requirements for taking into account environmental factors related to privatization is connected, in particular, with the creation of a specialized Fund for the environmental rehabilitation of privatized objects. (Protasov, 2018).

IV. Consideration of acceptable environmental risk factors in decision-making. An important element of sustainable development is the mandatory analysis and assessment of acceptable environmental risk due to the uncertainty and unpredictability of many natural processes and phenomena. Any environmentally significant economic event is subject to an environmental assessment to determine its environmental feasibility. Risk accounting for such an assessment is necessary at the pre-project and post-project stages.

In current practice, the environmental impact assessment is aimed at meeting the maximum permissible concentration standards for pollutants in the environment, but does not take into account the risks. Practical implementation of projects in industries related to environmental risk has shown the need to review approaches to environmental assessment. To determine acceptable risk, it is important to identify individual elements of risk, give an overall assessment of it, and compare the results with similar indicators in less risky industries. A set of risk management measures can be considered sufficient if the overall assessment of the project is comparable to the specified actual indicators, for example, for the key parameter of human mortality and injury.

Among the management decisions to reduce the risk of environmental pollution, the most developed economic mechanism for environmental insurance can be identified. Environmental insurance is based on a system of distribution of responsibility for possible accidental pollution of the environment. An important point here is the Law of the Russian Federation "on mandatory environmental insurance". Its characteristic features are: more complete compensation for damage from accidental pollution, which is currently almost non-existent; formation of mandatory funds for financing environmental insurance companies; insurance of sources of increased risk of damage to natural objects (Perelyet, 2018).

Environmental insurance is developing in three directions.

1. Creating a system of responsibility distribution based on probabilistic characteristics of environmental pollution risk.

2. Creation of a flexible insurance system for objects whose activities are associated with a relatively high risk with great uncertainty in assessing the consequences of accidents. (Abroad, this type of insurance is based on the principle of "Deposit-return". It is known, for example, that the destruction of the ozone layer negatively affects the health of the population, but it is impossible to determine the

sources of destruction of the ozone layer. Flexible liability insurance for companies that produce ozone-depleting products can be a solution (Novoselov, 2019).

3. Insurance of investments in environmentally hazardous production and projects. In particular, foreign investments under the carbon credit; investments made under the production sharing agreement. It should be borne in mind that economic mechanisms for achieving sustainable development can only be effective with significant institutional support. This requires improvement of standards, improvement of legislation, control, assessment and certification of environmental impact, environmental audit, inventory of natural resources and development of a system of regional, national and regional environmental monitoring.

Indices and indicators of sustainable development

The following indicators are used to characterize the stages of transition to a sustainable development model:

- levels of reduction of anthropogenic load on the natural environment of individual territories, countries, continents and the planet as a whole;
- real positive results in solving the problems of conservation and restoration of various natural complexes, certain types of natural resources, and improving the habitat of the population;
- reduction of disproportions between the volumes of total national wealth attributable to different social groups, segments of the population, regions and territories;
- reducing the material and energy intensity of a unit of gross national output (produced product);
- increase in the total national wealth in accordance with the optimal proportions between the environment, natural resources, favorable environmental conditions, environmental protection measures, national product, national wealth, the level of education and skills of the population, social security.

There are a number of large-scale macroeconomic indicators similar to those used by traditional statistics for gross domestic product and gross national product, which take into account the cost of environmental components (various environmental costs, benefits, and effects). These include a number of indicators.

The traditional "net domestic product" indicator, calculated as the difference between GDP and the depreciation (depreciation) cost of anthropogenic (or man-made) capital, does not take into account the depletion, degradation of conditionally renewable or mineral resources or the negative effects of pollution. It turns out that a country can Deplete its natural resource base, while GDP can grow. Thus, the cost of deforestation increases GDP, but worsens the natural potential. The resource-adjusted net domestic product is used to account for this situation.

The Resource - Adjusted net Domestic product (RANDP) is equal to the gross domestic product minus the depreciation of man-made capital, the cost of degradation of conditionally renewable resources, and the depletion of non-renewable resources. This indicator is poorly related to the environmental aspects of the economy, since it is not possible to determine from the point of view of sustainable development whether the growth or decline of RANDP is a positive or negative trend. Therefore, environmental economists suggest using the indicator eco-GDP or Green GDP.

Environmentally adjusted gross domestic product or "green domestic (national) Product" is an adjusted GDP that includes environmental costs, benefits, and absolute (net) changes in all assets, including changes in environmental assets (resources, benefits). Green GDP is formed by subtracting environmental costs from resource-adjusted GDP (Dyatlov, 2017).

Within the framework of the model concept of sustainable development adopted in Russia, in order to manage the transition to sustainable development and evaluate the effectiveness of the means used, targets and restrictions should be set, with a procedure for monitoring their achievement and compliance.

Targets can be expressed in indicators that characterize the quality of life, the level of economic development and economic well-being. These indicators should reflect the levels at which Russia's economic, social, environmental, defense, and other aspects of security are ensured.

Key indicators of quality of life:

- human life expectancy (expected at birth and actual);
- health status of the population;
- level of education;
- deviation of the state of the environment from the standards;
- level of knowledge and educational skills;
- income as measured by gross domestic product per capita;
- level of employment;
- the extent to which legal, economic and environmental rights are realized.

Indicators that determine the degree of environmental intensity of the economy are a system of indicators that characterize the level of consumption of natural resources and the level of the disturbed ecosystem as a result of economic activity (per unit of final product).

Similar indicators per capita are informative, as well as macrocharacteristics that Express the relationship between the needs for natural resources and their availability (reserves).

As targets and limiting indicators of sustainable development in the economic sphere, the levels of specific (per capita and per unit of gross domestic product) consumption of energy and other resources, as well as waste production can be set. The production and use of all hazardous substances used in the economy are subject to control.

The target parameters for sustainable development should include characteristics of the state of the environment, ecosystems, protected areas, and environmental health of the population. This group of indicators, called controlled parameters, includes indicators of the quality of the atmosphere, air, water, territories that are in a natural and modified state, forests, taking into account their productivity and degree of preservation, the number of species that are threatened with extinction, etc. Similar indicator systems can be used to solve the problem of transition to sustainable development in the country as a whole, as well as in individual regions.

The level of environmental sustainability is assessed by The Environmental Performance Index, which was developed in 2006 by the Yale center for environmental law and policy (Yale University, USA) and the Columbia center for the international earth science information network (Columbia University, USA). The report is compiled on the basis of an international study, which includes a rating of countries in the world in terms of environmental load and rational use of natural resources. This index is calculated together with a group of independent international experts using analytical developments and is based on statistical data from national institutions and international organizations. The purpose of this study is to reduce pressure on the environment, promote the viability of environmental systems, and ensure the stability of natural resource management. This study is published every two years and is based on 22 indicators in 10 categories. In turn, the categories are divided into two large groups: environmental health and ecosystem viability. Each country under study is evaluated according to each indicator. After that, each state gets a certain number of points on a one-hundred-point scale-from the worst (0) to the desired goal (100). The desired goal is formed in the course of international standards and treaties (EPI).

In November 2019, the second peace forum was held in Paris, France, where, after numerous meetings, conferences and seminars, several projects were selected that, in their opinion, are worthy of receiving international financial support. The purpose of the forum was to promote international cooperation and collective action to solve global problems. More than 6 thousand people took part in the forum. They had the opportunity to learn about the 100 best public initiatives selected in the competition in 6 thematic areas: peace and security, environment, development, new technologies,

inclusive economy, culture and education (Project of FoE Russia).

Interfax– Era, an environmental energy rating Agency, has been created in Russia to analyze the environmental and energy efficiency of the economy and rational use of natural resources. Interfax-Era also prepared a report on comparisons of the country's regions on fundamental factors of production efficiency for the International day of environmental protection, which was held on June 2019. Fundamental factors include energy and resource efficiency of economic activity, technological perfection of the equipment used in production, development of municipal infrastructure, social responsibility of business and General dynamics of efficiency. This set of criteria reflects the ability of regional businesses to perform useful work with low environmental impact, economical use of resources and energy, with minimal loss of ecosystem stability in the regions where they operate, with increased efficiency and a socially responsible approach to disclosure of environmental reports of companies.

Conclusion

The world community is tasked with creating an effective environmental and economic mechanism for implementing sustainable development goals. This mechanism includes the following elements:

- national, interregional and global institutions for achieving sustainable development goals;
- economic measures to promote greening of production and reduce carbon emissions into the atmosphere;
- a system for integrated monitoring of the environment, public health and environmental protection;
- tax incentives for energy-saving and environmental projects;
- environmental insurance;
- system of indicators, indices and indicators of sustainable development: index of sustainable development.

All the positive world theoretical, methodological and practical experience should be used in the member States of the Eurasian economic Union (Selischeva, 2018). Ultimately, the use of interrelated criteria and indicators should ensure that the main goals and objectives of the transition to sustainable development are met. The transition to sustainable development should ensure a balanced solution to the problems of socio-economic development and the preservation of a favorable environment and natural resource potential at all levels and in all areas of the national and global economy. The basis of sustainable development is the balance of economic, environmental and social interests of society. Russia, which is actively involved in international cooperation, must take effective measures at the state level aimed at implementing the principles and goals of sustainable development set by the international community.

The Concept of Researching the Accounting Information System in The Management of Small and Medium - Sized Enterprises

Malgorzata GRZESZCZAK

UTP University of Science and Technology, Bydgoszcz, Poland
malgorzata.grzeszczak@utp.edu.pl

Abstract

The purpose of the article is to present the concept of research in the field of the accounting information system in the management of small and medium – sized enterprises in Poland. The article presents a review of the literature on the accounting information system. Planning the research, the impact of the financial accounting and management accounting subsystem on the management function in a small and medium-sized enterprise were taken into account as well as the growing role of outsourcing in financial and accounting services among enterprises in the SME sector. Formulated research goals and hypotheses that the author wants to verify and the research plan are presented. The conclusions justify raising the subject and conducting the research.

Keywords: Accounting Information System, Management, SME.

Introduction

The dynamics and complexity of changes taking place in the functioning of small and medium-sized enterprises in the Knowledge-Based Economy means that the accounting information system is gaining new significance. Accounting is a fundamental source of information used in the assessment of enterprises by intensifiers as well as making operational and strategic decisions. The demand for information from the accounting system results from various decision-control situations arising in the management process. According to Stoner, Freeman and Gilbert, management is "a process of planning, organizing, leading and controlling the work of members of the organization and using all available resources of the organization to achieve its goals". Management and information are closely related. The concept of information has gained scientific value after the quantitative definition of information was presented by C.E. Shannon in 1948 (Shannon 1948). According to Błażyńska J. (Błażyńska 2015), information should have features enabling its evaluation and assessment of usability, while information can be considered useful when it brings the user closer to achieving the intended goals. Enterprises in the SME sector play a key role in the economy of highly developed countries. They have an impact on building economic growth and bring a competitive advantage to all industries. Small and medium-sized entrepreneurs operating on local markets are entrepreneurial, hard-working, inventive and committed, which results in innovation and the development of advanced technologies.While building a competitive advantage, managers use information from the accounting system. Good information is therefore the basis of the decision-making process, which is based on the information necessary for making the appropriate decisions. The true and fair view principle is considered one of the most important ideas, concepts and essence of financial accounting goals. This principle appeared in the accounting of European countries with the accession of Great Britain to the EU in 1973. In British legislation, it was included as early as in 1948 in the Commercial Code - Companies Act and then also to European Union countries, through the provisions of the Fourth Directive (Haskins et al. 2000). The overriding aspect of accounting is generating true faithful and reliable information. The importance of information from accounting is underlined by the definition presented by the American Accounting Association (AAA) - "accounting is the process of identifying, measuring and passing information on economic content for making assessments and decisions by information users" (Martyniuk 2016, Świderska 2012).There is no explicit definition of accounting in the literature on the subject that would apply in Poland or worldwide. The concept of accounting as the information system was used in Poland by (Jaruga

1992), who stated that "accounting is now understood as the information system that allows users to make economic decisions, especially the financial ones, and evaluate the management's for responsibility and effectiveness the of entrusted assets." Other definitions highlighting the importance of accounting as an information system: J.L. Evanstone (1966), W.B. Meigs, R.F. Meigs, (1986), A. Kinserdal, (1995), Micherda, (2014). Along with the changes taking place in the economy of highly developed, knowledge-based countries, caused by globalization processes, there was the demand for new information necessary in the decision-making process (Lawson 2019). New challenges faced accounting (Micherda 2011) states that "in literature and economic practice of countries with a developed market economy the pragmatic convention of functional accounting division was adopted leading to the distinction of financial accounting and management accounting". Modern accounting has a dual role:

• the source of reliable retrospective information enabling settlement and assessment of the business entity and meeting the information needs of the external environment,
• the source of prospective information, allowing for rational management of managerial behavior ensuring market success, capital increase and economic development of the enterprise.
The essence of management accounting is the provision of information supporting the implementation of the management process. Its goals have been described, among the others, by Hansen D.R., Mowen M.M., (2003), indicating that they include:
a) providing information on the costs of services, products and other facilities of interest to managers,
b) providing information for planning, control, evaluation and continuous improvement,
c) providing information needed to make decisions.

Definitions of management accounting are also provided by the International Federation of Accountants (IFAC) "management accounting is the process of identifying, measuring, collecting, analyzing, preparing and communicating financial and non-financial information that is used by managers for the purposes of planning, evaluation and controlling the organization, as well as ensure the efficiency use of resource and accounting for its consumption".

The accounting information system as a component of the enterprise information system provides information necessary in the process of making management decisions. Reliable information from the accounting information system allows you to effectively compete on the market to reduce the risk of making decisions.

Research Methodology

The main objective of the research will be to assess the degree of the use of information from the accounting information system in the management process of small and medium-sized enterprises and to indicate scenarios for the use of information from the accounting information system for the needs of management.

Five auxiliary goals were developed in the research designing process:

1. Identifying information coming from the accounting system used in decision-making processes.
2. Determining the degree of use of the financial accounting subsystem tools
and management accounting used in decision-making processes.
3. Identifying the of dysfunctional phenomena of the accounting system focused on decision making processes.
4. Establishing the relationship between the size of the enterprise and the information needs provided by the accounting information system.
5. Developing of scenarios for the operation of the accounting information system
based on one's own finance and accounting department or using outsourcing services.

Main hypothesis
The accounting information system for small and medium-sized enterprises is not adapted to support decision-making processes within management.

Specific hypotheses:

1. Information provided by the accounting information system is the subject to dysfunctions.
2. The area of using financial accounting and management accounting tools is insufficient in managing a small, medium enterprise.
3. There is a relationship between the size of the enterprise and the information provided by the accounting system in the management process.
4. Outsourcing of financial and accounting services fills in the competence gap related to the low level of knowledge in the field of tax and legal provisions.
5. The weak side of the cooperation of SME sector enterprises with accounting office's is related to communication processes and errors in financial and accounting documentation

The research sample was divided into 3 groups:

Group I – SME sector:
- owners, directors, managers of enterprises with headquarters in the Kuyavian-Pomeranian Voivodeship,
- enterprises that meet the statutory definition of micro, small and medium-sized enterprises,
- enterprises from the production, trade and services industry,
- enterprises with their own financial and accounting departments,
- companies using outsourcing services,
- companies which keep accounting books in accordance with the provisions of the Accounting Act

Group II - employees of financial and accounting departments and accounting office's participating in training and specialized courses in finance and accounting organized by the Accountants Association in Poland, District Branch in Bydgoszcz.
Group III - Expert interview with the Directors of Regional Branches of the Accountants Association in Poland and the Presidents of Members Associations in the Kuyavian-Pomeranian Voivodeship.
- District Branch in Bydgoszcz,
- District Branch in Toruń,
- District Branch in Włocławek,
- Branch in Grudziadz,
- Member Association in Inowrocław,
- Member Association in Chojnice.

The research methods and techniques used are shown in Table 1

Table 1: The research methods and techniques

Source: Own study.

The following methods will be used in the research:

- literature study
- analysis of legal acts
- conducting empirical research
- application of the synthesis method to determine the conclusions of the tests carried out
- application of qualitative methods and factor analysis in the development of empirical material from the conducted research.

In Poland, the research on the accounting information system in making management decisions in enterprises was carried out by Turyna (Turyna 1997). The study did not concern the SME sector, since at that time it was underdeveloped in Poland. In recent years, numerous studies have been conducted on the provision of financial and accounting outsourcing services in the SME sector, e.g, Wysłocka 2011, Jóźwicka, Zakrzewska – Bielawska 2014, Marcinkowska, Sawicka 2015, Halmeenmäki 2015. Due to the dynamic development of small and medium-sized enterprises, some research has been done, e.g. the research on the significance of cost information in the opinion of SME managers (Jaworski 2014) or the accounting organization in the opinion of managers (Jóźwicka 2013). The analysis of the literature on the subject, the lack of comprehensive studies on the impact of the accounting information system on the management process of a small and medium - sized enterprise led the author to plan the research in such a way. The development of modern technologies in IT accounting systems, such as the use of advanced ERP technologies or the automation of RPA processes (Robotic Process Automation) create new opportunities to use information from the accounting system.

The identified scientific gap relates to updating the results of research on the information accounting function in the system approach implemented by internal or external accounting services in the SME sector. In the empirical aspect, the results of the study will allow to identify the accounting system solutions resulting from the internal needs and context factors that meet the information needs of SMEs. The main research problem will focus on learning, understanding and explaining the role of the accounting information system in managing micro, small and medium – sized enterprises. The planned research will determine the relationship between financial and management accounting and the basic management functions: planning, organizing, motivating and controlling. Financial accounting provides information resulting from accounting documents, allows for ongoing cost calculation. The financial accounting subsystem is responsible for the information derived from the financial statements. Information from financial accounting is used by the management accounting subsystem. On their basis operational and strategic decisions are taken in enterprises of the SME sector. Financial accounting has an informative, analytical, control and reporting function. Both management and accounting are related to the same control function. The management practice shows that the planning process is based on analytical function, motivating and organizing is related to reporting.

The research project also noted the development of outsourcing of financial and accounting services, which was part of the management concept of "Lean management". The use of outsourcing of financial and accounting services by micro, small and medium-sized enterprises on a large scale has contributed to a different view on the accounting information function (Gopal 2009). A special role is assigned to the internal accounting information function within management accounting, strongly focused on the decision-making process by entrepreneurs.

The research will allow to develop a concept of for adjusting the financial accounting and management accounting subsystem to the needs of managing a small and medium - sized enterprise. The author will also develop scenarios for the functioning of the accounting system in managing a small and medium - sized enterprise when running her own finance and accounting department or using outsourcing services.

Conclusions

According to R.W. Griffin (2004) "information resources are all data useful for effective decision making." The dynamics, intensity of changes in the external and internal environment of the enterprise and competitive struggle make management of an enterprise from the SME sector difficult. It sets new requirements for entrepreneurs. To be successful on the market, an entrepreneur must anticipate changes using the available information resources, including those from the accounting system (Xing, Yan 2018). The management information system is a system of collecting and processing data into information based on information and communication technologies, and then into knowledge which is useful for managers to make decisions, i.e. for management at various levels (Jelonek 2018). Part of the management information system is the accounting information system,

and in it the most important information functions today. Modern accounting is an important element of an enterprise's information system. The accounting information system is used primarily for making business and financial decisions (Stoica, Stefan 2018), simultaneously constituting the basis for assessing the effects of managing the company's assets by their management.

Analysis of Consumer Demand in The European Union Countries Based on The Working Model: Spatio-Temporal Approach

Mateusz JANKIEWICZ

Nicolaus Copernicus University, Toruń, Poland
m.jankiewicz@umk.pl

Abstract

The article presents an analysis of consumer demand in the European Union countries in the years 1996 - 2017. The aim of this paper is to analyse changes in household consumption expenditure caused by changes in the level of disposable income of households and the imitation effect. Economic changes in the EU countries influence disposable income of households, and as a result cause changes in their level and structure of consumption. The analysis concerns the level of expenditure on two types of goods: food goods, as well as superior goods, which include expenditure on restaurants and hotels, recreation and culture. The model proposed by Working was used to analyse the demand for both types of goods. In addition, in order to show the impact of the imitation effect on the level of consumer spending, the Working model was extended to include spatial effects - i.e. the impact effect of consumer spending and disposable income level of households from neighbouring countries. The study uses spatial autoregression models (SAR) and spatial error models (SE) that allow estimating and examining the statistical significance of spatial effects on consumer spending.

Keywords: Elasticity, Food Expenditure, Spatial Models, Superior Goods Expenditure.

Introduction

The largest share of the state's consumption expenditure is household consumption expenditure. Consumption is one of the factors driving the economy, which is influenced, among others, by the socio-economic development of the country (see: Cheba, 2015; Łapińska, 2016; Cheba, Szopik-Depczyńska, 2017; Simionescu et al., 2017; Kurowska-Pysz et al. 2018; Nowak, 2018; Simionescu et al., 2018; Cyrek, 2019; Pietrzak, 2019; Kuc-Czarnecka et al., 2020). Economic growth is a determinant of changes in the disposable income of society, which causes changes in the level and structure of household consumption (see: Gavurova et al., 2017; Głodowska, 2017; Jankiewicz, 2018a, 2018c; Jankiewicz, Pietrzak, 2019; Pietrzak, Jankiewicz, 2019). Thus, the level of consumption and the level of economic development of a country interact on each other. In addition to economic growth, the level and structure of consumption are influenced by: households' savings (see: Trębska, 2018; Verba, Kudinova, 2019), quality of institutions (see: Balcerzak, Pietrzak 2016; Balcerzak, 2020); the process of digitization (see: Balcerzak, Pietrzak, 2017), level investment and innovation (see: Jakimowicz, Rzeczkowski, 2019), progressing globalization and international relations, including interdependencies between capital markets (Pietrzak, Łapińska, 2015; Meluzín et al.,2017; Pietrzak et al., 2017; Meluzín et al., 2018a, 2018b, 2018c; Skalická et al., 2019a, 2019b; Skare, Porada-Rochoń, 2019a; 2019b).

The most important determinant of the level and structure of consumption is households' disposable income (Banks et al. 1997, Cupák et al. 2015, Jankiewicz, 2018b, 2019a). Richer households can afford to consume more goods. In addition, their consumption is also more diverse. According to Engel's law (1895), as the disposable income increases, the share of food consumption in total final expenditure decreases. Thus, the increase in the level of disposable income increases the possibilities of spending money on goods that are not basic goods. Not only economic determinants have an impact on the level and structure of household consumption, but also demographic (age of households' members, its structure), technological and cultural (De Mooij M., Hofstede, 2002; Schaefer, Crane, 2005; Zukin, Maguire, 2004, Bywalec 2009; Jankiewicz 2019b; Janoś-Kresło, Mróz 2006) determinants. The imitation effect plays an important role in research on household consumption. Less wealthy households tend to change the structure of consumption, making it more similar to richer households.

This is partly due to the ongoing process of economic and social convergence (Carnicky et al., 2016; Dall'Erba, Le Gallo 2008; Kulhánek, 2012), which leads to the levelling up of disposable income among households. Nevertheless, an excessive desire to make the level and structures of consumption similar to those set by wealthier households may lead to the development of consumerism.

In classic consumption demand models, such as the Törnquist model or the Working model, it is hard to look for a reference to the imitation effect. This approach assumes the dependence of consumer spending only on its most important determinant, i.e. the amount of disposable income. A good reflection of the imitation effect may be to include spatial interactions in the model. In the consumer demand study, spatial models were applied, among others, by Ciccarelli and Elhorst (2016, 2018) who used spatial interactions in the study of cigarette demand. They examined such demand in Italy at NUTS-3 level. In addition to shifting the dependent variable in the model, they used the impact of disposable household income from neighbouring units. The conclusions were based on the estimation of the dynamic spatial panel model for 69 Italian provinces in the years 1877 - 1913. The demand for cigarettes using spatial models was also examined by Yang (2006), who, in addition to disposable income, added other consumption determinants, such as the price of a pack of cigarettes or demographic structure of the population. He used data on the demand for cigarettes in the United States in 1963–1992. In another study, Baltagi and Li (2006) applied spatial models to study the demand for alcohol in the United States (based on data from 43 states) in 1965–1994. In each of these studies, spatial interactions are added to the linear form of the demand model.

The aim of the study is to assess the occurrence of the imitation effect in households of the European Union countries in the years 1996 - 2017 using the Working consumption model. The level of expenditure for two groups of goods - expenditure on food (variable Y1) and expenditure on superior goods, including expenditure on restaurants and hotels as well as recreation and culture (variable Y2) will be analysed. In addition to disposable income (variable X), spatial interactions will be included in the Working model. The spatial scope of the survey is 27 European Union countries (excluding Croatia due to unavailability of data). The adopted temporal and spatial range of the study allows the use of spatial econometry tools to study the level of consumption. The hypothesis set out in the study says that the level of household consumption in a given territorial unit is influenced by both the level of disposable income in this unit and the level of consumption and disposable income of households in neighbouring units.

Methodology

In the first stage of the analysis, the presence of spatial interactions in the level of expenditure on food, expenditure on superior goods and the level of disposable income in the European Union countries will be examined.

The similarity of the households consumption levels and disposable income level is analysed, based on the Moran's *I* statistics (and its significance). The test statistic takes the following form (Schabenberger and Gotway 2005, Suchecki 2010):

$$I = \frac{1}{\sum_{i=1}^{n}\sum_{j=1}^{n} w_{ij}} * \frac{\sum_{i=1}^{n}\sum_{j=1}^{n} w_{ij}\,[y_i - \bar{y}][y_j - \bar{y}]}{\frac{1}{n}\sum_{i=1}^{n}[y_i - \bar{y}]^2} = \frac{n}{S_0} * \frac{\boldsymbol{z}^T\boldsymbol{W}\boldsymbol{z}}{\boldsymbol{z}^T\boldsymbol{z}}, \tag{1}$$

where: y_i – an observed value of the phenomenon in the region i, $\boldsymbol{z}$ – a column vector with elements $z_i = y_i - \bar{y}$, $S_0 = \sum_{i=1}^{n}\sum_{j=1}^{n} w_{ij}$ – a sum of the corresponding elements of the weights matrix **W**, n – the number of regions. In this research the matrix **W** of connections based on the common border is used. This part of the analysis will show if there are conditions to introduce spatial interactions into the model of food demand and superior goods. In the next step of the study, the classic Working models for panel data (2) - Pooled model and panel Working models with individual fixed effects (3) - FE model (Baltagi, 2008) will be estimated, given by the formulas:

$$Y_{i,t} = e^{\alpha + \beta\frac{1}{X_{i,t}} + \varepsilon_{i,t}}, \tag{2}$$

$$Y_{i,t} = e^{\alpha_i + \beta\frac{1}{X_{i,t}} + \varepsilon_{i,t}}, \tag{3}$$

where: $Y_{i,t}$ – the level of consumer expenditure (on food or superior goods) of households, : $X_{i,t}$ – the level of households' disposable income, $\varepsilon_{i,t}$ – residual component of the model. For estimation purposes, models (2) and (3) were transformed to a linear form, respectively:

$$ln(Y_{i,t}) = \alpha + \beta \frac{1}{X_{i,t}} + \varepsilon_{i,t}, \tag{4}$$

$$ln(Y_{i,t}) = \alpha_i + \beta \frac{1}{X_{i,t}} + \varepsilon_{i,t}. \tag{5}$$

The model selection between the Pooled and the FE model was made using Wald's test (Baltagi, 2008). Then, in order to show the significance of the imitation effect, spatial effects were introduced to the models (2) and (3), resulting in the following models :

$$Y_{i,t} = e^{\alpha+\beta\frac{1}{X_{i,t}}+\gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right)+\rho \boldsymbol{W}\left(ln(Y_{i,t})\right)+\varepsilon_{i,t}}, \tag{6}$$

$$Y_{i,t} = e^{\alpha_i+\beta\frac{1}{X_{i,t}}+\gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right)+\rho \boldsymbol{W}\left(ln(Y_{i,t})\right)+\varepsilon_{i,t}}, \tag{7}$$

$$\begin{gathered} Y_{i,t} = e^{\alpha+\beta\frac{1}{X_{i,t}}+\gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right)+\varepsilon_{i,t}} \\ \varepsilon_{i,t} = \lambda \boldsymbol{W}(\varepsilon_{i,t}) + \eta_{i,t}, \end{gathered} \tag{8}$$

$$\begin{gathered} Y_{i,t} = e^{\alpha_i+\beta\frac{1}{X_{i,t}}+\gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right)+\varepsilon_{i,t}} \\ \varepsilon_{i,t} = \lambda \boldsymbol{W}(\varepsilon_{i,t}) + \eta_{i,t}. \end{gathered} \tag{9}$$

Models (6), (7), (8) and (9) were transformed to a linear form (similarly to models (2) and (3). As a result, there are two forms of spatial autoregression models and two forms of spatial error models (Pooled and FE):

$$ln(Y_{i,t}) = \alpha + \beta \frac{1}{X_{i,t}} + \gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right) + \rho \boldsymbol{W}\left(ln(Y_{i,t})\right) + \varepsilon_{i,t}, \tag{10}$$

$$ln(Y_{i,t}) = \alpha_i + \beta \frac{1}{X_{i,t}} + \gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right) + \rho \boldsymbol{W}\left(ln(Y_{i,t})\right) + \varepsilon_{i,t}, \tag{11}$$

$$\begin{gathered} ln(Y_{i,t}) = \alpha + \beta \frac{1}{X_{i,t}} + \gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right) + \varepsilon_{i,t} \\ \varepsilon_{i,t} = \lambda \boldsymbol{W}(\varepsilon_{i,t}) + \eta_{i,t}, \end{gathered} \tag{12}$$

$$\begin{gathered} ln(Y_{i,t}) = \alpha_i + \beta \frac{1}{X_{i,t}} + \gamma \boldsymbol{W}\left(\frac{1}{X_{i,t}}\right) + \varepsilon_{i,t} \\ \varepsilon_{i,t} = \lambda \boldsymbol{W}(\varepsilon_{i,t}) + \eta_{i,t}. \end{gathered} \tag{13}$$

Model (10) is a classic spatial autoregression model for spatio-temporal data (SAR_Pooled), model (11) is a spatial autoregression model with individual fixed effects (SAR_FE). Model (12) is a spatial error model for space-time data (SE_Pooled), while model (13) is called a spatial error model with individual fixed effects (SE_FE). The choice between the SAR model and the SEM model was made using Lagrange statistics significance tests in the basic version and robust to poor model specification (Anselin et al., 2004).

From the presented Working models, income elasticities of demand for food and superior goods can be determined. In this study, two types of elasticity were calculated: income elasticity related to changes in disposable income in directly spending households (14) and elasticity related to changes in disposable income in neighbouring households (15).

$$E(X) = \frac{\partial Y}{\partial X} \cdot \frac{X}{Y} = \frac{-\beta}{X}, \tag{14}$$

$$E\left(\boldsymbol{W}\left(\frac{1}{X}\right)\right) = \frac{\partial Y}{\partial \boldsymbol{W}\left(\frac{1}{X}\right)} \cdot \frac{\boldsymbol{W}\left(\frac{1}{X}\right)}{Y} = \gamma \cdot \boldsymbol{W}\left(\frac{1}{X}\right). \tag{15}$$

Empirical Results

The first step of the study examines the spatial differentiation of the level of expenditure on food and superior goods as well as the spatial differentiation of households' disposable income in the European Union countries. Figure 1 shows the spatial differentiation of the expenditure level on selected types of goods in the boundary years of the survey.

Territorial units were divided into two groups - the limit between them is the median of consumer spending on a given type of goods in the respective years of the survey. Figure 1 shows the differences between expenditure in the eastern and north-western part of the European Union. Western countries, recognized as more developed, are characterized by higher values of consumer spending on both food and superior goods. There is a similarity noticed in the level of expenditure between neighbouring countries. Figure 2 shows the spatial differentiation of disposable income in the European Union in 1996 and 2017. Territorial units were divided - as in the case of Figure 1 - into two groups, where the limit value was the median of disposable income in 1996 and 2017, respectively.

Source: Own study.

Similarly to the situation with the development of consumer expenditure, on the basis of Figure 2, it can be stated that there is a division of the European Union into the eastern and north-western parts. More developed countries have higher values of disposable income than less developed ones. Based on Figures 1 and 2, it can be assumed that the EU countries with similar values of examined processes

are clustered. In order to verify this assumption, the values of Moran I statistics were estimated and their statistical significance examined. The results are shown in Table 1.

Moran I statistics for disposable income as well as the level of expenditure on food and expenditure on superior goods have positive values throughout the entire period considered. In addition, in all years of the survey it is statistically significant, because p-value is lower than the adopted significance level of 5 %. Thus, there is a positive spatial autocorrelation, indicating the similarity of neighbouring countries in relation to the level of expenditure on selected types of goods and disposable income. The Moran I coefficient for disposable income over the entire study period is higher than for expenditure, which means a greater similarity of neighbouring countries in relation to this process. The occurrence of positive spatial autocorrelation entitles to include the spatial aspect in the analysis of food demand and superior goods.

At the beginning of modelling demand for selected types of goods in the European Union, classic Working models were estimated - covering the dependence of household expenditure only on their own disposable income. Table 2 presents the results of estimation and verification of Pooled and FE panel models for food expenditure (Y1) and expenditure on superior goods (Y2).

Table 2: Results of estimation and verification of Working's panel models for food and superior goods

Parameter	**Food (Y_1)**		**Superior (Y_2)**

In all estimated models in Table 2, the β parameter describing the impact of disposable income on household expenditure is statistically significant (p-value is less than 5%). According to economic theory, the sign of the parameter is negative, which indicates that there is an increase in the level of expenditure with an increase in disposable income. The impact of income on expenditure is stronger in the case of expenditure on superior goods than on food. This means that each additional unit of income causes a greater increase in expenditure on restaurants and hotels as well as recreation and culture. Wald's test indicates the significance of fixed effects in spending models for both types of goods, which means significant differences in the formation of parameter α for each country. The Moran test for residuals indicates the importance of spatial relationships in analysing the demand for both goods. Based on LM tests, spatial error models for Pooled models and spatial autoregression models for FE models should be selected for further analysis. Nevertheless, both types of spatial models (for Pooled and FE models) have been estimated for both food expenditure and superior goods. Table 3 shows the results of estimation and verification of panel spatial models for the level of food expenditure.

According to the results of the model estimation in Table 3, the significance of the individual fixed effects of the model resulting from the statistical significance of Wald's F statistics can be noted. In the SAR_FE and SE_FE models, the β and γ parameters describing the impact of disposable income from a given territorial unit and neighbouring units are statistically significant. Nevertheless, the signs at the parameter γ differ. The correct estimate was obtained for the SE_FE model - in this case the γ parameter is negative. The spatial effects included in FE models are statistically significant. It is worth noting that there is a weaker impact of the increase in disposable income of households in neighbouring units than on the level of expenditure on food (the value of parameter γ is smaller as compared to the absolute value than parameter β) in a given unit. Table 4 presents the results of estimation and verification of Working's spatial models for panel data in relation to the level of expenditure on restaurants and hotels as well as recreation and culture.

Table 3: Results of estimation and verification of Working's spatial panel models for food expenditure

Parameter	Food expenditure (Y_1)			
	SAR_Pooled	SE_Pooled	SAR_FE	SE_FE
α	7.6289 (0.0000)	7.6181 (0.0000)	-	-
β	-2330 (0.0000)	-2299 (0.0000)	-1112.9 (0.0000)	-1389.1 (0.0000)
γ	-159.240 (0.0000)	-178.930 (0.0091)	208.12 (0.0016)	-866.49 (0.0000)

Similarly to the case of models of the expenditure level on food, the individual effects of each EU country proved to be significant under the Wald test (p-value less than 5% for statistics F). Therefore, spatial panel models with constant effects (SAR_FE and SE_FE) have been estimated. The β parameter for both FE models is statistically significant and its sign is negative. Differences occur for the parameter γ, describing the impact of changes in disposable income from neighbouring countries. For the spatial shift model this parameter is positive, while for the spatial error model it is negative. On the economic theory basis, the correct estimation of the γ parameter was noted in the SE_FE model. The spatial interactions introduced in FE models are statistically significant.

Table 4: Results of estimation and verification of Working's spatial panel models for expenditure on superior goods

Parameter	Superior expenditure (Y_2)

Analysing the models in Tables 3 and 4, it was found that spatial error models with individual permanent effects (SE_FE) best describe expenditure on both food and superior goods. There was a positive impact on the expenditure level of factors not included in the model observed in neighbouring countries (positive and statistically significant parameter λ). The impact of a unit change in disposable income causes greater changes in expenditure on superior goods than in food expenditure. To confirm this relationship, income elasticity coefficients were calculated for both types of goods, using data from models with the best verification characteristics (for the classical model and with spatial interactions). The results are presented in Table 5.

Table 5: Average value of the income elasticity coefficient in the years 1996-2017

Elasticity	**Food**		**Superior**	
	Model			
	FE	**SE_FE**	**FE**	**SE_FE**
$\boldsymbol{E(X)}$	0.2999	0.2078	0.4345	0.3403
$\boldsymbol{E\left(W\left(\frac{1}{X}\right)\right)}$	-	-0.1246	-	-0.0799

Source: Own calculations.

An analysis of income elasticity shows that every one-percent increase in disposable income of households causes a higher percentage increase in expenditure on superior goods than on food. Elasticities vary depending on the estimated model - for models without spatial interactions, the percentage increases in consumer spending (regardless of the type of goods) resulting from a one-percent increase in their own disposable income are higher than for spatial models. Nevertheless, the effect of the total increase in income (both in households of a given country and neighbouring countries) is almost identical for spatial models and for models without spatial interactions. A one-percent increase in the disposable income of households of neighbouring countries also indirectly increases the level of household expenditure in a given territorial unit. Income elasticity coefficient in this case has a negative value, because it is calculated for the inverse of disposable income.

Conclusion

Household consumption expenditure is closely linked to the country's economic development. Richer societies tend to spend more and their income is considered to be spent in more diverse way. Therefore, their consumption structure differs. Consumer demand is of interest to many researchers who often use classic methods of analysis such as the Törnquist function or the Working function. Nevertheless, there is no literature to supplement these models with spatial interactions that illustrate the effect of imitation among consumers. There is demand analysis using spatial models, but these models are only linear.

The study supplemented the Working model with spatial effects, analysing the level of expenditure of EU households on food, restaurants and hotels as well as recreation and culture. A positive impact of income growth on the level of consumer spending on both types of goods was noted. Nevertheless, most of the additional households' income is allocated for superior goods, which results from the analysis of the income elasticity coefficient of demand. In addition, the process of getting wealthier by households in neighbouring countries results in an increase in the level of consumer households'

expenditure in a given territorial unit. Therefore, the so-called consumer imitation effect turned out to be significant. The society (in order to show its wealth) tends to increase the level of consumer spending regardless of the type of good purchased.

Abstract

The recent turbulent market development is causing problems to numerous enterprises, and it raises a question: how can be a positive reputation maintained in the long term? Even today, enterprises still tend to underestimate the power of reputability and reputation management, depriving themselves of what they have been building up for years – their good name and image. It does not take much for the enterprise to lose everything in a short time – a small misstep is just enough, for instance a false step having the form of the lack of environmental friendliness or of unethical or arrogant conduct towards customers and the public. Customers and the public can sense each and every foul trick, act of disrespect or lie, and after getting disappointed, they spread the information further (even unconsciously sometimes), which contributes towards the destruction of good name and the public's positive feedback. The enterprise can lose its reputation easily. However, repairing a damage takes much longer and requires a careful practice of reputation management. Currently, a majority of enterprises and stakeholders are aiming at protecting their good name in the off-line world as well as on the internet by trying to avoid problems endangering enterprise reputation. Avoiding problems and crises lies in doing sustainable socially responsible business. Therefore, the following research has been carried out based on an analysis of enterprise crisis situations that have affected the overall reputation of an enterprise. Conducting the research, it was subsequently possible to deduce and produce recommendations and principles to be followed in order to build enterprise reputation by doing a socially responsible business.

Keywords: Reputation, socially responsible business, sustainability.

Introduction

Enterprises are becoming more and more interested not only in marketing activities and tools that can sell their products, establish their brand and relationship with customers but also in their reputation. Reputation represents any opinions, judgements, standpoints about the enterprise and its products shared by customers based on ongoing activities in all spheres of the enterprise's life, determining the attractivity of the enterprise, its employees and management, products and its brand. The enterprise's ability to meet expectations of customers, the public and other interested parties affects individual opinions and standpoints shaping an overall view of the enterprise. That ability should be mastered by enterprises, and it should be one of their fundamental priorities and main business objectives. In order to work properly, the enterprise needs to manage activities concerning its reputation like it runs its business activities. Therefore, the article is focused on an analysis of actual negative events and crisis situations, revealing the enterprise's missteps not only in the field of socially responsible business.

Reputation, Reputation Management and Socially Responsible Business

Reputation is a strong accelerator driving the enterprise forward even in unfavourable times of an economic crisis. The enterprise must do its activities with respect to possible consequences because a single unfavourable event may cause a loss of its competitiveness and customer base in favour of its competitive rivals. Monopolies are perhaps one of few enterprises that do not need to worry about their reputation, but that may be true only temporarily until market conditions change and someone starts competing with them. Klučka (2006) defines reputation as a complex of attitudes, expectations and judgements of the entities who are relevant for the enterprise, which implies that all interested parties' opinions, attitudes and judgements have a direct or mediated impact on the enterprise and its activities. Gattiker (2008) like Klučka (2006) states that reputation represents the expression of several interested parties' view on the enterprise based on an effort the enterprise has made. According to Farmer and Glass (2010), reputation means the information which is used for creating a value judgement about an object or a person, that is about the enterprise and its representatives. Reputation represents individuals' opinions on the enterprise, its products or its employees, which are often connected with their personal experience or based on the information obtained from others and the mass media. Positive reputation helps the enterprise to be competitive, and it may affect its market value. According to Argenti and Druckenmiller (2004), enterprises are recognizing the importance of enterprise reputation more and more as a tool for achieving business objectives and maintaining competitiveness. Reputation shows a prognosis of future conduct which is based on the assessment of how its past conduct met the expectations following the comparison of social status (Barnett, 2012). In the present day, reputation is very important and highly recognized not only in business, and the public has become aware of its importance in other fields as well. It represents a concept of the creation of the enterprise's positive image. The concept not only offers the enterprise a positive image of itself from the viewpoint of the public, but it also helps it to gain a certain level of prestige and positive references, creating something like a brand in essence. (Ferenc et. Al, 2017; Jankalová, Jankal, 2016).

An objective and a role of reputational management is predominantly to maintain, enhance and build favourable positive reputation inside out, that is in relation to all interested parties, and to determine acceptable procedures, strategies, systems, methods and standards that will prevent enterprise reputation from being ruined; reputational management also aims at developing guidelines for solving individual situations that have occurred especially in case where enterprise reputation has been tarnished (Schultz, Werner, 2017). According to Svoboda (2009), "reputation" is a better synonym to "image", even though the means and forms of implementation are not the same as in case of image formation. There are four essential attributes of reputational management: (Svoboda, 2009)

- credibility,
- reliability,
- conscious responsibility,
- trustworthiness.

Currently, online environment plays a significant role in building reputation. Users or potential customers, as well as rivals, keep generating a huge amount of various data having a significant informative value for decision-making processes taking place in the enterprise (Soviar et. al, 2017). From that perspective, reputational management refers to comprehension, understanding and influencing a certain subject or entity's perception in online environment. Online environment allows the enterprise to acquire data about potential business opportunities (Stokes, 2008). Therefore, it is necessary to include online environment in reputational management, i.e. online reputational management. Online reputational management refers to the practice of monitoring the online reputation of a human, a brand, a product or business, and it represents a solution for dealing with negative changes by eliminating, supressing or reducing the visibility of those changes in browsers by pushing them down (e.g. If the negative content is displayed in the first page of Google search results, it will be moved to the tenth page). Managing enterprise reputation in online environment does not mean getting rid of negative references to the enterprise or its products completely, but it is

about mitigating their negative impacts by means of a strong, visible and consistent content (Lieb, 2019). In reputation, a significant role is played by the enterprise's sense of values, social responsibility as well as ethics. Social responsibility frequently refers to the enterprise's duty to implement strategies, adopt decisions and proceed in such a way that is required and compliant with the public's objectives and values, thus being in line with the ones of the whole society. In this respect, the enterprise does not have a right to criticise general values, and it is expected to avoid ignoring socially acceptable values and promoting its business objectives or enterprise values over the society's values. (Varmus et. al, 2015; Beal, 2014; Veber, Srpova, 2012)

Nowadays, a higher number of enterprises is devoted to social responsibility and philanthropy than it used to be in the past, not only due to legislation but also as a result of the pressure exerted by the public, investors, the media, clients and various organisations. Enterprises keep monitoring what their customers and potential clients believe, how to treat their employees and how to approach their rivals and the environment. Currently, the enterprises predominantly adhere to a broader view of the interested parties expressed through their effort to satisfy the parties' needs in line with ethical and socially responsible conduct with the final impact on shareholders – increasing a profit. Socially, it is an endeavour to help, strengthening mutual relationships with interested parties as well as reputation in the upshot. In addition to socially responsible business, the activity that also is important for the enterprise is philanthropy or similar initiatives, such as volunteering, donating and the like. As regards philanthropy, appreciation or even respect from the interested parties bring about a similar effect on the enterprise as socially responsible business, besides a good feeling of helping others. In the present, philanthropy constitutes a modern form of donation that helps a receiver solve their issues which occur in the society, who can use resources for education, skills or potential development of people who will thus not be dependent on alms but be able to take care of themselves on their own. (Hittmar et. al, 2015; Marošiová, Majchrák, 2004)

Materials and Methods

The material for preparing this article was obtained from the research carried out. The research was conducted by identifying and analysing negative reputation based on the online information available about the enterprises' crisis situations and events having global or regional consequences. The situations and the enterprises were selected intentionally in order to get the greatest information value as possible. The analysis of negative reputation cases aimed at producing possible recommendations for mitigating crisis situations and at identifying principles for avoiding the occurrence of such situation and risk of the loss of built-up positive reputation. A subject-matter of the analysis was the cases of the enterprises that were solving a crisis situation while the items that were analysed were crisis situation impacts on the enterprise, steps taken by the enterprise in the crises and consequences occurring after the measures carried out, that is the way how customers and the public reacted, allowing us to deduce recommendations for mitigating the impacts on the enterprise' reputation. Analysis criteria included a size of the enterprise, which means that big enterprise was analysed, connection with a conduct against socially responsible business, and the fact that a case study must show a connection with a damage to reputation and crisis situation consequences. The analysis of the cases of solving negative reputation comprises solutions to crisis situations adopted by the enterprises, that is particular steps taken by the enterprises in order to live up to their reputation, and it also points out crisis situation impacts on the enterprise and its reputation.

Analysis of Negative Reputation Solution Cases

The past saw various events that pointed out the importance of enterprise reputation, especially in case of an unfavourable situation that was perceived by customers as a huge lack of ethical conduct on the part of the enterprise. Providing an example of a negative impact on enterprise reputation, we may mention the Bhopal disaster in December 1984 when gas and chemicals leaked in the American enterprise Union Carbide in Indian Bhopal, killing 20,000 people and injuring 100,000 up to 200,000 people. The event caused the disappearance of the enterprise while the accident had a direct impact on enterprise reputation, leading to the drop in the enterprise's shares and product sales (Shaw, 2011).

In addition to making forecasts and doing regular check-ups of online reputation, it is necessary to know options to solve a potential crisis situation in order that the enterprise can avoid suffering severe damage associated with the loss of positive reputation.

Johnson & Johnson – Tylenol crisis

Johnson & Johnson is a global American pharmaceutical company with a 130-year tradition which hires more than 130,000 employees across the world, producing consumer products and doing research in this field. Secondly, it is devoted to development and production of medical devices, for instance for surgery, and its third field of activity is pharmaceutical products (Johnson & Johnson, 2020). Tylenol, which contains paracetamol as its main active substance and reduces pain, fevers etc., had a negative impact on Johnson & Johnson's reputation in 1982. Johnson & Johnson Company was selling the product in the USA. The product caused the death of seven consumers as a result of its improper quality. (The Tylenol Crisis, 2020)

Originally, Tylenol had 37% market share, and revenues from the sale of the product amounted to 1.2 million dollars. The subsequent crisis caused product withdrawal, inflicting the loss of 100 million dollars on the company. In addition to withdrawing the most profitable product, the company stopped all promotional activities to avoid damaging its reputation as much as possible. After achieving the required quality, the product was launched onto the market again. However, the company ran a campaign to restore customer trust. Sales support for the new products was ensured by various promotional activities and discounts (e.g. discount vouchers, TV commercials, a new price strategy etc.) In order to recover professional trust, the enterprise was giving presentations and organising conferences for medical community for the product to win their trust and for them to recommend it to consumers afterwards. That resulted in restoring customer trust, thanks to which the company still exists in the present day. (The Tylenol Crisis, 2020)

Based on the afore-mentioned findings, it is obvious that if the enterprise wants to remedy a damage that was suffered during and after crises, it needs to mind its customers' opinions and feelings – in such a sensitive matter as a death of customers, it was indeed reasonable to withdraw all products from the market and confirm its customers in the fact that the company strives for their safety and health. Subsequently, when the enterprise intended to put its product on the market again, it had to make convincing changes in the product and packaging to assure the customer that nothing is going to happen to them in future. The important thing is to communicate your intention to the public, and in that case, it was a confirmation of product safety, restoration of trust and customer motivation to purchase the product. As the enterprise invested huge financial resources, it needed to attract as many new and former customers as possible.

Jonson & Jonson's procedure for solving the crisis situation and rebuilding their reputation

- withdrawing the product from the market,
- terminating marketing activities connected with the product,
- research and innovations in the old product,
- after the situation calms down, relaunching the renewed product onto the market,
- a new promotional campaign for sales support,
- PR activities to restore trust with emphasis on safety,
- new price strategy,
- addressing the professionals and gaining a positive feedback on the product from them.

Volkswagen – Dieselgate

Volkswagen, which is an automobile manufacturer who created the term "clean diesel", admitted that up to 11 million diesel vehicles globally were equipped with a faulty device or a sophisticated

software that was able to hide actual levels of vehicle emissions. In the USA, the vehicles having those control units were exceeding a permitted level of emissions by 40 times under applicable standards. Environmental Protection Agency (EPA) prohibited the sale of VW vehicles in 2016. The tested cars having the faulty software included the following models with the year of manufacture: Jetta (2009-2015), Jetta SportWagen (2009-2014), Beetle a Beetle Convertible (2012-2015), Passat (2012-2015), Golf (2010-2015), Gold SportWagen (2015) and Audi A3 (2010-2015). (Majerčík, 2017; Jung, Park, 2016; Reputation Institute, 2016)

The automobile manufacturer admitted that a total sum to have been paid for the incurred scandal amounted to a sum higher than its budget of 18.2 billion dollars which it had planned to use to settle the affair. When the problem arose, and the public learned about it, a value of the automobile manufacturer's shares dropped by 40 % below 100 dollars per share in the course of a few days. Even though the value of its shares is currently around 152 dollars, it has still not regained the value it had prior to the crises, which was more than 160 dollars (Jung, Park, 2016; Reputation Institute, 2016). In 2015, a reputation survey study Global RepTrak 100 was carried out, and the company took fourteenth place in the first quarter. In the last quarter after the scandal erupted, the company dropped from leading places by 20 points in Europe and by 9 points in the USA. According to Reputation Institut, more than 50 % of Volkswagen' s reputation consisted of its ability to be a reliable company offering high-quality products, having sound corporate culture and doing socially responsible business. The scandal is significant for reputation, and it has created huge impacts especially due to the fact that the revelation of reality has shown what the company considered important in fact. Albeit, the reality revealed bad company management, a lack of ethical conduct, intentional reduction of vehicle quality, misleading representations, non-ecological behaviour and associated ignorance towards the environment. The scandal led to reduction of saleability, loss of customer trust, loss of interested parties' trust, negative economic results and a drop in the price of its shares. (Soviar et. al, 2018)

After the fraud over emissions was revealed, the vehicle manufacturer admitted that the cars are not all right and emissions were manipulated. They apologized and replaced the CEO in the next step. Firstly, the Group reacted to the situation by trying to change its management style and structure as well as its corporate ethics. New Director General declared that he was aware of the urgency of the situation and his main task was to restore customer trust. Its second reaction was the creation of "recall" with service interferences to modify control and drive units. The company assured customers that it had begun developing more ecological technologies, in order to confirm its clients in the company's willingness to change. Right after the scandal broke in the USA, the company also started to communicate with customers through PR and personal meetings with journalists at public meetings when they highlighted that they had ruined the most important part of their business, namely trust, and they assured customers that the faulty vehicles will be repaired. Simultaneously, Volkswagen stopped "clean diesel" promotional campaigns. (The Tylenol Crisis, 2020; Bizibl Marketing, 2020; Soviar et. al, 2019; Majerčík, 2017)

In 2017, their tarnished reputation was still visible, which was implied by 422 top negative reviews and comments concerning VW Jetta. However, in 2018, customers began to show more trust in Volkswagen vehicles. According to FOcus2move, the 5th best-selling vehicle in the world was Volkswagen Golf, which had shown a year-on-year drop like Volkswagen Jetta taking 20th place. However, the 6th and 7th place went to Volkswagen Tiguan and Volkswagen Polo with a year-on-year increase above 10 %, which can imply that management replacement, communication improvement, willingness to redress and settle a damage incurred by customers and all endeavour and activities to restore reputation have been successful and beneficial for the company. (Soviar et. al, 2019; Consumer Affairs, 2019)

Volkswagen's Procedure for Solving the Crisis Situation and Rebuilding Their Reputation

- acknowledging the mistake of manipulating emissions, and apology,

- changing the enterprise's management style and structure,
- replacing CEO with bad management,
- new strategy aimed at restoring customer trust,
- withdrawing the "clean diesel" advertisement,
- PR activities and public meetings,
- indemnification in the form of "recall" for service interferences to repair vehicles,
- Indemnification in the form of the repurchase of vehicles
- research and development in more ecological technologies

Alfa Bio – Chickpea Spread

In 2015 Slovakia, a scandal over chickpea spread erupted, as it allegedly contained dangerous botulinum-producing bacterium Clostridium botulinum. After years, the accusation has not been proved to be truthful. Nevertheless, the State Veterinary and Food Administration of the Slovak Republic (ŠVPS SR) issued a notice about the findings concerning the Chickpea Vegetable Spread during the period when the scandal was being publicized. The spread concerned was tested for the presence of botulinum toxin, which resulted in a final recommendation for consumers to avoid consuming the product Chickpea Spread with the best before date of 21 August 2015 from producer Alfa Bio, s.r.o. and to return the product to a store where they had bought it. Based on the findings, the Regional Public Health Authority ordered the withdrawal of the given batch of Chickpea Spread from the market. However, accredited laboratories did not confirm the presence of dangerous poison based on analyses carried out. But the crisis situation brought about an impact on business. Slovak and Czech retail chains considered cancelling orders not only for the spread concerned from the enterprise. (Mikula, 2018)

When solving the crisis situation, the enterprise used its own marketing department consisting of several employees from foreign big enterprises, conducting customer market surveys when making changes and developing new products. The enterprise is trying to communicate that they produce tofu in a traditional way with a long-term history, presenting the fact that they do not use any preservatives and artificially produced soya products in their products. As regards direct steps for solving the crisis, the given batch of Chickpea Spread was withdrawn from the market, and its distribution was suspended. The enterprise collaborated with national authorities without reservation, which supported its trustworthiness (Adamický, 2019). The enterprise inspected the whole production process ranging from the maintaining temperatures, through pasteurization up to storage, and it preventively withdrew the respective batch of Chickpea Spread not only from the market but also from its warehouse (Čimová, 2019). After multiple tests on samples were done, the enterprise's fault was ruled out, and the enterprise issued a declaration, assuring the public of its maximum endeavour to produce non-toxic and high-quality products (Lunter, 2019). Currently, the enterprise strives to strengthen its position on the market, replacing Seesame agency, which was providing it with services in product communication, for Wiktor Leao Burnett, which is going to change the design of product packages to ensure that the enterprise achieves more positive visibility among customers and that the crisis situation with Chickpea spread, which is again in sale after the situation calmed down, is forgotten (HN, 2019; Jankalová, Jankal, 2018; Kubina, Lendel, 2015).

Alfa Bio's Procedure for Solving the Crisis Situation and Rebuilding Their Reputation

- managing the company with a new management approach, and preliminary preparation of process taking place in the enterprise for an unexpected crisis situation,
- apologizing to customers for the situation that had arisen,
- refusing the guild and pointing out their innovative certified food safety and production system ISO 22 000 in press releases,
- using the services provided by professionals - Wiktor Leo Burnett,
- a plan to change packaging and continue selling the product,
- comprehensive change in communication,

- PR statements and the company's CEO's statements,
- PR and communication through social networks under the baton of the agency,
- new strategy aimed at restoring customer trust,
- withdrawing the contaminated batch of spread from the market.

Alfa Bio's procedure for solving the crisis situation and rebuilding their reputation

The individual steps that were taken by the enterprises identically to save their reputation and solve the crisis situations are as follows:

- apology to customers for the situation that has occurred,
- indemnification of customers and refund of financial resources for a purchased faulty product,
- terminating promotional activities related to the product concerned,
- pointing out the introduction of innovations into a production process of the products,
- putting emphasis on safety and eco-friendliness,
- PR activities during the crisis situation, based on a strategy aimed at restoring and strengthening customer and public trust,
- relaunching the product concerned onto the market after the situation calmed down,
- comprehensive change and new promotional activities to support sales of the product concerned and distract attention from future reminders of the crisis situation with the help of professionals,
- early or post-crisis change in management, processes and leaders, supporting the better managing of the crisis situation and faster restoration of positive reputation in the awareness of customers and the public.

Conclusion

Based on the analysed cases, we may deduce principles to be followed by enterprises with the strong possibility of avoiding the occurrence of negative situations, and therefore, these principles should be considered a certain type of prevention when doing business. The principles which we have formulated and which the analysis indicates are basically a foundation for doing sustainable socially responsible business, and they read as follows:

- create a code of ethics in cooperation with all management levels of the enterprise in order that the code of ethics is followed, respected and received positively by all employees,
- certification and regular re-certification,
- avoid creating false recommendations, ratings and reviews,
- avoid misleading and lying to customers and the public,
- avoid covering up, and honestly admit to the act after making a false step,
- keep trying to correct mistakes, if possible,
- respect customers, making no distinction between them, and avoid judging them,
- avoid underestimating any situation that has arisen, and anticipate,
- deal with complaints in the cold light of day,
- think over answers to negative comments and ratings, and consider the legitimacy of complaints,
- respond politely and respectfully in all circumstances,
- avoid ignoring any events or risks,
- never give up and always keep trying to find a solution to all problems,
- take care of your employees,
- employee participation in decision-making and participative management is a better choice than a directive approach when expecting ideas, benefits and innovations from employees on a long-term basis.

Based on the research carried out, we can confirm that ignoring a situation that has occurred may cause and result in a reduction in saleability and business with loyal customers, occurrence of customer distrust in the enterprise, its products and brand, and in sharing negative experiences, which

brings about a negative impact on enterprise reputation in the offline and online environment. The research also shows that even if a problem or a crisis situation already exists, it is vital to keep trying to solve problems honestly with the participation of customers or clients, which implies that it is crutial to endeavour to do socially responsible business sustainably while bearing in mind that the enterprise will have to devote a considerable effort, time and even financial resources in some cases to restore its reputation.

Event Industry in Russia: Problems and Prospects

Elena DOROKHINA
Plekhanov Russian University of Economics, Moscow, Russia
elena_dorokhina@mail.ru

Elena SMIRNOVA
Plekhanov Russian University of Economics, Moscow, Russia
e.smirnova@live.ru

Abstract

Event Industry is an independent branch that includes the entire range of services associated with organizing an event. The event market in Russia is relatively young and fast-growing. The growth is accompanied by certain threats along with considerable opportunities. Research efforts in this area are very few and are undertaken mostly by the event market players. The objective of this study was to analyze the current situation in the industry, reveal the problems associated with its development and the prospects open to event marketing in Russia. It exhibits some specific features associated with the national mentality along with the government's fiscal policy. Still, Event Industry is a quite successfully developing branch of the Russian economy, since Russian business community has realized the importance and effectiveness of special events for the needs of teambuilding and creating a positive corporate image.

Keywords: Event Industry, Event Marketing, Special Events.

Event Industry is an independent branch that includes the entire range of services associated with organizing an event. "Event Industry" may be considered an "umbrella term" for a wide scope of activities alternatively referred to as MICE (Meetings, Incentives, Conferences and Exhibitions) or as just "meeting industry". There is a meaningful distinction between business and non-business events. Business events include tradeshows, seminars, workshops, product launches, team-building retreats or training sessions, etc., and non-business events include festivals, social events, holidays, sports events, etc.

The most important problem that has been accompanying the event industry development in Russia is the one that arises from a superficial understanding of the very term "event". In the consciousness of Russians an opinion has been formed that event management deals with organizing birthday, wedding and other parties, generally - with a single, one-time activity. However, the official dictionary of the IAPCO (International Association of Professional Congress Organizers) suggests the following definition for the meetings (therefore, event) industry: «The Meetings Industry consists of a broad range of organizers, suppliers and facilities engaged in the development and delivery of meetings, conferences, exhibitions and other related events which are held in order to achieve a range of professional, business, cultural or academic objectives».[i]

Currently we start to observe an important shift in public opinion. The business community has realized that in Russia, as well as all over the world, correctly organized events are a powerful tool for promoting companies to the market. Special events not only can make a company known in a wider range, but also help to build its reputation.

It is well known that an original, out of the ordinary corporate event can be widely covered by the media. The more journalists are interested in what is happening and the more interesting and rich the program is for the participants of the event, the more positive emotional and behavioral feedback the company can get. In the conditions of the oversaturated Russian advertising market, event marketing

is one of the ways to influence the audience in a subtle way, aiming primarily at forming the company's image.

One of the main advantages of event marketing is its long-term operation, since any event is provided with information support, which begins long before the event itself. It includes announcements in the media (for major events), in social networks, on posters, banners, or in internal mailings (for corporate events). If successful, the event will be discussed for a long time through various communication channels.

For example, conferences promote productive and, in many cases, long-term cooperation. They imply bringing together people from one industry at the same time and in the same place where they can comfortably communicate. Such events may be very useful, as they allow the participants to build partnerships, exchange experience, therefore contributing to the development of the industry.

Events are often entertaining in nature; they are supposed to involve active participation of the audience and subtly affect the subconscious of attendees. That is what one of the agencies claims: "We develop unconventional concepts, create performances and address all five senses of our guests: you can see our events, hear them, taste them, inhale them and touch them. They excite, involve and impress..."[ii]

The following companies can be pointed out among the main players in the Russian event management market: "Eventum Premo", "Podegiki", "Redday". They were chosen among 2019 Top-50 best event companies by the *Special Events* Magazine (US) which is the premier magazine for professionals in the special events industry[iii]. According to the *Special Events* Magazine, these companies' expected annual revenue from special events in 2019 was $15.5 million, $14.8 million, and $10.0 million with the average number of special events per year of 73, 157, and 32, respectively[iv]. Leading market players adhere to the following strategy: they try to remain in the market and increase their market share by using their competitive advantages, developing their brands, establishing long-term and mutually beneficial relationships with business partners, using various marketing tools. The second goal for them is to increase capacity of the market. According to the management of "Podegiki", the main trends are: "connecting events to digital and media channels to increase efficiency, and providing individualized experiences to attendees, enabling them to be "fully emotionally" immersed in the essence of the event and to be "a participant in the action."[v]

According to the *VTB Capital* forecast, in 2020 the Russian event market is going to be worth about $350 million[vi]. As follows from the research undertaken by the *Adindex.ru* marketing agency, companies in Russia allocate up to 20% of their marketing budgets to events and MICE[vii]. With respect to their willingness to pay for an event to be organized and hosted, the customers of the event market in Russia can be divided into five main categories:

- VIP: they spend more than $100 thousand for an event;
- business class: they spend $65−100 thousand for an event;
- top-economy class: they can pay $30−65 thousand for an event;
- economy: they are willing to pay no more than $30 thousand;
- public (state-run) organizations, whose expenditures are practically unpredictable.

Obviously, the share of each category strongly depends on the economic conditions in Russia. If we consider the three above mentioned companies, "Eventum Premo", "Podegiki", "Redday", the average revenues from one special event will be $212, $94, and $313 thousand, respectively, which means that their customers are mostly VIP, which is no wonder. Range Rover, Johnson & Johnson, Raiffeisen Bank, Avon, E&Y, Beiersdorf, PepsiCo are just some of them to mention. At the same time one of the most influential trends now is being cost efficient. That is the strategy of the majority of the regional companies. To stay afloat they have to be very creative, which is, for instance, being reflected by the shortlists of the national professional contests. According to the latest results of BEMA! (Best Experience Marketing Awards!), from year to year the number of projects from the regions is increasing - it is already more than a third, and the share of prize winners among the

applicants from the regions approaches 90%. The BEMA! figurines most often go to cities such as Kazan, Rostov-on-Don, Novosibirsk, Yekaterinburg and St. Petersburg. Very notable: the budget of the 2017 winner in the most popular HR category was only about $7 thousand.[viii]

To better understand the state of the event market in Russia, we conduct a SWOT analysis and present its results in Table 1.

Table 1: SWOT analysis of the Russian event market [developed by the authors]

Strengths	**Weaknesses**
Long-term effect of corporate events Heightened receptivity of participants during the event Teambuilding, strengthening the corporate spirit Formation of the company's image Effective building of emotional and economic ties between the event agency and the customer Maximum involvement of attendees in the event that ensures future loyalty	Lack of professional event organizers Lack of a carefully developed strategy Lack of correspondence between the format and concept of the event and the target audience Large labor costs (physical and emotional) Risks of quickly boring the audience
Opportunities	**Threats**
Growing recognition and acceptance of event industry by the business community Considerable saving prospects	Worsening economic conditions Tax legislation

As illustrated by Table 1, the event market in Russia exhibits common features that are typical to all countries of the world and stem from the undeniable advantages of this company's promotion technique along with specific features, in particular – with those associated with the national mentality.

Another problem stems from the fiscal legislation of the Russian Federation. Full costs of an event cannot be deducted from the tax due on income of the companies (customers), so they have to pay most of the costs out of their net profit. In this regard, contracts with event agencies do not reflect the full range of services that are provided to the customer. That is why very few companies announce open tenders for choosing an event agency. Therefore event market in Russia cannot operate clearly and transparently.

Nevertheless, event industry is a quite successfully developing branch of the Russian economy, since Russian business community has realized the importance and effectiveness of special events for the needs of teambuilding and creating a positive corporate image.

Experience of the Robotic Process Automation implementation at the accounting services enterprise: A case Study

Natalia BUCHALSKA-SUGAJSKA

UTP University of Science and Technology, Bydgoszcz, Poland

Email: natbuc002@utp.edu.pl

Abstract

The article presents the results of a case study of the implementation of the Robotic Process Automation (RPA) at the accounting services enterprise. The introduction presents a definition and the essence of the RPA and the grounds justifying the RPA application to the accounting processes automation. Then, with a literature review, the benefits and limitations of the office processes automation, especially accounting processes, are discussed. The main part of the article presents the experience of the implementation of the RPA at an accounting services enterprise in Poland. The empirical study has involved a case study method and an individual uncategorized interview. The results show that not all the accounting processes have been successfully automated and the RPA software must be still improved. The experiments justify further studies of the RPA implementations at accounting services enterprises.

Keywords: RPA, Business Process Automation, Accounting Services Enterprise, Robotic Processes

Introduction

Information Technology keeps on evolving in the world of accounting. Literature stresses a growing importance of computerization and computer science for the accounting profession (IFAC 2007). Robotizing of the accounting processes provides both many opportunities and many challenges. Entering the data manually has been gradually replaced by automation. The scope of the accountant's works keeps on changing as a result of introducing the automation (Richins et al. 2017). The report Practice of Now (Redstrom 2019) presents forecasts on the accountant's work in the decade to come. It has been mostly noted that the accountants will only monitor the process of the automatic entering of the data into the system, instead, as it has been the case so far, entering the data by hand.

The Robotic Process Automation is a relatively new yet dynamically developing IT area focused on the process automation. The RPA software operates in the user interface layer and it replaces the man with data recognition, entering and processing (Willcoks et al. 2015). The process automation involves the use of intelligent software to perform repetitive and time-consuming actions (Institute for Robotic Process Automation 2015; E*mbracing robotic automation during the evolution of finance* 2018). One of the top RPA technologies is the Optical Character Recognition (OCR), facilitating an automatic document reading and the right content recognition.

The article 'Robotic process automation: The next big disruption' in Financial Express (2016) has defined the RPA as an automated software tool the enterprises apply to process the low-class tasks without the personnel participating. The software operates autonomically based on the process pattern rules prepared and in exceptionally difficult situations it directs the process to the man. The RPA technology does not require any platform development, replacement or progress, as it supplements the existing systems.

Commercial RPA tool providers have observed an increase in the demand for such tools and hence a growing number of new RPA providers on the market, which is due to the number of accounting

services enterprises which search for cost-cutting measures. Besides, the RPA is now considered a way for a fast return on investment (ROI) (Van der Aalst et al. 2018; Hindle et al. 2018).

The study shows that the personnel spend little time on the tasks which require analytical thinking as they spend much of their working time on repetitive actions, to-much-extent involving transferring data from one system to another. Accountants should get free from such unstructured routine tasks to focus on the tasks which require strategic and analytical thinking (Kaya et al. 2019).

The RPA software can perform administrative tasks which have so far required the involvement of a few personnel and which involved e.g. the transfer of data from the input sources to the recording systems, such as e.g. the ERP. "Robot" is a software which does not require the accountant to have any programming skills. A few-week training is enough to start working using the RPA tools (Lacity, Willcocks 2015).

The main objective of the article is to present the experience of the implementation of the Robotic Process Automation at the accounting services enterprise. The presentation of the results of the empirical study has been preceded by the explanation of the term and the essence of the RPA and discussing the potential benefits of implementing the RPA to the automation of accounting processes. To do so, a literature review was made, including the journals and Internet sources which cover the RPA and IT solutions for accounting. The empirical study involved a case study and an individual uncategorized interview. The measurement tool was made up by an interview questionnaire. The interview was made with an accountant of the Liberty Tax accounting services enterprise headquartered in the kujawsko-pomorskie province.

Limitations and benefits of the RPA implementation at the accounting services enterprise

Accounting services enterprises need tools which will facilitate cost-cutting and which will release the accountants from time-consuming repetitive actions, thus enhancing their productivity. The enterprises which have chosen to implement the RPA expect a full automation, which is not quite possible yet. An ongoing improvement of the systems, however, offers more and more benefits. With the literature analysis the following benefits are found for the RPA implementation:

- cost-cutting (Willcoks et al. 2015; IRPA 2014, IRPA 2015),
- speeding up the task execution (Willcoks et al. 2015; (Lacity and Willcocks 2015; Fernandez and Aman 2018; IRPA. 2014; Schatsky et al. 2016; Chen et al. 2012),
- it does not disturb the existing systems and it can be used by non-programmer personnel (Willcoks et al. 2015),
- a decrease in the load of the repetitive simple tasks of the personnel, limiting the routine (Aguirre and Rodriguez, 2017; Fernandez and Aman 2018; IRPA 2014),
- work quality and accuracy enhancement (Fernandez and Aman 2018; IRPA 2014; Schatsky, Muraskin and Iyengar 2016; Lacity and Willcocks 2015; Chen et al. 2012),
- an increase in the personnel motivation to learn (Fernandez and Aman 2018),
- a greater competitiveness than the other such enterprises (Fernandez and Aman 2018),
- transferring the accountants to the execution of the tasks which require strategic and analytical thinking (IRPA 2014; Jędrzejka 2019; Kaya et al. 2019; Fernandez and Aman 2018),
- it facilitates working 24 hours a day for 7 days a week (Fernandez and Aman 2018).

Considering the above one can state that the performance of tasks by "soft-robots" enhances the productivity of the personnel of the accounting services enterprises. Thank to that technology it is possible to serve the business processes which involve considerable data loads; from data mining,

processing data from various documents, sending files and folders to be read and saved and from databases, etc.

The RPA at accounting services enterprises can help the automation of acquiring the monthly activity reports, entering buying and selling documents, vacation application processing.

Petersen and Rohith have indicated that the cost of the "robot" can be equal the cost of one fifth of the price of a full-time employee (2017). Interestingly, robotisation does not have to result in job losses, however, it makes it possible for the accountants to focus on more important tasks (Spanicciati, 2016).

However there are some challenges and risks that affect the expected outcome of automation. According to estimates, from about one-third to even half of RPA implementations fail first time (EY 2016). One of the reasons is targeting RPA at the wrong processes. The misstatement consists in introducing improvements in a complex process. This generates high costs. Low or medium complexity processes or sub-processes are the best initial target for RPA. Complex processes should be automated later (EY 2016). It should also be remembered that RPA does not improve processes themselves, but the tasks that create processes. If the processes are poorly designed, they will not be automated (Jędrzejka 2019). In addition, tasks that are automated should be identified and documented. Often, this documentation is incomplete or out of date.

Another limitation is forgetting about the IT infrastructure and assuming that RPA is all that' s needed to achieve a great ROI (EY 2016). Servers and storage should be secured for backup. Another limitation is the cost of purchasing software and creating preliminary processes. In subsequent years, there are costs associated with updating the implemented RPA systems (Jędrzejka 2019).

Cyber security is also a threat to RPA. Tasks performed so far by hand are converted into their digital counterparts. As a result, there is a risk of hackers (Jędrzejka 2019). There is also a threat that RPA will be used for hack and online crime (Gotthardt 2019).

Adequate management and control of RPA should help reduce these risks (PwC 2017).

Experience of the RPA implementation at the accounting services enterprise

Launching the study described in this paper is justified by the application of the RPA for the automation of accounting processes being a relatively new problem. At the same time such processes are one of the most frequently automated office processes (Mazilescu 2019). In Poland there operate a few dozen thousand accounting services enterprises serving about 2 million enterprises. For accounting services enterprises, the RPA implementation is a big challenge. For the ones which will be first to face the challenge, the RPA can assure a competitive advantage.

The study has involved a case study. It is a method used e.g. for investigating new problems, for instance the RPA application at accounting services enterprises.

An accounting enterprise located in the kujawsko-pomorskie province; Liberty Tax, established in 2008, has been selected for the study. The aim of the study has been to demonstrate the automation process implementation for entering documents at the accounting enterprise. There have been presented both the advantages and the disadvantages of the RPA software used. The research method selected was an individual uncategorized interview made with a Liberty-Tax accountant and the measurement tool – an interview questionnaire.

From the start of its operation the enterprise has been licensed by the Ministry of Finance. At the time of the project the enterprise included a chartered accountant, seven accountants, two HR specialists and two lawyers. It was serving 300 clients. The accounting software used was the Comarch ERP Optima.

Every month the company used to receive, on average, a few dozen thousand buying and selling documents to be entered into Optima.

The decision to test the RPA was taken when in the middle of last year only one client provided about one thousand purchase invoices and more or less the same number of the sales invoices. The first program used was the Scanye intelligent OCR. A poor transparency, not recognizing all the data and repeating the same counter parties are some of the program drawbacks mentioned by the accountant. At the end of last year, the program was replaced with the Invoice Digitizer. That solution has been implemented by the Liberty-Tax personnel under an IT supervision. The enterprise decided to do so mostly due to the fact that the documents can be entered directly from the Invoice Digitizer to the Comarch ERP Optima.

The system is user-friendly and it does not require any personnel's programming skills. Once the documents were collected from the client, they were adequately chronologically ordered, divided into buying and selling documents. It was also necessary to remove the staples from the documents. Once the invoices were placed in the ring-binder it was possible to start scanning. To do so the accounting enterprise purchased a special scanner to recognize the invoice data without having to take the invoices out from the ring-binders. The documents scanned were sent to computers where the accountant was verifying the data correctness. The program identified the following taxation data:

- invoice issue date,
- sales date,
- document number,
- seller's tax identification number (NIP),
- buyer's tax identification number (NIP),
- amounts of the net sales values, VAT, gross sales values divided into the VAT rates,
- bank account number of the counter party.

The Invoice Digitizer verifier facilitated an automatic data verification to make sure that the data is correct and it can be endorsed by the accountant. The Invoice Digitizer Verifier module facilitated verifying the following data:

- client identifier,
- NIP number of the counter party,
- invoice data,
- invoice number,
- VAT values divided into VAT rates.

The data verified was approved and then transferred directly to the accounting program. One employee was manually entering, on average, 80 invoices per hour into the program. The application of the program facilitated performing those actions 25% faster.

With the program it is possible to scan even a few hundred documents a day. The processing time gets shorter and so does the time of entering the documents into the program. The action not requiring any expertise is performed by an automated process. Scanning can be made by a single employee, while verifying the data – by the other ones. As a result, the documents are booked and the accountants can perform the tasks which require their specialist knowledge. The accountant has stressed that it refers only to the documents which are "recognizable" for the program. Otherwise the operation of the "robot" is much poorer than if the documents are entered by the accountant.

The problem appeared when the invoices were hardly recognizable. Most often those were the documents printed with dot-matrix printers. It was when the invoice numbers and dates were incorrect. Besides the documents which contained more than one table were recognized by the program incorrectly. The document issue dates used to be mistaken with the payment date – similarly as the amounts provided in the document, mostly net and gross.

The cost of introducing a single invoice by the program as compared with the cost generated by one employee entering the document by hand is definitely lower. However, as stressed by the accountant, the errors which are too frequent, instead of saving the time and simplifying the work, often make it longer and generate unnecessary costs.

Any incorrect recognition of the documents is notified of by the accounting enterprise to the software producer. Thanks to it, it is possible to improve the system. Despite the software corrections made by the manufacturer, an incorrect data recognition is often the case. The personnel noted some improvement, however they have been still searching for the solutions which help automating their work more efficiently.

With those suggestions in mind, the objective of this publication has been to present the potential benefits of implementing the RPA at accounting enterprises and a proposal of expanding the research with a higher number of the entities studied to improve the RPA systems offered by the providers.

Conclusions

The accounting enterprises should estimate the scope of the changes required and develop effective automation implementation strategies. The work of the accountants is mostly a huge number of documents to be processed. There are created more and more work-facilitating tools drawing on the OCR technology. Accountants gradually stop copying data from documents and start verifying the data.

The preliminary study results and the literature review have facilitated accomplishing the objective of this publication. The author decided to perform the preliminary study as the accounting enterprise has been making the first attempts at implementing the RPA to its operation. The tests show that the enterprise is open to introducing new technologies facilitating the automation of entering the documents to the accounting program. Despite the numerous benefits of implementing the RPA, some software defects making work considerably more difficult have been pointed to. Nevertheless, the accounting enterprise has not found a better method of facilitating the work of the accountants yet.

The literature seems to be lacking the empirical studies on the effectiveness of implementing the RPA systems at accounting enterprises. The case studies showing the effects of implementing such technologies are to provide more knowledge about the subject matter and to demonstrate any potential imperfections of the systems. It is then justifiable to perform further studies at accounting enterprises with the multiple case study method.

Many accounting services enterprises, despite the eagerness to launch the automation, might not have the sufficient funds to help “robots” learn and to experiment with the tasks they could optimize. The experience of the successive accounting enterprises which have implemented the RPA could be used to improve the systems by the manufacturers. They could help indicating the accounting processes most adequate for automation and those for which automation is doubtful. Additionally, the conclusions from this publication can be a guideline for the enterprises still considering the introduction of accounting processes automation.

Abstract

Most countries are on the threshold of transition to the fourth industrial revolution which will undoubtedly determine the future of economic development. A study conducted on formation, development, use, impact and evaluation of intellectual capital in cluster associations revealed inadequate research of formation of the intellectual capital and its structural parts. Therefore, the purpose of this work was to study the formation of the intellectual capital of an innovation active industrial cluster. The paper defines the intellectual capital, the innovation active industrial cluster and presents the structure and formation of the intellectual capital in the innovation active industrial cluster. The authors propose stages of intellectual capital assessment in an enterprise of innovation active industrial cluster, which include estimation of intellectual capital of innovation active industrial cluster; allocation of share of value of the intellectual capital included in each unit of its products from the received value of the intellectual capital; distribution of the received share of the value of the intellectual capital included in each unit of its products among enterprises that participated in creation and production of the products on basis of individual agreements concluded between them; summing of the intellectual capital for all products of the enterprise created in the innovation active industrial cluster to determine an increase in the intellectual capital of the enterprise formed in the process of finding this enterprise in the cluster; summing of results obtained with the value of the intellectual capital of the enterprise at the time of entering the cluster.

Keywords: Intellectual Capital, Structural Capital, Relational Capital, Innovation Active Industrial Cluster.

Introduction

As noted in the work of German economist Klaus Schwab, "The fourth industrial revolution" (2017), the fourth industrial revolution is a transition from simple digitalization (the third industrial revolution) to the following:

– innovation based on combinations of technologies (the fourth revolution);
– information platforms that combine supply and demand and violate existing production structures;
– new organizational forms and business models.

In this regard, it is appropriate to say that most countries are on the way to the fourth industrial revolution, which will undoubtedly determine the future nature of economic development, as described by Shipunova et al (2018), forms of integration processes in the field of industrial production, studied

by Schepinin and Skhvediani (2018), as well as key indicators of the functioning of economic sectors, which Babkin et al (2019), Zeng at al (2019), Molina-Morales at al (2017) draws attention to. Analyses of innovative platforms and technologies can be found in different papers, for example, in the article of Alekseeva and Stroganova (2019).

In the context of economic modernization and its transition to a new level of "digitalization", the issues of innovative development of enterprises that are part of the structure of industrial clusters, studied by Babkin and Tashenova (2019), and actively implementing innovative developments, become particularly relevant. In terms of its potential and special structure, the cluster approach, which is actively applied to industrial enterprises, is an integral mechanism for improving the competitiveness of economies around the world, as analyzed by Schepinin and Skhvediani (2018), accelerating processes of innovative development in various sectors, as explored by Gutman et al (2017) and Kuzovleva et al (2019), stimulating local initiatives to intensify interaction between industrial enterprises, the state and end consumers.

The founder of the cluster approach, M. Porter (1990), considered it to be a comprehensive approach to understanding conditions and trends of the innovative development. Nowadays theoretical provisions of the cluster approach are being developed in various areas of scientific research. Tong and Tao (2017) propose a method for evaluating effectiveness of high-tech industry cluster policies based on fuzzy deployment of a quality function. Varshneya et al (2018) offer an optimization model for industrial cluster design. Buyanova et al (2018) consider clustering as an effective factor of import substitution. Selentyeva et al (2018) analyze the role of state cluster policy and results of the development of the innovative clusters and offer improved approaches to evaluating these results.

Moreover, we can emphasise studies that are devoted to the formation, development, use, and impact of the intellectual capital in cluster associations. Agostini et al (2017) focused on the study of a relationship between power of the intellectual capital and innovation activity of small and medium-sized enterprises combined in a cluster. Empirical research by Cavalheiro and Brandao (2017) shows that the formation of structural capital is more intensive in clusters than in individual enterprises. Li et al (2019) found that the cluster's innovation environment has a direct impact on the innovation activities of enterprises that are part of the cluster. These papers develop an extensive line of research on the use of the cluster intellectual capital. This topic is very relevant due to the fact that the intellectual capital, according to Roos et al (2010), is involved in creating value, according to Stewart (1994) and Sudarsanam (2003), increases competitiveness, and Skaikh (2004) and Petrash (1996) consider it a former of wealth, income, value, and increasing value, which are an important area of research for cluster formations.

A review of literature on the formation, development, use, impact and evaluation of the intellectual capital in cluster associations identified inadequate research of the formation of the intellectual capital and its structural parts in the innovation active industrial cluster and evaluation of intellectual capital of enterprise in innovation active industrial cluster. In this regard, the purpose of this work is to study the formation of the intellectual capital of the innovation active industrial cluster. To achieve this goal, we had the following tasks.

1. To define and present the structure of the intellectual capital of the innovation active industrial cluster.
2. Define and present the structure of the innovation active industrial cluster.
3. To present the formation of the intellectual capital and its structural parts in the innovation active industrial cluster.
4. Propose stages of assessing the intellectual capital of the enterprise in the innovation active industrial cluster.

Materials and Methods

The methodological apparatus of this work is based on a combination of basic methods of general scientific and natural science knowledge. The work uses methods of observation, generalization, abstraction, and a graphic method.

Results

The paper presents the structure of the intellectual capital (Fig. 1).

Fig. 1: Structure of the intellectual capital of the innovation active industrial cluster

The paper proposes the structure of the innovation active industrial cluster, shown in figure 2.

Fig. 2: Structure of the innovation active industrial cluster

Figure 3 schematically depicts the formation of the intellectual capital of the innovation active industrial cluster by creating its innovative products.

Discussion

The Intellectual Capital

The intellectual capital is a set of intangible assets that bring or can potentially bring their owner income through their use. In this case, by the intangible assets we understand a much larger set of assets than it is accepted in accounting. We remove restriction on including such requirements as the availability of title documents, the possibility of the allocation and separation of the object, the absence of an assumption about the sale of the object in the composition of intangible assets. This view of the intangible assets in the management of the intellectual capital is not new and is supported by scientists such as Roslender and Fincham (2001) and Kozyrev and Makarov (2003). We include loyalty, business cooperation, resources related to relationships, relationships with suppliers, customers, partners, and any stakeholders as part of the intangible assets. The listed assets will be a part of the relationship capital. The human capital includes the creative abilities, knowledge, skills and professional competence of the staff. The intellectual capital also includes technologies, licenses, and intellectual property. In this paper we schematically present the structure of the intellectual capital in figure 1.

The Innovation Active Industrial Cluster

At this stage, it is worth defining the concept of "an industrial cluster" which should be understood as a set of subjects of activity in the field of industry and related organizations that work together and solve production, marketing and innovative tasks effectively. Development of innovations and introduction of innovations in the field of information technologies provides industrial clusters with a high level of competitiveness, as well as gives an opportunity to move to a new level of organization and effective functioning in conditions of modern economic development. Hence, we consider "innovation clusters" or "innovation active industrial clusters" to be the clusters that use innovations that have already been created or developed independently (usually technological or technical) and carry out production including innovative products.

Therefore, the innovation active industrial cluster should be understood as a group of interconnected industrial, scientific and educational enterprises, as well as other organizations (financial, consulting, engineering and other companies) actively working together to achieve key performance indicators and interacting with each other to develop, implement, and commercialize innovations and innovative products. In other words, the innovation active clusters are the clusters that actively use various innovations (process, structural, organizational, technical, etc.) in their activities and, accordingly, ensure the production of a significant share of high–tech competitive products with a high degree of added value.

Here the authors consider the structure of the innovation active industrial cluster. The innovation active industrial cluster consists of companies that produce raw materials, manufacturers of materials and components, enterprises that provide services of a production nature, and, finally, mandatory companies that produce final products. At the same time, there must be at least 1 manufacturer of the

final product. All or most of them are linked by economic relations (Fig. 2) aimed at creating the ultimate innovative and highly competitive product.

Formation of the intellectual capital of the innovation active industrial cluster

The existence of relationships between entities in figure 2 indicates the presence of relationship capital represented by business collaboration and relationships with partners in the cluster. Each entity working in the cluster acquires and strengthens its relational capital by creating trust and reliable relationships within the cluster. At the same time, the totality of all relationships between cluster entities can be classified as the relational capital of the innovation active cluster. This relational capital will be related to internal relational capital of the cluster. The formation of external cluster capital can occur due to recommendations that can be given by cluster partners to each other regarding their contacts that are external to the cluster. In case of the internal relational capital, the cluster receives all the benefits from its presence. In event of the external relationship capital, the benefit of its presence is distributed between the cluster and the entity outside the cluster. Moreover, this distribution is not necessarily equal, the proportion will depend on the benefits that each party will receive from cooperation.

Due to the fact that the cluster is interested in innovation activity, the emergence of relations between the partners in the cluster is possible in the field of research activities. Research activity is the use of creative abilities and professional skills of people; thus, the authors move to consideration of the formation of human capital of the cluster.

In the context of business and scientific cooperation, scientific and technical cooperation is greatly simplified. Modern digital communication systems also contribute to this. The management of the innovation active industrial cluster can specifically conduct events that allow employees of the cluster enterprises to meet at conferences, forums, and exhibitions that facilitate exchange of ideas and creative implementation. For example, hackathons held among IT-specialists have recently become very popular. Holding such events among the employees of the innovation active industrial cluster allows the cluster to expand its scientific and technical potential on the basis of existing enterprises. These activities can also be carried out with involvement of external entities in relation to the cluster. Therefore, occurrence of a promising and meaningful cooperation between the subjects of the innovation active industrial cluster and external subjects can affect the development of the external relationship capital or attract new partners to the cluster, which will lead to the development of the intellectual capital of the innovation active industrial cluster.

New ideas and solutions often arise in communication with new people through new information, experience, or external evaluation. In this regard, the development of research interaction is possible between the employees working in different organizations of the innovation active industrial cluster. We can say that the interaction of the human capital of different enterprises within the cluster is based on the relational capital that is acquired and accumulated there. If the employees of different organizations of the innovation active industrial cluster manage to obtain successful R&D results, create a working prototype and issue a patent for an invention or utility model because of the research interaction, then the result will be an intellectual property, which is a part of the structural capital.

Nevertheless, a complex issue of distributing the contribution of each participant of the innovation active industrial cluster that participated in cooperation and created new products exists and is subject to legal settlement, preferably at the initial stages of such interaction. However, if this invention begins to be used for the production of the final product of the innovation active industrial cluster, it can be attributed to the structural capital of the cluster. It should be noted that creating a successful invention is not enough: its use should be included in production processes to create products of the innovation active industrial cluster that requires the passage of bureaucratic procedures and is also built on effective internal communication and partnership between the enterprises of the cluster, i.e. on the structural capital.

In this part of the paper the authors want to dwell on distribution of the contribution made by each subject of the innovation active industrial cluster to the creation of a new product of the cluster. It is

obvious that the greater contribution to the creation of the product the participant makes, the greater share of the intellectual capital they have a right to claim to. Investment in creating the product can be made by transferring fixed assets, allocating time for qualified employees to create the product, paying for materials, energy resources, as well as the ability to use the company's existing licenses, patents, and R&D resources. If the licenses and patents are granted to create the new product, then we are talking about providing the part of the company's structural capital. R&D, which is unexecuted by proper documents, and the time allocated to the qualified employees represent the human capital. If several employees of the company are provided for the implementation of the project, representing a cohesive team, then we are talking not only about the human but also about the relational capital. Therefore, the enterprise can provide all the elements of the intellectual capital to create the new product.

Thus, it can be seen that the use of elements of the intellectual capital for the innovative activities of the innovation active industrial cluster is intertwined, mixed and integrated so tightly that the allocation of currently working elements becomes a very difficult task and largely depends on specific agreements between the cluster participants, which are individual in its nature, taking into account a huge number of factors of the internal and external environment.

The formation of the intellectual capital of the innovation active industrial cluster by creating its innovative products is schematically shown in figure 3.

Stages of Assessing the Intellectual Capital of An Enterprise in The Innovation Active Industrial Cluster

The diagram shown in Fig. 3 allows us to present the stages proposed for assessing the intellectual capital of enterprises in the innovation active industrial cluster, which generally consist of five stages.

1. Estimation of the value of the intellectual capital of the innovation active industrial cluster.
2. Allocation of the share of the value of the intellectual capital included in each unit of its production from the received amount of the value of the intellectual capital.

3. Distribution of the received share of the value of the intellectual capital included in each unit of its production among the enterprises that participated in the creation and production of the products on the basis of individual agreements concluded between them.
4. Summing of the intellectual capital for all enterprise products created in the innovation active industrial cluster to determine the increase in the intellectual capital of the enterprise formed during the presence of this enterprise in the cluster.
5. Summing of the result obtained in a clause 4 with the value of the enterprise's intellectual capital at the time of entering the cluster.

The first stage, which consists of assessing the intellectual capital of the innovation active industrial cluster, is proposed to be carried out using known methods of assessing the intellectual capital which are presented in the following table with the use of research materials made by Sveiby (2010), Idchenko and Elkin (2013), Lisevich (2015) (table 1).

Table 1: methods for evaluating the intellectual capital of the innovation active industrial cluster

Name of a group of methods	Essence of a group of methods	Disadvantages of a group of methods
Direct Intellectual Capital methods (DIC)	A monetary assessment of the intellectual capital is made. The assessment is based on the identification of the intellectual capital components. The components are evaluated either individually or aggregated.	The complexity of identifying the components of the intellectual capital. Possibility of double counting of the components. Laboriousness.
Market Capitalization Methods (MCM)	A monetary assessment of the intellectual capital is made. Evaluation is based on the difference between the company's value and the value of its non-tangible assets.	Application is difficult if the company's shares are not listed on the market or their liquidity is low. Laboriousness.
Return on Assets methods (ROA)	A monetary assessment of the intellectual capital is made. The assessment is based on a comparison of the return on assets of the company, whose intellectual capital is estimated, and the companies in this industry. The excess of the industry average return is attributed to the cost of the intellectual capital.	The estimation error is based on the fact that medium-sized companies also have the intellectual capital.
Scorecard Methods (SC)	The assessment is based on the creation of a system of indicators and indexes, which will be presented later in the indicator system or in charts.	The results of the evaluation are informational in its nature and do not allow us to give a monetary estimate of the value of the intellectual capital.

On the second stage, the question about how to divide the value of the intellectual capital of the innovation active industrial cluster between the products it produces arises.

Due to the fact that the use of the elements of the intellectual capital for cluster innovation is intertwined, mixed and integrated tightly, it is very difficult to allocate the cost of its elements using direct counting methods and it can only be done with a sufficiently large confidence interval. At the same time, it should be noted that all the elements of the intellectual capital of the subjects of the innovation active industrial cluster should be equal to the intellectual capital of the entire cluster. This assumption is the basis for the formula proposed by us for determining the value of the intellectual capital of the innovation active industrial cluster in each type of product that it produces.

The amount of the intellectual capital in the i-product of the innovation active industrial cluster will be determined by the following equation:

$$\boldsymbol{IC_{p_i} = IC_c \times \frac{K_i^1 \times K_i^2}{\sum_{i=1}^{n}(K_i^1 \times K_i^2)}} \quad (1)$$

where ICp_i is the share of the intellectual capital in the *i*-product; *i* – the cluster product ($1 \leq i \leq n$); *n* – the number of types of products produced by the innovation active industrial cluster; *ICc* – the intellectual capital of the innovation active industrial cluster; *K1* – the coefficient of the achieved result;

K2 – the coefficient of complexity of the problem solved.

The coefficient of the achieved result reflects the characteristics of the products that are produced using the intellectual capital. The rating scale should be created within the cluster, taking into account its industry orientation. In general, the following scale can be used.
– Secondary characteristics of the created product have improved – 1.
– Improvement of the primary characteristics of the created product has been achieved – 2.

– New products that are superior in their characteristics to those available on the market have been created – 3.
– New products that have no analogues in the market have been created – 4.

The complexity coefficient of the problem solved can generally be measured using the following score scale:

– One parameter of the mechanism has changed – 1.
– Non-basic design of the mechanism has changed – 2.
– The basic design of the mechanism has changed – 3.
– The mechanism has changed completely – 4.
– A particularly sophisticated mechanism has changed completely – 5.
–

The third stage of assessing the intellectual capital of the subjects of the innovation active industrial cluster has an individual character and takes into account the contribution made by each subject of the cluster to the creation of the new product within the cluster. The share of the intellectual capital of the company that participated in the creation of the product will be determined as follows:

$$IC_{c_j p_i} = \boldsymbol{IC_{p_i}} \times \frac{\boldsymbol{CCi\ (Mat., ER, Depr., ITA, Sal.)}}{\sum_{i=1}^{m} \boldsymbol{CCi\ (Mat., ER, Depr., ITA, Sal.)}} \qquad (2)$$

where ICc_jp_i is the share of the intellectual capital of the j-company in the i-product; ($1 \leq j \leq m$); m – the number of companies involved in creating the product of the i-product; ICp_i – the share of the intellectual capital in the i-product; CCi – the contribution made by each cluster company to the creation of the i-product; *Mat.* – the cost of materials, *ER* – the cost of energy resources, *Depr.* – the depreciation of fixed assets, *ITA* – the intangible assets in form of the patents and licenses provided to create new products, *Sal.* – the monetary value of time and skills of employees working on product creation (salary).

The sum of the intellectual capital for all products of the enterprise created in the innovation active industrial cluster will represent the added intellectual capital of the enterprise formed during the process of presence this enterprise in the cluster. The resulting value must be added to the value of the enterprise's intellectual capital at the time of entering the cluster.

Consequently, the implementation of the proposed stages allows us to get the assessment of the intellectual capital of the enterprise in the innovation active industrial cluster.

Conclusion

The authors of this paper proposed the definition of the intellectual capital which is presented as a set of the intangible assets that bring or can potentially bring their owner the income through their use and consists of the human, structural and relational capital. The paper also defines the innovation active industrial cluster as a cluster that uses innovations that have already been created or developed independently (usually technological or technical) and carries out production including innovative products. The innovation active clusters are clusters that actively use various innovations (process, structural, organizational, technical, etc.) in their activities and, accordingly, ensure the production of the significant share of the high-tech competitive products with the high degree of the added value. The innovation active industrial cluster consists of the companies that produce raw materials, the manufacturers of materials and components, the enterprises that provide services of the production nature, and, finally, the mandatory companies that produce the final products.

All the participants contribute to the formation of the intellectual capital of the innovation active industrial cluster by allocating and integrating both material and non-material resources. The use of elements of the intellectual capital for the innovation activities of the innovation active industrial cluster is intertwined, mixed and integrated tightly. The formation of the intellectual capital of the innovation

active industrial cluster happens due to the creation of trusted and reliable links within the cluster. The interaction of the human capital of different enterprises within the cluster is based on the relational capital that is acquired and accumulated there through the organization of scientific and technical cooperation.

The paper presents five stages, the implementation of which will determine the value of the intellectual capital of the enterprises in the innovation active industrial cluster, taking into account the value of the intellectual capital of the innovation active industrial cluster, the complexity of the problems solved and achieved results of the innovative products, created and produced by the cluster, the contribution made by each individual cluster to the creation of the new product in the cluster and the value of the intellectual capital of the enterprise which it had before the entrance to the cluster.

Acknowledgment

Abstract

A review of the literature on the subject suggests that the potential benefits for organizations from the occurrence of diversity do not arise automatically as a result of increasing the diversity of employees due to age in the workplace, but are, among others, the result of complementarity of competences of employees from different age groups. It can be assumed that the positive effects of diversity due to age require the transfer of knowledge between employees. Knowledge transfer is understood as learning from internal and external experts, other teams and departments. On the other hand, the transfer of knowledge among age-diverse employees refers to the process of knowledge exchange among themselves, for example through discussion, imitation and cooperation. The purpose of this article is to discuss the age diversity of organizational performance and to propose knowledge transfer as a mechanism to help improve these results.

Keywords: Employee Age, Knowledge Transfer, Financial Results, Non-Financial Results

Introduction

In the recent years, scientists and practitioners have become increasingly interested in the widely understood diversity of employees in organizations (Shemla, Meyer, Greer, Jehn, 2016). The presence of age-diversity phenomenon within an organization is a more and more common and heterogeneity is becoming an increasingly important organizational issue (Avery, McKay, Wilson, 2007). The topic has recently gained importance because demographic changes have altered the age composition of workforces (Shultz, Adams, 2007): First, age diversity is increasing, which means that, in some companies, members of up to four different generations are working side –by-side, thus providing numerous opportunities for interactions between age-diverse coworkers (King, Bryant, 2017). Second, the number of older workers is increasing, requiring organizations to find ways to retain the valuable knowledge of older workers before they enter retirement (Burmeister, Deller, 2016).Results of conducted research indicate that there are differences in approach to the older and younger employees (Furunes, Mykletun, Solem, 2011). Older employees are perceived as persons not willing to acquire new skills and reluctant towards new technologies and changes (Armstrong-Stassen, Schlosser, 2008). On the other hand, very young employees are considered to lack of actual substantive knowledge and experience (Hysa, 2016).

There are conflicting views on the impact of age-diversity on the organizational performance. Some researchers claim, that it has a positive impact (e.g. (Kilduff, Angelmar, Mehra, 2000), other researchers have indicated that there is no significant impact (e.g. (Backes-Gellner and Veen, 2013), and – moreover - other studies indicate that this impact is negative (Zenger and Lawrence 1989).

As age-diversity in the workplace is increasing, we believe it is necessary to understand how to boost its positive impact on performance. We propose, that knowledge transfer may serve as an important mechanism that mediates between age diversity and performance. The purpose of the article is to discuss age-diversity on the organization's results and to propose the transfer of knowledge as a mechanism that helps to improve these results.

The Importance of Employee Diversity Based on Age

Diversity is a term describing the distribution of differences between members of a given entity (e.g. organization, group) in relation to a specific feature. When describing the diversity of a given attribute within the examined entity (e.g. group or organization), this entity is described as a whole, not the differences between members - which is the subject of most intergenerational differences currents. It is often described as heterogeneity, relationship demographics, or organizational demographics. Research from the perspective of diversity understood in this way has shifted the interest of individuals to organizations as a whole (Appannah, Biggs, 2015). Diversity can be understood as a construct composed of two dimensions: diversity at shallow and deep levels. The first level refers to the easily noticeable (and thus useful due to quick assessments) characteristics of the members of the organization, or groups such as gender, race or age. The second level contains similarities such as attitudes, values and beliefs, network connections, or even results, as well as personality, i.e. traits that are difficult to observe.

Diversity due to age is defined as differences in the age distribution among employees (Boehm, Kunze, Bruch, 2014). In previous studies on the diversity of employees by age, the focus was rather on the characteristics of a particular age group, for example on the group of employees aged over 50 and supportive measures for their work (Komp-Leukkunen, 2019). The literature on the subject rarely indicates the diversity of employees due to age and the benefits of this diversity for the organization. The concept of employee diversity due to age is primarily related to the results of the organization. This diversity can have a positive and negative impact on the organization's results (Komp-Leukkunen, 2019). This positive impact results from the complementarity of competences and professional experience of employees in such a diverse team, more diverse possibilities of problem solving, more developed motivational processes and more diverse and more effective transfer of knowledge from older to younger generations, which contributes to the synergy effect (Horwitz, Horwitz, 2007). The diversity in terms of employees' age shows a wide variety of knowledge, values and professional experience (Cannella Jr, Park, Lee, 2008). Therefore, the team, diversified in terms of age, has a greater amount of knowledge and greater opportunities to solve problems. Knowledge can be from different areas (e.g. technical, social) or at different levels (e.g. beginner or advanced). Younger people may have a high level of theoretical knowledge, but may have less professional experience, unlike older people. Connecting employees with such different knowledge, levels of competence and skills reduces the risk of one-sidedness and unwillingness to innovate compared to employees with a very similar set of features, skills and experience. It is assumed that the joint operation of employees who are different in terms of age contributes to the increase of employees' general knowledge, which has a positive impact on problem solving and increase in employee productivity (Backes-Gellner, Schneider, Veen, 2011). In teams of various age, the creativity of employees is stimulated, the ability to solve problems increases, the decision-making process is improved, and ultimately the organization's efficiency increases.

Research shows that greater diversity due to age can also help counteract problems related to employee motivation. An excessively homogeneous age group of employees may hinder promotion and development opportunities for young or older employees. A homogeneous group of employees uses incentives that suit them and thus take full advantage of opportunities for promotion or development in the company, discouraging other age groups from becoming more involved in work (Gibbons, Waldman, 2006). Conversely, greater diversity due to age should increase employee productivity by providing diverse, attractive to all, professional motivators. In addition, a homogeneous group of employees prevents the transfer of specific, often hidden knowledge, to younger employees. Only if the employee teams are diverse in terms of age will it be possible to transfer valuable specialist knowledge to younger employees, which is the basis of their development (Gibbons, Waldman, 2006). A more diverse team of employees due to age makes the transfer of tacit knowledge, important for the company, between employees easier (Backes-Gellner, Veen, 2013). To sum up, one can expect greater benefits resulting from the growing diversity of employees due to age, with proper use of human resource management tools.

Age diversity and organizational performance

Researchers distinguish between two groups of results: financial and nonfinancial. To cite only a few research on financial results, based on a review of the literature on entrepreneurship, Murphy et al. (Murphy, Trailer, Hill, 1996) identified four main dimensions of the organization's results: (1) performance (e.g. return on investment ROI, return on equity ROE), (2) growth (e.g. increase in sales), (3) profitability (e.g. net income) and (4) volume (e.g. net sales). The researchers also suggested that the fifth dimension add: survival (being competitive on the market). In turn, Woo and Willard (1983) analyzed organizational results and found the following four dimensions: (1) profitability (e.g. return on sales), (2) relative market position (e.g. product quality towards competitors), (3) change in profitability and cash flow (e.g. ROI volatility) and (4) increase in sales and market share (e.g. market share). Rowe and Morrow (Rowe and Morrow Jr. 1999) pointed to such organizational results as: (1) subjective feelings (e.g. reputation and happiness surveys), (2) finance / accounting (e.g. return on assets (ROA)) and (3) market results (e.g. Sharpe index). Similarly, Tosi et al. (Tosi, et al. 2000) analyzed over thirty measures relating to the organization's results to distinguish eight dimensions of these results. In general, these studies confirm that the results of the organization are a multidimensional construction, often depending on analytical (qualitative data sources and survey measures.

The relationship between the diversity of employees due to age and the results of the organization is most often presented at the individual or group level (Harrison, Klein, 2007) less often at the organizational level. At the organization level, the impact of dependencies on financial results is analyzed, such as: return on assets and return on equity (Wei, et al. 2005) and sales growth (Richard and Shelor 2002). The diversity of employees who have reached the age needed to achieve a positive impact on first-level results (e.g., Turnover) and second-level organizational results (e.g., Profitability). Based on the analysis of results of conducted studies, it may be stated that the age-related diversity of employees is positively related to the rate of return of assets and return on equity (Wei, et al. 2005), sales increase (Richard and Shelor, 2002) as well as the method of reaching business decisions (Goll, Sambharya and Tucci, 2001). Additionally, As the indicated correlation between the diversity of employees due to their age and results is related most frequently to the individual or to the group level than to the level of organization, it is worthwhile to carry out an empirical study facilitating the verification of assumption that the age-related diversity of employees affects the improvement of results at the level of the entire organization.

When it comes to non-economic results, most often the literature on the subject gives examples of these results e.g.: creativity, innovation and flexibility In general, non-economic goals, including social ones, are difficult to quantify and their implementation shapes the image of the company as per the record in the declaration (Backes-Gellner, Schneider and Veen, 2011). The theoretical perception of diversity that refers to nonfinancial results is indicated by Harrison and Klein (2007). The three types of diversity are essentially distinct. Separation describes the differences among unit members in their position. Diversity describes the differences among members of units from different categories, reflecting access to unique sources of knowledge. Disparity is defined as a composition of (vertical) differences in proportion of socially valued assets or resources held among unit members; inequality or relative concentration. Referring to quoted definitions, age diversity may be classified as a variety type of diversity which should produce results such as greater creativity, innovations, higher quality of the decision, less task conflicts, increased unit flexibility (Harrison and Klein 2007, p. 232). Takin above into consideration, we hypothesize:

H1. Age diversity in the workplace will be positively related to organizational performance.

H1a. Age diversity in the workplace will be positively related to financial performance.

H1b. Age diversity in the workplace will be positively related to nonfinancial performance.

Knowledge transfer as a mediator of relationships between age diversity and organizational performance

Knowledge transfer in age diverse coworker dyads refers to the process whereby two employees who belong to different age groups exchange knowledge with each other, for example, via discussion, imitation, and cooperation (Gerpott, Wenzel, Lehmann-Willenbrock, Voelpel, 2015). However, while research on ageing in the workplace has been burgeoning (Truxillo, Finkelstein, Pytlovany, Jenkins, 2015), scholars have only recently begun to examine knowledge transfer in age-diverse workforces (Burmeister, Deller, 2016). Initial empirical evidence suggests that knowledge transfer between younger and older employees can be valuable as they can benefit from each other's diverse knowledge (Gerpott, Wenzel, Lehmann-Willenbrock, Voelpel, 2015). However, age diversity can also impede knowledge transfer (Williams, 2016) as individuals have a natural tendency to prefer interactions with peers that are similar to them (Tajfel, Turner, 1986), especially with regard to their socio-demographic characteristics such as age. Thus, age differences can hamper communication, cooperation, and knowledge transfer (Ellwart, Bündgens, Rack, 2013). Accordingly, knowledge transfer among age-diverse coworkers is a difficult process that needs to be facilitated by organizations.

While engaging in knowledge transfer can benefit employees in several ways, for example, by feeling valued and connected to others, and by being able to generate more creative ideas (Burmeister, Deller, 2016), knowledge transfer is a challenging process. Specifically, knowledge transfer may be in conflict with individuals' self-interest due to the sacrifices and risks associated with sharing and receiving knowledge. First, sharing valuable knowledge may be perceived as diminishing one's individual competitive advantage as shared knowledge is no longer someone's exclusive resource (Bock, Zmud, Kim, Lee, 2005). Second, receiving knowledge is associated with considerable time investments, and the willingness to admit knowledge gaps, which might be perceived as a reputational risk (Burmeister, van der Heijden, Yang, Deller, 2018).

Yet, bidirectional knowledge transfer (i.e., the sharing and receiving of knowledge between two employees) is a difficult process that requires investments of time and effort from both actors (Szulanski, 1996). In the context of age-diverse workforces, it can be further inhibited by age effects resulting from age norms. Age norms are 'widely shared judgments of the standard or typical age of individuals holding a role or status' (Burmeister, van der Heijden, Yang, Deller, 2018). The applicability of this perspective to work context remains untested to date (Rudolph, Zacher, 2015). However, initial empirical evidence suggests that older workers seem predestined to be perceived as knowledge senders (Voelpel, Sauer, Biemann, 2012), while younger workers seem to be expected to occupy the role of knowledge recipients (Deal, Altman, Rogelberg, 2010). These perceptions seem to operate regardless of individuals' tenure, experience and expertise (Dunham, Burt, 2011), which might be indicative of normative expectations about the roles that individuals should hold at certain ages when engaging in knowledge transfer.

However, this one-directional conceptualization of knowledge transfer, in which older workers only occupy the role of knowledge senders and younger workers only occupy the role of knowledge recipients, has two main limitations. First, younger workers possess valuable knowledge that, only when shared with other organizational members, can foster individual and organizational productivity (Gerpott, Wenzel, Lehmann-Willenbrock, Voelpel, 2015). For example, younger workers can contribute their latest scientific and technical knowledge (Gerpott, Wenzel, Lehmann-Willenbrock, Voelpel, 2015), and they can function as catalysts that unlock the knowledge base of older workers through questioning and discussion (Tempest, 2003). Second, older workers, who are only required to share their knowledge but are not expected to seek knowledge, may be deprived of the opportunity to learn and further develop their career, a factor that has been shown to be important for their motivation to continue working (Kooij, de Lange, Jansen, Dikkers, 2008). Consequently, while it seems appealing to conceptualize older workers as knowledge senders and younger workers as knowledge seekers, organizations that only facilitate one-directional knowledge transfer between older and younger workers may not use the full potential of their age-diverse workforces.

It was not long ago that scientists started studying knowledge transfer among employees at a different age (Kulik, Ryan, Harper, George, 2014). Initial empirical evidence suggests that knowledge transfer between younger and older employees may be valuable, as it is possible to make use of versatile knowledge of the other person. However, age diversity may also hamper knowledge transfer, since individuals have a natural tendency to prefer interactions with one's peers, with similar characteristics, particularly with reference to socio-demographic features, such as age. Age differences, then, may make communication, cooperation and knowledge transfer more complicated. Consequently, knowledge transfer among employees are diverse in age a difficult process, which must be supported by organizations (Burmeister, van der Heijden, Yang, Deller, 2018). The study would allow providing an answer regarding the degree in which the transfer of knowledge between various age groups mediates between the age-related diversity of employees and the results of the organization. Taken together, we hypothesize:

H2. Knowledge transfer will mediate the relationship between age diversity in the workplace and o organizational performance.

Conclusions

Studies of demographic diversity in teams and organizations, including age diversity, are based on two competing theoretical perspectives suggesting that diversity is a double-edged sword with positive and negative effects on the organization's results (Kunze, Boehm, Bruch, 2011); (Kunze, Boehm, Bruch, 2013). Age diversity creates a pool of complementarity of age-specific knowledge and skills differences, which can contribute to synergies (Horwitz, Horwitz, 2007). In organizations where employees are in the similar age often compete with each other, showing a low level of feasibility of tasks (Cho and Mor Barak 2008), hence the polarization of employees' age may have a negative impact on the organization's results.

According to the information / decision perspective, mixing employees of all ages could therefore stimulate employee creativity, problem solving ability, quality decision making, employee performance, and ultimately have a positive impact on the organization's results. On the other hand, based on the theory of social similarity and categorization, researchers of demographic change argued that age diversity may also entail different references to values that may impede cohesion, social integration and employee collaboration (Carton, Cummings, 2012), ultimately having a negative impact on the organization's results. Given these competing forces, it is not surprising that empirical research on the effects of age diversity is very often fragmentary and ambiguous (Klein and Harrison 2007). For example, Kunze, Boehm and Bruch (2011) reported that age diversity has a negative impact on solid results through emotional involvement. By contrast, according Grund and Westergaard-Nielsen (Grund, Westergård-Nielsen, 2008) this age diversity has an inverted U-shaped relationship with labor productivity. In summary, these ambiguous findings "can be attributed to the neglect of researchers by possible mediators and moderators in the relationship between age diversity and organizational demographics" results (Kunze, Boehm, Bruch, 2011).

Age diversity - referring to age heterogeneity - is to be manifested by differences in knowledge, courage conducive to synergies that increase the company's efficiency. Conversely, age polarization - referring to the division of the workforce into separate homogeneous subgroups - is expected to trigger age-related subgroups of the group, causing negative effects of diversity (e.g., difficult collaboration) that diminish organization's performance. Secondly, taking into consideration recent studies on the diversity of working groups in organizations, e.g. (Carton, Cummings, 2012), (Kunze, Boehm, Bruch, 2011), we argue that the impact of the age composition of the workforce probably depends on the basic context in which people cooperate. That is why we believe transfer of knowledge between employees is so important. Knowledge transfer by may contribute to increasing employee motivation, increasing the ability to transfer and receive knowledge, exchanging knowledge not only individually but in groups for the benefit of a larger number of recipients. There is also rise in creativity and the thinking perspective expands and valuable knowledge is preserved in the company. By determining the factors that mediate or moderate the relationship between age diversity and organizational performance, we are able to reconcile opposite theoretical perspectives and take into account the conclusive results reported in the literature.

Abstract

The role of the education system as a strategic resource for the development of economic and social processes is of particular importance since it is thanks to it that the successful, dynamic sustainable development is largely ensured. The modern period for universities determines the priority tasks of their development, the main emphasis today is not only educational and scientific activities but on improving the principles and methods of management of the processes of integration of educational, scientific and entrepreneurial activities to ensure high quality education, competitiveness of in the market of research and innovative products. The purpose of this study is to analyze the effectiveness of the implementation of the research and entrepreneurial functions of universities on the materials of the Russian system of higher education and develop ways to improve of knowledge spillover efficiency. The effectiveness of the implementation of scientific and entrepreneurial functions of universities in the Russian system of science and higher education was empirically analyzed. The recommendations for the development of project activities of the university through the organization and implementation of group project learning as a tool for developing entrepreneurship activity in science and higher education are discussed. To activate universities in innovation and entrepreneurship, it is necessary not only to conduct research but also to effectively organize the processes of managing the commercialization of university innovations. The algorithm and recommendations for the using of group project training for commercialization of intellectual activity and enhancing of knowledge spillover were present.

Keywords: Innovations, Spillover Effects, Regional Innovation Ecosystem, Higher Education System, University, Group Project Training.

Introduction

Humanity, followed by the economy and the higher education system, is currently undergoing significant changes in the context of the 4th industrial revolution. These trends are changing the path of development of the education systems, determining a number of new features of its functioning. The implementation of the modern post-industrial paradigm of economic development and a knowledge-based economy is possible only on the basis of increasing the efficiency of innovation systems and the intensification of innovative processes of all its actors.

In modern conditions, the role of the education system as a strategic resource for the development of economic and social processes is of particular importance, since it is thanks to it that the successful, dynamic development of science is largely ensured.

The paper discusses the increasing role of entrepreneurial activity of the university in the transformation of the economy, science and education in conditions of modern economy.

The purpose of this study is to analyze the effectiveness of the implementation of innovative and entrepreneurial functions of universities on the data of the Russian system of higher education; to develop ways to improve its efficiency and to offer recommendations for the development of project activities of the university through the organization and implementation of group project learning as a way of developing of entrepreneurial activity in science and higher education.

Theoretical Background

The main vector of the movement of science and education determines the new status of universities as a generator of innovations and facilitator of new knowledge spillover for economic growth and development of the economy and society.

The effectiveness of the innovation process in the university ensures the efficient commercialisation of R&D and the functioning of the regional and national innovation ecosystem. Mechanisms to support and stimulate innovation in the university's innovation ecosystem are important to overcome barriers to the commercialization of innovation.

The literature discusses the transformation of the university's mission in terms of "Mode 1", "Mode 2", "Mode 3" and changes in the university's relationship with society (OECD, 2010; Pruvot, Claeys-Kulik and Estermann, 2015). The researchers identify the following stages of the university model evolution: educational university, research university and entrepreneurial university (Röpke, 1998; Etzkowitz, 2004; Kirby, Guerrero and Urbano, 2011; Gibb, 2013; Goddard, Chatterton, 2002). Today the activities of the university, which can be considered as ways of implementing innovative and entrepreneurial functions are the creation of technology parks, generation of spin-off companies, patenting and licensing, contract research for regional companies, educational courses for business, consulting, participation in grants, publication of academic results, patenting of inventions (Arbo, Benneworth, 2007; Clark, 1998).

Innovative spillover effects from universities in the innovation system contribute to the development and diffusion of new ideas and innovations as facilitators of the indirect transfer of knowledge and significantly affect regional innovation systems (Firsova, 2016; Ogurtsova, 2019). An important mechanism is the mutual influence and coordination of the priorities of regional strategic development and university trajectories and strategies. Therefore, the choice of educational models of the university is important for the directions of development of the region.

One of the models that enhance innovative spillover effects in the region's economy is undoubtedly the model of an entrepreneurial university — the University 4.0 model. This is an open innovation system that implements not only the transfer of knowledge, technology, innovations, but also initiates and commercializes innovations both at the university and outside the university, taking into account the spillover effects of the regional economy.

In these circumstances, the leading role of the university implies a change of its mission: it becomes entrepreneurial — both in education and in management. Entrepreneurial activity in universities is an innovative activity that forms and develops the educational potential of society by conducting activities in accordance with the laws of the market economy. The basic and helper functions of a modern university, which should be implemented by universities in the framework of their entrepreneurial development, presented in fig. 1. (Goryacheva, Burenina, 2016).

Fig. 1: University entrepreneurial functions

The modern period for universities determines the priority tasks of their development, the main emphasis today is not on educational and scientific activities, but on improving the principles and methods of management of the processes of integration of educational, scientific and entrepreneurial activities to ensure high quality education, the competitiveness of universities and regions, and the formation of entrepreneurship abilities of graduates in the market of research and innovative products and services for sustainable regional development.

Materials and Methods

Russian educational system play a significant role in producing innovation and transfer technology. There were 830 universities in 84 Russian regions, 4.4 million students were enrolled in higher education programs and 260 thousand teachers worked in the Russian Federation in 2018 (Rosstat, 2019). Because of the scale and strategic importance of higher education, assessing the role of universities in the knowledge spillovers and innovations transfer are of high relevance.

The development of entrepreneurship in the form of small innovative enterprises is a relatively new direction for the infrastructure of the education and science system in Russia. Only since 2009 university has the opportunity to become founders of economic societies and partnerships in the form of small innovative enterprises, whose activities consisted in the practical implementation of the results of intellectual activity. Within this form, it is possible to observe mutually beneficial cooperation of higher education institutions and economic society. Despite the existing different institutional preferences since 2013, the slowdown in the development of small innovative enterprises with the participation of universities has been observed since 2015 (Fig. 2).

Fig. 2: Quarterly dynamics of creation of economic partnerships by scientific and educational organizations of higher education, 2009-2019, unit (Ministry of education RF, 2019)

Against the background of the decrease in innovation activity in the creation of small innovative enterprises with the participation of universities, it should be noted that universities, having a real opportunity to commercialize the results of intellectual activity obtained in the course of R&D, did not fully take advantage of these opportunities. The transformation of these results into knowledge-intensive competitive goods and services has not yet taken place (Fig. 3).

Fig. 3: Share of small innovative enterprises of universities in innovation, % (Ministry of education RF, 2019)

At the same time, it is important to note the uneven development of small innovative enterprises with the participation of universities in the regions and federal districts (Fig. 4).

Fig. 4: Development of small universities' innovative enterprises by the Federal districts, % (Ministry of education RF, 2018)

%

More than a quarter of the established enterprises are located in the Central Federal district, together with the Siberian Federal district they give half of the total number of small innovative enterprises. Minimum indicators are recorded in the North Caucasus, Far East, and Southern Federal districts. The specificity of the location of enterprises is explained not only by the high concentration of university and scientific potential in these regions but also by the level of development of the market of consumption of innovative products and reduce the effective demand for the results of scientific and technical activities.

High concentration in the central regions of scientific and research activity inhibits the R&R results diffusion and knowledge spillover. Only a balanced structure for the spatial placement of universities as innovation centers throughout the country can enhance the flow of knowledge and diffusion of technologies and ensure the effective functioning of the national innovation system. For this, special state measures are needed to equalize the socio-economic conditions and the financing of universities throughout Russia.

Results

The needs of innovative development of the economy make relevant the research processes of transformation of universities.

The success of this activity depends on many factors, drawing an analogy with a commercial company, the university has its own staff, which should be cohesive and coordinated to work for the best results. So it is important to develop a corporate entrepreneurial spirit and university culture and to earn money to invest in the development of innovation infrastructure.

Education programs at most universities do not include entrepreneurship courses. Sometimes they are replaced by student meetings in well-known businessmen and entrepreneurs with succes stories in the region.

In order to develop the entrepreneurial functions of universities as part of the processes and changes at the university, great importance is given to introducing new educational technologies into the educational process and creating a creative space.

One of the initiatives aimed at developing entrepreneurial activity is the use of group project teaching methods in university training, which is implemented in the form of project work in teams formed from students of different areas of study on certain scientific ideas.

The effective use of group project training should be integrated into the scientific and educational activities of the university.

To activate universities in innovation and entrepreneurship, it is necessary not only to conduct research but also to effectively organize the processes of managing the commercialization of university innovations.

One of the priority initiatives for the development of entrepreneurship in the main functions of the university is the introduction of group project training and the use of the methods of project management R&D, integrated into the scientific and innovative activities of the university in the practice of organization of entrepreneurial and innovative activities.

But as practical experience shows, the university administration system, employees are often not prepared to accept such modern forms and methods (Roberts, Wallace, 2002). This greatly complicates such processes at the university, and the restructuring of perception takes a long time. Staff are slowly adapting to the new environment, and as a result, time is lost that could have been used more efficiently.

The technology of group project training also allows to include in the educational process the business community, which, on the one hand, is the main interested party in determining the goals and results of training at the university, and, on the other hand, a potential customer of the results of group project training.

The introduction of group project management techniques provides universities with a complete innovation cycle from the creation of new knowledge to their commercial implementation in the core market. New knowledge obtained in the course of fundamental and exploratory research is further implemented within the stages of a complete innovation cycle along various trajectories.

The formation of a new contour of the organizational structure of the modern university is aimed at creating infrastructure conditions for the development of entrepreneurial activity of the university, attracting students and employees to innovative activities, establishing partnerships with employers, representatives of the financial community, business and commercialization of the results of innovative activity of the university.

The achievement of the goals sets the task of corresponding changes in their organizational structures using group project training (GPT) (Fig. 5).

Fig. 5: Outline of the organizational structure of the university

Here we present recommendations on university R&D commercialization model thorough the use of group project training. The organizational component of the implementation of group project training methods is characterized by a clear hierarchy, from the university administration to teachers and students in the implementation of the adaptive competence approach. Responsible persons are identified for each stage of the group project training process. Projects are initiated by university staff or structural units. Research teams and researchers, in turn, hold a project competition, which selects promising projects. The best projects are presented for participation in competitions for grants and continuation of work on the project in university small innovative enterprises.

One of the two models of its implementation, according to which the work is built within the projects, can be used as the basis for the design. The first model is group project training aimed at obtaining research results within the framework of solving individual subtasks of large research projects of the university. The result of the work of the project team is integrated into the overall research system of the entrepreneurial university.

Such a model of group project training is applicable in the presence of a bank of research projects that require improvements. It is also worth noting that the reverse process is also possible, when the group project training becomes a platform for solving small tasks at the initial stage, which can later develop into a full-fledged research work.

The group project training can also be represented by the second model, in which the implementation of the project is considered as an integral independent process of achieving the final result. Such projects are initiated for further commercialization and reflect the entire chain of product creation: from idea generation to its commercialization.

This model of group project training is more related to the entrepreneurial tasks of the university and is focused more on obtaining a specific product, service, technology or methodology than on the educational process.

When implementing the project under the second model, educational goals are pursued only in the absence of the necessary competencies of the project participants. The result of such a project can be evaluated in terms of the possibility of creating companies at the university.

The implementation of the group project training under the second model contributes to the development of an integrated business culture. The ideological field created at the university allows to develop practical initiatives with the business community, thus the entrepreneurial culture becomes an important distinctive feature of improving the individualization of the university.

Group project training will allow university projects to grow into new companies that can become successful market participants in the future. Successful projects of group project training will face the task of commercialization, as in the process of commercialization there is a possibility to choose different ways of bringing innovations to the market.

We present an algorithm for commercialization of intellectual activity results (Fig. 6).

Fig. 6: Algorithm for organization of R&D activity results implementation

Discussions

Implementation of this process begins with the selection of successful group project training projects, after which there is a search for stakeholders and customers who may be interested in the results of this activity. The presence of the customer allows implementing the first way of commercialization of innovation by granting the right to use the result in the form of a license. In case of a positive decision, the following actions will be performed: determining the form of transfer of the right to use (license), determining the term of transfer of the license, the territory of action, the type of payment (lump-sum payment or royalty).

The next stage is the conclusion of a license agreement between the university and the customer. If the customer is not ready to acquire the right to use in the form of a license, it is possible to commercialize the innovation in the form of the sale of the exclusive right to R&D. In the case of a positive decision, determined by the cost of the sale of R&D, an agreement on the alienation of the exclusive right to R&D.

This model of commercialization of university's R&D is the most successful and relevant for a number of reasons:

- does not require significant financial investments in technology development;
- has a simple form of transfer of intellectual development to the market, does not require scientific and technical support of the project;
- save time for the university and the developer to transfer the development to the market.

In the event that the customer does not intend to acquire the rights to the result of intellectual activity, it is possible to commercialize the R&D in the form of a contract for carrying out custom research works.

This way is expedient if the use of R&D is periodic; if the acquisition of rights requires high costs of commercialization; there are no specialists in the enterprise who are able to competently manage R&D, etc.

To implement the model of commercialization of R&D by carrying out custom research work between the university (as a contractor) and the organization (as a customer) is a contract for research work, according to which, the university will subsequently make a profit.

If the customer is not interested in acquiring the rights to R&D, it is advisable to commercialize R&D in the form of creating a small innovative enterprise at the university. This way of commercialization is most common. But it should be noted that the commercialization of the results of intellectual activity of the university in the form of small innovative enterprises has a more complex algorithm.

In order for the results of intellectual activity in the development of small innovative enterprises to be considered as a key driver of the company, it is necessary to introduce new methods and approaches to the management of the company. To do this, the following measures can be used:

- development of new markets, including foreign ones, for the sale of own products;
- search and attraction of investors, including foreign sources;
- submission of applications to venture funds to attract venture investments;
- participation in state, regional, municipal competitions, grants on the terms of public-private co-financing;
- use of the results of intellectual activity as an intangible asset.
- international cooperation.

Thus, the developed algorithm allows to determine the most significant stages of the process of commercialization of the results of intellectual activity obtained within the framework of group project training and thus to identify the most effective way of commercialization of the university's R&D.

Conclusions

The formation of the university as an entrepreneurial center of innovative economy is a complex task and is aimed at the development of modern standards of management, research and entrepreneurship. Enhancing the influence of the university spillovers on technology transfer and regional economic development is possible only in the creation of an effective university's entrepreneurial management. The formulation of the university in the centre of the economy requires a redefinition of its role, alterations in relationships, and therefore targeted efforts to change the rules of the management and teaching staff.

The consolidation of the norms of activity and ethical principles corresponding to the new role of the university allows the implementation of the code of corporate entrepreneurial culture. The code is now an emerging institution and an element of new governance. The maturity of this institution will be determined by its influence on the development of a new role by the university — the subject of economic development. Technologies of practice-oriented and project-organized training play the role of a component of training specialists for high-tech sectors of the economy.

The development of entrepreneurial activity of the university, the introduction of group project training, improving the organization of university management and the development of the code of corporate entrepreneurial culture are aimed at the functioning of the university as a center of innovative economy and strengthening of R&D commercialisation and enhancing the knowledge spillover and innovation diffusion and increasing of effectiveness of national innovation system.

Abstract

Relocating electrical facilities underground, makes planners should pay attention to several other factors, namely the design and aesthetics of underground buildings and their effects on the people who work in them. Thermal, audial, and visual comfort, influence the building design. Otherwise, there were only recent study that design and its accompanying physical symbols been considered as an upcoming factor to increase the employees' motivation. This study holds a questionnaire survey that was applied to explore how the employees conceive their comfort perception about working in the above-ground Gas Insulated Substation (GIS) and the possibility if they are placed in the underground GIS. In quantitative analysis, data from the questionnaire were analyzed by statistical assessment using SPSS software. The regression analyzes that the hypothesis "motivation of working in underground space is affected by the working comfort" is accepted. Using correlation and regression analysis as described in the result section, the most influential factor to increase motivation is thermal comfort. This study supports previous study where workspace design correlates to the organizational culture. The results show that motivation of working in underground space is affected by the working comfort. That is why thermal comfort is the most important factor for this research

Keywords: Management; Comfort; Motivation; Underground

Background

Plans to relocate electrical facilities underground, like Gas Insulated Substation (GIS) makes planners should pay attention to several other factors, namely the design and aesthetics of underground buildings and their effects on the people who work in them. A comfortable work environment creates emotional factors, motivation, and closeness of workers with the company (Soh, *et al*., 2016). Workspace design is used as physical settings in the work environment. It can be a tool to achieve higher organizational performance via changes in employee behaviour and work efficiency (Danielsson & Bodin, 2008). Workspace design is also an effective strategy for performing organizational alteration (McElroy & Morrow, 2010) This study contributes to how to improve employees' performance using thework company's physical attributes. Previous research, ranging from psychology, environment, architectural, to management, have provided a conclusion that physical attributes affect human's view, manner, and behaviours (Danielsson & Bodin, 2008; Kornberger & Clegg, 2004; Brennan, Chugh, & Kline, 2002; Cohen, 1980). The workspace environment can also influence employees' interpersonal interactions and knowledge availability (Samani, 2015). Otherwise, there were only recently study that design and its accompanying physical symbols been considered as an upcoming factor to increase the employees' motivation (Worley & Lawler III, 2006; O'Reilly & Pfeffer, 2000; Turner & Myerson, 1998).

The multidisciplinary concept is needed to explain human interaction with the physical building of its workspace (D'Oca, Chen, Hong, & Belafi, 2017). Building comfort is influenced by thermal, audial and visual comfort (Satwiko, 2009). Sakellaris, *et al*. (2016) then explain some of the parameters that affect the perception of work comfort, as described in Table 1.

Table 1: Perception Parameter of Working Comfort

No	Parameter	Indicator	Criteria
1	Thermal Comfort	Air circulation	Very disappointing – Very Satisfying
		Air Quality	Very moist – very dry
2	Audial Comfort	Noise from outside	Very disagree – very agree
		Noise from building system (heater system, plumbing, etc)	Very disagree – very agree
		Noise from the building inside (co-worker, photocopy machine, etc)	Very disagree – very agree
		Privacy	Very disagree – very agree
3	Visual Comfort	Natural light	Very disagree – very agree
		Artificial light	Very disagree – very agree
		Reflection	Very disagree – very agree
		Cleanliness	Very disagree – very agree
		Layout & decoration	Very disagree – very agree

(*Source: Sakellaris, et al., 2016*)

Many environmental factors are associated with perceptions of working in the underground space, such as air quality, noise, lighting, and thermal comfort (Soh, Christopoulos, Roberts, & Lee, 2016). These effects can be overcome by engineering a building, but there are still some aspects in the underground space that are reduced and cannot be made to resemble workspace on the surface, namely (Zhao & Künzli, 2016):

a. Above-ground visibility
b. Above-ground access
c. Visual contact to nature
d. Space inter-connection

Labbé (2016) suggests that design considerations should be given to the purpose of underground space to create large communal relationships and connections between workspaces that can influence the perception of working underground. This is in line with the opinion of D'Oca, Corgnati, Pisello, & Hong, (2014) which states that the condition of comfort is not only related to the physical building and environmental parameters, but also social aspects that reflect the beliefs, values, expectations, and motivations of building occupants. The lack of windows and ventilation affects on increasing productivity and decision making in the context of workspace design (Kaplan & Berman, 2010). Underground GIS development can also utilize online monitoring systems and system resilience analysis, which can evaluate the temperature of each GIS equipment and maintain the required temperature, thus bringing convenience to Underground GIS workers (Wang.T, Wang, Wang, & Zhang, 2018).

Methods

Survey

A questionnaire survey was applied to explore how the employees conceive their comfort perception about working in the above-ground GIS and the possibility if they are placed in the underground GIS.

The survey also investigated the correlation between the behavior and the perception of working in the underground GIS

Methodology

Data used in this research gathered from a manual survey. The questionnaire was prepared using a manual questionnaire then distributed to the 41 respondents. The form began with the introductory paragraph described this research's background and aims. Personal information of the respondent will be asked in the next page. Respondents have to fill their name, position, and work period at this position before continuing the next step of the questionnaire.

The next pages are the main part of this survey. Three variables were captured perception about working comfort management. One variable was captured behavior in working either they are above-ground and underground. Each variable contains some questions to indicate respondents' level agreement using a five-point Likert scale. In quantitative analysis, data from the questionnaire was analyzed by statistical assessment using SPSS software.

Results and Discussions

General Figures

After questionnaires were gathered, as Figure 1.a, 56 percent were supervisor, 12 percent were staff senior, and 12 percent were junior staff. Most of them, as described as Figure 1.b, have been worked for this company for more than 10 years (54%).

Fig. 1: Respondents information

Working comfort perception and motivation when working in underground space

The percentage of each question of the thermal comfort parameter in this study was described in Fig. 2. From those diagrams, it can be illustrated that most employees working in the above-ground workspace felt satisfied with their workspace thermal system (46%) and they did not feel any complaint with the air quality (49%).

Table 3 described that most of the empbuilding loyees did not feel auditory distracted either from outside (36.59%) or building system (36.59%) source. On the other side, they still had a noisy condition due to their office mate or the other office equipment like a photocopy machine.

Table 2 concluded that most employees felt satisfied with their above-ground visual condition, and they expected that it is the most important factor to be considered when they work in underground space. It was also described that most of the employees (90.24%) still have motivation and confidence to meet their target when they work in underground space

Fig. 2: Thermal comfort perception

Table 2: Visual comfort perception

	I have enough natural lighting	I have sufficient lighting	I do not feel distracted to light reflection	I feel satisfied with the workspace cleanliness	If working in underground space, I feel that lighting, decoration, and space layout are a very important factor
Strongly Disagree	2.44%	0.00%	2.44%	2.44%	0.00%
Disagree	19.51%	9.76%	12.20%	21.95%	2.44%
Neutral	17.07%	12.20%	14.63%	24.39%	12.20%
Agree	51.22%	65.85%	60.98%	39.02%	26.83%
Strongly Agree	9.76%	12.20%	9.76%	12.20%	58.54%
Total	100%	100%	100%	100%	100%

Table 3: Audial comfort perception and motivation while working in underground space

	I have auditory distracted from outside	I have auditory distracted from the building system (plumbing, heater system)	I have a noisy workspace (office mate, photocopy machine)	When working in underground space, I still have motivation and confidence to finish my target
Strongly Disagree	4.88%	0.00%	0.00%	0.00%
Disagree	36.59%	36.59%	34.15%	0.00%
Neutral	24.39%	31.71%	24.39%	9.76%
Agree	26.83%	29.27%	41.46%	70.73%
Strongly Agree	7.32%	2.44%	0.00%	19.51%
Total	100%	100%	100%	100%

Table 4: Correlation between variables

	Thermal Comfort	Audial Comfort	Visual Comfort
Motivation	-.116	.015	-.075

Table 5 : Regression result

	Constanta	Thermal Comfort	Audial Comfort	Visual Comfort	Thermal Comfort
Motivation	4.701	-.116	.015	-.075	-.116

Regression Analysis

Regression then analyzed to find correlation using SPSS. Table 4 summarized the correlation among the variables. Meeting space had the largest correlation number with organizational culture and overall job fulfillment, while distraction had the smallest one.

The regression result as informed in Table 5 measured all the variables. All sig values from that regression analyses were above .05, therefore the hypothesis "motivation of working in underground space is affected by the working comfort" is accepted.

Discussion

Using correlation and regression analysis as described in the result section, the most influential factor to increase motivation is thermal comfort. Once the workers do not feel the comfortable feelings to their thermal situation, they will not gain the optimum condition to finish their job. It is important to consider the scope of work that influences employees' characteristics in their daily job. The employees who have been a sample of this study used to work in electrical facilities. Moreover, the findings of this research can implicate senior managers to develop employee's performance by giving attention to the physical environment. The same thing with the conclusion from Kwon, Remøy, & van den Bogaard (2019), the findings of this research also influence interior designers or architects to understand how design correlates to employees' satisfaction. They can find which alternative design that relates to a user's view of the workspace.

Conclusion

This research was conducted based on the correlation between comfort attributes and motivation. Relates to the previous research, physical attributes in a workspace can assist in employee and company's competitive benefits. This study supports the previous study where workspace design correlates to the organizational culture. The results show that the motivation of working in underground space is affected by working comfort. That is why thermal comfort is the most important factor for this research. This study can be applied to map the employees' preference for the optimal working comfort that potentially increases their motivation. By collaborating core business with preferred workspace design in the company, it will be easily set the target for employees to achieve the company's goal.

Abstract

The most important task in the current economic situation in Russia is GPD doubling. Taking into consideration the priorities in the development of the world community in the third millennium provided in the UN reports on poverty reduction, environment enhancement, sustainable development, etc., the objective should be focused on sustainable social and economic development. In this regard, the quantitative measurement of the sustainability of the development, the balance of quantitative and qualitative factors of the economic growth are of immediate interest. The authors analyzed the current ecological and economic security of Russia, assessed the ecological and economic situation, studied threats to the ecological and economic security of the Russian Federation, analyzed the introduction of environmental indices into the system of the assessment of the socio-economic development and economic security of the Russian Federation. Some proposals were worked out to increase the level of environmental and economic security by improving the mechanisms of environmental and economic incentives, as well as the management system of environmental and economic development. The process of creating an ecopolis as a model of sustainable ecological and economic development of an area was studied.

Keywords: Sustainable Development, Eco-Economic Security, Social and Economic Development, Indices, Hazards, Eco-Economic Incentives, Ecopolis.

Introduction

The growth of global threats to the civilization along with the progress of the modern society, instability and increasing diversity of economic, social and environmental components of the development urgently require the development of a national security strategy that would combine political, economic, defense and other needs of the country with the requirements of comprehensive environmental recovery (J. Burger, 2008). In this regard, the concept of the national security of the Russian Federation provides for the transition to sustainable development, ensuring a balanced solution of both socio-economic problems and the problems of environmental conservation in order to meet the needs of the current and future generations as an important condition for national interests ensuring (V.I. Danilov-Danil'jan, 2006).

At the end of the twentieth century, it became clear that the contradictions between the development of the economy, the growth of material needs and the limited capabilities of the biosphere threaten the sustainable development of the civilization. Increasing environmental problems indicate the impasse in the development of traditional economic models. The world is aware of the need to develop new approaches to measuring and assessing scientific and technological progress and development of economic systems, since the concept of GDP does not reflect the sustainable development goals in accordance with the provisions of UN documents and requires significant

adjustments. Nowadays, considerable experience has been gained in the development and application of sustainable development indices (L. Segnestam, 2000).

In our opinion, the integral index of adjusted net savings of the World Bank is the most developed one in theoretical terms, having a good statistical base and calculation capabilities. Currently, adjusted net savings are calculated for more than 100 countries, including Russia (World Development Indicators 2015, 2016).

Results and Discussion

Analyzing the ecological and economic state of the Russian Federation it should be noted that for the implementation of long-term tasks of socio-economic development, the primary objectives should be the development of human capital assets, the rejection of export energy-source development and the formation of an innovative economy based on structural and technological reorganization (The strategy of ecological safety of the Russian Federation until 2025, 2017). This means a different logic of the development and measurement of the socio-economic progress. It is not necessary to strive to maximize traditional quantitative indices, whether they are cost indicators (GDP, etc.) or physical volumes of production (energy resources, etc.). The new economy should focus on qualitative rather than quantitative development. Let us consider the values of indices of such sustainable development presented in Table 1, where Russian indices are compared with those of some developed countries, Eastern Europe, BRICS and CIS countries.

Table 1: Indices of sustainability in some countries

Country	Adjusted net savings (% of GNI)	Human development index	Proportion of fossil fuel (% of the total volume)	Proportion of renewable energy sources (% of total volume)	Carbon dioxide emission per capita (t)	Natural recourses depletion (% of GNI)	Forest zone (% of the area)	General satisfaction with life (0-10)
1	2	3	4	5	6	7	8	9
Norway	12.800	0.943	58.6	45.3	10.5	10.6	32.4	7.6
Australia	1.700	0.929	94.6	5.4	19.0	5.1	19.7	7.5
The Netherlands	11.600	0.910	92.5	4.4	10.5	0.8	10.8	7.5
Canada	5.800	0.908	74.9	17.0	16.4	2.3	34.1	7.7
Germany	11.400	0.905	80.1	8.9	9.6	0.1	31.8	6.7
France	7.000	0.884	51.0	7.6	6.1	0.0	29.0	6.8
The Check Republic	11.300	0.865	81.2	5.4	11.3	0.3	34.3	6.2
Great Britain	2.200	0.863	90.2	2.8	8.5	1.2	11.8	7.0
Poland	9.700	0.813	93.8	6.3	8.3	1.0	30.5	5.8
Belarus	16.900	0.756	92.1	5.5	6.5	0.9	42.2	5.5
Russia	-0.800	0.755	90.9	3.0	12.1	14.5	49.4	5.4
Kazakhstan	-1.200	0.745	98.8	1.1	15.3	22.0	1.2	5.5
Ukraine	5.600	0.729	81.8	1.4	7.0	3.8	16.7	5.1
Brazil	4.600	0.718	52.6	44.5	2.1	3.1	61.9	6.8
China	39.700	0.687	86.9	12.3	5.2	3.1	21.6	4.7
India	24.100	0.547	71.1	28.1	1.5	4.2	22.9	5.0

Source: Human Development Report 2012. Sustainability and Equity: A Better Future for All. N.Y.: Palgrave Macmillan. UNDP, NY, 2014

The analysis of the values of the human development index shows that the leading place in the ranking of countries according to this index belongs to Norway, while Russia occupies a lower position in the ranking even compared to Belarus. With a higher level of education and income per capita than those in Belarus, Russia occupies a lower position in the ranking due to the lag in the life expectancy along with the increasing longevity in the vast majority of the countries.

The analysis of the adjusted net savings index shows that in Russia, along with the formal economic growth, natural capital is depleted, and the environmental correction leads to a significant decrease in traditional economic indices, down to negative values. In practical terms, the index shows the need for a radical improvement of the resource efficiency in the country (I. Kirilchuk et al., 2018).

The analysis of the ecological and economic situation in Russia, the policy in the field of nature management and environmental protection, mechanisms of controlling and ensuring the eco-efficiency of the economic activity revealed a number of problem areas that pose a threat to further sustainable development of the country. The systematized economic, environmental and social hazards are presented in Figure 1.

In order to ensure an appropriate assessment of the country's development achievements and its compliance with the principles of sustainable development, the system of macroeconomic accounting in the Russian Federation should be supplemented with the indices of environmental development (System of Environmental-Economic Accounting). It is proposed to include the following indicators (Table 2) in the official statistics to monitor the country's environmental achievements.

Fig. 1: Hazards in an eco-economic security system

In order to ensure an appropriate assessment of the country's development achievements and its compliance with the principles of sustainable development, the system of macroeconomic accounting in the Russian Federation should be supplemented with the indices of environmental development (System of Environmental-Economic Accounting). It is proposed to include the following indicators (Table 2) in the official statistics to monitor the country's environmental achievements.

Table 2: Ecological criteria of economic security and their threshold values

Indicator	Threshold values	Actual sate
Genuine savings, as % of GNI	0	-0.8
Proportion of renewable energy sources, %	10	0.5
GDP energy intensity, toe/$1000. at PPP	0.2	0.47
Mean utilization of wastes as secondary raw materials, %	75	30
Processing MSW, %	50	5
Volume of greenhouse gas emissions, % over the level of 1990.	100	70
Ecological footprint, gha/man	2.1	3.7

Source: prepared by the author on the basis of Federal State Statistics Service data

The comparison of the actual indices and threshold values shows an unfavorable situation. Only in terms of one index — greenhouse gas emissions — Russia is in the field of positive values. The introduction of this system of threshold indices will allow us to take into account the environmental component of the national security, to determine the level of sustainability, development of the socio-economic system in the long term. The results of various studies conducted in the EU showed that the overall macroeconomic effect of the introduction of more stringent environmental policy had no negative impact on the process of economic development expressed in GDP growth. Improvement of the mechanisms of encouragement of greening the economy contributes to innovation development, emergence of new markets of eco-products and eco-technologies (P. A. Lawn, 2003).

The ways of improvement of mechanisms of ecological and economic incentives are presented in Table 3.

Table 3: The ways of improvement of mechanisms of ecological and economic incentives

Mechanism	Development trend
IMPROVEMENT OF THE EXISTING MECHANISMS	
Ecology payments	Short-term prospects: a significant increase of the amount of ecology payments in order to assign a regulatory incentive function to them. Introduction of ecology payments for noise emission. Long-term prospects: transition to a system of licenses for emissions and creation of emission market after initial pilot project testing
Taxation	Abatement of profit tax for ecoproducts manufacturers. Reduction of VTA rate for ecoproducts. Increase of VTA rate for not environment-friendly production.
Depreciation mechanism	Introduction of accelerated depreciation of basic assets enabling the transition of an enterprise to the use of the best appropriate technology.
Government-sponsored programs	Expansion of the program of ecological development, e.g. “Power industry development based on renewable sources”, “Development of projects and creation of ecopolises”, “Development and productization of ecotechnologies”, “Ecologization of consumer culture” including some similar regional programs.
INTRODUCTION OF NEW MECHANISMS	
Tariff regulation	Introduction of fixed rates covering the expenses of power producers for a guaranteed time/amount of electric power generated applying RES. The size of subsidies on electric power depends on the renewable energy source and plant capacity
Eco-economic interregional compensatory mechanism	Inter-budget transfers based on the balance of ecosystem services and negative region’s economic impact

Conclusion

In our opinion, the development of projects and the creation of ecopolises as the objects of territorial sustainable ecological and economic development is of particular interest. Differences between ecopolises and settlements of industrial type are presented in Table 4.

Table 4: Difference between ecopolises and industrial settlements

Criterion	Industrial settlement	Ecopolis
Power generation	Centralized power generation on the basis of hydrocarbon resources (cogeneration units)	Small stand-alone generation based on the renewable and inexhaustible resources (mini hydroelectric plants, solar batteries, biodiesel and biogas plants, wind tribunes, geothermal power stations, use of biomass energy and others)
Construction	Concrete high-rise buildings with low energy efficiency. Wide use of plastics and other artificial materials.	Houses are built taking into account modern, cost efficient, energy-saving technologies. These can be quick-erect houses, using technologies of environment-friendly individual housing construction (TICE), houses of thatch blocks, etc. Local naturally-occurring materials are prevalent.
Waste management	Waste collection in special skips and further landfilling. Use of waste burning plants.	Waste recycling. All waste is first sorted by the residents, then it is sent to different places as intended. Waste effluents are recycled into fertilizers and biogas.
Water supply	Centralized water supply, chlorine treatment.	Well or artesian drinking water. The use of biotechnology in water purification. Collection of rainwater and its use for technical needs
Employment	The majority of population are employers in big companies, working 8 hours a day, concentrated in offices.	An ecopolis necessarily includes at least one or several business projects. Some citizens are employed in local production. Some work remotely via the Internet, the others are engaged in their own business projects in the city. People do not have to pay for an apartment, for light, for garbage disposal, most of the products they produce on their own. Therefore, they can afford to work 5-6 hours a day.
Transport	Gas-powered transport (traffic jams due to high population concentration)	Biofuel transport, electric cars, bicycles (low congestion of the transport system due to the low population density and reduced traffic intensity due to the increased use of communication technologies)

An ecopolis should combine interrelated components of economic, environmental, social and institutional environment. The implementation of an ecopolis model in Russia is possible on the basis of the creation of special ecological zones, as one of the types of economic zones with a special economic policy and financial support for the creation of an eco-oriented infrastructure. At the core of such settlements, there should be a number of innovative environmental business projects, construction and architecture technologies, and the involvement of people who share the value of environmental development. The state should provide support for purchasing housing in ecopolises

(long-term government loans with a low interest rate) in return for the obligations of the residents to comply with the requirements of the ecological behaviour.

The creation of ecopolises will have a significant impact on solving the following problems:

1. solution of the housing issue;
2. improvement of the ecological environment;
3. development of small businesses;
4. intensification of innovative activities;
5. development of unoccupied territories;
6. improving the demographic situation;
7. improving the quality of life of the population.

It can be argued that the creation of a healthy, environment - friendly space of a human activity is a sustainable way of development, making it possible to achieve the goal of harmonization of the economy, community and ecology.

Acknowlegements

This work was carried out according to a research grant of the President of the Russian Federation MK-941.2019.5 for the support of young Russian scientists.

Abstract

The growing Industry 4.0 concept requires to introduce modern technologies and also change industrial management. The aim of the article is to present the new business model Canvas which includes identified needed changes in industrial management resulting from the implementation of the Industry 4.0 strategy. This model allows the Industry 4.0 strategy in manufacturing companies to be effectively implemented. Furthermore, it helps to gain competitive advantage on the market through a great increase in flexibility and efficiency and quickly produce personalized products using advanced technologies, wireless networks and mobile devices.

Keywords: Industrial Management, Business Model Canvas, Industry 4.0 Strategy, Internet of Things

Introduction

The Industry 4.0 concept is to combine physical objects with the information network and forms the basis of the Fourth Industrial Revolution. It plans to set up sophisticated business networks linked by intelligent resources that communicate by the Internet. This means that today's businesses face the next challenge of building and collaborating on cyber-physical systems. The fourth industrial revolution is a big challenge for industrial enterprises. First of all, it means integrating people with digitally controlled machines using the Internet and information technologies and creating extensive networks - Internet of Things, Connected Things and Cloud Computing (Clark, 2016; Bruner, 2013; Wyrwicka et al., 2017; Jakubowski et al., 2016).

As a result of the Industry 4.0 concept implementation, the economic production of personalized products in short production series is developing, which gives the possibility of previously unknown flexibility in adapting to the expectations of customers and the possibility of achieving a significant competitive advantage. New market expectations necessitate many changes in manufacturing companies. They mainly concern much greater automation, the use of modern IT systems and the introduction of new paradigms in management of a production company. Modern Factories of the Future require changes in the employment structure. As the experience of the model plant implementing the Industry 4.0 concept - Robert Bosch GmbH shows - the number of employed planners, constructors and managers with higher education increases (up to 23%) as well as highly qualified employees, technical managers and technicians (up to 42%) (Krzyżanowski, 2017). Manufacturing processes must be standardized. A network infrastructure is created in which data from machines, devices and production processes are obtained in real time and used in machine control systems, entire production lines not only in a given plant, but also in dispersed plants around the world (Soldaty, 2016).

Changes also appear in the company's strategy. The pace of plants in the fourth industrial evolution causes the need to very quickly determine the strategic goals of plants and equally fast their implementation. A productivity plays a big role in companies using the Industry 4.0 concept. Key Performance Indicators (KPIs) should increase, such as (Parmenter, 2015; Soldaty, 2016):

- productivity,
- reduction of machine downtime,
- reduction of warehouse costs,
- shortening the time to launch a new product on the market.

The Industry 4.0 concept means the purchase of many systems to support flexible production processes and their integration with applications that allow quickly place orders for many personalized products and comprehensive customer service. The introduction of new technologies is expensive and requires well-qualified human resources, but enables a rapid increase in production efficiency and better management of both processes and the resources. It enables improving quality and significantly shortening the time of implemented production and logistics processes, as well as high quality customer service. New solutions must bring a quick return on investment and a rapid increase in efficiency, which requires constant monitoring and control of processes implemented in the company (Jasiulewicz-Kaczmarek et al., 2019). The introduction of Industry 4.0 strategy means not only major technological and technical changes in enterprises, but also requires changes in industrial management. Therefore, there is a need to develop new industrial management solutions dedicated to the Industry 4.0 environment and completely new business models (Moeuf et al., 2017; Piccarozzi et al., 2018; Jiménez-Zarco et al., 2017; Lu Y., 2017).

The paper presents the results of research on changes in industrial management resulting from the implementation of the Industry 4.0 strategy. The aim of the article is to present the new business model Canvas which includes identified needed changes in industrial management resulting from the implementation of the Industry 4.0 strategy. This model helps to gain competitive advantage on the market through a great increase in flexibility and efficiency and quickly produce personalized products using advanced technologies of the Industry 4.0, wireless networks and mobile devices.

Advances Technologies of the Industry 4.0 Concept

The Industry 4.0 concept is based on 9 advanced technologies. The most important solutions of this concept are: Big Data and Analytics, autonomous robots, simulation, Internet of Things (IoT), Cyber Security, Cloud Computing, additive manufacturing, augment reality horizontal and vertical system integration (Want et al., 2015). The Cyber-Physical Systems (CPS), machine-to-machine components, autonomous vehicles, nanotechnologies, biotechnologies, energy storage and quantum are also a key to ensure the degree of connectivity and communication during the Industry 4.0 development (Almada-Lobo, 2016; Wang et al., 2015; Grzybowska et al., 2016). All efforts are provision for connectivity, communication, networked entities, real-time data and pervasive information throughout the entire value chains to achieve full automation, digitalization, and intelligent manufacturing environment. Manufacturing companies must construct a connection network fulfill with 3 features which are vertical integration (intra-organization systems integration), horizontal integration (inter-organization systems integration) and end-to-end digital integration of engineering to achieve the above results (Bauernhansl et al., 2014).

Internet of Things is to ensure trouble-free communication between devices and communication with people thanks to the use of a large number of intelligent sensors and controllers. For enterprises, flexibility and the possibility of a wide use of devices connected to the IoT network are particularly valuable, and consequently shortening costly downtime, increasing the efficiency of operations and reducing production costs. Big Data technology allows analyzing large amounts of data and providing end users with the needed, properly selected data in real time. Large data sets are converted into useful information. Cloud Computing allows data from around the world to be collected and accessed. The use of these technologies also allows the detection and resolution of problems related to the wear of machines and optimization of the use of manufacturing resources (Rußmann, 2015; Kagermann et al., 2013; Stock & Seliger, 2016). The growing Industry 4.0 concept requires not only the introduction of many very modern technologies, but also the use of a new business model in management of a production company. Network forms of cooperation are developing, in which many small and medium production and logistics companies (SMEs) jointly produce and deliver personalized products to the customer (Saniuk et al., 2019).

The increase in production flexibility and organization of production of more personalized products means the ability to meet the needs of the customer which is the user of the product without detriment to the profitability of the production process by dynamically aligning the autonomous modules of the entire process of preparing, producing and delivering the product to the customer using Internet of Things and information stored in Big Data and Cloud Computing (Lasi et al., 2014; Roblek et al., 2016). In addition, it is possible to significantly improve production efficiency through the use of material, manufacturing, labor resources of network partners working together with unused production capacities (Thoben, et al., 2017).

Industrial Management within New Manufacturing Paradigms

The main production paradigm in the Industry 4.0 environment, which is currently developing, is personalized production, which consists in creating own product configuration by customers from modules pre-designed by the manufacturer, and only then production. Manufacturing systems must be reconfigurable. The client becomes an active participant in product design, which completely distinguishes this paradigm from mass customization, where the client chose the configuration from the catalog of proposed options. In the fourth industrial revolution, intelligent products configure production systems using advance technologies and determine the locations of implementation of individual stages of manufacture based on the customer's location. Personalization also applies to the operational phase thanks to the possibility of individual product monitoring (Schlechtendahl et al., 2015).

Another paradigm is the change from centralized production to decentralized. The decentralization paradigm means a departure from centralized management and control by creating networks of autonomous, intelligent process units that exchange information and configure themselves for optimal implementation of the production process by processing huge amounts of data in real time (Bochmann et al., 2015; Soldaty, 2016). Operation in the network requires orientation towards the company's own key competences and shifting other activities to subcontractors. This leads to a change of business models from product orientation to service orientation. Service orientation means offering the best services in the network for the implementation of a given fragment of the manufacturing process. In the value chain in M. Porter's approach, the product or service moves one-dimensional to subsequent organizational units, which successively add value. In contrast, there are multidimensional value networks in the Industry 4.0. The source of value here is the combination of different network links that interact with each other. The functioning of the value network is based on platforms that mean a business model that creates value by connecting suppliers and customers or producers themselves and enabling the exchange of values created by

network participants (Teece, 2010; Santos et al., 2017; Grabowska et al., 2020). Thanks to the development of digitization and new possibilities of collecting, processing, analyzing and exchanging information, platforms enable building value in the business model in a completely different dimension. They create a digital layer that allows business partners to be connected and interacted with any application and device.

The paradigm shift also applies to human-machine relations. The current industrial revolution will bring a higher level of cooperation between man and robot. The development of intelligent interfaces fosters such cooperation. The employee's role will change in the direction of managing the activities performed by the robots cooperating with him. The surge in productivity will combine human contextual decision making with the precision and capabilities of robots what is called Human-centered automation. New technical solutions such as augmented reality are conducive to changing the profiles of current jobs, expanding employee capabilities and creating completely new jobs. Competence development will be integrated with production processes. It will be assisted by the introduction of employee digital assistants (Chromjakova, 2016; Grzybowska & Gajsek, 2016). Continuous skill development will become a standard. Remote communication with devices also gives the possibility of completely new business models regarding, among others participate in online production processes in various places. There will be a rapid increase in the performance of work according to the rules home office.

New business model Canvas dedicated in the Industry 4.0 environment

Currently, manufacturing enterprises can gain competitive advantage on the market, which will increase their flexibility in a stepwise manner and will be able to quickly produce personalized products. This causes the need to build completely new business models (Moeuf et al., 2017; Piccarozzi et al., 2018) that use the huge potential of modern technologies, wireless networks and mobile devices. The coronavirus epidemic also increases the need for modern solutions based on new technologies that enable the production processes realization by minimizing human participation.

The paper proposes a new business model Canvas adapted to the specifics of personalized production and modern solutions related to the Industry 4.0 concept. The model is dedicated to small and medium production enterprises that manufacture products in the network of enterprises containing other production and logistics companies communicating via the Internet. Manufacturing of products consists in planning real-time production schedules for networks of enterprises that are able to produce a given product configuration and are located closest to the customer.

The presented business model Canvas describes online production process which consists of technological process and supporting activities and three main stages can be identified. The diagram of the business model Canvas is presented in Figure 1.

Stage I begins during a confirmation of payment for the client's order. The customer places an order using the e-commerce platform by configuring the product in according to available finite sets of features.

Stage II The order is processed using Big Data Analytics technology, and the network production schedule is configured along with the schedule of logistic operations in real time. The priority of planning is the ability to produce a personalized product in the customer's closest location.

Stage III The network partners receive schedules and at the same time the production of the product starts automatically on machines, devices, robots, etc. communicating via the Internet.

Appropriate sensors and conveyors collect information from machines and devices and automatically start further technological processes and auxiliary activities such as logistics processes (picking, packaging, creating pallet loading units, transport, etc.).

Fig. 1: New business model Canvas.

The use of the new technology to process huge amounts of data in real time allows storage and transport costs to be reduced by creating production networks of enterprises located closest to the customer each time. The Internet of Things enables automatic communication of machines and devices in real time, thanks to which machine and device downtime is significantly reduced and the time of technological operations and auxiliary activities is significantly reduced.

The new presented business model Canvas includes nine elements.

Customer Segments. The main advantage of the model is the extension of the number of customers by directing it to several customer segments. The recipients of personalized products are both the segment of demanding customers who expect products tailored to their needs, preferences and tastes (niche market), as well as the segment of mass product customers due to the price of products similar to mass production (mass market). In addition, production in the enterprise network and the choice of manufacturing site closest to the customer allows personalized products quickly to be delivered and an unlimited market by location to be won.

Value Propositions. The model allows the production of highly varied products, the configuration of which is created by the customer from a limited set of available, selectable product features. The competitive advantage is ensured by automatic ordering, convenient for the customer and automatic real-time production planning taking into account the customer's location, which allows quick delivery (as in mass production) of personalized products with individually tailored configurations (as in time-consuming make-to-order production).

Channels. The model uses the e-commerce platform via mobile devices using wireless networks to reach the customer, which breaks the barriers of the local market and allows reaching customers all over the world as long as they have access to the Internet.

Customer Relationships. Customer relationships are established by mobile devices increasingly popular and willingly used by especially at young and middle age customers. Comfortable sales from anywhere in the world and at any time provides automated-service.

Revenue Streams. The model envisages several attractive revenue streams that they provide: yield management, high quality personalized products, real-time-market, quick production of personalized products, products with personalized properties and demanding customer segment.

Key Resources. The competitive advantage that builds the application of the proposed model is possible due to the use of many resources related to the Industry 4.0 concept. The most important of them are: new technologies such as: Big Data Analytics, Cloud Computing, Internet of Things; specialized staff, product configuration with an extensive number of features, mobile devices and wireless networks.

Key Activities. Key activities which guarantee the functioning of the model and generate revenues are as follow: e-commerce platform development, communication by mobile devices using wireless networks, personalized manufacturing, machine-to-machine, machine-to-people communication by the Internet and many different configurations of SMEs created in real time in the client's nearest location.

Key Partners. The proposed model is generated by a network which is built by connection resources and possibilities of manufacturing and logistics SMEs from different places in the world communicated in real time.

Cost Structure. The communication technologies connected partners are the most cost-intensive in this model. However, their use enables the benefits associated with is economies of scope and combining resources of partners for common manufacturing and sharing of costs, which is especially important for small and medium-sized enterprises whose capital is not large and the ability to raise capital is very limited, as well as enterprises from the make-to-order sector that have problems related to irregularity of demand.

Conclusions

Nowadays is observed a growing customer need of personalized products which are tailored to individual tastes, requirements, preferences and lifestyle. Therefore, industrial enterprises to gain a competitive advantage on the market have to increase enterprise flexibility in a stepwise manner. The Industry 4.0 strategy helps meet this challenge through implementation advanced technologies (such as Big Data Analytics, Cloud Computing, Internet of Things, etc.), automation and application of wireless networks and mobile devices. The Industry 4.0 concept is oriented towards high productivity of industrial systems, but requires changes in industrial management and using new business models.

In the paper a new business model Canvas is presented dedicated for small and medium enterprises which manufacture their products in the networks of industrial and logistics SMEs using the Industry 4.0 strategy. This model is a kind of a description of main firm potential includes key partners, resources, activities, customer segments, relationships, value propositions, cost structure and revenue streams. The proposed model can help to significantly improve enterprise flexibility. The advanced technologies allow machine-to-machine and machine-to-people communication in a real time what leads to shorten time of manufacturing and logistics processes and reduce downtime as well as time of planning and communication. An important advantage of using modern technologies is also the possibility of creating networks of enterprises located closest to the client to fulfill orders, which reduces the time of storage and transport.

As part of future research, the authors will develop accurate procedures for introducing advanced technologies related to the Industry 4.0 strategy into small and medium enterprises building

together production networks. The new procedures will allow quickly and effectively new technologies to be implemented and a competitive advantage to be developed.

Is Islamic Bank stable enough? Stability Analysis of Islamic Banks in the Middle East and Southeast Asia

Suhail SUHAIL
University of Indonesia, Jakarta, Indonesia, suhaileresmair@gmail.com

Abdul MUTA'ALI
University of Indonesia, Jakarta, Indonesia, moetaalingua@gmail.com

Abstract

This study aims to measure efficiency and productivity and determine the factors that influence the level of efficiency of Islamic Banks in the Middle East and Southeast Asia in 2014-2018. Calculation of the level of efficiency in this study is relative, not absolute. This study uses the Data Envelopment Analysis (DEA) method. This research consists of 3 input variables namely Operational Costs (X1) and Salary Costs (X2) Socialization Costs (X3) and 2 Output Operational Income (Y1) and Distribution or Financing (Y2) output variables)). There are 5 Sharia Banks that are perfectly efficient (Constant). And the rest is fluctuating (Increasing and Decreasing). Islamic banks with the lowest relative efficiency levels are in Southeast Asia.

Keywords: Islamic Bank, Efficiency, Stability , Data Envelopment Analysis (DEA)

Introduction

The development of the Islamic banking industry in the world shows a positive trend. This can be seen from the increasing number of Sharia Banks present in countries in Southeast Asia, such as Indonesia and Malaysia, to countries in the Middle East and North Africa. The more developed Islamic banking industry, the greater the challenges faced by this sector, especially in terms of operational activities. The sharia banking industry has the same important role as the conventional banking industry, which is to meet the needs of the community in the financial sector and encourage the realization of national and global economic growth. So to carry out this role properly, Islamic banking is demanded to increase efficiency in its operational activities. The level of efficiency of a bank shows the ability of a bank to optimize all its resources and is able to provide greater benefits to the community as its customers.

According to Pramono and Darmawan (2004) there are several reasons that make the issue of banking efficiency a very important thing to study, including: (1) Increasing competition; (2) Problems arising as a result of reduced resources; and (3) improvement in customer satisfaction standards. The development of Sharia Bank performance in Indonesia can slow down, this is marked by a decrease in the growth of assets, the financing side and the side of Third Party Funds (DPK), while the ratio of problematic financing or Non Performing Financing (NPF) has increased even to exceed the BI regulation by 5 % in February 2015.academically, research on the contribution of Islamic banking industry to the quality of life for measuring the extent to its impact investment is still limited as conducted by Aggarwal and Yousef (2000), Uddin and Masih (2015), and Kumru and Sarntisart (2016). Previous research mostly tended to be concern on the effects of Islamic bank financing on economic growth as conducted by Abduh and Omar (2012), Rama (2013), Farahani and Dastan (2013), Hachicha and Amar (2015), Imam and Kpodar (2016) and Zirek et al. (2016).

Table 1
Sharia Bank Performance
Period 2011 - March 2015 (in Million Dollars)

Indicator	2011	2012	2013	2014	Jan 2015	Feb 2015	Mar 2015
Asset total	*145.467*	*195.018*	*242.276*	*272.343*	*263.468*	*264.813*	*268.356*
Total financing	*102.655*	*147.505*	*184.120*	*199.330*	*197.279*	*197.543*	*200.712*

Source: (Financial Services Authority, March 2015)

The Financial Services Authority (OJK) Banking Supervisory Board of Commissioners, Mulya E. Siregar, also considered that the development of sharia banking in 2015 was having a difficult time. Asset growth in July 2015 was only at 7.98%. Whereas in 2013, the growth of Islamic banking assets could reach 49%. According to him, the decline in the growth of Islamic Banks did not only occur in terms of assets, but also in terms of financing and third party funds (DPK). The slowing growth in Sharia Banks was also exacerbated by the increasing non-performing financing (NPF) ratio which reached 4.89% in July 2015 (Sugiarti, 2015).

Based on the research results of Syafrida and Aminah (2015), the slowing growth in the performance of Islamic banking in 2015 was due to external factors and internal factors. When viewed from the external side, there has been a slowdown in global economic growth, including in Indonesia, which affects the performance of the Islamic banking industry. Meanwhile, from an internal perspective, the cause of the slowdown in growth of Sharia Banks was due to the sharia financing segmentation which was dominated by the retail sector, especially MSMEs, financing which was dominated by murabahah contracts, lack of variation in sharia banking financing and efficiency in bank operations.

Islamic banking is considered still less competitive with conventional banking in terms of efficiency. In 2010-2012, the efficiency of Conventional Commercial Banks reached 98.43% while the efficiency of Islamic Commercial Banks only reached 82.1% (Wahab, Hosen, & Muhari, 2014). According to Hidayat (2014: 54), the level of operational efficiency of Islamic banking, one of which is determined by the very high cost and initial investment. This has an effect on the low profits distributed to depositors. In addition, Islamic Bank financing equivalent rates are relatively higher than conventional bank loans. This can lead to decreased interest in financing customers in Islamic Banks (Syafrida & Aminah, 2015).

Efficiency is a concept that has generally been used in measuring the performance of a company. According to Srivastava (1999), a company is said to be efficient if the company can minimize costs in producing certain outputs or can maximize profits by using a combination of existing inputs. Efficiency can also be interpreted as the ability to obtain fixed output using minimal amounts of resources (Daraio and Simar, 2007).

According to Farrell (1957) the efficiency of a company consists of two components, namely technical efficiency and allocative efficiency. Technical efficiency reflects the ability of the company to produce output with a number of available inputs. Whereas allocative efficiency reflects the company's ability to optimize the use of its inputs, with its price structure and production technology. These two measures are then combined into economic efficiency (economic efficiency). A company can be said to be economically efficient if the company can minimize production costs to produce certain outputs with a level of technology that is generally used and prevailing market prices.

Previous research on this is from Miah and Uddin (2017) examining the differences between Islamic Banks and Conventional Banks with business orientation, stability, and efficiency. Data for this study were collected from 48 conventional banks and 28 Islamic banks from the Gulf States Cooperative Countries (GCC) during the period 2005-2014. The results show that conventional banks are more efficient in managing costs than Islamic banks. Islamic banks are denser in terms of short-term solvency but there is no difference in the long run. The results also showed that banks with large capital were not efficient enough.

Other previous studies are from Sghaier (2016) which measures the performance and efficiency of Islamic and conventional banks in the Middle East or MENA region and determinants. For this purpose we use the Data Envelopment Analysis (DEA) method and the Stochastic Frontier Analysis (SFA) method to calculate technical efficiency scores. The results reveal similar trends for both types of performance measurement. Analysis of the bank category reveals that conventional banks are more efficient than Islamic banks. Despite the technological changes experienced by the banking system in the MENA region, efficiency analyzes show that technical inefficiencies result from pure technical inefficiencies. Finally, the effectiveness of banks in the MENA region is sensitive to variables such as crises, deposits, capital, and includes mainly variables related to business lines. While what distinguishes this study from previous research is in terms of period, number and type of bank, and research variables. From the above background, this study is therefore entitled "Is Islamic Bank Stable Enough? Stability Analysis Of Islamic Banks In The Middle East And Southeast Asia 2014-2019" by using the Data Envelopment Analysis (DEA) method.

Efficiency Concept Review

Simply stated, efficiency can be interpreted as the ability to complete a job properly. The mathematical view states that efficiency is a calculation of the amount of output produced from various inputs used (Muharam & Pusvitasari, 2007). The concept of efficiency was first introduced by Farrell in 1957. According to Farrell, efficiency in a company is related to how to produce a maximum level of output with a certain number of inputs (Firdaus & Hosen, 2013). Efficiency in general is the ability of a business unit to achieve targets using the minimum amount of available resources (Martić, Novaković, & Baggia, 2009). Efficiency measurements can be simply formulated as follows (Tanjung and Devi, 2014):

$$\text{Efficiency} = \frac{\text{Output}}{\text{Input}}$$

According to Tanjung and Devi (2014), the formula is no longer sufficient for current conditions. In fact, there are currently a lot of inputs and outputs that have different relations with resources, activities and environmental factors. Therefore, the relative efficiency measures that are usually used are:

$$\text{Efficiency} = \frac{\text{Amount of output}}{\text{Amount of input}}$$

Based on some of these definitions it can be concluded that efficiency is one measure of performance that refers to the ability of organizations to produce optimum output by empowering existing input resources. Something can be said to be efficient if; first, using the same number of inputs can produce a greater number of outputs; second, with a smaller number of inputs producing the same amount of output; third with a greater number of inputs produces greater output.

According to Leibenstein (1966) inefficient companies are caused by two factors, namely failure to use resources efficiently and failure of companies to optimally combine resources (Hidayat, 2014:). To be clearer, Figure 1 will illustrate the concept of efficiency.

Figure 1. Efficiency Concept
Source: (Hidayat, 2014)

Hidayat (2014) explains the concept of efficiency illustrated in Figure 2.1. It is assumed that companies use one input (X1) to produce one output (Y1). The 0S line is a production frontier that describes the boundary where companies will produce optimally. For example, if a company uses X2 as an input, the optimum amount of output produced is Y2. Companies operating at point A are considered inefficient in terms of technique compared to companies operating at point B. This is because by using the same number of inputs (X2), companies operating at point B can produce more output (Y2) than the output produced by the company operating at point A is Y1. So that companies operating at point A can be efficient, the company can reduce the use of its inputs (from X2 to X1) with the resulting output Y1. From a company perspective, efficiency is known to be of three types, namely (Tanjung & Devi, 2013):

1. Technical efficiency or technical efficiency
Technical efficiency illustrates the company's ability to achieve maximum output with a certain number of inputs. The technical license will measure the production process in producing a certain number of outputs using the minimum input possible. According to Tasman and Aima (2013), technical efficiency is related to fixed resources within the company. Something is said to be technically efficient if the company is able to achieve the maximum possible output from a number of existing inputs. Meanwhile, according to Tanjung and Devi (2013), a production process is said to be technically efficient if the output of an item can no longer be increased without reducing the output of other goods.

2. Allocative efficiency or allocative efficiency
Allocative efficiency illustrates a company's ability to maximize the use of its inputs with its price structure and technology. If the input is allocated to produce output that cannot be used or needed by consumers, it means that the input is not used efficiently.

3. Economic efficiency or economic efficiency
Economic efficiency is a combination of technical efficiency and allocative efficiency. A company can be said to be economically efficient if the company uses the most minimal costs to produce certain outputs.

Methodology

Data Envelopment Analysis (DEA)

Data Envelopment Analysis (DEA) was first introduced by Farrell in 1957 (Firdaus & Hosen, 2013: 170). DEA is one of the analytical tools used to measure the efficiency of organizations both profit-oriented and non-profit-oriented organizations where operations use a number of inputs to produce a number of outputs. The DEA technique creates an efficient banking frontier set and compares it with other inefficient banks, this is done to make a score or the value of efficiency (Hidayat, 2014: 99). Furthermore, bank efficiency scores are limited between 0 and 1, the most efficient banks have a score of 1 while the most inefficient banks have a score of 0. Islamic banking efficiency levels, such as research conducted by M. Faza M. Faza Firdaus and MN Hosen (2013), Abdul Wahab, MN Hosen and Muhari Intercession (2014). Research with the DEA method is not only

done domestically, but many also use the DEA method in research abroad. As M. Abdelkarim Almumani (2013) who examined the efficiency of Islamic banking in Saudi Arabia and research conducted by O. L. Salami and A. A. Adeyemi (2015) which measures the level of efficiency of Islamic banking in Malaysia.

According to Tanjung and Devi (2013: 332), the DEA method uses two commonly used model approaches, namely the Charnes, Chooper and Roodes (CCR) model developed in 1978 and the Banker, Charnes and Cooper (BCC) model in 1984. First is Model Charnes, Chooper and Roodes (CCR), this model was developed in 1978. The DEA-CCR model is known as the Constant Return Scale (CRS) model because this model assumes that the production process follows the CRS. The CRS assumption assumes that each increase in one input will increase one output. This assumption applies to business units that have been producing at their maximum capacity (optimum scale). The Second is Banker, Charnes and Cooper (BCC) models, this second model was developed in 1984. This model assumes Variable Return Scale (VRS), which is the development of the previous model. The VRS assumption assumes that an increase in one input will not affect the increase in output because the business unit is not operating at its optimal scale.

This research framework will be explained in the following figure :

Figure 2. Research Framework

Source: Data processed by the author

Inputs to banking consist of three parties. First party funds are funds originating from paid up capital by investors and shareholders. Socialization costs such as for promotion. After the input is collected, then the bank will use the input to produce output. Output can be in the form of distribution of funds to parties in need in the form of financing, credit and services. The most important output for the bank itself is income, because the bank is a profit-oriented institution.

Results and Discussions

In the table below shows the efficiency values of each Sharia Bank analyzed from the Annual Financial Statements on the website of each Sharia Bank.

Table 2 Islamic Bank Efficiency Scores In The Middle East And South East Asia

No	Name	Period	Score	Scale
1	QATAR ISLAMIC BANK	2014	99.43	Increasing
2		2015	100	Constant
3		2016	95.54	Decreasing
4		2017	100	Constant
5		2018	100	Constant
6	BANK QATAR ARRAYAN	2014	91.48	Increasing
7		2015	89.73	Increasing
8		2016	98.64	Decreasing
9		2017	91.65	Decreasing
10		2018	85.03	Increasing
11	DUBAI ISLAMIC BANK	2014	88.01	Increasing
12		2015	97.31	Increasing
13		2016	97.01	Decreasing
14		2017	86.97	Increasing
15		2018	96.03	Decreasing
16	EMIRATES ISLAMIC BANK	2014	80.85	Decreasing
17		2015	98.99	Decreasing
18		2016	95.12	Increasing
19		2017	80.45	Decreasing
20		2018	99.13	Increasing
21	BANK MUAMALAT INDONESIA	2014	98.21	Increasing
22		2015	86.82	Decreasing
23		2016	75.54	Decreasing
24		2017	62.25	Decreasing
25		2018	71.22	Decreasing
26	BNI SYARIAH	2014	89.33	Decreasing
27		2015	79.63	Increasing
28		2016	88.34	Increasing
29		2017	99,4	Decreasing

30		2018	100	Constant
31	BRI SYARIAH	2014	96.77	Increasing
32		2015	100	Constant
33		2016	94.77	Increasing

Source: Data processed with MaxDEA 6.1

In the 2014-2018 period in Islamic Banks in the Middle East and Southeast Asia, which experienced 100% efficiency (constant) only a few Sharia Banks such as Qatar Islamic Bank in 2015, 2017 and 2018, then BNI Syariah Bank in 2018, BRI Syariah Bank in 2015 , Bank Syariah Syariah in 2016 and Bank Syariah Mandiri in 2017 the rest experienced fluctuations in inefficiency, while the lowest Sharia Bank was Bank Muamalat Indonesia in 2017. Increasing Status states that the Islamic bank is heading for efficiency and Decreasing status states that the Sharia Bank has been over the edge efficiently.

The factors causing inefficiency in Islamic banks are divided into two factors, namely input factors and output factors. The most dominant input factor causing inefficiency in Islamic banks is the factor of labor costs that are too expensive. Based on the calculation results, the labor costs incurred by the Islamic Bank are very high exceeding the specified target so that the Islamic Bank is considered wasteful in the expenditure of labor costs. The high number of workers without adequate skills and knowledge will reduce bank productivity. Given the scarcity of Human Resources who understand Islamic finance, the Islamic Bank must incur additional costs to provide training and skills for its employees. Furthermore, there are also output factors that cause inefficiencies in Islamic banks. The output factor is the lack of distribution of funding and operating income, obtained by the Islamic Bank. This is related to the still low funding rolled out by the Syraiah Bank.

MUAMALAT BANK INDONESIA

The level of efficiency of the Indonesian Muamalat Bank is one of the lowest, on a scale from 2014-2018 experiencing fluctuations, although it experienced a decline that was not too significant in 2015 and 2017, an explanation related to the efficiency trend of the Muamalat Bank Indonesia on the three approaches of each variable will explained in the following table:

Table 3. BANK MUAMALAT INDONESIA 2014-2018 Efficiency Trends

	2014-BMI (RTS : Increasing)	2015-BMI (RTS : Increasing)	2016-BMI (RTS : Increasing)	2017-BMI (RTS : Increasing)	2018-BMI (RTS : Increasing)
Technical Efficiency Score(CRS)	0.746309	0.68595	0.914283	0.52175	0.578375
Pure Technical Efficiency Score(VRS)	1	1	1	0.671511	0.733539
Scale Efficiency Score	0.746309	0.68595	0.914283	0.776979	0.788472

Source: Data processed with MaxDEA 6.1

Based on Table 3, the technical and overall calculations show a lower value than the VRS value in 2014, 2015, 2016, which shows a 100% efficient score. Bank Muamalat Indonesia's Return To Scale results show increasing from 2014-2018 which means that although there is a low level of efficiency, Muamalat Bank Indonesia can still increase the use of its inputs to provide financing and obtain greater revenue. The results of the 2017 Muamalat Bank Indonesia efficiency level according to each variable according to actual data and target data as well as recommendations for each variable based on potential improvement will be explained in the following table:

Table 4. Potential Increasing Efficiency of 2017 Muamalat Bank Indonesia Input Orientation

BANK MUAMALAT INDONESIA 2017 Efficiency Score : 0,62	Variable	Actual Amount	Target	Potential Improvement %	Reccomendation
Input	Operational Cost (X1)	$2.973.483	$550.774	-81,5 %	-$2.422.709
	Salary Cost (X2)	$1.913.918	$998.588	-47,8 %	-$915.330
	Socialization Cost (X3)	$297.671	$155.310	-47,8 %	-$142.361
Output	Total Revenue (Y1)	$9.406.889	$9.406.889	0,0 %	Rp0
	Total Financing (Y2)	$7.458.738	$7.661.369	2,7 %	$202.630

Source: Data processed with MaxDEA 6.1

Based on Table 4. with the input orientation approach, the main source of inefficiency in Muamalat Bank Indonesia in 2017 is in terms of Operational Costs. Following is an explanation of the potential improvement of each variable that must be carried out by Muamalat Bank Indonesia:

1. The operational costs used by Muamalat Bank Indonesia are too excessive 81.5%. This means that $2.422.709 of the total operational costs of Muamalat Bank Indonesia must be reduced to produce efficient output.
2. Muamalat Bank Indonesia personnel costs are too much to exceed 47.8% of the actual figure. To reach an efficient level, Muamalat Bank Indonesia can reduce $915.330 from the personnel costs incurred.
3. The cost of socializing Muamalat Bank Indonesia is too excessive 47.8%, for that the amount of socialization costs must be reduced by $142.361 to achieve efficiency.
4. Receipt of Muamalat Bank Indonesia has been efficiently seen from the same amount of actual value and target value of $9.406.889 therefore this condition must be maintained in order to remain efficient.
5. The amount of distribution of Muamalat Bank Indonesia must be increased a little more, namely around 2% or $202.630 to achieve efficiency

Comparison between actual data and target data for 2017 Muamalat Bank Indonesia for each variable will be explained in the following figure:

Figure 3. Comparison between Actual Data and Target Data for Muamalat Bank Indonesia For Each Variable

Source: Data processed with MaxDEA 6.1

Based on the explanation above, in 2017 Muamalat Bank Indonesia again experienced an inefficiency of 0.52 with operational costs as the main source of inefficiency, the increase in the amount of operational costs, personnel costs and socialization costs exceeding the target should not be offset by an increase in total revenues and distribution. So there are idle funds, and therefore it affects the efficiency of Muamalat Bank Indonesia which only reaches 52%. The recommendation is Muamalat Bank Indonesia needs to reduce costs incurred for operations, labor, and outreach, while distribution must be increased in order to realize efficiency.

QATAR ISLAMIC BANK

The level of efficiency of Qatar Islamic Bank is one of the highest, on a scale from 2014-2018 has increased. In 2014,2015, and 2016 the results of the Return to Scale Qatar Islamic Bank showed increasing meaning that the level of efficiency of the qatar islamic bank was slightly to 100% efficient, Qatar Islamic Bank could still increase the use of its inputs to provide distribution and obtain greater revenue explained in the following table:

Table 5. 2014-2018 Qatar Islamic Bank Efficiency Trends

Source: Data processed with MaxDEA 6.1

Based on Table 5. technical calculations (CRS), on a scale, as well as VRS in 2015 and 2016 showed an efficiency score of 100%, as well as the Return To Scale results that showed constant, meaning that in 2015 and 2016 Qatar Islamic Bank was in the best condition, so the suggestion is that this condition must be maintained. The results of the 2017 Qatar Islamic Bank efficiency level according to each variable according to actual data and target data as well as recommendations for each variable based on potential improvement will be explained in the following table:

Table 6. Potential Increasing Efficiency of Qatar Islamic Bank 2017 Input Orientation

QATAR ISLAMIC BANK 2017 Efficiency Score : 1	**Variable**	**Actual Amount**	**Target**	**Potential Improvement %**	**Reccomendation**
Input	Operational Cost (X1)	$1.369.033	$1.369.033	0	Rp0
	Salary Cost (X2)	$3.624.999	$3.624.999	0	Rp0
	Socialization Cost (X3)	$368.904	$368.904	0	Rp0
Output	Total Revenue (Y1)	$25.157.518	$25.157.518	0	Rp0
	Total Financing (Y2)	$20.693.748	$20.693.748	0	Rp0

Source: Data processed with MaxDEA 6.1

The comparison between the actual data and the 2015 Qatar Islamic Bank target data on each variable will be explained in the following figure:

Figure 4. Comparison between Actual Data and Target Data for QATAR ISLAMIC BANK 2017 for each variable

Source: Data processed with MaxDEA 6.1

Based on Figure 4. with the input orientation approach, the Actual Value and the target value of Qatar Islamic Bank have the same value, meaning that the Qatar Islamic Bank is always efficient every year from 2012-2016 and is in the best condition and produces an efficiency score of 100%, so the suggestion is this condition must be defended for the next years.

Conclusions

Based on the discussion that has been presented above, there are several implications both theoretically and managerially. Theoretical implications relate to the contribution of research results on the development of theories in economics, especially in the study of measuring the level of banking efficiency. The findings in this study also indicate that inefficiencies experienced by Islamic banks are caused by high labor costs and still not optimal operating income. Therefore this finding has managerial implications for the banks to increase the amount of financing channeled, because with a high amount of channeling, operational income can also increase. Islamic banks must be more courageous in taking the right and careful financing decisions to reduce the risk of default.

Abstract

The sharing economy is an economic principle that has risen thanks to technological advances. With the rise of this type of C2C markets in the context of the sharing economy, it is important to understand the factors that affect the intention to use these services. Using the theory of planned behavior and the antecedents of trust, we propose a conceptual research model that outline the factors that may affect the consumer's intention to engage in such economy. We test the model on the Airbnb service using an online survey.

Keywords: Sharing economy, Theory of Planned Behavior, Trust.

Introduction

The exponential growth and advances of information and communication technology in the recent decade has led to the proliferation of new business models and economic principles that are changing consumption behaviors around the globe. The sharing economy is a recent economic principle that is driven by such technological advances as peer to peer platforms. The sharing economy has risen as a creative C2C business model that serves customers by allocating effectively excess in goods or services (Abramova et al. 2015). It allows individuals to revive unexploited assets by making them available for other individuals in exchange of money. According to Price Waterhouse Coopers (PwC) projections (2015), the sharing economy has the potential to reach global revenues of around $335 Billion by 2025.

Often described as crowd-based business model, the sharing economy has showed a great potential and enabled the startups to enjoy valuations beyond its revenues. In fact, Airbnb raised funds at a valuation of $20 Billion which is 20 times its revenues (Libert, Wind, & Beck, 2014) In addition, Libert et al. showed that companies operating under the sharing economy which they labeled network orchestrator model enjoy a competitive advantage over the other companies in terms of higher valuation over revenues, higher profit margins and faster growth. Nonetheless, the sharing economy is subject to numerous threats and obstacles. Accordingly, the sharing model implies a high context peers interaction, which eventually, makes the trust factor curtail. More importantly, companies need to focus on making the communication between the platform operators as fluid and effective as possible (Horton& Zeckhauser, 2016). Because of the nature of the model, trust is pointed as the most important factor in the long-term success of customer-to-customer (C2C) relationship (Cook & State, 2015; Strader&Ramaswami, 2002). Additionally, trust is an important factor in the notion of sharing. PWC (2015, p.16) said that "convenience and cost-savings are beacons, but what ultimately keeps this (sharing) economy spinning-and growing-is trust."

In this paper, we will analyze the role of trust in the sharing economy from the client perspective. Using the Theory of Planned Behavior (Ajzen, 1991) and the antecedents of trust developed by Gefen (2003), we empirically test a model of factors affecting client's intention to use a sharing service such as Airbnb.

Research Model and Hypotheses

The research model of our study is presented in figure 1. The model is based on the theory of planned behavior (Ajzen, 1985) and trust antecedents as developed by Gefen (2000). Our goal is to identify the factors that best predict the intention to use in the context of the sharing economy model of airbnb.com from the customer's perspective. A previous study by Mittendorf's (2016) explored trust in the sharing economy from the provider's perspective using the research model developed by Gefen (2000). Mittendorf (2016) found out that both trust constructs, trust in the room provider and trust in Airbnb, are important for a successful sharing transaction. Our research model presents trust from the renters perspective in addition to trust in the platform provider.

Fig. 1: Research Model

Trust in online environment and Theory of planed behavior:

Developed by Icek Ajzen (1985), the theory of planed behavior explains the human behavioral process. According to the theory, human behavior is regulated by three variables: the positive or negative evaluation toward an action (Attitude), the general beliefs towards the action (Subjective norms) and finally the level of control that the person has on the behavior (Behavioral control). Combined, behavioral control, subjective norms and attitude impact the behavioral intention, which leads to the actual behavior. The theory has been studied in different contexts such as education, m-learning, mobile apps, and e-commerce (Seyal & Mohd, 2017; Lim & Dubinsky, 2005).

Trust has always been an important factor in building business and personal relationships (Mcknight,2001). Without it, transactions would become difficult to establish, especially in situations where risk is present. The greater the risk and the level of uncertainty the more important is the role of trust in the transaction. Regardless of the nature of the risk, trust is what facilitates the transactions. Conscious about the importance of trust in E-commerce transactions, Gefen (2000) explained the role of building trust in the e-commerce industry through two variables: Familiarity with the e-vendor and disposition to trust. Familiarity refers to the understanding process of why,

how, when and what people do what they do (Luhmann, 1979). Disposition to trust deals with the degree of faith and trustworthiness that a person has toward others' future actions (Gefen, 2000).

In the sharing economy, the level of uncertainty is notably higher compared to other models. First, because of the online interaction characterized by its complexity and uncertainty. The second reason consists of the lack of regulations around the collaborative economy. Third, the triadic relationship characterizing the sharing economy model makes the notion of trust even more complex. Airbnb's users, for example, are exposed to different threats such as properties' damage and privacy issues. In this context, trust is less likely to be built, and therefore is where it is more needed. Overall, we can say that Airbnb, is one of the most trust-dependent platform, taking into consideration its sharing nature and process.

Based on our research model, we hypothesize the following:

H1: *Attitude will positively affect Trust in Airbnb.com*
H2: *Behavioral control will positively affect Trust in Airbnb.com*
H3: *Subjective norms will positively affect Trust in Airbnb.com*
H4*: Familiarity will positively affect Trust in Airbnb.com*
H5: *Disposition to trust will positively affect Trust in the provider*

H6: *Disposition to trust will positively affect Trust in Airbnb.com*
H7: *Increased degrees of trust in Airbnb.com will increase the renters' trust in the provider*

H8: *Trust in the provider will positively affect renters' intention of booking*

H9: *Trust in Airbnb.com will positively affect renters' intention of booking*

Research Method

To test and validate our research model, we used quantitative survey methods. To collect data we shall use online survey. Online questionnaires are very convenient and very feasible in this context. Especially that the target population are university students from generation Z who are very tech savvy and are potential users of the sharing economy services. Born and raised at the pinnacle of the technological development, the generation Z is comfortable with the usage of Internet platforms and E-services. Thus, we believe that our population is appropriate for testing our sharing economy-based model.

Instrument Development

To measure the constructs in our research model, we used previously validated measurement scales. Table 1 lists the variables and the source of each scale. Some scales were slightly reworded to reflect the context of Airbnb.

Table 1: Variables and their respective measurement sources

Construct	Source
Familiarity with Airbnb.com	Gefen, 2000; Kim et al. 2008
Disposition to trust	Gefen, 2000.
Trust in Airbnb.com	Gefen 2000 ; Jarvenpaa et al. 1999 ; McKnight et al. 2002.
Trust in Provider	Gefen, 2000.
Attitude	Jarvenpaa et al. 1999 ; Taylor and Todd 1995
Subjective norms	Taylor and Todd 1995 ; Mathieson 1991 ; Paul and

	Mendel 2006
Perceived Behavioral Control	Taylor and Todd 1995; Paul and Mendel 2006
Behavioral Intention	Pavlou 2001 ; Kim et al. 2008 ; Mathieson 1991 ; Taylor and Todd 1995

Conclusion

This research will enable us to enrich our knowledge, explore the sharing economy framework and attempt to widen our spectrum of future research. As a trending model, the sharing economy can be an alternative to the traditional business models and can therefore be considered as disruptive. As such, Airbnb.com is propose an alternative service in the hospitality sector and can be a source of economic growth. This study will put emphasis on the factors that influence the renter's booking intention and will therefore help shed light on the adoption of such service in the Morocco context.

Abstract

The article discusses the features of the socio-economic stratification in the Republic of Kazakhstan, including the stratification of the population of the Republic of Kazakhstan on the basis of "the level of income, quality of life index" (with the release of 5 groups of households and individuals), and proposed a classification dividing the regions of Kazakhstan in terms of income. In 2018, assistance from the state is not needed, only a third of the population of the Republic of Kazakhstan, the rest in varying degrees, need social support. The results of the socio-economic stratification of the population of the Republic of Kazakhstan will enable the social policy not only directly in need of protection, but also to determine the critical group, which will take timely measures of state support in order to maintain political stability and social cohesion of the Kazakhstan society.

Keywords: Kazakhstan, economics, stratification, income and opportunity inequality, government support, statistical research, median, middle class, poor, rich.

JEL Classification: C23, R20, Z13

Introduction

In conditions of unequal distribution of income, economic, intellectual, informational and other resources, stratification defines social identification and borders of interaction between people and groups with different social status. The term "stratification" is used to describe the structure of inequality in a society where people:

- have differentiated structural positions;
- are in layers (strata) that are evaluated hierarchically according to certain recognized standards.

The need for in-depth studies of yield stratification was articulated more than a quarter of a century ago by scientists who considered yield distribution to be one of the most important foundations of

social stratification (Esping-Andersen, 1991; Lenski, 1984; Rytina, Form, Pease, 1970; Townsend, 1979, 2013) and who have done much in this direction. Nevertheless, the need for such research is still relevant today (Ceriani, Verme, 2014). For economists, income and income inequality are integral attributes of the concept of "capabilities" based on economic theories of wealth and fair distribution. This traditional approach to measuring well-being is based on comparing levels of resources available to individuals (Sen, 1992). At the same time, the development of the problem of income inequality by economists often overlaps with key topics for the concepts of social stratification and theory of social structure in general. These are justice, inequality, poverty, and the middle class; the issue of wealth is less well researched in the literature in this context (Brzezinski, 2011; Eisenhauer, 2011). At the same time, in general, the experience of singling out certain income groups in academic literature, regardless of their sectoral affiliation, is much more often associated with the study of individual elements of the social structure (the poor, middle class, etc.) than with the description of models of social stratification of society as a whole.

Interdisciplinary advancement in the study of income stratification is significantly complicated by confusion in terms of concepts, namely, that, for example, sociologists and economists have different interpretations of the basic concepts of social structure, in particular - groups, strata, layers and classes. Despite the fact that sociology has developed a tradition of analyzing social groups, which dates back to the works of G. Simmel (Simmel, 1898), economists actively use this concept to describe the income categories and ranks allocated by them, without taking into account the traditional criteria for identifying groups in sociology. Exceptions are cases when the division of population is based on the attitude of individuals or households to this or that income percentile or index methods of income stratification (Yitzhaki, Lerman, 1991), when the division of population into groups is obviously based not on social theory but on practical needs of research (for example, the necessity to control nonlinearity of the processes under analysis). Sociologists, on the other hand, rarely use such formal divisions, preferring theoretically more elaborate classifications, for example, class schemes of J. Goldthorpe and his colleagues (Erikson, Goldthorpe, 1992; Goldthorpe, McKnight, 2006). Wright (Wright, 1989, 1997), D. Gruski and his colleagues (Liu, Grusky, 2013; Weeden, Grusky, 2005), D. Treiman (Treiman, 1977), or even express skepticism about attempts to link income differentiation of the population with the logic of social stratification (Wodtke, 2016).

Nevertheless, the task of linking social stratification and income inequality, according to current research on social and economic inequality and stratification, still remains important in Kazakhstan, not only in practice but also in theory. While income-based stratification is somewhat limited in its heuristic possibilities when analysing the social structure as a whole, it can eloquently testify to ongoing socio-economic processes, their trends and scales. At the same time, income groups themselves form an ordered single-criteria social classification scheme, albeit a simple one, but already established as a separate tradition in structural sociology (Grusky, 2001; Parsons, 1940).

As a rule, the classifications used to describe objectively existing social groups are either one-, two-dimensional or multidimensional structures. As multidimensional models by virtue of their complexity cannot be a reflection of the principles of stratification of society existing exactly in the consciousness of people, a two-dimensional model can claim for the role of a common classification representing representations of the majority of people.

Stratification of the population with allocation of certain income groups on the basis of several attributes and description of these groups is important not only from the point of view of political stability, but also for applied purposes, for example, more effective market segmentation or coordination of social programs.

In EU countries, stratification is constructed by calculating the relative poverty line. If an individual's equivalent disposable income is below 60% of the national median income, he or she is considered poor because this approach takes into account not only the minimum needs for physiological survival, but also exceptions from socio-cultural standards and norms of public life (access to information, communication, etc.).

Identification of three income groups of the population (low, medium and high income groups) allows for the analysis of income polarization, which is fundamentally different from the analysis of income inequality and poverty in that changes in income distribution are analyzed with an emphasis on changes in income distribution as compared to the center.

Thus, studying the change of three income groups, we can talk about polarization of society as a manifestation of inequality. In the case of income polarization, the shares of the upper and lower income groups increase, while the share of the average group shrinks. In people's perception, such a situation is perceived as an increase in inequality and, to a high degree, can jeopardize political stability and social cohesion of society. If the average income of a group decreases in relation to the other two, but without a decrease in the share of the group itself, we can say that there is relative polarization. In the same case, when there is an increase in the share of population with low income along with a decrease in the average income in this income group, we are talking about absolute polarization of income.

Actuality of a theme of research

on social and economic stratification of the Kazakhstan society is caused, first of all, by practical importance of object of research. **The research hypothesis:** self-stratification of society does not coincide with official statistical studies, which should already be considered an important social problem. The given mismatch for Kazakhstan is more explained by features of mentality of the Kazakhstan society.

Methodology of research

The research included a complex of methods of quantitative and qualitative analysis. The preliminary stage included the study of epistemology of the issue by analyzing the works on this problem. Further research on the stratification of Kazakh society will be based on theoretical and methodological approaches proposed by D. Gordon (Gordon, 1995, 2000, 2005), which allow to divide the population into groups on the basis of relative criterion (income level) and deprivation (number of deprivations).

In 2000, D. Gordon (Gordon, 2000) and a group of researchers presented a study conducted in the UK, which used a fundamentally new approach to defining the division of the population into two groups: poor and not poor. This approach combined the deprivational and income lines of poverty, i.e., on the one hand, the necessary benefits of household deprivation were taken into account and on the other hand, the income level was taken into account. D. Gordon recognizes that in the systems of stratification of modern societies, the material and economic elements never exhaust all its factors. Since it is the criterion of ownership and income that plays a decisive role in Kazakhstani society, which has received its own value, as well as the level of deprivation allows for a more objective assessment of the level of poverty it is the work of D. Gordon that formed the basis of the study.

Kazakhstan currently has a high degree of stratification of society into rich and poor, and this is one of the most pressing problems, especially given the declared ideas of social and economic equality of Kazakh citizens.

As mentioned earlier, modern scientific research has revealed that excessive inequality of the population is not only a destabilizing factor, creating a potential threat of conflict, but also adversely affects the economic and demographic indicators of the country, affecting the labor motivation of the population.

At the same time, according to official data from the Committee on Statistics of the Republic of Kazakhstan, between 1997 and 2018, the Gini coefficient fell markedly from 0.338 to 0.289, as did the fund coefficient (calculated as the ratio of average per capita income of the 10% of the most and 10% of the least wealthy population) from 10.2 to 5.99, the share of the population with income below the minimum subsistence level in 2018 was 4.3% (It makes it possible to numerically estimate

the degree of inequality. The Gini coefficient for 20 per cent of the population sets the degree of deviation of the actual distribution of income by quintile group from its even distribution line).

It should also be noted that according to official statistics, the average per capita income of the third and fourth quintiles (at 20% distribution) exceeds the minimum subsistence level only by 1.5-1.9 times, and this indicates that in fact 80% of the population of the Republic have income not exceeding twice the minimum subsistence level, i.e., the minimum subsistence level is not higher than the minimum subsistence level.e. 170 Euros per person (as of 2018, the minimum subsistence level is 26,440 tenge or ≈ 65.02 less than, for example, in 2014, ≈ 85 Euros, which is also due to past devaluations of the national currency in Kazakhstan), half of which is vulnerable to the risk of becoming poor.

Estimating the stratification of the population of the Republic of Kazakhstan in 2018 by the Eurostat methodology using the scale adopted in Germany:

1) 23.7% of the population belongs to the low-income group (less than 70% of the median of monetary income);
2) 56.3% belong to the average income group;
3) 20% belong to the high-income group (over 150% of the median of monetary income).

The median of monetary income in Kazakhstan is 85 euros per person, while more than half of the population of Kazakhstan had income below the average in the period under review (Fig. 1).

Fig. 1: Population distribution by income groups in the Republic of Kazakhstan in 2018

Source: composed by the authors

In the last 2 years, the share of low-income households has decreased by 4.2% (due to the introduction of targeted state assistance to socially vulnerable groups in Kazakhstan), but the share of high-income families has also decreased by 1.6%. The expansion of the middle layer indirectly shows a decrease in income polarization.

This survey and distribution of Kazakhstani society by income groups is quite standard and in our opinion does not allow us to get a complete and more detailed picture of socio-economic stratification in the Republic of Kazakhstan and to identify those promising groups of the population, whose social assistance will lead to a real improvement in their quality of life. According to the Committee on Statistics of the Republic of Kazakhstan, as of 1 January 2019, the population of the country was 18,376.2 thousand people. The share of the urban population increased slightly, to 55.1 per cent, while that of the rural population decreased to 44.9 per cent. Unfortunately, the rural population of

Kazakhstan is characterized by a lower standard of living than the urban population and, above all, a lower level of access to social services (e.g., lack of specialized medical care) and worse engineering and transport infrastructure. Also in 2018, the poverty rate in rural areas exceeded the urban level by more than 3.8 times; in 2009 the difference was 3.0 times.

Main Part

The model of socio-economic stratification of Kazakhstan's population proposed by the authors is based on 2 features:

- income level;
- quality of life index.

Application of this model allowed dividing the population into 4 main groups:

1) "poor", which includes households and individuals with low values of income and living standard index;
2) "vulnerable" - a group of households and individuals with low incomes but a high quality of life index;
3) "out of poverty" - households and individuals with high income but low quality of life index;
4) "not poor" - a group of households and individuals with high incomes (consumption) and a high quality of life index; from this group 5 group can be distinguished "wealthy", i.e., the population with a maximum income level and a quality of life index.

The results of calculations of socio-economic stratification in Kazakhstan, which takes into account both income and living standard index, according to the data of 2018 are presented in Figure 2, dividing households and individuals into 4 groups. This division is explained by the fact that in Kazakhstan the number of individuals in low-income households is higher than in high-income households.

Fig. 2: Stratification of the population of the Republic of Kazakhstan in 2018 by indicators of "income level - quality of life index" (by households and individuals)

Source: composed by the authors

The "non-poor" group, which includes households and individuals with high values of income (consumption) and standard of living index was 40.5% and 30.3% respectively. This is the group to which we refer households with low deprivation rates (i.e. high living standards) and high incomes. The main location of this group is the urban population living in cities with a population of over 50,000 people. (small towns). Kazakhstan is the most urbanized country in Central Asia. The urban population accounts for more than 60% of the total number of inhabitants, there are 86 cities in total in Kazakhstan, but 54 of them are small towns, so the main part of the "not poor" group lives in 32 cities, the most populated city of Kazakhstan is its "southern capital" - Almaty, where today live about 1.5 million people. Other large cities of Kazakhstan in terms of population are: Astana (over 828 thousand people), Shymkent (over 680 thousand people) and Karaganda (over 480 thousand people).

The "poor" group, which included households and individuals with low incomes and living standard index values, was 25.5 and 34.2% respectively. The main location of this group is the rural population and the population of 28 monocities in Kazakhstan (i.e. every third city in Kazakhstan). According to the modern classification, monocities in the Republic of Kazakhstan are considered to be urban settlements with 10 to 200 thousand inhabitants, where at least 20% of the adult population in such a city works at the city-forming enterprise. Only 4 monocities of the republic have the population over or about 100 thousand (Temirtau, Rudny, Zhanaozen, Ekibastuz); the population of the rest does not exceed 50 thousand people.

The group "leaving poverty" - households and individuals with high income but low quality of life index of 9.6% and 7.1% respectively. This group is not income poor at the time of the survey, but if their income remains high, they will be able to acquire the necessary benefits over time and their quality of life will increase. Unfortunately, most of this group in Kazakhstan is rural, whose access to benefits is limited by the poor state of the engineering and transport infrastructure in rural areas.

The "vulnerable" group is a group of households and individuals with low incomes but a high quality of life index of 24.4% and 28.4% respectively. This group is not experiencing massive deprivations at the time of the survey, but with no increase in income the situation will change for the worse. The main location of this group is the urban population, both large and small cities. In Kazakhstan, a rather high share of this group is conditioned by the state policy aimed at ensuring equal access to social benefits (guaranteed volume of health care, education, quality of infrastructure in cities, etc.).

Analysis of the population groups received showed that there is a small but clearly distinguishable population group with an income above the median, with no deprivation. Allocation of such households allowed obtaining the fifth group - the wealthy ones.

Distribution by groups of households also differs from distribution by persons (Figure 3).

Fig. 3: Stratification of the population of the Republic of Kazakhstan in 2018 by indicators of "income level - quality of life index" (with allocation of 5 groups by households and individuals)

Source: composed by the authors

The "poor" group comprised 25.5% of households and 34.2% of individuals, the "vulnerable" group 23.0% of households and 26.8% of individuals, the "leaving poverty" group 9.5% of households and 7.1% of individuals, and the "non-poor" group 35.0% of households and 25.2% of individuals. Finally, 7% of households and 6.7% of individuals were included in the "wealthy" group.

Conclusions and Recommendations

Based on the analysis, it can be assumed that in 2018 only one ***third of the country's population did not need government assistance, while all the rest, to varying degrees, needed social support***.

Features of social and economic stratification in the Republic of Kazakhstan are due to the presence of significant regional unevenness in the distribution of income:

1) The population of capitals is in the most advantageous position: the current city of Astana and the former city of Almaty, which has the status of a city of national importance;
2) Next in profitability oil-producing regions, namely Aktau, Mangistau and West-Kazakhstan regions (there is a very strong stratification of living standards of the employed population and not in this sector);
3) Relatively stable regions of Kazakhstan - Akmola, Aktobe, Karaganda, Kostanai, Pavlodar and North-Kazakhstan regions.
4) Agrarian regions with minimal profitability - East Kazakhstan, Zhambyl, South Kazakhstan, Almaty and Kyzylorda regions.

Uneven distribution of income generates a number of problems in the leading regions of Kazakhstan:
- Large flows of internal migrants to capitals (Astana, Almaty) and oil regions of Kazakhstan from agrarian regions increase social tension. The local population is experiencing strong competition from both foreign and Kazakh workers;
- wages in the extractive sector are 4-7 times higher than in other sectors of the economy. This leads to sharp stratification of the population. High wages in the extractive sector with limited supply of goods and services in the regions lead to higher consumer prices. Consequently, the cost of living in the region is becoming more expensive;
- as a result of strong income differentiation in the extractive regions of Kazakhstan, there is an outflow of workers from the social and infrastructure sectors, which again deteriorates the quality of life of the population.

Agrarian regions of Kazakhstan also face a number of problems:
- there is a high concentration of poor people in these regions: about 50% of the poor in Kazakhstan live in three regions - Almaty, South Kazakhstan and East-Kazakhstan regions, these regions have the highest proportion of self-employed people with unstable income;
- the processing industry of agricultural products is underdeveloped, so the economy of these regions is characterized by low added value and, accordingly, low wages.
Nevertheless, despite the obvious stratification of society in Kazakhstan, the negative consequences of the crisis, rising prices for products, goods, utilities, fuels and lubricants, sociological studies, including foreign analytical structures, have long recorded a high level of satisfaction with life.

The reasons of this phenomenon can be divided into 2 groups: common for the population of CIS and specific for Kazakhstan.

The first group of reasons may include a subjective approach to self-identification, based on the mentality of CIS residents: "If I'm not hungry, I'm not poor, and if I'm not poor - I'm the middle class!" In Kazakhstan, at least 42.7% in the focus groups in 2014 identified themselves as the middle class, and in 2018 - 59%, while many of them do not allow allocating sufficient funds for the purchase of durable goods (with more specific questions). We have also brought here a desire for stability, quite organic for the general public - the fear that mass marches on a political and economic basis may turn into a large-scale, nationwide inter-ethnic conflict (in the example of Georgia in August 2008, Kyrgyzstan in June 2010, Ukraine in 2013-2014, etc.) really shows the level of protest of Kazakh society. Again, it is necessary to note the consequences of "shock therapy" of the 1990s. The overwhelming majority of the population of Kazakhstan, especially middle and older generations (age cohorts 40-50, 50-60, 60 years and older) have been fully affected by the transformation of the entire social system. They remember the sharp decline in living standards and other social costs of forced modernization. It is enough to compare the inflation rate in Kazakhstan for 2018 - 5.3% - with hyperinflation in the first half of the 1990s, when it exceeded one thousand percent year on year.

The specific reasons for the high level of satisfaction with life in Kazakhstan include the rather pronounced conservatism of Kazakh society, primarily the population living in the aul (village). On the one hand, it is socially passive, and on the other, it is quite loyal to the authorities. In particular, the loyalty of the villagers is due to several reasons. The fact is that social ties in the village are to a large extent characterized by patron-client relations, based on high loyalty to the authorities. They are projected on the whole system of relations with persons in power. This is explained by traditionalism

and social trends in the rural areas. And despite the low standard of living and income of the rural population compared to the urban population, the rural population shows an equally high degree of satisfaction with life.

And the second factor, let's call it Central Asian. Kazakhstanis in their masses, especially those living in border areas, are well aware of the standard of living of our neighbors: in Kyrgyzstan, Uzbekistan, Turkmenistan and Tajikistan, including hundreds of thousands of migrant workers. According to the CIS Statistical Agency, in 2018 the average salary in Kazakhstan was second only to that of Russia and was higher than in Belarus, Azerbaijan, Ukraine, Armenia, Moldova, not to mention Kyrgyzstan and Tajikistan, where it was 3 and 4.6 times lower than ours, respectively.

The above listed main factors form a relatively low correlation between the socio-economic stratification of Kazakhstani society, the negative impact of rising prices, utility tariffs, poor health care, education and other spheres on the one hand, and the level of protest among the population and various social groups on the other.

Until 2020, targeted social assistance in Kazakhstan was provided exclusively to low-income families in the form of cash payments and assistance in helping a family get out of a difficult life situation by providing them with training, employment and support to start a business. We recommend a comprehensive approach and targeted social support measures:

1) Introduction of state benefits for all families with many children and 4 or more underage children or full-time students under the age of 23 years;

2) Quarterly assignment of targeted social assistance to all family members as a difference between the poverty line and the average per capita income of the family, provided that able-bodied family members will work and the state will help them to find a job, engage in business;

3) Provision by the State of a guaranteed social package for children from poor families: from 1 to 6 years old - child nutrition, hygienic means and educational services, and from 6 to 18 years old - free hot meals in schools, free daily city transport, school uniforms and school supplies.

The mechanism for providing targeted social assistance should be transparent, fair and motivating to work and not to engage in idle lifestyles and benefits.

Perfecting the Procurement Process in The Security Management System in The Supply Chain

Paweł Ślaski

The Faculty of The Security,
Logistics and Management at The Military University of Technology Poland
pawel.slaski@wat.edu.pl

Summary

The aim of the article is to develop a model for perfecting the procurement process in the security management system in the supply chain based on the case of the surveyed automotive trading company.
The model uses EPC notation to present the basic disruptions in the supply chain and proposals for their elimination or reduction. The model verification was carried out based on the statistical data collected during several years of observation of the procurement execution time delays in the surveyed company and on the application of the Monte Carlo computer simulation method.

Keywords: EPC modelling, supply chain, procurement process

ORCID Identifier: 0000-0002-1950-9910

Introduction

Supply chain management is a skillful way of linking the processes of sourcing, manufacturing, distribution and recovery logistics to the market needs and the way to properly adapt to the ever faster changes of these needs. The objectives of supply chain management, i.e. the minimisation of costs, improvement of the quality of goods and services, increased flexibility, diversity and responsiveness, can be achieved by treating the chain as a whole, consisting of individual processes and activities interlinked. The procedural approach allows concluding that the objectives set for each process are the components of the main supply chain objectives only and not the objectives existing for themselves.

Process management in today's supply chains addresses the increasing turbulence of the environment and the individualization of customer needs and expectations. It consists in optimizing the structure of the company's elements by striving for maximum share of value-adding elements in this structure and minimizing the share of inefficient activities.

One of the basic value-adding processes in the supply chain is the sourcing process, in which nine basic activities can be distinguished.

Action 1. The procurement of commodities

This action is related to determining the result of the process, i.e. output parameters. A demand for commodity, service or information that is accepted by a customer, may constitute a need (a product). The needs are reported to the company's procurement department based on a purchase order with a detailed specification of a commodity or a service or a reordering method.

Action 2. Description

At this stage, a detailed description of the product follows, which is a source of information for potential suppliers. There are a number of ways to describe a product or service, all of which must accurately communicate the needs of customers to suppliers. The basic methods of describing a product or service may include:

- description by quality or standard (standard products and services, partners in a supply chain know market needs),
- description by brand (products and services preferred from one supplier),
- description by specification (detailed characteristics of the product or service required, e.g. the production process, control systems, physical dimensions),
- description by result (e.g. technical support in the process of device exploitation).

Action 3. Identification and assessment of suppliers

In this action, the organisation shall define criteria for the assessment of identified potential external suppliers. These can be, for example: the possibility to design products, the competence of the management, the business condition of the company, planning and cost structuring, the possibility to establish long-term cooperation, planning and controlling systems, etc.

Action 4. Selecting a supplier

Finalisation of identification and evaluation is the other action related to selecting a supplier finally. Selecting can be made from the list of preferred suppliers, by tendering or by negotiation.

Action 5. Procurement preparation

This action involves drawing up a document which authorises a supplier to deliver a product. The document sets out the conditions, i.e. price, date and place of delivery and quality requirements. EDI (Electronic Data Interchange) technology is very often used at this stage. Based on the Internet, the real needs of customers go to suppliers, often without intermediate entities. This shortens the procurement execution time, minimises stock levels and thus reduces logistics costs.

Action 6. Control of procurement execution

This action is related to the determination of the status of procurements at each stage of their execution.

Action 7. Collection and control

This action includes the collection of a product in accordance with the procurement specification and the quantitative and qualitative check of the product. Statistical methods of receipt and quality control of goods may be used here.

Action 8. Approval of invoices and payment

After collecting the product, the company usually transfers the money electronically to the supplier's bank account.

Action 9. Updating data

The process can be repeated, so after execution of the procurement, the database on cooperation with suppliers is updated.

Among the activities described in the procurement process, **the procurement of commodities** deserves special attention. This action covers a number of complex methods for procurements of commodities in a free market economy environment. This environment is characterised by irregular demand and delivery times and is subject to a number of disruptions associated with the proper flow of goods, services and information in supply chains.

Later in the article, the term “action” shall be replaced by the synonym “process”.

Literature Review

The procurement process in the supply chain is related to different ways of procurement. It is essential to choose the right method to solve the main problem. The literature describes a number of procurement methods in both deterministic and probabilistic environments. The model of the economic procurement size, in which there is no risk of shortage in the deliveries, assumes a balance of the costs to create (order) inventory and maintain commodities in the warehouses, Goyal (1985); Goh M. (1994).

In turn, classic stochastic procurement models define:

- Minimum procurement level, at which a fixed delivery volume is executed, Peng (2018).
- Constant inventory survey periods with variable delivery volumes, Korponai and others (2017).
- The procurement method under conditions of demand discontinuity.

Stochastic models require determining a safety stock level that guarantees an appropriate level of customer service, Chan and Suk-Chul (2019); Hernandez-Ruiz and others (2016). The procurement problems also concern the group procurement methods and the associated economies of scale. The economies of scale resulting from the grouping of procurements relate to the minimisation of costs to create (order) and maintain inventories, Sarjusz – Wolski (2000).

Classic theoretical procurement models described in the literature do not always "work" under real conditions. Choosing a model that meets the company's expectations is not an easy task and depends on the strategic skills of the management. The interview with the management of the surveyed company showed the author of the article the direction of research consisting in the skilful use of combined methods to develop a model of effective management of the flow of commodities in the supply chain.

Research Question

The aim of the article was to develop a model for perfecting the procurement process in the supply chain based on the case of the surveyed automotive trading company.

The research problem was posed as the question:

How to improve the efficiency of the flow of commodities in the supply chain with selected ordering strategies and methods?

To solve this problem, the author proposed an original model. The following research methods were used to develop the model:

1. The process modelling in EPC.
2. Security inventory control strategy in a supply chain.
3. Index analysis.
4. Hybrid inventory control.
5. Monte Carlo computer simulation method.

Research Design and Methodology

- **Assumptions and limitations** of the model.

The model was developed on the basis of the EPC notation of the ARIS platform. The study concerned an analysis of the supply chain, of which the automotive trading company was a key link. The statistical data obtained, which made it possible to verify the model, covered the period from 2016 to 2019.

- **The structure of the model**

The model consists of three phases (levels). The first phase concerns the analysis and assessment of disruptions to a sustainable supply chain. The second phase consists of proposals to apply selected security inventory control strategies and methods in the supply chain. The purpose of this phase is to increase the efficiency of a sustainable supply chain by effectively eliminating possible disruptions. The third phase is related to the verification and implementation of the model in the company (Fig. 1).

Fig. 1: The model of perfecting the procurement process in the security management system in the supply chain

Source: the in-house elaboration in EPC, Ślaski (2017).

The analysis and assessment of distortions covered three dynamic phenomena destabilising the sustainable supply chain, i.e.: the Forrester effect (bullwhip), the Burbidge effect and the Houlihan effect. The Forrester effect, also known as the bullwhip effect, consists in transferring changes in the volume of deliveries resulting from the structure and dynamic properties, as well as from ineffective ordering strategies. In the processes of information and material planning, due to inappropriate algorithms for controlling inventory levels (mainly security levels), oversized inventories are

accumulated, which generate excessive costs of their maintenance Alizadeh (2012), De La Fuente and others (2007), Disney and Towill (2003), Forrester (1961), Kristianto and others (2012), Shukla and others (2009), Panda and Mohanty (2011), Lee and others (1997).

The Burbidge effect, on the other hand, is the use of a classic ordering machine based on economical sizes. This phenomenon is also connected with group orders of goods and economies of scale in the production process. The synchronisation of group orders over time in a supply chain results in a sharp periodic increase in order volumes followed by an equally sharp decline, Disney and other (2003).

The last of the distinctions is the Houlihan effect. It concerns the reaction of company strategists to temporary shortages or delays in deliveries. In this case, decision-makers plan orders beyond the current needs to replenish security inventory, as more inventories are created at the individual links in the chain. The effect of such planning leads to a reduction in orders, which increases the effect of destabilization through a temporary lack of flow of goods, Houlihan (1987) .

The second phase contains strategies, methods and techniques for the total or partial elimination of disruptions in the supply chain. It consists of four main activities, i.e.: determining the allocation point, determining the structure of inventory, choosing inventory control methods and the use of the Monte Carlo method to determine optimal order parameters.

Inventories, especially safety stock, play an important role in determining procurement parameters, as they guarantee continuity of flow in demand and supply streams.

According to APICS (APICS The Association for Operations Management), inventories are "the inventories of commodities used in the production process (raw materials and work in progress), in auxiliary activities (maintenance and repair materials) and in customer service (finished products)".

Inventories are used to ensure continuity of production and distribution processes. Maintaining inventories is related to the need to ensure the regularity of production and to the economies of scale of production, and inventories reduce uncertainty about the deliveries themselves, their timeliness and protect against sudden events.

Other reasons for maintaining stocks include:

- the seasonal nature of raw material supplies,
- seasonal nature of demand for the products concerned,
- ensuring a constant level of employment in companies over short periods of time.

It is important from the point of view of **the structure of inventories** to divide them into an inventory used to secure current needs, called current inventory, and a safety stock, which prevents fluctuations in demand and guarantees an adequate level of customer service.

The size of the safety stock shall be determined by formula (1), Chan-Ju Lee (2019), Trapero and others (2019), Stephen and others (2000), Gary and others (1998), Sharma and others (2015).

$$\boldsymbol{Zb = \omega \cdot \delta_{pt}} \tag{1}$$

Where:

Zb– The safety stock,
ω– The security factor,
δ_{pt} – Standard deviation of demand forecasts for the replenishment cycle.

The security factor $\boldsymbol{\omega}$ is a multiple of the standard deviation $\boldsymbol{\delta_{pt}}$ and depends on the Level of Customer Service $\boldsymbol{\omega = f(LoCS)}$. This relation is shown in Fig. 2.

Fig. 2: The function chart

Source: the in-house elaboration.

Standard deviation of demand forecasts in the inventory replenishment cycle is determined from the formula (2) Sharma and others (2015):

$$\boldsymbol{\delta_{pt}} = \sqrt{\boldsymbol{\delta_p^2 \cdot T + \delta_t^2 \cdot P^2}} \tag{2}$$

Where:
δ_p, δ_t - Respectively - standard deviation of demand forecasts, standard deviation of replenishment cycle time

The second action is related to the identification of a contractual split point that separates the dependent demand for components from independent demand for components based on market needs. For the optimal distribution of the split point, the author of the article proposed to apply the empirical rule. The formula describing the rule determines the size of the security inventory in the central warehouse of the enterprise, the so-called centralised inventory holding (3) Krzyżaniak (2002):

$$\boldsymbol{Z_{bc} = Z_{bi} \cdot \sqrt{n}} \tag{3}$$

Where:
Z_{bc} – The security inventory of the central point,
Z_{bi} – The security inventory of the i-th warehouse,
n – Number of warehouses.

The conversion of the formula (3) allows for the decentralisation of the safety stock, i.e. its transfer to regional warehouses serving local markets. What is important here is that the level of customer service in both cases does not change.
Determining the optimum size of the safety stock is important when **selecting the inventory control method**. Classical, theoretical methods of inventory control do not always work in economic practice. In the model described above, the author proposed a method of hybrid inventory control.

The hybrid method is a combination of an information level system and a periodic review (Figure 3). The assumption of this system is a variable or fixed order volume. Procurement in the combined ordering system is carried out in two modes:

- Periodic procurement mode,
- Emergency procurement mode.

Under the periodic procurement mode, the procurement is determined and placed in accordance with to the rules appropriate for the periodic review system. The essence of this system is the fact that the procurement is placed in a specific, fixed cycle (T_0), the size of the procurement is variable and determined as the difference between the assumed maximum level (Z_{max}) and the current level of available (free) stock, while the delivery is carried out within a specific deadline (T), Korponai and others (2017), Hernandez-Ruiz and others (2016).

In the emergency procurement mode, before the T_0 procurement period, orders for a fixed volume are placed on principles appropriate for the information level system. A characteristic feature of this system is that the decision to place a procurement is taken when the level of available inventory is lower than a defined level, the so-called information level (ZI); Sellitto (2018), Peng (2018), Hernandez-Ruiz and others (2016).

The advantage of combined replenishment is, in addition to the possibility of creating collective procurements, the security against depletion of the inventory, which does not require a large security inventory. The disadvantage of the system is the need to keep track of the safety stock level at all times.

Fig. 3: Hybrid inventory control

Source: the in-house elaboration.

In economic practice, continuous monitoring of the level of available inventory is sometimes limited, and the reasons for this may be:

- Placing the delayed procurements in relation to the information level,
- Human errors, omissions, unplanned events,
- Organisational restrictions on the moment of the procurement placement or delivery deadline.

Simulation studies allow us to make a thesis:
When calculating the informational inventory level both the Expected value variance E (ΔT) of the ΔT delay and the standard deviation of the ΔT delay should be taken into account. Therefore the following formula for an adjusted information inventory is proposed Sharma and others (2015):

$$ZI = P \cdot [T + \Delta T] + \omega \cdot \sqrt{\delta_p^2 \cdot T + \delta_t^2 \cdot P^2 + \delta_{\Delta t}^2 \cdot P^2} \quad (4)$$

The research also confirmed that in this case the distribution of delays occurs in the uniform distribution form with parameters:

$$E(x) = \frac{a+b}{2};\ V(x) = \frac{(b-a)^2}{12} \tag{5}$$

Where:

$E(x);\ V(x)$ – Expected value variance of random variable
[*a, b*] – continuous uniform distribution interval

Verification of The Tests

The third phase of the model is related to the verification of the tests. Verification of the developed model was carried out based on statistical data collected during several years of observation of ΔT procurement execution time delays in the surveyed company and Monte Carlo computer simulation method. A sample of 50 delays was used for the analysis.

During this stage, it is important to determine the type of distribution of the studied characteristic. With this information, you can estimate the parameters of the distribution. The methods commonly used are: matching the empirical distribution to the theoretical and arraying. In the developed identification model, the distribution type was made by means of arraying. As a result of the measurement of the size of a specific characteristic (number of replacements of spare parts), a typical sequence of quantities is described in the form of an array. Observations can be divided into (6); Ślaski (2017), Brown (1959), Patrykiejew (1998), Sarjusz – Wolski Z (2000):

$$R = \sqrt{n} \tag{6}$$

disjoint classes of the same length equal to (7):

$$L = \frac{x_n - x_1}{R} \tag{7}$$

where:

L, R, n, x_n, x_1, denote in turn: class length, number of classes, number of observations, the nth characteristic of the ordered sequence ascending, the first value of the sequence.

In connection with the above, r-class (r=$\overline{1, R}$) includes observations that satisfy inequality (8):

$$x_1 + (r-1) \cdot L \le x_i < x_1 + r \cdot L \tag{8}$$

The mean of class can be determined from formula (9):

$$x^s{}_r = x_1 + (r - 0{,}5) \cdot L \tag{9}$$

After determining the number of classes, the number of elements in the class and the means of classes, the class probabilities should be determined using the classic definition. Couples: the mean of the class

and the probability of belonging elements to classes, create a probability distribution that can be written in the form of an array (Table 1), Patrykiejew (1998).

Table 1: Distribution of the probability of delays in order processing time of commodities (days) and the empirical cumulative distribution function of the variable x; F(x)

x	*p(x)*	*F(x)*
0	0.02	0.02
1	0.15	0.17
2	0.19	0.36
3	0.3	0.66
4	0.15	0.81
5	0.14	0.95
6	0.05	1

The code of the pseudo-random number generator has been developed (Fig. 4), which generates pseudo-random numbers according to the adopted uniform distribution. The corresponding code developed in VBA for Application uses the reverse distribution method. Randomly determined values of the y variable determining the procurement execution time delays, allowed for flexible decision making in regards of creation of appropriate sizes of information level (ZI) for different commodities procurement scenarios in the company.

Discussion

There are the number of methods for ordering goods and inventory management described in the literature. These are the methods of ordering goods in terms of homogeneous and various groups of assortments. Ordering parameters ranging from safety stock, maximum stock, information level, optimal delivery volumes are determined statistically.

The methods described in the literature are the empirical and theoretical methods - they cannot always be applied in practice and be verified. They are burdened with large statistical errors and their design causes that they are not flexible enough to respond to the changing economic situation, Trapero and others (2019), Stephen and others (2000), Gary and others (1998), Sharma and others (2015).

In practice, a computer simulation can provide a flexible response to changes in a company. The method based on the pseudo-random number theory described in the literature allows you to make decisions based on various ordering scenarios Brown (1959), Patrykiejew (1998), Sarjusz – Wolski (2000).

The author also noticed the need of combining the empirical methods into a hybrid form because he believes that only such a combination can bring benefits in the form of optimal ordering and minimization of costs. The author also paid attention to the need of correcting some ordering parameters what minimized the risk associated with shortages in deliveries and delays in order processing. The combination of these elements into one whole resulted in an innovative ordering model that flexibly responds to any economic changes Brown (1959), Murdoch (1965), Lewis (1975), Ślaski (2017), Sarjusz – Wolski, (2000), Krzyżaniak, (2002).

The presented model for perfecting the procurement process in the security management system in the supply chain based on the case of the surveyed automotive trading company may contribute to the elimination of uncertainty, thus improving the synchronization of the activities of the links in the supply chain. The synergy effect associated with the activities integrating the optimal safety stock with the ordering and control methods will contribute to shorten the duration of supply chain processes, guarantee an appropriate level of customer service and reduce costs.

According to the author, the directions of further work related to perfecting the procurement optimization in supply chains hould be related to the use of fuzzy logic and neural networks. The use of artificial intelligence would allow better verification of classic methods of ordering goods and controlling safety stocks, and thus would increase the efficiency of flows of goods and services.

Conclusions

The research conducted confirms that the use of the hybrid method to improve the procurement process in the surveyed company, as well as the use of Monte Carlo computer simulation to correct the procurement parameters, resulted in improved efficiency of the flow of commodities throughout the supply chain.

The company decided to move the security inventory from its own local warehouses, which supply the local market, to the finished goods warehouse of the manufacturing company, with which it cooperates in the supply chain. Due to increased inventory circulation (double increase of inventory circulation ratios) and reduced safety inventory, frozen working capital was released, warehouse space was released and thus storage costs were reduced.

The EPC notation described in the article is an effective tool for analyzing business processes, as it allows for continuous monitoring, control and analysis of processes. It allowed to describe the processes in a way that is understandable for the recipient and to recognize them precisely on the technical and application level. Today's organizations struggle with problems related to maximum use of IT systems and financial resources, but linking them into a single notation or standard can be a starting point for companies to gain a lasting competitive advantage in the market.

Towards an Inclusive Approach to City Marketing Communication

Magdalena DASZKIEWICZ

Wroclaw University of Economics and Business, Wroclaw, Poland,
magdalena.daszkiewicz@ue.wroc.pl

Abstract

This paper aims at developing an inclusive approach to city marketing communication. The theoretical considerations are based on literature studies on integrated marketing communication, city branding and inclusive place branding. The author proposes to develop the concept of integrated marketing communication by adding the dimension of inclusiveness, which is particularly essential in city branding. Inclusive marketing communication is to inspire, motivate and engage diverse stakeholders in city brand co-creation processes. The author considers the inclusiveness of city marketing communication in various areas, indicating selected conditions and instruments for the concept implementation.

Keywords: City Marketing Communication, Inclusive Marketing Communication, Inclusive City Branding, Inclusiveness.

Introduction

Social inclusion generally refers to an inclusive society in which every individual has the capabilities, opportunities and resources to participate in the economy and their community (Merrilees et al., 2014). The 'inclusion' philosophy focuses beyond the concept of 'some' and shifts the group effort towards the term 'all', while taking into account diversity. In practice, it means developing an environment that increases the motivation, satisfaction and commitment of diverse people (April and Blass, 2010).

'Inclusive place branding is made inclusive by adopting the idea of participation, enhancing it and facilitating stakeholder engagement' (Lichrou, Kavaratzis and Giovanardi, 2018). Creating inclusive city brands requires a multidimensional approach to marketing communication that is not limited to transferring messages, but includes dialogue and cooperation of various stakeholders in value creation.

This paper aims at developing an inclusive approach to city marketing communication. The theoretical considerations are based on literature studies on integrated marketing communication, city branding and inclusive place branding. The author proposes to develop the concept of integrated marketing communication by adding the dimension of inclusiveness, which is particularly important in city branding. The author considers the inclusiveness of city marketing communication in various areas, indicating selected conditions and instruments for the concept implementation.

The development of the theory of inclusive branding is supported by scientific achievements in the field of marketing communication. An inclusive approach contributes to the development of the concept of integrated marketing communication by expanding its dimensions.

From Traditional Marketing Communication to Inclusive Marketing Communication

The traditional marketing communication focuses on a message, a sender and a receiver of the message, having regard for noise, miscommunication or distortion that occur and interfere in the communication process. The process is linear, beginning with one message that is to be

communicated from an active sender to a passive receiver (Finne and Grönroos, 2009, 2017). The traditional marketing communication can be briefly described as one-way and single-source.

Using several sources and coordinating messages and media (one-voice) leads to what can be labeled traditional integrated marketing communication (Finne and Grönroos, 2017). Traditional IMC is a one-way, outbound system that is controlled and directed by the marketer (Schultz, Kim and Kang, 2014), who tries to integrate all outgoing messages into one voice and achieve the synergy effect (Finne and Grönroos, 2017). The concept represents the inside-out perspective, in which the marketer drives integration and a consistent message is conveyed to the consumer (Schultz, 1996). This approach reflects IMC in the first stage of concept development.
Moriarty and Schultz (2012) present (IMC) as a dynamic concept whose development is associated with a series of evolutions of familiar and established marketing and communication concepts. They identify a number of theories that support the evolution and various aspects of IMC (Table 1).

Table 1: Theories supporting the evolution of IMC (based on Moriarty and Schultz, 2012; Schultz et al., 2014)

Theory	Short description
Perceptual Integration Theory	People automatically integrate messages and experiences to create the integrated brand perception. Brands exist in the minds of consumers only through the process of conceptual integration.
Consistency theory	The natural tendency for consumers to strive for consistency in what and how they believe, experience, feel, and act. Message consistency is presumed to lead to communication efficiency based on synergy.
Reciprocity theory	Reciprocity occurs when marketers and customers both create value and share that value in some type of exchange system. Tilting the value too far on one side or the other will likely result in the relationship failure.
Relationship theory	Brand relationships and relationship marketing rely on, as well as lead to, interactive communication, creating such relationships. Long-term brand interactions solidify positive relationships within the stakeholder network and drive brand loyalty and advocacy.
Systems theory	The movement of communication from linear chains to complex systems of networked communication.

Perceptual integration theory gives a deeper understanding of how customers integrate messages and experiences to create an integrated brand perception. Brand images and positions exist in consumers' minds as subjective impressions. The degree of brand perceptual integrity results from the connections of individual impressions and associations. Therefore managers can only use marketing communication to attempt to cue an intended favorable response (Moriarty and Franzen, 2009). Consistency theories address the need for integration without conflict when a variety of messages are presented. Therefore are relevant to IMC, primarily to message consistency, which is presumed to lead to communication efficiency based on synergy. (Moriarty, 1996; Moriarty and Schultz, 2012).

A key element in the new view of IMC as interactive communication is reciprocity. It is related to the idea that all communication must sum to "win-win" situations, in which the marketer and consumers receive value from the communication activity for it to be continued. The IMC theory is built around the concept of stakeholders (individuals and groups who have an interest in an organization or an activity) and the connected relationship theories. IMC concerns a network of stakeholders in which people and their roles overlap. Various communication activities should be interlinked with some central brand message (core brand idea) resulting from the brand and communication strategy. Related to the stakeholder concept is the idea of brand relationships that drive brand loyalty and advocacy and relationship marketing that strives to develop long-term brand interactions that solidify positive relationships within the stakeholder network. (Moriarty and Schultz, 2012).

The systems theory moves communication from linear chains to complex systems of networked communication. The social network engages stakeholders in a variety of word-of-mouth and increasingly electronically delivered digital social media. The communication system includes the organization and its stakeholders, people they contact and the voices of their various stakeholder communities. Moriarty and Schultz (2012) view IMC as a communication system, which requires the use of holistic approaches: message synergy, communication network models, and non-linear analytical approaches.

Porcu, Del Barrio-García and Kitchen (2017) reviewed extant conceptualizations, definitions and theoretical models of IMC and conducted a detailed analysis of the construct dimensions identified in prior literature. Based on a comprehensive literature review, the authors proposed the modern IMC construct composed of four dimensions: message consistency ("one voice"), interactivity, stakeholder-centered strategic focus and organizational alignment.

The "one voice" dimension refers to the coordination and coherence of messages and channels, which constitutes the most basic level and the starting point of integration (Duncan and Moriarty, 1998; Schultz and Schultz, 1998; Kliatchko, 2008). Interactivity establishes a two-way symmetrical communication, leading to a dialogue between organization and stakeholders (Porcu et al., 2017). It refers to reciprocity being the basis for building relationships, speed of response and responsiveness (Johnson et al., 2006). Interactivity is enhanced by the use of digital technologies, which play a crucial role in the implementation of an integrated approach (Kliatchko and Schultz, 2014).

The stakeholder-centered strategic focus relates to the strategic goal of creating value for stakeholders and building long-term relations (Porcu et al., 2012; Porcu et al., 2017), which requires establishing and promoting a shared vision and working towards stakeholder-oriented solutions (Luxton et al., 2017; Porcu et al., 2017). The organizational alignment dimension refers to internal communication and integration, which allows cross-functional planning and horizontal and vertical cooperation (Porcu et al., 2017).

In marketing communication, we are increasingly dealing with co-creation processes. Marketers and consumers co-create brand-related content and social experiences on social media (Barger et al., 2016). Recent research emphasizes the importance of the customer's role in brand co-creation, and the impact of brand co-creation on brand knowledge and brand value (France, Merrilees and Miller, 2015). Brand communities and interactivity provide increased opportunities to co-create brands and play an influential role in the inclusion of consumers in co-creation processes (Muñiz and O'Guinn, 2001; O'Hern and Rindfleisch, 2010; France et al., 2015).

Inclusiveness can, therefore, be considered as the goal and the important dimension of marketing communication. Inclusive marketing communication is to inspire, motivate and engage diverse stakeholders in co-creation processes. Inclusion is associated with the degree to which individuals believe that their role is critical in the organizational process (Mor-Barak and Cherin, 1998), and the feeling of value and belonging (Bourke and Dillon, 2018). Therefore marketing communication aims to demonstrate the importance and value of participation and joint actions.

Inclusive Marketing Communication for Cities

Inclusive marketing communication is to inspire, motivate and engage diverse stakeholders in city brand co-creation processes. Anholt, an authority on city branding, states that 'the people make the city'(Anholt, 2006, p. 20). Referring to the concept of the service-dominant logic (Vargo and Lusch, 2004), Warnaby (2009) claims that stakeholders create from a specific combination of city elements value-in-use, which incorporate both economic dimensions (e.g. inward investment) and social dimensions (e.g., quality of life, regeneration), or a combination of both. Therefore they are at the same time consumers and creators.

Stakeholders play a multitude of roles within the creation of city brands. They are an integrated part of city brands and their identity through their characteristics and behavior (van Gelder, 2011; Braun, Kavaratzis and Zenker, 2013). Stakeholders serve as ambassadors for the place brand, who grant

credibility to any communicated message (Braun, Kavaratzis and Zenker, 2013). The city ambassadors can be residents, people associated with the city in various ways (in the present and the past), as well as tourists who visited the city. Residents also contribute to creating the city's brand as voters, which gives them real influence on the political elections of local government authorities (Braun, Kavaratzis and Zenker, 2013). Stakeholders can contribute to the city's brand by active participation in city-related initiatives at various stages of their implementation.

In recent years, the development of place branding and city branding theory is strongly associated with concepts of stakeholder's involvement (Kavaratzis, 2012), citizen engagement and participation (Braun et al., 2013; Hereźniak, 2017; Kavaratzis and Kalandides, 2015; Molinillo et al., 2019; Rehmet and Dinnie, 2013), co-branding city brand partnerships, relationships, networks (Hankinson, 2004; Kavaratzis and Ashworth, 2007; Harrison-Walker, 2013; Merrilees et al., 2016; Lucarelli, 2018). The scientific achievements in these areas provide the basis for the development of the concept of inclusive city branding.

Inclusive city branding is a form of place branding that: goes beyond economic interests and goals; focuses on the residents; integrates the voices of many non-powerful. Inclusive city branding adopts the idea of participation, enhancing it and facilitating stakeholder engagement (Lichrou et al., 2018). The development of the theory of inclusive branding should be supported by scientific achievements in the field of marketing communication. An inclusive approach contributes to the development of the concept of integrated marketing communication by expanding its dimensions.

The inclusiveness of city marketing communication can be considered in various areas. The first refers to the activities of stakeholders for the external promotion of the city, which can be undertaken by them independently or can be inspired by organizations responsible for city promotion. Because of the perceived authenticity and trustworthiness of word-of-mouth, internal stakeholders play an important role in the place brand communication process. They are considered informal, authentic and insider sources of information about the place by external target audiences (Braun, 2011; Braun et al., 2013). Therefore, city stakeholders may be treated as ambassadors or influencers. A simple way to involve stakeholders in city promotion is to provide them with relevant and interesting information, which can be forwarded to other recipients (especially through social networks). Cities can also involve stakeholders in city campaigns in various ways. They can become co-creators of the content of official city campaigns, participating in working teams and contests or sharing their personal stories related to the city.

Marketing communication can be used to involve stakeholders in city development planning. Participation in policy-making can be implemented at various levels: listening only (receiving information); listening and giving information; consultations and discussions; participation in analysis and agenda-setting, participation in reaching consensus on the main strategy elements; and involvement in decision-making on the policy, strategy or its components. At each level, participation may be narrow (few actors); or broad (covering many stakeholders). (Bass, Dalal-Clayton and Pretty, 1995).

The purpose of inclusive marketing communication is also to motivate stakeholders to participate in urban initiatives at various stages of their implementation. Communication and cooperation platforms are the basis for the inclusion of multiple stakeholders in joint activities for sustainable development and positive social changes. Marketing communication should also encourage and create conditions for interactions and relationships between various stakeholders and entities operating in the city.

The active participation of stakeholders in the planning processes and implementation of various programs can take the form of working groups, collaborative workshops, discussions, and debates. Muñoz and Bolívar (2019) highlight that the context of smart cities favors the development of technological and innovative spaces, increasing citizen participation. Local governments offer citizens different types of e-participation, which provides support with collective knowledge, ideas, and expertise (Muñoz and Bolívar, 2019). Interactive technologies and tools (web self-service portals, social media, interactive mobile applications) provide increased opportunities for the inclusion of different stakeholders in dialog and co-creation processes.

A critical aspect of participatory processes is that of consensus thinking. Therefore coherency and the formulation of a shared vision are generally highlighted as central in city branding literature (Jernsand and Kraff, 2018). A number of authors suggest that a city should have a clearly defined, shared vision (Moilanen and Rainisto, 2009; Stubbs and Warnaby, 2015; Warnaby et al., 2015) and communicate it to its stakeholders, especially to residents and entities operating within the city. However, an inclusive process must acknowledge diverging views of diverse stakeholders, which requires an ongoing 'dialogue, debate and contestation' (Kavaratzis and Hatch, 2013, p.82).

In business management managers usually prioritize and focus on selected key stakeholders. Such an approach in public sector management and place branding increases the risk of distorted stakeholder representations (Jernsand and Kraff, 2018) and 'leads to elitism, lack of inclusiveness and stakeholder representations where only certain groups are heard' (Kavaratzis, 2012, p.13). The diversity that is associated with bringing forward different perspectives can lead to creative tensions that allow expressing the essence of the city brand through different meanings. Therefore the task of city marketing communication is to support activities for diversity and social inclusion.

The basis of inclusiveness is to be a sense of identification with a place that can be reinforced by communication activities that refer to a sense of belonging. Inclusion is associated with the degree to which individuals believe that their role is critical and the feeling of value. That is why city marketing communication is also to demonstrate the importance and value of participation and joint actions.

Conclusions and Future Research

Scientific achievements in the field of integrated marketing communication and city branding provide the basis for the development of the concept of inclusive marketing communication for cities. The inclusiveness can be considered as the essential dimension of city marketing communication, and the condition and the goal for the development of city brands. Inclusive marketing communication is to inspire, motivate and facilitate stakeholders' participation in city brand co-creation processes. The inclusiveness of city marketing communication concerns city promotion, city strategic planning and implementation of various programs serving sustainable city development.

An important task is also strengthening the sense of belonging and demonstrating the importance and value of participation and joint actions. Inclusive city marketing communication is to increase the motivation, satisfaction, and commitment of diverse people, which means undertaking and supporting activities for diversity and social inclusion. A challenge for further research is the conceptualization and development of a measurement instrument for the identification and evaluation of inclusive marketing communication for cities. The exploration and clarification of the role of inclusiveness in marketing communication can contribute to such an approach to city branding, and as a result, sustainable development of cities.

Assessment of The Machining Centre Effectiveness on The Basis of Measures Used by An Enterprise

Katarzyna SZWEDZKA

Technical University, Poznan, Poland
katarzyna.szwedzka@put.poznan,pl

Abstract

The article focuses on selected indicators and their assessment on the basis of real data from a selected machining centre used for serial production. The author, after conducting an analysis based on the indicators proposed by the enterprise, proposes to separate failure times lasting less than 10 minutes, which are valuable information but do not require the intervention of maintenance services.

Keywords : Management Decisions, Key Performance Indicators, Machine Break Codes, Production Planning, Micro-Stop.

Introduction

Ensuring high effectiveness of production lines is possible if operational management decisions are rational and based on valid data reliably recorded by operators and maintenance staff [Jasiulewicz–Kaczmarek and Bartkowiak, 2016]. Based on this data, one can more accurately replicate the work of a technical system. The said data should make it possible to learn about and analyse the studied system and processes at such a level of detail that it would be possible to develop rational and effective methods of controlling activities implemented in them. Knowledge about the operational capabilities of technical systems and accurate interpretation of obtained data may allow in the future to perform more effective planning of maintenance work and more effective time management of operated facilities [Kosicka, et al., 2006]. In relation to machining centres, one assumes the assessment of a system that is beginning to operate, presuming that the system will be able to perform functions and that it will not undergo failure during the performance of tasks.

To assess effectiveness in enterprises, a system for measuring achievements is created using various measures and indicators. These measures are used to assess key activities carried out in various functional areas of the enterprise and indicate their effectiveness in relation to the assumed organizational objectives [Jasiulewicz–Kaczmarek and Żywica, 2016]. Enterprises should also precisely define what a technical failure is and how long it can last in order to perform irregular, yet effective, maintenance depending on the execution of the production plan [Linquist, 2010; Ratnayake, 2013].

Selected Effectiveness Indicators for Technical System Operation

The implementation of activities related to the operation of machines and devices [Florek and Barczak, 2004] is a process of continuous decision making, and thus a process of deliberately choosing one of the variants of future activity identified and recognized as possible. The proper definition of a technical system effectiveness indicator requires the determination of a measurement object. This means that the features tested are measured, for example, by numerical value or by the degree of intensity of a particular feature. Among the indicators, there are fixed and variable partial measures. Fixed partial measures refer to the initial input expenditure for the construction of an object and its implementation in production and is independent of the further course of the operation

process. Variable measures depend on the variable operation process and relate to the probability of events and relationships occurring during the use of a technical system.

The choice of model assessment relates directly to the technical system in use, activities implemented with it and the technical and organizational environment. The selection of appropriate measures should be based on [Loska, 2011; Żółtowski, 1996]:

- technical condition, being a measure of the object's ability to be operated at a given time;
- reliability, describing the object's readiness for operation in statistical terms;
- quality, determining the object's ability to satisfy needs;
- functionality, referring to the machine-human relationship;
- effectiveness, related to functionality;
- serviceability, describing the object's susceptibility to performing maintenance activities;
- diagnosability, determining the object's susceptibility to obtaining information about the technical condition.

An overall assessment of the effectiveness of the operation process of machines and devices can in many cases be sufficiently obtained on the basis of the use of synthetic indicators [Loska, 2011]i.e.

- indicators related to using one machine, production line or general use of the entire technology park;
- indicators concerning device performance;
- indicators concerning profitability.

Among contemporary models, which are the basis for the quantitative assessment of the operation of technical systems, [Loska, 2011] distinguished measures which are most often described in the literature at theoretical and functional levels. They are:

- a reliability model;
- an Overall Equipment Effectiveness (OEE) model;
- a Key Performance Indicators model.

Key Performance Indicators

Effectiveness assessment measures refer to financial and non-financial key performance indicators, which are used to assess the operation of machine parks in the enterprise. They allow to use information collected by the enterprise on the operation of technical facilities for diagnostics of ongoing maintenance activities through [Biały and Hąbek, 2016]:

- measurement of the condition of the facility and operational services;
- presentation of current and historical values of measures of operational properties and relationships between them;
- comparing internal and external activities of operational services;
- diagnosing weak points in maintenance activities;
- tracking changes and progress in the operational system;
- implementing a continuous improvement process by searching for and eliminating deviations from assumed values;
- constant supervision over organizational and technical changes.

KPIs for maintenance are included in the PN-EN 15341: 2007 Maintenance – Maintenance Key Performance Indicators, developed by the European Committee for Standardization (CEN), which contains a unified set of measures. The standard contains 72 measures along with a detailed description of their elements divided according to the following criteria:

a) Type of decision, i.e. activities taken by maintenance services:
- economic measures (indicators) expressing the cost value of a selected operational aspect;
- technical measures (indicators) expressing the time value of a selected operational aspect;
- organizational measures (indicators) expressing the paraoperational value of a selected operational aspect.

b) Decision level [Adamkiewicz and Burnos, 2012]:
- 1st level describing indicators at a general level;
- 2nd level describing indicators at an intermediate level;
- 3rd level describing indicators at a detailed level.

Using the markings used in the PN-EN 15341: 2007 standard, the division of indicators is shown in Table 1.

Table 1: Structure of KPIs. (Source: elaboration based on PN-EN 15341: 2007)

Description	Technical indicators	Economic parameters	Organizational indicators
General level (machine park in an enterprise	T1, T2, T3, T4	E1, E2, E3, E4, E5, E6	O1, O2, O3, O4, O5, O6, O7, O8
Intermediate level (production line)	T5, T6, T7, T8, T9, T10, T11, T12, T13, T14, T15, T16	E7, E8, E9, E10, E11, E12, E13, E14	O9, O10
Detailed level (power supply)	T17, T18, T19, T20, T21	E15, E16, E17, E18, E19, E20, E21, E22, E23, E24	O11, O12, O13, O14, O15, O16, O17, O18, O19, O20, O21, O22, O23, O24, O25, O26

The standard shows the indicators that can be considered the most important and specifies the method of their proper selection taking into account the selection criterion (Table 1.):

– selection of indicators among those available;
– choice of a method based on the functional analysis of various machine maintenance processes.

In enterprises, in relation to the management and supervision of technical systems in operation, one strives to obtain data on reliability, serviceability and effectiveness. Among the available KPIs, the most common ones which can be found in enterprises with production lines for serial production are: MTBF (Mean Time Between Failure), MTTR (Mean Time To Repair) and Mean Time To Failure (MTTF).

MTBF - mean time between failure:

The most commonly used reliability measurement indicator shows the arithmetic mean of the times between system failures. The measure assumes that the system is ready for operation and can be used immediately after failure has been removed [Szwedzka, et al., 2017].
The measure is described by the following relationship:

$$MTBF = MTTF + MTTR \tag{1}$$

where:
$MTTF$ - *mean time to failure;*
$MTTR$ - *mean time to repair.*
The MTBF indicates how often from a statistical point of view a given technical object fails. In enterprises, this indicator is used to develop schedules for preventive reviews.

MTTR – mean time to repair:
This measure is the most commonly used measure of maintenance effectiveness and measures the average time that is needed to perform repair activities in all moving parts of the system. This indicator provides information about the time of device repair and maintenance [Pourjavad, et al., 2011].

$$MTTR = \frac{total\ repair\ time}{number\ of\ repairs} \tag{2}$$

The range of activities measured can vary, but generally includes:

- time needed to correctly diagnose the cause of failure;
- time needed to order and deliver components necessary to repair the failure;
- time needed to access the damaged part;
- time needed to replace the damaged part;
- time needed to restore the device to its operational status;
- time needed to verify that the device is functioning in accordance with its specifications.

MTTF - mean time to failure:

The measure indicates the average working time from the start of the operation of the technical system or from the time of the last maintenance activity until the moment of the next failure [Szwedzka and Jasiulewicz - Kaczmarek, 2016]. The indicator is presented as follows:

$$MTTF = \frac{available\ working\ time - failure\ time}{number\ of\ events} \tag{3}$$

The MTTF indicator defines information on the time of repair and maintenance, including, among others, time needed for: the correct diagnosis of the cause of failure, ordering and delivering components necessary to remove the failure, restoring the operational status of the technical system. In the event of replacing the damaged parts, it assumes time necessary to deliver the defective technical system element.

Scope of Research

The enterprise uses the MTTR, MTTF, MTBF indicators to assess the time of proper operation and the time of production line repair. Table 2 summarizes the measurement results obtained from each month in the period of one year for the selected machining centre.

Table 2: Example of the MTTR, MTTF, MTBF values from the period of one year for the selected machining centre

Month	**I**	**II**	**III**	**…**	**X**	**XI**	**XII**	**Average failure time in a year**
Total number of failures								
time [min]	2154	2547	1797	…	1627	1910	2538	1739
number of failures [pcs]	246	249	219	…	213	231	206	208

MTTR [min]	9	10	8	...	8	8	12	8
MTTF [min]	161	152	196	...	202	166	155	184
MTBF [min]	170	162	204	...	210	175	168	192

Adding up downtime regarding the failure status of the production line (Table 2), it results that the average failure time is 1739 minutes. One can also expect about 200 failures each month with an average repair time of 8 minutes. In such a short time it seems impossible to simultaneously locate the place of the event, determine the cause of it, call and wait for maintenance services and carry out the appropriate repair or replacement of the worn-out part. Also, the probability that a failure may occur, on average, every 184 minutes is low because of becoming acquainted with the execution times of a given product batch.

Of course, it can be concluded that the indicators (MTTR, MTTF, MTBF) used by the enterprise give information that, to some extent, provides knowledge about the state of machine failure. However, the indicators can be quite easily "manipulated" by adding "micro-failure" times (failure up to 10 minutes), which both applies to an employee's short break or refers to a machine failure. Due to this, drawing conclusions does not offer greater probability that it will actually occur. However, such information is important when preparing production plans, indicating areas that should be improved with the participation and involvement of all employees of the enterprise.

In order to make the research more detailed, it was verified how and what information is saved in the system by production line users. Reporting methods adopted by enterprises were also analyzed. Bearing in mind the object of the research, the further part of the paper focused mainly on the events and failures of machines being part of the production line.

Methods for Reporting Downtime

The enterprise under study uses a specialized IT system. The system is used to supervise the technical condition of machines and prepare reports on the production process, including the number of units produced and the times of their technological processing. The software allows to collect information on production effectiveness, constituting the basis for KPI calculations such as OEE (Overall Equipment Effectiveness), MTTR, MTTF, MTBF and defining the production planning framework. It also allows to calculate the production capabilities based on the electronic order and execution report, and makes it possible to record all events that cause each break in the operation of the machining centre. Among the information reported by operators, one can distinguish:

- records of the performance of production orders for each shift;
- records of information regarding the stoppage of the production line, including information on the failure status of its elements;
- system records of material turnover management, machine documentation, warranties and records of performed inspections;
- exchange of information by technical supervision staff between other plants with a similar profile in order to manage parts more effectively;
- archiving of information to eliminate potential errors and improve the functionality of the future machine park.

Example information about the studied complex technical system is saved in the form of codes (Table 3), which are kept by the production line operator in the system. In the event of a technical failure, additional information is supplemented to the system by a member of maintenance staff.

Table 3: Example code list with interpretation. (***Source: own elaboration based on enterprise data***)

1	Waiting for material	21	Turntable failure
2	Machine setting	22	Milling machine failure
3	Starting the machine	23	Mechanical failure
4	Adjusting during production	24	Receiver failure
5	Meal break	25	Feeder failure
6	Meeting	26	Transporter failure
7	Machine maintenance	27	Electric failure
12	Failure-undefined	32	Drill failure
13	Control failure	33	Sensor failure
14	Scanner failure	34	Lift failure

When saving information about the reason for downtime, the operator selects one of the available codes, which automatically displays the reason for the event. Descriptions and interpretation of each code are available in the system and in the event of misinterpretation, the employee can read them. An example of a code regarding failure of lifts and failure due to lack of compressed air is shown in Table 4.

Table 4: Example of codes used by the enterprise. (Source: own elaboration based on enterprise documents)

Code usage standard				
Failure time - downtime during which the machine does not produce components due to technical problems directly related to the infrastructure or the object itself.				
Code type/family	Code number	Code description	When should the code be used?	Why should the code be used?
Failure time: [min] type: *failure*	45	Compressed air	The "compressed air" code should be used to report: technical problems related to compressed air; lack of compressed air in machines/lines.	To obtain reliable data on downtime and reduce future machine and device failures.
Failure time: [min] type: *failure*	34	Lifts	The "lifts" code should be used for reporting: technical problems related to the system of lifts in machines/lines	To obtain reliable data on downtime and reduce future machine and device failures.

New Failure Reporting Concept

In the following part, codes regarding the analyzed production line related to the failure states of its elements are distinguished. Four categories of downtime are singled out [Loska, 2013; Szwedzka and Jasiulewicz-Kaczmarek, 2016]. The first group depends on the operational effectiveness in technical

terms, focusing on the observation of downtime at the time of technical system damage, i.e. transition from the state of operability to the state of inoperability. The second group was described on the basis of codes relating to the preventive actions taken for the production line. The third group of downtime was described by codes depending on the method used to manage the organization and the adopted performance standards for manufactured elements [Żółtowski, 2012]. In the fourth group, it was assumed that the failure status of production line elements lasting less than 10 minutes does not cause damage to the machining centre requiring maintenance services intervention. On the other hand, the reasons for the occurrence of micro-failures can provide valuable information about problems occurring during the implementation of technological processes, indicating the most common faults employees face. The characteristics of the downtime categories for the above concept are presented in Table 5.

Table 5: Characteristics of the downtime category

Downtime category	**Technical level**	**Preventive level**	**Management level**	**Information level**
Characteristics	Specifies the technical condition of failures of technical system elements	Specifies service activities to extend the life of technical system components	Determines the state of implemented technological and organizational processes in the enterprise	Provides information about the potential failure of technical system components
Object	Machine failures: milling machine, drill, transport, feeder and receiver, scanner, lifts, compressor, electrical and mechanical failure, starting (voltage drop)	maintenance, machine cleaning, calibration of settings, reorientation	breakfast break material shortage no space	micro-stops up to 10 min

Selection of the fourth information category (Table 5) was based on the analysis of all occurring micro-stops, where it was noted that problematic situations were solved by operators. It follows from it that there was no need to call for maintenance services to solve the problem. Examples include, e.g. the *machine cleaning* code when the operator uses compressed air to clean a photocell that indicates that the machine is to perform a specific operation. Such an event occurs as a result of excess sawdust and dust generated both during machining and drilling. This is not a failure that would require maintenance services intervention, but it provides information that the blowing system should be improved. Another example is the *feeder failure* code, where the operator noticed that an element intended to lift the semi-finished product from the pallet fell out of the feeding arm. This means that it had not been properly installed or became loose during use. The above situation can be treated in two ways. This may be a mistake made by the operator responsible for fixing the element or information that this part loosens up during operation. In each case, conclusions should be drawn to prevent such situations from occurring in the future. An example of similar events is shown in Table 6.

Table 6: Example of micro-stops recorded by enterprise operators.
(***Source: own elaboration***)

Downtime site	Event description	Stoppage time [min]
Drill	No power in the second drill	7.66
Milling-tenoning machine	Limiting switch failure	9.08
Milling-tenoning machine	Clogged lift	1.01
Receiver	Software reset	4.04

Based on the above interpretation of micro-stops (Table 6), a comparative analysis was performed in relation to calculations carried out and presented in Table 4 with the use of machine and device effectiveness indicators used by the enterprise. The obtained results are shown in Table 7.

Table 7: Values of the MTTR, MTTF, MTBF indicators for the period of one year for the selected machining centre (*Source: own elaboration based on the assumptions from Table 3.6*)

Month	I	II	III	…	X	XI	XII	Average failure time in a year
Total number of failures								
time [min]	1835	2238	1609	…	1250	1535	2211	1459
number of failures [pcs]	37	42	43	…	26	57	54	37
MTTR [min]	50	53	37	…	48	27	41	40
MTTF [min]	1079	907	1001	…	1669	680	599	1106
MTBF [min]	1129	960	1038	…	1717	707	640	1146
Production line downtime below 10 minutes/month/average per year								
time [min]	319	309	188	…	376	375	326	279
number of failures [pcs]	66	65	37	…	77	97	74	60
MTTR [min]	5	5	5	…	5	4	4	5
MTTF [min]	628	616	1201	…	575	412	463	710
MTBF [min]	633	620	1206	…	580	416	467	715

The summarized data contained in Table 7 in the last column show the average time in minutes which may be the probability of a production line's inoperability. One should expect that the enterprise, as a result of the analysis and using KPIs, may receive information on how many times a month a failure

occurred – hence, it can be concluded that approximately 40 independent events of the system failure state may take place.

The research results presented in the "information" column contain machine downtimes of less than 10 minutes, which the enterprise currently classifies as "technical failure". Comparing the numerical values presented in Table 2 with the results obtained and summarized in Table 7, there was no change in both times and frequency of stoppages as a result of planned maintenance activities carried out by maintenance services aimed at extending the life of the technical system. Also, no changes were made to the calculations relating to management methods. On the other hand, the "micro-stops" described from the information level average 5 minutes, which is consistent with the adopted assumption that they do not require maintenance services intervention. Also, the time considered from the technical level increased from the average value for one year of operation from 184 minutes to 1106 minutes (time of remaining in the operational condition). The repair time was 40 minutes on average. Both the time of correct operation of the system and the time of its repair confirms the author's belief that both the first and second values are probable.

Conclusions

The paper describes the total time of failures lasting up to ten minutes in a specified period of machining centre operation and is compared with the effectiveness assessment model used so far. It was assumed in the paper that the failure of a complex technical system cannot last 8 minutes and that the correct working time of the machining centre is longer than the obtained average of 184 minutes. Table 6 shows that the micro-failure time may be interpreted as "annoying" information and activities for the machining centre staff, not requiring, at the same time, the intervention of maintenance services.

Abstract

This article analyzes the potential role of financial inclusions in social networks and formulates a number of hypotheses about future financial intermediation based on social networking platforms. To describe financial inclusion in social networks, new models are needed that allow us to analyze the complex behavior of agents at different points on the complexity scale. The article identifies the main trends leading to the formation of financial inclusions, outlines a number of approaches to the analysis of the stability of these inclusions. A specific problem is discussed - the condition for generating financial inclusions in social networks and a simplified model is developed by which a real system is characterized. Financial inclusion in social networks is presented in the form of a potential set of financial services received by users of the network when using a social site. Financial inclusion is different from traditional financial intermediation and financial start-ups, but they depend on them and can act as their element, but (i) are built into social networks or (ii) financial functions that are performed directly by social sites. There are three main scenarios for the development of financial inclusions based on social media platforms: (i) super mediation - turning social media platforms into a platform for various types of mediation, including financial intermediation, (ii) stabilization of financial inclusion in social networks and becoming their main form of financial intermediation, and (iii) a re-intermediation scenario in which financial inclusion in social networks will play an insignificant role in financial intermediation and there will be a further differentiation of financial intermediation in the electronic market. The probability of each scenario depends on many factors, including the exact functions that intermediaries play in each case, usefulness for agents of the chosen methods of interactions, state regulation. The paper proposes approaches for discussing each development scenario.

Keywords: Multi-Agent Systems, E-finance, S-commerce, Social Networks

Introduction

Social networks are an example of spontaneous development (Mahmoodi et al. 2020) and a high level of self-organization (Eigen, 2017; Nicolis and Prigogine, 1977). They are constantly being transformed from one state to another. Currently, a promising area of change is, firstly, the attraction of social media platforms for the promotion of goods and services, as well as for payments, and secondly, the use of social networks by financial and commercial intermediaries as a source of information about consumers. Under the influence of electronic technologies and interactions with social networks, financial intermediation is moving to a new stage of development (Ghost, 2016), and social networks significantly expand their area of activity (Huang and Benyoucef, 2013). The interaction of social networks with financial and commercial intermediaries is capable of revolutionizing the information and financial space, the organization and structure of mediation, as well as the forms and methods of providing financial services to the end-users.

Social networks are able to offer all the same services and products as traditional financial and commercial intermediaries (Nelms et al. 2018) but, firstly, do it all in a “single window” - along with other information and during social communications, that is, transfer service to network users into omnichannel, including in this concept the whole complex of social, communication and financial interactions. However, at present, such prospects from the technological, organizational and legislative sides, as well as from the point of view of transaction security, are not yet sufficiently developed and there is no clear understanding of the conditions for their fulfillment. However, development trends in this direction are clearly visible.

Secondly, decentralize and delocalize the place of supply of services. There are opportunities to eliminate the attachment of financial services to the time and location of the office of the financial intermediary or directly to the consumption of the service. In this case, the services are combined with social interactions and performed directly at the location of the network user.

Thirdly, to personify the offer of services by reorienting the universality, mass character and homogeneity of financial services to their individualization, accurate execution and full compliance with the interests of the user. At the first stage, the digitization of financial services allowed the prevailing wholesale nature of banking to be translated into a massive wholesale and retail channel. This process took place mainly through the universalization of financial services. At the present stage, new algorithms have made it possible to switch to the personification of the offer of financial services.

Nevertheless, the prospects for the interpenetration of e-finance and e-commerce with social networks are still not completely clear. It is at the initial stage but tends to accelerate (Bharadwaj et al. 2013). At the same time, a notable trend is the monetization of social networking platforms and their participation in scaling financial services and trade. Monetization can act as a kind of guarantee for the further development of this process. Especially the problem of monetization of financial inclusion in social networks relates to smartphones and various applications (Hawley, 2019).

Modern social media platforms are a combination of Web 2.0 technologies that enable commercial activities to be included in the social platform (Constantinides and Fountain, 2008). Financial intermediaries are moving to the use of these platforms since they will allow connecting the business with end consumers. The interaction of a financial intermediary, a social network, and a user can be thought of as a multi-agent system (Jascanu et al., 2007). Doing business on a social platform provides interested parties with the information necessary to achieve the goals of each party. Information exchange, user content, and interaction with different types of users are three very important functions of social networks.

The introduction of the Internet and e-commerce has led to the automation of many tasks performed by financial intermediaries, as well as the emergence of additional intermediary links. Moreover, in a number of cases, the significance of these additional intermediary links increases significantly and, in connection with this, the role of traditional financial intermediaries changes. However, the key point is whether updated intermediaries bring value to new paradigms (Yinping 2007). Social networks have not accidentally included the position of electronic financial intermediation in their activities. For this, they had appropriate prerequisites, among which mediation in social communications stands out.

The problem boils down to the ability of social networks, firstly, to provide a variety of value-added services, as traditional financial intermediaries do; secondly, whether social networks can compensate for the negative consequences of additional costs that are added to the value chain in connection with the advent of additional mediation (Giaglis et al., 2002); thirdly, how useful are the efforts of all participants in the value chain in the context of adding a new element in the form of social networks, that is, do the utility have new functions.

A general approach to value chain analysis was proposed by Bakos (1998) and Giaglis et al. (2002). Basically, value-added intermediary services are associated with an integrated approach, including

ensuring the connection of buyers with sellers, finding a price compromise, facilitating a transaction, and ensuring the appropriate infrastructure. Social networks offered all of these features. Their platforms are fully suited to serve digital market activity (Turban et al., 2002), including financial intermediation.

The conceptualization of the behavior of financial intermediaries, social networks and their users in the process of their interaction is possible with the accumulation of statistical data. Nevertheless, a hypothetical review of changes is important both for assessing the possible options for the impact of changes on financial intermediation, and the role of mediation of social networks in the interaction of financial intermediaries with customers.

A Formal Framework for Studying

A fairly large amount of academic and practical literature is devoted to social networks and the establishment of their commercial functions (Nelms et al. 2018), to financial intermediaries and digitization of their activity (Ghosh, 2016; Oskarsdottir et al. 2020), and the development of electronic commerce (Iyer et al. 2020). However, there are extremely rare works explaining the inclusion of financial services in social networks (e.g., Nyagadza, 2019; Macmillan, 2016) and there are no works on conceptualizing the nature of financial intermediation in social networks.

Design/Approach

This article sheds light on the breakthroughs in traditional financial intermediation that are caused by the use of social networks in this area. This article aims to identify the conditions and reasons for embedding financial services in social networks.

To determine the structure of the work, it is divided into two sections:

1) Financial inclusion in a social network is considered as the result of a multi-agent system - financial intermediaries, social networks, network users. Conditions, properties and interpretations of stability and instability of the financial integration system in social networks;

2) A specification of the environment of agents is carried out - direct and indirect interactions are determined. The formulation used is based on a proposal for a model of action and reaction (Genesereth and Nilsson, 1987). The effect of direct and indirect (through social networks) impact of financial intermediation on network users is estimated.

Agents behavior in the system of financial inclusions in social networks

Currently, a new resource allocation system has been created, which is based on the Internet. This system is responsible for the distribution of information, financial, commodity resources between its users. It creates an alternative to the traditional supply and demand system and participates in the preparation of decisions at all levels of activity. It also includes the use of all types of electronic services, such as e-finance, e-commerce, electronic entertainment, and even electronic medical diagnostics. Homes, workplaces, training centers, and vehicles use web networks to offer more options. However, the overall management of such a multi-agent system remains a challenge (Perez et al. 2013), especially when matching supply and demand (Leon, 2015) in mobile and complex financial services. In this area, a system of multi-agent networks that interact with each other is emerging (Franchi E. and Poggi A., 2011). The article discusses the interaction of the financial intermediation system with the social networking system (Jiang and Jiang, 2014) and the formation on this basis of financial integration in social networks. The interaction of various sides of the system of financial inclusion in social networks can be considered as a multi-agent dynamic stochastic system.

Systems such as “financial intermediary — social network — network user (FI-SN-U)” can generate various types of behavior, from asymptotically stable to chaotic (Leon, 2015). The stability of the system is ensured by the constant formation of supply and demand for financial services, as well as

the participation of social networks in its provision (Castelfranchi, 2014). The FI-SN-U system is a multi-agent system. It has a specific architecture and is characterized by the behavior of its participants (Birkin and Wu, 2012). By dividing the system into simple interactions and finding out simple rules of behavior for individual agents, one can consider a rather wide range of behavior that helps to understand the functioning of financial inclusions and the behavior of various agents (Sun, 2009).

Any actions of various agents are based on a certain decision-making process, during which behavior is coordinated, during which certain restrictions arise. The coordination problem in such systems is a complex task, since the actions of agents, although rational, are asynchronous and on the wholly random. Variations in the behavior of individual agents can affect the state of financial inclusions and lead to further their extension or contraction.

This study does not examine an agent such as the state and its regulatory bodies, which has a significant impact on the development of the entire system. Legislative standards under development can stimulate or change and completely inhibit trend leading to the formation of financial inclusions in social networks (e.g., by licensing financial activities of social sites). An important factor in the development of this system is also a change in the behavior of agents over time (Hofbauer and Sigmund, 1988), which can be associated with both cooperative and non-cooperative behavior. As a result, changes are possible in the mechanisms, forms, and dynamics of cooperation (Novak et al., 2004) and the spread of financial inclusions.

Financial inclusion in social networks can be represented as the result of group behavior, which can be described in terms of evolutionary game theory (Smith, 1974). At the same time, the actions of random network users are evaluated using simple adaptive rules of rational behavior, rather than a form of coherency of opinions and strategies (Wallace and Young, 2015). Nash equilibrium means the coordination of behavior between a financial intermediary and a network user. Moreover, equilibrium serves as a rest point of the dynamic process at the level of network users who have chosen financial services, and not a form of coordination between beliefs and strategies. These interactions are not limited to the formation of financial inclusions. They also lead to changes in agents - financial intermediaries and social networks.

The development of financial inclusion occurs in stages. At the first stage, social networks include simpler forms of financial services, for example, related to payments for goods and services, cross-border money transfers. Gradually, there is a transition to the following stages - more difficult, including investment and stock consulting, stock trading, lending, and insurance. In this case, the transients in the system are different. They are associated with a sudden change in system properties. So, certain leaps in development are possible, for example, a change in the behavior of Facebook and its users in connection with the introduction of Facebook's own digital currency. In such cases, a certain parameter of the system undergoes a change in the threshold. Similar transitions were observed earlier in various fields, for example, in graph theory, when there was a transition to the study of random graphs (Janson, 2000). During phase transitions, agents update their state and some properties based on new information. In many cases, the problem arises of extracting basic information from noise (Liu et al. 2005). In digital systems, threshold transitions can be spasmodic (Briscoe and Wilde, 2008). In such cases, the accumulated changes overcome the threshold barrier for entering a new phase and state of agents.

Statistical and Game Interpretation Approaches

The evolution of financial inclusions can be considered from a statistical point of view as the evolution of a multi-agent system. It has the original matrix and transitions during the Markov process. The state of such a system at each time step represented is represented by a random variable Xn. It is a vector. It contains the probabilities of certain parameters that determine the actual state of financial inclusion (for example, agent positions, supply and demand for financial services and their characteristics). In this case, the system of financial inclusion in social networks can be considered stable (Moreau, 2005), since the distribution of states converges to the equilibrium distribution, that

is, to such a position: $P\ (Xn = j) \rightarrow \pi j$ when $n \rightarrow \infty$. In this case, the financial inclusion system is stable, since at large values of n the probability distribution of the states of the system is ensured regardless of the time step n (Wilde and Briscoe, 2011).

However, such an interpretation of the state of the system cannot be easily applied for multi-agent interaction, leading to financial inclusion in social networks (Mahmoodi and Gonzalea, 2019). There is a certain set of justifications for this. Firstly, the visible output of the system is discrete (expressed in several states), but continuous. Significant amounts of high noise data are difficult to process. It is especially difficult to identify unknown parameters behind a noise-contaminated system with a time delay. Different identification methods with noise correction are used for identification (Zhang and Xu, 2017). Secondly, all interactions in the financial integration system are deterministic. The slightest changes in the initial conditions change the overall picture. With a statistical interpretation of a larger number of behaviors, the probabilistic structure will only generate approximate values of the real evolution of a particular configuration. Nevertheless, the evolutionary theory of games allows one to determine the strategies of agents and their usefulness (Fogarty and Feldman, 2015), and in combination with phylogenetic methods, it is possible to establish the phased formation and phase transition from one transition to another stage and the type of financial accessibility (Greenhill, 2015). Thirdly, there is a significant accumulation of various nonlinear effects, which greatly complicates the estimation of transitions between different states of the system. The fact is that these transitions occur spontaneously and are independent of the decisions of one agent. Transitions are based on aggregated solutions of all participating agents. If we go over to a multi-agent system as a continuous Markov chain with discrete-time with a potentially unknown distribution of the transition probability, then the stability of the system is the result of the actions of all agents - it acts as a cumulative effect (Chapter 2009).

Stability is a developed and relatively well-understood concept in physics, where it is considered as a property of a system to constantly return to a state of stable equilibrium after a small disturbance. In turn, in mathematics, the definition of stability is not suitable for the context of multi-agent financial systems that are of a game nature and are stochastic systems (Chli et al., 2003). In the socio-economic sphere, the stability of multi-agent systems is defined as preserving the basic properties of the system and returning it to its initial state after various disturbances - noise, changes in parameter values, adding or removing agents.

If a small initial disturbance becomes significant, the system goes into an unstable state. A multi-agent financial system is in equilibrium when the statistical properties of its market performance indicators remain constant, including cases of changes in external conditions that can affect the system (for example, during changes in government regulation) (Lee et al., 1998). In the course of violations in financial intermediation systems (for example, under the influence of digitization of finance, the development of financial recommendation systems, etc.) and social networks, the final states of the systems change (Leon, 2014).

Multi-agent systems formed in the form of financial inclusions in social networks can be represented as a set of agents participating in a multiplayer game. In-game theory, stability is the leading property of equilibrium. In this case, the problem of finding equilibrium is reduced to choosing the optimal strategy. Then, stability can be used to describe the characteristics of a set of strategies in equilibrium. If the strategy of each player is the best response to the strategy of others and no player has an incentive to deviate from the chosen strategy, then this state is Nash equilibrium (Nash, 1950).

The stability of the financial inclusion system can also be defined as the totality of all actions that all agents in the system carry out. In this case, the equilibrium point will be the point at which each agent takes the current state and does not need further work in the system. The set of actions of various agents is stable. In this case, each agent in the set acts as if in concert and the behavior of each agent will be as if it were suggested by a crowd or predicted by many (Bracciali et al., 2004).

When considering financial inclusions in social networks as a multi-agent system, the main difference in the game approach will be that the observed behavior is taken into account, and not the decisions made by the agents.

Nonlinear Interpretations

In the context of the provision proposed by Zhang et al. (2019), systems related to financial intermediation and social networks can be represented as systems with an irreversible process of increasing entropy, which is created by many elements of these systems. Moreover, these systems are far from the equilibrium point. The state of movement of the elements seems chaotic due to instability (Klioutchnikov et al., 2017). The form of movement is very sensitive to the initial conditions and is not entirely random. The development of nonlinear science, especially the theory of chaos and fractals, allows us to consider the formation of financial inclusions in social networks in dynamics as a random deterministic process.

Interpretation of external behavior

From a practical point of view, stabilization of financial inclusion in social networks can be defined in a simple way as the absence of further changes in agent utilities, starting with a specific time step of modeling.

As Leon (2014) showed, a multi-agent system can exhibit many types of behavior, such as stable, periodic, chaotic, and non-deterministic unstable behavior. Therefore, for the system of financial inclusion, it is necessary to distinguish between stable and unstable behavior. Small periodic fluctuations in the utility function in the system are related to steady behavior.

The financial inclusion of the system may exhibit unstable behavior (deterministic chaotic or non-deterministic unstable). In this case, the agent utilities demonstrate changes throughout the simulation. System stability can be considered as statistically. According to a simple analysis of Hosseini et al. (2014), the probability of instability increases with the number of agents in the system, and the generation of random sequences increases. This conclusion is not surprising since instability clearly depends on the complexity of the interaction of agents. But it also indicates that the more complex the system and the more participants, the more successive random coincidences, which just lead to the formation of new quality - financial inclusions in social networks.

Internal interpretation of behavior

Despite the obvious usefulness of external interpretations of stability, they are not able to identify two fundamental issues of the stability of financial inclusion: the possibility of changes and even a complete change in the development vector after the occurrence of financial inclusion; the possibility of stability of financial inclusion after significant changes in the system and in the actions of agents. In fact, this solution to the problem relates to determining the conditions for maintaining the stability of the system in the long term.

The answers to these questions can be found only by opening the “black box”, which hides the actions of agents involved in the formation of financial inclusion in social networks.

Stability arises only when agent interactions follow a certain logic and have a certain structure. In accordance with the game-theoretic rules, the interaction of an agent with an agent is effective when utility arises for the first and second agents.

This situation corresponds to the following conditions: agent - financial intermediary (Z), agent - social network (X) has the greatest social result, and agent - user of the network (Y) interacts with agent X and Z (Figure 1). If all agents Y1-n continue to interact with agent Z, then the utilities they receive are the same at every time step, and their utility functions quickly converge. Moreover, if

these functions depend on Z, then the utility functions converge on the platform of social networks and participate in the formation of financial inclusion in social networks.

Agent Y's assessment of agents Z and X is very dynamic. The result of the function, the outcome of the utility for interaction agents, may decrease. In such cases, there may be a violation of the stability of financial integration in social networks. Agent Y may return to a relationship with agent Z directly, without intermediary X. In such cases, the stability of the financial inclusion system is undermined.

Three-Agent-Based Model

A hypothesis is put forward that social networks mediate the interaction of financial intermediaries and network users. In this case, the analysis can be carried out with the help of three-agent-based model: a financial intermediary, a social site and user of the site - the final consumer (Figure 1). To assess the impact of direct and indirect effects of financial intermediation on customers and the consequences on customer decisions about financial services. For this, we can consider a system in which a financial intermediary (Z) acts on a client (Y) directly or through an intermediary - a mediator (X). The formal impact on the client through additional mediation may be the problem of finding causations in a complex context (Anderson and Scott, 2012) or opening a “black box” (Bathaee, 2018; Bennett and McWhorter, 2016).

So, social networks increasingly mediate the interaction of financial intermediaries and users of social networks. An analysis of this interaction can be performed using a three-agent model: a financial intermediary, a social site, and a site user — the end consumer (Figure 1). This model allows you to evaluate the impact of direct and indirect effects of financial intermediation on clients and the consequences for decisions of clients on how to obtain financial services. You can offer a model in which a financial intermediary (Z) acts on a client (Y) directly or through an intermediary (X) - a social network. Formally, the impact on the client through an additional intermediary can be considered as a problem of searching for causality in complex circumstances (Anderson and Scott, 2012) or in the black box (Bathaee, 2018; Bennett and McWhorter, 2016).

Figure 1: Direct and mediated by a social network interaction of a financial intermediary with a client

In the proposed coordinate system, the financial intermediary acts as a predictor. He offers a financial service and can affect a network user directly (Z-Y) and/or indirectly - through a social network (Z-X, X-Y).

Settings

Input: financial recommendations: direct - financial intermediary - of the client, Z-Y (B2C); indirect - financial intermediary - social network - network user, Z-X-Y (B2B2C).

Output: as a client of a financial intermediary - the consumption of financial services; as a network user - the consumption of a financial service and being in a network space.

Key terms and concepts

The variable is the central idea in the study. The change may be in quantity, intensity, amount or type. A variable may be a specific situation. For example, a mortgage loan is a variable - size, terms, interest rate, other terms are an essential role in this variable. In addition, the assessment of the borrower – credit scoring - is determined during the collection and analysis of data including social networks.

The purpose of this section is (i) to explain the operation of the predicate (financial intermediary) in two cases: direct interaction with the client (Z-Y) and mediated by social networks (Z-X-Y), and (ii) determine the nature of the variables of the intermediary and the moderator. Particular attention is paid to discussing the ways in which the definition of mediator and moderator variables can help in understanding the functioning of the entire system.

Mediator: Intermediate variable. A social network platform is an intermediate variable that can take into account the relationship between an independent and a dependent variable. The mediator is an intermediate variable that can take into account the relationship between the predictor variable and the original variable. The mediator is involved in the changes but does not necessarily explain the processes of their occurrence. In addition, the intermediary may be a proxy for one or more other variables — be a common construct used by various financial institutions.

Predictor: An independent variable, or an experimental variable, which is manipulated in an experiment to observe the effect on a dependent variable, or an outcome variable. The alleged "cause" in the non-experimental study used in correlation studies. A variable that causes changes in the mediator and through the large-scale mediator appears as a result. A mediator is an intermediate variable that is believed to take into account the relationship between the predictor variable and the original variable. Conceptually, the mediation model assumes that the predictor variable causes changes to the mediation variable, and the mediation variable causes changes to the result variable.

Mechanisms: processes or events that are responsible for the change.

Cause: a variable (including recommendations) that leads and is responsible for the result (in particular, the choice of service).

Moderator: A variable that influence or moderates the relationship between two other variables - the financial intermediary and the client. As a result, an interaction effect is generated. Financial intermediary ➛ social network ➛ client and vice versa.

If the type of recommendations affects the choice, then it is a moderator of the relationship of financial intermediaries with customers. Also, a moderator may be a way to include financial services in a social network: using financial intermediaries of social networks as a platform for providing financial services and switching social network sites to independently offer financial services to their users. Moderators are associated with mediators, mechanisms, and causes, as they suggest that various processes may be involved.

Outcome variable: The presumed effect in a non-experimental study, or a criterion variable. Further study of the intermediary and moderator variables can provide valuable information on the role of recommendation systems in social networks for retaining and expanding clients both within social networking sites and with financial intermediaries in two cases - direct and indirect.

The moderating variable has a strong conditional effect on the ratio of the conditionally independent variable and the conditionally dependent variable. The presence of a third variable (moderating variable) can change the initial relationship between the independent and dependent variables. For

example, there is a strong relationship between quality by the availability of credit resources from a financial intermediary (X) and the need for them from a client (Y). These relations depend, firstly, on the interest and tendency of the financial intermediary to provide credit, secondly, on the demand for borrowed funds, and thirdly, on the credit scoring. This means that only those customers who, on the one hand, have a demand for credit, and on the other hand, meet the criteria for lending to financial intermediaries, will interact with the financial intermediary in the system. In these relations, an important role is played by the moderating variable, that is, which moderates the strength of the connection between the variables X and Y. The attitude refers to the observed reality, in particular, to the interaction of a financial intermediary with a client both directly and through a moderator - a social network.

This article puts forward a hypothesis about the universal intermediary function of financial intermediation and mediation of social networks, which allows you to enhance the effect of financial intermediation. This function is implemented on the platform of social networks. If the phenomena under consideration turn out to be an observable reality, then these statements can be verified empirically.

We have already seen that judgments are statements about variables that are considered true or false. If the phenomena under consideration turn out to be an observable reality, then these statements can be verified empirically. A proposal that can be verified to determine its reality is a hypothesis. Therefore, we can say that the hypothesis is a testable analog of the proposal. A hypothesis can be defined as a logically assumed relationship between two or more variables, expressed in the form of a verifiable statement. Communication is proposed using rigorous logical reasoning. These logical relationships can be part of the theoretical basis of research. Let's look at some of the hypotheses: 1) The network user has an interest in financial services (variable). 2) The level of interest in financial services is related to their level of consumption. 3) The level of consumption of a network user is related to the level of income. 4) If the income level decreases, but consumption remains, then the demand for loans grows. 5) If the number of family members changes, then there is a demand for mortgage lending. These are verifiable offers. Moreover, the first hypothesis contains only one variable. And this hypothesis is quite abstract. The second and third hypotheses have two variables, which are related to each other, but the nature of the association is not defined (there is no directional connection).

In the fourth and fifth hypotheses, in addition to the relationship between the two variables, directions are given (in the fourth - negative, and in the fifth - positive, but in both cases they are aimed at increasing demand for borrowed funds). These hypotheses are checked by means of a credit scoring.

In its most general form, mediation exists when a predictor indirectly affects a dependent variable through at least one intermediate variable or intermediary. In general, financial intermediation develops according to the following principle: the owner of money, investing in a bank or investing in the stock market, affects the dependent variables - entrepreneurs and debtors. This relationship is shown in fig. 1, where (Z-X) represents the effect of the predictor variable on the proxy, (X-Y) represents the effect of the proxy on the output variable, (Z-Y) represents the effect of the predictor on the output variable in the absence of a proxy.

In its most general form, mediation exists when a predictor indirectly affects a dependent variable through at least one intermediate variable or intermediary. In general, financial intermediation develops according to this principle, when the owner of money, through investing them in a bank or through trading in the stock market, acts on dependent variables – entrepreneurs and debtors. In the proposed system, the most important participant is selected. The definition of the “most important” participant in this system depends on the goals and subject area. Although statistics in some cases make it possible to determine the most important variables in a regression model, the choice of a predicate in a model depends on the domain and analysis tasks. Analyzing the influence of financial intermediaries on consumers in order to provide financial services, the financial intermediary is a predictor, and the social network is an intermediary. If it is necessary to find out how the desires and preferences of the consumer affect the activities of the financial intermediary, then the consumer

becomes a predicate. A social networking site can also be a predictor. In this case, its influence is considered both on the financial intermediary in the direction of placing recommendation systems on the network, and on the network user, who in this way is under great influence from the network.

An assessment of the participation of parties in a triangle can be carried out from the standpoint of graph theory. Facebook launched the social graph in 2008. With their help, you can derive and calculate user interactions with each other on a social network. In addition, they allow you to introduce recommendation systems into a wide circulation, which takes a business relationship with customers to a new level and scale B2C.

Directional graphs can be used to model information flows of financial intermediaries with customers. In this connection, the connection between the nodes, give the necessary orientation. In graph theory, the Tutte-Berge formula (Berge, 1962) characterizes the size of the maximum correspondence in a graph. With its help, you can determine the smallest distances between the vertices. Typically, the formula is used when organizing traffic - search for the best routes (Bondy and Merty, 2010). However, it is quite appropriate for understanding the processes that determine the user's interest in financial services when introducing recommendation systems based on social networking sites. Thus, network users seek to minimize their time searching for the necessary financial services. This principle follows from the laws of minimizing free energy, which explains thermodynamics. Like gas molecules, network users interact with each other. Collective interactions can affect individual behavior. In the chart below, there are two routes for the movement of financial information to customers Z-Y and Z-X-Y. The first involves direct contact of a financial intermediary with a client, and social networks mediate the second. A financial intermediary strives to minimize its time and costs of maintaining customer relations.

In turn, each user of the network tries to minimize the search for necessary financial services - to find the services that are most optimal for them, based on their various characteristics. The digital channels that connect customers to a financial institution are much faster and more capacious than physical offices. In stationary mode, the direct route (Z-Y) and the route mediated by the social network (Z-X-Y) take the same amount of time. However, the first route is associated with a specific group of customers - current customers and potential customers, but those who have previously selected a specific financial institution to contact. The second route is intended for any user of a social network, that is, it has a potentially larger number of participants. Suppose that a financial intermediary decided to use a system of recommendations and chat-bots to communicate with users of social networks, as well as to communicate with customers, using a telephone line managed by bank employees. With direct contacts of a financial intermediary with a client (Z-Y), additional time is required associated with finding a phone number, dialing it, connecting and overloading a telephone line. Therefore, formally, direct contact becomes problematic for the user - and this applies both to direct analog contact and direct digital. Recommender systems in combination with chat-bots can offer a continuous and simpler service (Zarouali et al., 2018).

In fact, all three agents are independent and hysteretic agents (Macia-Perez and Garcia-Chamizo), that is, to start the changes for each agent, quite a significant start-up effort is necessary and, despite a rich information environment, they operate in conditions of insufficient da

Findings

We define financial inclusions in social networks as a potential set of financial services received by network users while using a social site. Financial inclusions differ from traditional financial intermediation and financial start-ups, but they depend on them and can act as their element, but (i) embedded into social networks, or (ii) financial functions that are performed directly by social sites. We consider the first option as a result of the expansion of financial intermediation into social networks - the use of social networks by financial intermediaries to scale their activities; the second option is the expansion of social networks into the financial sector to preserve network users, expand network traffic and monetize network services.

The results of the study of this article can serve as a guide for further studying the evolution of financial inclusion in social networks as a dynamic process with non-degenerate equilibrium points.

Social networks have the broadest communication features and properties. At present, it has become possible to use these properties for financial purposes. In general, social networks facilitate communication between consumers (P2P), financial intermediaries with consumers (B2C). Thus, various channels are provided for promoting financial services to the consumer. Therefore, social networks can be considered as tools and resources that become forms of contact between financial intermediaries with consumers. Thus, social networks are increasingly becoming the basis for the formation of new business models and business processes, among which financial inclusion in social networks currently stands out. The key mechanism ensuring the functioning and performance of financial inclusions is recommender systems.

The stability of the new financial services system depends on various internal circumstances - the development of financial inclusion in social networks, and external circumstances - associated with the activity of financial intermediaries and social networks, as well as the usefulness of the intermediary role of social networks in the interactions of financial intermediaries with end-users. In addition, government regulation can have an important impact on the stability of the system of financial inclusion in social networks.

An Analysis of the Romanian Cultural Environment of The Main Ethnic Groups

Andrei PUNGAN

The Bucharest University of Economic Studies, Bucharest, Romania

andrei.pungan@outlook.com

Abstract

The study below analyzes the cultural environment that can be found in Romania and carefully follows the similarities and differences between the cultural profiles encountered in the main two groups. The context of the two ethnic groups that we will investigate is somewhat exceptional, as in two counties of Romania, the most important minority group, became the majority one with its own values and beliefs as the dominant ones.

Keywords cultural environment, ethnic groups, ethnic minorities

Introduction

Romania is a country situated at the intersection of Central, Eastern and Southeastern Europe, having a population of 20 million people and more than 20 ethnic groups dispersed across its territory.

This multicultural situation can be explained due to the fact that throughout history, different portions of the territory of the modern state of Romania have been composed, or were under the direct administration of Dacia, the Roman Empire, the Ottoman Empire, the Russian Empire and off course the Austro-Hungarian Empire.

As a matter of fact, Romania first appeared as a state in 1859, by the union between Moldova and Wallachia, while still being a tributary state to the Ottoman Empire. In 1918, Transylvania, Bukovina and Bessarabia were united with Romania and most of the country current territory was formed.

Precisely because the country has been under various occupations throughout history, we now have in Romania various ethnicities, that can be found in the territories that were once ruled by other nations. Of course, this means that in terms of the cultural environment we have different values and beliefs that are common or specific to certain groups, and exactly these differences will be analyzed at the level of the most important ethnic groups found in Romania.

Cultural Environment of the Main Ethnic Groups

The meaning of the noun ethnicity is “the fact or state of belonging to a social group that has a common national or cultural tradition” (Oxford Dictionary, 2019). Based on the last Romanian census from 2011, Romania’s population is 20 million people and we can see that 83% (16.8 million people) of the entire population are Romanians; followed by the most important ethnic group at 6% (1.2 million people) represented by the Hungarians; while other groups are at more than 10% (2.1 million people).

Table 1: Main Ethnic Groups by Population

Ethnic Group	Population %	Population
Romanians	83.46%	16,792,868.00
Hungarians	6.10%	1,227,623.00
Other	10.44%	2,101,150.00
	100.00%	20,121,641.00

Source: Romanian National Statistics Institute (2011), adapted by author

One mention upon the Hungarians situation, is that most of the ethnics' population (33%) is located in two counties of Romania, Covasna and Harghita were we can find them as the majority ethnic group (the only situation of this kind). Also, they have kept their native language and only 1.69% speak the official language of Romania.

We can ask ourselves what the situation of the cultural environment between the majority and minority ethnic groups in Romania is, and can we see similarities between the cultural environment of Hungarians from Romania to the ones from Hungary.

In this initiative, we will use the World Values Survey Database, a global research project that examines the values and believes of people through representative national surveys. As this paper focus is to understand the cultural environment, we have chosen a list of question from the survey that follows that topic.

Table 2: List of followed questions of the survey

1. People have different views about themselves and how they relate to the world. Using this card, would you tell me how strongly you agree or disagree with each of the following statements about how you see yourself? I see myself as an autonomous individual -> Strongly agree
2. People have different views about themselves and how they relate to the world. Using this card, would you tell me how strongly you agree or disagree with each of the following statements about how you see yourself? I see myself as part of my local community -> Strongly agree
3. For each of the following, indicate how important it is in your life. Would you say it is very important: Work
4. For each of the following, indicate how important it is in your life. Would you say it is very important: Religion
5. Taking all things together, would you say you are very happy
6. How proud are you to be own nationality
7. Here is a list of qualities that children can be encouraged to learn at home. Which, if any, do you consider to be especially important? Independence
8. Here is a list of qualities that children can be encouraged to learn at home. Which, if any, do you consider to be especially important? Tolerance and respect for other people
9. Generally speaking, would you say that most people can be trusted or that you need to be very careful in dealing with people? Most people can be trusted
10. Emancipative values -> Mean

Source: World Values Survey: Round Six (2014), adapted by author

Since the cultural environment is a very important factor both from a financial, social and cultural point of view, we have chosen questions that can help us follow all these points as we consider that the cultural environment is a resource for any country, moreover as the globalization phenomenon diminishes the cultural differences more and more every year.

It can help build strategies that consider the cultural profile of a locality, region or country, in this way maximizing their effectiveness and using them appropriately for the efficiency of the actions that must be taken.

Table 3 : Results by Location

Location	Romania	Covasna	Harghita	Hungary
Autonomous Individual	28.0%	89.0%	18.9%	49.9%
Local community	34.5%	81.0%	29.3%	38.7%
Work	55.9%	47.2%	63.2%	55.1%
Religion	50.5%	90.2%	65.2%	17.1%
Happiness	13.6%	23.4%	18.6%	17.1%
National Pride	43.0%	14.1%	17.7%	43.3%
Independence - value for children	42.2%	76.0%	60.0%	81.4%
Tolerance - value for children	65.2%	82.6%	53.9%	76.1%
Trust - Most people can be trusted	7.7%	4.0%	28.8%	28.7%
Emancipative values	0.42	0.48	0.41	0.50

Source: World Values Survey: Round Six (2014), adapted by author

Analysis on the Main Ethnic Groups

There is usually in the collective mind the idea that major differences between different regions of the country can be identified. However, if we analyze the results, we can find that there are indeed differences, but are those significant enough to be categorical?

The cultural differences do not hold firmly to the magnitudes of important practical effects. Work importance, emancipative values, level of happiness, and the tolerance that is taught to children is as important for the average Romanian as his fellow countrymen from Covasna and Harghita, and like the average person from Hungary.

Or, we can find similitudes that brings closer the profile of a citizen from Covasna and Harghita to the one of a citizen from Hungary as Independence as a value for children, or the opposite as the differences found in the importance of Religion.

We can also find unique characteristics of the cultural environment, such as an increased allegiance to a community in the case of Covasna, or a low result in national pride in the case of Covasna and Harghita.

Also, we can find characteristics of the cultural environment and depending on the socio-professional groups ((Dutu, C., Luchian, A., Starcu, E., Savulescu, F., 2015, Popescu, A.L., Costache, R.S., Savulescu, F., Jinga, M., Ionita-Radu, F., 2019) in general and characteristics of the socio-professional groups within the main ethnic groups. This will be the subject of future research.

Conclusions

Therefore, these results show the existence of cultural differences between the counties where the Hungarians are the majority ethnic group and that the profile offered by this study is representative for sketching a cultural environment.

But we can say that we observe a uniformization of the environment and that the differences between them are rather important nuances, than completely different cultures. However, further studies should be undertaken to verify the relationships between the items presented in this paper, and to and expand the study with a more representative sample.

In the end, as in Romania foreign companies have employed more than 25.9% of the workforce in 2018 (Romanian National Statistics Institute, 2019) knowing the cultural environment of each county or region, will help companies to search for the right behavior in a specific location and to diminish the cultural shock when entering a new market.

Entrepreneurial Orientation and Value Creation: Towards A Micro-Foundational Perspective

Wojciech DYDUCH

Katowice University of Economics, Wroclaw, Poland
dyduch@ue.katowice.pl

Katarzyna PIÓRKOWSKA

Wroclaw University of Economics & Business, Wroclaw, Poland
katarzyna.piorkowska@ue.wroc.pl

Abstract

Purpose and research questions. The aim of the paper is to initiate the research on a micro-foundational perspective within the relationship between entrepreneurial orientation and value creation. The aim has been realized by answering the following research question: How might the micro-foundations concept in strategic management develop the understanding of the relationship between entrepreneurial orientation and value creation? **Design/Methodology/Approach**. The method that has been used is a systematic and critical literature review of the following concepts: entrepreneurial orientation and value creation, micro-foundations of value creation. Moreover, a critical literature review on the micro-foundations concept has been made as well. **Findings.** The overarching findings are as follows. First, the micro-foundational perspective constitutes a promising research direction in examining the linkages between entrepreneurial orientation and value creation. Second, the value creation (both internal – for a company itself regarding performance, competitive advantage, etc. and external – for stakeholders) is determined by entrepreneurial orientation at both the organizational level (including higher and lower order dimensions) (the Coleman's relation no. 4) and the individual one. Moreover, organizational entrepreneurial orientation determines individual-level entrepreneurial orientation antecedents (the Coleman's relation no. 1). In turn, individual-level entrepreneurial orientation is determined by individual-level entrepreneurial orientation antecedents such as, for instance, managerial cognitions. cognitive dynamic capabilities, emotions, particular values and interests, entrepreneurial proclivity, alertness, high locus of control and opened world view (the Coleman's relation no. 2). Finally, individual-level entrepreneurial orientation determines organizational value creation (the Coleman's relation no. 3). **Research implications**. The findings fill the research gap in the strategic management field concerning a micro-foundational perspective of examining the entrepreneurial orientation-based value creation concept.

Keywords: Strategic Entrepreneurship, Entrepreneurial Orientation, Value Creation, Micro-Foundations, Multi-Level Research, Coleman's Bathcub

Introduction

Value creation, as essential for a strategic success, is one of crucial concepts in the strategic management field. The value-based approach was originally developed by Brandenburger and Stuart (1996). Remarkably, different groups create different amounts of value, which reflects the heterogeneity in the underlying resources and capabilities of the players (Chatain and Zemsky, 2011). However, despite the considerable growth of the research on value creation (and value capture[1]) and its triggers, there is a need to develop both theoretical and methodological lens of this phenomenon by

[1] The paper does not involve the considerations about the concept of value capture and appropriation as, on the one hand, different mechanisms occurring at various levels of analysis are involved in those phenomena, i.e. value creation versus value capture and value appropriation and, on the other hand, the focus of the paper presented is on triggering just value creation, not value capturing and appropriating, by entrepreneurial orientation.

implementing new perspectives that allow a deeper understanding of how companies may create the value for itself and stakeholders. As such, a promising view emerges from the entrepreneurial orientation, which as one of the most predominant constructs of interest in strategic entrepreneurship research (Anderson *et al*., 2015), constitutes the organizational capability that might trigger the value creation mechanisms (Wales *et al*. 2020). Moreover, entrepreneurial orientation as an organizational phenomenon is determined by lower-level constructs. As well as this, the value creation phenomenon involves many levels of analysis, specifically individual, organizational, and network (e.g. Corte and Gaudio, 2014). As such, it is justified to ontologically and epistemologically incorporate a micro-foundational perspective and its methodological multi-level analysis.

Consequently, to address recent calls for microfoundations, the aim of the paper is to initiate the research on a micro-foundational perspective within the relationship between entrepreneurial orientation and value creation. Specifically, the following research question has been formulated: *RQ*. How might the micro-foundations concept in strategic management develop the understanding of the relationship between entrepreneurial orientation and value creation?

The method that has been used is a systematic - critical literature review. First, the papers were selected by means of the SCOPUS database with keywords ("entrepreneurial orientation" AND "value creation") including TITLE-ABS-KEY. As a result, twenty-seven papers were found dated from 2001 to 2020. They cover the following fields: Business, Management, and Accounting, Economics, Econometrics and Finance, Social Sciences, Arts and Humanities, Decision Science, and Engineering. Second, the same procedure (with the inclusion criterion: only reviewed papers) was implemented for the EBSCO database. Only four papers dated from 2013 to 2019 have been found. Then, there was a second round for selecting papers. On the basis of the SCOPUS database fourteen papers have been gained by means of keywords ("microfoundations" AND "value creation") including TITLE-ABS-KEY as well. The papers date from 1996 to 2019 and cover the following fields: Business, Management, and Accounting, Economics, Econometrics and Finance, Social Sciences, Arts and Humanities, and Computer Science. Consequently, the same procedure was incorporated into the EBSCO database and only one paper was found (dated a year 1996). After analysing seminal papers in the fields of entrepreneurial orientation and value creation as well as implementing the snowball method, additional papers have been considered. Finally, the seminal and overarching papers concerning the micro-foundations concept in strategic management have been added and critically analysed as well.

The structure of the paper is four-fold. The first section presents the micro-foundations concept in strategic management. The theoretical background of entrepreneurial orientation and the value creation concepts has been presented in the next section. Then, the insights on a micro-foundational perspective, incorporating the Coleman's diagram, within the relationship between entrepreneurial orientation and value creation have been posed. Finally, the conclusions, encompassing the most salient findings, limitations and future research directions have been presented.

Micro-Foundations – A Concept in Strategic Management

The microfoundations concept has appeared in the management theory landscape over the past decade (Foss and Linder, 2019). Micro-foundations constitute cognitive fundamentals in strategic management rooted in individual actions and interactions between individuals (Abell *et al*., 2008; Barney and Felin, 2013). It is 'an attempt to unpack collective (or 'macro') concepts and phenomena so to foster improved understanding of them (…) explaining how micro-level factors like individuals' characteristics, their decision rights, their interactions…impact meso- and macro-level outcomes (…) how the interaction of individuals leads to emergent, collective, and organization-level outcomes (…) and how relations between macro variables (…) are mediated by micro actions and interactions' (Felin and Foss, 2019, p. 2). For instance, an individual level (micro) is a key for explaining phenomena at the organizational level (macro) such as routines, capabilities, organizational performance (Foss and Pedersen, 2014). As such, micro-foundations are responsible for explaining a mediating character of influencing individual level (micro) phenomena and/or interactions between them on the relationships between organizational

level variables (Abell *et al*., 2008; Foss and Pedersen, 2014). Moreover, micro-foundations of a given phenomenon constitute its main elements and processes (Lippman and Rumelt, 2003b), because they refer to aggregated phenomena and/or relationships between aggregated variables (Barney and Felin, 2013). The explanation how individual level factors as a result of aggregation contribute to occur collective phenomena and constitute *sine qua non* the micro-foundational analysis (Barney and Felin, 2013). Hence, the 'micro-foundations' concept does not refer to individuals and theirs characteristics *per se*, but also to additive and emergent forms of aggregation (Barney and Felin, 2013; Felin *et al*., 2015). Nonetheless, aggregation is not a primary premise of micro-foundations (Devinney, 2013). The reason is that the 'micro-foundations' concept is rooted in methodological individualism which premise is to seek causality mechanisms (at the individual level) as well as it reflects how intentional activities and/or interactions between individuals constitute phenomena in the strategic management field (Abell *et al*., 2014; Molina-Azorin, 2014). Yet, it ought to be mentioned that whereas micro-foundations constitute a research programme with the main aim of understanding collective/aggregated macro level phenomena by means of actions of and/or interactions between lower level constructs, the lower level construct does not have to mean individuals (Foss, 2016). Additionally, a crucial hallmark of the microfoundations programme is emergence. Indeed, the purpose of micro-foundations is to explain (*via* seeking causality) how higher level constructs emerge from constructs that reside and interact at lower levels of analysis (Devinney, 2013; Felin *et al*., 2015; Molina-Azorin, 2014). Trying to operationalize the definition of microfoundations, Felin *et al*. (2012, p. 1353) described it 'as a theoretical explanation, supported by empirical examination, of a phenomenon located at the analytical level N at time *t* (N_t). In the simplest sense, a baseline micro-foundation for the level N_t lies at the level N - 1 at time *t* - 1, where the time dimension reflects a temporal ordering of relationships with phenomena at the level N – 1 predating phenomena at the level N. Constituent actors, processes, and/or structures, at the level N – 1 $_{t\text{-}1}$ may interact, or operate alone, to influence phenomena at the level N_t. Moreover, actors, processes, and/or structures at the level N – 1 $_{t\text{-}1}$ also may *moderate* or *mediate* influences of phenomena located at the level N_t or at higher levels (e.g. N + 1 $_{t+1}$ to N + n $_{t+n}$)'. A micro-foundational analysis therefore needs specifying the components of the micro-foundational construct, interactions between those components, causative mechanisms that contribute to emerge a collective phenomenon from micro-foundational components. The boundary conditions are necessary (Felin *et al*., 2012). Consequently, a micro-foundational analysis is multilevel (ontologically, epistemologically, and methodologically) (Foss, 2016; Molina-Azorin, 2014).

Micro-foundational studies (mainly theoretical) have been evidenced in many research fields. Referring to the recently published systematic review on micro-foundations made by Foss and Linder (2019), there are four papers considering value as *explanandum*, namely three connected with value creation and one associated with value appropriation. Specifically, Gottschalg and Zollo (2007) conceptually and theoretically examined value and rent-creation at the individual level where the *explanans* referred to different kinds of motivation. The authors stated that individual motivation is crucial to understanding organizational outcomes. In turn, Harrison *et al.* (2010) investigated (also conceptually and theoretically) that the *explanans* of firm-level value creation (*explanandum*) was organizational justice, which allows more fine-grained managerial access to employee utility functions. Obloj and Zemsky (2015) studied (conceptually and theoretically) value creation and division of value in contracting relationships (*explanandum*) and they found supplier heterogeneity as *explanans* for value creation and division. With regards to value appropriation, Lippman and Rumelt (2003a) researched resource-level value appropriation (*explanandum*) and concluded that bargaining behaviour and strengths of individual resource owners constituted the *explanans* of the resource-level value appropriation. When it comes to the entrepreneurial orientation, there is just one paper evidenced in the review made by Foss and Linder (2019). Specifically, Dai *et al*. (2016) investigated (theoretically and empirically drawing on 148 firms in China) organizational entrepreneurial orientation with regards to venture teams' transactive memory, intra-team trust, and venture's structural organicity. They explained how individuals, their social relationships, and interactions influenced firm-level behaviour, processes, and strategies. Moreover, they strongly called for the need of explaining organizational entrepreneurial orientation within the micro-foundational programme what was in line with the recent studies on the entrepreneurial orientation concept (i.e. Wales *et al*., 2020).

Entrepreneuarial Orientation and Value Creation –Theoretical Background

Entrepreneurial orientation is an important and widely researched concept in the both entrepreneurship and strategic management literature (e.g. Andersén, 2010; Anderson *et al.,* 2009; Anderson *et al*., 2015; Rauch *et al*., 2009; Wales *et al*., 2013a; Wales *et al*., 2013b; Wales *et al*., 2020). Entrepreneurial orientation is comprehended as a firm's (a firm-level) strategic posture (Anderson *et al*., 2015; Covin and Wales, 2012), an organizational attribute (Wales *et al*., 2020), and a fundamental organizational orientation (Li *et al*. 2010, Wiklund and Shepherd, 2003; 2005, 2011) towards entrepreneurship. When it comes to the components / dimensions of entrepreneurial orientation there are two approaches. The first one assumes there are three components, namely innovativeness (the introduction of new products, processes, and business models, novelty, experimentation, and creative processes), proactiveness (actively entering new product/market spaces and seeking market leadership positions, creating a first-mover advantage), and risk taking (a willingness among strategic decision makers to contribute resources to projects with uncertain outcomes, a willingness to commit large amounts of resources to projects where the cost of failure may be high) (e.g. Anderson *et al*., 2009, Anderson *et al*., 2015, Covin and Slevin, 1989, 1991, Miller, 1983, Miller and Friesen, 1978, Wiklund, 1999, Wiklund and Shepherd, 2003). Importantly, while innovativeness and proactiveness are thought to be behavioural (higher order) dimensions, the risk-taking is regarded as attitudinal (lower order) dimension. The second approach is in line with five-dimensional entrepreneurial orientation conceptualization (autonomy, innovativeness, risk-taking, proactiveness, and competitive aggressiveness) (Lumpkin and Dess, 1996). Whereas the autonomy dimension reflects 'the ability and determination of self-directed decisions and actions' (Ljungkvist *et al*., 2020, p. 286) and 'refers to the independent action of an individual or a team in bringing forth an idea or a vision and carrying it through to completion (Lumpkin and Dess, 1996, p. 140), competitive aggressiveness 'focuses on how a firm challenges and reacts to competitors' (Ljungkvist *et al*., 2020, p. 287). This approach is definitely, in contrary to the traditional strategic posture, a processual concept covering the changes of practices and new entries (Ljungkvist *et al*., 2020) and is also called a strategic entrepreneurial orientation (McKenny *et al*., 2018).

There is a limited number of studies on strategic entrepreneurship, especially entrepreneurial orientation, from a value creation perspective, however, the entrepreneurship is said to be a value creation process (Hunter and Lean, 2018). Entrepreneurial orientation corresponds to a type of entrepreneurial transformational process that enables organizations to turn inputs, broadly defined, into higher-value outputs (Lumpkin *et al*., 2013, p. 763). Remarkably, in turbulent markets a firm's internal capabilities are seen as major sources of value creation and sustainable competitive advantage (Khan *et al*., 2019). Criado-Gomis *et al*. (2019), for instance, prove that sustainable entrepreneurial orientation, determined by entrepreneurial orientation, as an organizational capability, in terms of innovativeness, proactiveness, and risk taking, significantly influence customer functional value creation, which in turn had impact on firm performance (customer and business one). In other words, their findings indicate that a sustainable entrepreneurial orientation not only has a positive and direct relationship with firm performance, but also that this relationship improves when it is mediated by customer functional value creation. In turn, Eshima and Anderson (2016, p. 772) investigated that new resource combinations exposed by firm growth, which enhance the ability to recognize ways to satisfy changing market needs, exposed specific new opportunities for value creation as well. In details, an adaptive capability uncovers new entrepreneurial opportunities for value creation since to capture this potential value, companies expand their entrepreneurial orientation. Hence, entrepreneurial orientation and value creation may also be perceived from the RBV perspective. Entrepreneurial orientation is associated with the successful exploration of resources (White and Vila, 2017). Entrepreneurial orientation is therefore vital through which companies based in emerging economies can create value by bundling and orchestrating resources thus improving performance (Zeng and Khan, 2019). Moreover, taking the form of new entrepreneurial opportunities and the presence of an exploitable opportunity is a necessary precondition for a change in the firm's entrepreneurial orientation (Slevin and Covin, 1997). Runyan *et al*. (2008) state that small companies, which adopt an entrepreneurial orientation in their business are likely to achieve competitive advantages, perform better, and create value. Mütterlein and Kuns's (2017) results show that company's (a media one) entrepreneurial orientation has positive effects on its ability to innovate value creation and value proposition, but not

on its ability to capture that value. Significantly, the linkages between entrepreneurial orientation and value creation depend on the development stage of the entrepreneurial orientation. Ljungkvist *et al.* (2020) investigated the development of the five dimensions of entrepreneurial orientation (which account for specific contexts and stakeholders) over time by taking a founder's perspective and they found that the entrepreneurial orientation dimensions changed from being personalized and directly solution-oriented *via* being administrative-based to being intangible value-creation-oriented. Significantly, intangible-focused entrepreneurial orientation is strongly affected by external-based drive promoting short-term oriented value-creation. It might be realized when internal autonomy is high, external autonomy is limited, innovativeness is high, risk-taking is high, proactivity is high, and competitive aggressiveness is limited.

Not only are the linkages between entrepreneurial orientation and value creation considered from the perspective of the organizational level entrepreneurial orientation. Criado-Gomis *et al*. (2019) highlight that the managerial predisposition to adopt a strategic position fosters value in use (instead of regular property value), according to the current school of thoughts engaged with innovation and sustainable development. Wang *et al*. (2020) examined the relationship between management's entrepreneurial orientation and its relative strategic emphasis on value-creation *versus* value-appropriation. They found that entrepreneurially oriented managers tended to focus more on value-creation (e.g., new product development) over value-appropriation (e.g., advertising), but this influence was contingent on, at least, three factors: (1) relative firm performance, (2) compensation strategy, and (3) capital market patience. Keil *et al*. (2017) investigated how CEO entrepreneurial orientation affected firm value creation and how this relationship was moderated by three sources of CEO entrenchment. As a result of a longitudinal analysis, they found that CEO entrepreneurial orientation enhanced firm value creation and that this positive effect was reduced when CEOs were entrenched (1) due to corporate governance provisions that protected them from the majority will of shareholders, (2) due to substantial ownership that provided them too much decision-making power, and (3) because their family had substantial holdings in the corporation.
Taking into account the aforementioned premises and considerations we have formulated the following proposition:

Proposition 1. The value creation (both internal – for a company itself regarding performance, competitive advantage, etc. and external – for stakeholders) is determined by entrepreneurial orientation at both the organizational level (including higher and lower order dimensions) (the Coleman's relation no. 4 – see the following section) and the individual one.

The proposition opens a black-box connected with considering the relationships between the entrepreneurial orientation and value creation form a micro-foundational perspective,

Entrepreneurial orientation and value creation – towards a micro-foundational perspective

While some studies have been conducted with regards to the associations between the entrepreneurial orientation and value creation in general, little is known about the opportunities that a micro-foundational programme might provide in that field.

Entrepreneurial orientation's influence on value-creation potential depends not only on the organizational entrepreneurial orientation on the whole, but especially on managers having some sense of the potential value of an entrepreneurial opportunity before expending critical resources to create and / or capture that value (Eshima and Anderson, 2017, p. 777). Nonetheless, when shifting utmost focus from an organizational-side entrepreneurial orientation to individual factors, the entrepreneurial orientation–based explanation of value creation requires augmenting also the lower levels conceptualizations and finding lower levels antecedents of value creation determined by entrepreneurial orientation. Given this, we draw a Coleman's conceptualization of micro-foundational interdependencies called Coleman's diagram (bathcub / boat) (Abell *et al*., 2010; Vromen, 2010). In a generic way, it depicts four relations involving two levels: a macro-level and a micro-level. The first relation is from the macro-level (higher levels conditions) to the micro-level (conditions of individual

actions). The second one is micro (conditions of individual actions) – micro (individual actions). The third relation begins at the micro-level (individual actions) and ends at the macro one (higher level outcomes). The last relation is macro- (higher levels conditions) macro- (higher level outcomes).

We have incorporated the Coleman's bathcub to conceptually reflect the potential relations in the entrepreneurial orientation-based concept of value creation. Adapting Wales's (2016) settlements and promising research directions, we follow that entrepreneurial top management / TMT style (an individual / team level) is determined by entrepreneurial orientation in terms of organizational configuration (an organizational level). Hence, we have formulated the following proposition:

Proposition 2: Organizational entrepreneurial orientation determines individual-level entrepreneurial orientation antecedents (the Coleman's relation no. 1).

We propose to consider individual-level entrepreneurial orientation (see Hughes *et al.,* 2018, Kollmann *et al*., 2017) as the one of main individual level antecedents of the entrepreneurial orientation on the whole. While it is generally recognized that individuals throughout organizations can be entrepreneurial actors, the concept of individual-level entrepreneurial orientation has not been widely embraced, largely because 'the entrepreneurial orientation was introduced to the literature as a firm-level construct by definition' (Wales *et al*., 2020). As such, while considering the Coleman's bath, it is significant to explore individual-level antecedents of individual-level entrepreneurial orientation, which in turn influences value creation processes. Given this, Wilkens *et al.* (2016) discovered the salience of managerial cognitions concerning new market opportunities, managerial perception of the necessity to change and of managers' coping patterns for resource allocation. The authors' key finding was that increasing sense-making activities inside and outside the organization help it adopt to new ways of value creation. Moreover, they found that the cognitions related to "reconfiguring resources" showed the high consciousness for an overall change process leading to new forms of value creation in interaction with the customer (Wilkens *et al.*, 2016, p. 499). Cognitive maps and shared cognitive maps (Wales *et al*. 2020): develop a shared cognitive schema among top managers characterized by an enthusiastic support for the pursuit of new entry initiatives, innovations, and value creation opportunities, even when the outcomes of such experiments are unknown (Covin and Slevin, 2002; Wales *et al*., 2020). Similarly, Wales *et al*. (2020) found that collective top managerial cognitions favoured entrepreneurial activity. As well as this, Chen *et al*. (2017) stated that managers in the fast-growing industry should have dynamic managerial capabilities to anticipate other service elements that customers consider valuable. Based on managerial cognitive dynamic capabilities, their research explored the influences of customer-perceived functional benefit, experiential benefit, financial benefit, and psychosocial benefit on perceived instrumental and terminal values of stakeholders (customers). As well as this, increasing sense-making activities inside and outside the organization to adopt to new ways of value creation is crucial (Wilkens *et al*., 2016). The authors analysed how managerial cognitions influenced a firms' capability to realize new business model opportunities and to seize and reorganize its resources in order to take advantage from these opportunities. They discovered, on the basis of a qualitative case study analysis, comprising of interviews and cognitive mapping, managers' cognitions concerning new market opportunities, their perception of the necessity to change and their coping patterns for resource allocation as crucial for value creation. Additionally, it has been evidenced that the emotions, values and interests support the cognitive and conative processes required to develop an entrepreneurial mind-set that contribute to create any value (Hunter and Lean, 2018). In a similar vein, it is believed that entrepreneurial proclivity (top managerial beliefs) have impact on entrepreneurial activities (Matsuno *et al*., 2002). Additionally, Castro-Solano *et al*. (2017) identified the entrepreneur's personality traits (alertness) as an antecedent of entrepreneurial discovery of business opportunities. Individual trait approaches and entrepreneurial orientation in enterprises may combine and explain the finding of opportunities. In turn, Ishak *et al*. (2015) found two antecedents of entrepreneurial orientation, namely locus of control and world view. They concluded that individual high locus of control and opened-world view determined the existence of entrepreneurial orientation in social entrepreneurial endeavour. With regards to the aforementioned findings we have formulated the following propositions:

Proposition 3: Individual-level entrepreneurial orientation is determined by individual-level entrepreneurial orientation antecedents such as, for instance, managerial cognitions. cognitive dynamic capabilities, emotions, particular values and interests, entrepreneurial proclivity, alertness, high locus of control and opened world view (the Coleman's relation no. 2).

Proposition 4: Individual-level entrepreneurial orientation determines organizational value creation (the Coleman's relation no. 3).

Conclusion

The systematic and critical literature review allowed us to organize the current knowledge and findings referring to the micro-foundational perspectives (on the basis of the Coleman's bathcub) of the entrepreneurial orientation-based value creation concept. Specifically, it has been stated that the value creation is determined by entrepreneurial orientation at both the organizational level (including higher and lower order dimensions) and the individual one. Moreover, we argue that organizational entrepreneurial orientation determines individual-level entrepreneurial orientation antecedents and, in turn, individual-level entrepreneurial orientation is determined by individual-level entrepreneurial orientation antecedents such as, for instance, managerial cognitions. cognitive dynamic capabilities, emotions, particular values and interests, entrepreneurial proclivity, alertness, high locus of control and opened world view. Finally, we believe that individual-level entrepreneurial orientation determines organizational value creation.

Our findings fill the research gap in the strategic management field concerning a micro-foundational perspective of examining entrepreneurial orientation-based value creation and have potential for the future development. The literature review results presented have some limitations. First, both the value creation concept discussed and stakeholders mentioned are very general (not specified). Second, individual level entrepreneurial antecedents are definitely not exhaustive. Third, the concept of value creation has been separated from the value capture and value appropriation realms. The research presented is in progress and it requires conducting empirical investigation (incorporating multi-level micro-foundational methodology) what constitutes our main research direction.

Abstract

The implementation of continuous internal control ensures the proper organization and conduct of sports and physical education events. Different in their orientation and sources of financing, the events have a unified algorithm for conducting internal control. To solve the problem of organizing internal control, a classification of sports was carried out, the tasks, types, methods of internal control, typical errors in accounting and planning costs for events were investigated, control procedures and technologies for their implementation were proposed. The cost estimate for the event is considered as an object of internal control of expenditure of funds for each source of financing. The digitalization of continuous internal control of the organization and conduct of sports and physical education events in the digital economy is aimed at promptly confirming the accuracy of accounting and reporting on the event, automatically ensuring transparency of calculations and the targeted nature of the use of funds received for events.

Keywords: Sports and Physical Education Events, Expenses, Internal Control, Estimates

Introduction

In matters of organizing sports and physical education events, it is important to ensure continuous internal control and create competitive advantages, including by extracting benefits from "belonging to a cluster" according to research Razminiene(2017). The ongoing transformations in sports management, the successful solution of economic, educational, recreational, and socio-cultural problems in organizing events make sport an, according to research Zuev et al (2018),"important tool for promoting the interests" of their organizers and participants. The totality and variety of costs for the organization of events require the provision of control procedures continuously and comprehensively, studies of the features of financing events taking into account their classification, the target nature of the funds used and the result. The conducted "cost-benefit analysis justifies, first of all, the social result obtained"mentioned Stratan et al (2018), which allows you to perform a socio-cultural task, ensuring the social effect of the event. In a research study by Katzer et al (2018), sport is "an effective tool for states to advertise themselves and a means of social mobilization", which "promotes public health" mentioned Ainsworth et al (2018), therefore it is important to monitor the completeness and timeliness of reflection of the received investments and their direction in accounting use. Sport as a "social phenomenon" mentioned Bykhovskaya et al (2017) makes it possible to attract various sources of financing, control over the use of which is the primary task of effectively organizing events.

Research Methodology

The primary logical determination of the purpose of the study made it possible to identify the economic content of the internal control of the organization and conduct of events. The approach adopted in the study has two aspects:

firstly, the designation of goals and objectives, the development of types and methods of internal control of the organization and conduct of sports and physical education events, taking into account the classification of sports and sports events; secondly, an analysis of the execution of control procedures in order to confirm the targeted use of funds for the event provided for in the estimate. It is necessary to carry out continuous methodological work to improve the technology of control measures, taking into account the competencies of employees exercising internal control in their area.

Research Results

The economic content of the internal control of the organization and conduct of sports and physical education events: the process carried out by the event organizers in order to obtain information on the significance and effectiveness of the event, the rational use of funds, and the reliability of reporting. The construction of an internal control system for the organization of sporting events should begin with the control of the justification of goals, objectives, methods, followed by building the technology of internal control for each type of sports and physical education events. Among the sports and physical education events include tournaments, competitions, training camps and other events held by federations, sports organizations at various levels. Participants in sporting events are athletes, referees, coaches, attendants and specialists in accordance with the rules of the competition. The variety of events requires their systematization, taking into account the classification of sports, which is presented in Table 1. In the register of sports, each sport is assigned a code number and the corresponding sports disciplines are identified. The history of sport is “a movement from local to regional, national and then global contexts” mentioned Nauright et al (2018).

Table 1: sports classification

Classification feature	Sports
Multisports	Olympic, non-Olympic, Paralympic, national
Level	interregional, all-Russian, international
Seasonality	summer, winter, off-season
nature of sports	game, non-game, the sport contains game and non-game disciplines, military-applied, service-applied
gender and age category	men, (boys, boys, juniors), women, (girls, girls, juniors), all categories
subject of development	the sport is being developed by the international sports federation; Federation recognized by the International Olympic Committee (IOC); included in the program of the Olympic Games.

With the participation of the state, exclusively official physical education and sports events are included in the Calendar Annual Plan. In it, sporting events by category of participants are combined in the corresponding age groups. When planning the costs of events, the type of sport and sports discipline are taken into account.

To implement internal control for each sporting and physical education event, we suggest using the following unified control actions algorithm:

1. preliminary and current control of estimated indicators, incomes, expenses and final results of the event;
2. preliminary risk assessment of the organization and conduct of the event, analysis of the risk matrix taking into account their significance and probability;

3. the formation of a list of control procedures for the control of individual sites and business operations, including the control of the construction of information accounting and analytical system, local acts, directories;
4. current internal control, including analysis and evaluation of the organization, support, conduct, training, sports, physical education events; control the rational use of labor, material, financial resources, assets; reflection in the contract of significant moments of interaction with counterparties; assessment of the qualitative and quantitative composition of athletes, coaches

Tasks of internal control of the organization and conduct of sports and physical education events:

– checking the stability of the composition of the participants in the events, the effectiveness of training, sports, physical education events;
– establishing compliance with the content of events to the stage, plan, program of preparation and conduct;
– prevention of risks of reducing the effectiveness of the event and adverse effects on participants;
– assessment of the level of preparedness and qualification of the coaching staff, physical development of athletes;
– generalization and dissemination of practices of internal control of sports and physical education events.

Types of internal control:

1. Preliminary control, which is leading in nature.
2. Current internal control at the stage of organization and holding of the event.
3. Thematic control in order to identify the implementation of activities for sports of the annual calendar plan.
4. Operational control in order to identify the actual state of the participants at a certain stage of the event.
5. Frontal control provides for the substantive activities of an individual trainer and the event as a whole.
6. Comparative control in order to compare the results of the event, the work of trainers, the quality of knowledge, skills of athletes.
7. Self-control, involving self-esteem, self-analysis of activity.

Methods of internal control of the organization and conduct of sports and physical education events: questioning, testing, interviewing, monitoring, observation, studying documentation, analysis of training and the results of sports training, combined testing, conversation, inspection.

The focus of internal control

Internal control is carried out in relation to:

– compliance with the standards of physical and sports training;
– the full involvement of persons who have undergone sports training in sports competitions;
– the effectiveness of sports and physical fitness;
– systematization of accounting features of training in sports disciplines of sports;
– fulfillment of the conditions for the organization and conduct of sports and physical education events in accordance with training programs for sports, in terms of personnel, logistical, infrastructural equipment in accordance with the standards of sports training.

Internal control is aimed at:

– assessment of the level and quality of professional training of trainers and sports training of event participants, collaboration of efforts to achieve the best results;
– assessment of the condition and safe use of material and technical assets for the intended purpose;

– analysis of the effectiveness and efficiency of the actions taken to organize and conduct sports and physical education events;
– adoption of decisions based on analysis of information and practices aimed at ensuring favorable conditions for the implementation of high-quality training and sports and physical education events;
– ensuring information transparency, accounting credibility and transparency for organizers and participants of events.

It is important to establish the conformity of the information contained in the estimate to the accounting data and reporting forms. A forecast analysis of the income of a sporting event should be based solely on objective information about possible sources of funding. It is important to verify the reality of assessing gratuitously received objects of fixed assets and inventory at the stage of organizing competitions, to take into account "the unrealized potential for increasing revenues from the sale of tickets to competitions, and the realization of broadcast rights" mentioned Lokhman et al (2018).

Typical errors identified during the internal control of sports events:

– lack of approved rules for document circulation and technology for processing accounting information; internal control rules;
– the reasons for writing off assets during the organization of sporting events are not justified, among which may be:

1. Physical wear, improper operation, damage as a result of emergency, other situations during sporting events.
2. The obsolescence of facilities, their subsequent modernization and reconstruction is not possible or inefficient.
3. Re-equipment and updating the material and technical base of the event organizer.
4. The decision of the property owner to write off the asset, the conclusion of the commission on the disposal of the asset based on the results of a survey of an unusable object.

– non-observance of the established limit for settlements in cash;
– low effectiveness of sports training;
– the use of financial and material resources not in accordance with the standards and for other purposes;
– carrying out events in violation of the terms and plan of events.

The verification technology in the context of the control procedures of sporting events is presented in Table 2.

Table 2: control procedures and technology

Control procedures	Technology of their implementation
Monitoring the accuracy of indicating the start and end dates of sports events in the estimates, their compliance with the period of organization, holding of events and planned sources of funding	Correlation of start and end dates with the period of planned activities in the amount of approved funding sources
Monitoring compliance of actual cash payments with approved expenses on estimates and reporting documents to them	Comparison of cash payments to approved estimated and reporting documents, excluding unreasonable payments
Identification of possible doubles of legal entities and individuals in the directories “Contractors”, “Employees”	Exclusion of duplicate entries and non-existent employees, counterparties
Identification of accounts payable and taking measures to repay them	Monitoring accounts payable for sports events
Monitoring the proper preparation of documents justifying direct and indirect costs of organizing and	Identification of compliance of these primary documents with estimated

conducting sporting events (rent, accommodation, meals, payment for trainers, communications, transportation, medical services and other expenses)	indicators, reflected facts in accounting and reporting on a sporting event

The main element of cost accounting is the estimate of a sports event, which includes:

– number of people involved in sporting events (participants, coaches, medical staff, accompanying persons), date, place of its holding, sources of financing;
– remuneration and insurance premiums;
– rental price of sports facilities and sports equipment;
– the cost of souvenirs, gifts, food;
– transportation, escort and overhead costs.

Justification of the estimate avoids inefficient costs. Analysis of the results of the event makes it possible to find discrepancies in the planned and incurred expenses and identify the causes of deviations.

Estimates can be made in different ways:

1. Index, which allows the calculation of regulatory indicators, adjusted for the current price index.

2. The analog method in which costs are calculated from the prices of similar events.

3. The resource method is based on the actual cost of the planned types of costs (labor, material, financial) and their summation. Since the estimate is preliminary, it is possible that the planned prices may change during the actual execution period, therefore it is necessary to include expenses in the estimate taking into account the inflation index and unforeseen expenses.
Estimated costs of events are compiled on the basis of the calendar plan of events, taking into account a certain number of participants, serving staff, the size of wages. This allows us to consider the estimate as an object of internal control, since it is the estimate that provides for the types of expenditure of funds, taking into account the source of funding for events. In case of joint financing of events by several organizers, the estimate reflects the amount of those expenses that each organizer agrees to pay.

Sports and athletic organizations are entitled, at their own expense and attracted funds, to change the norms of material support for events. Living expenses are based on the reimbursement of travel expenses. For traveling while traveling to and from events, participants are paid a daily allowance set for business trips. The rental costs of sports facilities and equipment, transportation and other expenses are incurred at contractual prices in the rational use of funds. Events can be carried out using the funds of participants in the competition, through application and entry fees. The implementation of "control procedures provides some practical importance for management" mentioned Mullakhmetov (2016) of the effective organization of sporting events, specially when "developing the concept of effective management in sports" mentioned Gardiner et al (2017).

The Discussion of The Results

Organizational and financial documents for a sporting event include: a provision on an event; cost estimate for the event; cost of food for secretaries and judges; list of prizes; report of the chief judge on the event and others. The purpose of budgeting is to know before the start of the event the aggregate amount of money requirement and to assess the possibility of covering it at the expense of own and attracted sources of financing. For competitions and fees of national or international scale, the estimate is presented with a detailed list of the main items of income and expenses. The target nature of the use of the amount of financing of sporting events is an object of continuous internal control aimed at identifying the accuracy of accounting, transparency of calculations and confirming the targeted nature of the use of funds received for the event for each sport event.

Conclusion

The reliability of the internal control system is rated as high with the complete exclusion of risks. The digitalization of the control procedures and methods described in the article is a priority when conducting internal control of the organization and conduct of sports and physical education events of various sports, in order to quickly reduce risks, ensure the implementation of estimates, confirm the validity and effectiveness of spending in the digital economy.

Abstract

Full involvement of employees in improving enterprises and their processes is one of the flagship assumptions in modern management methods. Widely used solution supporting this approach are the employee suggestion systems (ESS), allowing the use of the intellectual potential and creativity of own staff. It is generally assumed that the main purpose of such systems is to increase employee involvement in enterprises improvement and to increase their sense of engagement and process ownership. Additionally, ESS generates savings and new revenues as a result of implemented suggestions. However, in many cases despite seemingly large number of improvement ideas submitted and implemented, they do not bring the assumed level of savings or do not generate financial benefits expected by the company. In this paper, authors present selected results of the research conducted on a group of 23 manufacturing companies from Poland, discuss resulting conclusions and research gaps and propose the direction for further work. The aim of the research was to find the answer on the following research questions: do and how applied ESS solutions allow to achieve expected results (the level of savings); are there any key factors that influence economic efficiency of ESS and if these effects are missing or if there is an insufficient level of return on investment, which problems cause it.

Keywords: Employee Suggestion Systems, Continuous Improvement, Lean Management, Economic Efficiency

Introduction

Present-day enterprises naturally operate in conditions of a high business competitiveness. The emphasis on a high quality of products or services, short delivery times and low prices, combined with the requirement to keep the costs of own activities at a sufficiently low level entails the requirement for the most effective use of the company's own resources. It is assumed that a qualified and committed crew is one of such key resources, alongside of being an element of strategy to build a company's long-term competitive advantage, which was pointed by both Womack (2011) and Balle (2019). Thus, the requirements for employees of such organizations are also growing, as they are not only expected to work effectively and efficiently, but also to be fully involved in the processes and individually propose ideas for process improvement, like Zupancic (2018) mentioned.

In this context, many authors e.g. Womack and Jones (1996), Womack (2011), or Jakubik and Kagan (2018) confirmed that it is recommended to notice the concept of Lean Management (LM), which from late 90s appears to be the critical way to achieve a competitive advantage of the enterprise. In the works of Womack and Jones (1996) and Harada (2015), the basis of LM is the elimination of all the possible waste, supported by internal processes improvement and employee involvement. The similar concept is repeated in the works of Imai (1986) and Balle (2017), where the success of LM implementation is defined as based on strongly motivated and efficient workers on each organizational level of a company.

In a widespread approach, potential inefficiencies in business management are manifested by the presence of 7 main waste types supplemented by an additional, eighth waste type, i.e. unutilized employees' skills (Figure 1).

Fig. 1: 8 types of waste (sketch based on Womack and Jones (1996), graphics by PresentationGo.com)

In the vast majority of cases the occurrence of these factors results in companies achieving lower-than-expected profits and observing reduced reliability and efficiency of the main and supporting processes, thus lowering their market competitiveness. This kind of conclusions can be found in many papers and case studies e.g. Womack (2011), Koch et al. (2012), Harada (2015) or Kagan and Jakubik (2019).

The waste of an employee's unutilized potential is a crucial issue here, because it may result in the decrease of an enterprise efficiency. It may lead to an underestimation of people's potential and therefore loss of many possible ideas and concepts that could otherwise be implemented and improved. It minimizes the possible ownership of areas and processes, self-engagement and subjectivity. For that reason, Balle et al. (2018) as well as Kagan and Jakubik (2019) mentioned that emphasis should be put on the enterprise relying on development coming from workers' qualifications and their creative improvement ideas.

One of the forms of abovementioned approach is well known concept of Kaizen Teian, originating from the Japanese management school and mentioned in the works of Japan Human Relations Association (1997), Lasrado (2013, 2015) and Krasiński (2017). The idea of Kaizen Teian is based on an employee suggestion system (ESS), relying on small and medium improvements suggested and implemented directly by the employees at their workplaces, processes and working areas. Most often ESS exist in a form of formalized systems allowing employees to submit their process or product improvements suggestions, which after supervisor's assessment can be relatively quickly implemented or rejected as either not fulfilling the planned criteria or inappropriate (Figure 2). Such systems are sometimes defined, for example by Japan Human Relations Association (1996) or Lasrado (2013), as systems of *kaizen* ideas or improving suggestions. As a rule it is assumed that the company's employees have the greatest knowledge of the processes or machines or workstations they operate, thus gain wider opportunities to exert influence on their workplace, while employers receive an excellent source of benefits from reducing company's operating costs or creating additional business potential.

Fig. 2: Basic scheme of ESS and a flow of the submitted idea (based on Japan Human Relations Association (1997) and Gibs (2017))

ESS - Two Approaches

Practical implementation of ESS in the business environment allows to notice two main concepts of their operation. Imai (1986), Kejna (2014) and Dekier (2017) called it *Japanese* and *American* approaches. The Japanese approach is the dominant one and specific for the Japanese way of managing, it can be characterized by a high sense of teamwork and a well-established need to strive for excellence in action. It is based on the assumption, that it is worth to submit and implement every single process or product improvement, even the smallest one having an inconsiderable influence on processes. The declared aim of ESS pointed by Imai (1986), Fairbank (2001) and Tucker (2012) is to enhance the operators' morale as well as their influence on management decisions, increasing the responsibility for their own workplace and processes. In itself, this approach assumes no primary emphasis on the on the economic effects of the system implementation or individual improvement ideas, any resulting benefits and added value are treated as secondary.

What is also of high significance is the notion that the literature of the subject from Al-Noorachi (2016) and Vanharnata (2018) specifies the differences between kaizen and innovation and their implementation. The concepts assume that the true savings come from innovations, while kaizen ideas used in ESS are rather dedicated for daily and small process improvements (Table 1). The consequence of abovementioned assumptions is the fact that ESS is considered a success only when certain number of ideas are implemented in relation to the number of the company's employees, which is to be an emanation of their involvement in the company's development – Robinson (214), Witt (2015) or Dekier (2017). At the same time, ESS effectiveness is often measured by e.g. number of days from submitting to idea implementation or percentage of employees contributing to the system, unfortunately overlooking the quality of ideas.

Table 1: Comparison of kaizen and innovation concepts (based on Al-Noorachi (2016))

Kaizen	Innovations
Adaptability	Creativity
Small steps	Large steps
Every employee participates, general preparation	Only chosen specialists participate
Collective work	Individual work
Small investments	Large investments
Focus on details	Focus on the main issues
People-oriented	Technology-oriented
Relying on existing technology	Searching for new technologies
Interdisciplinary groups	Employees + top management
Strong feedback loop	Limited feedback loop

From this perspective, most of the scientific studies focus largely on the technical aspects of the ESS, aimed at the different phases of their implementation and capability: from the development and study of the effectiveness of various ways of encouraging employees to submit ideas, through methods of material and non-material motivation, to the specifics of the sheets for submitting such ideas and their translation into the number of improvement proposals, methods of supporting the implementation of ideas, the way of evaluating proposals, to methods of obtaining as many ideas as possible per one company employee.

The most often used efficiency indicators of such ESS according to Kagan and Jakubik (2019) are:

- The total number of ideas submitted by employees within a year (number of ideas/employee)
- The percentage of implemented ideas amongst all submitted ones (the higher, the better)
- The average time from submitting the idea to its implementation (working or calendar days)
- The percentage of employees submitting the ideas [%]

The second trend in the design and operation of ESS, described in the book by Imai (1986) is the so-called *American* approach which emphasizes enterprise's economic benefits resulting from the implementation of improvement ideas, thus strongly changing the function of the goal at the foundations of such a system. This is because the measurable effects of the ESS, which is supposed to provide the company with certain savings or increase other economic benefits resulting from the implementation of number of improvements, come to the fore. Often emphasized, one of the features of this approach is a common use of financial motivators which are supposed to encourage employees to be more and more active and therefore by default associate idea with money. A lot of research has been done on an *American* approach e.g. Leach (2006) or Lasrado (2015), but these methods are often boiled down to the control of the ways of financial motivation or examination of the relations between inducing and generating of ideas. For example, Lasrado (2016) and Gibbs (2017) mention the obligation of submission of minimum two ideas quarterly per employee results in enhancing the level of savings. The impressive case studies of Townsend (2009) and Lasrado (2013) showed a significant relation between the level of savings coming from ESS and the levels of return on investments (even more than billion dollars in 5:1 ratio).

The superiority of one of the above concepts is questionable. According to Dekier (2017), the *Japanese* approach is chosen by many Western companies, assuming that the system itself is a strategic tool for employees' engagement in the company's operations and that improvement of processes is in both employees' interest as well as their responsibility. Other companies, in turn, focus on the measurable effects of using suggestion systems, sometimes even going as far as sharing a large extent of the improvement-induced financial benefits with employees.

Definition of Research Problem

Although the ESS systems are not a new solution, their implementation and operation processes have not been yet examined deeply in Poland. Research study on 201 manufacturing and service enterprises in Poland made by Grycuk and Dekier (2014) shows that the dominant motive for the ESS implementation is the desire to improve the company (56%), which is to manifest itself in the improvement of processes, improvement of work organization by reducing waste, shortening the time of realization of customers' orders and reducing the emerging technical problems (Fig. 3).

Fig. 3: Reasons for implementing ESS in Polish enterprises (based on Grycuk and Deikier 2014)

On the second place, respondents mentioned the desire for a broader and stronger involvement of their employees (54%). The third place went directly to the intention to achieve measurable savings, reduce costs and avoid excessive expenses (38%).

This way it seems that ESS implemented in Poland could be considered as a hybrid model of *Japanese* and *American* approaches, emphasizing the need for employees' involvement and anticipation of measurable effects. What is surprising over 85% of responded companies apply additional reward systems for employees submitting improvement ideas. On the other hand, only 21% of respondents measure the results of taken advantages coming from the improvements. What is more – the various methods of measurement are applied (i.e. by the amount – after 12 months period following the implementation of the idea – by the equivalent of full-time savings etc.). It is difficult to compare results from different companies and to draw conclusions.

Based on these research gaps, in 2015-2019 in-depth ESS case study examination was carried out at 23 manufacturing companies in Poland. The main goal was to check the implemented ESS solutions, especially their measurable gains and ESS economic efficiency. The research questions were also sought to determine whether and how the ESS solutions achieve the expected results (savings or additional revenues), whether are there any key factors influencing the economic efficiency of such ESSs and, in the absence of such effects or effects below the assumed level of return on investment, which problems stand most often in the way of the expected ESS efficiency.

Research Work and Selected Results

The first stage of the research was done on selected 23 manufacturing enterprises from Poland, which implemented the structured ESS. The companies represented 6 main types of manufacturing industry: automotive, home appliances, machinery, electronics, food and metal industries.

The exploration research work had been done by a direct interview method and the respondents were individuals directly responsible for the ESS implementation and maintenance in their companies (positions like Lean Manager, Lean Leader, Lean Coordinator, Continuous Improvement Specialist, Lean Management Specialist).

The questionnaire consisted of 31 questions (22 closed and 9 open questions) and was structured around three main areas:

- ESS effectiveness: what are outcomes of ESS, how these outcomes are measured, evidenced and controlled in the organization, what is the level of savings or new revenues generated as a result of implemented suggestions, what indictors are in use, where are the dominant benefit areas coming from employee suggestions, etc.
- ESS capability: how is the system organized, how is the idea submitted, how are evaluation and feedback processes structured and maintained, what kind of rewards are used for the submitted and implemented suggestions, how the management supports and motivates all employees to participate in the continuous improvement processes,
- ESS barriers: what are the main problems and largest difficulties in implementing ESS, how companies managed and addressed the organizational impediments.

Obtained information were both qualitative and quantitative. Chosen answers reflected respondents' experiences and knowledge about Lean Management and ESS. In 7 from 23 enterprises the respondents did not take a part in ESS implementation from the very beginning, but they followed the system maintenance on a daily basis.

74% of examined enterprises were considered large companies, the remaining 6 enterprises belonged to SMEs. A distribution of the surveyed companies by employment level is shown in Figure 4.

Fig. 4: Number of surveyed enterprises by number of employees

In every single case, the ESS has been performing in formalized and structured way for at least 1,5 year. The initial phase was devoted for a research on the field of a maturity level according to Lasardo-Gomiscek method described by Lasardo (2015). It allows 5 areas of operation of the ESS to be examined and each of them to be evaluated according to an appropriate scoring scale. The areas are as following: leadership and management support, system properties, system efficiency, organizational support, system limitations. Out of the surveyed companies, nearly 74% received the "Development phase" rating (average level). The phase of advanced development was achieved by only one of the examined systems (Fig 5).

Fig. 5: Number of surveyed enterprises in the terms of the degree of maturity of the system

Respondents were asked to determine three dominant benefits that motivate the enterprise to implement and maintain ESS. The detailed results are presented in the Figure 6. Sixty-nine answers were obtained. Respondents declared: willingness to improve the processes and products (74% of all answers), direct achievement of measurable and quantifiable financial benefits thanks to the ideas submitted as part of the ESS (70%) and strengthening the employee involvement (48%).

Fig. 6: Declared reasons for implementation of ESS in the surveyed enterprises

The question: *Measuring the economic efficiency of ESS has a key role for my company* turned out to be very important (Fig 7).

Fig. 7: Effectiveness of ESS in the surveyed enterprises - expectations versus reality

In Likert scale 78% of the questioned chose the option: *I strongly agree,* or *I agree.* It points to the high significance level of ESS operation. On the other hand, only the 43% of the enterprises turns out to possess the measurement tools. It shows the broad gap between the declarations and practical system maintenance (Fig 7).

Examined enterprises use various scales and ways to calculate the benefits coming from the implemented systems during the measurement of the financial results of ESS operation. A few main ways are listed below:

- the entire growth of company's revenues or savings, achieved thanks to submitted ideas, without considering the costs of their implementation and ESS maintenance as a whole, which are considered only in the general company's costs,
- the level of measurable company-wide savings made thanks to the ideas, taking into account direct costs, but not taking into account the translation of a given idea into areas which were not directly related to the impact of a given solution (i.e. a small structural change in the assembled product results in material savings and increases the efficiency of the process by 1.5%, and these benefits are properly recalculated, however, the same idea also eliminates the need for servicing and calibration of pneumatic wrenches from the assembly stations, which is no longer taken into account for the calculations),
- the level of financial benefits from improvement ideas according to the departments where the idea was first implemented, however with such cost allocation, where the costs of ESS operation are included partly in the overall enterprise costs and partly in the costs of operation of the departments involved,
- the level of net return on reported and implemented ideas considering the 12 months period from the time of full idea implementation,
- the level of net benefits obtained from the implemented idea within 24 or 36 months depending on the scale of proposed solution and the impact of the change on the process or product,
- the level of measurable savings calculated as the sum of benefits coming from implementation in the scale of the whole enterprise, but only considering the ideas giving more than 500 PLN (about 125 USD) net for one idea (this means the elimination of minor ideas from the list, the sum of which, however, may give a significant value, currently overlooked in the system),
- the equivalent of the full-time posts eliminated thanks to performed actions,
- additionally applied company's financial benefit indicator per one implemented idea.

Abovementioned examples make the situation even more complicated, because companies consider their general costs, or they additionally consider the cost of idea improvement. Consequently, the lack of a common ground prevents finding the correlation between solutions of ESS and the scale of obtained measurable benefits.

It should be emphasized that 6 from 23 examined companies (23%) declare caution in calculating the direct benefits of implementing employees improvement ideas. They motivate it by the fear of the entire systems' stigmatization where only financially beneficial ideas are demanded. It suggests that the ideas that do not bring benefits, are underestimated. Nevertheless, those ideas are very valuable as well (i.e. in the area of work safety, ergonomics).

Next issue concerns three areas, where the financial benefits are particularly significant. The question was addressed to 11 companies declaring application of such indicators. The results are shown in Table 2.

Table 2: Areas of highest economic impact of improvement ideas in the surveyed companies

Area of financial impact of ESS	Percentage of companies indicating the area of influence [in %]
Efficiency of production processes	91
Product quality	55
On-time delivery	45
Level of stocks of semi-finished products and materials	27
Lead time	27
Other	27
Efficiency of supporting processes	18
Consumption of materials	9

There is a clear indication of three main areas, which are production process efficiency (indicated by 91% of the surveyed companies), product and service quality and on-time delivery of products and services to customers. This is directly related to the thematic scope of submitted employee ideas. However, the areas of "safety at work" and "ergonomics of the workplace" are on default not included in the list, which, although indicated as frequent subjects of submitted improvement ideas, their translation into financial results is not counted by companies. Table 3 shows the other indicators, which refer to ESS in enterprises.

Table 3: ESS indicators used in the surveyed companies

ESS indicators	Percentage of companies using the indicator [%]
Number of ideas submitted by employees (total per company)	100
Number of implemented ideas (total per company)	100
Percentage ratio of ideas submitted to implemented	100
Number of ideas submitted and implemented by the company's organisational departments	78
Average number of ideas per employee	78
Number of ideas waiting in line for implementation (delay scale)	48
The level of savings from ideas per company and per areas	48
Number of ideas in priority areas (e.g. safety or quality)	39
Level of financial (or point) rewards for employees for implemented ideas	39
Time from notification to idea evaluation and feedback	35
Time from submission to implementation of the idea	35
Percentage of employees involved in the ESS	22
Level of financial benefit per improvement idea	17

A certain group of indicators commonly used in all companies can be observed. They concern the number of submitted ideas. The indicators showing the financial influence of improving ideas are mentioned rarely (22% and 17%).

The respondents were also asked to list the four most important problems and limitations of a proper operations of ESS in their company. Overall, 92 answers were obtained, where the percentage of the answers is showed in the Figure 8. The quality of ideas and processes show the anticipated problems in achieving measurable benefits (70%), or make it difficult or impossible for supervisors to make an accurate decision to reject the application or accept it for implementation (61%) or cause a large number of ideas to be put forward by employees, but they are insufficient in quality (52%).

Fig. 8: Problems of companies in the operation of ESS declared in the survey

Even though all companies reported various problems in everyday operations and maintenance of ESS, only 3 from 23 enterprises analyzed the situation to investigate the source of the problem. 20 from 23 companies performed only interim corrective actions. This way of action gives little chance to draw conclusions for structural improvement of ESS and to generalize recommendations.

Discussion and Conclusions

The research was done on the group of 23 manufacturing enterprises in Poland. Even though manufacturing companies differ from service companies, the results may be generalized to formulate some common conclusions and to ask even more research questions.

1. Based on the described research probe and previous research work from Grycuk (2014) it may be assumed that the dominant reasons to implement and maintain ESS in Polish companies are both the willingness to encourage the employees in constant improvement and maximizing their sense of identification with the company (*Japanese* approach) as well as the expectation of achieving measurable effects from such a system and translating it into business results of the company (*American* approach).

2. The ESS solutions commonly used in the surveyed companies put the emphasis on the number of submitted ideas, the greatest increase in the percentage share of ideas implemented to the submitted, broad involvement of the company's employees in the system and shortening the time from idea submission to its implementation. The indicators used in these companies also focus on these aspects. Only a few of the companies have metrics allowing to measure the financial translation of the implemented ideas within the ESS into the economic effectiveness of the system itself or the whole enterprise in general. This makes it difficult or impossible to take appropriate corrective actions to increase such effectiveness. Further research in the area should be designed and conducted.

3. The measures of the economic efficiency of ESS do not share the common ground, what hinders creating the cause and effect relationship and discovering the correlation between the parts of ESS and economic results of ESS in a research probe. Largely, the way of calculating the measurable economic benefits do not consider the obtained additional indirect benefits

coming from the implementation of employee ideas in the remaining company's areas, limiting calculations to financial savings only.
The literature research like Leach (2006), Arthur (2017) or Dekier (2017) does not suggest clearly how to measure the efficiency of ESS. Many indicators are mentioned in the literature:

- The increase of the final customer satisfaction and the increase in the quality and efficiency of the processes,
- The increase in safety level of employment and trust towards an employer,
- The increase in employee engagement,
- The increase in revenue and savings level.

4. Currently used models of calculating the economic efficiency of ESS do not solve the problem of the proper quantifying the scope of the benefits, which are related to process influence, i.e. in the form of the quality-focused preventions enabling faster problem-solving process. The mentioned aspect has been already discussed by Trenkner (2015), but the subject has not been fully exhausted.

5. Characteristic of the survey is that among the problems with the operation of the ESS in their enterprises mentioned by the respondents, the first place (70% of the indications) was given to under-reported savings in terms of investment in the entire ESS. The dissatisfaction was most often related to the costs incurred for the implementation and maintenance of the system, implementation of the improvement ideas themselves and the analysis and corrective actions of the already implemented solutions (without taking into account the ideas aimed at the improvement of work safety, which were not evaluated).
At the same time, 52% of the respondents indicated problems with applications that propose mutually exclusive solutions or too trivial from the perspective of improving the process correctness. Potential causes were seen in poor communication of objectives to employees or irregularities in the way of implementing motivational solutions to submit ideas, as well as low level of employees' knowledge of continuous improvement.
By combining these two indications, it can be concluded that the problem in accomplishing a certain economic efficiency of the ESS is not a small number of submitted ideas, but their quality, which does not allow achieving an adequate rate of return on a running ESS.

6. The interesting phenomena is the stagnation effect (or even its decrease) in the number of submitted ideas at a particular time of ESS development (it occurs in 61% of the companies). This issue is relatively poorly examined and described in the subject literature. The sources of those events are supposed to come from the slowly developed competence level of the employees in the scope of the constant improvement and its methods and solutions of Lean Management, which causes persistent "exhaustion of ideas" among company's crew. The other causes may be also: the indirect negative correlation of idea number decrease and longer time from idea reporting to its realization and insufficient resources to accomplish all of the ideas, what was pointed by Jakubik and Kagan (2015) and Kagan and Jakubik (2019).

7. The additional aspect of ESS operations in the context of anticipated economic efficiency of the system is assigning the goals, creating the adequate area and the atmosphere in the company to operate effectively and to communicate these goals to the employees. In the context of the survey results, which indicate that 26% of the surveyed companies refrain from directly declaring their expected financial benefits, reasoning it by their concerns regarding the lack of submission of valuable improvement ideas from areas that are difficult or impossible to accurately quantify. It seems important to configure the ESS in such a way as to give equal priority to ideas with financial translation also to ideas outside such an impact pool.

The results collected in the research mentioned above and a review of the literature on the subject indicate clear gaps in the field of knowledge about ESS, especially in the terms of the impact of various factors on the economic efficiency of such systems. It is assumed that there is such ESS model that

will not only allow to achieve a large number of ideas submitted by employees, but also a large translation of these ideas into measurable economic results for the system itself and, therefore also for the entire enterprise.

Such studies will require the determination of an algorithm for measuring the economic efficiency of the ESS, which can be universally applied under given boundary conditions to various types of enterprises and thus enable finding a correlation between such economic efficiency and factors affecting them.

Abstract

Assessing modern approaches to manage the policy of ensuring the continuity of public catering enterprises we need to take into account multifactorial external and internal environments of their activities. A great number of elements of external and internal environments, many of which can vary widely, create a problem of choosing the accounting tool that will help these enterprises to carry out ordinary course of business in terms of the specific character of their development. The developments of a group of special reserves taking into account peculiar features of performance of public catering enterprises, and the improvement of their accounting and internal control both in theoretical and practical plans are of a great interest within the ensuring of continuity process of these business entities. In the process of solving the tasks set to achieve the research objectives scientific provisions have been formulated that are the basis for the improvement of business accounting and internal control of the reserves at public catering facilities aimed at ensuring the continuity of public catering enterprises. The scientific novelty consists of the updated set of the concepts "the continuity of public catering enterprises", "reserve complex", "special reserves" proposed by the authors, as well as the procedure for processing accounting information of public catering facilities based on the formation of a reserve complex, which is required to ensure the continuity of public catering enterprises.

The developed procedure for the formation of a group of special reserves is based on the risk-oriented approach and depends on compliance with the rules to the service provision in the field of public catering, sanitary and hygienic rules for enterprises, products, transportation and storage. The proposed methodological approach to the assessing, business accounting and identification of a group of special reserves in financial statements includes the calculation of interest and value indicators taking into account the amount of the estimates, the percentage of natural losses and product damage.

Keywords: Risk, Continuity, Reserve, Reserve Complex.

Introduction

At present, catering industry in Russia is one of the attracting scopes of activities, which is profitable from the viewpoint of investments. Large restaurant networks around the country and small cafes and canteens performing many functions represent this industry, which determines their importance for ensuring modern life. Due to the increasing competitiveness and a large selection of specific character of catering enterprises, the issue on ensuring the continuity of their activities is very topical.

To implement the principle of continuity of public catering enterprises such accounting tool as the formation of reserves aimed to support an ordinary course of business is used to a limited extent, the specific character of activities is not taken into account when they are formed. Thus, for example, the reserves related to the investing and financial activities are widely introduced in scientific research; however, they are not relevant for public catering facilities due to the lack of these types in the small business sector.

The reserves for current activities are the special category of reserves. Since the catering industry involves a special technological process, for example, a culinary processing of food products, enterprises of this area are subject to the specific types of risk. This factor significantly affects the continuity of their activities, and as a result, reserves applied to these peculiarities of enterprises are required.

In well-known economic studies there is no single conceptual approach to the formation of a reserve complex taking into account the specific character of public catering industry and helping to respond to the risks of this sector in a rational way. The reason is the lack of understanding by the administration of catering facilities of the necessity to create the reserves to ensure the continuity of their activities. The lack of research on the formation of accounting reserves at public catering facilities, and the lack of a single point to the structure of a group of risks at catering enterprises, the lack of a methodology for reserve assessing and accounting as well as the lack of internal control of reserves require a scientific study of these issues.

Thus, at present, the problems of the formation and application of reserves at public catering enterprises in Russia have not been studied enough and need further analysis, which determines the relevance, goal and objectives of the dissertation thesis.

Main Problem

The problems of functioning of accounting systems of different types of activities have been considered in the works of the Russian scientists: P.S. Bezrukikh, N.A. Breslavtseva, V.G. Getman, N.P.Kondrakov, V.F. Paliy, Y.V. Sokolov, V.I. Tkach, A.D. Sheremet, V.B. Ivashkevich, E.A. Mizikovskiy, A.M. Ilyshev, N.N. Ilysheva, T.V. Zyrianova and others. Among foreign scientists involved in business accounting, recording and analysis one should mention D. Middleton, B. Needles, J. Richard, P. Samuelson, E.S. Hendriksen, R. Anthony and others. The studies of these scientists are of great importance for the development of business accounting. However, they considered the concepts of reserves, its content and accounting in general without sector characteristics of enterprises.

The problems of ensuring business continuity are described in the works of such scientists as I.T.Balabanov, P.G. Graboviy, M.G. Lapusta, E.A. Utkin, A.S. Shapkin, A.E. Shevelev, E.V. Sheveleva and others. This category of scientists considered such concepts as “business continuity”, “uncertainty”, “risk”, and proposed methods to ensure business continuity. However, the considered types of risks and their classification are generally not applicable to public catering enterprises; therefore, further scientific research is required.

The study of business accounting of financial reserves was conducted by a number of foreign and domestic authors such as R. Adams, J. Betge, D. Middleton, R. Anthony, S.V. Romanova, L.T. Giliarovskaia, Y.V.Sokolov, A.D. Sheremet, L.R. Robinson, A.P. Rudanovskiy, I.M. Ageev, L.A. Melnikova, E.V. Riabova, E.A. Popova and others. The scientists considered the concept “reserves” and gave their assessing and accounting for different types of business activities, however, those specialists considered reserves for enterprises in general or in relation to individual industries. In this connection different approaches have been formed, which are practically inapplicable to public catering industry.

Despite the large number of articles on business accounting for reserves we may speak about the lack of a single approach to the formation, accounting and control of a complex of reserves to determine the goal of further research.

Methods

The research to improve business accounting and internal control of reserves at public catering enterprises to ensure business continuity has been conducted on the principles of an integrated and systematic approach using logical and economic analysis, monitoring, comparison and grouping.

To ensure the continuity of public catering enterprises we have proposed the procedure for accounting data processing based on the creation of a reserve complex, which helps to identify and assess risks, and create reserves based on them.

Within the public catering enterprise activities, information is obtained both from external and internal sources. Information obtained from external sources means documents from buyers, suppliers, tax services, etc., information from internal sources refers to documents created within the company by different departments.

The procedure for accounting information processing consists of the following operations (Fig.1):

1) registration of facts of business life;
2) determination of materiality of the influence of the revealed factors on business continuity. If there is no information on risks, the documents are registered further on accounts and combined statements, then in reporting (operations 7 and 9). If the documents contain information on risks, then the following operations are fulfilled;
3) identification of risks at public catering enterprises;
4) quantitative and qualitative risk assessment;
5) determination of the necessity to create a reserve complex. If the administration decides not to divert resources to create reserves, then the same operations follow as when registering documents without information on risks;
6) formation of the reserve complex: depending on the risk identified the required reserves, their amount, selection of the account are determined;
7) registration on business accounts and in combined statements;
8) reserve internal control system involving the assessment of the efficiency of a reserve complex. If there is inefficiency of a reserve complex during the internal control, the initial parameters are adjusted to create reserves;
9) preparation of financial statements.

Specialists studying the reservation and the reserve system of enterprises have offered reserves for industrial enterprises, agricultural companies but not with regard to public catering enterprises. This sector has its own specific character, which is necessary to be taken into account when developing a reserve complex. At present, the legislation regulates the creation of the following reserves: statutory (reserve capital), fair value (reserves for depreciation of tangible assets, reserves for impairment of investments in securities, reserves for doubtful debts) and reserves for future expenses. These reserves are not always created by public catering enterprises and there are no reserves that take into account the peculiar features of this industry.

The rightly assessed risks and the possibility of unfavourable events help to direct available assets into reserves for certain purposes in a rational way. It contributes to the increase of the financial stability of the company. The riskiness of public catering enterprise performance involves the necessity to form reserves to cover possible losses in order to ensure business continuity.

Thus, the use of the given procedure when processing the accounting information of public catering enterprises, which is based on the formation of a reserve complex, will contribute to the reduction of risks inherent to this industry ensuring the principle of business continuity.

Fig. 1: Procedure for accounting information processing at public catering enterprises based on a reserve complex formation

(Source: compiled by the authors)

Results and Discussion

In order to form the efficient reserve complex for public catering enterprises it is necessary to analyse basic economic parameters to identify basic ways of the formation of reserves. Based on the analysis of statistical data on catering enterprises we may make a conclusion that the production costs are the most significant ones. The production costs include not only the cost of manufacturing goods but also the costs of writing off unsold products with a short expiry date. Therefore, it would be advisable to

form a reserve for product spoilage in order the costs would be uniform and be prepared in case of writing off a large amount of spoiled products.

In this regard the procedure for the formation of a group of reserves used at the formation of a reserve complex has been clarified, which includes the following actions:

1) identification of peculiar features of the performance of catering enterprises;
2) identification and qualitative assessment of a risk caused by these features;
3) identification of the necessary reserve using the classification of reserves.
Various situations related to the peculiar features of catering enterprises performance form different types of risks. Depending on the situation, we may accept a number of risks, while with other risks we should take actions to reduce undesirable consequences.

Based on the analysis of the reserves of catering enterprises we have concluded that we need to systematize them for the right selection during the procedure of accounting information processing.

The current catering enterprise performance includes such operations as the production of own products, their sale as well as semi-finished products, goods and services, the acquisition of goods necessary in the production process of the company, etc.

In the current catering enterprises performance the following reserves can be identified:

1) reserves, formed in accordance with the legislation and constituent documents (reserve capital belongs to this category);
2) valuation reserves:
– inventory reserve;
– reserves for doubtful debts;
3) reserves for future expenses:
- reserve for the payment of annual leave;
- reserve for the payment of remuneration for length of service;
- reserve for the repair of fixed assets;
- reserve of future expenses related to the production activities of public catering enterprises;
4) reserve for natural losses;
5) reserve for unsold spoiled products;
6) reserves related to conditional facts of business activity:
- reserve for pending litigation;
- reserve for pending proceedings with Rostekhnadzor (Federal Environmental, Industrial and Nuclear Supervision), sanitary and epidemiological station, etc;
- reserve for pending proceedings with tax authorities, the Pension Fund, etc.

The financial activity of the company is the attraction and repayment of borrowed sources of financing (credits, loans), the payment of dividends, fines, penalties, and other non-sale operations.

In the financial activities of public catering enterprises, one can distinguish such reserves as the valuation reserve for the impairment of financial investments; guarantees issued; notes payable.

The investment activity of the company is the set of processes of investment decisions making and practical actions for their implementation to achieve a stable position of the company in the market and maintain or create competitive advantages.

The following reserves can be identified in the investment activity of catering enterprises:

- reserve for the sale or termination of any type of activities;
- reserve related to the wrong choice of a "market gap".

There are both known reserves and special reserves proposed by the author. The proposed reserves considering the specific character of public catering enterprises performance will ensure the continuity of enterprises in combination with well-known reserves:

1. Reserves for guarantees issued. This reserve is formed when goods for sale are accepted for commission. Such operations are recorded on off-balance accounts; however, the issued guarantee limits the right to use their property in the amount of the issued guarantee for the terms of the contract.
2. Reserve for natural losses. These reserves are important for public catering enterprises, since inventory holdings, which tend to decrease under the influence of external factors, occupy a large share; therefore the reserve makes it possible for even losses to be included in expenses from natural losses.
3. Reserve for spoiled products. This reserve is formed when you have to write off damage to unsold products, sometimes these amounts are significant. Quite often, the following situation arises in the public catering enterprises performance, especially with canteens and cafes: they have prepared more dishes than they have sold, and the shelf life of the products was short.
4. Reserve for future expenses related to the production activities of public catering enterprises. This reserve is formed to reduce such production risks as violation of cooking technology, equipment malfunction, etc.
5. Reserves related to conditional facts of business activity. This reserve is formed, since the use of food products in production and the production of ready-made dishes is very risky, poor-quality raw materials may be used, or the production technology and sanitary rules that will affect the quality of the final product, thus causing litigation can be violated, etc.
6. Reserve related to the wrong selection of enterprise specifications. This reserve is formed at the beginning of enterprise performance when the administration of the company is not sure that the selected specifications will be in demand.
7. Reserves for the sale or termination of any type of activities. This reserve is formed before the launch of a new enterprise project, when the administration of the company is not sure that it will be profitable.

Conclusions

Thus, the proposed procedure for the formation of a group of reserves considering the specific character of public catering enterprises performance, based on a risk-oriented approach and depending on compliance with the rules for the provision of public catering services, sanitary requirements for enterprise and food products, food transportation and storage, will help to form an effective reserve complex to ensure business continuity. The results of the study can be recommended for use in economic practice of public catering enterprises.

Abstract

The article is devoted to the problem of evaluating the economic efficiency of digital investment projects. The genesis of the development of digital projects has been formed. The genesis is based on the evolution of global digitalization processes. The topic of the presence on the market at the present time of a wide variety of projects. The paper presents a classification of digital projects identifies five features based on this classification. Based on these characteristics, various types of projects have been identified and investigated. An analysis of each type of project made it possible to identify their specific properties. In the article, the authors examined the most important properties such as the intangible nature of the objects of investment and the reduction of the project life. The latter leads to a significant increase in risks in a rapidly changing environment. The analysis of the most popular methods for assessing investment performance showed that none of these methods takes into account the identified specific properties of digital projects. The authors propose to form a system of continuous environmental monitoring at the enterprise to reduce the risks of losing the effectiveness of projects in a rapidly changing environment. The basis of such a system is proposed to use the mechanisms of weak market signals.

Keywords: Digitalization Development, Digital Project, Performance Evaluation, Acceleration of Environmental Changes, Methods, Risks, Monitoring System, Theory of Weak Market Signals.

Introduction

Nicholas Negroponte conducted the first research in the field of the digital economy *(Negroponte, 2000)*. In 1985, he founded Media Labs at the Massachusetts Institute of Technology (USA) and contributed to the development of digital literacy for children. In the next thirty years, digital technologies developed rapidly, and this caused an active discussion of these processes in science and practice. It seems to us expedient to single out five stages of this development.

The first stage falls on 1990-2000. It is characterized by the emergence of a large number of companies whose business model involves the mandatory use of Internet technologies. For example, eBay (online auction), Amazon (online store), Yahoo! The result of combining companies into a single chain was the growth of prospects for their rapid development. They actively attracted money and invested in advertising, increased brand awareness, and sent the proceeds to marketing again. Within the framework of this scheme for implementing digital investment projects, the idea is formed: "grow fast or disappear." The proliferation of digital investment projects in business has led to a reassessment of the value of companies, the formation of a bubble from dotcom companies (companies' business model is based on the Internet). This bubble burst in 2001 due to a fall in the NASDAQ. Ultimately, the reason was the lack of understanding that the Internet is a tool in a business process, but not a separate business process *(Safronov, 2019)*.

The next step in 2005-2010 is the implementation of digital investment projects to create the first digital products and electronic services, creating electronic advertising, e-commerce.

In 2010-2015, digital technologies are included in all sectors of the economy, as well as in traditional business. Using of an artificial intelligence, neural networks, and robotics confirms this trend.

Digital investment projects for the implementation of Industry 4.0 technologies are implemented in the industry from 2015 to 2020. In 2017, the Digital Economy of the Russian Federation program was approved in the Russian Federation, indicating the beginning of digital transformation across the country.

According to experts, an active transition from the implementation of single digital investment projects to large-scale digital transformation should occur starting from 2020. This transformation involves the widespread use of cross-cutting technologies of Industry 4.0.

Cross-cutting digital technology spans multiple markets or industries. At the scale of one enterprise, it covers the entire value chain, from production to after-sales service, destruction at the end of its life. At the beginning of the development of the digital economy, individual investment projects were implemented in which cross-cutting technologies were not applied, and digitalization concerned individual stages of the production process or sphere of activity, however, a trend has developed towards the implementation of complex digital investment projects involving the use of cross-cutting digital technologies since 2015 (Figure 1).

The analysis of the formed genesis shows that currently there are projects on the market for each of the formed stages. Despite the prospects for significant business growth predicted by many experts, the implementation of digital projects is low. One of the reasons for this situation is the lack of adequate methods for evaluating the effectiveness of digital projects.

Fig. 1: The evolution of digital investment projects

(Source: compiled by the authors)

The purpose of this research is to identify the specific features of various types of digital investment projects, to review the methods for evaluation of the efficiency of investment projects in terms of their adequacy to the identified specifics, and to propose a method for analysing the key features of such projects.

Problems of Research

A significant variety of digital projects present on the market today makes it difficult to achieve this goal. We tried to classify it.

We used five features that we used to classify digital projects (table 1). Consider each identified type of project and try to characterize the specifics of each.

I. According to the scale of the on-going changes, digital projects can be classified into two groups: operational and digital transformation projects.

1. Operational digitalization projects.

These are projects related to the digitalization of a single business process. For example, the introduction of a technology or the automation of individual business processes. This type of project is typical for modern industrial enterprises in many developing countries. Its advantages are an implementation in the short term and the possibility of quickly gaining effect from the implementation.

The specificity of projects of this type is the local transformation of business processes, suggesting the need to embed digital equipment in an existing technological system. The implementation of this task is quite resource intensive, requiring time. Sometimes such projects require additional costs associated with the formation of infrastructure and training. Increased risks of implementing individual projects are associated with their short life cycle.

Table 1: Classification of digital investment projects

<table>
<tr><th>Classification characteristic</th><th colspan="5">Types of digital investment projects (DIP)</th></tr>
<tr><td>1. Scale of changes</td><td colspan="3">Operational Digital Projects</td><td colspan="2">Digital Transformation Projects</td></tr>
<tr><td rowspan="2">2. The approach to structuring and triggering changes</td><td colspan="2" rowspan="2">Fail-Fast – project</td><td colspan="2">AGILE – project</td><td rowspan="2">Waterfall- project</td></tr>
<tr><td>scrum-project</td><td>Kanban-project</td></tr>

</table>

(Source: compiled by the authors)

In a digital economy, industrial enterprises need a global restructuring of the process of organizing activities in order to maintain their competitive position. This requirement corresponds to the second type of digital project - digital transformation.

2. Digital Transformation Projects. Transformation involves the implementation of a group of digital projects that allow not only optimizing time and material costs, but also a qualitative change in the entire business model.

A key specificity of digital transformation is the on-going process of changing the business model. The specifics of this type of project are associated with the high cost of a variety of resources. At the same time, various functional centres and various specialists are involved in the transformation process. This circumstance leads to an increase in the so-called “switching costs”. Another specific feature of this type of project is the increased threat to reduce information security. Currently, the specifics of these dynamic projects are also manifested in increased risk, primarily due to great uncertainty. The latter is associated with fast, constantly accelerating changes in the environment. At the same time, scenarios and roadmaps for the implementation of such complex projects have not been developed.

Digital transformation in industry is carried out in various ways. The following approaches to digital transformation can be distinguished, depending on this.

Process approach. In this approach, digital technologies are implemented throughout the production chain, from product development to its implementation and post-sales service.

Industry approach. This approach is a model of digital transformation of industry, taking into account its interaction with other industries. This is TechNet (digital factory), digital city, FinTech (digital financial technology).

Technological approach. This approach to transformation consists in choosing the technologies used in its implementation, for example, sensors and sensors, the Internet of things, Big Data, quantum technologies.

II. As a second feature of the classification, an approach to structuring and launching digital changes was used. Depending on this, digital projects are proposed to be divided into the following groups.

1. **Fail-Fast - projects**

Projects involve rapid testing of technologies to determine their economic value and applicability. After that, projects are implemented on a limited scale and the conclusion is made: fail or success. If a positive result is obtained, the technology is introduced at the factory *(Comel, 2018)*. The specific of Fail-Fast projects is the need for a rapid estimate of their economic value, which requires the use of a scoring model.

2. **AGILE – projects**

Agile is flexible. The definition accurately reflects the following essence of the approach: it is an iterative development of the project, which involves phased work with the assessment of the results and the adjustment of the previous stages of work. Groups of specialists of various profiles carry it out. Agile projects are classified into scrum projects and Kanban projects.

Scrum project. The development team consists of universal specialists and a curator, and the work is done in parallel and divided into sprints, as a result of each a working version of the product should be obtained. The problem of implementing such a digital project is to form an effective team. This determines its specificity. Universal training of specialists can cause surface immersion in each area, resulting in a shallow study of various aspects of digitalization: ensuring information security, optimal allocation of resources, IT support. Thus, we have high "switching costs".

Kanban-projects are implemented by a team of narrow-profile specialists, a balance must be maintained in the team (specialists of different profiles have approximately the same scope of tasks). At the same time, the process is divided into the stage of performing specific tasks, for example, planning, development, testing of a product. The specificity lies in the problem of the “pulling” scheme: until one task is completed, another is not taken into work. In the context of digitalization, the scheme does not allow you to quickly adapt the entire project to changes and fix the incorrectness of the results of the previous stage in time, since an intermediate assessment of the results is not carried out, in comparison with Scrum-projects.

Waterfall Project

Waterfall - the project involves the work in stages. Each stage is strictly regulated, strictly meets the originally specified requirements. Go forward without completing the previous step, or forward is not possible. The key problem of such projects is the lack of flexibility; therefore this approach in the case of digital projects, as a rule, is ineffective

III. Depending on the scope of implementation of digital projects, the following groups of digital projects are distinguished.

1. Projects of process control systems.

Individual projects can be implemented in the management of the production process, taking into account the requirements of digitalization. For example, the management of the production process or the activities of the entire industrial enterprise using the MES (manufacturing execution system) system. The specific of digitalization projects for control systems is associated with a fairly wide range of problems; they are associated with a wide variety of management tasks, both in content and in degree of complexity. Firstly, it should be noted the lack of complete, correct and relevant information to perform these tasks of information in many examples. Secondly, the need for full integration of the software used in management. Thirdly, there are problems with reducing the number of jobs. In principle, all projects relate to the release of personnel, but management tasks without the participation of qualified experts are difficult to solve.
2. Digitalization of production processes. As a rule, these projects are related to the type of operational projects. Hence, their specificity consists in the additional costs of integration into existing equipment, the costs of training and retraining of personnel, a large degree of uncertainty.

3. Projects on digitalization of product life cycle management systems.
Lifecycle management projects are related to the implementation of PLM software. PLM-system provides data collection during the operation of the facility, identifying strengths and weaknesses, during disposal allow you to determine the value of the components of the facility, the possibility of their further use.

4. Digitalization projects of transaction management processes.

One of the first digital projects was online sales projects. Today, transaction management can be considered more broadly, including projects related to supply chain management (SCM). According to experts, the digitalization of transaction management should be carried out in three areas. The first is value creation. Secondly, the digitalization of the leverage of these processes. These include organization, personnel, performance management, and cooperation. Experts estimate that as a result, EBITDA margins can be increased by 3-5% *(Schnellbaecher, 2019).*

5. Projects for after-sales service of digital products.
For example, UAZ is implementing the PROF-IT Service Management project, optimizing the work with dealers and post-sales service processes for automobiles. The program is adapted for dealers, provides a catalogue of spare parts, routings (maintenance instructions), information on standards for service time, the possibility of interactive viewing of electrical circuits, sections with troubleshooting and training.

IV. The implementation of digital investment projects affects various sectors of the economy. Accordingly, with this feature, it is possible to distinguish system and cross-cutting project groups.

1. System projects involve changes in industry in various sectors: in production, in the transportation system, in the energy sector.

System projects are classified, in turn, into the following types:

i. digital factory (factory) (smart factory, virtual factory);
ii. digital city (smart city);
iii. digital road and digital transport (smart road and smart transport);
iv. smart home and smart goods.
The specifics of large projects are their high cost, the need for a large amount of resources, the costs of changing consumer attitudes, the problem with the release of personnel. In addition, they are characterized by a high degree of uncertainty.

2. Cross-cutting projects affect the development of several sectors of the economy.
V. Depending on the scale of the on-going changes, digital investment projects in industry can be classified into projects with integrated supply and with the replacement of individual units and parts. In the first case, it implies the replacement of the entire production line and the installation of a complex of new equipment. In the second case, only part of the production equipment is updated. Specificity is associated with the main problem of these projects - the need to incorporate new elements into an existing system.

The analysis showed that today there are many types of digital investment projects with the following specific properties.

1. Limit the long-term investment.

In modern conditions, due to the significant acceleration of technological progress, an effective technology may be morally obsolete by the time the digital investment project is completed. This trend significantly reduces the planning horizon of a digital transformation and limits the ability to use “long” money in the digital economy (Parakhina, Popovicheva and Bazarnova, 2018).

2. The high level of risk associated with cyber security and the protection of intellectual property.
Digital investment projects use large amounts of data. Even with the implementation of the pilot project, violation of their confidentiality causes serious damage to the company. In addition, digital investment projects are based on modern digital technologies that allow them to maintain a competitive position in the market. Disclosure of information about the technologies used jeopardizes the competitive advantages of the company. In this regard, the implementation of digital investment projects is associated with a high vulnerability of companies in the field of cyber security.

3. Dematerialization of assets in a digital environment.
In a digital economy, most of the assets are intangible. A special approach evaluating and accounting for the acquisition costs or development in digital projects is required. In addition to intangible assets in the classical sense, there are also informal assets known as capital equivalents. Under them is actually considered revenue growth because of increased customer loyalty through the introduction of digital technology. This indicator is not reflected in the financial statements, but at the same time, it is one of the criteria for the success of the implementation of digital investment projects.

4. The increase in the speed of launching a new product on the market.
Advanced production technologies have reduced the time to market a new product and, using an iterative approach to improve it, make changes and adapt it to customer requirements in real time. For example, Facebook updates the software twice a day, tracking user reactions and making adjustments based on observational data.

Consider whether these properties take into account modern methods of evaluating the effectiveness of investment projects.

Currently, among the existing methods, the most popular are the following.

1) Model Goldman, Sachs & Co;
2) Ernst & Young model;
3) EBRD model;
4) World Bank models;
5) The analytical model of “cost-benefit” (cost-benefit analysis);
6) Model of United Nations Industrial Development Organization (UNIDO);
7) Little-Mirrlee's model.

The first three models from this list are mainly used for business planning and creating a business plan - a key document of the investment project.

Goldman, Sachs & Co experts recommend evaluating indicators based on official statistics, which are less prone to falsification. For example, data on the average cost of energy and building materials.

Ernst & Young researchers use adjusted present value (APV) to determine the investment efficiency of investments. But this indicator corrects NPV by the amount of financial expenses for the issue of shares, and does not take into account investment risks.

The EBRD’s methodology is the most concise of this group of methods. The user needs significant experience in creating business plans and characterizing project performance indicators for applying this technique. The World Bank considers the analysis of design efficiency in terms of design analysis. However, this technique is for assessing social project productivity, not the financial and commercial side. A project is appropriate for investment if it is reliable, feasible and meets the goals of the UN. A variety of performance parameters, including NPV and PP (payback period), are used to evaluate indicators according to the Bank's methodology.

The criterion parameter of Bruno is of considerable interest. It allows you to determine design efficiency in the shadow prices of cleared savings. A serious disadvantage of this methodology is the lack of a PI index reflecting comparative project performance.

The "cost-benefit" model originally arose in France in the 19th century, and it developed in the 40s of the 20th century in the USA *(Kalinovskaya, 2016)*. At that time, the researchers decided to find the optimal balance of costs and benefits. The problem solved using the criteria of NPV and IRR.

The disadvantage of this technique is its long-term focus with a relatively low reliability. In addition, the model does not take into account non-commercial effects and the impact of resource redistribution on productivity, allows subjectivity in the estimates.

A further development of the cost-benefit model was the creation of the UNIDO's model. According to this model, in addition to the levels of commercial performance, the public performance of the implementation of the investment project is measured *(Simić, Vratonjić and Berić, 2011)*. The analysis showed that its key drawback is the poor accounting of investment risks.

We consider the methodology by Little-Mirrlees as an alternative to the UNIDO's model *(Simić, Vratonjić and Berić, 2011)*. Experts *(What is the digital economy? Trends, competencies, measurements, 2019)* note its following disadvantages:

- the parameters for choosing an investment project in an implicit form are based on the concepts of a planned economy with an endless supply of labour;
- international commodity prices are highly dependent on speculation, which can lead to errors in the characterization of project performance indicators using this model;
- the calculation of the parameters for price recalculation may contain significant inaccuracies due to lack of data or incompetence of staff;
- the model is based on a significant amount of additional calculations when implementing a capital investment project due to potential transformations in international prices and the need to establish new parameters for price conversion.

Thus, the review showed that modern popular methods for evaluating investment projects do not take into account the specifics of digital projects. Existing methods make it impossible to take into account the rapid change in the environment, and therefore the lifespan of digital projects is steadily decreasing and the risks of investing are growing.

Reducing these risks requires a system of continuous market monitoring. It seems to us that the basis of such a system should be based on mechanisms for seizing weak market signals.

Methodology of weak market signals as a mechanism to reduce uncertainty in the implementation of digital projects.

The terminological diversity of the meaning of the term "weak signal" *(Hörner, 2012)* requires highlighting the main features of the phenomenon, such as (1) the high uncertainty of the existence of the phenomenon, (2) the causal relationship between the weakly and implicitly observed phenomenon at present and the predicted significant consequences in the future, (3) lack of transparency and awareness of the phenomenon, etc.

For the purposes of this study, we define weak signals - these are early, implicit signs of upcoming significant events, both in the internal and external environment of the enterprise, the influence of which will be strictly indefinite.

The development of the concept of weak signals in particular, (Garcia-Nunes and da Silva, 2019) led to the emergence of the concept of "Management of market signals" as a management based on inaccurate and incomplete information *(Ansoff et al., 2019)*. In principle, this means control under conditions of uncertainty, i.e. precisely in the conditions in which the vast majority of enterprises are today. And this means the need for the leadership of these enterprises to begin to act at the first weak market signals.

As part of the control for weak signals, it is advisable to introduce the concept of a significant weak signal. Significant weak signals will be considered the totality of weak signals, which, with a certain set of them in the future, may have the most significant impact on the results of the project and the enterprise.

Using the theory of weak market signals in predicting environmental changes, we distinguish two key tasks: identifying signals and identifying the most significant of them. These tasks correspond to the theory of management; accordingly, the business needs constant monitoring of the market. This requires the formation of a mechanism for the systematic collection, analysis and selection of important information for companies about competitors and market conditions, internal factors of the project / activity of the enterprise.

In the framework of this study, the following steps are required to identify weak signals (Fig. 2):

- formulate a list of identifiers of weak signals;
- build a monitoring system for identifiers of weak signals;
- typify weak signals.

Fig. 2: Diagram of a method for predicting changes in weak signals
(Source: compiled by the authors)

Note that the Ansoff model for strategic management of an enterprise according to a weak signal involves the classification of weak signals into external and internal *(Ansoff, 1975)*.

The general list of external weak signals should include identifiers of all levels of the economy, from macro to microeconomic. It is advisable to classify this list for external weak signals based on the PESTEL methodology.

It is clear that we share Ansoff's approach to the classification of weak signals into internal and external. The author's classification of internal weak signals is based on the theory of risk management in project management. It involves classifying identifiers for internal weak signals by types of potential project risks.
It is important that for each project or enterprise an individual set of identifiers is created for both external and internal weak signals.

An extremely complex management task is to identify significant signals for the timely adoption and implementation of proactive decisions on the timely transformation of digital projects.

The complexity of the task is because each forecasting object (in the scientific, technical, political, economic, environmental, and marketing and other fields) manifests itself in various fields,

directions, expressed by indicators of different dimensions, different meanings, different nature and directions. In other words, it is among the complex, dynamic and multi-criteria, often with multidimensional problem solving. It is clear that it is necessary to determine the appropriate methods and tools for solving problems.

In the early studies of the authors of the article, it was shown that the most adequate to such tasks are the tools of nonlinear dynamics and a synergistic approach (Fig. 3).

Fig. 3: Justification of the choice of nonlinear dynamics tools for predicting environmental changes by weak signals

(Source: compiled by the authors)

The advantage of such a tool of nonlinear dynamics as a phase portrait, from the point of view of the solving problem, consists in the possibility of representing an arbitrarily complex system by several, up to a single point.

The method for identifying significant weak signals is based on the construction of phase portraits of each of the weak signals.

One of the existing and proven tools for macroeconomic spline analysis of phase spaces is a split-picture, used to build and analyse the dependencies of economic indicators in the form of split-curves. The growing interest in the use of split-pictures is due to the ever-increasing rate of changes in macroeconomics, as well as a change in the nature of dependencies in macroeconomics from hierarchical to network. Split pictures are also used for visualization, interpretation and analysis of macroeconomic dependencies of two or more variables.

The next step in predicting environmental changes from weak market signals is the development of phase portrait archetypes for weak environmental signals for a specific digital project. This is the task of future research by the authors.

Conclusions

Today the development of digital projects is characterized by significant industry differentiation. The speed of their implementation in the financial sector and public administration is significantly higher than in industry. The key problem of less active use of digitalization projects in industry is the lack of adequate methodologies for evaluating efficiency. Methods should take into account the short lifespan of digital projects and the high risk of the emergence of a new, more effective solution. To mitigate this problem, it is proposed to use mechanisms of weak market signals that allow us to predict, with a certain degree of accuracy, technological changes.

Abstract

Society is increasingly aware of the environmental impact of industry, therefore, the environmental impact of the products commercialized became a current and pressing concern of customers. Individuals prefer eco-friendly and durable products and are interested in buying from companies that have implemented environmental protection measures. Due to these aspects and also due to the tightening of EU environmental protection regulations, organizations should implement environmental management systems in order to reduce the impact of their products and services in accordance with sustainable development goals. Particularly, in regard to product development companies, a fundamental aspect of an environmental management system is the use of eco-design as a design methodology. Eco-design can help companies minimize the environmental impact of their products over their entire lifecycle, reduce the raw materials use, energy and water, produce less waste and pollution and increase the products' efficiency and service life. Introducing eco-design into the product development process requires a high level of expertise regarding the potential environmental impact and advanced knowledge of the methods and tools that can be used to support this initiative. In this context, the present paper tries to highlight the importance of integrating the eco-design process when developing new products and proposes a selection of relevant methods and tools that can be used during the eco-design phases in order to help designers accomplish their environmental targets and obtain eco-friendly products. The literature review research conducted is based on the standards outlined by the ISO 14006:2020 *Environmental management systems - Guidelines for incorporating ecodesign*.

Keywords: Design, Eco-Design, Product Development, Sustainable Development.

Introduction

In the current economic context, companies whose core business is product development and manufacturing must be at the forefront of dynamic changes in customer requirements related to product customization as well as their rapid availability on the market. Therefore, in order to remain competitive in the current business environment, these companies must launch products that not only meet and exceed customer expectations, but also help grow their turnover and maximize their profits. In addition to the dynamic market changes, a company that wants to develop a new product must also take into account the current regulations on sustainable development in product design and manufacturing. These regulations mainly concern the reduction of material and energy consumption, the reduction of gas emissions and the use of recyclable materials. Consequently, starting with the product design phase, designers have to take into account, in addition to the constructive-functional characteristics, other conditions related to product life cycle – reuse/ repair/ recycling.

As stated by Fernandez (2018), product development and manufacturing companies need to demonstrate their commitment to sustainable development goals by strengthening their product life cycle with actions that demonstrate their involvement in this process. In order to accomplish this, companies should take actions and use tools which will help them make the transition from a linear economy model to a circular economy model, as mentioned in Michelini (2017), Jørgensen and Pedersen (2018) & Rosu and Rohan (2018). Regarding the transition to a circular economy, one of the main actions a company should take is using eco-design methodology when developing their products, as stated in Navajas et al. (2017), Prieto-Sandoval et al. (2018), Gallagher et al. (2019) and

Neto (2019). Additionally, Fernandez (2018) stated that eco-design has become the main methodology that can be used by companies in order to make their products more sustainable and eco-friendly, because it incorporates environmental and sustainability criteria as basic requirements in the design process. Therefore, raw materials, manufacturing, packaging, distribution, sale, use, maintenance, reuse and disposal are analyzed during the design process in order to reduce resources consumption, cut emissions and reduce pollutants output throughout the entire product life cycle, Fernandez (2018).

Since the late 1990's, when awareness regarding the environmental impact of the manufacturing industry increased, the research focus has been primarily directed towards developing eco-design methods and tools which can reduce the environmental damage during the life cycle of products, Pigosso et al. (2010), Sihvonen and Partanen (2017), Ahmadzadeh et al. (2017), Fernandez (2018). The eco-design approach focuses on obtaining sustainable solutions for products with a low environmental impact during their life cycle, without compromising their performance, functionality, aesthetics, quality and cost, as mentioned in Pigosso et al. (2010) and Dostatni (2018).

Because of the necessity of increasing attention towards the environmental impact, the European Union developed regulations and legislation regarding the way companies should use and implement environmental features when developing their products. Such regulations were also developed for eco-design, standards such as ISO/TR 14062:2002 and ISO 14006:2020 have been developed in order to provide guidance on how to integrate eco-design into the management systems of companies, Maderna-Fernández et al. (2013) and Zouari (2019).

The EN ISO 14006 standard introduced in 2011 and updated in 2020 presents the definition and the basic principles for eco-design in order for them to be integrated into the product design and development process, Maderna-Fernández et al. (2013).

Consequently, the main purpose of this research study is to identify, by literature review and analysis, the most representative methods and tools that can be used during the eco-design process as it is outlined by the ISO 14006 standard. In essence, the paper is a literature review manuscript, however, it tries to present the methods and tools developed for eco-design that, from the author point of view, simplify the design process by making it easier and faster.

Eco-Design Process – General Presentation

ISO 14006:2020 defines eco-design as a *systematic approach that considers environmental aspects in design and development with the aim to reduce adverse environmental impacts throughout the life cycle of a product*. This design approach is also known as *environmentally conscious design (ECD)*, *design for environment (DfE)*, *green design* and *environmentally sustainable design* (ISO 14006 and Ahmadzadeh et al. 2017).

Several other definitions of this concept can be found in the literature, some being listed below:

→ Pigosso et al. (2010) defined eco-design as *a new way for developing products where the environmental aspects are given the same status as functionality, durability, costs, time-to-market, aesthetics, ergonomics and quality*.
→ Chou (2014) states that most definitions conceptualize eco-design as *a systematic process that identifies the environmental aspects of a product and integrates them into the product design in the early phase of product design and development process.*
→ Marconi and Favi (2020) defined eco-design *as the integration of environmental considerations within product design and development*.

ISO 14006 presents six phases for the eco-design process (figure 1). However, even if the standard presents a set of steps for the eco-design approach, both in literature and in industrial practice there are several other approaches for this design methodology. All of these approaches, Pigosso et al. (2010), Chou (2014), Farhane et al. (2014), Sihvonen and Partanen (2017), Tao et al. (2018), Dostatni

(2018), nibusinessinfo.co.uk (2020), etc, focus on the reduction of the environmental impact of products, taking into account manufacturing, usage and disposal.

Fig. 1: Eco-design phases (ISO 14006)

As Fernandez (2018) stated, the eco-design process does not represent a new way of designing products, however it does provide a new point of view, by taking into consideration aspects of sustainability as key requirements. She presented a parallel between a traditional design methodology and the eco-design methodology (figure 2), in order to highlight the environmental criteria added to each design stage.

Fig. 2: Traditional design and eco-design steps [Fernandez C. (2018)]

The eco-design process is based on several principles (nibusinessinfo.co.uk 2020), as follows: → using low environmental impact materials; → reducing the resources and materials used during the manufacturing process of products; → producing less pollution and waste during manufacturing; → diminishing the environmental footprint of the distribution process; → ensuring that products attain a high degree of resource efficiency during operation; → reducing waste and pollution caused by products when in use; → optimizing product service life and maintenance sustainability; → reuse and recycling focused design; → reducing the environmental impact of products by optimizing disposal methods.

Eco-design is an eco-friendly design methodology that generates products that not only present benefits for the environment when compared to products designed with traditional methodologies, but are also able to provide potential savings and efficiencies for businesses. Ahmadzadeh et al. (2017) made a literature review and subsequently identified the following advantages of using eco-design for developing new products: → increased competitiveness; → decreased variable costs; → less use of toxic materials; → increased product functionality; → improved economic performance; → increased revenue; → increased sales volume; → less energy use; → prolonged product life; → improved company image; → reduced material use.

As it can be inferred from the above, eco-design is defined by eco-friendly and efficient products, but designing such products presents the need for appropriate and efficient methods and tools. There are

a large number of tools to support eco-design (Pigosso et al. 2010), from specific guidelines and checklists, to dedicated software and databases on materials and processes. Depending on the project target and on the availability of tools, the product designers can choose which tool they should use in order to complete each eco-design phase. However, given the existence of a wide variety of tools, it was deemed beneficial for any design team to develop a selection of tools which can be used for each eco-design phase.

Eco-Design Methods and Tools

This paper section will present a selection of eco-design tools developed by scientists and industry and used during the eco-design process. As it was also mentioned in the paper introduction, the author tries to present the relevant methods and tools that can be used in order to support the eco-design process. The main criteria used to select these methods and tools was the ease of use within the product design process. A correlation between these tools and the eco-design phases proposed by the ISO 14006 standard will be developed.

As stated by Pigosso et al. (2010), the decision regarding the methods and tools to be used when developing a product depends primarily on the product design phase. Several authors have developed methods and tools that can be used during the eco-design process. However, most of them did not corroborate their developments with the eco-design phases proposed by the ISO 14006 standard. Additionally, evidence of industrial use of currently existing tools is scarce, Vallet and Glatard Mahut (2013). Mandolini et al. (2019) identified that some eco-design tools also raise issues related to the fact that they are not or are hard to be integrated with the typical design tools, are heterogeneous (developed for a specific product sector), and require a very large amount of knowledge and knowhow on environmental issues in order to be properly implemented. During her research projects focused on eco-design tools, Lofthouse (2006) identified that designers need tools that combine guidance, information and education and simplify the process by making it easier and faster.

In order to fulfil the objective of this section of the research paper, the main phases of eco-design, as outlined in ISO 14006, and representative tools will be presented as follows.

Specify Product Functions

The identification of functional requirements is considered as a starting point for many of the classical product design process methodologies, as can be seen in Roche (1999), Campbell (2002) and Cross (2008). This design phase is regarded as a key factor for obtaining a successful design for a product and has a critical role on its entire life cycle, because a product which is not designed oriented on its functionality will never have market success.

This eco-design phase consists in the identification of the product functions and is not different from similar phases proposed in classical design process methodologies. Special tools specifically designed for tackling environmental issues are not mandatory.

The best way to represent a functional structure of a product is by means of functional models, such as: functional trees, as presented in Robotham (2002), Kitamura et al. (2006), Viola et al. (2012), Simpson et al. (2014); and Function Structure Diagram, as presented in Aurisicchio et al. (2013). There are two main methods to develop a functional tree: Functional Analysis System Technique, FAST, as stated in Bartolomei and Miller (2001) & Borza (2011), and the Subtract and Operate Procedure, SOP, approach presented in Aurisicchio et al. (2013).

Of particular importance is the fact that before starting this phase of the eco-design process for a new product development certain activities should be performed, such as: market analysis in order to identify the need for new or eco-revised products, finding and selecting product ideas in relation to the identified need, task clarification, determination of the product requirements, etc. The identified need and the customers' requirements are the main inputs when developing the product functional

structure. The survey and benchmarking are the most appropriate tools that should be used in order to perform these activities.

Define Important Environmental Parameters

In this eco-design phase, the environmental assessment of the product is determined, in order to identify which stage or process of the product life cycle will have the highest environmental impact. The main activities which should be performed are: the analysis of the environmental demands of stakeholders and the evaluation of the environmental aspects in relation to the product in development.

It is important to highlight the difference between the environmental aspects of a product and its environmental impact. The *environmental aspect* is defined by ISO 14001:2015 *as an element of an organization's activities or products or services that interacts or can interact with the environment*, and the same standard defines the *environmental impact* as *a change to the environment, whether adverse or beneficial, wholly or partially resulting from an organization's environmental aspects*. The product environmental aspects are related to: consumption of materials, energy and water, both during manufacturing and while in use, emissions, waste generated, etc., conversely, its environmental impact can be assessed by: pollution and contamination of the air, soil and/or water during manufacturing, use and disposal.

As stated by Vallet (2013), this phase is important for providing a good understanding of the environmental problems caused by a reference product and for the evaluation of the redesigned product.

There are several eco-design tools developed in order to support this design phase, as presented by Pigosso et al. (2010), Vallet et al. (2013) & Dostatni (2018). However, most scientists consider that Life Cycle Assessment, LCA, is the most objective eco-design method that can be used for determining the environmental profile of a product, Navajas et al. (2017).

Muralikrishna and Manickam (2017) defined LCA as *a cradle-to-grave or cradle-to-cradle analysis technique to assess environmental impacts associated with all the stages of a product's life, which is from raw material extraction through materials processing, manufacture, distribution, and use.* LCA framework is presented in figure 3.

Fig. 3: LCA frame work [adapted from Muralikrishna and Manickam (2017)]

Regulations and legislation regarding LCA implementation are defined in standards such as: ISO 14040:2006, ISO 14044:2006, ISO 14047:2012, ISO/TR 14048:2002 and ISO/TR 14049:2012.

Software tools that were developed in order to facilitate the study of the Life Cycle Assessment: Open LCA developed by GreenDelta, One Click LCA developed by Bionova, SimaPro developed by PRE-Consultants, Instant LCA Packaging developed by RDC Environment, LCA Calculator

developed by LCA Calculator Ltd, LCA4waste developed by Chair of Ecological Systems Design, ETH Zurich etc.

Brezet and Van Hemel (1997) identified eight eco-design strategies, as follows:

- *new concept development;*
- *selection of low impact materials;*
- *reduction of materials usage;*
- *optimization of production techniques;*
- *optimization of distribution system;*
- *reduction of impact during use;*
- *optimization of initial lifetime;*
- *optimization of end-of-life system.*

The Eco-design Strategy Wheel (figure 4) is the tool widely used in this phase of the eco-design process. Brainstorming and Matrix prioritization are other tools that can be used in order to identify the environmental strategies and the sub-strategies and ideas for improvement, Fernandez (2018).

Fig. 4. Eco-design Strategy Wheel [adapted from Fernandez (2018)].

Develop environmental objectives and targets

After the identification of the environmental protection strategies, the environmental objectives and targets should be established by the design team and they should be in correlation with the general environmental objectives and targets outlined by the company management. There are no specific tools designed only for this phase of the eco-design process. The basis for the environmental objectives and targets should be the requirements set by the available legislation and a proper evaluation of the corporate environmental policy. Specific checklists and matrices can be used, where the objectives and targets can be correlated.

ISO 14001:2015 defines the *environmental objective* as *the objective set by the organization consistent with its environmental policy*, and the environmental target as *a detailed performance requirement, applicable to the organization or parts thereof, that arises from the environmental objectives and that needs to be set and met in order to achieve those objectives*.

For example, if an objective can be *to use recyclable materials for manufacturing and packing the new developed products inside the company*, then the target will be *to reduce with 15% the usage of non-recyclable materials for manufacturing and packing of products.*

Establish Product Specifications

This is the eco-design phase that consists of the design of product characteristics and specifications based on client requirements and the technical life cycle of the product. The output of this design phase is the specifications list. The listed specifications can be expressed in terms of: product geometrical and material characteristics, safety, ergonomics, manufacturability, quality, assembly, maintenance and transport possibilities, recycling characteristics, costs, deadlines, etc.

Establishing product design specifications is accomplished by applying methods such as: Quality function deployment, QFD, Theory of Inventive Problem Solving, TRIZ, Benchmarking and tree diagram. Product specifications should be precise and measurable and should detail what a product has to do in order to satisfy the identified needs. The product specifications do not explain how to address the needs, but instead they present what should be achieved in order to satisfy the needs.

The main difference between the classical design approach and the eco-design approach in this design phase, is that eco-design focuses on the critical points at an environmental level, with internal and external environmental requirements that should be taken into account, Fernandez (2018).

Develop Technical Solutions

Traditionally, this phase of the design process consists of developing technical solutions for the future product based on the specifications outlined by the design team. Eco-design proposes that these solutions should also incorporate proposals for environmental improvements. In eco-design, environmental parameters and their criteria needs to be analyzed, synthesized evaluated and improved at every stage of the design process.

Methods which can support the starting point of this design activity are QFD, TRIZ, morphological charts, etc. To support these methods, various software tools and design repositories were developed. Some examples are: QFD software developed by the Statistical Design Institute, Eco-Design Tool developed by Chang and Chen (2004), the tool developed by Dostatni (2018), etc.

In regard to software, the most useful tools for completing this eco-design phase are the CAD system-integrated tools. Dostatni (2018) made a brief review of the CAD tools which can be used for environmental impact assessment. Nowadays, specialized CAD software such as Autodesk Inventor, CATIA, Solidworks, LogiCAD, etc. have special modules which can be used for environmental assessment purposes. Granta Design Solutions developed by Granta Design and ECODESIGN+ developed by Eco-design are also tools which can be taken into consideration for this design activity.

The design solutions should be elaborated by taking into account a wide variety of aspects, including: functionality, costs, materials, manufacturing processes, distribution and sale, use and disposal. All this will be evaluated in relation to raw materials and energy consumption, impacts, generation of waste and pollution.

Conclusions

This paper contains a literature review research study on eco-design methods and tools as support for sustainable product development, based on the requirements specified by the ISO 14006:2020 standard. The first part presents general data on eco-design: definitions, process methodologies, principles and advantages of eco-design, while the second part outlines a correlation between the eco-design phases presented in the ISO 14006 standard and representative tools developed by scientists which can be used to support the eco-design phases. The presented eco-designed tools are selected by the author having as a main criteria the ease of use of these tools during the product design process and their simplicity.

Eco-design is not limited to being only a design approach, but rather it is a part of the corporate environmental management system. Introducing eco-design as a process for developing products within a company affects activities and processes at all levels, starting with corporate management. ISO 14006:2020 also provides guidelines for incorporating eco-design into the environmental management system. Implementing eco-design methodologies can provide companies with environmental, economic and social benefits. By studying eco-design methodologies, it can be determined that the eco-design process is similar to the traditional design process, the primary difference being given by the fact that in the eco-design process the environmental impact must be analyzed, synthesized, evaluated and improved at every stage of the process.

The literature review shows that there is a wide variety of methods and tools developed to support the eco-design process, however some of them require an advanced level of knowledge regarding environmental aspects and polices. Consequently, this paper tried to present the ones that, in the author point of view, can simplify the product designer's work.

The correlation of the eco-design phases proposed by the ISO 14006 standard with methods and tools which can support these phases is highly beneficial when a company decides incorporating the eco-design process as a part of the corporate environmental management system. The information presented in this paper can be used as guidance when developing and implementing a specific eco-design process into a product development company. The author contributions consists in: developing the literature review and analysis, the selection of the most relevant methods and tools to be used during the implementation of the eco-design process, making the correlation between these methods and tools and the eco-design phases as outlined by ISO 14006. This research will be also the basis of the further research of the author, research that will consist in developing an eco-design methodology to support circular economy model integration in small manufacturing companies.

Abstract

Innovativeness is becoming the main guideline in the policy of many enterprises intending to build its and its environment's driving force. The environments in which it is becoming more difficult to compete without building an innovation strategy, where small and medium enterprises achieve successes characterised by the following distinguishing features: awareness in which innovativeness becomes a feature strongly related to success; the sense that innovativeness leads to faster development or greater successes than in the case of non-innovative enterprises; the belief that innovativeness will lead to greater share in the market and improvement in profitability. Strictly innovative activity in enterprises is profitable in many ways. R&D activity demonstrates strong correlation between the achieved research results and new products. The purpose of the paper was to present the entrepreneur's attitude towards the executed implementation project and check the model applied by the entrepreneur. The study was conducted using the in-depth interview (IDI) method, classified as one of the basic techniques of qualitative studying. It is based on having a talk with the respondent. The interview's purpose is to obtain a detailed opinion and information from the company's owner concerning the executed innovative project. The applied technique was aimed at check whether the innovation process was executed according to the specified stages, which allowed the entrepreneur to plan and implement the innovative solutions in an effective manner. The model's aim was to check what was the process of seeking the solution that was later implemented.

Introduction

Innovation is key for European competitiveness in the global economy. EU implements the policy and programmes supporting the development of innovation in order to increase investments in R&D and to improve the conversion of research into better products, services or market processes. Poland is effectively adapting to these guidelines by promoting various criteria that support enterprises intending to develop their innovative potential. Companies investing in innovative solutions can count on EU subsidies both from national and regional programmes. Nearly half of Polish companies deems innovativeness as a strategic goal of their activity, as stated by the "Innovation Maturity of Polish enterprises 2014" report. According to the study, as many as 78% of medium and large enterprises is conducting works on innovative solutions. Slightly less, i.e. 71% is implementing their results. Over 80% of companies intend to increase the scale and area of related activity. In truth, the aforementioned data concerns mainly entities with stable situation and many years of presence on the market, however the trend is increasingly disseminating (Cho, H.J., Pucik, V., 2005, pp. 555-575.). An increasing number of enterprises – including small and medium – notices a chance for competitiveness and capturing new foreign markets in the creation of innovative and unique solutions or implementing processes furthering innovativeness (Maj 2017a; Maj 2017b, Maj 2018) . Migration also favors this proces (Kubiciel-Lodzinska, 2017, 2018; Kubiciel-Lodzinska & Ruszczak, 2016).

Models and features of the innovative process

R. Rothwell presented and discussed the model of executing innovative processes by relying on all kinds of changes affecting the economy, starting from the 1950s (Dodgson M., Rothwell R., 1996).

- **The supply-based model of innovation processes**

It is the first-generation model – innovations pushed by science. It functioned from the 1950s to the middle of the 1960s. Its causes were the huge needs and fast economic growth, which were characteristic in the post-war period. Enterprises awaited for the evolution of scientific discoveries that would be possible to be implemented into production. In that time, enterprises followed the dependency "the more resources and research and development, the more new products in the market", however over time the number of introduced innovations that brought no benefits and even caused losses for enterprises increased. This situation was inspiring and changed the approach, which gave way for the creation of the second-generation model.

- **The demand-based model of innovation processes**

It was established in the mid-1960s and lasted until the mid-1970s, where the battle for the market share was a specific feature of the economy. The basis for this model was the increase in competitiveness and market share losses, which pointed to the consumer needs. It is related to analysing the benefits and costs of given research projects. It is also necessary to note the establishment of stronger relations between the R&D unit and the enterprise by combining engineers and scientists into teams working on a given product. The main intent of this activity was to reduce the time of product implementation into the economy. Due to the fact that the market was the main source of the concept for R&D work, the focus was too much on improving the products available, which halted the activities on radical innovations.

- **Supply and demand chain model taking into consideration feedback**

The model functioned from the mid-1970s to the mid-1980s. The reason for it was the need to continuously monitor the environment when executing an innovative process. The main focus was on lowering the costs of development and the only work done was the developmental work that was to provide the greatest benefits.

- **Fourth-generation model – co-operation model**

The model encountered between the mid-1980s to the mid-1990s. The reason for its creation was the acceleration of civilizational development and an increase in the demand for capital. The focus was on strengthening the processes taking place inside the enterprise, which lead to expanding the entire concept. The biggest limitation of the XX century were financial resources, which is why the focus was on the overall network integration the ensure flexibility and fast growth. The basis for the above described model was the co-operation of all company elements (A. Pomykalski, 2013, pp. 5-15).

- **Fifth-generation model – strategy and integration model**

In this model, we can distinguish feedback between the processes taking place inside and outside the company. It also takes into consideration the "trade-off" type dependency between time and the innovation formulation cost. The basic competitiveness factor was the ability to effectively develop and implement a suitable innovation. This was the decisive factor in vigorously developing areas where the product's life cycle became considerably reduced (Tidd J., Bessant J., Pavitt K. 2006; Knosala R., Boratyńska-Sala A., Jurczyk-Bunkowska M., Moczała A., 2014).

When executing an innovative project, each enterprise knows that there can be a certain risk. With this in mind, the enterprises divide the projects into certain stages to systematically control the course of the executed activities and in the case shortcomings, to be able to eliminate errors or repair them

on an on-going basis, systematically evaluate the resource allocation and engage many internal structures in the project's execution (Tidd, J., Bessant, J., 2013, ; Postawka M, 2007, pp. 4-22).

Innovative Process Implementation

Service Innovativeness

Through the term of service innovativeness, we can understand both the products offered by the given enterprise and the process of the services provided by it, the logistics process, enterprise management process or the relations with the environment (Hawrysz, 2016). However, specific features referring to the services make the innovation process to be relatively different from the production activity. The main and most important factor in service enterprises is the contact with the customer, who is a very important source of innovations for the given company. This is not only a reference to the opinions issued by the customer, but also to his or her reactions during the service offering. The way that a given innovation source is used depends largely on the employees – their sensibility and competencies and positive emotions (Sauberer et. al. 2015).. It is worth noting that customer behaviours will be varied during the provision of services, which is why some of the offered innovative solutions will not be repeated by the enterprises (Kusa R., 2004, p. 380–386).

Table 1: Areas of innovation in service enterprises

Area of innovativeness	What methods should an entrepreneur use to increase its company's innovativeness?	Examples of the entrepreneur's actions
New concept of service provision	Knowledge on the existing competitive services in the market: who provides them? What is their quality? What are the prices of the offered services? Who buys them? Are there substitutes for them?	• In-house market studies • Benchmarking • Employment of a consulting company • Employment of an expert
New concept of co-operation with the customer	Knowledge on the current and potential customers	• In-house market studies • Employment of a consulting company • Employment of an expert • Inviting customers to co-operate (through crowdsourcing, i.e. creating innovation through customers, etc.)
New system of service distribution	Knowledge of our employees: their skills, attitudes. Knowledge of competitive companies' employees	• Employment on competitive conditions of the competitive companies' employees • Establishment of a customer club • Establishment of a franchise system • Watching foreign solutions (e.g. the founder of the

		Starbucks coffee shop used inspirations gained during his holidays in Italy, when he observed Italian coffee shops).

Source: Jan Fazlagić, Is your company innovative? How to seek innovations in the services sector? Advice for Small and Medium Enterprises, Polish Agency for Enterprise Development

Designing and implementation of innovative solutions

An increase in an enterprise's creativity is the main element that can support the designing of innovations, mainly with the use of inventive creation methods. The objective of such methods is problem solving using an unconventional, sometimes even unrealistic thinking which leads to the finding of new goods or processes. It allows for finding undiscovered solutions, minimising expenditure and time for innovation implementation, resulting in the company's improves competitiveness and innovativeness (P. Bębenek, 2015, pp. 165-175).

Characteristic features of the science of inventive creation:

- *"constructing and establishing new products"*
- *"solving difficulties, problems in a creative manner"*
- *"progress and supporting attributes related to the creative process"*
- *"delegation of relationships between facts"*
- *"individual result achievement"*
- *"specification of theories and assumptions"*
- *"lack of protection and guarantee of developing a solution to the problem"* (Jagoda-Sobalak D., Marek-Kołodziej K., Łapuńka I., 2018, p. 1229-1240)

An innovative enterprise uses three basic, however very important elements: creating innovative ideas, using them in practice, incurring the costs of their execution.

An innovative enterprise develops and uses pioneer products, but is also fully ready for the changes occurring in its environment. All activities executed prior to innovation implementation are aimed at gaining innovative technologies, but also preparing the company to implement specific processes. It is important for the enterprise's preparatory period to be used effectively, because it contributes to the first measurable financial benefits deriving from the implementation.

The innovation implementation in an organisation is based on two basic documents which include: the technology documentation and business plan, whereas the technology implementation consists of the following steps:

- *Implementation initiation (all activities executed in earlier stages, which allowed for obtaining the technology and developing the suitable documentation)*
- *Implementation planning (appointing the implementation team, planning the organisation and communications, planning the scope of activities, preparation of the implementation schedule, planning the resources, planning the quality, planning the risk)*
- *Preliminary implementation (infrastructure, human resources, material resources, financial resources)*
- *Proper implementation (production/manufacturing, production/manufacturing control and monitoring activities, distribution and sales, recipient surveying)*
- *Secondary implementation (technology or process modification)*
- *Implementation completion (standardised mass production, servicing)*

All innovations that can be initiated in the organisation require regulating the receivables, i.e. purchase of patent or license or purchase of software. The product's performance quality, which

is synchronised with the potential buyer's needs is obligatory during each step of activities related to the implementation. At the time of test implementation of its innovative product or service, the enterprise should establish a scope of activities enabling it to conclude whether the product or service implementation is fitting and beneficial.

Development And Implementation Works – Product Development And Testing

Development works can be defined in many ways, these especially include the developmental processes for a new product. A ***product*** is nothing but offering goods that will satisfy the consumers' needs. The term of product development is understood as the designing of a new model that will undergo testing. At the time of prototype creation, the design engineers should conduct precise reviews to their adequacy and competence, whereas the team tasked with designing the given product develops the documentation that includes an accurate technical specification (required parameters, structure, composition). The same group is also tasked with developing the technical and production documentation, which include such data as the production processes' and technologies' specification. The conducted prototype testing enable transitioning to the next step, which is the testing in laboratory conditions to check whether the given product (P. Bębenek, 2017, pp. 121-128) model complies with the expectations and the design documentation.

Potential customers can check and evaluate the product that is to be launched on the market. It is a way of testing the given goods, both in natural and laboratory conditions. This form of testing has many advantages including the ability to observe and compare the new product with other products and lack of urgency.

The testing can be as follows:

- Blank test - offering customers product samples that are encoded for the person participating in the test. Product encoding is to exclude factors that can affect the customer's opinion.
- Occasional test – based on providing answers in a survey used for information purposes. The surveyed participant knows the product he or she is testing (Frąś J., 2013, p. 175-186).

Implementation - economic analysis of a new product

In order to avoid additional costs, prior to commencing the work on the development of a prototype, an economic and financial analysis is conducted during the new product concept's implementation. This analysis should allow us to answer the following questions:

- What is the market capacity? (how many can be sell)
- What are the fixed and variable costs?
- What are the marketing costs?
- What quantity of the new product must be sold to achieve the safety margin?
- What prices guarantees the product's sales and profitability?
- What sales volume should be planned in a given period to guarantee profit?
- How should the production plan be developed to include the possessed production cycles?
- How to achieve the assumed objectives, especially the financial objectives?

The notions that can be encountered when conducting an economic and financial analysis are notions concerning the costs that will be incurred during the preparation, implementation and launching the product on the market. When we implement a new product, it is worth considering the phenomenon of the so-called cannibalism – it is a phenomenon when a part of the given company's employees gives up on purchasing the currently available products to be able to buy a new innovative product. An effect of this phenomenon is the lowering of the costs on available products in favour of the new implemented product (Frąś J., 2013, p. 175-186).

Research Method

The study was conducted using the in-depth interview (IDI) method, classified as one of the basic techniques of qualitative studying. It is based on having a talk with the respondent. The interview's purpose is to obtain a detailed opinion and information from the company's owner concerning the executed innovative project. The applied technique was aimed at check whether the innovation process was executed according to the specified stages, which allowed the entrepreneur to plan and implement the innovative solutions in an effective manner. The model's aim was to check what was the process of seeking the solution that was later implemented. By using this technique, we are able to clarify the nature of the tested phenomenon, to get to the essence of things and obtain information which would be hard to obtain by other methods, like surveys, among others.

Main subject of activity: purchase of grain, rape and legume seeds, warehousing and warehouse services, production of seed, providing services using agricultural equipment, providing farmers with materials for agricultural production, crop production on owned fields. AGROPOL Łosiów executes the project as part of measure RPOP.01.01.00. Innovation support. Project title: Development of a prototype system for the test sampling of storage mass based on visual technology and conducting industrial research and developmental works in terms of the effectiveness of the applied method in the drying process – process testing and validation

Brief description of the technological process' stages

- Weighting; the transport mean is weighted on a scale
- Sampling; the sampling from transport means (e.g. trailer) is done using a special crop sampling device (Rakoraf sampler) in various trailer points. At the same time, a device for the visual impurities' evaluation method is fastened to the penetrator's lance. The test will take place simultaneously using the conventional method and the new visual method to ensure continuous results' comparison. The basis of the conventional method: the probe collects a seed portion from the transport mean, then it transports it to the laboratory, where the seeds' parameters evaluation is conducted. In the visual method, which is strictly correlated with the conventional method, the evaluation device will be paired with the seed collecting probe and will evaluate the seed's parameters directly on the transport mean. The data will be sent via electronic impulses to the laboratory. The parameters of each sample will be confronted using two methods to achieve the best possible evaluation.
  The device is equipped with specialist accessories and software based on the so-called Artificial Intelligence (neural network), in which the crop is evaluated using various parameters and data is collected for research purposes, where the computer is learning to recognise all seed parameters.
- Unloading, internal-lift transport;
- Cleaning (separation);
- Drying; Aspiration, separation and receipt of impurities;
- Storage, transport and maintenance;

The main purpose established as result of the project's execution is the development of the seed quality evaluation devices, which will use the white light spectrum in an innovative manner to evaluate the quality of the seed accepted at crop warehouses. A prototype intended for the testing and checking of the developed device is being created to achieve the aforementioned objective. At first, it was planned for the sampling to take place during the product's acceptance and issue (from/to the warehouse). The current concept assumed the creation of a prototype from the devices available in the market. On the other hand, the warehouse sampling, which was also intended to be a prototype element, was initially based on a manual sampling system.

Innovative Process Stages

INTERVIEW – in-depth analysis
Condition fulfilment: condition met 2; condition partially met 1; condition not met 0,

Stage I – Creation of ideas

- Was there a consumer needs' analysis conducted and what was it?
- What was the basis for determining the enterprise's technical and market capabilities?
- What was the decisive factor in the selection of this branch of industry?
- Were the assumptions of a single idea achieved, what is developed gradually?
- Were the competitive solutions available in the market studied?

Result:
5 questions – maximum score: 10 points
Condition met – 4 points
Condition partially met – 2 points
Condition not met – 0 points

Stage II – Feasibility analysis

- What innovative products or services were to ensure the project's success?
- What was the project's feasibility analysis? Were the strengths and weaknesses as well as opportunities and threats analysed?
- What was the basis for establishing the initial price and was the target market analysis conducted?
- Were you focusing on a preliminary market forecast? (current market trend analysis, market tests, analysis of the factors shaping the demand and its formation)
- Was a preliminary analysis on the customers' opinion conducted and were you able to evaluate whether the offered services attract the interest of potential buyers?
- Was the project's preliminary profitability evaluation conducted?
  If so, what was it, what were its effects.
- Was there an estimation of the initial benefits deriving from the functioning of the brand and the products/services belonging to the brand conducted?
  What is a brand for you?
- Was the market analysed to get to know the suppliers' offers?
- Was there a preliminary analysis of the financing sources that would have a positive effect on the enterprise's success conducted?
- Was the project's preliminary plan developed? What did it include? Was it modified over time?

Result:
9 questions – maximum score: 18 points
Condition met – 16 points
Condition partially met – 2 points
Condition not met – 0 points

Stage III – Plan and project development

- Was the concept tested? If so, what was the test?
- Did you make a detailed product/service makeup during the plan's development? What did it include? Was the prototype developed?
- Was there an on-going demand forecast conducted to determine the demand for the offered services?
- Did you have a specific project execution plan and was it necessary (weaknesses, strengths)?
- Was the plans and indices' credibility evaluated?

Result:
5 questions – maximum score: 10 points
Condition met – 6 points
Condition partially met – 2 points
Condition not met – 0 points

Stage IV- Development and testing

- Was the production technology developed and approved, what was it and what did it include?
- Were the product's/service's performance and reliability tests conducted and what were their results?
- Was the price specified earlier changed, how was it changed?
- Was a repeated market forecast conducted?
- How was the brand's image built and how did it distinguish the brand from the competition?
- Have you received any certificates?

Result:
6 questions – maximum score: 12 points
Condition met – 2 points
Condition partially met – 4 points
Condition not met – 0 points

Stage V- Commencement of production and sales

- Were the employees trained and is there further training planned?
- How is quality assurance planned?
  What are the quality systems?
- Were promotional materials developed, if so, then what were they; what was the advertising campaign – if no, then why?
- Was a repeated product/service price correction required after the precise market analysis and competition identification?
- Was action related to the product/services distribution strategy organisation in the enterprise undertaken (were you able to select adequate distribution channels)?
- Do you recognise complaints and if so, what are the rules?
- In terms of geographic range, in which market do you operate and are you planning to expand the sales market?
- Was there a project summary and evaluation conducted, what conclusions were drawn?

Result:
8 questions – maximum score: 16 points
Condition met – 6 points
condition partially met – 1 point
condition not met – 0 points

Stage	% of execution
Stage I – Creation of ideas	60
Stage II – Feasibility analysis	100
Stage III – Plan and project development	80
Stage IV- Development and testing	50
Stage V- Commencement of production and sales	43.75

Summarising stage V – commencement of production and sales, the enterprise is focusing (simultaneously fully meeting the condition) mainly on training the employees in the implemented project and is currently applying for a subsidy for a products' storage training. Another element that is fully met by the company is the enterprise's advertising, which in comparison to others is rather specific, because if is based on sending an employee to the customer, which results in the consumer seeing the engagement of the company, which relies on aid and consulting. The condition that is also fully met is the enterprise's complaint recognition. At the moment, the company does not have any quality systems, but it cannot be ruled out that this will not change in the future. Referring to the repeated correction of the offered services or products, the company did not feel such a need, which is why it does not meet the condition. However, as for the market in which the company operates, it is currently the domestic market, but the company has a positive attitude towards changes and may enter the foreign market in the future. At the moment, the condition concerning the project's

evaluation and summary is partially met, because the project is still in progress and an in-depth summarising analysis will be conducted when the activities are concluded.

Conclusion

Innovative processes differ substantially depending on the sector in terms of degree of development, rate of process changes, relations and access to knowledge, as well as in terms of organisational structures and institutional factors (e.g. Malerba, 2005, Hawrysz, 2017). Some sectors are characterised by sudden changes and radical innovations, whereas others feature smaller, gradual changes. Research and development play a key role in innovative activity in the high-technology sectors, whereas other sectors rely more on knowledge and technology acquisition. The differences in the scope of innovative activity between sectors (e.g. advantage of incremental or radical innovations) are also related to different requirements for the company's organisational structure, whereas the role and significance of institutional factors, such as legal regulations or intellectual property protection, can vary. Important is also the possibility of use competencies of employees (Kubiciel-Lodzińska, Solga, 2019) It is important however to take these differences into consideration when creating a public policy. It is important however to take these differences into consideration when creating a public policy. They also pay an important role when conducting measurements, both when collecting data allowing for conducting a sectional analysis of various sectors and regions, and when it is necessary to ensure the measurement system's usefulness for a broad group of activity types.

The main purpose of the paper was to check whether the enterprise is implementing innovations (Malerba F., 2005, p. 14, 1-2, 63-82) and how does it used them. The innovation implementation model analysis was developed using the example of an enterprise that executes the "*innovativeness support' innovative activities*, specifically the project titled "*Development of a prototype system for the test sampling of storage mass based on visual technology and conducting industrial research and development works in terms of the effectiveness of the applied method in the drying process – process testing and validation*". The purpose of this process is to create a device that will evaluate the seed quality by using the white light spectrum in an innovative manner to evaluate the quality of the seed accepted at crop warehouses. Referring to the warehouse sampling, which as it turned out will be based on the manual sampling system and considering the fact that it is necessary to correctly shape the crop storage prism to enable the correct sampling and sample checking, the company started to analyse the market to find a device that serve the structural changes and eliminate the human factor. Thanks to these activities, the enterprise created a new prototype solution that will enable controlling the product in the future through the construction of the given device.

In summary, it is possible to state that the innovation implementation is an important factor that contributes to the high level of competitiveness (Jakubiec, M., 2016, pp. 63-76.). It does not come down solely to improving the available solutions, but also includes the generation and implementation of completely new methods that are not yet present in the market. Agropol is a great example due to the fact that the idea for constructing a new devices will not only streamline the company's activities, but also eliminate the human factor.

Challenges of Working in Multicultural Environment From the Perspective of Members of Intercultural Teams

Agnieszka KNAP-STEFANIUK

Jesuit University Ignatianum in Krakow, Faculty of Education, Institute of Political and Administrative Sciences, Department of Law, Management and Economics, Krakow, Poland, agnieszka.knap.stefaniuk@ignatianum.edu.pl

Ewa SOWA-BEHTANE

Jesuit University Ignatianum in Krakow, Faculty of Education, Institute of Educational Sciences, Department of Social Pedagogy, Krakow, Poland, ewa.sowa@ignatianum.edu.pl

Abstract

The article presents the challenges connected with working in multicultural environment. In the authors' opinion, these challenges include the employees' and managers' levels of cultural intelligence, effective intercultural communication, and the efficient and effective functioning in a multicultural team. The article is based on a review of the subject literature and the study conducted as part of the project: Social Integration Leaders (Liderzy Integracji Społecznej). The model programme for the improvement of migrants' social competence under the Operational Programme Knowledge Education Development (Program Operacyjny Wiedza Edukacja Rozwój) 2014-2020, co-financed by the European Social Fund in the field of social competence of migrants working in intercultural teams. The aim of the article is to analyse the challenges of working in multicultural environment identified by the respondents of the study conducted among the Ukrainians who live in Poland and work in culturally diverse teams. In order to compare the challenges of working in multicultural environment, the authors also referred to other studies conducted among employees of other nationalities.

Keywords: Multicultural Environment, Multicultural Teams, Intercultural Managers, Challenges

Introduction

Culture begins with the appearance of man. The results of human activity are visible immediately, and they are conditioned by certain goals, values and needs that motivate human behaviour. Every society creates culture, because culture begins when man appears. But the culture a given society creates is the culture specific to this society and represents its typical values, attitudes, and behaviours.

This article presents the analysis of the challenges of working in multicultural environment, understood as a community made up of representatives of different cultural groups in terms of their nationality. The authors present the difficulties connected with working in multicultural environment indicated by the Ukrainians living in Poland and working in intercultural teams and compare these difficulties, in the article called challenges, to the opinions of employees of intercultural teams of other nationalities.

Nowadays the challenges of working in multicultural environment include, first of all, communication, cultural intelligence, and deficits in the effective functioning in culturally diverse teams. They are primarily negative attitudes towards cooperation with other people working in the same team, the inability to appropriately react to conflict in a team, and intercultural relationships in a

team. In the authors' opinion, they are the key challenges that should be of particular interest to managers of culturally diverse teams.

In the theoretical part the authors describe the concept of multiculturalism and discuss significant, in their opinion, challenges connected with working in multicultural environment.

In the next part the authors present those results of the study which are relevant to the issues analysed in the article. The study was based on individual in-depth interviews conducted with the use of the interview scenario developed by the authors and in-depth focus group interviews. Then, the comparative research method was applied to compare the results obtained in this study and in other studies whose authors also analysed challenges in multicultural work environment.

Considering the above premises as well as the aim of the article, the following research question was formulated: What are the key challenges of working in multicultural environment in the opinion of Ukrainian employees compared to employees of other nationalities?

Cultural Diversity as A Key Element of Work in Multicultural Environment

Human societies differ in terms of culture, thus, according to Ch. Taylor (2001, p. 121), "Perhaps they are mutually disproportionate, and just as we recognize that in general the existence of certain goods depends on the existence of people, so we may have to accept that certain goods are such and not others only because of the existence of people within certain cultures". It can be reasonably claimed that members of different societies represent different ways of being a human.

As G. Mathews observes (2005, p. 17), "Cultures (...) are like a buffet table. You just take what you want. This way we can define culture as information and identities available in the global cultural supermarket". The term "cultural supermarket" is also frequently used and denotes a space where everyone has the right to choose one of the cultures that suits them best.

The term multiculturalism first entered the lexicon in the late 1960s in Canada. In the United States, Australia, and New Zealand the issue of the country's ethnic structure became the topic of public debate later, and next the term appeared in Europe. The idea of multiculturalism was an alternative to previously used assimilation concepts which supported a dominant group at the expense of minorities. One of them was a melting pot concept that aimed at turning diversity into uniform mass - into a "new man", an emigrant assimilated to the life in new conditions. The melting pot ideology did not work because many groups lost contact with their native roots, but did not adopt the patterns of their new country and did not create their own patterns. The second concept was Anglo-conformity based on the slogan: One Country! One Language! One Flag!, and the third concept was multicultural pluralism. This new approach to multiculturalism was referred to as a "salad bowl" in the United States and as a "cultural mosaic" in Canada, and meant that each culture maintained its own characteristics, did not mix with others, and did not create one homogeneous culture (Czerniejewska, 2016).

Whatever definition of multiculturalism we adopt, there is no doubt that multiculturalism has become something irreversible, just like migration or the use of the Internet. M. Krajewski (1997, p. 24) rightly observes that "multiculturalism (the interpenetration of contradictory traditions, patterns, laws, models of social regulation, thought systems, co-existence in the same neighbourhood of individuals differing in skin colour and attitude to the world, God and people) has become a necessity, something irrevocable and already existing, rather than a utopian project requiring a perfect idea and necessary justification for its realization".

A. Śliz and M. S. Szczepański (2011, p. 11) write: "the mere co-occurrence of two or more groups with different culture is not enough to talk of the existence of multiculturalism, which occurs only when permanent, multifaceted and voluntary forms of intercultural contacts appear. They result in the qualitatively new and culturally diverse whole. Its characteristic feature is the end of overt cultural domination, the end of the superior position of the previously dominant culture over other cultures".

A. Sadowski (1999, p. 14-15) adds that "multiculturalism is therefore used to designate a differentiated cultural system created on the basis of democratic principles, which, apart from this significant diversity, is characterised by elements of such coherence that allows for joint actions". Canada is an example of a country without dominant culture - the notions of majority and minority do not exist there because its society has been built by successive, equally-treated groups of immigrants. Contemporary European societies are no longer homogeneous communities in terms of their identity, history, axiology and culture (Krajewska-Kułak and Łukaszuk, 2016). The situation is similar in contemporary companies operating on an international scale. Multicultural teams are currently a normal part of the functioning of an organization.

Work In Multicultural Teams - Implications For Employees And Managers

Cultural diversity in the workplace emerged as a result of globalization. Its "one positive effect is that employees belonging to different cultures usually have different ways of thinking and can thus analyse a matter at hand from a variety of perspectives. This is hard to achieve when employees belonging to the same culture are asked to analyse the same matter" (Martin, 2014, p. 89).

Identifying work values of each culture is an important part of this process. According to Hofstede (2001), work values are significant due to two different reasons. First, they are an excellent measure of culture because they are shaped more by sociological and cultural factors than by individual psychological differences. Secondly, work values of employees of a given organization affect it in many ways, including the ability to change, conflict resolution, communication, and motivation.

Moving beyond the idea of work values as the foundation for important and popular theories of motivation, work values in and of themselves have important implications for the organization. Cultural differences in work values can be used to explain differences in the individual's performance and to predict job satisfaction, to develop committed workforce and to prepare the organization for functioning during periods of change. In addition, understanding employees' work values can aid negotiation, assist in developing effective reward systems, affect leadership and management style, and facilitate communication and organizational performance. If employees are unable to meet their work values through their work, they may become dissatisfied, envious of co-workers, or even resign from their job (Matić, 2008).

The level of cultural intelligence of employees and managers and its formation is undoubtedly a challenge in multicultural work environment. Organizations employ many different types of individuals, often those who do not want to adapt to co-workers, business partners, or customers. These employees can nevertheless be beneficial for organizations based on intercultural interactions if their motivational cultural intelligence (CQ) is increased. The motivational CQ factor can lead to adaptation through behavioural CQ. Apart from increasing their employees' CQ, organizations should guide their human resource managers to find extroverts who will be engaged in international work and train them to increase their self-confidence and self-efficacy. Multinational organizations should also develop special training programmes aimed at enhancing positive psychological capital of their employees. Such programmes will be beneficial to all employees, not only the ones who are directly engaged in international operations. It might also be a good idea to organise short cultural training programs in the host-country which are not connected with work. To improve the effectiveness of employees in multicultural organizations, efforts should be made to recruit the right people, to match them to the right managers, and to provide adequate training for them. Following these suggestions can support developing motivated and culture-savvy workforce and give the organization a competitive advantage on the market (Day, 2017).

D. Simpson (2017, p. 164) points out that companies operating on the global market should pay more attention to recruitment and training, including cultural training, of their managers, especially the ones engaged in international operations. This applies in particular to projects run by teams composed of representatives of different cultures, whose contacts are mainly or exclusively virtual. It is recommended that recruitment and selection procedures should include tests verifying the candidates'

level of cultural intelligence, which would help to plan and adapt cultural training to the employees' needs.

Another challenge in multicultural work environment is effective intercultural communication. The term *intercultural communication* refers to a process of interpersonal communication, direct and unmediated, which takes place between people aware of their cultural differences. Intercultural communication was born "due to the interaction of several common notions such as: cross-cultural communication, international communication, intercultural relations" (Jandt, 2004).

In the process of intercultural communication, it is important "to search for perspectives that will create a specific community and, at the same time, will recognize the diversity of visions and will build social unity, taking into account the diversity of views and specificity of groups. Multiculturalism seems to create a public space that enables different groups to interact and thus proposes different forms of pluralism, which can only be understood as the co-existence of different cultures, which might even lead to the creation of ordered social structures (...). The problem is how we perceive Others, whether and how we understand them, what we approve in them, and what qualities - other than our own - we value" (Nikitorowicz, 2013, p. 10).

Intercultural communication also depends on the individuals' socio-cultural identity and the degree of their (un)awareness of this identity, which is a derivative of their reflective or non-reflective life. M. Sobecki (2016, p. 99) observes that "the fact that an individual is aware of his inner cultural heterogeneity, understood as belonging to many cultural communities, is an important factor facilitating intercultural interaction".

Elaborating on the issue of developing intercultural competence, P. E. Gębal (2010) advocates training in four areas:

- perception: training should include free associations with the visual stimuli and films, noticing stereotypes and cultural standards (one's own and other's), telling the same story from the perspective of behaviour typical of one's own country, describing the material following the scheme: description – interpretation – one's own feelings - similarities and differences in the Polish culture and the listener's culture;
- interpreting utterances and situations: training should be aimed at developing strategies of interpreting the meaning of what was said and in what circumstances and include describing one's own associations connected with given concepts and comparing them with the associations of the Poles, sensitizing to conflict situations and ways of dealing with them, and role-playing in various situations;
- comparing cultures: putting on the Other's cultural shoes, creating the third culture, and developing tolerance for meeting the Other;
- communicating: being able to effectively communicate in intercultural situations, paying attention to conflict situations, polite forms of address, non-verbal communication (significant gestures, facial expressions).

The four areas of training listed above can lead to understanding other people's behaviour, tolerance of ambiguity, communicative competence, the ability to deal with uncertain situations, openness to Others and cultural differences.

Multiculturalism of organizations has markedly increased in the past three decades. As a result, organizations now face a growing need for human resource management (HRM) able to deal with the consequences of such increased cultural diversity. Among various processes and practices used in HRM, process training and negotiations seem to be most useful as far as employees' multiculturalism is concerned (Narkhede, 2011).

Methodology

The study was conducted as part of the project: Social Integration Leaders [Liderzy Integracji Społecznej). The model programme for the improvement of migrants' social competence under the Operational Programme Knowledge Education Development (Program Operacyjny Wiedza Edukacja Rozwój) 2014-2020, co-financed by the European Social Fund. 58 individual in-depth interviews were conducted with Ukrainians working in intercultural teams, i.e. in teams whose members are representatives of at least two different cultural groups (taking into account their nationality). Employees' social competence significantly determines the effectiveness of the functioning in multicultural work environment, therefore, the aim of the study was to demonstrate - on the basis of the analysis and evaluation of selected competences of the Ukrainian immigrants (members of intercultural teams) - what challenges are important for working in multicultural environment. The in-depth group interviews were held in three groups consisting of six persons and investigated, among others, the impact of employees' social competence on their functioning in intercultural teams. The results served as the basis for identifying other challenges related to work in multicultural environment.

Most respondents who participated in individual in-depth interviews (38 persons) worked in international corporations, in teams characterised by a great diversity of nationalities. The positions held by them included: project coordinator, human resources specialist, human resources manager, EU project specialist, development manager, technical director and regional manager.

A special research tool was created for individual in-depth interviews, namely a scenario of an individual in-depth interview. The interviews took place in Cracow between March and May 2019 and lasted from 45 to 85 minutes. Three focus group interviews were conducted in September 2019. All the interviews were recorded on a voice recorder and then transcribed, coded and categorised, which allowed for performing the qualitative analysis of the respondents' statements. The quantitative analysis of these statements was also conducted. In the section presenting the results of the study, bearing in mind the qualitative nature of the interviews and following the standards, the authors quote selected statements of the respondents.

58 respondents, including 36 women and 22 men, took part in the individual in-depth interviews; they were aged between 17 and 50, with the average age 31. 42 respondents were university graduates, 13 - high school graduates, 1 – did not complete his university education, 1 attended a vocational school, and 1 – a junior high school. The respondents had lived in Poland between 1 month and 14 years, with their average stay in Poland 3.5 years. The average period of employment of 48 respondents who had been working in Poland was 3 years. The study covered, among others, the following areas: communication, the functioning in a team, and the expectations of employees working in intercultural teams. In the article the authors refer only to those results of the study which are the relevant in the context of the analysed problems, i.e. challenges related to multiculturalism.

In order to compare the challenges of working in multicultural environment, the authors used the comparative research method and referred to the results of three other studies. The first one was conducted by M. Jayanthi (2014) among the employees of a leading software company in India, which operates internationally. The team consisted of two groups, one operating in Mexico and the other in India. The second one was conducted by H. Ors and N. Soğancılar (2018) among the executive directors of MNC (multinational companies) operating in Turkey, while the third one - by A. Gut, M. Wilczewski, and O. Gorbaniuk (2017) among 20 Chinese employees working for one of the largest global manufacturing companies operating in international environment (in one of the company's subsidiaries in China).

Challenges of working in multicultural environment – the results of the study

The results of the study discussed in the article refer to challenges connected with working in multicultural environment. The following facets of the respondents' social competence were investigated in the individual in-depth interviews: motivation, assertiveness, self-

presentation/building one's own image, communication - building interpersonal relationships, stress and conflict management, emotional intelligence, functioning in a team, and change management, all of which – in the authors' opinion – significantly affect working in multicultural environment. Deficits in the above mentioned competencies pose a challenge, both for employees and managers, to working in multicultural environment.

The authors of the article analysed only selected data obtained during the interviews: the ones referring to the competences specifically indicated by the respondents as linked with the greatest challenges they faced in their work in multicultural environment.

The individual in-depth interviews revealed that the respondents considered communication and efficient and effective functioning in a culturally diverse team to be the main and definitely predominating challenges of multicultural work environment. These two elements were closely related to the attitude towards cooperation with other people within a team, the awareness of the factors conductive to efficient and effective teamwork, the ability to react appropriately to conflict within a team, and noticing the positive features of working in a multicultural team.

The analysis of the results of the study (individual in-depth interviews) demonstrated that as many as 52 respondents reported communication problems. The majority of them also pointed to the knowledge of the Polish language, emphasizing that this was not the only problem in the area of communication. The analysis of the respondents' statements revealed that the spoken word was only a small part of the message, and other elements, including cultural significance, were equally important.

During the interviews, the respondents' opinions on the functioning in a multicultural team were also investigated. The analysis of this part showed that 11 persons declared a negative attitude towards cooperating with other people as a team member. These were the respondents who felt better doing the kind of individual work in which they did not have to be responsible for the work of others.

The respondents defined the characteristics of an effective and efficient team, paying particular attention to such features of its members as: positive attitude, discipline, responsibility, education, manners, honesty, and having a common goal. "People in a team should have common goals, values, purpose" (Respondent 26, male, aged 28); "Calm people, integrated, positive people" (Respondent 43, female, aged 27); "Adequate education, be disciplined, responsible, polite in relationships" (Respondent 7, male, aged 21).

The respondents were also asked about the ways of reacting to conflict in a team. Almost all of them unanimously declared that the basic method of conflict resolution is dialogue. "Dialogue is the most important, being able to explain your point of view calmly" (Respondent 3, male, aged 34); "You have to sit down together and solve the problem together, explain it" (Respondent 50, female, aged 26). 9 respondents admitted to being unable to constructively react to conflicts in a team.

The respondents answered the question whether working in a multicultural team had more positive or negative aspects. Almost all of them (56 persons) stated that multiculturalism was definitely the team's asset, and listed its following positive features: "It is better when the team is mixed because it is always some new experience, you can learn more about the country" (Respondent 22, female, aged 31); "It's nice to work in a mixed team, e.g. a wider range of foreign language skills" (Respondent 22, female, aged 31). Only 2 respondents indicated negative features of working in a multicultural team.

As the study was aimed at, among others, obtaining information regarding the challenges of working in multicultural environment on the basis of the deficits in the area of the respondents' competences, they were asked whether they had participated in any form of support or assistance in the development of their professional and language competences or in the process of adapting to their work environment, and what forms of support they would expect in this area. Nearly half of them (25 persons) declared that they were the recipients of various forms of support, including 21 persons who

attended language courses. Most of them were satisfied with the help they received, but there were also several answers (3 respondents) which pointed to failure and discouragement. The remaining persons (as many as 33 respondents) did not participate in any form of support.

The focus group interviews revealed that, in the respondents' opinion, challenges in multicultural work environment were related to the areas influenced by employees' social competence, which includes interpersonal relationships (15 persons), effective communication (16 persons), effective cooperation (15 persons), the ability to look for constructive solutions (12 persons), and the ability to solve difficult, conflict situations (15 persons). The respondents also drew attention to other challenges, e.g. the cultural context of cooperation within a team (15 persons), positive intercultural relationships (14 persons), how quickly tasks are completed (12 persons), work quality (15 persons), openness to changes (12 persons), and creativity and innovation (11 persons).

The analysis of the results of the individual in-depth interviews demonstrated that almost all the respondents (except 6 persons) mentioned communication problems as a challenge. The majority also considered their deficits in the area of effective functioning in a multicultural team to be a challenge. The analysis of in-depth group interviews pointed at the challenges of working in multicultural environment resulting from inadequate social competence of members of such teams.

Summing up, the results of the study reveal that communication and the effective functioning in a team are the key challenges related to multiculturalism in work environment, which means that special attention should be paid to them in managing culturally diverse teams. Other challenges connected with the efficient functioning of an intercultural team include: interpersonal relationships, cooperation, searching for solutions, conflict resolution, and intercultural relationships in a team.

The study investigating challenges of working in a multicultural team was also conducted by M. Jayanthi (2014). The respondents were the members of the Technology Analysts team working in a leading software company in India, which operates internationally. The team consisted of 120 members divided into two groups, one working in Mexico and the other in India. The sample size was 42, and convenience sampling was used for the sample selection. The questions used in the questionnaire were based on the conclusions from previous studies devoted to multicultural teams. The questionnaire was sent to the respondents via e-mail. The results of the study pointed to the challenges faced by multicultural teams and included communication problems, unfamiliarity with culture, attitudinal issues, perception issues and the impact of cultural diversity on the decision making process.

Another study in this area was conducted by H. Ors and N. Soğancılar (2018). Criterion sampling, which is a kind of purposeful sampling method, was used to select its respondents. The data was collected through 14 in-depth interviews held with executive managers of MNCs operating in Turkey. The managers' responses were analyzed by means of the content analysis and divided into conceptually corresponding categories. The results identified the following as the most frequent challenges faced by managers: ineffective communication, misunderstandings, different working styles and expectations of group members, as well as a lack of tolerance towards and knowledge of diversity. In order to cope with these challenges, managers suggested embracing diversity by encouraging group members to acknowledge it, by becoming approachable and eager to learn more, and, last but not least, by communicating in the simplest possible manner. Summing up, successful managers should be able to implement different management styles, depending on a situation, and be flexible enough to switch from one to another.

In May 2014 A. Gut, M. Wilczewski, and O. Gorbaniuk (2017) conducted a survey among 20 Chinese employees working for one of the top global manufacturing companies operating in international environment in one of the company's subsidiaries in China. The company has around 70 factories worldwide and employs over 100,000 people. Among the employees who completed the questionnaire, 10 were specialists, 7 - managers, and 3 - administrative workers; 9 of which worked in the support service department, 6 in the production department, and 5 in the communications department. All the managers reported that their intercultural communication took place with their

subordinates, while the remaining respondents communicated with their co-workers. Accordingly, the results refer to intercultural communication between managers and their subordinates as well as between employees at the same level (within in-groups).

The authors found that the respondents had encountered negative consequences of cultural diversity in their workplace, reflected in difficulties in communication with supervisors and co-workers from different cultures, both during work hours and after work, which, in some cases, even led to a decrease in their performance and, frequently, to a decrease in their satisfaction levels. Whatever the negative consequences were reported, the respondents displayed positive attitudes towards intercultural interactions and indicated cultural adaptability as a means to overcome those consequences. The results demonstrated that in the Chinese culture, with its collectivistic mode of making decisions and the interdependent perception of the "self", the respondents' beliefs included the following: the basic source of barriers in intercultural communication is ignoring or even disrespecting cultural diversity and stereotypical perception of the employees with a different cultural background; communication problems in intercultural interactions can be avoided when a different cultural background is respected. Chinese respondents saw cultural differences as a factor hindering the performance of their professional duties, however, it was not enough to discourage them from work. Most respondents believed that disrespecting cultural values was the greatest source of dissatisfaction and led to a decrease in their well-being and in positive attitudes towards co-workers. The results of the study indicated that the participants looked forward to cultural training as well as formal and informal meetings during which they could become familiar with other cultures (which corresponds with cultural adaptability as a way to overcome negative effects of intercultural interaction problems), so that, eventually, their cultures could be respected more.

The analysis of the results of all the studies presented in the article demonstrates that the key challenges related to working in multicultural environment are communication and the efficient functioning in a team.

Discussion

The aim of this article was to identify the challenges connected with working in multicultural environment which were indicated by the respondents - the Ukrainians living in Poland and working in intercultural teams - and to compare them with the challenges identified by employees of other nationalities.

The analysis of the results of the study conducted by the authors allowed for answering the research question. It was discovered that almost all the respondents mentioned problems with communication, although they observed that the spoken word was only a small part of the message, and other elements, including cultural significance, were equally important. Similar results were obtained by M. Jayanthi (2014): the employees of intercultural teams taking part in her study also listed communication problems as the greatest challenge in their work. Likewise, the study of H. Ors and N. Soğancılar (2018) found that ineffective communication and misunderstandings were the most common challenges faced by employees of intercultural teams. Similarly, A. Gut, M. Wilczewski and O. Gorbaniuk (2017) reported that their respondents faced negative effects of cultural diversity in the workplace, which were reflected in difficulties in communicating with superiors and colleagues from different cultures, both during working hours and after work. Ignoring or even disrespecting cultural diversity is the basic source of barriers in intercultural communication. Therefore, the comparison of the results obtained by the authors of the four studies quoted above clearly indicates that communication problems are the key challenge of working in multicultural teams.

The results of the study conducted by the authors of this article revealed that the respondents noticed deficits in their functioning in multicultural teams. The respondents defined the characteristics of an effective and efficient team, paying particular attention to such features of its members as: positive attitude, discipline, responsibility, education, manners, and honesty. They also mentioned that having a common goal was an important element conditioning effective functioning in multicultural

environment. Almost everyone unanimously declared that dialogue was the basic method of conflict resolution.

The mangers who took part in the study conduced by H. Ors and N. Soğancılar (2018) emphasized their employees' positive attitude to the challenges connected with working in intercultural teams, and encouraged them to acknowledge diversity and become approachable and willing to learn. Also A. Gut, M. Wilczewski, and O. Gorbaniuk (2017) paid attention to the respondents' positive attitude towards intercultural interactions and pointed to cultural adaptation as a way of overcoming conflict. Thus, a common conclusion drawn from these studies states that it is the employees' attitude that forms the basis for their proper functioning in intercultural teams.

The study conducted by the authors of the article also revealed that the challenges associated with working in multicultural environment include human relationships in culturally diverse teams, cooperation between employees from different cultures, and their ways of searching for solutions, resolving conflict, and maintaining intercultural relationships in a team.

Summarizing the results of the study, the authors would like to underline that the greatest challenges related to multiculturalism in work environment include communication and efficient functioning, and managers of culturally diverse teams should pay particular attention to them. Similar conclusions are offered by H. Ors and N. Soğancılar (2018), who believe that successful managers should be able to match different management styles to given circumstances, and to be flexible enough to enable their intercultural teams to function efficiently. The study conducted by A. Gut, M. Wilczewski, and O. Gorbaniuk (2017) found that the respondents expected cultural training as well as formal and informal meetings during which they could get to know other cultures better so that their own cultures could be more respected.

Conclusions

In the authors' opinion, the key challenges connected with working in multicultural environment include effective intercultural communication and efficient functioning of members of intercultural teams (which, to a great extent, depend on cultural intelligence of both employees and managers as well as their social competence), in the context of developing interpersonal relationships, shaping cooperation between employees, resolving conflict, and building positive intercultural relationships.

Culturally diverse employees are characterised by different features, working styles, motivation, needs and expectations. Managers of such teams should be aware of the challenges they pose to effective management of employees in multicultural work environment. They should extend and update their knowledge in this area and use their experience in order to, on the one hand, mitigate the negative effects of cultural diversity, such as conflicts and misunderstandings and, on the other hand, optimally develop the potential of multicultural teams, also in the area of creativity and innovation.

Multicultural teams are more susceptible to numerous challenges resulting from cultural diversity of their members. Employees and managers of such teams should be approachable, open, tolerant, willing to learn from others and possess excellent communication skills. Moreover, they should be able to understand and respect their co-workers' different values, working styles and their ways of communicating, problem solving, finding solutions, sharing knowledge and experiences.

According to the authors, the results of the study described in the article provide managers with information regarding the challenges they should pay particular attention to in multicultural work environment. Effective communication in intercultural teams is definitely more difficult than in culturally homogeneous teams and might pose a serious problem for many managers. Undoubtedly, the working styles, values and expectations of employees from various cultures differ, thus managers must be aware of these differences in order to better understand their employees and intervene in difficult situations when their intervention is required.

On the basis of their study, the authors recommend undertaking such initiatives (training and workshops) in multicultural work environment which can significantly improve the competences of employees and managers necessary to function effectively in multicultural work environment. The authors are convinced that it is crucial to increase employees' language competences and their knowledge about the culture and history of the country where they work and the countries from which they come, to extend their knowledge about multiculturalism, cooperation in culturally diverse teams, intercultural communication, as well as to implement training projects aimed at developing employees' cultural intelligence and social competence.

Acknowledgment

The research was funded as part of the project: Social Integration Leaders (Liderzy Integracji Społecznej). The model programme for the improvement of migrants' social competence under the Operational Programme Knowledge Education Development (Program Operacyjny Wiedza Edukacja Rozwój) 2014-2020, co-financed by the European Social Fund in the field of social competence of migrants working in intercultural teams.

Abstract

Social media has significantly influenced forms of communication in both private and professional life. Social media users leave digital footprints of their activity that can be used to analyze their behavior on an unprecedented scale. The process of discovering knowledge about the activity of social media users is called social media analytics. SMA uses advanced techniques to analyze patterns in social media data to enable informed and insightful decision-making. This is still a growing research area. Can information explored from social media create value and affect competitive advantage through intelligent marketing? In this paper, we present a theoretical framework that explains how and why companies create value with big social data. Due this we can specify our research goal as present the benefits of big social data analytics in company on the example of the company's marketing activities. To achieve this goal, we set the following research questions: What is big social data? What is the difference between traditional data analytics versus big data analytics? Then, based on the review of the three fields (brand perception, consumer psychology and social media data as a support for business analytics system), we showed the directions of using big social data in intelligent marketing. It turns out that social media analytic can introduce many benefits for the company via sentiment analysis, network analysis or expanding knowledge of consumer psychology. Based on such conclusions, empirical studies estimating the benefits of including the social media mining process should be carried out in the future.

Keywords: Social Media, Big Social Data, Twitter, Social Media Marketing

Introduction

Currently, social media are no longer trivial and optional, it causes and redefining business landscape. A number of companies use Twitter, Facebook or Instagram to provide a variety of services and interact with consumers by official account (global and local) or / and by using global, current trends in user activity (e.g. Coca-Cola activity around Valentine's day hashtag on Twitter: 'last minute #ValetinesDay). Many consumers use different social media platforms to get information about products / services, participate in user groups with the same interests, share private life events, and track relevant information. Each activity in social media leaves a digital footprint, the set of them will be generally called as user generated content. Deep analysis of these datasets offers opportunities and challenges to business. There has been strong interest in the power of social media analytics to create new value, to support decision making and to enhance competitive advantage by track and analyse relevant user generated content. We studied how social media analytics could bring competitive advantage in marketing. Our research goal is to present the benefits of big social data analytics in company on the example of the company's marketing activities. To achieve this goal, we set the following research questions: What is big social data? What is the difference between traditional data analytics versus big data analytics? Then we showed the directions of using big social data in intelligent marketing.

Big Social Data Mining – Theoretical Background

Conceptualization of Big Social Data

One of the effects of the technological revolution was the emergence of social platforms. In a short time, a rapid increase in their popularity and a dynamic increase in their number was observed. According to Kaplan & Haenlein (2010, 2011) "social media is a group of web-based applications that are based on the ideological and technological foundations of Web 2.0 which allow the creation and exchange of user-generated content." Drab-Kurowska (2017) defines social media as "communication channels through which users interact", she lists such technologies like forums, blogs, messengers, emails, sharing music. According to Mount & Martinez (2014) social media are a set of (open to users) online tools using which it is possible to exchange the ideas, emotions and opinions by creating and editing content. Evans adds that social media allow to sharing information relevant to online communities (or virtual social group). In turn, some emphasizes the social function of social media thus, the modifies and consumed content is the result of the interaction of users in virtual social groups. Defining social media is also based on understanding the individual functional blocks that make them up: presence, relationships, communication, reputation, groups, sharing and identity. The whole creates so-called honeycomb of social media. The scheme was developed by G. Smith (2007), developing the theory proposed by Webb (2004), Butterfield (2003) and Morviell (2004) and it is presented in many papers as base definition (next to the Kaplan & Haenlein definitions). Individual blocks of honeycomb allow to understand social media aspects in relation to user experiences and behaviour. The patches consistently describe social media, which should be considered both when creating and learning about social networking sites. However, the individual honeycomb blocks are not closely integrated. The dominant honeycomb significantly affects the functionality of the website, the forms of user activity and, as a result, the set of data that describes the behaviour of users. In fact, understanding the rules that affect website functionality should be considered when conceptualizing big social data. The first functional block of social media is *identity*. It refers to the scope of information that users share in social media about their identity, such as: name, surname, age, gender, occupation, interests, and presentation in the online community. Users can publish real or fictitious information about themselves, is difficult to verify. This is part of the user's image on the web. The information that can be mining about the user makes up the accuracy of the created consumer profile. *Communication* is the second functional block of social media. It refers to forms of communication between their users. Most social networking sites built around this area have numerous conversation-related tools (for both users and user groups). Companies are starting to notice the benefits of the process of obtaining the content of these messages and the development of tools for pattern extraction (e.g. sentiment analysis). Finding out what customers think about a product and brand can bring many benefits to business. *Sharing* is another block; it concerns the exchange of content between users. We collect data about the availability of users in the virtual and real world through social media. This is done by means of shared statuses (e.g. available, hidden, busy, I come back soon, I feel, think, do, etc.) as well as so-called check-ins in the real world. Enterprises can use this area to popularize their own content because social media are perceived as new distribution channels for information about the company, product and company activities. The *relationship* block refers to the connections of social media users with other users. The patch represents the form in which social media users create groups, friends lists and make friends on social networks. Creating relationships in social media is significantly different from those created in reality, both parties involved (i.e. companies and users) must accept this form and understand it. Enterprises can engage in exploring the structure and strength of relationships. It is recommended to identify entities that have a strong influence on a certain group of users (so-called opinion leaders). Another block of social media is *reputation*, which can be viewed differently by members of online communities. For most users, it is associated with trust and applies to both users and published content. Reputation is important for companies that should be involved to protect and monitor it, in the sense of tracking information emerging about the company. The key area is the construction of indicators that objectively would allow monitoring changes in the image. The last functional block of social media are *groups*, it concerns how users can create communities. Grouping contacts, creating subgroups, groups: open, closed or secret. Enterprises should use this functionality mainly in grouping their contacts into certain categories. With social networks defined in this way, we try to specify common features: (1) social media are platforms that allow users to interact around events, topic or products and

services; (2) are accessibility for everyone; (3) the adaptation of social media technology has caused social changes in the way information is created, consumed and disseminated, we can observed visible trend to being "always-on society"; (4) social media are a fertile ground for expressing attitudes, emotions, beliefs and opinions, also the content created by users is varied: text, images, video, link; (4) social processes occurring in different platforms depend on the functionality of the site (according to the theory of social media honeycomb structure); (5) an average Internet user consumes and shares large amounts of digital content every day through popular social online services (so-called 'phenomenon of data floods').

In literature, data generated in social media are called as big social data (BSD). According to Ishikawa (2015) and Olshannikova (2017) big social data refers to large data volumes that relate to people or describe their behaviour and technology-mediated social interactions in the digital realm. We treat these data as a big data, in term of 3V dimension model (table 1), from which social insights can be extracted. Social media provide us with high-volume and highly semantic data. Dynamic sets describing the behaviour of many at one time point with varying levels of granularity. BSD are highly unstructured (photo, video, text), with a real time flow and a short time of informativeness, thus the change is visible in every dimension of data (table 1) Adjerid & Kelley (2018). The datasets are mainly utilized to extract social insights for descriptive or predictive purpose. Data for every intra-daily interaction in social platform of individual (that can be retrieved) reflects their daily behaviour, habits, emotion valence, unusual events or activity in online social network Porshnev (2016), Sprenger (2014), Stacey (2012). These data are in different formats, different frequencies and are integrated from autonomous platforms Michalak (2016).

Table 1: Characteristics of big social data in the 3V model

3 V	Characteristics
Volume	Size is driven by the popularity of social networking sites. The collected large data allow measurement of effects with high precision and sufficiently reflect the behaviour and habits of users. Access to data allows in some cases repeated sampling. In caste of Twitter, 360 million active reports events on a big scale - it is estimated that about 500 million messages are sent via Twitter per day, due to the unprecedented scale of interaction social networking sites are perceived as source of collective intelligence.
Variety	Variety is driven by the functionality of social media, for example variables explored from Twitter are mainly short text messages, from Instagram are photos, from YouTube to video.
Velocity	Real time, instant messengers allow users to contact and react, and report events in real time; spreading messages is not limited to friends but has global reach. The measurement of some behaviours is carried out at ultra-high frequency (continuous or semi-continuous), and the adjustment of the time window and the level of data aggregation can be a big challenge for the researcher (for example: Oh & Sheng).

Source: own work based on: Adjerid & Kelley, pp. 901-905.

In recent years, we recognized the potential of big social data analytics on the example of many research projects as well as in business. One of the consequences of social media development is an emergency need to develop methods and tools capable of processing big social data. Social media analytics requires advanced IT tools and models to process data. Therefore, the development of effective and efficient analytics techniques for social media analytics becomes essential. Especially data mining, sentiment analysis and social network analysis techniques are recommended. As part of scientific research, there are a number of papers that discuss the use of massive datasets and exploring the value of it Jansen (2009), Luna-Nevarez (2016), Li (2013), López-García (2016) or improving the tools and methods used for social networks analysis Sprenger (2014), Stacey (2013), Giachanou (2016), Kaplan (2011).

Big Social Data Analytics Versus Traditional Analytics

Before the rise of online social media, gathering data on opinions was expensive and usually achieved at very small scale. When users on the Web started communicating massively through their channels, social networks became overloaded with opinionated data. In that aspect, social media has opened new

possibilities for human interaction. Big data requires the use of analytical techniques that are beyond the standard set of methodological tools. Table 2 compares the traditional approach with the big data approach by showing individual stages of the analysis process. Big data sets primarily introduce the possibility of observing individuals without intervention on an unprecedented scale. Alternative data sources describing the behavior of individuals are an important source for researchers and business. Big data can be a solution to some problems: (1) costs of large-scale research and the time devoted to conducting the study. (2) some patterns are visible only at high frequency datasets and may not be revealed in a traditional study, this is especially true in dynamic constructs that should be considered over time (e.g. sentiment about product and services, brand perception), (3) Big social data may be the answer to the problem of replication, avoidance of certain measurement burdens seen in traditional studies, e.g. tendency to improve responses.

Big data is a promising but demanding area - among the restrictions on the use of big data are the following: (1) little experience of researchers for the collection, preparation and analysis of massive data sets, (2) lack of technical knowledge necessary to collect and organize large data. The challenge is to manage this data in an acceptable time. Due to the high frequency and size of the data set, their analytics primarily include machine learning algorithms that look for unexpected relationships and summarize data in such a way that they are both understandable and useful in further considerations. Results from data mining are summarized in non-trivial patterns - in the form of social networks, classification models, graphs and more. How to formulate the problem of data mining to bring out the added value for the company? Due to the complexity of the problem, one should extract one source of data which is social media and build a dedicated framework for analysis.

Social Media Mining for Marketing Decision-Makers

The Importance of Social Media in Companies

Bell (1973) and Grant (1996) believe that knowledge is an important resource for enterprises. Used to develop domain knowledge, solve problems and initiate new opportunities as well as competitive advantage. In the so-called global information society, information is treated as an economic good, a basic resource and a basic economic category. In the modern world, social media are increasingly used as a source of economic insights. Companies are increasingly perceiving the information potential hidden in new technologies. For example, in 2013 the Securities and Exchange Commission (SEC), knowing that companies are increasingly using social media, approved Facebook and Twitter as the two most influential corporate knowledge sites for the organization. Among others, this is supported by Corso (2006) who believe that companies should use informal and formal channels, such as intranet or corporate portals, to access knowledge. Jarvenpaa (2011) emphasize that the rapid development of new social media platforms has contributed to building an important, important and engaging space for organizations, providing them with better and greater access to knowledge. Also, Aral (2012) note the potential of information from social networking sites by correlating the activities involved in social media with increasing competitive advantage of company. According to Iskikawa (2015) digital environments have some social (or/and psychological) properties. Ishikawa is interested in understanding the nature of bidirectional relationship between real and digital world. Adequate analysis always implies interdependence because the real world and the virtual world are closely related. Big social data have value when they represent the wisdom of the crowd.

Social media has changed the role of modern consumers and entrepreneurs. They transform passive users into powerful creators and intermediaries of corporate information. Thanks to this, anyone with access to the Internet can publicly disseminate their opinion about the company. On the one hand, this

is an unprecedented opportunity for organizations, but also a huge challenge in the proper management of the information environment.

Social Media Mining as Support for The Business Analytics System

Before the rise of social media in order to understand human behaviour, companies based on costly research characterized by small samples. These small samples are affected by replication crisis. Feedbacks are analysed with time delay; therefore, they may have lower value for decision-makers. Questionnaire data are on low granularity level of data (choosing between database size and depth). Decisions are made based on static analysis, processed by using descriptive statistics with basic data visualization. In opposite to traditional methods, based on BSD by using more sophisticated methods, most these disadvantages can be ignored. Research of social media sentiment has growth exponentially in recent years. Most of them are based on sentiment analysis. Sentiment analysis is and increasing popular instrument for the big social data analysis. The product of the analysis are sentiment scores that inform about the emotional state of the writer. Sentiment analysis is the way of summarization complex and high dimension data. Growing interest in the quantification of feeling started the methodological debates within the social sciences which indicates that proper research requires not only appropriate know-how, domain knowledge but also a deep understanding of big social data. Most of researcher are inspired by this scientifically objective approach to measuring subjective states. Discovering non-trivial patterns can be achieved by lexicon approach or machine learning approach. The second is more often used because of the better matching to the domain and as a result higher classification accuracy. The research process includes stages such relevant data retrieval, pre-processing, feature engineering model learning and evaluation Giachanou (2016). At each of these stages, tools and techniques to improve the quality of research are developed, and they make up the rich landscape of research. Sentiment may refer to various entities (e.g. products, brand, services), for each entity sub-level of analysis may be done. If we look at datasets related to product or services thus, we can get the answer to the following questions. Do consumers like our product? Which aspect of the product need change? How often the discussion about our product is repeated? As the main advantages are listening to the market with high granularity of the data, survey representativeness, capture the dynamics of the behaviour, possibility of resampling in data, low costs and continuous monitoring of the market. Product offer tailored to the expectations of the public (consumer).

Social Media as a Part of Marketing Information System

According to Cisło (2004), Kotler (1996) every enterprise needs to build an efficient information system to support decision-makers. This is influenced by the following factors, the complexity and volatility of consumer behaviour, growing competition in the industry, opening to new markets, saturation of some markets Cisło (2006). Creating and implementing marketing strategies as well as monitoring effects, managing public information requires the support of an efficient information system. The marketing information system should not only meet the information needs of the company, but exceed the expectations of decision-makers, e.g. by searching for new sources of information. Oleński (2003) as an information system understands the complex of related information processes. However, the information process defines as actions occurring in a certain sequence aimed at: (1) generating information, gathering information, archiving information. Processing and interpretation of information depending on the needs of the company. Smith writes that the Enterprise Information System is a formalized and internally related components, such as a team of people, devices and procedures created to meet the enterprise's information needs. Unold (2011) lists the following components of the marketing information system: data sources, data collection subsystem, data bank, model bank and analytical techniques, information sharing subsystem, report preparation subsystem. One of the commonly used architecture of the marketing information system was presented by the Kotler (1996). By using the architecture of the marketing information system to place big social data analytics, it can easily be linked to other information processes in the company. Social media are a new source of data describing users' activities. However, due to the nature of the data, the need to use advanced analytical techniques and adapt computer resources to big social data, the company is required to modify the system accordingly. This is in line with the concept of SIM presented by Unold (2011).

Information from social media feeds the marketing decision-makers. What can these patterns be used for? First, they are used in communication of the company with the consumers. Let's look at two sides of the communication process: entrepreneur and customer. Both sides of the process feel information needs Grębosz (2016). The enterprise meets these needs by appropriate data processing and obtaining knowledge about market behaviour. Consumer information needs are different. Consumers are looking for knowledge about products and services, they are looking for recommendations and knowledge about the company's activity. In addition, they are looking for people who will share their interests and concert together around the company. The company in social media conducts a dialogue with them. By using dialogue supported by information and behaviour of social media users, the company can perform the following functions:

1. brand management functions: through properly conducted dialogue, it affects customers through various stimuli in the form of text, graphics, symbols, and colours,
2. creating virtual communities to which you can personalize content, so – called tribal marketing,
3. build and strengthen relationships with consumers as part of broadly understood social marketing by personalizing content,
4. quickly respond to negative product and brand information that appears on the web.

Consumer Psychology

Second filed closely related to market analysis is consumer psychology. Big social data make it possible to understand the psychological aspects of consumer behaviour. Patterns explored from data are relate to (1) stable psychological traits (e.g. personality) that help explain the general trend of consumer behaviour, and (2) mental states that express consumer attitudes and feelings at some point and help describe the context of behaviour. Explored patterns are relate to daily habits and consumer preferences. This approach is in opposite with the traditional research, in which getting to know the consumer takes place through: (i) analysis of data from loyalty programs, (ii) analysis of cash and transaction records, (iii) focus groups, observations and interviews. They mainly contributed to: (i) assessing consumer preferences, (ii) understanding brand perception, (iii) inferences about future consumer purchases, while consumer attitudes and emotions received little attention in research. Matz (2017) argue that an eccentric and open-minded consumer feels more positive emotions and attaches greater importance to a retail brand that specializes in eye-catching and unusual, eccentric and creative ideas. Second example of studies that being developed are research on the personality of the user. Individuals by participating in social networks and publishing content, personalizing their profiles, reaction to the content of other users, music lists on YouTube and Spotify manifest certain aspects of their behaviour that may be correlated with personality trait Quercia (2012). On the basis of UGC, variables representing personality traits are created. The relationship between social media data and personality traits is considered on the basis of the PMO model. Many authors, for example Quercia (2021) indicate that he is the most comprehensive, reliable and useful personality concept. Two groups of data (1) profile, (2) text - linguistic analysis are taken from social media. Researchers check whether two groups of data - data from questionnaires and big social data are correlates. The system analysing data from Twitter creates a meta-base of attributes from tweets consisting of information about the user's social behaviour (average number of likes, average number of links, hashtag, mentions, etc.) and the grammar of tweets (average length of messages, number of punctuation / emoticons, average number of positive / negative words Kalghatgi (2015). The advantages of this filed is manifested in deep knowledge about the market and the ability to influence this market. Communication tools (e.g. social media profile or website) and the appearance and content are tailored to consumer expectations.

Brand Perception

Third field is impact assessment of engagement of online retails with the online brand communities on user’s perception of brand. Practitioners have been at the forefront of attempts to understand, define, and build customer engagement. Customer engagement is a key factor in competitive advantage of company. The consumer has limited time and incomplete information about the market, where there are many substitutes. By using additional attributes, among which the brand plays a key role (which not only makes the product stand out but also carries information about the product), the company

makes its products stand out from others. Social media engages users in conversation with the company. Through proper communication it is possible to build strong engagement. Communication has individual character and must be integrated with related marketing activities of company.

Summary

Increasingly, companies are using social media to promote products or services and to communicate with customers. Also, more and more customers interact with company and share their experiences and opinion about products or services. However, fewer businesses perceive social media are a new source of data for enterprises. These data are large sets, multidimensional, requiring appropriate processing techniques. Their potential is huge therefore, they cannot be overlooked by enterprises. Getting the right information from social media is only possible by develop strong social media analytical skills. The article discusses the differences between the traditional data set (the so-called small data) and big social data, places social media in the marketing information system, and shows examples of research conducted in this area. In conclusion, big social data sets are promising. By using market knowledge and skilful management of this knowledge, enterprises can gain a competitive advantage. There are many studies discussing the tools and methods of big social data analysis, but less research into the effect of including this information in the decision-making process. The information system in the company should be consistent, it is not based solely on an external data source such as social media. Therefore, according to the authors, there is a need for broad and interdisciplinary research on the development of a model for combining information with big social data and small data. Competitive advantage is manifested in the possibility of obtaining knowledge about the consumer, processes occurring in the social network, brand opinions. As a result, this knowledge is used to improve the quality of the relationship between the enterprise and the consumer.

Abstract

Companies are driven to go international by a variety of reasons. It is crucial for managers, governments and scholars to get a deeper understanding of those reasons and location factors in host countries as they affect the success of foreign operations and the future of the company.
The aim of the paper is to present the results of research studies on identifying FDI determinants of the host country among Polish enterprises and differences in the perception of the factors depending on the ownership equity-based entry mode. The paper presents results of a field surveyed carried out in 2012-2013 through direct interviews among Polish companies – direct investors. The research results confirmed that Polish investors are mainly driven by market seeking motives and market-related factors are the most important determinants of undertaken FDI projects regardless of the ownership equity based-entry mode. Furthermore, there were no evidence of a relationship between institutional and legal framework-related factors and the ownership equity-based mode as initially we assumed.

Keywords: Foreign Direct Investment, FDI Determinants, FDI Location Factors, Ownership Entry Mode, Joint Venture, Wholly Owned Subsidiary.

Introduction

Cross-border investment carried out by multinational enterprises (MNEs) is one of the main features of today's global economy. A rapid expansion of globalization process leads managers to a higher awareness of the need to be present and compete internationally. Therefore a growing number of firms has been increasing their involvement in international operations. The past decades have witnessed a rapid and steady growth in global foreign direct investment (FDI) flows. Aggregate FDI outflows (FDI outward stock) increased over 4 times from USD 7408.9 billion in 2000 to USD 30974.9 billion in 2018 (UNCTAD, 2018). Polish enterprises seem to be an active player as well, however their share in the generation of global FDI flows is still negligible. Polish investors invested abroad by the end of 2018 capital in the form of FDI with a value of USD 28509.7 million, which is over 73% more than at the end of 2010 (USD 16406.5 million).

A decision about expansion on overseas markets is a complex and complicated process which has strong implications for a success and a performance of an enterprise. Enterprises are faced with the challenge of defining a product or products they want to deliver to a foreign market, identifying a target market or markets in which they want to offer their products, choosing the entry mode they want to use to serve the market and finally determining the timing of entry (Root, 1994). The choice of entry mode and as a part of it the choice of ownership mode is widely regarded as one of the most critical decisions in international expansion being a key element of the success of foreign operations and the future of the enterprise (Hennart and Slangen, 2015).

When a company decides to enter overseas markets by operation modes linked to ownership and equity investment (FDI), it has two entry alternatives to choose. The company may decide to enter a foreign market alone and establish a wholly owned subsidiary or involve a (local) partner and start a joint venture (a subsidiary with shared ownership). Making this decision mangers must take into

consideration many various factors including country-specific factors. However, before they do it, managers must define clearly the reasons for going abroad and company's objectives. Companies go abroad for different reasons which affect the MNE's location decision and the ownership entry mode choice. It is essential for mangers to get a deeper understanding of those reasons and investigate certain locational factors in host countries to make the key decision about the location of an investment as well as the ownership entry mode (Hill, Hwang and Kim, 1990; Dikova and Witteloot uijn, 2007).

While there is a large volume of empirical literature on the behaviour of MNEs and FDI determinants (Wheeler and Mody, 1992; Bitzenis, 2007; Jaworek, 2013; Kowalewski and Radło, 2014; Gorynia et al, 2015; Huyen, 2015; Jaworek, Karaszewski and Szałucka, 2019), the amount of studies on the ownership-based entry mode is less abundant and often limited in the research area (Hill, Hwang and Kim, 1990; Kim and Hwang, 1992; Brouthers, 2002; Chen and Hennart, 2002; Yiu and Makino, 2002; Dikova and Witteloostuijn, 2007; Chiao, Lo and Yu, 2010). Many of the scholars seem to examine firm-level factors more often than country-level factors (Dikova and Witteloostuijn, 2007). They also seem to investigate factors in the narrow scope. Thus, a clear understanding of FDI location factors in relation to the ownership equity-based entry modes is essential to develop knowledge about the inter-relationship between FDI location determinants and ownership mode choices.

The aim of this article is to present the results of research studies on identifying FDI determinants of the host country among Polish enterprises and differences in the perception of the factors depending on the ownership equity-based entry mode, i.e. whether to establish wholly owned subsidiaries or form joint ventures with local partners.

The paper is organized as follows. The following section provides a brief, general overview of the literature related to reasons why companies go abroad and FDI location determinants. Next, the methodology employed in the research is presented. The third part of the paper describes the research findings. Finally, the general conclusions are drawn with some limitations that researchers faced and useful insights regarding future research.

Literature Review

Companies go abroad for various reasons. The most popular classification, initially used by J.N. Behrman, and later extended by J.H. Dunning, identifies four types of motives for MNE activity abroad: market seeking, resource seeking, efficiency seeking, and strategic asset (or capability) seeking. When enterprises are driven by market-seeking motives, they invest in particular country or region to supply goods and/or services to markets in these and neighbouring countries. To the market-related factors which might prompt enterprises to engage overseas we include e.g. a market size, prospects for markets' growth, a need to follow main suppliers or customers or an avoidance of trade barriers (Dunning and Lundan, 2008).

The expansion on overseas markets can be also related to resource-seeking motives. This means that companies invest abroad to acquire natural resources, workforce, technological capability, organisational skills as well as management or marketing expertise. Initially, most enterprises undertake FDI because they seek new markets or resources, but when their degree of multinationality increases they might want to improve their global market position by raising their efficiency (efficiency-seeking investments) or gaining access to new strategic assets (strategic assets-seeking investments). The first are motivated by the expectation of achieving benefits from the common governance of geographically dispersed activities, which are mainly related to the economies of scale and scope, and risk diversification (e.g. the lower costs of labour, materials or natural resources and operational risk reduction). The second means that companies engage abroad to acquire the assets of foreign corporations which might improve their global competitiveness (Dunning and Lundan, 2008).

Except the factors described above, the host country-related determinants (FDI location determinants) also include a policy framework for investments (institutional and legal framework-related factors) and a business facilitation (UNCTAD, 1998; Dunning, 2006). The first group consists of rules and regulations governing the entry and operations of foreign investors, the standards of treatment

according to them, and the functioning of the markets within which they operate. The second includes proactive measures, aimed at facilitating the business that foreign investors undertake in the host country, e.g. the incentives for foreign investors or amenities that contribute to the quality of life of expatriate personnel (UNCTAD, 1998).

As mentioned earlier, there is a large volume of empirical literature about FDI determinants, but the amount of studies on FDI location factors in relation to the ownership equity-based entry modes is less abundant (see e.g. Kim and Hwang, 1992; Brouthers, 2002; Chen and Hennart, 2002; Yiu and Makino, 2002; Chiao, Lo and Yu, 2010; Morschett, Schramm-Klein and Swoboda, 2010; Shen, Puig and Paul, 2017). The research studies which focus on market-related factors give different results, which may suggest that the ownership equity-based entry mode often depends on other factors such as company's size or international experience. For example, Agarwal and Ramaswami (1992) based on a study of service companies, found that small firms with limited multinational experience preferred joint venture in high potential markets, while larger, more multinational firms more often tended to use wholly owned subsidiary. Similar conclusions received Shi, Ho and Siu (2001), who noticed that small Hong Kong manufacturing firms investing in the mainland China, which followed a market-seeking strategy, preferred joint venture to wholly owned subsidiary. On the other hand, Gil et al (2006) found that companies investing in CEE countries preferred to enter the markets by wholly owned subsidiary.

Furthermore, a study carried out by Brouthers (2002) among EU firms indicated that high growth markets had no impact on decisions about the ownership equity-based entry modes. Morschett, Schramm-Klein and Swoboda (2010) based on an analysis of 72 independent studies in 67 articles found that – in contrary to the most conceptual arguments contained in the literature – increasing market size and its growth do not lead to a higher propensity to enter a market using a wholly owned subsidiary. Also Dadzie et al (2018), who conducted a study among foreign manufacturing companies in Ghana, noticed that market-seeking motives did not have any impact on the mode of ownership. Taking into account the above conclusions and the research results indicating that the market-related factors play the most important role for Polish investors (Jaworek, 2013; Kowalewski and Radło, 2014; Gorynia et al, 2015; Jaworek, Karaszewski and Szałucka, 2018), we hypothesize that: **(H1)** Regardless of the ownership equity-based entry mode choice, market-related factors are the most important for Polish investors.

Unlike market-related factors, most empirical literature concerning other host country-related determinants in relation to the ownership equity-based entry modes – which we are aware of – points out that enterprises prefer to start a joint venture when they go abroad mainly to gain access to specific resources or new assets, or when they want to improve their efficiency (e.g. Shi, Ho and Siu, 2001; Gil et al, 2006; Kaynak, Demirbag and Tatoglu, 2007; Chun-Ping, 2018; Dadzie et al, 2018). They form joint ventures for utilizing local partners' network and resources as well as reducing operational potential risks.

Joint ventures are also a preferred option when MNEs make investments in countries with relatively less institutionally developed environment, perceived as risky (e.g. Rajan and Pangarkar, 2000; Brouthers, 2002; Demirbag, McGuinness and Altay, 2010; Dadzie et al, 2018; Lu et al, 2018). Many scholars suggest that through joint ventures with local partners enterprises reduce the investment risk due to economic and political uncertainties by limiting their resource commitment (e.g. Kim and Hwang, 1992; Brouthers, 2002) and gaining knowledge about local economy, politics and culture (Beamish and Banks, 1987) as well as a help in negotiations with host government (Agarwal and Ramaswami, 1992). In the other word, it can be said that a favourable policy framework for investments encourages to enter the market by wholly owned subsidiary. Thus, we hypothesize that: **(H2)** The institutional and legal framework-related factors as drivers of investing abroad are more important for Polish investors which enter host markets by a wholly owned subsidiary rather than a joint venture.

Research Methodology

The results presented in this paper come from a study conducted between 2012 and 2013. It covered 622 enterprises based in the Republic of Poland, which engaged their capital abroad through direct

investment. All of them, regardless of their ownership of capital, had the status of Polish companies according to the current laws. The bulk of these companies held only Polish capital (61.7%). The remaining 38.3% were companies with foreign capital, with only 26.3% of them having solely foreign capital (26.3% with majority ownership and 42.1% with minority ownership).

The research sample was selected in a non-random way (target selection). The study used a direct interview method and was conducted by interviewers from a market research company using a standardized questionnaire developed by the research team. 64 questionnaires were filled out correctly, which meant a return rate of 10.3%.

The number of enterprises in each group classified according to their type of business activity was different. Almost 40% of them conducted exclusively commercial operations. Enterprises that operated exclusively in the service sector accounted for 30% and those exclusively in production – only 5% of the total number of companies. The share of enterprises operating in all three: production, trade and services, was 19%.

Most investors participating in the survey decided to expands into foreign markets by wholly owned modes (51 out of 63 respondents indicated solely, wholly owned subsidiaries and/or branches as their ownership entry mode). 7 respondents entered strictly the foreign markets sharing control of their subsidiaries (joint ventures). The remaining 5 enterprises decided to set up their overseas subsidiaries using both wholly owned modes as well as joint ventures.

The companies that participated in the study had completed a total of 273 FDI projects. Out of these, 140 projects had been undertaken as wholly owned subsidiaries (51.3%) and 87 as branches (31,9%). Only 46 projects were completed as joint ventures (16,8%).

Research results presented in this paper refer to two out of three groups of respondents considered in this survey: enterprises that have chosen only wholly owned modes and those that entered foreign markets solely via joint ventures. Excluding from the analysis those enterprises that decided to set up overseas subsidiaries using both ownership entry modes is dictated by the fact that it cannot be definitely said to what extent each of the ownership mode choices shaped the indicated FDI limiting factors.

While analysing the results of the study, an importance index was used, which had the following formula (Karaszewski and Sudoł, 1997):

$$W = \frac{\sum_{i=1}^{k} n_i w_i}{k \cdot N},$$

where: W – importance indicator; i – evaluation index; n_i – the number of indications for a given factor at the *i-th* position; k – maximum rating on a scale of 1 to k (the order of the factors meant assigning them ratings in reverse order); N – the number of respondents who answered the question; w_i – a rating corresponding to the location of the i factor.

Furthermore, Fisher's exact test was also used to verify the hypothesis with the conventional significance levels at p<=0.01, 0.05, and 0.1. Statistical calculations were performed using the IBM SPSS Statistics software version 25.0.0.1.

Research Results

Enterprises that participated in the study, regardless of their ownership equity-based entry mode (joint venture vs. wholly owned subsidiary) identified **market-related factors** as the most important determinants of FDI. Only some minor differences were found in the position of the factors within this group. Among both groups of companies, the market factor related to the access to new markets was considered to be the most important factor. In addition, Polish investors on the second position ranked another market determinant "the proximity of existing markets". It should be noted that the main

direction of foreign expansion among the studied companies was Europe, where 97% of direct investment companies were established. Investors in both groups also evaluated similarly the importance of the factor associated with the economic growth prospects of the host country. This factor was ranked third among the companies that established wholly owned subsidiaries and fourth among those who made joint ventures. Investors who entered foreign markets via wholly owned subsidiaries regarded a factor "finding a niche market" as an important determinant of their investment (4th position vs. 5th position for joint ventures). The biggest difference among the market-related factors can be seen in the evaluation of the ability to avoid trade barriers. This factor was considered more important among the companies that made joint ventures (5th position vs. 9th position for wholly owned subsidiaries). Higher ratings in the group of companies that made a joint venture may be explained by the fact that in some countries with significant entry barriers, the only possibility to enter the market and avoid the barriers is to create a joint venture. It must be stressed out that all the market-related factors were ranked in the top 10 of the most important FDI determinants regardless of the ownership equity-based entry mode choice.

Table 1: FDI location determinants among Polish enterprises (wholly owned subsidiaries vs. joint ventures)

FDI location determinants			Wholly owned subsidiaries		Joint ventures		Fisher's Exact Test	
			Index	Pos.	Index	Pos.	Value	P-value
I. An institutional and legal framework		the tax system in the host country	0.64	10	0.62	9	4.040	0.319
		legal regulations governing business operations in the host country	0.68	8	0.64	8	2.929	0.530
		regulatory stability	0.68	8	0.62	9	2.571	0.657
II. Economic determinants	Market-related	new markets	0.85	1	0.87	1	1.259	0.704
		proximity of existing markets	0.79	2	0.80	2	0.673	0.869
		low competitiveness among companies in the host country	0.65	9	0.69	6	2.632	0.660
		finding a niche market	0.72	4	0.71	5	5.259	0.283
		avoiding trade barriers	0.65	9	0.71	5	1.360	0.919

Source: own study on the basis of survey results.

When analyzing the responses related to **resource-related factors**, it should be emphasized that they were considered a little bit more important by investors who established joint ventures with a local partner than those, who created wholly owned subsidiaries. Three out of the four factors in this group were ranked higher by the first group of investors. The biggest differences in the evaluation of determinants in this group apply to the access to new technologies (10th position for joint ventures vs. 15th position for wholly owned subsidiaries). Investors who made joint ventures also evaluated higher the availability of natural resources, (13th position vs. 16th position) and the availability of materials, semi-finished products (11th position vs. 12th position). It could mean that joint ventures were a way of obtaining such resources. The collaboration with a local partner may provide MNEs an effective access to local complementary resources, including modern technology and the know-how. Ranking these factors very low by investors who established wholly owned subsidiaries may indicate that investors from this group were not interested in such assets and were not focused enough on obtaining them. However, it should be pointed out that Polish investors who entered a host market via wholly owned subsidiaries and joint ventures perceived resource-related factors as not very important ones among the FDI determinants.

Polish investors who established joint ventures with local partners evaluated **efficiency-related factors** higher than those who set up wholly owned subsidiaries. It should be noted that within this group of determinants, there were the biggest differences in the two groups of Polish investors. Benefits of replacing exports with production in the host country was ranked third by the group that made joint ventures while companies setting up wholly owned subsidiaries located the factor on the 17th position. There were also significant differences in the evaluation of the factor related to reducing operational risk. Investors who made joint ventures ranked this factor 5th, while investors who only established wholly owned subsidiaries ranked it 11th. A higher ranking of this factor among the investors who made joint ventures may result from the fact that running a business with a local partner may lead to a reduction of operational risk. These enterprises also ranked higher factor related to property prices (8th position vs. 12th position for wholly owned subsidiaries) as well as the cost of materials, half-finished products (7th position vs. 13th position). Among the efficiency-related factors, the possibility to make a better use of own resources was ranked the highest by Polish investors who made wholly owned subsidiaries. They ranked this factor third, while investors who had made exclusively joint ventures

ranked it 8th. The remaining **efficiency-related factors** connected with the cost of natural resources, regardless of the ownership equity-based entry mode choice, was ranked much lower (12th position for joint ventures vs. 17th for wholly owned subsidiaries).

In principle, there was no difference between the responses of the two studied groups of investors in relation to the FDI determinants referring to **business facilitation**. Both groups of investors ranked "positive attitude to entrepreneurship" on seventh position.

Some minor differences can also be identified in the evaluation of factors related to the **institutional and legal framework**. However, it should be emphasized that they are insignificant. Polish investors who established wholly owned subsidiaries evaluated the factor related to the regulatory stability higher than those who set up joint ventures with a local partner (8th position vs. 9th position). On the other hand investors who created joint ventures assessed the determinant related to the tax system in the host country higher than those who set up wholly owned subsidiaries (9th position vs. 10th position). The legal regulations governing business operations in the host country were evaluated in the same way by the two groups of investors (8th position).

Additionally, the statistical analysis confirms no significant differences between the two groups of companies. No relationship between the ownership equity-based entry mode and the importance of the FDI location factors was found at the 0.01 and 0.05 significance level. Only having set a threshold significance level at 0.1, the Fisher's exact test revealed a significant statistical difference once with respect to the better use of own resources ($p = 0.084$), which played a more crucial role as a location factor for companies establishing wholly owned rather than jointly owned subsidiaries (the frequency distribution and interrelated with it the value of the importance index back wholly equity-owned modes). The findings support a theory which allow us to assume that a wholly owned subsidiary will allow a company to use their own resources better as a joint venture due to high level of control over a subsidiary. A high level of control allows a company to coordinate better all operations and resources in different countries without a burden of an uncooperative partner as well as allows a company to protect its valuable resources such as technology competency (Root, 1994).

Conclusions

The purpose of this study was to identify FDI determinants of the host country in relation to the ownership equity-based entry mode choice as different factors might encourage companies to use various ownership entry modes in order to better exploit locational advantages of the host country. The findings of the study indicated that Polish investors are mainly driven by market seeking motives and market-related factors are the most important determinants of undertaken FDI projects for the companies establishing wholly owned as well as jointly owned subsidiaries. No significant differences were observed between the two groups of companies what allow us to confirm the first hypothesis.

The results of the study also clearly demonstrate that the favourable institutional and legal conditions do not play a critical role in terms of the ownership equity-based entry mode choice. The institutional and legal framework-related factors as drivers of investing abroad were not more important for Polish investors who enter host markets by a wholly owned subsidiary rather than a joint venture as we originally assumed. The findings didn't provide us enough evidence to accept the second hypothesis.

Surprisingly, the biggest differences between the two groups of companies were identified within efficiency-related factors (however based only on the importance index analysis). They seem to play more important role for companies who set up joint ventures with a local partner rather than those who established wholly owned subsidiaries. Additional studies are needed to understand these results better.

Evidently, the study has several limitations. First, data protection laws in Poland prevent researchers from accessing the database of Polish companies which are foreign direct investors (such databases are owned by the Central Statistical Office and the National Bank of Poland). This has influenced the way companies were selected for the research sample and the structure of the investor groups studied. Second, the study was also limited by the small size of the study sample, which prevented the use of

tests planned for this research procedure. It must be highlighted clearly, that due to the number of entities that took part in the study, there are no grounds for the generalization of these results. The research hypothesis can be conceived as a pointer for future research based on larger and more representative sample where also more objective based measures could be applied.

The above findings may also have some implications for future research. For instance, an integrative approach to motives, ownerships-specific advantages and FDI location factors would provide an in-depth insight for better understating of the study findings. Second, future research should explore more deeply location factors (especially to better understand the difference within efficiency-related factors) using more objective based measures. Third, international business research could benefit from cross-industry and cross-country comparison studies to identify the differences in the nature of FDI location factors between the companies investing in different sectors or developed and developing countries. Finally, a research analysing changes over time would enrich our understanding of the role of particular factors.

Financial Aspects of the Economic Activity of The Latvian Fish Processing Sector

Inese BIUKŠĀNE

Institute of Agricultural Resources and Economics, Riga, Latvia
inese.biuksane@inbox.lv

Abstract

Since embargo imposed by Russia and deterioration of the situation in markets, the Latvian fish processing sector has faced difficult times. Due to political situation, fish processing companies had to lose important export channels, which led them to rapid worsening of solvency, and to improve the financial situation production was partly (in separate companies even completely) suspended and also the employees were dismissed for (in)definite period. To acquire new markets and stabilize the situation, the support of the European Maritime and Fisheries Fund and the state was used; it provided an opportunity for companies to participate in several international exhibitions. The progress made at the international exhibitions suggest that the export market is going to stabilise in the future. The aim of the research is to evaluate and reflect the most significant aspects in the Latvian fish processing sector, at the same time providing proposals for improvement of financial stability of enterprises, operating in the sector. On the basis of the available data and selected indicators, the most important aspects in the Latvian fish processing sector related to financial situation were analysed and reflected, paying greater attention to the existing situation in micro, small medium-sized and large enterprises, and simultaneously providing an insight in the need of structural reforms. The information reflected in the research can assist the institutions, entrepreneurs and researchers involved in establishment and implementation of fisheries policy to understand and plan the common policy of the sector more successfully.

Keywords: fish processing, enterprises, financial analysis, financial situation, Latvia.

Introduction

Latvian fish processing sector deals with the production of sterilized and unsterilized canned fish, production of smoked and salted fish, production of refrigerated and frozen fish, as well as production of mixed fish products, which is a part of the manufacturing industry and is the secondary sector. The fish caught in the Baltic Sea and the Gulf of Riga, as well as the oceans are the main raw materials employed in the production of fish products and canned fish. In the recent years, also the freshwater fish bred in the Latvian aquaculture are used in the production of canned fish (Agriculture Ministry, 2014). The most popular product in the fish processing sector is canned fish called *Rigas sprotes* (Riga sprats), which has been a consumer beloved dainty and one of the main export products for more than 100 years.

The total amount of fish products and canned fish sold in 2017 was 58.16 thousand tons with the market value 142.71 million EUR (Central Statistical Bureau, 2020). The main markets were Sweden, Lithuania, Germany, Denmark, Czech Republic, Poland and Estonia. The production was also exported to Hong Cong, Canada, Mexico, Mongolia, Norway, Taiwan, Japan, the United Arab Emirates, the USA, Australia, Egypt, Israel, China, Macedonia, Serbia, Switzerland, Turkey, and other countries. In 2017, fish products and canned fish were exported to more than 60 countries overall. Since 2005, the volume of the sold products has reduced per -52%, what is largely related to the embargo imposed by Russia and the deterioration of the situation in the markets. In August 2014, the ban of Russia included import of processed and fresh fish products, and in 2015 – canned fish from Latvia. The ban affected 43 Latvian fish processing companies. Due to the lost export market the solvency of fish processing companies deteriorated and in order to improve the financial situation, production was partly (in separate companies even completely) suspended and also the employees

were dismissed for (in)definite period. To stabilise the financial situation of the companies the state provided support in terms of compensations aimed at partial repayment of loan interest according to the introduced legislation (Cabinet of Ministers, 2015).

To acquire new markets and stabilize the financial situation, entrepreneurs, using the available support from the European Maritime and Fisheries Fund, participated in several international exhibitions in 2016 and 2017: 'Prodexpo', 'SEAFOOD EXPO GLOBAL', 'World of Private Label', 'Summer Fancy Food Show', 'WorldFood Moscow', 'SIAL', 'FHC China', 'Gulfood', 'Foodex', 'SEAFEX' and 'ANUGA'. In the framework of the exhibitions the entrepreneurs managed to establish new business contacts (2 322 contacts in 2016 and 3 492 in 2017) as well as to conclude new cooperation contracts (64 contracts in 2016 and 73 in 2017) (Rural Support Service, 2020). The target audience of the attended exhibitions were the countries of the European Economic Area, CIS, Eastern Europe, South America, Scandinavia, Far and Middle East, Asia and other parts of the world. The progress made at the international exhibitions suggest that the export market is going to stabilise in the future.

The operation of the Latvian fish processing sector may also face the influence of the developments related to Brexit. British fish processing companies buy important raw materials, such as mackerel and herring, which are used to produce canned and smoked products. If the tariff and custom conditions of the EU and UK become unfavorable, Latvian fish processing companies will may have to look for new suppliers of raw materials. This in turn may lead to higher prices and changes in sales markets, at the same time causing the companies lack of financial stability and uncertainty about the future.

Research aim – to evaluate and reflect the most significant aspects in the Latvian fish processing sector, at the same time providing proposals for improvement of financial stability of enterprises, operating in the sector. To reach the aim, the following work tasks were put forward: 1) to select the most important indicators for description of financial situation; 2) to evaluate the financial situation of the micro, small, medium-sized and large enterprises operating in the Latvian fish processing sector.

The novelty of the research – the most significant aspects related to the financial position in the Latvian fish processing sector reflected, focusing on the current situation in the micro, small medium-sized and large enterprises. The research provides a comprehensive insight into financial stability of the companies operating in the sector and the further measures to be taken for strengthening the financial sphere, being a valuable informative material for formation, implementation and planning of the common policy in the fisheries sector and its companies.

The general scientific research methods, statistical research methods and mathematical methods were used in the study. The author mostly applied analysis and synthesis methods in development of conclusions and proposals. Microsoft Excel, Microsoft PowerPoint and IrfanView program were used in processing and analysis of the research results.

Materials and Methods

Evaluation of financial stability will include micro, small medium-sized and large enterprises operating in the fish processing sector in Latvia. Pursuant to the EU legislation, micro, small and medium-sized enterprises are economic operators, which comply with the definition reflected in the Appendix 1 to the Regulation of the European Commission No.651/2014. Categories of the enterprises are determined on the basis of the number of employees and financial thresholds (Table 1).

Table 1: Conditions to Determine the Status of an Enterprise (created by the author **according to European Commission, 2014)**

Enterprises size	Criteria				
	Number of employees		Turnover		Balance
Micro	<10	*and*	≤ 2 million EUR	*or*	≤ 2 million EUR
Small	<50	*and*	≤ 10 million EUR	*or*	≤ 10 million EUR
Medium-sized	<250	*and*	≤ 50 million EUR	*or*	≤ 43 million EUR
Large	>250	*or*	> 50 million EUR	*or*	> 43 million EUR

In 2017, in general there were 95 enterprises in the Latvian fish processing sector according to these categories; 15 of them were micro enterprises, 29 – small enterprises, 15 – medium-sized enterprises and 1 – large enterprise. Since 2005, the number of enterprises in the Latvian fish processing sector has reduced per -15%.

The evaluation of the financial situation of the enterprises will be performed using financial analysis in the framework of which the data available from the financial reports will be analysed (balances, profit and loss accounts). Liquidity, solvency, efficiency and profitability will be assessed in the framework of financial analysis (Fig. 1).

Fig. 1: Indicators for Evaluation of Financial Situation (created by the author according to Altman, 1968; Deakin, 1972; Rurāne, 1997; Saksonova, 2004; Fabozzi et al., 2007)

The liquidity analysis will include assessment whether enterprises are able to pay their short-term obligations by available current assets (Bednarskis et al., 1994). Solvency analysis will enable clarification whether enterprises are able to pay their short-term and long-term obligations by available equity (Bednarskis et al., 1994). Efficiency analysis will allow an assessment of the sufficiency of enterprise assets to generate turnover and enables a judgement whether investments in the assets are sufficient (Bednarskis et al., 1994). While profitability analysis will reflect the ratio of profit to the consumed resources, evaluating the profitability (Zariņa & Strēle, 2009). To assess the financial situation, in general there were selected 6 indicators: Total Liquidity Ratio, Debt to Equity Ratio, Total Assets Turnover Ratio, Return on Sales Ratio (ROS), Return on Assets Ratio (ROA) and Return on Equity Ratio (ROE). The evaluation was carried out for the period between 2005 and 2017. Considering data confidentiality, the evaluation does not include information about medium-sized enterprises and large enterprises in 2017.

Results and Discussion

Using the available data and chosen indicators, the liquidity, solvency, efficiency and profitability of micro, small, medium-sized and large enterprises operating in the Latvian fish processing sector were evaluated (Fig. 2).

From 2005 to 2017, liquidity in the Latvian fish processing sector can be evaluated as optimal (Total Liquidity Ratio on average 1.15), suggesting that in general the sector has no problem to pay its short-term obligations by its available current assets. The exception was 2011, when the sector showed reduced liquidity, suggesting that there is a lack of current assets for payment of the short-term obligations. Currently, the sector shows no tendency for the liquidity to get worse.

Fig. 2: The Financial Situation of Micro, Small, Medium-Sized and Large Enterprises in the Latvian Fish processing Sector from 2005 to 2017 (coefficient, %) (calculated and created by the author according to Central Statistical Bureau, 2020)

Analysis of the situation at the level of enterprises enables a conclusion that from 2005 to 2017 the large and small enterprises had a better liquidity (Total Liquidity Ratio ≥1) than the medium-sized and micro enterprises (Total Liquidity Ratio <1). The large and small enterprises were liquid enough, except for 2009, 2010 and 2014, when the small enterprises showed low liquidity suggesting that there are insufficient availability of current assets to settle the short-term obligations. The lowest liquidity, in turn, was observed in micro enterprises, except 2007 and 2015-2017, when the liquidity was within normal limits. Insufficient liquidity was observed also in medium-sized enterprises, except 2005, 2007, 2008 and 2011-2013, when the liquidity was evaluated as optimal. Since 2005, the liquidity of the micro and small enterprises has improved. Creditors usually prefer lower liquidity, as it involves lower financial risk.

From 2005 to 2017, the Latvian fish processing sector established unbalanced capital structure, suggesting that the sector used a lot of debenture capital, failing to balance it with the equity (Debt to Equity Ratio >1).

In this period, medium-sized enterprises showed especially unbalanced capital structure, the total obligations of which exceeded the equity many times, thereby exposing themselves to big financial risks. Also, the small and large enterprises created a disproportioned capital structure. The micro enterprises, in turn, were the only companies, where negative equity was observed (in 2005, 2006, 2010, 2011 and 2014 the equity was smaller than fixed capital), suggesting that the enterprises had financial difficulties. One of the ways for micro enterprises to reduce the obstacles for obtaining funding is to increase the fixed capital. Fixed capital can be increased by money investment, investment in kind and on the basis of undistributed profits. Capital structure is particularly important for creditors, as opportunities to attract financing depend on it.

Financial equilibrium in the Latvian fish processing sector can be improved by creating a well thought-out and balanced structure of equity and debenture capital, which can be achieved at the national level by stipulating in the legislation the maximum admissible ceilings of financial equilibrium when a sector could qualify for the funding of the EU financial instruments, state and credit institutions. Exceptions could be acceptable in cases of innovative, long-term viable and profitable projects, implementation of which would benefit not only the fish processing enterprises themselves but also other participants of the fisheries sector and the country in general. Setting such ceilings would defend from unhealthy debt commitments and inexpedient squandering of national budget resources.

From 2005 to 2017, the Latvian fish processing sector used its available assets in generation of net turnover effectively enough (Total Assets Turnover Ratio on average 1.49), however, not in all the groups of enterprises. The medium-sized and large enterprises used their assets the most efficiently, whereas the small enterprises – less efficiently, showing that the investments made in enterprise assets have been useful and have been used skilfully. Micro enterprises used their assets inefficiently, which indicates to insufficient investments in creation of assets and problems in facilitation of sales. The potential of the fish processing sector was not used completely; and to facilitate the efficiency of assets, the sector has to find a way to increase turnover and to utilize a part of assets unfit for production.

From 2005 to 2017, the Latvian fish processing sector can be evaluated as a profitable sector, (Return on Sales Ratio on average 0.22%, Return on Assets Ratio on average 0.47% and Return on Equity Ratio on average 1.26%), except in 2006 and 2009, when there were financial problems, and 2014-2017, when the sector lost significant markets due to embargo imposed by Russia. The large and small enterprises can be considered to be the most profitable enterprises in the sector. Conversely, micro and medium-sized enterprises can be considered to be less profitable enterprises.

The financial stability of the Latvian fish processing sector can be enhanced by creating a well thought-out and balanced capital structure and distribution of financial means. In its framework, it is desirable for the enterprises to finance their long-term investments not only from the equity but also

from the long-term obligations. In turn, it is desirable to finance current assets from short-term obligations. It is not obligatory to follow the financing conditions, but desirable from the aspect of enhancement of financial stability.

Conclusions

The most significant financial aspects of the Latvian fish processing sector were evaluated and reflected using the globally widespread and important financial management instrument – financial analysis. In its framework the liquidity, solvency, efficiency and profitability of micro, small, medium-sized and large enterprises was assessed. The indicators used in the process of evaluation allow understanding the role of financing in the management of an enterprise and acquire new techniques how to make the right decisions to ensure successful operation of enterprises analysing and evaluating the financial indicators of the enterprises. Financial analysis provides an opportunity to understand and plan the common policy of the sector more successfully, at the same time enabling the understanding about the need in structural reforms.

Financial stability of the Latvian fish processing sector in general can be evaluated as sufficiently good, but not in all the groups of enterprises. The large and small enterprises can be considered to be the most financially stable enterprises in the fish processing sector, which, despite their unbalanced capital structure, could ensure optimal liquidity and could efficiently use the available assets in generation of net turnover, thereby ensuring financial benefit. Medium-sized enterprises, in turn, showed especially unbalanced capital structure, suggesting that the enterprises used a lot of debenture capital, failing to balance it with the equity and thus exposing themselves to additional financial risks. Although the investments made in enterprise assets have been expedient and assets were skilfully used, the enterprises were unable to ensure sufficient liquidity and profitability. The micro enterprises can be considered to be the most unstable enterprises in the fish processing sector; in comparison to the other enterprises, they showed the lowest liquidity and negative equity, suggesting that there existed financial difficulties. Low level of assets was observed in the enterprises, showing that there was a lack of funding for restoration of the assets and problems in facilitation of sales. The economic activities of micro enterprises cannot be evaluated as profitable.

The financial stability of the Latvian fish processing sector can be enhanced by following several financing rules, setting the maximum admissible ceilings of financial equilibrium, and by efficiently and rationally using the production resources available to the enterprise, simultaneously providing for commensurate investments in their restoration.

Customer Experience Management In Omni-Channel Retailing

Aleksandra RADZISZEWSKA

Czestochowa University of Technology, Czestochowa, Poland
E-mail: radz_a@wp.pl

Abstract

The omni-channel, as an emerging trend in retail, aims to coordinate processes and technologies across supply and sales channels. This paper describes the factors that influence omni-channel consumers' experiences, their acceptance of different distribution channels and intention to use new technologies interchangeably with traditional channels during the shopping process. This study shows how digital channels can be combined with traditional retailing, in order to enhance the value of the shopping experience, and to improve customer satisfaction in omni-channel settings.
The primary purpose of this research is to study the relationships between the dimensions of omni-channel retailing and consumer shopping behavior, experiences and satisfaction.
This study developed a conceptual framework for customer satisfaction assessment in omni-channel retailing and explored properties across multiple retail and supply chain channels in the context of customer experiences management. The proposed framework can be applied to a wide range of retail supply chains. It helps managers to develop and monitor omni-channel systems with aim of better customers' requirements fulfillment. Findings of this study confirm the positive and significant influence of all customer satisfaction dimensions on shopping experiences and fulfillment of consumer requirements and expectation connected with purchase in omni-channel environment. It validates that customer evaluation is not only based on product quality, but also includes every touch point with retailer. Understanding of particular consumer experience dimensions in omni-channel retailing can be helpful to managers in executing strategies that have the most positive effect on consumers' behavior and purchase satisfaction.

Keywords: Omni-Channel Retailing, Customer Experience Management, Shopping Channel, Customer Satisfaction.

Introduction

Business competition today is getting tougher and a company can survive long only by increasing the competitive advantage, but competitive retail business requires more than just low prices and innovative products. The development of new technologies has changed the retailing process. Additional retailing channels are emerging, causing consumers to change their habits and shopping behavior. The increasing diffusion and adoption of alternative business-to-consumer retail channels through both traditional and modern retail settings has transformed retail practices and consumers' shopping behavior. Current significant advances in technology, including the emergence of new purchase and communication channels such as the Internet, mobile application and social media, have opened up a new way for customers and firms in retailing process (Pauwels and Neslin, 2015). With the growing importance of online sales, retailers are investing in their omni-channel strategies. The omni-channel, as an emerging trend in retail, aims to coordinate processes and technologies across supply and sales channels. An omni-channel strategy is a form of retailing that, by enabling real interaction, allows customers to shop across channels anywhere and at any time, thereby providing them with a unique, complete, and optimal shopping experience that breaks down the barriers between channels (Verhoef et al., 2015). A growing number of customers use various channels during their shopping process. They might research the characteristics of a product using a mobile application, compare prices on several websites, and finally, buy the product at a physical store. They use new technology to search for information, offer opinions, explain experiences and make

purchases. In an omni-channel environment, channels are used interchangeably during the product's search and purchase process. Omni-channel retailing is a perfect approach to retailing that offers a single and unified shopping experience across all accessible retail channels. The concept of customer experience has emerged as a strategy for the retail business, because customer experience includes every point of contact at which the customer interacts with the retailer, product, or service.

This paper identifies the factors that influence omni-channel consumers' experiences, their acceptance of different distribution channels and intention to use new technologies interchangeably with traditional channels during the shopping process.

The primary purpose of this research is to study the relationships between the dimensions of omni-channel retailing and consumer shopping behavior, experiences and satisfaction. This study shows how digital channels can be combined with traditional retailing, in order to enhance the value of the shopping experience, and to improve customer satisfaction in omni-channel settings.

This study applies the following research methods: analysis of scientific literature, online survey, and statistical analysis of data.

The paper is organized as follows: After this introduction the relevant literature in omni-channel retailing have been reviewed and its contribution to current knowledge and practice has been identified. Afterwards, the recommendations that can help retailers recast the customer experience and manage all interactions across channels in an integrated and consistent manner have been proposed. Then the paper presents research methodology and proposed model of customer satisfaction assessment in omni-channel shopping environment. After that the results of research have been presented and discussed. Finally, the main conclusions from the study, its limitation and recommendations for future research are summarized.

Literature Review

Omni-channel retailing integrates processes and technologies across all accessible shopping channels, to provide consistent and more reliable services for consumers (Verhoef et al., 2015). Recent years have witnessed the emergence of new retailing channels. Thanks to new technologies, retailers can integrate all possibilities of these channels (Brynjolfsson et al., 2013). Omni-channel retailing integrates shopping experiences and connects the advantages of physical stores with the experience of online shopping. The omni-channel concept is perceived as an evolution of multi-channel retailing. While multi-channel retailing implies a division between the physical and online store, in the omni-channel environment, customers move freely among channels (online, mobile devices, and physical store), all within a single transaction process (Melero et al., 2016). Omni-channel retailing has many elements, which need to interact with each other, for example in form of information and material flows (Saghiri et al., 2017).

When channels work independently of each other they create fragmented supply chains, and struggle to deliver a consistent and reliable consumer experience. Omni-channel retailing aims to address this issue by coordinating processes and technologies across all channels, to provide most favorable, consistent and more reliable services for consumers (Verhoef et al., 2015).

To enhance the consumer omni-channel experience, retailers have attempted to make the product and service information consistent across all channels (Müller-Lankenau et al., 2006). In such system, consumers can easily switch from one channel to another in their buying experience, where they may find a product in one channel, place the order via another channel, and have the product delivery from a third channel, for example in the form of home delivery.

Customers expect a consistent, uniform, and integrated service, regardless of the channel they use, they are willing to move easy between different shopping channels (traditional store, online, and mobile), depending on their preferences, their current situation or the product category (Cook, 2014). Contemporary customers want to take advantage of the benefits offered by each accessible shopping

channel. They want to use their own device to perform searches, compare products, ask for advice, or look for better alternatives during their shopping process. The omni-channel system assures maximum information availability, visibility and consistency across different shopping channels (Piotrowicz and Cuthbertson, 2014). This provides various benefits such as total sales growth, cost saving and extended trust (Kumar and Venkatesan, 2005; Tate et al., 2007). Cross-channel retailers that adopt coordinated omni-channel strategies can be more profitable than those who employ multiple channels independently (Chatterjee, 2010). But omni-channel systems may need various requirements such as: broadband Internet accessibility, well-located and well-designed distribution centers, efficient and extensive logistics network, cross-channel integration, omni-channel visibility to customers, and product digitization (Cortiñas et al., 2010; Saghiri et al., 2017).

By using integration and optimal combinations of shopping channels, retailers can explore the benefits and overcome the deficiencies of each channel to create an appealing and safe shopping experience for consumers. Shopping channels should integrate promotion, pricing, product information, transaction, order fulfillment and customer service (Oh et al., 2012; Das and Chowdhury, 2012).

Integrated promotion and product information refers to connecting and synchronizing all channels with promotion and product information. The same information about product should be distributed to all members of the omni-channel system as well as the consumers. Product information may include product description, technical data, as well as stock status. Therefore, all promotion data sources must be shared across all accessible channel types (Avery et al., 2012; Weathers et al., 2015). Integrated transaction involves different available payment instruments and linking them with existing authorization mechanisms. Transaction integration may also imply a secure accessibility to consumer transaction data via various channels (Carton et al., 2012).

Integrated pricing synchronizes the products' prices, and makes changes in them, for example in the form of discounts, visible for consumers in all available channels. The omni-channel retailing adds a new aspects of competition among retailers, and pricing integration is key to managing pricing strategies across channels (Yan and Pei, 2011; de Carvalho and Campomar, 2014; Chen et al., 2015).

Integrated order fulfillment enables easy choice and change of product, transport mode, stock keeping point or delivery point across all channels. A high level of order fulfillment integration leads to a higher service quality experiences. Integrated customer service implies the same or compatible service standards in all accessible channels. Integrated customer service should be provided prior to the purchase, for the period of the purchase, during the product delivery, and in the product return stage (Ma et al., 2014).

When channels work independently of each other they create fragmented supply chains, and insufficient customer shopping experience. Omni-channel retailing integrates processes and technologies across all accessible shopping channels, to provide consistent and more reliable services for consumers (Verhoef et al., 2015; Cao and Li, 2015).

Researchers proposed different factors crucial for customer satisfaction and high quality experiences in omni-channel shopping. Some authors emphasize that omni-channel shopping has numerous advantages, such as: online shopping possibility and its convenience (Amrouche and Yan, 2012), wide range of touch points and channels for communication and transaction with customers (Verhoef et al., 2015). Furthermore, higher synergy and more information make channels complement each other and therefore enhance high quality customer shopping experience (Blázquez, 2014). Perceived quality and risk of omni-channel shopping have been found to be affected by diverse factors like customer digital literacy and brand recognition (Schoenbachler and Gordon, 2002), offline store service (Verhagen and van Dolen, 2009), channels integration (Herhausen et al., 2015), and advanced logistics processes (Hübner et al., 2016).

The most important factors influencing consumers' preferences are: accessibility, convenience, perceived risk, uncertainly reduction, transaction security, purchase costs, immediate product

availability, website design and quality, that influence customers' use of an online channel. The degree of integration of the various channels also appears to be an important driver of customer channel preferences, so higher levels of integration and the transparency of this integration are associated with desirable customer behaviors. The different attributes and capabilities of channels help understand customer decisions to use these channels (Avery et al., 2012).

In general, researchers tend to agree that customers who use multiple channels to purchase the firm's products and services are more profitable than single-channel customers and the monetary value of omni-channel customers is almost double that of single-channel customers (Kushwaha and Shankar, 2013).

Customer satisfaction and customer experience are distinct constructs and shows a contributory relationship with each other. Furthermore, better experiences leads to positive feelings and emotions due to that consumer want to repeat these experiences that not only influence satisfaction of the customer but also results into brand loyalty (Klaus and Maklan, 2013). The appropriate combination of shopping channels enables retailers to provide value-added services to consumers, which improves their shopping experiences and satisfaction with purchase. Therefore, the present study examined the influence of different shopping experience dimensions on customer satisfaction in omni-channel retailing.

Research Methodology

Because of numerous gaps and controversies in omni-channel retailing literature, this research aims to develop a conceptual framework for customer experiences assessment in omni-channel environment.

The factors for customer satisfaction in omni-channel environment have been selected from prior literature studies. The proposed model of customer satisfaction ties together factors representing major contexts of consumer satisfaction in omni-channel environment.

The proposed methodology of customer experience assessment in omni-channel retailing divides the factors connected with customer satisfaction into two groups. The first group takes into consideration factors related to experiences connected with purchase. The second group of customer satisfaction determinants in omni-channel concerns integration of shopping channels. The proposed framework for customer experiences assessment in omni-channel environment has been presented in the table 1.

Table 1: The conceptual framework for customer satisfaction assessment in omni-channel retailing.

Experiences connected with purchase	- transaction security - shopping convenience - reduction uncertainly and risk connected with purchase - accessibility of all shopping channels - possibility of easy product return - help by product choice and recommendation tools - personalization

Shopping channels integration	- product availability in different retail channels - integrated customer support across all sopping channels - compatible customer service standards in all accessible channels - integrated order fulfillment - compatible product prices and discounts in all accessible shopping channels - synchronizing all channels with promotion and product information.

Source: own elaboration.

The empirical sample was the young customers, that make purchase with help of different shopping channels. The respondents were asked to indicate the dimensions which influence their evaluation of shopping quality and satisfaction in omni-channel environment. The study population was members of academic community. The data was collected in the form of an online survey. The online questionnaire applied in this study included two sections. The first section collected information about respondents, their shopping habits and behaviors. The second part collected the information required for running the main analyses. All survey participants were young people, aged under 25. Each participant of the study was asked to answer the survey questions. Among 92 respondents, that replied the online questionnaire, 3 of them indicated that they have little or no experience of omni-channel shopping, and 9 questionnaires were uncompleted. The remaining 80 questionnaires were the basis of the study and have been used in the analysis of data, by using correlation coefficient (V-Cramer's coefficient) analysis. Respondents included 35% males and 65 % females. All surveyed respondents, that have been taken into consideration, browse regularly e-commerce sites, have experience of online shopping and shopping in omni-channel environment. They confirm that they often join different shopping channel, for example make an order online, watch the product in physical store, use recommendation and suggestion of salespeople, and search for online opinion and recommendation of others consumers.

The reliability test used was Cronbach's alpha. For all research variables values were higher than 0,8. Cronbach's alpha for transaction security was 0,831, shopping convenience 0,843, reduction uncertainly and risk connected with purchase 0,874, accessibility of all shopping channels 0,827, possibility of easy product return 0,819, help by product choice and recommendation tools 0,876, personalization 0,869 and shopping channels integration 0,842. Cronbach's alpha showed high internal consistency, what implies that the measures are reliable and the evaluation instrument is appropriate for use in research.

In questionnaire, each respondent determines the importance of every factor with a five-point Likert scale (very unimportant, unimportant, neutral, important, very important). Correlation analyze was used to estimate the unique effect of each factor typical for shopping in omni-channel environment on consumers' satisfaction levels.

The main limitation of this research is sampling. Therefore, results of the online questionnaire and all findings can be applicable only to the study sample.

Results and Discussion

Customer experience management is considered as an important issue in today's highly competitive environment in retailing business. New technologies offer retailers opportunities to bring together Internet, mobile, and offline channels into integrated customer experiences, therefore consumers may benefit from online and offline advantages.

The proposed factors, which determine customer's satisfaction in omni-channel shopping and their correlation with customer's satisfaction have been presented in table 2.

Table 2: Customers' satisfaction assessment in omni-channel retailing

Determinants of customers' satisfaction in omni-channel shopping	χ^2 – value	V-Cramer's coefficient
- transaction security	8,67	0,917
- shopping convenience	8,52	0,651
- reduction uncertainly and risk connected with purchase	8,49	0,893
- accessibility of all shopping channels	9,23	0,694
- possibility of easy product return	8,97	0,712
- help by product choice and recommendation tools	9,41	0,548
- personalization	8,76	0,746
- shopping channels integration	9,18	0,879

Source: own elaboration.

The results in table 2 show that the correlation between all investigated factors and customers' satisfaction level in omni-channel environment is statistically significant, because the χ^2 – value is higher that critical value (8,43).

Transaction security has the greatest positive impact on customers' shopping experiences (V= 0,917). Reduction uncertainly and risk connected with purchase is the second most important element driving satisfaction level in omni-channel environment (V=0,893), because consumers can see, touch, and feel products before buying and they have easy access to product information. Results demonstrate also that shopping channel integration (V=0,879), personalization (V=0,746), possibility of easy product return (V=0,712), and accessibility of all shopping channels (V=0,694) are very important for customers satisfaction in omni-channel shopping. Shopping convenience (V= 0,651), help by product choice and accessibility of recommendation tools (V=0,548) are the next important determinants of omni-channel shopping satisfaction. The results show that all investigated factors, significant for shopping experiences in omni-channel environment, have positive relationships with customers' satisfaction.

Shopping channel integration, personalization, customer trust connected with transaction security, risk and uncertainly reduction are key factors for a successful customer experiences management in omni-channel retailing. Transaction security is crucial for customers' satisfaction, because customers are aware of all information that they give away to firms, such as purchase histories, shopping behaviors or personal data.

Reduction of risk connected with purchase plays the crucial role in creation of positive customers' experiences connected with purchase. Within an omni-channel environment consumers have an opportunity to search product information both online and through visiting stores in order evaluate the alternatives and gain higher product familiarity prior to the purchase decision.

Positive customers' experiences and their satisfaction in omni-channel environment is connected with channel integration and possibility of easy change of shopping channel according to customer needs. The various channels differ in several factors, including whether they are physical or virtual, their degree of accessibility and convenience, and their switching costs. From a customer perspective, the creation of new shopping channels has offered new opportunities to transact and communicate with the firm. As a result, customers increasingly use alternative channels to purchase products or services and to contact the firm for other purposes including requesting information, asking technical advice, facilitating feedback about the products and services, and inquiring about a product's use or availability. The results of this study show an increasing number and complexity of customer-retailer interactions. Therefore, retailers should adopt optimal channel integration, which is associated with increased consumers' satisfaction and loyalty. The appropriate combination of different channel

reduces uncertainly and risk connected with transaction and plays a critical role in creation of personalized and high quality customer experiences.

Consumers require not only information about product in different marketing channels, but their have need of help by product choice, recommendation and support by purchase, contact with salespeople, and get in touch with product before purchase, because they can make clear characteristics of the products and make sure they are taking a good decision.

The availability of a better customer support that firms can provide through various channels causes that customers' complex needs are better satisfied with a coordinated omni-channel strategy. Understanding the consequences of customer behavior with respect to the various channels is necessary for the effective customer relationships management across particular shopping channels.

Conclusions

This study developed a conceptual framework for customer satisfaction assessment in omni-channel retailing and explored properties across multiple retail and supply chain channels in the context of customer experiences management. This research can help to understand the performance of omni-channel retailing systems, their development and improvement possibilities. It create also a framework for future studies on the omni-channel, support more effective management of omni-channel systems, and contribute to both the theoretical and practical aspects of omni-channel research. The proposed framework can be applied to a wide range of retail supply chains. It helps managers to develop and monitor omni-channel systems with aim of better customers' requirements fulfillment.

Findings of this study confirm the positive and significant influence of all proposed customer satisfaction dimensions on shopping experiences and fulfillment of consumer requirements and expectation connected with purchase in omni-channel environment. It validates that customer evaluation is not only based on product quality, but also includes every touch point with retailer. Overall experience comprises every touch point between customer and company, from product searching to product delivery, therefore companies should develop an integrated omni-channel strategy, identify, understand, and respond to their consumers, with aim of increasing the possibility of profitable and long-term relationships with them. Additionally, a satisfied customer though the pleasurable and well managed experiences generally generates positive word-of-mouth about the retailer. Understanding of particular consumer experience dimensions in omni-channel retailing can be helpful to managers in executing strategies that have the most positive effect on consumers' behavior and purchase satisfaction. Consequently, this will allow to manage customer experience properly that ultimately results into customer satisfaction, loyalty and positive word-of-mouth. Furthermore, this study establishes a direct linkage between consumer satisfaction and retailers activity in their omni-channel strategy improvement.

This research has a number of limitations too. The recommended omni-channel framework lacks an empirical validation, because of the limited study sample. This limitations provide perspectives for future research. A future study should try to validate and generalize the findings by using a wider sample. Moreover, the recommended framework reflects only limited management perspectives connected with customer experiences management in omni-channel retailing, and does not address other crucial dimensions of customer satisfaction. Further research is also required about the possibilities of the use other shopping channel such as mobile channels or social media. One of the issues that most concerns customers is their privacy. Therefore, more research is required into how companies can guarantee customers privacy protection and the correct use of all their private information across the different channels. Future research should explore the impacts of other variables connected with purchase experiences in omni-channel environment, which can determinate increasing of consumers' satisfaction.

Customer Satisfaction in Online Shopping – The Application of Kano Model in Service Quality Management of B2C E-Commerce Website

Aleksandra RADZISZEWSKA

Czestochowa University of Technology, Czestochowa, Poland
E-mail: radz_a@wp.pl

Abstract

Customers' requirements fulfillment and their satisfaction evaluation can be accomplished via various methods. This study uses Kano model as a theoretical framework to recognize and distinguish factors influencing quality perception and explores the possibilities of a better understanding of customers' expectations connected with B2C e-commerce quality attributes. The aim of this paper is creation of a conceptual framework of quality assessment based on e-commerce customer satisfaction and application of Kano model in service quality evaluation of B2C e-commerce sites. The paper attempts to study the various dimensions of e-service quality affecting online shopping satisfaction and uses Kano model to examine customers' requirements and satisfaction level in e-commerce. The Kano model has been used on a pilot sample of respondents. This research develops and tests empirically this framework for evaluation of e-retailing quality. The results of this study provide guidelines to encourage improvements in B2C e-commerce and effective customer experiences management in online environment. This study investigates empirically the determinants of high-quality customer experiences, develops a measurable framework for customer online satisfaction assessment, and indicates factors, which are significant for fulfillment of customers' requirements and expectations in online shopping. Understanding the most influential elements for customers' decision-making is not only beneficial for future development of e-commerce but also for increasing customer satisfaction and successful improvement of quality management in e-commerce companies.

Keywords: customer requirements; e-service quality management, B2C e-commerce, Kano model.

Introduction

An increasing number of consumers shift their buying activities from physical stores to retail websites and the reasons for this changed purchase behavior range from lower prices, greater convenience, and time savings, to better product and service selection available in online environment (Brunner-Sperdin et al., 2014). The quality of this service plays a similar role as the quality of services to consumers in other domains. Therefore, companies apply to improve the design of their websites, to enhance the quality of customers' interaction experiences, and to deliver a superior service quality, which are the key determinants of online retailers' success. It could be stated, that investments into the technical as well as service quality of the website increase the possibility of attaining satisfied customers (Al-Qeisi et al., 2014). Developing the right quality of service is extremely important and essentially involves shaping and modifying its individual features. Each of them can be treated individually and perceived by a given client. In order for the client to be fully satisfied, there is a need to constantly measure the quality and customer satisfaction of these services, allowing for continuous improvement of customer experiences in online shopping. One of the models to measure customer satisfaction is the Kano model of customer satisfaction which classifies quality attributes based on how they are perceived by customers and their effect on customer satisfaction (Chu, 2002; Grigoroudis and Spyridaki, 2003; Kano et al., 1984).

The Kano method can significantly facilitate the recognition of customers' expectations in e-commerce. This method is based on the assumption that the quality features are multidimensional

and affect the level of customer satisfaction to varying degrees. Some features have an impact primarily on creating satisfaction, while others contribute to causing dissatisfaction. Therefore, understanding what the client expects allows to focus on developing the right characteristics of the e-commerce site.

Understanding the most influential elements for customers' decision-making is not only beneficial for future development of e-commerce but also for increasing customer satisfaction and successful improvement of quality management in e-commerce companies.

The aim of this paper is creation of a conceptual framework of quality assessment based on e-commerce customer satisfaction and application of Kano model in service quality evaluation of B2C e-commerce sites.

The paper attempts to study the various dimensions of e-service quality affecting online shopping satisfaction and uses Kano model to examine customers' requirements and satisfaction level in e-commerce. The Kano model has been used on a pilot sample of respondents. This research develops and tests empirically this framework for evaluation of e-retailing quality. This study investigates empirically the determinants of high quality customer experiences, develops a measurable framework for customer online satisfaction assessment, and indicates factors, which are significant for fulfillment of customers' requirements and expectations in online shopping.

The study is structured as follows. After this introduction, the theoretical foundations and literature review have been presented. Next section details the methodological procedures, followed by an analysis of data and defines the dimensions of the proposed framework and its indicators. Than the results of research have been presented and discussed. Finally conclusion and suggestions for the continuation of the research have been presented, limitation are described, theoretical and managerial implications are explored.

Theoretical Background

Studies in the field of traditional services and online services have indicated that not all service quality attributes have the same level of impact on overall service quality perceived by customers (Jiang et al., 2013). In the traditional service environment, there are many studies using the SERVQUAL scale (Parasuraman et al., 1988) to evaluate the relative importance of service quality attributes, which is composed of five dimensions or underlying factors (tangibility, reliability, responsiveness, security, and empathy). SERVQUAL has been a popular measurement scale to evaluate service quality in many different traditional service environments characterized by direct interactions between customers and employees of service providers. With advances in the Internet, ICT technologies, and the growth of e-commerce and e-services, the SERVQUAL turns out to be inappropriate for evaluating and measuring e-service quality characterized by interactions between customers and websites of service providers. As a result, a number of studies attempted to develop e-service quality measurement scales. For example, Loiacono, Watson, and Dale (2000) developed WebQual, an e-service quality measurement scale which consists of 12 items: trust, response time, ease of understanding, tailored communications, intuitive operations, visual appeal, innovativeness, emotional appeal, consistent image, relative advantage, and inline completeness.

Yoo and Donthu (2001) developed an e-service quality measure called "SITEQUAL" for evaluating website quality that includes four factors – security, processing speed, ease of use, and aesthetic design. Jun and Cai (2001) identified 17 dimensions that are grouped into three categories for measuring e-service quality – online system quality, product service quality, and customer service quality. Zeithaml, Parasuraman, and Malhotra (2002) constructed a framework that can be utilized to measure e-service quality, consisting of 11 factors: security/privacy, assurance/trust, responsiveness, personalization, efficiency, reliability, flexibility, access, ease of navigation, site aesthetics and price knowledge. Wolfinbarger and Gilly (2003) advanced e-TailQ scale, including four factors to evaluate e-service quality. These four factors are customer service, website design, security, and reliability. DeLone and McLean (2003) constructed an updated information system success model with factors

determining the success of information systems such as service quality, system quality, and information quality. Han and Baek (2004) developed a four-factor scale for measuring e-service quality. These factors are tangibles, reliability, responsiveness, and empathy. Yang, Jun, and Peterson (2004) identified credibility, security, attentiveness, reliability, access, and ease of use as important dimensions for measuring e-service quality. Parasuraman, Zeithaml, and Malhotra (2005) developed a framework for measuring e-service quality, which includes E-S-Qual as a core online service quality scale (efficiency, privacy, fulfillment, and system availability) and E-RecS-Qual as an online recovery service quality scale (contact, compensation, and responsiveness).

In recent years, various authors have identified many determinants of customer satisfaction regarding electronic commerce. In the online service environment, many studies indicated that service quality attributes are of different importance in shaping overall online service quality. Liu and Arnett (2000) argued that four factors, namely, information quality, system use, system design quality, and playfulness determined the success of websites in the e-commerce context.

Jun and Cai (2001) argued that responsiveness, reliability, and accesses were the most important online service quality attributes. In the opinion of Polatoglu and Ekin (2001), reliability, access, and savings have the strong influence on online service quality. The important role in measuring the level of online customers satisfaction play also: content, ease of use, and accuracy (Pikkarainen et al., 2006). Yang and Jun (2008) conducted a survey of the quality of online services perceived by Internet purchasers and Internet non-purchasers. The six service quality attributes perceived by Internet purchasers were: reliability, access, ease of use, personalization, security, and credibility. The seven service quality attributes perceived by Internet non-purchasers were: security, responsiveness, ease of use, reliability, availability, personalization, and access. Considering the relative importance of service quality attributes to overall online service quality, the authors argued that the quality attribute connected with reliability was the most important for Internet purchasers, while the quality attribute connected with security was the most important for Internet non-purchasers.

According to Cyr (2008), the most significant determinants of customer satisfaction in e-commerce are : navigation design, visual design and information design. Safa and Ismail (2013) identified several factors connected with customer satisfaction in e-commerce: perceived site quality; customer experience in e-commerce; less time transaction; perceived usefulness; perceived ease of use; customer segmentation; customize products; fast response to customer inquiries; variety of goods and services; rewards and discounts; system quality; information quality; personalized web feature; language options; search and comparing facilities; product and service information; using other systems; collecting and analyzing customer information; fast and easy payment.

Other authors proposed eight determinants of customer satisfaction in e-commerce: commitment - efforts of the company to ensure that there is no breakdown in customer service and the responsiveness to customer concerns, problems, and complaints; engagement - overall image projected through the website; assortment -variety of products or services provided in the website; network - customer communication among themselves through the website; interactivity - two-way communication through the website among company and customers; transaction ease - extent to which a customer feels that the website is simple, intuitive, and user-friendly; fostering - relevant post purchase information provided for customers from the website; and adaptation - customer's feeling that value propositions in the website are adapted to him (Anderson and Swaminathan, 2011).

According to Christodoulides and Michaelidou (2010) the most influential quality attributes in online environment are: convenience, information seeking, variety seeking, and social interaction. Other evaluation criteria proposed in literature are: user interface quality, information quality, perceived security, perceived privacy (Eid, 2011); navigational functionality, perceived security, transaction cost (Kim et al., 2011); information quality, system quality, service quality, product quality, delivery quality, perceived price (Lin et al., 2011).
Although many evaluation criteria are proposed in the literature, the focus here is to choose those criteria which serve to determine customer satisfaction in e-commerce. It is argued that the quality of

e-commerce systems is related to quality of factors, which are connected with web site features, e-service quality, and promised customers' expectations fulfillment. For purpose of this study, the following dimensions of e-retailing quality evaluation have been selected: features of e-commerce website, e-service quality, and reliability. The detailed criteria of service quality assessment in B2C e-commerce have been presented in the table 1.

Table 1: Quality attributes in B2C e-commerce

Features of e-commerce website	E-service quality	Reliability
- Website design, aesthetics, functionality and usability - Ease of use- easy and convenient navigation - Information usefulness, adequacy and accessibility	- Help by product choice - Transaction security - Privacy - Personalization possibilities	- Fulfillment of promised delivery time and conditions - Responsiveness and ability to solving problems - Website accessibility and its correct technical functioning

Source: own elaboration.

Thus, though all of the e-commerce satisfaction models provided in literature are different in their determinants of e-commerce satisfaction, but it can be stated that many determinants of customer satisfaction regarding e-commerce identified by different authors could be considered as equivalent.

This paper reviews the most recognized criteria of e-commerce quality assessment in the context of customer online satisfaction and proposes a general comprehensive framework for evaluating the quality of any e-commerce service regarding to website features, e-service quality, and reliability.

Research methodology – Kano's Model of Quality

In this study, an evaluation method has been developed based on Kano model, which is widely used to classify and prioritize customer requirements connected with product or service quality, based on how they affect customer's satisfaction. It illustrates the relationship between customer satisfaction and quality performance. Kano developed the model of customer requirements fulfillment which identified the impact of products or services attributes on customer satisfaction. It classifies customer preferences into five categories, that is, attractive, one-dimensional, must-be, indifferent, and reverse quality (Kano et al., 1984). Attractive quality attributes are not normally expected, provides satisfaction while being achieved fully but does not cause dissatisfaction while are not fulfilled. These attributes, which are classified as one dimensional quality, result in satisfaction while are fulfilled and dissatisfaction while are not fulfilled. The attributes, which are taken for granted while are fulfilled but result in dissatisfaction while are not fulfilled, are categorized as must-be quality. In different quality means that these attributes refer to aspects that are neither good nor bad, and they do not result in either customer satisfaction or customer dissatisfaction. These attributes for reverse quality refer to a high degree of achievement resulting in dissatisfaction for some customer groups. In addition, there is a dimension of questionable quality requirements, that contains attributes that do not influence quality perception (Shahin et al., 2013; Lee et al., 2011).

Zhang and Von Dran (2002) developed a website quality model by applying the Kano model and it was used in an exploratory investigation of customer quality expectations. The study indicated that users of a website distinguish three types of quality factors corresponding to their quality

expectations. The nature of this quality factors may change over time and the same factor may have different quality identifications in different domains.

Customer satisfaction opposed to product quality has mostly been deemed as one-dimensional relationship. But, fulfilling individual customer expectations does not represent a high level of customer satisfaction, because the definitions of two types of customers' expectations, product quality perception and customer satisfaction, are different (Matzler et al., 1996).

The Kano model employs inquiring techniques with pairs of functional and dysfunctional questions about each requirement. The functional situation considers the element sufficient, while the dysfunctional situation supposes the element to be insufficient. In a Kano questionnaire, customer is required to choose one of the following responses to express their feelings: (a) I like it; (b) I expect it; (c) I am neutral; (d) I accept it; and (e) I dislike it (Kano et al., 1984). The classification is then made using an evaluation table in which service quality elements can be classified into one of five dimensions that exhibit different impacts on customer satisfaction depending on whether customer requirements are fulfilled (Table 2).

Table 2: Kano's Model of Quality - evaluation table

Service quality elements		**Dysfunctional**				
Functional		Like	Expect	Neutral	Accept	Dislike
	Like	Q	A	A	A	O
	Expect	R	I	I	I	M
	Neutral	R	I	I	I	M
	Accept	R	I	I	I	M
	Dislike	R	R	R	R	Q
A: attractive; O: one-dimensional; M: must-be; I: indifferent; R: reverse; Q: questionable						

Source: Kano, N., Seraku, N., Takahashi, F. and Tsuji, S. (1984), „Attractive quality and must-be quality", The Journal of Japanese Society for Quality Control, 14(2), 147-156.

From the evaluation table, Kano model classifies service quality elements into categories that exhibit different impacts on customer satisfaction depending on whether customer requirements are fulfilled. Categories are evaluated and interpreted according to the frequency of answers. On basis Kano questionnaire consumer satisfaction and consumer dissatisfaction coefficient are calculated.
Customer satisfaction coefficient indicates whether the customer delight can be improved or not, by achieving the quality requirements. The normal effect on satisfaction or dissatisfaction can be calculated using the following equations (Gupta and Srivastava, 2011):

Extent of satisfaction:

$$SI = (A+O) / (A+O+M+I) , \quad (1)$$

Extent of dissatisfaction:

$$DI = (-1) (O+M) / (A+O+M+I). \quad (2)$$

Where:

SI – satisfaction index,
DI - dissatisfaction index,
A – attractive requirements.,
O - one-dimensional requirements.,
M - must-be requirements.,

I - indifferent requirements.

The minus sign is used in second equation to indicate the nullifying result on customer satisfaction if the expected quality level is not achieved. The positive customer satisfaction coefficient with range starts from 0 until 1. As the value approaches 1, the customer becomes more satisfied. However, when approaching the value of 0, the customer becomes less satisfied with the achieved requirement. If the negative customer satisfaction coefficient (dissatisfaction coefficient) approaches -1, the customer dissatisfaction is strongly affected when the quality requirements are not achieved. Last of all, the 0 value indicates a neutral impact on the customer when the requirement is not achieved (Gupta and Srivastava, 2011).

Results and Discussion

In this study, Kano model was used to find out what are the customer requirements need from their expectation for service quality in B2C e-commerce sites. A questionnaire was developed and distributed to the 80 respondents among students, aged from 19 to 24. The research was conducted in January 2020. For purpose of this study, the following dimensions of e-retailing quality evaluation have been selected: features of e-commerce website (website design, aesthetics, functionality and usability; ease of use- easy and convenient navigation; information usefulness, adequacy and accessibility), e-service quality (help by product choice; transaction security; privacy; personalization possibilities) and reliability (fulfillment of promised delivery time and conditions; responsiveness and ability to solving problems; website accessibility and its correct technical functioning). The result of Kano model questionnaire has been presented in the table 3.

Table 3: Result of Kano model questionnaire

Quality attributes	A	O	M	I	R	Q	Category
Features of e-commerce website							
Website design, aesthetics, functionality and usability	32	13	6	25	3	1	**A**
Ease of use- easy and convenient navigation	11	25	11	28	4	1	**I**
Information usefulness, adequacy and accessibility	21	19	12	26	1	1	**I**
E-service quality							
Help by product choice	18	10	7	42	2	1	**I**
Transaction security	13	23	29	12	2	1	**M**
Privacy	12	22	36	8	1	1	**M**
Personalization possibilities	38	15	6	17	3	1	**A**
Reliability							
Fulfillment of promised delivery time and conditions	15	30	14	19	1	1	**O**
Responsiveness and ability to solving problems	27	25	10	15	2	1	**A**
Website accessibility and its correct technical functioning	19	35	14	9	2	1	**O**

Source: own elaboration.

All features were classified in five categories proposed in Kano model: Must-be (M), Attractive (A), One-dimensional (O), Indifferent (I) and Reverse (R). The result shows that among ten features reflected service quality in B2C e-commerce, three are attractive (A) for surveyed customers (website design, aesthetics, functionality and usability; personalization possibilities; responsiveness and ability to solving problems) and two must-be (M) – transaction security and privacy. Two quality attributes (fulfillment of promised delivery time and conditions; website accessibility and its correct technical functioning) represent category of one-dimensional requirements (0). Help by product choice, information usefulness, adequacy and accessibility, and easy and convenient navigation are quality attributes that have indifferent (I) influence on satisfaction of surveyed customers. This type of categories, similarly as questionable attributes, does not affect any customer satisfaction.

In order to decide which requirements should be satisfied, the consumer satisfaction (SI) and dissatisfaction (DI) coefficients have been calculated. The result has been shown in the table 4.

Table 4: Customer satisfaction and dissatisfaction coefficient.

Quality attributes	**A**	**O**	**M**	**I**	**Category**	**Consumer Satisfaction (SI)**	**Consumer Dissatisfaction (DI)**
Features of e-commerce website							
Website design, aesthetics, functionality and usability	32	13	6	25	**A**	**0,6**	**-0,3**
Ease of use- easy and convenient navigation	11	25	11	28	**I**	**0,5**	**-0,5**
Information usefulness, adequacy and accessibility	21	19	12	26	**I**	**0,5**	**-0,4**
E-service quality							
Help by product choice	18	10	7	42	**I**	**0,4**	**-0,2**
Transaction security	13	23	29	12	**M**	**0,5**	**-0,7**
Privacy	12	22	36	8	**M**	**0,4**	**-0,7**
Personalization possibilities	38	15	6	17	**A**	**0,7**	**-0,3**
Reliability							
Fulfillment of promised delivery time and conditions	15	30	14	19	**O**	**0,6**	**-0,6**
Responsiveness and ability to solving problems	27	25	10	15	**A**	**0,7**	**-0,5**
Website accessibility and correct technical functioning	19	35	14	9	**O**	**0,4**	**-0,6**

Source: own elaboration.

The satisfaction with the positive values included in the scope from 0 to 1. If the value is closer to 1, the impact of customer satisfaction is greater; positive coefficient, which approaches the value 0 indicates that there is very little impact on customer satisfaction. However, it is important to see negative satisfaction values too. If the value is approaching towards -1, customer dissatisfaction is very strong. Size, approximately equal to 0, meaning that a certain property does not feature such a high level of dissatisfaction. In this case, the minus sign is placed in a formula to emphasize its negative impact on customer satisfaction if this quality requirements are not fulfilled.

For surveyed customers, the most attractive quality attributes are: responsiveness and ability to solving problems, and personalization possibilities, because they have the highest satisfaction coefficient (0,7). Less important are: website design, aesthetics, functionality and usability (with satisfaction coefficient 0,6). Fulfillment of attractive elements will lead to greater than proportional satisfaction. However, the absence of these quality attributes does not result in dissatisfaction. These elements are usually not expected and are often currently unaware by customers, but they can provide a competitive advantage.

In contrast, such quality attributes as: easy and convenient navigation and information usefulness, adequacy and accessibility have indifferent influence on customers satisfaction level in online transaction.

These quality attributes as: fulfillment of promised delivery time and conditions, and website accessibility and its correct technical functioning are classified as one dimensional quality requirements. They result in satisfaction while are fulfilled and high dissatisfaction level (-0,6) while are not fulfilled. The higher the level of these expectations fulfillment causes the higher degree of customer satisfaction. Customer expect these elements, and thus view them as essential for their requirements fulfillment.

Insufficiency of a must-be quality attributes results in extreme dissatisfaction, but basic service performance is enough to satisfy customer requirements. Customers take must-be elements for granted when they are fulfilled, but high quality attribute performance does not generate equally high customer satisfaction. The surveyed customers require transaction security and privacy in online transaction. Absence of this elements can cause the extreme level of dissatisfaction, but they have indifferent influence on performance in customers expectation fulfillment.

Conclusions

This study presents the main pilot results of Kano model implementation to better understand customers' requirements in online shopping. The findings of this research have both theoretical and practical implications. It is believed that the findings of this research enable better understanding of the complexity of customer satisfaction and the Kano model itself. Above all, the research of customer satisfaction influences the improvement of quality management and in general the performance of a company.

This research contributes to identification the most important determinants of B2C quality perception and to implementation of the Kano model for assessment of customer expectation fulfillment in e-commerce. The findings of this study indicate which factors are the strongest predictors of customer satisfaction. This study links the Kano model with measuring customer satisfaction and presents a contribution for quality management research theory. Therefore, the results could be used to support optimization of business decision-making, as well as for further scientific research. Among the possible implications and contributions of this research is the differentiation of e-commerce website design features and e-service quality attributes that customers take for granted from those that add value in the consumer satisfaction performance.

Quality management in e-commerce is an interesting area which certainly deserves more systematic attention. From the methodological point of view, limitations in the research can be found in the number of respondents. Having a sample size which is large enough, ensures a representative

distribution of the population and finding significant relationships from the data. This study has also limitations stemming from the general formulation of the questions about factors that influence customer satisfaction in B2C e-commerce. This pilot study did not investigate other important factors affecting customers' satisfaction in online transaction, but they may be interesting for further research initiatives in this area. The direction for future research could be seen in building a new model of customer value in online shopping which requires anticipating what else customers might consider valuable. Future research should enable e-commerce companies to find new combinations of value for better fulfillment of customers' expectations, which are connected with B2C service quality.

Abstract

Enterprise risk management has been in the focus of scientific interest since the beginning of the 21st century, but it gained on relevance in the period following the global financial crisis. One of the main current academic challenges in the field of enterprise risk management research is establishment of a valid measure of enterprise risk management systems maturity that would enable comparison of enterprise risk management systems in different surroundings. Therefore, the first aim of this study is to present a theoretical background for development of enterprise risk management system maturity measure that is based on concurrent academic research. The second aim of this study is presentation of a conceptual model aimed at describing the theoretical foundation for research of interconnection between enterprise risk management system maturity, entrepreneurial orientation and business performance of the company. To our knowledge, up until now there has been no scientific research oriented on exploration of connection between enterprise risk management and entrepreneurial orientation. Having on mind prevailing academic evidence concerning positive effects of entrepreneurial orientation on business performance (Rauch et al, 2009) and based on academic foundation, i.e. available academic research in the fields of enterprise risk management and entrepreneurial orientation, we are building a conceptual model and defining assumptions on path of influence between the researched constructs.

Keywords: Enterprise Risk Management, Entrepreneurial Orientation, Innovation, Proactivity, Risk-Taking, Company Performance

Introduction

Enterprise Risk Management (ERM) is a contemporary strategic approach to risk management aimed at a consistent and an all-encompassing risk management process, established at the level of the entire business entity, incorporating assessment of interconnection between different types of risks a company is exposed to. Its rapid development as a scientific discipline started at the beginning of the 21st century and may be attributed to several researchers who have realized that a new approach to risk management, in which risks are seen holistically and not in silos like in Traditional Risk Management (TRM), is required (Colquitt, Hoyt, Lee, 1999; Kleffner, Lee, McGannon, 2003; Liebenberg and Hoyt, 2003; Lam, 2004; Beasley, Clune, Hermanson, 2005; Beasley et al., 2006; Nocco and Stulz, 2006; Beasley and Frigo, 2007).

A growing body of academic literature and best business practices have focused its attention on emphasizing the importance of ERM for companies. The relevance of ERM has become evident not only in the period of recent global financial crisis that has painfully reflected the consequences of inadequately implemented ERM systems (Miloš Sprčić et al., 2016; Marc, Miloš Sprčić, Mešin Žagar, 2018), but is also reflected in daily opportunities for companies to improve their adequacy of decision making, compliance with strategic goals, improvement of business process quality and increase in company value and corporate sustainability by implementing and constantly improving ERM systems

(Nocco and Stulz, 2006; ISO 31000, 2009; Institute of Actuaries Australia, 2009; Hoyt and Liebenberg, 2011; COSO, 2017).

On the other hand, researchers accentuate that the results of ERM research indicate certain inconsistencies (Miloš Sprčić, Kožul, Pecina, 2017) and attribute it to non-existence of a unique reliable measure of ERM components and its development (Lundqvist, 2014). The first aim of this paper is, therefore, to present a background for necessity to develop an ERM maturity measure that may be used in different research and thus provide comparison between different research. On the other hand, the results of research on the relationship between ERM and company performance are very ambiguous (Pagach and Warr, 2011; Hoyt and Liebenberg, 2011; McShane, Nair and Rustambekov, 2011; Farrell and Gallagher, 2015; Kommunari et al., 2016; Florio, 2017; Miloš Sprčić et al., 2016; Danisman and Demirel, 2018; Callahan and Solileau, 2018; Peljhan, Miloš Sprčić and Marc, 2018), mainly due to the fact that different authors are using different ERM measures, but also different performance measures and perspectives. These results present an incentive for further empirical research that has a strong conceptual background based on existing scientific knowledge. While analyzing the ERM literature, we have also come to the conclusion that ERM is mostly studied isolated, i.e. there is not much research that would research ERM within wider entrepreneurial context and theory. All of the mentioned reasons have been an incentive for us to build a conceptual model that will be oriented on explanation of relationship between ERM, entrepreneurial orientation and company performance.

This paper is organized in manner that following the introductory notes we will present a literature review on ERM and current practices of ERM maturity measurement. Further on we give rationale for connecting the concept of entrepreneurial orientation with ERM and finally we will present the conceptual model of our research and conclusions together with implications for future research.

Literature Review on Concurrent ERM Topics

Historical Development of ERM

Historically seen, risk management as a business function within a company has started to develop in the United States in the insurance sector at mid-1950's (Verbano and Venturini, 2011). At the time the existing scientific theory has not been very benevolent towards risk management. Dominant scientific models in financial theory have been the Capital Asset Pricing Model – CAPM (Sharp, 1964; Lintner, 1965) and the Modigliani-Miller theorem (1958). According to the CAPM the total risk a company is exposed to may be divided in two basic components: the systemic risk component and the specific risk component. The systemic risk component reflects variation in the movement of stock prices due to the market movement, while the specific risk component arises from within the company. Key assumption of the CAPM is that the specific risk component may be eliminated by investment strategy and that, consequentially, movements within the company have no influence on market movement of stock prices. This means that within the CAPM only the systemic risk component is relevant.

According to the Modigliani-Miller theorem (1958) the structure of capital and risk management are irrelevant for companies under the perfect market assumptions, because companies are making values by quality investment that are leading to increase in operational cash flows, while the source of investment is irrelevant for the company. Further on, Modigliani and Miller (1958) also imply that risk management is unnecessary for creating additional value for companies. According to the CAPM and Modigliani-Miller theorem, risk management not only does not generate value for companies, but also has indirect influence on decrease of owner's welfare through the costs associated with risk management. But the examples from the business practice have suggested that risk management makes a lot of sense and is suitable for protection of the company from high external financing costs and costs that may arise in case of financial problems. These practical understandings have led to the need that scientific theory offers an explanation for this and corroborates on the reasoning that risk management has practical relevance for companies. This has led to intensification of scientific research in the domain of risk management. Two approaches that have offered an explanation for risk

management relevance may be pointed out. The first is related to the shareholder value maximization hypothesis (Mayers and Smith, 1982; Myers, 1984; Smith and Stulz, 1985; Shapiro and Titman, 1998, Jensen and Meckling, 1976; Dobson and Soenen, 1993, Smith and Stulz, 1985; Stulz, 1990; Froot, Scharfstein and Stein, 1993), and the other to the managerial utility maximization hypothesis (Smith and Stulz, 1985, DeMarzo and Duffie, 1992; Breeden and Viswanathan, 1996). Both of these approaches share a common characteristic and that is relaxation of the perfect market conditions that have been existent within the CAPM (Sharp, 1964; Lintner, 1965) and the Modigliani-Miller theorem (1958).

Further on, in the time period from 1980's to the end of the 20th century, the dominant approach to risk management has been the Traditional Risk Management approach (TRM), according to which risk management has been regarded as an isolated function within a company, with no clearly defined responsibility for risk management, leading to the so called risk management "in silos", where each risk a company is exposed to is managed separately and without a holistic and strategic approach to all risks. The end of the 20th century has led to the awareness that risk management should be seen from the financially-strategic aspect (Verbano and Venturini, 2011) and both a scientific and a practical move has been made towards what is nowadays called ERM. According to McShane (2018) main point of difference between the TRM and ERM is that the focus within ERM is on holistic approach that implies all risks a company is exposed to are interconnected and their correlations are assessed, while analyzing both internal and external context of risk occurrence. It is important to mention that within the ERM a mental move has been made from managing only or dominantly financial risk to all types of risks a company is exposed to, including also risks such as strategic or operational risk that are difficult to quantify. The risk management function has strategic relevance and top management and the company management board are actively included in the risk management process and are defining a clear statement on risk appetite of the company. Also, decisions on capital allocation are made, aimed at achieving the highest possible risk adjusted rate of return. All responsibilities related to risk management are clearly defined, employees are educated on all types of risks, a positive view on risks is practiced within a company. All of these ERM characteristics defined by McShane (2018) are in accordance with some other authors' findings, such as Miloš Sprčić, Kožul and Pecina (2017) who state that in TRM risks are managed isolated and within one business unit and there is no control or communication on how risks are influencing the business strategy execution, while in ERM interactive effects of different risk events are strategically considered in order to achieve balance between efficient threat from risks and seizing opportunities arising from risks. When reflecting on advantages that ERM has for the company, Cican (2014) has noticed that within the ERM philosophy risk occurrence may be seen and seized as a chance to gain extra profit or non-material advantage for the company. Hoyt and Liebenberg (2011) have noticed that by practicing ERM duplication of risk management costs are avoided and improvements in capital efficiency may be noticed.

Up until now, there has been no single definition of ERM, probably due to the fact that it is a complex process that is incorporated on all levels of a company, but although some standards for ERM implementation exist (COSO 2004; ISO 2009; COSO 2017; ISO 2018), there is no legislation that requires implementation of these standards and the companies that operate in any sector other than the non-financial sector have the freedom to organize and implement ERM as it is most suitable for them. There have been attempts to define ERM (Dickinson, 2001; Meulbroek, 2002; Miloš Sprčić, 2013 and 2014; Lam, 2014 and 2017; Mikes and Kaplan, 2014 and 2015), and the elements that are common to most definitions include: integration (ERM system is present in all business lines), all-encompassing (all types of risks are encompassed) and strategic orientation (risk management is connected with company's business strategy) (Abrams et al., 2007).

When analyzing the available ERM scientific literature, we have noticed that, although ERM is a young scientific discipline, a body of empirical research exists on the topic and it is profiled in four dominant directions: 1) basic components of ERM, 2) measurement of ERM development or maturity, 3) determinants of ERM implementation and 4) influence of ERM on company performance. All of these directions of empirical research have in common the fact that certain inconsistency and ambiguity of results is present. According to Lundqvist (2014) the most probable reason for this lies

in the fact that there is no consensus among ERM researchers which are the basic ERM components and how to measure ERM, thus making comparison of results very difficult. In the continuation of this paper we will focus our attention on giving a short literature overview on measurement of ERM development or maturity and influence of ERM on company performance.

Current practices of ERM maturity measurement and effects of ERM on company performance

The state of development or maturity of ERM systems has been a subject of researchers' interest and in this section we provide a short literature review on these findings. Desender (2007) has been one of the first researchers to measure development of ERM systems. He made a preliminary review of items important for ERM and assesses their relevance for ERM development by building a model around the COSO (2004) standard. The positive side of this model is that it is the first attempt to systematically approach measurement of ERM development and it has provided a platform to connect the practical experience to COSO (2004) framework. On the other hand, since this model has been developed, many new findings have occurred in the ERM research and therefore it cannot be considered up-to date for ERM development measurement.

Gordon, Loeb and Tseng (2009) have approached the question of ERM measurement by constructing an ERM index based on four basic aims of COSO (2004) framework (strategy, operations, reporting, compliance). Main critique of this research lies in the fact that the ERM index developed is a measure of ERM effectiveness and not of its development or maturity. Also, the index is based only on eight items which may be insufficient to encompass the ERM systems complexity. A similar research has been conducted by Callahan and Soileau (2017) who have measured the ERM development by providing a questionnaire on compliance of the company with the aims of COSO (2004) framework (strategy, operation, reporting and compliance). Their results indicate positive impact of ERM development and operational performance of the company.

McShane, Nair and Rustambekov (2011) have used the existing Standard&Poor rating for risk management maturity measurement in order to measure its connection to company performance. The S&P rating is a fully developed rating system that ranks ERM systems within five categories according to their maturity and provides a reasonable platform for ERM maturity measurement, but it must be noted that this rating relates both to TRM and ERM. Also, although McShane, Nair and Rustambekov (2011) argue that there is a positive influence on business results of companies as they advance in TRM development stage, but not when they make a transition to ERM, the authors also pose a question of external rating reliability when measuring ERM maturity and possible conflict of interest of rating agencies when assigning a certain rating to a company. The same measure of ERM maturity has also been employed by Nair et al. (2014) and Bohnert et al. (2018) in their research.

Monda and Giorgino (2013) have identified 22 items relevant for ERM development, classified them into three categories (risk culture, organization and processes) and based on their importance for ERM constructed an ERM index. Positive side of this model is its scientific foundation (scientific methodology), but the number of items identified as relevant for ERM development is rather scarce since the current scientific literature offer evidence of more variables that have proved its relevance for ERM development. Also, the structure of the index that is divided into three categories is rather simplified when having on mind the complexity of ERM systems.

Lundqvist (2014) has researched the level of ERM development in Nordic companies based on the exploratory analysis of 59 different variables that she assumed to be relevant for ERM development. The results of the research have suggested that there are four underlying factors that are relevant for ERM implementation in Nordic companies: general internal surrounding, control activities, risk management activities and attributes of ERM implementation. But the results have also led to the conclusion that only factor called "the attributes of ERM implementation" is relevant for differentiation between companies that have implemented ERM and those that have not. As Lundqvist (2014) concludes, this implies that for "full" ERM implementation a company needs to invest significant effort in some dimensions that are not directly associated to risk management (such as general internal surrounding or general control activities) and she sees this conclusion as a

confirmation that ERM is not an isolated process, but that it requires resources and support on the level of the whole company.

Beasley, Branson and Pagach (2015) have used the self-assessment questionnaire consisting of three questions for measuring ERM maturity. Although each question could have been answered on a scale, leading to a total score of ERM maturity, we believe that only three items do not fully capture the ERM dimensions.

Miloš Sprčić, Kožul and Pecina (2015, 2017) have developed an ERM index based on 14 questions related to different ERM maturity characteristics and based on the answers measured the total ERM score. The results of the research indicate that the developed index is a good measure of ERM development in Croatian large listed companies, but having on mind newer findings in the ERM research area, we believe that index may be further on improved.

Florio and Leoni (2017) have measured ERM sophistication by employing 6 items important for ERM design. Results of their research indicate a positive impact of higher ERM score on company's performance, but main critiques of this ERM measurement include scarcity of variables included in the research and searching information regarding the variables in publicly available reports of companies, since companies are not obliged to report ERM practices in their reports.

Miloš Sprčić (2019) has been rethinking on quality and efficiency of ERM systems in a conceptual paper by connecting a set of characteristics important for ERM to regulatory standard COSO 2004. This standard is based on a process approach to ERM and is made of eight components: internal environment, objective setting, event identification, risk assessment, risk response, control activities, information and communication and monitoring. This paper has been an incentive for our research to broaden and improve the existing conceptual model by revising characteristics that are important for ERM with the newest literature findings and to connect it to the newest regulatory standard COSO 2017 that is somewhat different from the previous version of COSO dating in year 2004. Primary difference between two versions of COSO lies in the fact that COSO 2017 is no more dominantly process-oriented, but it considers ERM as a strategic process that is directly connected to company's strategy and business goals. COSO 2017 also provides greater insight into the value of enterprise risk management when setting and carrying out strategy (COSO 2017).

When regarding ERM in the context of company performance, we would like to accentuate that according to Peljhan, Miloš Sprčić and Marc (2018) prevailing evidence in scientific literature suggest that adequately implemented ERM systems have positive influence on company's performance, but they also draw attention on the non-negligible corpus of scientific literature indicating adverse results. Systematization of existing research conducted by Viscelli, Beasley and Hermanson (2016) indicates a positive impact of ERM on value creation and impels future research in this domain.

When we analyzed the existing research related to ERM and company success (Beasley, Pagach and Warr, 2008; Gordon, Loeb and Tseng, 2009; Pagach and Warr, 2011; Hoyt and Liebenberg, 2011; McShane, Nair and Rustambekov, 2011; Grace et al, 2015; Farrell and Gallagher, 2015; Kommunari et al., 2016; Florio and Leoni, 2017; Miloš Sprčić et al., 2016; Yang, Isthiaq and Anwar, 2018; Danisman and Demirel, 2018; Callahan and Solileau, 2018; Peljhan, Miloš Sprčić, Marc, 2018), we have found that two directions in measuring „company success" have been profiled: first, related to measuring the value of the company, and second related to measuring company's performance. Research oriented on measuring the impact of ERM systems on company value uses Tobin Q as an indicator (Pagach and Warr, 2011; Hoyt and Liebenberg, 2011; McShane, Nair and Rustambekov, 2011; Farrell and Gallagher, 2014; Kommunari et al., 2016; Florio and Leoni, 2017; Miloš Sprčić et al., 2016; Danisman and Demirel, 2018). On the other hand, research oriented on measuring company's performance uses the traditional accounting measures, such as return on assets – ROA (Florio and Leoni, 2017; Kommunari et al., 2016), return on assets – ROA and return on equity – ROE (Callahan and Solileau, 2018), self-assessment of companies related to financial and nonfinancial indicators in period of current and previous two years (Yang, Isthiaq and Anwar, 2018),

self-assessment of companies on financial and non-financial indicators in previous year in comparison to competition (Peljhan, Miloš Sprčić, Marc, 2018).

According to Florio and Leoni (2017) higher level of ERM development has influence on ROA. Kommunari et al. (2016) have not established a relation between ERM and ROA. Callahan and Solileau (2018) found a positive impact of more mature ERM systems on both ROA and ROE. The results of the research conducted by Yang, Isthiaq and Anwar (2018) indicate clear impact of ERM development to financial and non-financial indicators of performance, while Peljhan, Miloš Sprčić and Marc (2018) found a positive impact between ERM development and one non-financial indicator used in research (development of new products), but positive impact has not been reported for other financial and non-financial indicators used in the research (profitability, sales growth rate, market share and client satisfaction). Having on mind all the evidence introduced from the scientific literature, it may be concluded that it is necessary to provide more empirical evidence on the influence of ERM systems on company performance.

In continuation to the literature review we provided in this section, we would like to conclude that although there have been many valuable efforts by researchers to capture the extent of ERM maturity or development, there is no clear consensus on how to achieve this research aim and new methodologies and conceptualizations are required in this field in order to overcome the shortages of available measures.

Entrepreneurial orientation and implications for ERM research

The entrepreneurial orientation researchers suggest that entrepreneurial orientation is a concept that pervades through all organizational levels of the company (Covin, Green and Slevin, 2006; Wiklund and Shepherd, 2005; Wales, Monsen and McKelvie, 2011). Anderson et al. (2015) argue that entrepreneurial orientation is a dominant construct of interest in cases when research is focused on the company's strategy. According to Covin and Lumpkin (2011) and Anderson et al. (2015) the background for the entrepreneurial orientation development concept may be found in the work of Mintzberg (1973) who states that "entrepreneurial strategic behavior is characterized by active pursuit of new opportunities and a dramatic leap towards uncertainty".

Miller (1983) has defined entrepreneurial company as the one that is engaged in innovation of market products, taking risky ventures and being a leader in proactive innovation, altogether leading to outperforming the competition. In continuation, Miller (1983) has defined three dimensions of the concept of entrepreneurial orientation: innovativeness, proactivity and risk-taking. According to Anderson et al. (2015) innovativeness is defined as "conceptualization of new products, processes or business models on the level of the company", proactivity as "tendency to commercialization of these innovation on new products or markets" and risk-taking as "inherent managerial propensity present at the highest management level, aimed at development and implementation of the company's performance, favourising strategic actions with uncertain outcome".

Covin and Lumpkin (2011) state that there is present ever growing interest in both research of the concept of entrepreneurial orientation, but also in its practical implications for companies. Covin and Lumpkin (2011) also argue that it is characteristic for entrepreneurial orientation dimensions to be stable in time and that its key dimensions are risen up on the level of a company and are not only a matter of an individual or a specific department of a company. According to Wales, Monsen and McKelvie (2011) entrepreneurial orientation is manifested horizontally throughout the organization and they state that top management has a key role in pervasiveness of entrepreneurial orientation in the company by defining business philosophy and defining strategic orientation of the company.

As to the authors' knowledge up until now the relationship between ERM maturity and entrepreneurial orientation has not been a subject of scientific research. There are several scientific findings that have led to the idea of creating a conceptual model oriented on research of interconnection between ERM maturity, entrepreneurial orientation and performance of the company. Firstly, Brustbauer (2016), who has conducted a research on risk management and strategic

orientation of the company, has concluded his research findings by giving a recommendation for future research that "addressing the concept of entrepreneurial orientation would be a fruitful addition to the existing model" in the context of risk management (Brustbauer, 2016, p. 82). Secondly, research conducted by Obuljen (2017, p.213) indicates a statistically relevant mild positive relationship between risk management (as a part of the corporate governance mechanism) and entrepreneurial orientation construct. Thirdly, Farrell and Gallagher (2019) include innovation orientation of the company as a variable while researching the effects of ERM maturation on company's performance. It must be emphasized that the degree of innovation is measured by research and development intensity as s proxy, which is not consistent with the entrepreneurial orientation concept, but it does suggest the growing relevance of the innovation dimension in ERM research. Fourthly, Peljhan, Miloš Sprčić and Marc (2018) have been the first to our knowledge to analyze ERM in the context of being a mediator between company strategy and performance and this paper has been a methodological incentive for us to start thinking about ERM in a wider context of entrepreneurial theory.

In previous section, a rationale for suggesting the ERM and performance relation research has been given. At this point we give a short overview of research related to measuring the effects of entrepreneurial orientation and company's performance. Rauch et al (2009) argue that conceptual arguments suggest that entrepreneurial orientation leads to improved company's performance, but the intensity of this relation varies across scientific research.

Covin and Slevin (1986), Hult, Snow and Kandemir (2003) and Wiklund and Shepherd (2005) have found a significant and strong relationship between entrepreneurial orientation and company's performance. Lumpkin and Dess (2001) have come to the conclusion that there is a positive, but weak relation between entrepreneurial orientation and performance, while George, Wood and Khan (2001) have not confirmed the hypothesized relation. According to Rauch et al (2009) the effects of entrepreneurial orientation on the performance may be characterized as moderately high with the tendency of positive relation, also indicating the robustness of research on different performance measures, i.e. both financial and non-financial indicators of performance indicate the same results.

It is important to mention that in the entrepreneurial orientation literature there have been attempts to widen the scope of the term and concept entrepreneurial orientation. Lumpkin and Dess (1996) have defined entrepreneurial orientation by five dimensions: proactivity, innovativeness, risk taking, autonomy and competitive aggressiveness. We find all of these dimensions important in order to fully capture the term entrepreneurial orientation, but we also have on mind the fact that the data on entrepreneurial orientation may be received only by survey completion from the respondents. Since practical validation of our model will require an extensive questionnaire to gather the data that we need in order to test the conceptual model, and researching additional two dimensions of entrepreneurial orientation requires additional time from respondents, we have decided to focus our attention on three basic dimensions of entrepreneurial orientation.

Conceptual Model of the Research

In previous sections of the paper we have provided a short literature overview regarding concurrent topics of interest in the field of ERM maturity research and its interconnection to the business results of the company and also of entrepreneurial orientation and company performance. We have also tried to establish a scientific literature foundation for research of ERM and entrepreneurial orientation. In this section we will present a conceptual model of our future research that is aimed at setting hypothesis related to ERM, entrepreneurial orientation and company performance. The conceptual model of research is presented by the following Figure.

Figure 1: Conceptual research model

Source: Authors

The model is based on the following premises:

(1) Entrepreneurial orientation has a positive effect on company's performance,

(2) ERM has a positive effect on company's performance,

(3) Entrepreneurial orientation has a positive effect on ERM and thus ERM acts as a mediator variable between entrepreneurial orientation and performance.

The premises (1) and (2) are grounded in evidence from the literature review provided in previous and in this section. Premise (3) is based according to following line of reasoning:

a) According to the ERM Initiative Faculty (2014) innovation is related to wide spectrum of risks and it is therefore necessary for companies to develop and continuously improve its own decision-making model related to innovation in order to manage innovation risk more successfully;

b) Silva Etges, de Souza and Neto (2017) state that adequate risk management is a prerequisite for successful innovation introduction. Having on mind that it is in the interest of companies that the process of innovation introduction is adequately managed, primarily due to innovation-related risks, the assumption of this conceptual model is that the companies that are more prone to innovation have developed more advanced mechanisms for innovation risk protection and it is hypothesized that higher level of innovation dimension in the company has positive impact on the level of ERM maturity.

c) Proactivity may be perceived as the characteristic of the company related to seeking new market opportunities, consequentially leading to higher risk exposure, therefore we hypothesize that higher level of proactivity has positive impact on the level of ERM maturity. In an analogous manner, it should be logical for companies more prone to taking risks to seek mechanisms leading to risk mitigation and adequate risk management, therefore we hypothesize that higher level of risk-taking in company has positive impact on the level of ERM maturity.

After having defined the elements of the model, the question has arisen what the model consists of concretely, i.e. how to measure certain elements. We have therefore had to decide how to measure

ERM, entrepreneurial orientation and performance of the company. The easiest part of this design has been related to entrepreneurial orientation. Since many authors are using the standard and validated entrepreneurial orientation scale (Miller, 1983; Covin and Slevin, 1986) we have decided to use this scale in our research. The scale consists of nine items, three per each dimension of entrepreneurial orientation (proactiveness, innovation, risk-taking). These items will be estimated by respondents on Likert scale.

When reflecting on how to measure the company performance, we have decided to include both the financial and non-financial perspective, since there has been evidence that ERM might have influence on non-financial indicators (Peljhan, Miloš Sprčić, Marc, 2018). We have selected three financial and three non-financial indicators, namely: profitability, sales growth rate, market share, development of new products or services, quality of products or services and customer satisfaction. The next step has been to decide how to measure these variables. Since target respondents on the survey in companies are managers who have limited time available for participation in the research and revelation of concrete amounts of financial indicators might discourage the respondents from taking the survey, we have decided to use the approach as Peljhan, Miloš Sprčić and Marc (2018) and Kantur (2016) and the respondents will be asked to estimate the financial and non-financial indicators more generally, namely the trend of a certain indicator for the company in the previous year as compared to the competition on the scale from 1 to 5. We believe that this approach, other than being very appropriate for estimating non-financial indicators, has the advantage of possibly resulting in higher response rate on the survey.

The measurement of ERM represents a novel approach. Based on the literature analysis, we have extracted 29 characteristics of developed and mature ERM systems and the respondents of the survey will estimate each characteristic on the Likert scale from 1 to 5. We believe that, by employing exploratory factor analysis, it will be possible to extract a lesser number of factors that are representative for mature ERM systems and the calculated factor scores will be our basis for further analysis.

We plan for practical validation of our model on the sample of Croatian companies. When defining the population of the research, we took regard of the facts that the implementation of ERM requires significant material and human resources (Carroll, 2012; Lundqvist, 2014), the research that has been conducted on the sample of Croatian listed companies has indicated rather low level of implementation of ERM (Miloš Sprčić, Kožul, Pecina, 2015; Miloš Sprčić, Pecina, Orsag, 2017), the companies operating in financial sector have a strong regulatory incentive for implementing ERM (Miloš Sprčić, Kožul, Pecina, 2017) and up until now the research of ERM in Croatia has been conducted only on large listed companies. Based on these criteria we have defined the population of our research as the most profitable large and medium sized companies that operate in sectors other than the financial sector and that may or may not be listed on Zagreb Stock Exchange. The sample of the research will include two stratums: the stratum of listed companies and the stratum of other large and medium sized companies.

The methodology we plan to use in order to test our hypothesis largely depends on the survey response rate. In case we receive adequate number of responses, it would be practical to use structural equation modelling to test our model. Since structural equation modelling is a large sample technique, in case we achieve a lower number of responses, we will use classical multiple linear regression, by employing the Barron and Kenny (1986) approach to testing the mediation effect.

Conclusion

Main reflections of this paper are directed towards accentuating the importance of ERM systems and its maturity level on the performance of the company on one hand and on the other giving a rationale for determining a research model related to ERM, entrepreneurial orientation and company performance.

While analyzing the scientific literature in the field, we have come to the conclusion that researchers are "tapping in the dark" when trying to measure the maturity of ERM systems in their research. Although there have been valuable efforts related to defining a valid ERM maturity measure, there are still many open questions, possible biasness and practical research problems. Thus, we accentuate the need to develop a valid measurement instrument of ERM maturity.

We have also provided a literature foundation and premises to building a research model oriented towards explanation of relationship between ERM, entrepreneurial orientation and company performance.

Although we carefully methodologically defined our model, we must mention its possible limitations. Firstly, as we already mentioned, the questionnaire we plan to use is rather detailed and lengthy. Having on mind that the target respondents are managers with limited time available for participation in the questionnaire on one hand and that there may be certain resistance to disclosure of exact financial data of the company on other hand, we refer to approach used by Kantur (2016) and propose to gather the information regarding financial and non-financial indicators by asking the respondents to estimate these indicators for their company in last year compared to competition. Although this approach has its advantages, such as the fact that it may encourage higher survey response rate and that it is appropriate for non-financial indicators, we must remark that for financial indicators the usage of concrete financial amounts might be more precise. Also, in our conceptual model we proposed to analyze entrepreneurial orientation based on its three basic dimensions: proactivity, innovativeness and risk-taking. Since some authors also mention additional dimensions of entrepreneurial orientation, such as autonomy and competitive aggressiveness, we propose that the future research includes also these additional dimensions that might contribute to the literature and empirical findings.

In our future research we plan to provide empirical evidence based on the survey from the Croatian market. We hope to make a scientific contribution in terms of developing an appropriate ERM development measure, but also to gain new scientific insights on how ERM works and how it is connected to entrepreneurial orientation. We hope that our research will also result in practical guidelines and useful knowledge that companies may incorporate in their business activities.

Abstract

The urgency of the research is determined by current processes. They are the rapid development of all means of information technology and the necessity of their use for the efficiency of student future career; a changing variety of occupations. In this regard, this paper is devoted to the review of vocational becoming of students within the context of the information society development as a dynamic, focused process of progressive personality change influenced by the information environment development, aimed at vocational competency development, including IT competence. The authors examine requirements to prepare new methodological training systems which are able to promote learners' skills to keep IT practice for the development of qualities required for future career. When doing the research, the authors applied the following methods of philosophical, psychological and educational literature review; projection and modeling. According to the study, the authors note the special logic of accomplishing the identified requirements for the development of modern methodological training systems, focused on developing a learner's skills to perform information practice and educational information interaction independently to develop the abilities necessary for future career. The content of the paper has a practical interest for undergraduates, graduate students, university professors and teachers of other educational institutions who carry out research in this field, and those who are intent to make up projection models of student personal and vocational becoming.

Keywords: Student Vocational Becoming, Student IT Competency, Technological Approaches.

Introduction

The experience of the present-day society development is materially affected by information technology observed not only in engineering systems but also in higher education. These processes develop according to the requirements for career development.

Accordingly, at a targeted level in terms of a developing information-oriented society, it is focused on training highly educated and skilled professionals able to act independently and intensively, take effective solutions and adapt flexibly to constant changes in living conditions. Drawing from the special traits of this society in the competence of professionals, the basis of the information technology should definitely be distinguished both in the activity of inclusion in further human life, and the ability to solve emerging living and vocational problems in practice.

This study examines the opinion of defining the concepts of *student personal and vocational development*, *student information competence* and their key factors, as well as the one of describing

the technological and methodological approach to arranging the vocational training based on the current need to identify effective and efficient personal and vocational becoming and information competence of trainees.

Literature Review

The nature of student personal and vocational development observed in the research is revealed through various approaches. The authors single out the approach (Polichka, 2017) of interpreting vocational and personal-vocational development of a student who studies in the institution of higher education as a dynamic process aimed at the progressive change of student personality, in circumstances of meeting the requirements for professional qualifications; taking into account the external conditions arranged by a lecturer; one's own ambition in mastering all the elements necessary for learning of trade aimed at the development and self-development of an individual, developing professional competence and a willingness for continuous career advancement. In this consideration of personal and professional development of students, the directions of development are emphasized: career competencies dedicated to preparing for work according to the invariable part of the requirements of the education system; competencies defined by the variable part of the main curriculum in the institution of higher education. In this study, the authors correlate these fields of vocational training with the phenomenon of *student information competency*.

The development of essential modern methodological training systems is considered to be a technological basis for it. They are focused on mastering skills to perform information activities and educational communication for the development of qualities required for future career.

A number of studies are devoted to examining the particularities of student personal and professional development in various types of activities (Adolf and Stepanova, 2017). The research of different aspects of personal and professional development of students is carried out in (Kabanova, 2014; Plotkina, 2010) and others. According to their studies, personal and professional development of students is a complex and many-sided structure, which is influenced by various conditions.

Current studies of the phenomenon *personal-professional becoming* are conducted mainly in the following fields of acmeological approach (Bozhovich, 1997), psychology of professional engagement (Zeer and Symanyuk, 2017), becoming of a person as an active subject transforming the world and a person himself (Slobodchikov, 2005), personal growth pedagogy (Vorovshchikov, 2006), etc.

Several distinctions are distinguished when revealing the subject-matter of human information competence: understanding the phenomenon of *human information competence*, the development of human information competence and its features, self-development of the level of human information competence in a personality structure.

Many scientists reveal the distinctions by different approaches to this issue: anthropological; phenomenological (Tabachuk, 2019); pragmatic (Kosorukova, 2014); system-related; competence-based (Vorovshchikov, 2006; Tabachuk et al., 2018) and others.

Personal and vocational development of a student based on the development of information competence with identifying a personal component as a concept of *personal information competence* and viewing it as a key metadisciplinary competence was not regarded pointedly.

It involves the necessity to do research on reasoning and characterizing mastering relevant information competencies by a learner; the influence of a personal attitude both to these competencies and such an object of activity as information processing; treating information competencies as independent and intended social standards and requirements applicable to student training outcome.

Research Methods

The subject of the study is technological approaches of student personal and professional becoming based on the development of information competence.

According to the subject and purpose, the modern requirements imposed on the development of student information competence affecting their professional development are examined. The authors detail dialectic of the development of technological predictions for actualizing relations in professional becoming and information competence of students.

A variety of mutually complementary research methods was used to take on such a role: analysis of philosophical, psychological and educational literature, projection and modeling (Novikov and Novikov, 2010). The methods used were appropriate to the tasks to be solved. So the authors could record the outcomes in the measurement of the subject of study.

Results and Discussion

The meaning and peculiarities of professional becoming of students with the development of information society: competency-based approach

Contemporary science regards that there is an entire classification of theoretical methods to define the meaning of the phenomenon of *professional development of students* (Bozhovich, 1997; Tabachuk, 2019). Thus to sum up (Zeer and Symanyuk, 2017), in particular, the training that provides professional development should be based on a pragmatic approach. The review of the approaches observed makes the professional development of students clear due to their efforts. The issues of professional development in the research lead to the concepts and components of a competency-based approach. So, in (Boyatzis, 2008; White, 1959), the development of professionally essential skills and individual types of professional behavior called *major skills* was explored. Developing this approach in (Boyatzis and Sala, 2004), five groups of major skills are distinguished. In particular, personal or individual abilities, social abilities in (Schelten, 2004) are called major skills or basic skills. In particular, operating skills are distinguished. Since in contemporary science the phenomenon of *professional competence* and its structure has been interpreted according to the research background (Adolf and Stepanova, 2017), the authors include informational competence combined with professional know-how and ways of performing work.

Along with the studies conducted in (Polichka, 2017) on the interaction of concepts *personality* and *professional development* in this research, the authors report on the professional development of a student as a dynamic, focused process of progressive personality change influenced by the development of information-driven society focused on the development of professional competence, including informational competence.

Current requirements for the development of student informational competence to ensure the influence on their professional development

According to the specific and particular demand of contemporary society for skilled professionals, the information basis of including occurring daily life and professional challenges in further activities of daily living and their practical solutions should definitely stand out. According to the studies (Platonova et al, 2016; Tabachuk, 2019), the authors insist on the necessity to observe the informational competence of an individual as a subject of activity and its impact on the personal and professional development of students.

In the studies (McClelland, 1973; Mutavchi, 2018; Zimnyaya, 2004), there are several parts of competence differentiated in professional and general competence of an employee. They are informational (Lapchik, 2017, Robert, 2017); social and ethical ones (Pechenyuk, 2008). The contemporary requirements for the development of student information competence affecting their

personal and professional development, will be revealed through current fields of active research on the interconnection and relationship of academic subjects in the curricula as the main means of education, and competencies to be trained. In particular, a number of interpretations of the meaning *competence* are connected to a dynamic, focused process of progressive personality change influenced by the development of information-driven society related to the professional qualification of a student. In this research a dynamically focused process of progressive personality change influenced by the development of information-driven society related to the professional qualifications of students will correlate with *information competence*. According to the studies (Gerova, 2014; Khutorskoy, 2017), information competence will be regarded as a component of professional competence when interpreted as an integral personality feature. Then, the concept of student information competence has such a meaning of its investigation as a learner's knowing and mastering proper information competencies required for the efficient future career that based on information technology and their means. Creative informational competence is also interpreted (Luchaninov et al., 2017) as the experience of creativeness. Creativity is conscious and depends on an individual activity. It is dedicated to the satisfaction of personal cognitive, intellectual wants to search information independently and process it in order to perform work properly.

The studies (Boyatzis and Sala, 2004; Khutorskoy, 2017) pay particular attention to the necessity of involving approaches describing student vocational training and relations of the notions *competence, competency, informational competence of students, informational competencies, informational competence of a person, student information competence, pedagogical side of information competence* in the current education reform based on the competency-based approach. When defining the concepts of *informational competence of a person* and *informational competence of a student*, it can mean as one of the constituent elements of informational competence characterized by a combination containing knowledge; skills; experience in the subject field of computer science when actualizing Information and Communication Technologies (ICT) opportunities in such activities as future professional; educational in the context of information interaction; informational one between the subjects of education considered as a key meta-subject competence consisting of cognitive, motivational and pragmatic components. The content of them is given substance to with reasoning, interpretation of one's own meanings, and practical learning of individual subjective experience.

Technological foundations of actualizing relations between professional becoming and student information competence

The technological basis of activity, as a specific type of human activity, consists of a combination of such components as a set of methods, approaches and techniques of the required activity; a set of special means necessary for performing this activity; available skilled personnel specially trained to do this work. These components are based both on the subject of activity and on its means including their content.

The authors are going to base the dialectic of the development and technological foundations of functioning relations of personal-vocational development and informational competence of students on the relations between these models of educational issues and potential IT opportunities.

Particularly, as the research review, regulatory requirements and experience of higher education show, an important tool in arranging curricula has been a set of training academic courses, subject fields and special training (Polichka, 2017).

According to the theoretical study (Polichka, 2017), the authors succeeded in interpreting the concept of pedagogical support to ensure the influence of mastering informational competencies by a student on his professional development. It consists of management and development relations of the system of special groups of units, *Setting the didactic task* (goal- setting, determining the content, determining ways of performance)*; Condition arrangement optimizing the sociality development as an integrative quality of a person during education that uses units* (determining the effectiveness of conventional and innovative forms of arrangement, educational means, training methods, mutual actualization of available resources).

In this study, the actualizing influence of mastering information competencies by a student on his professional development is based on the arrangement of a teacher's work. It is meant as a process of selecting and performing purposeful activity on coordinating integration activities and the conditions of a teacher's activities in the curriculum; achieving mutual balance of functioning the components of a teacher's work in the curriculum (functions, goals, types, forms of performance); projecting the content of a teacher's activities in the curriculum in the context of actualizing a specific training field.

The experience of carrying out such an approach to fulfill relations of professional development and information competence of students allows the authors to identify the following principles of integration types of learning activities and the conditions of a teacher's activity: noting a content-related pattern in student classroom activities which is aimed at determining and performing the style of their work using ICT tools; the appropriate use of blended learning in teaching subjects using distance learning technologies; the application of innovation common factors in student and teacher's activities; the use of information in the information and communication object environment for future career with an interactive information interaction of a student and objects of the environment that reflect the patterns and special features of this subject field.

The following methods have been identified from the experience of completing relationships of professional development and information competence of students to achieve mutual matching: matching the components of a teacher's activities based on identifying the relations between components of competency and modular approaches; actualizing the information-activity learning model while determining the research subject by a student in a chosen field of occupation; separating the information component in all types of student activities.

When projecting the content of a teacher's work, such projecting approaches are denoted: emphasizing the relationship between the information and communication object environment and a chosen career based on the original style of occupation; noting the appropriate relationship between the potential of information system development and the skills to develop technologies for their use in education; step-by-step activities (development of a sufficient set of options for obtaining outcomes; substantiated effective necessary one for completing it); using navigation features in the information and communication object environment.

Conclusion

In conclusion, the authors would like to emphasize a consistency of performing the requirements for developing new methodological training systems focused on mastering a skill for doing independent information work and educational information interaction to develop necessary qualities required for future career.

Abstract

The article presents the results of testing the author's methodological approach to assessing the gerontoorientation of the consumer market. The market of leisure services was chosen as the testing area in view of its key role in the implementation of the strategy of active longevity. The study presents the demographic characteristics of the studied region of Russia and conducted a marketing study that allowed us to assess the level of gerontoorientation of each of the market participants. According to the results of the study, a conclusion is drawn about the low level of gerontoorientation of the Chelyabinsk leisure market and further areas of research are indicated. The results of the study can be used as a methodological basis for assessing the gerontoorientation of other consumer markets.

Keywords: Market Gerontoorientation, Marketing Research, Gerontomarketing, Consumer Market.

Introduction

In the context of the “silver economy” which was formed in response to global trends of the population aging, the formation and development of markets for goods and services aimed at older consumers is of particular importance. The study of consumer markets development issues in the context of aging population is one of the key tasks of gerontomarketing.

Elderly consumers are becoming a significant market segment, effective interaction with which provides companies with a stable market position and tangible competitive advantages. Nevertheless, studies show that various sectors of the Russian consumer market demonstrate an unequal desire to work with consumers of the older age group.

The article presents the results of testing the author’s methodology for marketing assessment of the gerontoorientation of consumer markets using the regional leisure services market as an example.

Methods and the Study organization

The methodological basis of the study was the classic and modern works on the theory of marketing and marketing analysis of the market, as well as research in the field of social sciences and humanities, considering various aspects of the population aging. In general, it can be stated that population aging is currently a global problem with long-term consequences and relevance for the next century.

Despite the growing influence of the effects of aging on the development of consumer markets, relevant research is currently fragmented, developing only within particular scientific schools. The earliest works on the economic and market aspects of the aging problem belong to a German scientific school (Hilbert, 2000; Pott, 2004; Kaib,2008; Nufer, 2010), the studies of which substantiate the relevance of research on the effects of aging on the economy and markets, present successful experience of practical gerontomarketing in German consumer markets. In Russia, key research in the field of gerontomarketing was developed in the works of the St. Petersburg Scientific School of Marketing (Bagiev, 2012). A feature of Russian research is that much attention is paid to the practical aspects of gerontomarketing in various market areas (Boyko, 2011; Larkina, 2014; Solovieva 2013; Khobotova, 2014). The indicated trends in research, in our opinion, are due to a significant lag in Russian consumer markets in the practical use of the gerontomarketing concept. Companies do not seek to expand the upper limit of their target audiences, which may be due to the widespread adoption of ageism. Older people, despite their numbers, continue to be perceived by businesses as an unattractive consumer segment.

In order to study the trends of increasing interest in elderly consumers in the market, in this study, we tested a methodological approach to assessing the gerontoorientation of the consumer market using the example of the leisure market in Chelyabinsk.

Gerontoorientation of the market is considered as the level of business orientation to consumers of the older age group (Astashova, 2019). According to the author's approach, the assessment of the level of gerontoorientation is carried out according to the following criteria:

- characteristics of the target audience;
- taking into account the specific requirements of older consumers in goods and services or other elements of the marketing mix;
- development and implementation of a gerontomarketing strategy.

Based on the proposed criteria, we propose the allocation of four levels of gerontoorientation, as shown in Table 1.

Table 1: methodological approach to the gerontoorientation assessment

Company gerontoorientation level	Gerontomarketing strategy	Target audience	Specific requirements
Level 0 (ignoring)	fixed bayer-ageism	Ignoring 50+ segment	no
Level 1 (neutral)	no	Upper bound not marked	no
Level 2 (intuitive)	no	Upper bound not marked	Partially implemented
Level 3 (deliberate)	yes	Older consumers are target or one of the target segments	yes

(Source: compiled by the authors)

The study is based on the analysis of secondary information: analysis of statistical data, databases, information on official websites of the companies. Also during the study, interviews were conducted

with business owners, which allowed us to draw conclusions about the elements of the company's strategy for interacting with consumers of the older age group. The research applied the methods of statistical data analysis, and the non-formalized desk methods of marketing research.

Results and Discussion

Chelyabinsk is an industrial city of Russia with a population of more than 1.2 million people. Chelyabinsk is a regional centre. The population in the Chelyabinsk region according to 2019 is 3 million 475 thousand people. The characteristics of the Chelyabinsk region population by major age groups are presented in Table 2.

Table 2: characteristics of the population of the Chelyabinsk region by major age groups, January 1, 2019

	All population, thousand people	including age:			The proportion of age groups in the total population, in percentage		
		younger than employable	employable	older than employable	younger than employable	employable	older than employable
Russian Federation	146 780.7	27 430.0	81 361.7	37 989.0	18.7	55.4	25.9
Chelyabinsk region	3 475.7	678.2	1 888.1	909.4	19.5	54.3	26.2

(Source: compiled by the authors according to the Federal State Statistics Service of the Russian Federation)

As shown in the Table 2 demographic aging in the Chelyabinsk region as a whole corresponds to the average indicators of the Russian Federation.

The organization of leisure for senior citizens is one of the most important areas for improving the quality of life in the context of active longevity. Elderly people, stopping the career, are faced with the destruction of habitual social ties, the narrowing of their circle of contacts, and often with loneliness. At the same time, the availability of free time creates opportunities for creativity, self-expression and the realization of opportunities that previously did not have enough time. Hobbies also facilitate contacts and formation of a new circle of contacts, and as a result, the extension of the social activity of senior citizens. In this regard, in each of the 7 districts of the city, social welfare agencies organized day care units that provide senior citizens with services in catering, life and leisure. The work is organized in the form of 14 shifts per year, services are provided free of charge or for a partial payment. The structure of the recreation, health and leisure program includes needlework; singing; dancing; wellness activities; Nordic walking; classes with a psychologist; legal consulting; computer literacy training; two balanced meals a day.

Nevertheless, the commercial sector of the market is not yet sufficiently focused on working with consumers of the older age group. Of the 263 organizations providing leisure services, only 23 are oriented toward working with adults. The characteristics of clubs by the type of services provided to adult consumers are presented in Fig. 1.

Fig. 1: Activities of organizations providing recreational services to adult consumers in the Chelyabinsk market

(Source: compiled by the authors)

The results of assessing the level of gerontoorientation of the studied organizations are presented in Figs. 2 and 3.

Fig. 2: Levels of gerontoorientation of leisure organizations working with adult consumers in the Chelyabinsk market

(Source: compiled by the authors)

Fig. 3: Levels of gerontoorientation of all leisure organizations in the Chelyabinsk market
(Source: compiled by the authors)

As shown in figs. 2 and 3, more than 90% of organizations initially focused only on working with children and only about 2% purposefully work with older consumers, offering those specialized products and services and building targeted communications with them. This indicates an underestimation of the potential of elderly consumers' segment, the interaction with which in the conditions of demographic population aging provides companies with competitive advantages and new development prospects.

Conclusion

Thus, the results of the study confirm the low level of gerontoorientation of the Chelyabinsk leisure services market, since there are practically no offers on the market aimed at older consumers. In the context of demographic aging of the population, it is advisable to regularly conduct similar market research, which will allow us to assess trends in the development of gerontorientation.

Abstract

Proecological strategies are resulting in both corporate social responsibility and environmental protection, especially when the company's competitive position relay on natural resources. Usually, companies announce-only positive effects of introduced green strategies, however sometimes disasters destroy the efforts of both companies and local communities. There are problems in the balance of relations between human activities and the natural environment that are particularly evident in the mining industry. In this sector, it is possible to identify some failures in pro-ecological strategies and this article presents a case study based on such accidents. The study has also the character of theoretical assumptions and operationalization of concepts for further empirical research, which going to be a continuation of the ongoing project of analysing strategies in a selected sector.

Keywords: Green Strategies, Mining Companies, Waste Management

Introduction

The mining industry is associated usually with a high negative impact on the natural environment and the loss of jobs in this sector during the economic and ecological crises. On the other hand, the rapid negative changes in the mining industry are the reason for many social protests documented also in modern history. Therefore, the mining industry is often classified as an element of the so-called brown economy, which stands in opposition to the pro-environmental, ecological, green economy (Bogusz and Sulich, 2019).

In the last decades, the investments in environmentally friendly businesses were growing at a high pace in almost all economic sectors, also in the mining industry (Bogusz and Ziemkiewicz, 2018). Today ecology became one of the main trends of modern business and changed environment perception among almost all members of the business environment (Kulhánek and Sulich, 2018; Sulich and Zema, 2017). Over the years the perception of the natural environment has changed. First, the natural environment was simply the source of raw materials for production and the waste collector, receiving all that was eliminated or discarded as no longer useful or required after the completion of a production process or consumption (Bogusz and Sulich, 2019). Then natural environment protection laws became an obstacle for the entities' development and example some mining industry companies, which avoided responsibility for environmental protection or just were never expected, neither asked to solve problems with pollution. Fortunately, this also begun to change and nowadays question is whether mining (especially branches which are not related to fossil fuels) can introduce successful pro-ecological strategies. There is a large group of modern business in the mining industry which present proactivity to reduce environmental scarcities and risk (Rothe et al., 2018). It is not clear whether business entities understand the difference between sustainable development (SD) and corporate social responsibility (CSR), and what kind of mechanisms stands as the background of their strategies (Demków and Sulich, 2018; Niemczyk and Stańczyk-Hugiet, 2014; Stańczyk, 2018). The distinction between these two ideas is not clear and there is no identified strategy type for this economy sector (Jonek-Kowalska, 2016; Niemczyk and Stańczyk-Hugiet, 2014; Sulich and Grudziński, 2019). Companies need to create

business strategies based on an understanding that the rapidly-shifting external context, disruptive technologies dislocation, and natural resource scarcity are not for sustainability, but are issues of business strategy (Bogusz and Ziemkiewicz, 2018; Khall Khalid, 2019). Sustainable strategy refers to an integration of business activities with environmental and social management to create economic value, healthy ecosystems, and strong communications if successfully implemented (Bogusz and Sulich, 2019; Grudziński and Sulich, 2019; Zema and Sulich, 2019). Therefore, it is often said that SD and CSR are connected or intertwined because of their aims, and there are some examples of companies' activities that can transform their perception in terms of green economy definition (Kryk and Skubiak, 2015; Sulich and Rutkowska, 2020).

This paper aims to investigate the impact of the activities performed in chosen companies which have led them to the failure in their pro-ecological strategies. Although these companies dedicated a lot of effort to be more sustainable, the natural forces were stronger and unpredictable. The adopted method was the case study of the mining industry company operating in the Americas. Based on this case study, in the future, there is a possibility to describe a model of sustainable development actions in the mining industry, which will be the next step of the research.

Introduction to the Case Study Company: Vale

Vale is a mining company operating worldwide, with a history of nearly 80 years. It is the largest mining company in the Americas and one of the largest in the world. This Brazilian corporation operates in approximately 30 countries around the world, directly and indirectly employing about 125 000 people. The core business of the company consists of the extraction of iron and nickel ore of which it has been the global leader for many years. The company produces also, among others, manganese, copper, bauxite, potassium, and cobalt. Furthermore, it is one of the largest logistics operators in Brazil. Figure 1 shows the Company's operations in terms of geographic presence (Vale, 2018a).

Fig. 1: Geographic coverage Vale operations
Source: Sustainability Report Vale 2018 (Vale, 2018b)

Strategy and Values of Vale

In line with the global megatrends that have been observed in the mining industry for several years, the business strategy of Vale clearly emphasizes its focus on environmental protection and sustainability. Both the mission: "To transform natural resources into prosperity and sustainable development" and the vision: "To be the number one global natural resources company in creating long term value, through excellence and passion for people and the planet" relates to the respect for our planet and nature. The company goes one step further in its statements and identifies the following guiding values (Vale, 2020a):

a) Life matters most;
b) Value our people;
c) Prize our planet;
d) Do what is right;
e) Improve together;
f) Make it happen.

The Vale 2019 strategy, published by the end of 2018, establishes five strategic pillars, including "sustainability". The main goal in this area to be achieved by 2030 is to recover 100,000 hectares of degraded land, to reduce greenhouse gas emissions by 16% and to reduce water consumption by 10% (Vale, 2018b). In its reports, Vale presents some activities and investments aimed at environmental protection and pro-social activities. Moreover, when listing its key commitments to the stakeholders, the company underlines “the aspiration to become one of the safest and most reliable mining companies in the world, always acting with due respect for its fundamental principle: life matters most” (Vale, 2020b).

An analysis of both, documentation and strategy show that Vale perfectly combines the mining business with responsibility towards the environment. And yet, an environment-oriented attitude is not always possible to maintain and some situations can suddenly destroy the image that has been fostered for years. Vale is the best example of such a sorrowful failure, and regrettably twice.

2015 Disaster at the Fundão Dam, Germano, Mariana, Minas Gerais, Brazil

In November 2015, Samarco, a joint venture of Vale and BHP Billiton (50% share each), caused one of the most serious mining disasters in the world. On 5 November 2015, in the afternoon, a dam on a post-mining waste reservoir burst, releasing an estimated 43 million cubic meters of iron ore production waste, creating a 10-meter-high wave, killing 19 people and causing irreparable damage to the environment. Contamination has spread along watercourses, by more than 600 kilometres. The Doce River, located near the cracked dam, was the most affected. 17 days later the pollution reached the Atlantic Ocean (Carmo et al., 2017). According to various estimates, the forest area affected was ca 1 200 ha, the loss of direct forest area was about 450 ha, within 74 km from the Fundão Dam (Omachi et al., 2018). Figure 2 shows the scale of damage and degradation.

Fig. 2: Elements of natural and cultural heritage damaged by the Fundão tailings dam.
Source: (Carmo et al., 2017)

The dam burst caused many negative social and environmental impacts in the short, medium and long term. The 19 fatalities were both employees and subcontractors of Samarco, but also residents of Bento Rodrigues. Another dramatic and visible effect was the destruction of human habitats. It is estimated that approximately 1 200 people lost their homes. Infrastructure, pastures, fields, and forests have been irreversibly damaged. Thousands of region-specific plants and animals have died. A large part of the Doce riverbed has been silted, which is likely to increase the risk of flooding in the coming years and to increase the territorial spread of floods to regions not previously affected (Wanderley et al., 2016). Depending on estimates, it is reported that the disaster has affected, directly or indirectly, 1 million people in 41 municipalities, mainly by restricting access to clean water, fish resources, plant growing sites, possibility to produce water energy and raw materials. It is particularly difficult for those communities that have based their livelihoods on agriculture and fishing. The landscape and biodiversity of the region have been permanently destroyed (Fernandes et al., 2016). Satellite images showing the area before and after the disaster are shown in Fig. 3.with riverbed marked in red.

Fig. 3: Satellite images of the Minas Gerais region before and after the Fundão Dam burst in 2015

Source: Own study based on (Philips, 2019).

When analysing the causes of the tragedy, there have been accusations against the company managers that allegedly they had been aware of the poor condition of the dam's construction for many months. In 2016, 21 people, including the CEO of Samarco, were accused of homicide. The case was suspended. The prosecution claimed damages for USD 48 billion. Besides, it was proven that the population was not warned about the imminent threat in any way. As Samarco pointed out, no warning sirens were required by law. There are allegations that the company has blindly focused on cost reduction and maximization of production (Philips et al., 2018). The Company disagrees. In the face of the tragedy that followed, it activated all available means to mitigate the negative effects of the disaster. After the tragedy, the Renova Foundation was established which is responsible for implementing recovery programmes to rebuild what had been lost as a result of the dam burst, in social, environmental and economic terms. Both Vale and BHP Billiton are financially supporting the Foundation to make sure that it fulfils its obligations established in agreement with the Federal and State Governments of Brazil. The budget of the Foundation in the first three years of its operations is to amount to ca USD 1 billion. After the disaster, Vale set up a department dedicated to the supervision of its dams to assess and enhance dam management processes, improve their supervision and thus increase safety and prevent similar disasters in the future (Vale, 2019). Today we know that this objective was not achieved. Another accident happened sooner than anyone would have expected.

2019 Disaster – Córrego do Feijão, Brumadinho, Minas Gerais, Brazil

On 25 January 2019, just over three years after the Samarco disaster, the Córrego do Feijão mining dam collapsed. It was located near Brumadinho, a large city in southeastern Brazil, about 75 km from the previous disaster site. The dam, which was a wall of sand and silt, devoid of steel or concrete reinforcements, collapsed suddenly and without any warning, releasing a wave of about 12 million cubic meters of waste and mud that devoured everything it encountered on its way. To illustrate the scale, this is the capacity of 5000 Olympic swimming pools. Once again, it was one of the most dangerous mining accidents in the history of Brazil. The state of Minas Gerais, where the dam was located, is the centre of the Brazilian mining industry, producing about 53% of the country's total output. There are still 87 similar mining dams in Brazil, 27 of which are located near municipal areas, inhabited by approximately 100 000 people. According to the critics, the mining law in effect is drafted by the companies themselves, so there is no question that it could be efficient and ensure actual control over the industry. In Brazil, the companies can choose auditors to assess the dam safety of their own. The experts claim that this causes a conflict of interest, as auditors are paid by the companies they control (Darlington et al., 2019; Penner, 2019).

For a long time, it was claimed that 259 people died and 11 were missing, but eventually, 270 people are considered to have lost their lives in the disaster. According to the National Water Agency (ANA), the released mud has polluted up to 300 kilometres of rivers (Pearson and Magalhaes, Luciana Kowsmann, 2019). Figure 4 shows satellite images of the dam area before and after the disaster.

Fig. 4: Satellite images of the Brumadinho dam before and after the disaster
Source: (Darlington et al., 2019).

Shortly after the dam burst, questions were raised concerning the warning system. Vale confirmed that it owned a warning system, including cameras and warning sirens, but as this tragic experience has shown, the system did not work when it was most needed. The company explained that the warning system was not automated, and required manual activation in the rescue centre and because of the rapidity of the event, there was not enough time to react. There were suspicions that the people who were supposed to operate the rescue centre were working in the mine at the time and were killed before they could take any action (Shukman, 2019).

The second catastrophe related to Vale in several years brought about a series of social protests. Greenpeace accused the company of "corporate greed, omission, and inefficiency". "We are not dealing with an accident, but with a crime against people and nature..." Greenpeace Brazil Campaigns director Nilo D'Ávila said in a statement (Reverdosa, 2019). Moreover, accusations have been raised against the Brazilian government, which did not pass the relevant legislation after the previous disaster (Reverdosa, 2019). One year after the collapse, the Brazilian prosecution charged Fabio Schvartsman, former Vale CEO and 15 other persons with homicide. In response to the allegations, Vale's representatives emphasized that the federal police report on this matter would not be issued until June 2020. The company maintains that the dam has been regularly inspected and the collapse has been caused by continuing high water levels, which have contributed to the loss of resistance and stability of the structure. Since 2015 no more waste has been deposited in the reservoir which, due to the cracking has released millions of tonnes of extraction waste. Vale adds that there have been no indications that the dam was unstable and could pose any threat (Garcia, 2020).

Consequences for Vale

The consequences of both disasters will be perceptible for many years to come not only in terms of environmental or social impact but also economically. The company has suffered severe financial consequences of its failures. An analysis of the company's share price shows that the capital market reacted to those tragic events very quickly. This was specifically the case of the 2019 disaster. On the following business day, the share price dropped by nearly 25% (a decrease in the company's value by about USD 19 billion). It was the most important drop in history recorded during a single session on the Brazilian stock market. The sales volume increased dramatically as investors sold their shares in the company and masse. Figure 5 shows the trends of the share price and trading volume of Vale shares.

Fig. 5: Price and trading volume of Vale shares
Source: Own elaboration, based on data from Bloomberg

As follows from an analysis of the development of analytical recommendations for Vale (buy/sell/hold), the market reaction was not as obvious as in the case of the company's share price. In 2015, just after the disaster, the number of recommendations to sell increased, whereas, after the disaster in 2019, the analysts advised to hold or to buy. Perhaps those who learned from the experience maintained relative peace of mind, expecting the company to cope with the crisis and the shares to be priced up again shortly. The exact pattern of the analytical recommendations is shown in figure 6.

Fig. 6: Structure of analytical recommendations concerning Vale, from Jan. 2015 to Jan. 2020
Source: Own elaboration, based on data from Bloomberg

A significant drop in the production of iron ore, which is Vale's flagship product, clearly resulted from the catastrophe in 2019. In the second quarter of 2019, the company recorded a decrease in the production of this raw material by nearly 34% y/y, i.e. by ca. 64 million tonnes. The Brumadinho catastrophe brought about the temporary or total closure of a few more key companies there, reducing production, which also translated into a decrease in sales of several percents in that period (Mano, 2019).

The Company also incurred clear financial consequences in the form of damages and fines. Depending on the sources, different amounts are mentioned, which include compensation to the families of the victims, penalties imposed by the state and supervisory bodies and expenses for rescue and recovery operations. It is officially reported that in 2016 Samarco and the Brazilian government agreed to the payment of BRL 20 billion to the State (at present, equivalent to ca. USD 4.4 billion) (Darlington, 2020). The penalty did not include compensation for the persons affected and the costs of recovery of the contaminated area. Concerning the 2019 crisis, Vale informed in a communiqué that it had allocated BRL 24.1 billion (ca USD 5.2 billion) to finance recovery actions and compensations (Vale, 2020b). The 2019 financial report contained a special item, "expenses related to Brumadinho", of USD 7.4 billion. The Company's key financial results in the years 2014-2019 are presented in table1.

Table 1: Key financial results of Vale in 2014-2019

Vale SA - Financial results						
In Millions of USD	2019	2018	2017	2016	2015	2014
Net operating revenues	37,570	36,575	33,967	27,488	23,384	35,124
Total costs and expenses	23,775	23,721	22,743	19,196	20,907	26,486
Adjusted EBITDA	10,585	16,593	15,338	11,972	6,513	13,075
Adjusted EBITDA margin (%)	28	45	45	43	28	37
Net income (loss)	-1,683	6,860	5,507	3,982	-12,129	657
Capital expenditures	3,704	3,784	3,848	5,191	8,401	11,979

Source: Own elaboration, based on Reports: Vale's Performance in: 2014/ 2015/ 2016/ 2017/ 2018/ 2019 (Vale, 2018a)

The key financial ratios do correspond to the tragic events that took place in Vale in 2015 and 2019. In those years, the company recorded a substantial loss, while in the remaining years it made a considerable profit. The levels of EBITDA and EBITDA margin also reflect the deterioration of the company's condition. Few companies in the world could afford such a crisis, and yet survive and continue to operate in a relatively undisturbed manner. One should bear in mind that the company operates in an industry that is extremely vulnerable to economic developments and raw material price quotations. Therefore, the downturn reported in 2015 and 2019 need not only be due to the catastrophes but also to the collapse in the raw material market, particularly evident in the context of iron ore prices in 2015.

Vale had to pay, literally and figuratively, a very high price for failing to meet its pro-environmental commitments, expressed in the company strategy. Aside from the financial repercussions, the image of the company has also been affected. Both disasters resulted in several prosecution charges, arrests, and dismissals. The company has been regularly informing on the progress of recovery activities related to both accidents. The programme designed to repair damages in the Brumadinho area is particularly extensive. The company describes all its activities and provides figures in great detail. Sadly, even the best repair programme cannot change the past.

Conclusions: Unreliability of Environmental Strategies

Over the last decade, business strategies based on pro-environmental assumptions, strongly related to sustainable development have become the standard practice. The "green" and "eco" trends are visible among companies with a global presence. In this context, the situation mining industry is extremely difficult. On the one hand, it is an industry that strongly interferes with the environment; on the other hand, had it not been for mining, the world would probably not have been able to develop to the level that humanity knows today. It would be hypocrisy to see this sector in a bad light only. However, it is undeniably an industry that, despite its attempts to be socially and environmentally responsible, faces considerable difficulties and shortcomings in this respect. The number of accidents that are recorded in the mining industry each year is the best evidence of such difficulties. Fig. 7 shows mining accidents recorded worldwide in the years 2007-2017.

Although Vale is not isolated in its environmental problems, the disasters it encountered were so significant and multidimensional that they have become the darkest history of the mining industry. The company has not managed to restore its good image. In February 2020, information spread around the world that a ship carrying 275 000 tonnes of Vale's iron ore has started to sink off the coast of Brazil. The company informed that it has initiated preparations in the event of a potential fuel spill into the sea (Teixeira, 2020). Surprisingly, Vale has not learned its lesson after the 2015 collapse. One might have thought that such a tragedy should provide sufficient ground for the company to take greater care of the security of its operations. We can only hope that the example of Vale will serve as a warning to other companies in the industry.

Nevertheless, the reliability and legitimacy of business strategies based, at least in theory, on the principles of sustainable development remain unsure. The mining industry emphasizes in its strategies the importance of safety and health of employees as well as the environmental and social issues. One may fear that companies simply want to keep up with the trends and expectations of their stakeholders and treat their commitments more in terms of the image than genuine responsibility. Indeed, in recent years companies have been very committed to compensating for their negative impact on the environment and have taken many positive initiatives. However, sometimes these are nothing more than a form of covering up, concealing a negative impact, a typical manifestation of greenwashing. One would like to believe that companies are guided only by noble ideas, but probably they will never be as the first and primary goal of any business is still to make a profit. It is worth quoting P. Drucker: "It is not enough for business to do what it does, it must also do good... but to do good, a business must first do what it does and the way it should be done". We should, therefore, expect companies to be simply honest and responsible and only then to start developing 'doing good' strategies."

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme “Regional Initiative of Excellence” 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

The article undertakes considerations aimed at bringing a closer view of effective time management in projects. Paper describes the important role of project management and the importance of project effectiveness in managing modern IT organizations. Particular attention was paid to the very definition of project effectiveness. An important element of the analysis is a discussion of the project's limitations and the proposed methodology for measuring effectiveness in IT projects. A model for measuring the project's effectiveness was proposed in this paper. Time was considered as the basis for the designed project's effectiveness measure. The concept of billability has been also defined. Based on the case study, the effectiveness of billability measurement in the diagnosis of project effectiveness was demonstrated.

Keywords: IT Project Management, Time Management, Effectiveness.

Introduction

The issue of project effectiveness in the modern era of Economy 4.0 (or Industry 4.0) and society, which applies frequently projects and programs, takes on greater significance. The modern world is filled with time-oriented projects and which provide also project management-related education, research, and marketing services, which can be perceived as a Project-Oriented Society (POS) (Garais, 2002). It is important, due to the impact of technology and technique (Sulich and Zema, 2017) and generally computerization or robotization of processes on almost every branch of the economy and of course the man himself (Gracel and Makowiec, 2017; Sulich et al., 2020). Project efficiency is a multidimensional concept and, like its successful implementation of an IT project, the final recipient depends on many factors, among others: from the manner and time of project competences being implemented by project teams, treated as specific tribes cooperating and the roles of their members (Tutaj et al., 2019). All these elements affect project maturity, which is "*the ability and readiness of the organization to effectively select a portfolio of projects - supporting the organization's strategy and goals as well as the use of professional techniques and tools, project management methodologies that are to lead to the successful completion of the project and to translate this success into further projects"* (Juchniewicz, 2012). Management effectiveness is *"the result of actions taken, described by the relationship of the results obtained to the expenditure incurred"* (Jedliński and Kruszczak, 2019; Yarnada, 1972). Management effectiveness contains descriptions of internal and external phenomena occurring in a given project (Skrzypek, 2012). Thanks to the effectiveness of constant monitoring, a competitive advantage is created and built, only if managers can effectively implement and enforce their decisions in practice (Pasetta, 2005). In the efficiency essence, the most important approach to performance as an element of effective management (Pearce, 2000), in this context the effectiveness is assessed by examining the results and organizational processes critically and holistically (Gaertner and Ramnarayan, 1983; Nürk, 2019a).

The goal of this paper is to develop a model of project effectiveness. Defining the concept of project billability as a measure of project effectiveness and areas of its measurement. Model verification was performed in the realities of IT projects and these were presented in the case study.

The Effectiveness of IT Projects

The time required for the project realization defines the date of commencement of implementation and the date of completion of the given project (Kamińska et al., 2019). The critical factor of the project's success is the proper and correct task prioritization within project constraints (Walczak, 2010). In e-business ventures, the most important is the time of the delivery product to the market (time to market). In the case of a good idea and its quick implementation, a competitive advantage can be built (Ciechan-Kujawa and Goldmann, 2012) and besides that also a successful development and implementation of the IT project. Manufacturing organizations must be both effective and efficient (Heikkila, 2002). Along with the development of project management, the analysis of a highly structured and bureaucratic approach in terms of efficiency and flexibility of work was started. Therefore, project risk is defined as an event or set of uncertain events that in the event of occurrence will affect the project ('Manifesto for Agile Software Development', 2001). Effective exploitation of risk efficiency implies highly proactive risk management that takes an integrated and holistic approach to opportunity and threat management (Sulich and Zema, 2017). In particular, if it is related to the testing and iteration phases in the IT project. Further, inefficiencies associated with too many iterations to get to a given level of analysis in a given area may add to the cost of analysis significantly, depending on how iterations are managed (Sulich et al., 2020). This reinforces the case for making the identity phase as complete as possible before proceeding to the next phase. If sources, and responses, and associated secondary issues (response chains) are not properly understood, any subsequent risk management can be a complete waste of resources (Kamińska et al., 2019; Kudłaszyk and Rutkowska, 2004; Parkitna et al., 2017). It is said, that time management pressures and availability are key that people may require getting on with some of the next phases while the identify phase is still in progress. Delays associated with an incomplete define phase can aggravate this difficulty (Chapman and Ward, 2003).

Project management is a process during which the person managing it carries out deliberate planning and controlling tasks included in the project (Packendorff, 1995). Looking from a management perspective, project effectiveness should be considered as a triad, the relationship between three dimensions of efficiency: project economy, project efficiency, and performance efficiency. These dimensions can be defined as:

- cost-effectiveness of the project, based on optimal cost management from the perspective of the feasibility of the assumed budget,
- project efficiency - proper implementation of the project within a specified and assumed time,
- project effectiveness is an activity that leads to the intended effect as an objective from the perspective of project implementation.

The success of the project, considered from the efficiency model, multiplies many of its dimensions, in which a change in one of the dimensions over time, entails the consequence of changes in the others (Rutkowska and Popławski, 2008). Along with the growth of project maturity, the efficiency of managing many projects - project portfolios increases, which translates into the possibility of IT companies achieving strategic goals more effectively (Litke, 2005). Clearly defining goals precisely – defining what is desired by the organization to achieve - allows it to determine the place and position in time. Such analysis allows an organization to address the question: where is the organization at the moment, where "it was yesterday and where it wants to be tomorrow". A well-defined goal connects and motivates people to work more efficiently and effectively (Wysocki, 2013). When defining the goals to be achieved, one should be guided by the SMART principle (Piwoni-Krzeszowska, 2014). It requires a very thorough analysis of the client's needs, which significantly increases the chance of achieving the assumed goals (Walczak, 2014). A well-defined goal connects and motivates people to work more efficiently and effectively (Wysocki, 2013). It requires a very thorough analysis of the

client's needs, which significantly increases the chance of achieving the assumed goals (Popławski et al., 2011; Walczak, 2014). In the context of understanding the interdependence of each of the elements contained in the "design constraints triangle" (Wirkus, 2014) which has a "scope" in the center of the triangle (Szyjewski, 2001). An effectively executed project, i.e. a successful project, is one that is efficient, effective and economical at the same time. It is undeniable that the effectiveness of the project takes place in a continuous cycle of its elements:

$$\Delta Ek_0 \rightarrow \Delta Sp_0 \rightarrow \Delta Sk_0 \rightarrow \Delta Ek_1 \rightarrow \Delta Sp_1 \rightarrow \Delta Sk_1 \rightarrow \Delta Ek_2 \rightarrow \cdots$$

The analysis of theoretical achievements carried out by numerous researchers of this issue in the interpretation of project effectiveness can be reduced to academic discussion, which indicated it is more important: time, scope or cost. Increasing the budget is not always the same as increasing the scope, and for example, reduces the time. Each of the elements additionally is related to the qualitative sphere (Ładoński, 1994), so choosing one path affects not only the outside and inside of the design elements. Maintaining the balance between these elements is the biggest challenge of efficiency management for project managers. It uses appropriate techniques and methods to achieve the imposed requirements within a specified period and at designated costs (Jędrych et al., 2012; 'Zarządzanie projektami', 2019a). Agile methods are often used in IT projects and include short-term task planning that takes into account the dynamically changing design environment (Kozłowski, 2010). On the other hand, the lack of an established design/time frame is primarily considered to be the biggest problem of this methodology. Working in this methodology, it is not possible to estimate (or it is very difficult) how much effort and time is needed to complete the project, due to the specificity of the project, it is very difficult to find users who can present their expectations without seeing the operating system (Nürk, 2019b). That is why most IT projects are managed in an agile way. Estimating and task planning, timeliness, and costs of individual parts of projects are inseparable elements for which the scope is responsible. The Project Manager should ensure that the budget is within the set limits or if there are risks of overruns, inform the client and decide what to do next (Kloze, 2009). Time is usually budget-related for project implementation. The client usually sets a time frame when he would like to start and finish work on the project, but the length of work often depends on the available financial outlays (Hernes, 2019). The number of employees participating in the project, the use of better technologies and additional tasks will affect the size of the budget. Of course, not always increase the number of people on a project will help and accelerate work, there may be an increase in the number of people and instead of greater efficiency, there is the opposite effect. The role of the Project Manager is to keep work in the schedule and match the right employees (in terms of experience) to the task ('Zarządzanie projektami', 2019b).

Significance of Billability of IT Projects

The simplest terms are billable ('Managing billable hours key for PR firms PRSA study benchmarks billable time performance of firms', 1996), billable time (Grandy, 2003) or billable hours (Zaffrann, 2017) as the time invoiced to the customer for which the customer should pay (Falsetta and Kaplan, 2018). The Service Recipient implementing the project commissioned by the client by registering the time spent on performing all project activities. Based on this time, an invoice should be issued at the end of each billing period (USLegal, 2019). The time that directly affects the invoice value is called billing time. Referring to the meaning of the word 'billability', one should check what impact the ratio of invoiced hours has on the time management level in IT projects. The point is, of course, whether all the time actually worked on commercial projects is invoiced to customers or whether there is a situation that the company, despite the hours worked, gives them away for free and does not earn on them. It should also be taken into account that the company has non-irrevocable hours, i.e. not directly profitable. These include: holidays, training, internal meetings.

The management of numerous projects in highly hierarchical organizations focused on permanent or repetitive activity raises numerous problems related to meeting the scope, budget or time of their implementation (Prawelska-Skrzypek and Jalocha, 2014). To determine the efficient time management of IT projects, the relationship between the work involved and the goals achieved should be examined. It is important to save time and resources. For time management in IT projects can be said about the ratio of hours worked invoiced per customer to all hours worked together - this is also one of the measures of project effectiveness (Parkitna and Buczkowski, 2009).

The assessment of project efficiency reduced to project billability is based on the analysis of metadata concerning the efficiency of design tribes. The metadata is "data about data" or simply "information about information" (Encyklopedia Zarządzaniania, 2019). In other words, we can talk about structured information by which various objects are described and they provide very detailed data. These data can be used to identify the object and to find or manage it (Wyman et al., 2013; Žumer, 2009). However, in world literature, many authors try to separate information from data. Information is defined as data that is contained in a specific message (Grabowski and Zając, 2009), and the data is a string of characters or their notation, which can usually be related to e.g. processes or some specific events. They have no meaning and no purpose in themselves. However, the string of these characters should be presented in a form that allows another person to properly interpret, transfer and process it. In the table below, to illustrate the differences between these terms, the literature definitions of both terms according to various authors will be presented.

In the era of the Internet and technological development, enterprises (especially the IT industry) have access to huge databases. They can collect data on market conditions, the latest trends, and customer reviews, but and they can also collect data on the operation of the enterprise itself. Every company that wants to gain a competitive advantage, provide the best services that will be based on quality and customer satisfaction should analyze internal trends (Zema and Walczyński, 2019). Namely, it should focus on the work of employees, analyze the project situation, examine all sectors of its activity, e.g. in terms of marketing effectiveness, or in terms of accountability of their projects and working times. A design tribe is understood as "a group of specialists who, once selected, work together for a long period, oscillate around one technology and, after completing work in one of the projects, do not solve, and then move on to the next project." (FED US, 2009; Nowosielski, 2018) : programmers, testers, project managers, analysts, graphic designers, etc. In their tribes, employees not only perform work related to commercial projects but have internal tasks and meetings where each employee registers times. Each tribe is assigned specific budgets and project times worked on their behalf.

Billability as a Measure of IT Project Efficiency - Case Study

To sum up, the considerations presented above clearly indicate the key importance of billability for the assessment of project effectiveness. They also prove the need to formulate additional postulates in this area, taking into account the specifics of the implementation of many projects in an IT enterprise related

to increasing project maturity and relating to tools supporting project management. Research shown in the literature shows the positive impact of IT tools on management in enterprises implementing many projects (Dammer, 2008, 2009), on the other hand, it is emphasized that these tools should be adequate to the level of project maturity. In practice, the organization must be ready to implement a new management support tool (Weidemann, 2017). The design of project effectiveness monitoring systems should additionally be linked to remuneration as well as a rebate system, which will allow for possible negative consequences.

The 153 IT projects were implemented simultaneously in the research period, which required supervision over the effectiveness of individual activities in which shared resources implemented by 6 tribes were used, in which there were a total of 135 employees. Therefore, in managing the effectiveness of individual projects in IT sector enterprises, metadata analysis and using them for development are very important issues. At present, strong competition on the IT market forces individual organizations to look for areas that will gain an advantage through the increasing profitability of individual projects.

The proposed tool was to monitor project effectiveness and give answers to two basic questions: Is the value of time spent on behalf of the client equal to the value of the invoice issued? Does the company devote sufficient time to training, development of employees' skills and knowledge, and development of own products thanks to which can enter the technology market in any way? In this context, it is very important to analyze the effectiveness of employees' working time. In the context of defining time reserves, bottlenecks and efficiency of time use, the context of its wasting or "giving away for free" in the form of giveaway and discounts.

In response to the issues presented above, a tool was created to measure the project's accountability, thanks to which the project's effectiveness was demonstrated in practice. The spreadsheet created for the work consisted of interrelated sheets such as the main table: Tribes, Tasks Division; E-Commerce Performance; Specializations Work; Technological Division of the Project; Developers; Non-Bill Projects; Billable Projects; Project Accountability; Toggle, Budget; Toggle Vs Budget (in comparison to individual monthly settlement periods). To precisely determine the working time, a tool was introduced to record working time with the possibility of splitting time into various projects, tribes, technologies, and specializations. The Toggl program was used for work. The data collected in the system from December 2017 to March 2019 are further analyses subject.

The most important issue of the whole analysed in subsequent tables as worksheets is the value named in the file as "% Billability". The values of its markings were also determined for this measure. The value from 90-100% is a very good level with maximum efficiency. The value of 80-89% is a good level that can still be optimized in terms of efficiency. A value of 60-79% of the accountability level is an acceptable level of efficiency but requires regular management control. The level below 60% is unsatisfactory and may bring more costs than benefits and the company should pay special attention to ongoing projects.

In the un-invoiced time, the company's client includes freebies and rebates granted, home affairs, staff unavailability, internal projects, etc. These data are used to examine whether the company X worked more time invoiced for the client on project X, whether it gave rebates and giveaways themselves and how these activities translated into the effectiveness of individual projects.

The proposed tool was to monitor project effectiveness and give answers to two basic questions: Is the value of time spent on behalf of the client equal to the value of the invoice issued? Does the company devote sufficient time to training, development of employees' skills and knowledge, and development of own products thanks to which can enter the technology market in any way? In this context, it is very important to analyze the effectiveness of employees' working time. In the context of defining time reserves, bottlenecks and efficiency of time use, the context of its wasting or "giving away for free" in the form of giveaway and discounts.

In response to the issues presented above, a tool was created to measure the project's accountability, thanks to which the project's effectiveness was demonstrated in practice. A spreadsheet created for the work consisted of linked sheets; in comparison to individual monthly settlement periods. To precisely determine the working time, a tool was used to record the working time of the "Toggl" program.

In the case of granting a significant number of free hours to the client, one can talk about the inefficiency of project management, and the company should in such cases focus strongly on analyzing why this situation occurs. Is it due to the poor work of the project team or other technological aspects? A spreadsheet showing globally the level of project efficiency overall months. If there are few discounts or giveaway it means that the project does not have a large number of errors, so the work goes smoothly and correctly.

In terms of efficiency, it is very difficult to say what level of % accountability and time devoted to tribal tasks would be appropriate. The full analysis should be added time devoted to internal projects and include them in the time invoiced per customer. Indirectly, a company can earn on projects and products created inside the company and thanks to them it reaches a new, wider pool of customers or it has the opportunity to gain and enter a new market. Therefore, % efficiency should include not only the time invoiced per customer but the time devoted to projects and internal products. Thanks to such data, it is possible to introduce an efficiency measurement in a given category that refers to the effectiveness of generating revenue.

A small amount of un-invoiced hours per customer may mean that the rebates granted are associated with maintaining customer relations (by the way and long-term cooperation). The efficiency measurement tool constructed in this way also gives the possibility to monitor the monthly level of accountability in the context of all projects carried out in the company and the total level of accountability of the entire project (carried out throughout the year). Therefore, % efficiency should include not only the time invoiced per customer but the time devoted to projects and internal products. Thanks to such data, it is possible to introduce an efficiency measurement in a given category that refers to the effectiveness of generating revenue. In terms of analyzing the work of employees, an effective level of work on IT projects was a 69% level of accountability - i.e. the ratio of invoiced hours in a given month per customer for all hours worked by the employee. Why was 69% taken as a measure of employee efficiency? This level was set since in IT companies it pays great attention to the essence of employee development and works on their skills and joint support. There are also hours devoted to supporting in recruitment, marketing, sales or development of internal products. These hours reduce the total level of accountability of individual employees, but this does not lead to a decrease in the level of project effectiveness. Analyzing the data, according to the authors, the 69% level is most appropriate for every employee. In 30% of the time, development opportunities and business matters are included. By introducing the division of employees of internal projects and those into commercial projects and by stabilizing the number of projects for one employee, work efficiency could increase significantly.

Analysis of projects according to work technology, which allows you to examine which technology "consumes" the largest number of hours per month (in theory, this can be the biggest revenue from it) and Are projects carried out in a given technology profitable - is the accountability indicator satisfactory? Theoretically, every IT company operates in specific technologies, according to tribal arrangements. Sometimes, however, there is a situation when for the development of employees, checking other development paths for the enterprise or the client, the enterprise provides services in a different technology. For example, in Technology 1, where annual accounting is at the level of 71%, which proves the effectiveness of work. Therefore, because in the hourly context (almost 50%), most of the hours the company provides its clients in technology 1. there is an example of such analysis (Table 2).

Through this structure, the company can conclude the work of specific specializations (Table 3). Each specialization should have a different level of% accountability, which results from the position held. For example, the level Chief %'s accountability should be lower because he has a lot of responsibilities involved with the organization of tribal work and hence should have a different assumed level of accountability than the Developers who are mainly employed to work on commercial projects. The appropriate level of accountability and effective distribution between positions allows you to maintain the continuity of the company's operations as well as its development and solvency.

Conclusions

The issue of billability presented in the article seems to be a critical element from shaping project effectiveness. The analysis of this issue carried out by the authors proves that the scope of problems measuring the effectiveness of IT projects from the perspective of the specificity of such types of enterprises is a complex issue. Proposals for changes in the method of measuring effectiveness based on the measure of accountability fit into the essence of this phenomenon. Identifying and diagnosing the level of project billability only can help improve project effectiveness and contribute to the economic efficiency of the entire organization. There are important elements when billability is measured, these are tools supporting project management. With the growing number of information and a high level of project complexity, the tool constructed in such a way allows supervision over the time factor and can be a key tool supporting the efficiency of project management in an organization. Thanks to the access to the program used to register working time and the possibility of including the hourly rate set for the project, an attempt was made to check whether the time worked and registered in the program agrees with the invoices issued to customers at the end of a given month. Thanks to the income analysis and the possibility of examining design effectiveness, it can gain a full picture of its current situation, whether there are deviations from the correct, assumed, stable position and functioning possibilities.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

Artificial Intelligence (AI) is surprisingly hard to define the term in the modern world. Although there are hopes harbored in development in progress based on the AI, there are also ethical doubts and questions related to this matter. The main goal of this paper is to discuss the main definitions and elaborate on one approach for future qualitative research. This paper presents a review of definitions in a view of ethics and choice theory. Definitions are presented early ideas to the big data era to set a decision-making problem. The presented research is important because most of the industry sectors depend on technology and computers in particular.

Keywords: Artificial Intelligence, Artificial Neural Networks, Decision-making Problem

Introduction

The topic of Artificial Intelligence (AI) to most people sounds like the current state of the art of the computer sciences (Yazdani and Kwaśnicka, 2016) or like a futuristic term taken from Isaac Asimov's novels (Asimov, 2004). We are living in times when AI became one of the disruptive and trendy terms and it almost seems like marketers just add it to the product as a feature (Stępień, 2019), which makes a toothbrush being advertised like a lightsaber or trashcan like R2D2 (Lucas, 1976). From the beginning of the human race, dexterity and intellect have been its domain, which enabled it to settle in almost every environment in every single place of the world (Niemczyk et al., 2018). To call a computer code Artificial Intelligence, which means that it can mimic the functionality of the brain, to some of the population is somehow offensive and it undermines the achievements of our ancestors (Sulich, Zema, et al., 2020). This term has been invented to rise this type of feeling. Some people, when they hear it automatically get offensive and contrary to that, some people see AI as a promise of a better future (Krzos and Olek, 2019). Either way, everyone will admit that this mixed usage of biological and IT terms rises a discussion at many levels. At the most recent, looking at the people's attitude to AI it seems like the majority of humanity decided, that if they cannot stop it, they may also "enjoy the ride" and get accustomed to self-driving vehicles (Gontarz and Sulich, 2019), custom phone applications, but also chatbots and surveillance of public activities.

From the Early Ideas to the Big Data Era

The scientific environment is not consistent when it comes to the definition of AI (Duan et al., 2019; Górski and Parkitna, 2008). It is widely accepted that AI refers to the ability of the machine to learn to fulfill human-like tasks based on the input data (Duan et al., 2019). The term *artificial* suggests that the model is based on the scientific approach and as an outcome, we get synthetic creation. There are several approaches to the definition of Artificial Intelligence. One of them is to put this term into the field of science of building computer-based *artifacts* or *items* mimicking various human tasks (Niemczyk et al., 2018). This approach gives a wide range of philosophical discussions about the nature of intelligence and how it is created (Sulich and Zema, 2017). It also puts under the question if the machine is making any decision because it is based on the previously-made decisions by the creator of the system (Ćwik et al., 2017). Also, automated tasks cannot be called intelligence, because there is no decision making involved. The machine is simply following given instructions and it is limited to possible situations that may occur at the time. This raises a question on how to "teach" a machine to make decisions as humans do (Niemczyk et al., 2018). Similarly, to humans, computers can learn to make decisions based on the observation of the decision-making process. The artificial intelligence algorithm always follows the similar steps which mimic the process of learning: Identification of phenomena, construction of artificial system designated to solve recognized phenomena, operation of the system in a given environment, data gathering, assessment of the outcome under given boundary conditions. This process of learning also takes under consideration failures in solution to drive them back to the database (Nürk, 2019; Steels, 1993). If we, therefore, consider AI as a field of science aimed at imitating people, we cannot omit the topic of human reasoning. The problem is that each person follows his or her reasoning while making a decision. From this point of view, AI becomes cognitive science more than a study of computers. These different views led scientists to further research on how human beings can live alongside AI and how to minimize the negative impact of technology.

Fig 1. AI papers published in SSIS/IJJM by year. Source: (Duan et al., 2019).

Reportedly, the AI systems are heading business to the new tracks and AI-enabled systems usage in corporations is expanding rapidly. The improvement is seen in the organization's ability to make data-driven predictions and has significantly reduced the cost of model preparations. According to some surveys AI is listed as the most strategic technology, which will reinvent business models and ecosystems, enhance decision making and reinvent the customer experience. The potential payoff of investment is predicted to happen in 2025 since 59% of organizations are still on the phase of information gathering and building their AI models, while the remainder is at the early stages of adaptation (Panetta, 2017). Although AI comes with great promises, early adopters are being cautious and pilot programs always give valuable lessons to future utilities. There is still a certain dose of dissatisfaction among academics with the lack of theoretical fundamentals and formulations. The aforementioned "AI springs" and "AI winters" among the history of the method has led to ignorance of research findings from years 1970 to 2000 and reinvention of concepts known from over four decades.

Decision-making Problem

The decision-making problem occurs when an individual or a group of people develop an idea of the desired state. This state often differs from the current situation, which requires certain actions to be undertaken. The aim is to prepare this set of activities, which will change the current situation to the target state in the short or long term. This difference between current and aimed state does not represent a decision-making problem, it appears when the goal can be reached by many means and ways. The decision-maker is then required to examine a set of possibilities to take the right course of action. The frequent negligence is not to investigate multiple possibilities but go straight away to action after inventing the first solution, whereas in almost all situations there is more than one option. A systemic approach is then highly advised and it will prevent the rush of being satisfied with the first idea. It is proven that a systemic approach provides better quality solutions in most cases. The decision-making problem can be then characterized by two main factors (Grünig and Kühn, 2005):

- A difference between the current state and the target state.
- At least two options for action to achieve the target.

The decision-making problem was widely recognized by both academics and practitioners, who proposed techniques including methods, models, algorithms and software tools (Zhang et al., 2015). The classification of different decision-making methodologies was undertaken by Zachary in his publication from 1986 (Zachary, 1986). According to his insight, we may distinguish the following decision-making techniques:

- Process models
- Choice models
- Information control
- Analysis and reasoning techniques
- Representation aids
- Human judgment amplifying/refining techniques

Most of these techniques include computational models with different emphasis on specificity like data mining, probabilistic modeling, data warehouse, goal programming, evidential reasoning, case-based reasoning, graphic user interface, heuristic judgments. The systemic solution of the decision-making problem may also include the integration of two or more techniques. AI finds its roots in heuristic methods and therefore in Zachary's taxonomy, it can be classified as Human judgment amplifying/refining technique (Zachary, 1986). Although Zachary's opinion on heuristic methods is not overly flattering, the change that they have faced over the years made them fairly popular and appreciated.

The decision is undertaken to reach the desired state, which differs from the current one. Although this problem may be approached from many perspectives: purely intuitively, without closer investigation of the problem, through described procedures taken from own or others experience, by taking a solution based on the expert knowledge or even choosing at random. All of these methods can be applied in different scenarios, but when it comes to the consistency of the outcome only systemic approaches give satisfying and predictable results (Sulich, Zema, et al., 2020). The rationality in decision making rises a question on layers of philosophy, logic and probabilistic theories. We, as people, tend to make rash decisions and act under the influence of the environment we are living in (Sulich, Rutkowska, et al., 2020).

Artificial Neural Networks

Work on Artificial Neural Networks has been motivated by the development of neuroscience. The discovery of the complexity of human brain functionality has triggered the change in conventional computer architecture. The conventional PC is based on linear operations, whereas the brain makes complex, nonlinear, and parallel computations every second. The main cell which is responsible for making this operation is a neuron and it is more efficient than any modern processor. When we consider basic everyday tasks like senses perception, the information processing takes brain approximately 100-200 ms, which is even beyond the capabilities of supercomputers. The other example may be taken from less cognitively evolved creatures than humans. Bats are using echolocation for perceiving the velocity and size of the object when flying in the dark. These complex computations are way more accurate than any of the available echo sonars, even though the bat's brain is a size of a plum (Haykin, 1994). In both cases, humans, as well as bats, were given this astonishing gift at birth. It does not grow that much in terms of the volume in the lifetime, but it builds up its structure and gains abilities through the experience it is exposed to. In the beginning, in the human body for the first two years of life, the brain is very flexible and has a high ability to the adaptation to the surrounding environment. This elasticity in adaptation is then crucial for the functioning neurons in the brain as information processors and so it is essential for the functioning of artificial neural networks. In general, neural networks are machines designed to mimic the cognitive process of a brain to solve a given task. The neural network is usually a computer system, which is designed to perform computations with the ability of self-adaptation through learning. This type of task with high intensity of interaction requires a special computer architecture with a lot of processing units called "neurons". Therefore we may quote the following definition of the neural network: A neural network is a massively parallel distributed processor made up of simple processing units that has a natural propensity for storing experiential knowledge and making it available for use (Haykin, 1994). The resemblance to the human brain has two layers:

- The learning process is based on acquiring experience from the environment;
- The main storage space of knowledge are neurons and synaptic weights between them.

The learning process modulates formulations between the neurons to adapt the model to solve the given task. This approach is already well established in theory and has enriched some successful applications in many diverse fields (Bernard and Samuel, 1985; Haykin, 1994). The neural network is also able to rebuild its topology by creating new synaptic connections, which is similar to the human brain in which neurons can die and create new connections as well. The main quality in terms of the utility of neural networks is the capability to adapt. The structure of synaptic connections can restructure and build new relations, which allows better adjustment to the surrounding environment. Minor changes in the environment can be easily incorporated into a neural network since the learning process is flexible and can be performed in real-time, which is especially valuable with nonstationary boundary conditions. Moreover, neural networks can transmit information from the cause to the effect (Marwala, 2015). The structure of the neural network determines the learning algorithm incorporated in it. Deciding on which system will be better in solving a given problem

than others, we need to consider aspects like computational limitations or calculation optimization. We may then consider the classification of artificial neural networks according to their architecture:

1. Single-Layer Feedforward Networks
   Neural networks can be organized in the form of layers. In the simplest architecture of the system, the inputs layer of source nodes is projecting directly onto the output layer. Described mapping is only one-sided. This type of neural network has been presented in Fig. 2.1, where we have four nodes on both sides: input and output. The described network is called a single-layer network because there is only one layer of output computation neurons. We do not count the input layer of source nodes, because no calculation is performed there.

Fig 2. Feedforward network with a single layer of neurons. Source: (Haykin, 1994).

2. Multilayer Feedforward Networks
   The other type of architecture of the feedforward neural network is extended to have hidden layers of computational neurons. They are called "hidden" nodes because they are not exposed to any of the sides of the model: input nor output. The role that they play in the model is to modulate data between input and output to provide a better solution. By adding hidden layers to neural networks, the performance of the system is enhanced. In this type of architecture, the input layer sends a signal to the computation nodes in the second layer, then the second layer sends a signal to the third layer and the chain of information continues through all hidden neurons to the output layer. In the standard setup, the signal travels through all the layers respectively, without omitting any calculation nodes. The overall data transfer in a multilayer feedforward neural network from the input to output has been shown in Fig. 2.2. To shortly describe the illustrated neural network, we can use markup 10-4-2, which means that there are 10 source nodes, 4 nodes in the hidden layer and 2 output nodes.

Fig 3. Fully connected feedforward network with one hidden layer and one output layer, Source: (Haykin, 1994).

3. Recurrent Networks

A recurrent neural network in diversity to feedforward neural networks includes an additional at least one feedback loop. The recurrent neural network presented in Fig. 2.3 includes one layer of neurons with each neuron feeding its output signal back to the inputs of all the other neurons. We can also distinguish self-feedback loops, where each of the output nodes provides the information back to its input. Furthermore, see that network architecture from Fig. 2.3 do not include any hidden neurons. If that was a case, a feedback connection can originate from the hidden nodes as well as from the output nodes. At any stage of the feedback loop, the neural network can be exposed to additional input if needed. This type of architecture is the most commonly utilized, because of better overall performance and ability to provide sufficient solutions despite data scarcity. This system model is especially valuable if we have little knowledge about the data source.

The Hopfield network is a specific type of Recurrent Network in which every neuron has corresponding unit-time delays as shown in Fig. 2 and 3. The number of feedback loops is equal to the number of neurons. On every loop, the time-delayed element is input back to the network and feeds every other neuron in the model, so that self-feedback will not occur (Haykin, 1994). The Hopfield network is initiated by setting up the values of the units to the desired start pattern. The feedback loop continues until reaching the convergence, which is indicated when any value cannot be changed in the updating phase.

Fig 4. Recurrent network with no self-feedback loops and no hidden neurons, Source: (Haykin, 1994).

All of the presented neural network architectures may be used in the creation of the system, which will enhance the decision-making process. The most applicable one will be chosen according to the input data structure and the complexity of the solution we want to output. We also need to take into consideration available computational resources (Kwaśnicka et al., 1998).

Artificial Intelligence in Decision Making

The early idea of incorporation of Artificial Intelligence into decision making is the Expert System presented by Pomerol (1997). The basic functionality of this model is to process input information to diagnose the output. The strategy is to input the facts, which best describe the given situation and output the recommendation of action or assessment of the proposed solution. The best performance of the Expert System can be observed with controlling live parameters of the current process. According to input data, the system can assess the recent state and determine the action to undertake. The basic functionality of an expert system in comparison to the decision-making process has been shown in Fig. 5. Standard decision-making process consists of:

1. Diagnosis - a perception of a current state from the perspective of past and presence;
2. Choice of action - definition of multivalued function which describes the future states $\psi(S_i, A, E)$, where S_i is available current state, A is chosen action and E is an aftermath of action A;
3. Look Ahead - the prediction of the future state according to A - action, and E – aftermath;
4. Preferences - maximization of the desired outcome.

Fig 5. The simplified decision process. Source: (Pomerol, 1997).

Expert Systems exclude user interference in decision making and that is why some academics describe them as being objective. On the other hand, there is a question of reliability on the system and that is why most system development is spent on verification of the inserted knowledge base. The interpretation of function ϕ is a set of rules supported by the system. This set can be a discrete function or fuzzy boundary conditions.

Knowledge-Based Improvement

The Knowledge-Based Improvement model introduced by Robinson et al. (2014) is presented. The main motivation behind the creation of this system was a curiosity about the decision-making process and eagerness to improve it using operating systems. Since sophisticated models are not always the best approach, the creator of KBI emphasizes that it is not meant to be complex. Instead, the main goal was enabling the prediction of an outcome of alternative decision-making strategies. Although it seems like a knowledge-based system has very limited capabilities, the author states that the real complexity of human decision making is impossible to model and so the involvement of decision-makers is vital in the process. In such a case, the main objective is to identify improvements to the decision-making strategies employed.

The KBI model has been shown in Fig 6 and it consists of five stages:

1. Understanding the decision-making process - At this stage, the decision-making process is being investigated. The recognition of decision-making strategy components like decision variables, decision options, decision attributes, and attribute levels is undertaken. We may take for instance the malfunctioning machine in an assembly line, as a case in which the person responsible for making the decision needs to decide: when to repair the machine and to whom he needs to hand-over this task. The decision variable may consider two options: immediate repair of the machine or waiting until it will stop working at the end of the shift. In the recognition phase, we need to take into account time, which will be needed for the repair and the type of failure, which will be taken as a main factor for the decision function formulation.

Fig 6. Knowledge-based improvement. Source: (Robinson et al., 2014)

To collect data from decision-makers we can make observations, but in many cases, it is very time consuming, because much time elapsed until the decision is reached. It is also difficult to note every significant decision-making factor solely based on observation, especially when most of them are changing in time. To solve this issue author of KBI proposes a Visual Interactive Simulation (VIS). In this case, the decision-maker is taking part in interactive simulation and being asked questions. The simulation ends with reaching a final decision by the user. The system then processes all collected data into decision variables $D_{i,j}$ and decision attribute A_i.

The decision-making process in KBI is represented with two-row vectors, where the first one represents a decision and the second one represents the attributes of the decision:

$$D_{i,j} = [d_1, d_2] \quad (1)$$

$$A_i = [a_1, a_2] \quad (2)$$

Where d - decision variables and - decision attributes. The relation between both of this vector can be described with the function:

$$D_{i,j} = f(A_i) \quad (3)$$

Where $f(A_i)$ is a decision-making strategy. Since this function is unknown, we need to proceed with steps 1-3 to determine it with the help of AI techniques. In this case, a set of collected example decisions will be needed.

2. Data collection - After establishing, which factors determine the decision-making process we may start the data collection stage. In this step essentially the system creator needs to create a matrix of data relevant for decision making. In each example, the data source should include the value of each decision option and attribute level.

3. Determining the decision-making strategies - At this stage, all data collected by VIS are processed into decision variables $D_{i,j,}$ and decision attributes A_i. These parameters are then used in the preparation of a decision-making strategy of individual decision-makers. We can create this model using the rule-based expert system or artificial neural networks. In most cases, an expert system is favored among the others because it can create decision trees, which represent the decision-making strategy and are more explanatory. In the decision, the tree system can assign priorities to each of the attributes according to the similarity to the data set with the correct decision. Since each decision tree represents one strategy there is a need for creating decision trees for each decision-maker.
4. Determining the consequences of the decision-making strategies - When all decision-making strategies are created for each decision-maker the next stage of KBI is to assess the results and choose the winning strategy. The simplest way to make such an assessment is to input expected results into Visual Interactive Simulation and compare it with a decision reached by the decisionmaker. Each time the decision is reached, decision attributes are passed to AI. Of course, the participation of best decision-makers is vital for the best performance of a system, since the winning strategy is chosen from those which participated in simulations. Any strategy reached this point can be improved and that is why we need to proceed to the last stage of KBI.
5. Seeking improvements - At this stage, only the best decision-making strategies are being considered in a search for optimization. There are two approaches to do that. We can create a discussion panel, which will aim to improve chosen strategies or we can make incremental changes by combining the best strategies. The alternative is to employ heuristic strategies with search algorithms. After optimizing the strategy, we need to verify it. We can do that by testing it in VIS.

There are clear benefits when using the KBI model. With the utility of VIS, we can collect data more efficiently. Moreover, we can control this input data at any stage of simulation. There is an ability to repeat the simulations with the same conditions, which is vital for verification purposes.

Conclusions

Most of the industry sectors depend on technology and computers in particular. In the USA we can hear that self-driving cars will lead to the unemployment of drivers. That may be the case in the future, but the labor market is constantly changing. In the past, there were thousands of people working on the connection of phone calls at the central office. Right now, it sounds almost ridiculous when we look at our smartphones. Fifty years ago, no-one would even think that people will be employed to write computer code and now millions of people are doing it and most of them are well off. The point here is that industry is constantly changing and we need to be aware that (Rudek and Heppner, 2020):

1. Even though some people may lose their job it is not happening overnight and there will be time to adjust to new conditions on the labor market;
2. Technology may take some of the jobs while creating new ones.

There is always a need to perceive emerging technology from different perspectives. Although some of the opinions sound very farfetched and alter reality it is good to exercise our trust. When we had our first sight on the internet most of the people didn’t know how to approach it from a legal standpoint. The United States Government decided at the time to let this technology to freely develop. Thanks to this decision we have internet everywhere and it has enabled economics to move to completely new directions. The main obstacle which may stand on the way of evolution of Artificial Intelligence is over-legislation.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

The term 'smart' has been used as a buzzword over the last decade. Its real-life understanding is shaped by citizens, enterprises, academics, public organizations, etc. This paper analyses the term 'smart' using the text-mining methodology with an iterative probabilistic model and provides a short as well as an intuitive definition based on the real-life understanding of the term. The term 'smart' is a subjective and multi-meaning concept. For most of the respondents, the term 'smart' perfectly fits with the words 'solution that is innovative and technological, an app'. There are rather limited linkages between the term 'smart' and 'Smart city'. The best fit provided variable containing words '(smart) urban planning and development'. Based on our research design and the discussion of the results, we propose a preliminary short definition of the term 'smart'. This research design can be used for more representative samples of the population. The paper aims to contribute to the debate about the real-life understanding of the 'smart' term. The citizens' understanding of the term 'smart' is important for the success of the 'Smart city' initiatives. With a better understanding of the term, researchers can adjust their socioeconomic surveys to ask better questions, while social and private entrepreneurs can implement problem-solving, innovative ICT ideas in the market and society.

Keywords: Citizens, Real-Life Understanding, Digital Economy, Smart, Definitions

Introduction

The term 'smart' is frequently used in scientific literature and citizen's everyday life (marketing campaigns, smart city, smart devices, etc.). Is there a reasonable real-life understanding of the term? The goal of this paper is to analyze the term 'smart' using the text-mining methodology with a probabilistic model and provide a short as well as an intuitive definition based on the real-life understanding of the term.

Literature dealing with 'smart' definitions are aimed mostly at the 'Smart city' concept (Albino et al. 2015). There is a multiplicity in definitions and frameworks dealing with 'smart' concepts. The most

popular Smart city frameworks are the Sharing cities (Boyko et al. 2017, Cohen and Munoz 2016, Hult and Bradley 2017) and the Sustainable cities (Ahvenniemi et al. 2017, Bibri and Krogstie 2017).

Frameworks should provide a real-life understanding of the term 'smart'. As suggested by D'Auria et al. (2018), when it comes to the term 'smart' and frameworks, it is necessary to analyze what activities agents do (innovation, learning, communication, etc.), then how they do them (organizational processes, devices, apps, computers, cars, etc.), and eventually who and with what or whom the activities are done (people, institutions, policies, etc.).

In the Smart city frameworks, we can find components or systems such as Smart economy, Smart mobility, Smart environment, Smart people, Smart factory, Smart Living, Smart Governance, Smart grids, Smart waste sorting and treatment, Smart spaces, housing and buildings, Smart devices, machines and things, Smart street lighting, Smart welfare and healthcare, Smart services, Smart government and governance, etc. Clearly, there is a common denominator of all these 'smart' terms and frameworks.

'Smart nation' is defined as: "*A smart nation applies digital technology and data to address strategic issues through a whole-of-government approach and in collaboration with citizens*." (Hoe 2016, p. 330). The adjective 'smart' in the term 'Smart grid' is about the application of ICT (smart meters) to end-users in order to monitor their consumption patterns. The adjective is not directly a characteristic of the grid itself (Kovacic and Giampietro 2015). The 'Smart (urban) mobility' definition is one of the most problematic and considered to be the vaguest of all 'smart' concepts. Working definitions are dealing with systems and technologies that generate data, information, knowledge, enhancing vehicles, infrastructure and deriving improvements for transport systems (Lyons 2016).

The term 'Smart factory' is considered to be the most extensive of the 'smart' terms. A systematic review of the literature found eight pillars of the term: decision making, cyber-physical systems, data handling, IT infrastructure, digital transformation, human-machine interaction, internet of things, cloud manufacturing and services (Osterrieder et al. 2019). 'Smart devices' or things and machines or the internet of things (IoT) are defined by their impact on individuals and society. They are considered to be social machines and provide new opportunities for humans and society (Smart et al. 2018).

We can define the term 'smart' or 'smartness' also in the context of devices and systems. "*Serious discussion of smart X needs to define what smart means in relation to IT-enabled devices and systems*." (Alter 2019, p. 2). Interacting dimensions of 'smartness' for systems, services and devices include 4 categories and 23 dimensions in total: (1) information processing, (2) internal regulation, (3) knowledge acquisition, and (4) action in the world. Considering different viewpoints (Vasauskaite et al. 2017) there are 4 pillars of 'smart': (1) smart system, (2) smart process, (3) implementation, and (4) orchestration.

Recent trends suggest an integrated 'organic' approach to the term 'smart'. 'Smart' frameworks have anatomy and spatial dimension. The approaches can be based on fuzzy logic and measured by key performance indicators. Furthermore, it means that 'smart' frameworks and concepts can be planned, managed and monitored (Koutra et al. 2019).

Technocratic and organic views are being integrated; however, recent frameworks forget the well-being and happiness of citizens. A definition suggested by Lara et al. (2016, p. 9) is based on social aspects: "*Smart city is a community that systematically promotes the overall wellbeing for all of its members, and flexible enough to proactively and sustainably become an increasingly better place to live, work and play.*"

What is the real-life understanding of the word 'smart'? To summarize current understanding, there is no commonly accepted short definition of the term 'smart' in the academic sector. In the business sector, the meaning of the term 'smart' is driven by the marketing departments that are offering 'smart' products and services. Positioning and branding play an important role. 'Smartness' is mostly a feature

of a product or a service in which ICT plays a major role; however, multiple meanings of the term are a feature of the business sector marketing strategies.

Definitions of the term 'smart' and 'Smart city' are normative. *"…connecting 'Smart' in 'Smart cities' to advanced ICT is the most constructive way forward. Thus, it is a normative choice to use the concept* instrumentally." (Höjer and Wangel 2015, p. 339). The synonym to the adjective 'smart' is 'intelligent'. It means that something or someone (a device, a system, a person, etc.) acts in an intelligent way.

'Smart' as an adjective means a lot of other things in both American and British dictionaries as well (fashionable, quick, clean, stylish, clever, effective, rude, etc.). As a result, the term 'smart' is an intended multi-meaning and subjective (normative) concept. That is why we applied the text-mining technique to basic open questions so that respondents can create their own definitions of the term 'smart'.

Materials and methods

We used a sample of students from social science studies at one university. The selection included a full sample of students from compulsory lectures (master and bachelor degree courses) from the academic year 2019/2020. The return rate was 100%; however, about 7% of responses were empty or incomplete. The total number of complete respondents is 180. The questionnaire was based on the concept of real-life understanding and Smart city linkages (Figure 1).

Figure 1: Concept of the survey

The Smart city linkages were added because the university is located in a Smart city and we want to test the relationship of the term 'smart' and 'Smart city' (Figure 1). The questionnaire was short and included only open questions. Respondents had about 20 minutes to complete the survey, there was no time pressure or other pressures as the submission was anonymous and voluntary.

1. How would you define the term 'smart'?
2. What does the word 'smart' mean to you in your daily life?
3. Do you personally use something that can be described as 'smart'? What is it or what purpose does it have?
4. In what context (areas) did you most often hear the term 'Smart city'?
5. What do you consider to be positive or negative in relation to the term 'Smart city'?

There is a selection bias toward the young population studying in a large city at a university. The representation bias is evident; however, this paper is considered to be rather a pilot survey. The goal is to test-drive a new iterative data-mining methodology and present the first results. The bias in data

processing is possible because data mining was performed by humans and not a software tool. Keywords were selected from the definitions and other answers.

We preferred manual data processing using two steps. One person selected the most used words that describes the respondents' views. In most questions, it was either an adjective, substantive, two-word or three-word phrases. In the second step, categories of the most used words were created. The threshold was 20 occurrences in one category and the rest of the words went to the category 'other'.

We created 5 definitions of the term 'smart' using the responses for the first question "How would you define the term Smart?". We then iteratively tested the relationship of each definition which had more words with factors derived from the rest of the questionnaire. The first definition is based on the words 'smart solution'. The second is based on the words 'smart solution, innovative, technological improvement'. The third definition is based on words in the second definition and the words 'something useful and effective'. The fourth definition is based on the words in the third definition and the words 'something that simplifies things' and to the fifth definition, we added all other meanings (Table 1).

Table 1: 'Smart' definitions – text mining summary

#	Q1: 'Smart' definition	Observations	Mean	*Smart$_i$ definitions*
1	('smart') solution	180	61 %	Definition #1
2	Innovative, technological improvement	180	23 %	Definition #2 (1+2)
3	Something useful, effective	180	18 %	Definition #3 (2+3)
4	Something that simplifies things	180	17 %	Definition #4 (3+4)
5	Other meanings	180	16 %	Definition #5 (4+5)
6	I do not know	180	5 %	

The regression uses logit probability modeling (Equation 1). It was used to test the concept (Figure 1) of the pilot survey. The key vision was to let the respondents shape their understanding of the term 'smart' using four dimensions (Figure 1). We considered for this pilot estimation only the two most pairwise correlated factors with the particular definition (in Table 1). In further research, we can use all of the factors at once. However, in this pilot research we used only a limited number of regressors to account for possible issues with statistical over-identification.

$$Smart_i \begin{cases} s_i^* = 1 \; if \; s_i = \left(X_{1i}\beta_1 + \varepsilon_{i_1}\right) > 0 \\ s_i^* = 0 \; if \; s_i \leq 0 \end{cases} \qquad (1)$$

The dependent variable $Smart_i$ (where i=1, 2, 3, 4 and 5) is estimated using the logic of the logit marginal effects procedure. The $X_1\beta_1$ is a vector of explanatory variables. Those are dummy variables based on frequencies in Tables 3-6. The ε_1 is a random-error term. The vector of parameters to be estimated is denoted β_1. All robust standard error coefficients are reported at 5% alfa.

The sample consists mostly of full-time bachelor degree students in their first year of studies at Jan Evangelista Purkyne University in Usti nad Labem, Czech Republic. There are more females (58%) which reflects the current trend in Czech universities. To add some variability, combined (distance) study (26%) and master's degree students (19%) were added (Table 2).

Table 2: Socioeconomic background of participants

Respondents	Observations	Mean
Master's program (MA/BS)	180	19%
Combined study (Yes/No)	180	26%
Years in the program (1-4)	180	1.41
Female (F/M)	180	58%

To sum up the rest of the survey, for most of the students the term 'smart' means something different in real life. It is something that simplifies things, it is a smart solution, it is also innovative, technological improvement, a smart device and for a fraction of the respondents, 'smart' means nothing special in their daily lives (Table 3).

Table 3: 'Smart' in real life (Variables)

Q2: Real-life meaning	Variable name	Observations	Mean
Simplifies things	RL Simplifying	180	28%
Smart solution	RL Solution	180	23%
Innovative, technological improvement	RL Innovative	180	21%
Smart device (phone, car, etc.)	RL Device	180	19%
Nothing special	RL Nothing	180	17%
Other meanings	RL Other	180	14%

To validate the understanding of the term, we asked about using something 'smart'. Most of the students use 'smart' devices (76%) like phones, car and other internet-connected devices. They use these devices for communication and it is represented by all kinds of mobile applications as well as ICT. About 14% of respondents do not consider themselves as users of something labeled 'smart' (Table 4).

Table 4: Use of something 'Smart'

Q3: Real-life usage	Variable name	Observations	Mean
Smart device (phone, car, etc.)	USE Device	180	76%
Mobile Apps and technologies	USE Apps	180	23%
Not a user of something 'Smart'	USE Nothing	180	14%
Other meanings	USE Other	180	4%

The third dimension adds links to the smart city concept. The words 'smart city' is for most of the students (45%) confusing and they don't know the context or meaning of it. The most popular dimension was transport and cars (16%), followed by innovations, technologies (16%) and in the last place was Spatial planning and development, environmental context and other meanings.

Table 5: 'Smart city' context

Q4: What is a Smart city?	Variable name	Observations	Mean
Don't know	SC Unaware	180	45%
Transport and cars	SC Transport	180	16%
Innovations, technologies	SC Innovation	180	14%
Spatial planning and development	SC Urban	180	11%
Environment	SC Environment	180	8%
Other meanings	SC Other	180	7%

The last question was about positive and negative connotations about the term 'Smart city' (Table 6). Mostly, the considerations were positive. For those who knew something about it (73%), they felt that Smart city facilitates something, which makes things faster and useful (32%), while they believed it indicated an improvement (24%). There were also negative considerations like dependency on technologies and other negative meanings which involved all kinds of costs (13%).

Table 6: Positive and negative 'Smart city' connotations

Q5: Smart city context	Variable name	Observations	Mean
Facilitation (faster, useful, etc.)	PN Facilitation	180	32%
Nothing, don't know	PN unaware	180	27%
Improvement	PN Improvement	180	24%
Dependency on technologies	PN Dependency	180	14%
Other negative meanings (costs)	PN Other costs	180	13%
Other positive meanings (benefits)	PN Other benefits	180	8%

Results

The iterative methodology shows some interesting dependencies. Statistically significant variables are in all four dimensions of our concept (Figure 1). In the first dimension (use of something 'smart' in real-life), the logit probability to define the term 'smart' is higher when we deal with devices, something innovative with other meanings. Those other meanings were mostly words like sustainable and ecologic. Other real-life meanings (making things simpler, smart solution, and nothing special) were not statistically significant.

In the second dimension (usage of something 'smart'), the situation is more complex. When it comes to narrow definitions (1st and 2nd), respondents were more likely not a user of something 'smart'. The higher probability to define something 'smart' is when using mobile applications. Other real-life use meanings were not statistically significant.

The linkages to 'Smart city' concepts and frameworks are quite surprising. Respondents are mostly unaware of what a 'Smart city' is when it comes to narrower 'smart' definitions. The only statistically significant variable is about urban development and spatial planning. Other smart city linkages (transportation, innovations, environment and other meanings) were not statistically significant.

Table 7: Logit probability - factors of 'smart' definitions

Logit Probability	Definition #1	Definition #2	Definition #3	Definition #4	Definition #5
RL Device	0.866	0.790	1.861**	1.754	
	(0.51)	(0.65)	(0.75)	(1.09)

Constant	0.894	0.746	1.629	1.032	1.535***
	(0.54)	(0.80)	(0.98)	(0.90)	(0.57)
Observations	180	180	180	180	180

In the last dimension, we explore the positive and negative connotations of the term 'Smart city'. Under the variable facilitation, we put together words like purpose, make something easier and simpler. This meaning reduced the probability of our definitions. Other variables dealing with 'Smart city' connotations (Dependency on technologies and other benefits) were not statistically significant.

Discussion and conclusion

The term 'smart' is a multi-meaning concept (Höjer and Wangel 2015). For most of them, the term 'smart' perfectly fits with the words 'solution that is innovative and technological, an app'. This meaning is based on innovations in information and communication technologies. There are rather limited linkages between the term 'smart' and smart city. The best fit provided variable containing words 'urban planning and development'. 'Smart city' frameworks solve urban planning and developmental problems.

The widest definition (number 5) offers a simple meaning to the term smart. The term 'smart' relates to the word 'application' (or App). Applications are based on hardware and software (ICT components) and have multiple uses. They are based on data, provide information and effectively contribute to the well-being of society. Apps are the output of processes' digitalization. They also utilize new ICT trends such as artificial intelligence and the internet of things.

This paper provided an experimental approach to untangle the meanings and definitions of the term 'smart'. To some extent, it seems we speak about innovations that involve ICT (Alter 2019) when we speak about 'smart' things, people, cities, etc. Our short definition based on the real-life understanding of the term is:

'Smart is a problem-solving and innovative solution based on ICT.'

ICT innovations and applications are fashionable which solve problems and tasks. They are faster than humans and can analyze data without getting tired. This makes them quick, stylish, clever, effective and sometimes rude because they are often without prejudice while they can replace humans. These technologies act in an intelligent way because they are made by humans (digitalized processes). Humans use ICT (systems, devices, solutions, etc.) that can collect data and intelligently interpret them to provide information and knowledge to solve problems.

Abstract

Immediacy of such a problem as information competence formation is due to the necessity of continuing improvement of pedagogical approaches, methods and technologies of educating specialists how to use information technologies in their professional activity to provide for their correspondence to the stable and outrunning level of society development. The article aims at the

formation of methodological approaches to the pedagogical process studying the use of information technologies in the framework of post-graduate continuing education taking into account the professional requirements and work specifics. The leading method of the problem study is the method of involved observation that enabled to make authentic comparison and analyze inquiries of 349 professionals attending the courses of continuing education.
The article shows that the applied pedagogical approaches and methods have to correspond to the modern level of information technologies and digital education development, characterized by qualitative changes in the technologies that process and transfer data and widely use the intellectual decision making systems. It states the results obtained in the practical implementation of the offered theoretical and methodological approaches to the process of health professionals' information competence formation. This results in the developed complex of methodological approaches to teaching information technologies at the general scientific, specific scientific and method and technological levels enabling the formation of health professionals' information competence. The article can be useful for teachers of the institutions involved in professionals' continuing education.

Keywords: Information Competence, Continuing Professional Education, Methodological Approaches, Health Professionals.

Introduction

Issue Urgency

Healthcare is currently one of the most significant and highly technological areas of human activity. It is stringent that specialists in any healthcare area (therapeutic, diagnostic, organizational, preventive and scientific) use information technologies in their activity.

Due to pressing social, economic and technological changes that occur at this time, health professionals are expected to constantly increase their level of information competence. The competence is a complex structure that unites learning criteria, psychological makers of the personality, potential capabilities, motivation, system of values, responsibility, and anticipation of action outcomes manifested when using digital technologies to solve practical tasks to provide population with medical aid, preserve and improve its quality of life.

Aggressive dynamics of environmental processes and phenomena, infomedia increased density, constant information update, and use of highly technological diagnostic and therapeutic equipment make continuous education in information technologies acquire particular importance for health professionals.

Scientific solution of any issue requires a distinct methodological regulation which is an important attribute of any conception determining its type, nature, the system of principles and methods of organization and building theoretical and practical activity. That is why developing a set of methodological approaches at the general scientific, specific scientific and methodology and technology levels of studying the way the information competence of health professionals is formed belongs to the pressing issues.

The current situation in the sphere of continuous professional education of health professionals

According to the Russian Ministry of Public Health Order 'On approval of the procedure and time for enhancing the professional knowledge and skills of healthcare providers and pharmacists using additional professional educational programs in educational and scientific institutions', it is the employer who determines whether professional retraining and pupillage is necessary after graduation of the university. However, they must be carried out at least once every 5 years during the entire labor activity.

The use of modern information technologies is one of the issues considered within the frames of the state additional professional training of doctors. The attendees belong to highly qualified professionals who use modern digital diagnostic and therapeutic equipment and software needed for proper functioning of medical institutions on a daily basis.

Peculiarities Of Teaching Information Technologies In The Courses Of Additional Professional Education Of Health Professionals

The educated health professionals represent various medical institutions that differ by a territorial attribute and department participation, size, equipment and specialization. A number of hours when informational support is studied is low. In a modern world, a competent specialist and a director must foresee how the situation can be developed, be aware that specific information must be obtained, know how to get the needed information selecting a proper source, be able to analyze, synthesize, use, transfer data using modern means of telecommunications and build it in its activity, and use it to solve practical and research tasks (Ovsyanitskaya L.Y., Yurasova E.V. (2015).

That is why it is necessary not only to cover the novelties of health maintenance hardware and software, changes in the legislation related to the informational support of medicine, features of automatized process of personal and confidential information but also to show the vector of medical informatics development.

Status of a problem

Health professionals are highly qualified people with a good professional and social status. They are capable of studying and are highly motivated to education: they study and participate in meetings, consultations and conferences on a daily basis. That is why they treat the process of education not as a new activity but as a continuing regular professional activity.

The educated health professionals represent various medical institutions from village hospitals to large federal centers. Thus, specific theoretical and methodological approaches to teach courses related to the use of informational technologies in medicine must be developed. The approaches should take into account the specific features related to the organizational, professional and psychological features of all health professionals who attend the courses.

Knowles (1984), Zmeev (2007), Chychuk, V. (2015) and others describe the features of methodological approaches that have to be used when working with adults. Sharlene Hesse-Biber (2015), Melanie Nind & Sarah Lewthwaite (2018), Clark, J., K.Laing, D.Leat,R,. Lofthouse, U. Thomas, L.Tiplady, and P. Woolner (2017), Knewstubb, B., and H. Nicholas (2017), Nilsa A. Bosque-Pérez P. Zion Klos Jo Ellen Force Lisette P. Waits Kate ClearyPaul Rhoades Sara M. Galbraith Amanda L. Bentley BrymerMichael O'Rourke Sanford D. Eigenbrode, Bryan Finegan J.D. Wulfhors tNicole Sibelet Joseph D. Holbrook (2016) discuss complex methodologies of teaching interdisciplinary disciplines at universities. Blumental & Glaser (2007), Masic, Pandza, Toromanovic (2011) reviewed the issue of teaching informational technologies to health professionals. Cartelli (2012), Ovsyanitskaya (2019) presented the results of modern technologies studies in digital literacy and medical competence.

Study Hypothesis

The authors solved the following tasks during the study: 1) select experimental and control groups of health professionals; 2) teach the experimental groups using the offered theoretical and methodological approaches; teach the control group using traditional methods; 3) compare the levels of information competence of health professionals in the experimental and control groups; 4) analyze the experimental results, estimate the effectiveness of health professionals' information competence formation.

Methodological Framework

Study Objectives

It is necessary to develop and implement the methodology of teaching the modules related to the usage of information technologies in medicine to form information competence of health professionals that will consider the age, module specificity and high educational level of doctors.

Theoretical and Empirical Methods

The authors used a complex of various complementary methods to check the hypothesis. These included theoretical (analysis of literature, regulatory, legislative, guidance, working documents and materials related to the study object; study and generalization of innovation pedagogical experience, analysis, and synthesis) and empirical methods (participant observation, summative and formative pedagogical assessment, questioning, testing, interview, conversation pieces and methods of mathematical statistics).

The authors used the authentic assessment to estimate how the material was studied. The assessment is used in practice-oriented education and estimates knowledge and practical skills of those who study in a classroom under the conditions that were close to the real life, both daily and professional.

Study Base

The Ural State Medical Academy of Additional Education and therapeutic institutions of Ekaterinburg, Zlatoust, Kurgan, Chelyabinsk, Magnitogorsk, Miass, Orenburg, Orsk, Tyumen formed the study base.

Stages of the study

The study had three stages.

During the first stage, the authors examined the specific features that have to be considered when teaching informational technologies in medicine and stated pedagogical conditions needed for successful achievement of the purpose.

The investigators developed the suggested theoretical and methodological approaches to health professionals' information competence and implemented them into the real pedagogical practice at the second stage.

The third stage generalized the results of the pedagogical experiment to produce information competence in health professionals using the traditional and suggested method and considering implementation of all substantiated pedagogical conditions.

Assessment Criteria

The authors assessed whether the education was effective based on the results obtained by health professionals when solving case problems that approached the real professional activity to the greatest possible extent. Tests reflecting various aspects of information competence were offered as well. The authors processed the results with the methods of mathematical statistics.

The course and description of the study

2.5.1. Uniar approach as the general scientific basis of research

By choosing the methodology that will be the general scientific basis of our study, the authors first and foremost examined the connection between informatics and medicine.
Medicine and informatics are sundered like the poles. They developed independently for thousands and decades of years, respectively. In the middle of the 20th century the sciences came into contact as

electronic means of data processing appeared. Joint developments occurred. However, there was no integration of these sciences.

Analysis of interrelation between medicine and informatics within the last decades showed that it is neither integrative (mutual penetration or union of any elements) nor transdisciplinary (joint trial or studying of either one subject, object, environment, or transfer of the study methods of one science to study another science in order to obtain the result). When informatics and medicine interact, one science helps the other one to reach a high qualitative level without interfering into the science that develops in parallel. A need in the development of subsequent technologies can initiate their development.

The authors introduced the term 'uniar' (unio (lat.) means union) denoting the principle of development for parallel sciences by joint solution of the occurring needs (Ovsyanitskaya, 2013). It results in the occurrence of qualitatively new technologies in every interacting science. Considering the uniar interaction between medicine and informatics and taking education as continuing professional activity of health professionals, the authors presumed that the approach to interaction between the teacher and healthcare professional must be uniar as well.

A uniar approach is a methodological approach that enables the interacting subjects of the pedagogical process to solve the occurring tasks. The main notion mentioned in the educational process when using the uniar approach is uniar interaction (communication between a teacher and a student aimed at the joint solving of occurring professional issues).

The basic method of educational process construction based on the uniar approach is the dialogue method. That is how the discussed issues became diversified and pressing. Moyles, J., S. Adams, and A. Musgrove (2002), Nind, M., D. Kilburn, and R. Wiles (2015) and Powell, E. (2005) discussed how to include the dialogue into the educational process.

Currently the situation changes so fast that to follow the points above, a teacher needs continuous knowledge of various aspects associated with the application of informational technologies in medicine. Health professionals attending the courses of post-graduation and continuous education for doctors form the only available source of reliable, pressing, diversified and adequate data.

Uniar interaction is a management process with an obligatory feedback. A teacher's task is to develop the educational process so that the data obtained during discussions or when doing home tasks associated with healthcare issues for their companies and institutions, public solution of cases could become the correcting module that makes a lesson pressing, useful and highly professional.

This approach is based on the elements of mutually profitable and interesting dialogue. It creates a climate of partnership in class enabling health professionals to improve their qualification in the sphere of information technologies and letting teachers be aware of the current needs of medicine in information technologies as well as modify and adapt the lesson for other groups.

2.5.2 Systemic and synergetic approach as the specific scientific basis of research

The specific and scientific methodology of our study includes the systemic and synergetic approach. The approach is a set of principles that determine the purpose and strategy of complex issue solution. This method takes an object (that has a problem) as a system, decomposes a complex problem into elements, and retains the elements as a whole. First, the synergetics appeared in studies of natural science. Then as the principles that manage the self-organization processes don't depend on the nature of the systems, the synergetics turned into a multidisciplinary approach within the frameworks of modern world view philosophical concepts. The system can never be taken separately from the environment which is also a complex system, in its turn. In synergetics, an emphasis is made on the conformity of interaction of elements when a single unity is formed (Bronwyn Hall, Kirsten Howard (2008).

According to the studies, the pedagogical system of continuing education of doctors is a functionally managed dynamic direct-feedback structure consisting of a set of subjects of the pedagogical process (teacher, health professionals and employees engaged in the organizational and methodological activity), contents, methods, forms, material resources and means of the pedagogical process. It was created to approve regular education of health professionals by statute.

To properly apply the methodology of synergetics when building health professionals information competence, the system of continuing education of doctors must correspond to the required criteria and represent an open, self-organizing and non-linear system.

An open system is a system that exchanges data, substance or energy with the environment. Continuing education of health professionals means that there is a constant exchange of data and knowledge between teachers, practitioners at the medical institutions where some classes are held, and attendees. When a conversation is managed based on the principles of synergetics, the obtained inconsistent data (facts, ideas, proposals bon during a conversation, personal and professional experience) can be turned into qualitative knowledge that can be implemented by attendees after the course.

Self-organization is a process or processes inside the system that enable its optimal functioning, self-restoration and self-change. It is typical of andragogical systems. Self-organization arises when there is an interaction between an accident and necessity. It is associated with the transition from instability to stability. Initially all attendees have different levels of theoretical and practical training in the sphere of informational technologies and a recognized necessity in generating a high level of information competence. Implementation of attendees' individual educational paths, change in the rate of group education if needed and use of individual means and methods.

Non-linear values are as follows: availability of alternative ways of development and possibility of their selection; ability to influence the rate of process development; irreversibility of the process after selection of a variant. The educational process is mostly optimized at the stage of its planning and design. However, a more freely format and lack of strict reference to training subject matter (as compared to secondary and higher education) allows a teacher to deviate from the selected plan and get an optimal decision considering the purpose set and pedagogical possibilities available. That is why professional training of a teacher (specializing in adragogy), intuition and additional lectures, multilevel study guides and control activities promote a reasonable change in the method, form and content of the lesson depending on the current need and initial training of attendees.

Optimization of the educational process means to study the required theoretical basis, solve pressing issues associated with the implementation of information technologies and getting practical skills needed for this group of attendees within a restricted interval.

Accidental replies and queries of attendees that arise during a conversation often seem important and interesting to everyone.

Adequate management of the educational process will lead to new knowledge and skills that could not be anticipated before.

Thus, use of the systemic and synergetic approach as a general scientific basis of the study enabled us to study the process of formation of health professionals' information competence by decomposing the systems, analyzing possible subsystems, their interrelation considering peculiar features attributable to the educational process of adult highly qualified people. Meanwhile, the basic attention was given to subsystems and their interrelation as parts of the whole i.e. the process of generating the information competence.

2.5.3. Cybernetic approach as the methodological and technological study basis of research

The cybernetic approach in our study forms its methodological and technological basis. As the system theory was cybernetic-based, the described methodological principles mostly reflect the cybernetic requirements. With the development of digital education, this approach acquires high prevalence (Ben Williamson (2015))

In cybernetic terms, the described system of advanced training as a whole is called 'a big system' i.e. it can be represented by a set of subsystems with constantly decreasing complexity. Cybernetic pedagogics treats the educational process from the point of view of management theory and on the basis of the systemic approach. Indeed, the educational process can be taken as a management process that has the managing (teacher) and managed (attendee) parties.

Considering the specific features of health professionals' continuing education environment, educational optimization is an algorithm of the teacher's actions related to the substantiation, implementation and control of qualitative educational decisions under specific conditions, and in the least necessary losses of time and efforts by attendees and teachers. A conscious need in motivated, responsible professionals with the system of values and capable of predicting their results when using digital equipment and technologies to provide for medical care of population can be considered as the basic control response.

Considering the formulated principles of cybernetics as related to the didactic systems (Mayer, 2013) we adapted the cybernetic sequence of management to the formation of information competence of health professionals.

First and foremost, the authors analyze the pedagogical system based on the systemic and synergetic approach. The target, component, comprehensive, deductive, subjective, and effective subsystems are selected and analyzed; their relations are assessed. Then the authors examine the management object (health professionals' activity), i.e. its basic knowledge, skills, experience, personality traits of the attendees associated with the age and digital equipment operation experience using the specialized initial testing or conversation. This is how gaps and achievements in the analyzed values were found.
Business Intelligence in MS Excel is an instrument analyzing the data of pedagogical monitoring. The use of data intellectual analysis provides for a multi-level processing of pedagogical monitoring data, reveals factors influencing the result and corrects the subsequent work of the educational institution i.e. produces pedagogical management.

Вырабатываем и реализовываем оптимальную стратегию (программу) управления:

Formalized visualized data promote scientific planning of not an abstract but a specific lesson for certain people anticipating possible difficulties in mastering the educational material or no need to study a topic in detail. The optimal strategy (program) of management is developed and implemented:

- a fixed program if a lesson is given according to a pre-defined plan with insignificant regulation;
- a flexible program which is adjusted to the changing conditions preserving the system targeting and expedience.

Joint use of cybernetic and systemic and synergetic approaches enable to achieve as follows: the cybernetic approach studies the interrelation between a subject and an object of management following the direct-feedback channels and enables to define the ways of influencing the objects. Meanwhile, synergetics examines the reasons for the system properties.

Results

Pedagogical conditions that promote the optimal achievement of the set objective

When conducting theoretical studies and pedagogical research, the authors set the pedagogical conditions that enabled to practically implement the theoretical approaches suggested above for every level. The list of pedagogical conditions that promote successful achievement of the set purpose, i.e. health professionals' information competence formation to the greatest extent, is as follows:

- to use the means and methods of education adapted to the andragogical environment;
- to organize lessons based on the principles of synergetics and uniar interrelation between a teacher and health professionals where their professional problems and requirements are discussed;
- to assign some material for self-learning;
- to look through some regulations covering how to treat the data;
- to use active methods of education (case-technologies, business games, context education);
- to use intellectual methods of data mining to reveal hidden regularities and generate recommendations on the introduction of dynamic corrections into the self-guided work, development of individual educational paths for health professionals based on the obtained recommendations.

The course and results of the experiment

The authors performed an experimental work that enabled mathematical substantiation of the revealed tendencies and checking the effectiveness of the integrity of the offered pedagogical methods to generate the information competence of health professionals within the framework of continuing professional education to confirm the effectiveness of the developed approaches.

The stated objective determined the type of the basic tasks solved during the exploratory work:

- to determine the level of health professionals' information competence before training and if the traditional method is used;
- to develop the programs that diagnose the formation of health professionals' information competence within the framework of continuous professional education considering the specifics of medicine;
- to select and argue representativeness of the sample and statistical criteria that evaluate the working results;
- to evaluate the significance and tendency of changes during training;
- to find the most significant factors influencing the process of health professionals' information competence formation.

Health professionals conditionally divided into two groups (control group (CG-172 people)) and experimental group (EG-177 people) participated in the experimental work.

At the first stage, a test was used to find the initial level of health professionals' information competence. Comparison of its levels showed that health professionals from the both groups had a similar level of information competence development.

The number of health professionals with a low level of information competence was 35.47% in the CG and 25.99% in the EG; mid-level – 64.53% in the CG and 74.01% in the EG; and there was no high level.

The obtained results showed that competence of health professionals in informational technologies was problematic. The conducted statistical estimation confirmed the significance of the obtained results and homogeneity of the initial experimental conditions.

The authors obtained the following results after health professionals completed the courses. The CG used traditional methods whereas the EG implemented the approaches described above. After the

training was completed, a number of health professionals with the mid-level of informational competency was 90.12% in the CG and 7.91% in the EG; high level – 9.88% in the CG and 92.09% in the EG; and there was no low level. Fig. 1 displays the results before and after the experiment.

Fig. 1: The ratio between the levels of information competence in the CG and EG before and after the experiment

The results of tests, questionnaire, observation and conclusion based on the results of discussion by health professionals of the tasks that display a real situation associated with the use of information technologies to provide medical assistance to people were the primary entry data sources.

The experimental results show that implementation of the described theoretical approaches into the pedagogical practice was effective and confirm the rationale.

Discussions

Currently occurring social, economic and technological changes were the main conditions of formation of health professionals' information competence. High level of education and specific activity of doctors require specific methodological approaches to the building of the pedagogical process.

The experiment compared the level of formation between the two groups of health professionals. The study showed a significant growth of the controlled parameters in the experimental group as compared to the control group educated using the traditional method.

Conclusion

The integration of the uniar approach as the general scientific basis, systemic and synergetic approach as the specific and scientific basis and cybernetic approach as the methodical and technological basis for the method of health professionals' information competence formation suggested in the article enables to form the process of continuing education for health professionals in the sphere of informational technologies considering modern pedagogical requirements and trends of society development.

Recommendations

The testing results described in the article will be useful for teachers of medical universities and institutions involved in continuing education of health professionals.

Abstract

Food waste issue has become the focus of global attention including Indonesia. An impactful intervention need to start at University scope. This quasi-experimental study aims to reduce food waste among university lecturers. We used descriptive and injunctive norms together in prompt. Based on the behavioral change literature, it was hypothesized that normative prompt encourage consumer to reduce food waste compared to groups that are not given a normative prompt. As expected, normative prompt reduce food waste behavior among lecturers in intervention group. However, there was no significant difference of food waste statistically between intervention and control group. This study also contribute as a reuse way in food waste management hierarchy. Further limitations and implications are discussed.

Keywords: Behavioral change (intervention), Food waste, Prompt, Social Norm.

Introduction

Food waste issue has become the focus of global attention including Indonesia. Referring to the Food Sustainability Index data, Indonesia is the second largest contributor to food waste in the world (Economic Intelligence Unit, 2018). Every single person in Indonesia is predicted to produce food waste at least 300 kilograms each year. The phenomenon of food waste accumulation also causes various disadvantages in economic, social and environmental aspects (FAO, 2011). Given that humans still need food for life, food waste will not be zero. However, food waste can be prevented through interventions that can be started from small and routine activities such as at the university level.

Universitas Indonesia as a green campus in Indonesia (http://greenmetric.ui.ac.id/, 2019) is also important to pay attention to the food waste issue. As one of the UI Green Metric assessments, organic waste must be managed properly. Campus residents who daily carry out activities and produce waste can also play a role in this issue, including lecturers. Lecturers as part of the academic community have an important role in implementing sustainable development in the context of the university (Lozano et al., 2013). In addition, lecturers always having routine activity like training. By starting to intervene lecturers, we assume it can be a policy or movement.

Previous studies related to food waste behaviour found the external and internal factors that influence it. Russell et al (2017) found that negative emotions and habit became important predictors of the food waste behaviour. Other internal factors such as motivation (Neff, Spiker, & Truant, 2015; Schmidt, 2016), ideology (Narvanen, et al, 2018), perceptions and beliefs (Rowe et al., 2015; Painter et al., 2016; Whitehair et al., 2013) also correlated with the food waste behaviour. While the external factors found correlate with the food waste behaviour such as positive affections from the family (Porpino et al., 2016), cultural factors (Bozzola, Palu & Giorgi, 2017), food conditions (Iftitah, Sari, & Waryana , 2017; Kariyasa & Suryana, 2016; Nuraini, 2016) and social norms (Dorn & Stockli,

2018; Schmidt, 2016; Templeton, Stanton, & Zaki, 2016; Young et al., 2017). Based on these factors, we predict that the presence of social norms is the strongest factor in the food waste behaviour.

Some psychological interventions have been carried out by academics and practitioners, such as the use of social media (Gupta, 2016; Young, Russell, Robinson, & Barkemeyer, 2017), using nudge (Kallbekken & Saelen, 2013; Duursma, Vrenegoor & Kobus, 2016; Jagau & Vyrastekova, 2017), prompting (Chen & Jai, 2018; Stockli, Dorn, & Liecthi, 2018; Dorn & Stockli, 2018) and so on. However, the intervention technique by using prompt was assessed to have the greatest effect size among other intervention techniques to reduce food waste behavior (Stöckli, et al, 2018). Therefore, we hypothesize that using prompt of social norms (normative prompt) can reduce significanly the food waste behaviour.

Literature Review

Food Waste Behavior

Some previous literature has determined the definition of food waste behaviour itself. Aschemann-Witzel, et al (2015) defines the food waste behaviour closely related to behavior that is not responsible for the environment, the economy and the social consequences of food sustainability in the world. Furthermore, Qi and Roe (2017) explained that the behavior of food waste arises because of a cost margin formula that is expected. Expectations of these cost margins are combined from personal costs for food, internalizing the social costs of removing food and internalizing environmental costs from disposing of food. So the more food is thrown away, the more the individual will expect personal, social and environmental cost margins.

Social Norms

Cialdini and Goldstein (2004) emphasize that social norms are individual guidelines for behaving in a particular place or context. Cialdini and Goldstein (2004) mention social norms that are often commonly known, namely descriptive norms and injunctive norms. Descriptive norms are the norm that actually occurs in the majority of individuals in a community. Whereas the injunctive norm is the norm that should be carried out by the majority of individuals in the community. Activation of social norms can be effective when not only express descriptive norms but also contain injunctive norms (Nolan et al., 2008).

Normative Prompt

Prompts can be in the form of verbal or written messages delivered in a certain place that shows the targeted behavior. This message can be a reminder of the cause of the targeted behavior. Steg, Keizer, Buunk, and Rothengatter (2017) identify that prompt s the most effective strategy. Meanwhile, prompts are also popularly used because they are easy to implement, relatively low manufacturing costs, and can be considered the impact if applied correctly on a broader scale. Russell et al (2017) suggested that using prompt as a short-term intervention was able to prevent food waste behaviour. One study shows that giving prompt can reduce food waste behavior by 15% with simple printed words "All taste no waste - Eat what you don't and don't waste food" (Whitehair et al., 2013). The prompt technique in this study uses the main content that is communicating social norms. This technique refers to the intervention technique that has been carried out by Stockli, et al (2018).

Reseacrh Method

Sample, Design, and Procedure

Participants of this study were 35 lecturers from all faculty has attended the lecturer training in Universitas Indonesia training center. This training held for lecturer to raise their academic

competences. So there was no any related issue between training material and data collection for this study. This study employed a pre-test post-test between subject group design with one intervention (control group and intervention group). Data was collected only on weekdays (monday-Thursday). Conditions were counterbalanced across weekdays. All food menu between control and intervention group were controlled. To controll leftovers data from both group, we serve two basket bins in front of training room. During data collection, experimenters were present as covert observer. Then, after intervention has finished, we give all participants in both group a manipulation check, debriefing and souvenirs. Finally, only 33 participants has eligible for sociodemograpic data in intervention group (51,5% men, 57,6% master graduates, M_{age} = 33,24 years, SD_{age} = 7,332 years).

Intervention Material And Measurement

Normative prompt were placed only in intervention group. The message were in Bahasa Indonesia and were displayed on dining tables in front of training room. Prompt were made from acrilyc table tag landscape A4. Intervention group were added mini food bank. Mini food bank were made from container box with size 35,5 x 23,5 x 12 cm. Mini food bank were placed as one of option to reduce food waste behavior and as real action to create injunctive norms. Prompt contains two types of social norms (descriptive and injunctive norms). This is based on findings that combining two types of social norms is more effective than only invoking one norms type (e.g., Schultz et al., 2007). We also used gain message framing in descriptive norms (30% lecturers has joined to reduce food waste).

On the day of intervention, we collected food waste from everyday training collectively. Collective food waste were recorded by portable digital scale**.** This was decided because we felt difficulty to separate leftovers from each participants. This food waste measurment also based on findings that actual weighing can give us clear measurement of food waste behavior. Pre-test score recorded every Monday, and post-test recorded every Tuesday until Thursday on both group. Only morning snacking and lunch were not finished qualified as leftovers. Cleaning service attendant were instructed to ask for participants to throw away their leftovers in basket bins only in front of training room. This very useful for us to control participants leftovers during training.

Figure 1: Normative prompt and mini food bank design

Findings and Discussion

Findings

We tested the post-test data in both groups. By using the Mann Whitney test, it is known that p value is 0.275 (p> 0.05). The critical limit of this study was 0.05 or 95% confidence level. Then it can be concluded that there was no significant difference in food waste from the intervention group when compared to the control group.

Table 1: Statistical results of the Mann Whitney Test

	Food Waste
Mann-Whitney U	2,000
Z	-1,091
Asymp. Sig.	0,275

However, there was a decrease in the amount of food waste in the intervention group when compared to the control group. As is known that the first day intervention began on Tuesday and the food menu in the two groups was the same. So that the comparison of the weight of food waste is analyzed based on the day. In addition, the biggest difference in the amount of weight of food waste occurred on Thursday. Overall, it was found that food waste was lower in the intervention group compared to the control group of 3.69 kilograms or around 11.56%.

Figure 2: Percentage of food waste weight (kilograms)

Discussion

There are several theoretical implications that can be reported. First, the diction of "new 30% UI lecturers who try to reduce food waste" apparently supports the concept of approach-oriented gain message framing. That is able to encourage changes in individual behavior desired by the designer of the intervention (Shen & Dillard, 2009). Second, the combination of descriptive norms and injective norms at prompt has been able to increase the activation of social norms to reduce food waste behavior (Schultz et al, 2007; Stockli et al, 2018). Third, the normative diction used in the prompt confirms previous findings by Schultz, et al (2007) which states that norms are capable of being constructive in influencing a behavior.

The practical implications of this intervention study are also important to report. First, normative prompt use can be replicated in routine activities that have the potential to cause food waste. Second, the use of mini food banks as environmentally friendly containers also supports the zero-waste movement. Third, this intervention study also has implications for reuse stage food waste management (FAO, 2011). Fourth, the results of this intervention can also be extrapolated into a larger scope. In estimating extrapolation of UI lecturer training activities carried out around 15 times a year, normative prompt interventions and mini food banks can reduce food waste at least 73.5 kilograms and save at least 151.2 kilograms of whole food. Last, this study also has a domino effect, namely alleviating environmental issues and promoting food security. The food at a mini food bank was given directly to the janitors.

One important note in this study is the lack of statistical power. Based on statistical analysis using G*Power (Faul et al., 2007), it is known that there are only 6 data points which only produce an

effect size of 0.45 with power 0.11. Whereas previously we predicted this intervention study would produce an effect size of 0.80 with power 0.95. So that it can be concluded that the intervention study lost power of 0.80. When referring to the post-hoc G*Power statistical analysis that further research must be carried out at a site that is able to produce 37 data points in each group or around 74 data points to produce an effect size of 0.80 with power 0.95. Other choices in measurement can refer to previous research (Osbaldiston & Schott, 2012 ; Sebbane & Costa, 2018).

Conclusion

In implementing the intervention it is known that the normative prompt is able to reduce the behavior of food waste to the lecturer. This claim is supported by the results of the collective weighing of food waste which decreased to 11.56% in the intervention group. When compared to the control group, the addition of mini food banks in the intervention group was also able to save whole foods up to 7.63 kilograms. However, the statistical analysis using the Mann Whitney t-test showed that there were no significant differences between the two groups ($p > 0.05$). In other words, the hypothesis in this intervention study was not accepted or rejected.

Abstract

At present the area of studies devoted to modern managers is highly topical and particularly important in the context of their work with the culturally diverse workforce. The attitudes, qualities, and skills of managers working with multicultural teams have an impact on the style and way of employee management, employees' behaviour and cooperation in a team, their motivation, the quality of their performance, atmosphere at a workplace, and achieving organizational goals. The aim of the article, based on the analysis of the subject literature and the results of secondary research, is to determine the desirable characteristics of managers operating in culturally diverse work environment. The authors of the article focus on cultural differences stemming from employees' different nationalities.

Keywords: Managers, Managers' Qualities and Skills, Cultural Diversity, Multicultural Work Environment

Introduction

Managers - especially those who work in culturally diverse environment - play a vital role in modern management and the achievement of organizational goals. The challenges they face and responsibilities they shoulder result from the need to reconcile different ways in which employees from various – sometimes poles apart – cultures think and behave.

Modern managers working in multicultural environment and managing culturally diverse teams should be equipped with appropriate and up-to-date knowledge, relevant attitudes, qualities, skills and predispositions, which allow them to effectively operate in intercultural work environment, and should possess relevant experience which enables them to perform their managerial functions and roles in this environment.

In order to manage culturally diverse teams that work both in one location and in different geographical locations, managers need to be open-minded, flexible, culturally sensitive, and able to adapt quickly to diverse cultural backgrounds, so that they can positively motivate employees to take up new challenges and implement changes or innovative solutions together with other team members.

In the theoretical part the authors indicate which managerial qualities and skills are, in their opinion, particularly valuable in intercultural work environment and describe the managers' role in managing culturally diverse teams. The limitation of the article, of which the authors are fully aware, lies in a lack of their own empirical study investigating the issues discussed. Hence, the article is based on the analysis of secondary data and refers to the results of studies conducted by other researchers who reported their findings from the area investigated in this article.

Bearing in mind the above premises and the aim of the article, the following research question was formulated: What attitudes, qualities, and skills are particularly important for managers working in culturally diverse environment?

The Qualities and Skills Necessary for Managers Working with Intercultural Teams

Cultural diversity has been defined as "the representation, in one social system, of people with distinctly different group affiliations of cultural significance" (Cox, 1993). The authors of the article focus on cultural diversity of employees in terms of their nationality, which still poses a considerable challenge for many managers of multicultural teams.

The most important factor conductive to the achievement of the organizational goals is effective management (Mehri and Ramezan, 2016). The authors are convinced that the managers' attitudes, qualities, and skills greatly influence the efficiency of employee management in culturally diverse work environment.

As mentioned above, crucial challenges faced by managers working in culturally diverse environment are those which stem from employees' nationalities. Cultural differences in the context of national cultures were extensively studied by Geert Hofstede, his son, Gert Jan Hofstede, and Michael Minkow (2010).

Hofstede defined national culture as the collective programming of the mind that results from growing up in a particular country (Hofstede, 2007). His team described cultural differences in several dimensions: Power Distance Index (PDI)1, Individualism versus Collectivism (IDV)2, Masculinity versus Femininity (MAS)3, Uncertainty Avoidance Index (UAI)4, and Long Term Orientation versus Short Term Orientation (LTO)5, (Hofstede 2001; Hofstede, Hofstede, Minkow 2010). The next step in analysing cultural differences was made by Fons Trompenaars and Charles Hampden-Turner, who distinguished seven dimensions: universalism versus particularism, individualism versus communitarianism, specific versus diffuse, neutral versus emotional, achievement versus ascription, sequential time versus synchronous time, and internal direction versus outer direction (Trompenaars and Hampden-Turner 1998).

Although the subject literature discusses also other cultural dimensions that allow for the differentiation of national cultures, the four basic ones defined by G. Hofstede (PDI, IND, UAI, MAS) are sufficient to determine general cultural patterns which can be expected in given culture. In the context of the issues analysed in the article, this also refers to managers' attitudes, behaviours or values.

Managers working in culturally diverse environment should possess knowledge about different dimensions of culture and be familiar with their characteristics and implications for effective management in such environment. This knowledge, in the authors' opinion, is essential to understand and accept cultural diversity of members of multicultural teams.

Managers working with employees of different nationalities should be familiar with and take into account differences in their cultural and social background, as well as communication barriers and difficulties resulting from their cultural diversity. Therefore, they should be open, tolerant and able to quickly and flexibly adapt to different cultural realities. They should also be empathetic and sensitive, and, at the same time, possess strong personality and charisma to face challenges of working in multicultural environment.

International organizations employ people from all over the world. Such human diversity offers managers an opportunity to exploit employees' varied skills, knowledge and experience (Namiq 2018), thus they should know the members of their teams well in order to be able to fully capitalise on their potential.

An important aspect of managers' work in intercultural environment is their ability to identify values that are particularly important for employees from different cultures (Matić 2008). The employees' diverse value systems can influence the functioning of an organization in many ways, affecting e.g. the area of conflict management, change implementation, adaptation to the dynamically changing market, communication in teams, or engagement in the achievement of organizational goals.

It is worth noticing that modern employee management requires managers to be able to assure employees of their great value for the organization. Neglecting proper management in this area may cause various problems in the effective function of a team (Hasim and Hameed, 2012), particularly difficult to solve in face of cultural diversity of its members.

Managers working with multicultural teams should be familiar with and take into consideration the findings of scientific studies and analyses. "Hofstede (2001) and others (Ronen and Shenkar 1985; House, Hanges, Javidan, Dorfman and Gupta 2004) have found that different cultures reflect different values. Recently, researchers (Lenartowicz and Johnson 2002; Leung, Bhagat, Buchan, Erez and Gibson 2005, p. 368) have argued that, rather than determining whether or not culture makes a difference, we need to address ... how and when it makes a difference" (Hoffman, Frank, et.al, 2011, p. 1).

Modern managers who work in intercultural environment should also possess such qualities as: a high level of motivation, the ability to continuously broaden and update their knowledge, especially in the context of different cultures and markets, openness to change, the ability to overcome the employees' resistance in difficult situations, the ability to convince employees to implement innovative solutions, and the willingness to unceasingly search for new areas of their professional activity.

The manager should also be a well-educated, cultured person with impeccable manners and excellent communication skills, should act ethically at work and in relations with people, be highly motivated and ambitious, and be able to adapt to a whole range of situations and people (Petkovski 2012). Such qualities and skills are extremely advantageous in managing culturally diverse teams.

Other essential qualities of modern managers working with intercultural teams include their self-confidence, being success-oriented, assertiveness, resistance to stress, persistence, decisiveness, intelligence and courage. As far as highly desired skills of such managers are concerned, the ones worth mentioning embrace creativity, innovation, tact, diplomatic skills, and the ability to make quick decisions, all of which are particularly beneficial in managing culturally diverse teams.

"Along with roles and skills, a third means by which to understand managerial activities is that of mindsets. According to Gosling and Mintzberg (2003), managers have five mindsets or perspectives each linked to a key management task and applied in an integrated manner (a) managing self: the reflective mindset, (b) managing organization: the analytic mindset, (c) managing context: the worldly mindset, (d) managing relationships: the collaborative mindset, and (e) managing change: the action mindset" (Laud, Arevalo, et al., 2015, p. 7). Therefore, it should be noticed that in culturally diverse environment it is not only the managers' attitudes, qualities, and skills that matter but also their way of thinking about, for example, the working style of people from diverse cultures, the ways in which they communicate, express emotions, understand and solve problems, approach changes, or build interpersonal relations.

Managers who work in intercultural environment should be characterized by relevant interpersonal skills, extraversion, creativity, leadership, adaptive skills, awareness, and sensitivity, especially cultural sensitivity (Tewari and Sharma, 2011).

The authors of the article want to emphasize that, in their opinion, cultural awareness and sensitivity as well as the level of cultural intelligence of managers working in culturally diverse environment are also very important.

Summing up, modern managers' efficiency to a great extent depends on their qualities and skills. Therefore, it is crucial to recruit and train such managers whose skills make them effective in managing people and positively influence the development of an organization (Mehri and Ramezan, 2016).

Managers and cultural diversity in work environment

Contemporary organizations and their managers face a number of challenges. These include, first of all, globalisation, increasing competition, technological change, new organizational structures, changes in working styles and methods (Nasir 2017) and require effective employee management, especially in culturally diverse work environment.

Employee management in culturally diverse environment is not easy because the diverse workforce consists of individuals belonging to unique cultures who will have different characteristics, aspirations, and expectations (Cennamo and Gardner, 2008). Moreover, employees from different backgrounds have different needs and feel the urge to be respected in their workplace. Management needs to understand the need of these diverse groups of people so as to avoid employee tensions and conflicts (Hill, Stephens, et al., 2003).

The development of international businesses has resulted in a situation in which employee management in multicultural environment requires managers who are able to make right decisions quickly, to learn how to use new technologies, to communicate with their teams effectively, and to coordinate their performance and task realization (Dike, Odiwe, et al., 2015).

"21st century approach of HRM is to utilize the knowledge and expertise of people efficiently and effectively to meet organizational targets" (Wong and Snell, 2003, p. 217). Managers who possess the qualities and skills necessary to manage culturally diverse teams can effectively use the knowledge and experience of employees from different countries to achieve the organizational goals on the global market.

Contemporary organizations "require not only the management of production sources in the traditional sense but also, due to the employment of people from different cultures and beliefs, the management of these differences" (Tutar, Altinoz, et al., 2014, p. 345). A crucial role in managing culturally diverse teams is played by managers who should be open, understanding, respectful, tolerant and fully approve cultural diversity of their employees.

Managing a whole range of relationships, behaviours, cultures and values within culturally diverse teams has nowadays become a major challenge for many companies (Aslam, Aslam, et al., 2013). As far as management of culturally diverse teams is concerned, it can pose a challenge especially for those managers who do not have the qualities, skills, or experience required to work with such employees.

"The cultural diversity of a company influences how business news is conceived, compiled, delivered, received and interpreted. Diversity can therefore be seen as a way in which individuals are unique and different from each other" (Sumathi, Sethupathy, et al., 2018, p. 14).

It should be observed that modern managers must be adequately prepared to face the reality of the 21st century. They should develop their skills in order to be able to achieve organizational goals, especially when they manage culturally diverse teams (Dike, Odiwe, et al., 2015). They should be aware that employees' cultural diversity requires the implementation of new solutions in the area of management of multicultural teams, specifically the ones connected with effective communication and motivation.

"Nowadays, employers are more and more aware that employee engagement is very important for their individual performance, and consequently for company survival and growth" (Rasca 2017, p. 478). In intercultural work environment it is mangers who are responsible for employees' motivation and engagement. Their ability to motivate and engage their subordinates, therefore, plays a key role in building effective teams.

Managers who are effective in managing culturally diverse teams can expect positive outcomes of their work. These positive outcomes, stemming directly from the fact that employees come from diverse cultures, include different ways of thinking, different experiences and the ability to analyse problems from different perspectives (Martin, 2014). Moreover, knowledge possessed by culturally diverse employees can be extremely useful for an organization, as they can provide managers with reliable information on their native culture regarding the area of relationships with employees and customers. Information about the culture of a given country can also help to mitigate culture shock (Martin 2014).

Undeniably, cultural differences can be the source of various problems in the area of relationships between employees and between employees and managers. Therefore, it is vital that managers understand cultural differences between employees of different nationalities and create such working conditions that enable them to contribute to the effective functioning of an organization (Leng and Yazdanifard 2014).

Employees' diverse cultural values can lead to conflict, misunderstanding, poor performance, poor efficiency and quality of work, or not achieving organizational goals, and thus lead to individual, team and organizational inefficiency (Narkhede 2011). Bearing this in mind, managers should positively influence employees' attitudes and behaviour, their motivation to work, and the way in which they build relationships with other team members (Teagarden and Glinow 1997).

"Becoming a successful manager is actually developing a capacity to understand the nature of results and achievements and their linkage within corresponding systems of values. This implies that the management is not and cannot be neutral when it comes to values and results" (Petkovski 2012, p. 92). That is why values and results should be of particular interest to managers of multicultural teams. Especially in culturally diverse work environment, the values appreciated by multicultural teams and the results obtained by them should be clear and comprehensible, accepted and meaningful in every manager's work.

The authors of the article are convinced that in the culturally diverse workplace managers' attitudes, qualities, and skills are of great importance, as they influence the effectiveness of their management of multicultural teams. Their efficiency in optimising the positive outcome of culturally diverse employees' work also depends on managers' attitudes, qualities, and skills.

Methodology

As far as research methodology is concerned, the study consists of the following steps. First, the authors provide the analysis of the abundant subject literature devoted to modern managers and challenges they face while working in multicultural environment. Even the most recent publications still refer to the ground-breaking studies conducted by Geert Hofstede, his son Gert Jan Hofstede, Michael Minkow, Fons Trompenaars, and Charles Hampden-Turner on cultural dimensions that influence the attitudes, behaviours, and values of managers from different cultures.

Next, the authors present the results of their query directed at obtaining information on these attitudes, qualities, and skills of modern managers which are important in working in multicultural environment in the context of different national cultures.

As it was mentioned in the Introduction, the authors are aware of the limitation of the article resulting from a lack of their own study of the analysed issues, so in the next step they refer to the results of secondary studies on various aspects related to managers and their work in culturally diverse work environment (including the perception of managers from different countries in the context of trust, the attitudes of managers related to the dimensions of their own cultures or their attitude to foreign workers).

Managers in face of cultural differences – the results of selected studies in the area

Modern managers should realise that today it is no longer language that is the most important competence of employees working in culturally diverse environment but their knowledge, predispositions, attitudes, qualities, and skill which facilitate cooperation in multicultural teams.

In this section the authors refer to studies investigating the ways in which managers are perceived in different cultures in the context of such elements as trust, cooperation, attitudes directly connected with one's cultural background, or the way in which managers appraise employees of other nationalities, i.e. their attitude towards employees from other cultures.

Information on the ways in which managers are perceived can be found in the Harris Research study, conducted among 1500 respondents, which took into account European managers. It revealed mental differences and attitudes of employees of different nationalities towards each other (Kuc and Żemigała 2010, p. 79). The results indicate that one's culture influences the perception of managers of different nationalities. Italian managers enjoy the poorest opinion: as many as 28% of the respondents considered them the least trustworthy members of multicultural teams. 25% of the respondents declared that they cooperate best with German managers (61% of those 25% were the Dutch employees), 17% preferred working with French managers, and 10% - with British managers.

The results of these surveys can be referred to the dimensions of national cultures defined by Hofstede. For example, the Italians, who were at the bottom of the list in the above mentioned Harris Research study, come from national culture which is characterized by high power distance, average uncertainty avoidance, high individualism, and high level of masculinity. Not surprisingly, Italian managers display attitudes and behaviours in line with the dimensions described in the context of their national culture.

Likewise, the Germans, whose culture, according to Hofstede's classification, is characterized by low power distance, low uncertainty avoidance, medium individualism, and high masculinity, also display attitudes and behaviours which are consistent with this characteristic.

With reference to the results of studies conducted by Geert Hofstede (2001) in IBM's branches and subsidiaries all over the world, it is worth noting that managers from countries with high power distance (e.g. Malaysia, Guatemala, Arab countries) more frequently seek the approval of their superiors than managers from other countries. Conversations between representatives of masculine cultures are highly competitive, as is the case with the Italians mentioned earlier. This is not true about representatives of feminine cultures (e.g. the Swedes, the Norwegians or the Dutch), where empathetic attitudes and the search for compromise are expected. Managers from societies with high uncertainty avoidance (e.g. Greece, Portugal) often base their activities on rules and procedures, which makes them feel less comfortable in uncertain situations. However, managers from cultures with low uncertainty avoidance function better when the rules of e.g. negotiations are unclear or changeable (Lewicki, Saunders, et al., 2005).

The results of the survey conducted among 160 Polish managers concerning their attitude towards foreign employees are also interesting (Wachowiak 2008, p. 99). The study demonstrated that the managers who participated in it thought highly of employees from well-developed European countries but had a low opinion of those from Central and Eastern Europe, South America, and Australia. The survey contained questions from the area of their knowledge, experience, and physical and demographic features directly resulting from their cultural background, as well as their appearance, behaviour, and working style. The respondents were asked to list their employees' negative features, and their answers included: unpunctuality and failure to meet deadlines (96% of respondents), talking too fast, using open gestures, expressive facial expressions (96% of the respondents), and an unclear, not very open manner of speaking (98% of the respondents). The results of this study clearly demonstrate different attitudes of Polish managers towards employees from various cultures.

The results of other studies conducted in China among American and Chinese managers in joint-venture companies, reveal a negative perception of American managers by Chinese managers. The United States is a country with a high level of individuality, and this very feature of American managers was badly assessed by their Chinese co-workers, who highly valued collectivism (Walsh, Wang, et al., 1999).

The studies mentioned above are only several examples of a great number of studies in this area. However, they are enough to conclude that managers working in culturally diverse environment are perceived differently by culturally diverse employees and this perception depends on managers' nationality, country of origin, attitudes, behaviours, qualities, and skills. Similarly, managers from different cultures display attitudes characteristic of their national cultures and have different attitudes towards foreign employees.

In the authors' opinion, managers working in the culturally diverse workplace should definitely possess intercultural competences reflected in their ability to adapt to such environment and in their openness and sensitivity to other cultures.

Discussion

The aim of this article was to determine the characteristics of managers working in culturally diverse environment, especially in the context of different nationalities of their employees. The analysis of the subject literature and the results of selected secondary studies allowed for determining, a relatively universal - in the authors' opinion – inventory of attitudes, qualities, skills that are important for the effective functioning of managers in the culturally diverse workplace.

The analysis of the subject literature and the results of the studies referred to in the article lead to the conclusion that managers working in culturally diverse environment possess various attitudes, working styles, qualities, and skills which depend on their country of origin. They also have different attitudes towards workers from different countries and cultures. Therefore, the authors believe that such managers should, first of all, be open and flexible towards employees from different cultures and be able to adapt quickly to culturally diverse work environment.

Referring to the study conducted in China among American and Chinese managers (Walsh, Wang, Xin 1999), it is worth noticing that a culture clash often takes place in culturally diverse environment. The results of the study revealed a clash between the individualism of American managers and the collective working style of Chinese managers. American managers' lack of openness, flexibility, and willingness to change resulted in their negative perception by Chinese co-workers.

Moreover, managers' attitudes and behaviour towards employees from various countries should be characterised by tolerance and respect. They should possess extensive knowledge regarding cultural differences and cultural awareness necessary to effectively manage employees of different nationalities.

Conclusions

Managers motivated to actively contribute to the achievement of organizational goals are one of the key factors in managing employees in culturally diverse work environment. In order to unlock their employees' potential, managers should pay particular attention to work environment and support their employees, especially those working in multicultural teams, in which tact, tolerance and acceptance of cultural differences are essential.

Firstly, managers working in culturally diverse environment should know their employees, know which countries they come from, and how culturally different they are from other team members. They should try to understand and accept their cultures and possess a high level of cultural intelligence, which includes the ability to engage effectively in relationships in diverse cultural environment.

Secondly, being a manager in culturally diverse work environment requires the acquisition of interdisciplinary knowledge, especially in the field of cultural differences and the ability to constantly learn about the employees' cultures in order to use their potential effectively.

Thirdly, effective management of employees from different cultural backgrounds also requires managers to be able to adapt the rules and procedures to their employees' specific culture and the country of origin. Managers should be able to modify their management styles, attitudes and solutions and adapt them to their culturally diverse employees.

On the basis of the subject literature and the results of studies referred to in this article, the authors main recommendation is to provide managers with cultural training, which should enhance their development, attitudes, qualities, and skills allowing them to function more effectively in culturally diverse work environment and to improve their management of employees of various nationalities and cultures.

Notes

1 The power distance is defined as the level of acceptance of inequality in the distribution of power, expressed by those less powerful, e.g. employees or members of an institution or organisation, in relation to their superiors or persons who are higher in hierarchy. Societies characterised by low power distance (e.g. Ireland, Switzerland, Norway, the United Kingdom) believe that inequalities between people should be reduced, whereas societies with high power distance (e.g. Croatia, Spain, Italy) are characterized by large inequalities between people (Hofstede 2007).

2 Individualism versus Collectivism is a dimension that determines to what extent society focuses on a group or an individual. Collective societies (e.g. Greece, Portugal, Spain) place human relations and belonging to a group above the achievement of an individual's goal. They teach to think in the "we" category. Individualistic societies (e.g. the Netherlands, Belgium, Denmark, Germany) put the achievement of an individual's goal above that of human relationships. They teach to think in terms of the "I" category (Hofstede 2007).

3 Masculinity and femininity are associated with the existence of the predominance of male or female characteristics in given society. Feminine cultures (e.g. Sweden, Portugal, Finland, Greece) are characterized by delicacy and protectiveness and consider care for and protection of others to be a fundamental value. On the other hand, masculine cultures (e.g. Austria, Switzerland, Germany, Belgium) appreciate and promote the following characteristics: activity, aggressiveness, competition, and value material success and progress most (Hofstede 2007).

4 The degree of uncertainty avoidance is an indicator of society's sensitivity to change, new and unknown situations, or innovations. Countries with a low degree of uncertainty avoidance include Denmark, Sweden, the United Kingdom, and Ireland, while those with a high degree of uncertainty avoidance: Greece, Belgium, Spain, and France.

5 Long-term cultures (e.g. China, Singapore, Vietnam) value modesty, economising, long-term planning, and thinking ahead. Short-term cultures (Philippines, Thailand, Malaysia) are characterised by strong commitment to stability and balance in society and pressure on consumption and instant results.

Monika KOZERSKA

Czestochowa University of Technology, Czestochowa, Poland
monika.kozerska@pcz.pl

Abstract

Scientific purpose of the article is to present current state of intermodal transport market in Poland. Later, based on studies, the authors define and describe main development trends that have contributed to this state: European Union's transport policy, development of so called: New Silk Road, attitude of companies that are present on the market. The authors note that the awareness of the factors that have shaped the development of the industry is important because allows to properly shape further pro-development policies.

Keywords: Modality, Road and Rail Transport, Trends on Market.

Introduction

Contemporary rail and road intermodal transport is developing on the background of such phenomena as globalization, growing customers' expectations and increased risk (Brzeziński, 2017). Conditions for running operations on intermodal basics are invariably shaped by volatility and unpredictability, which phenomena were described more than a decade ago by P. F. Drucker as environment turbulence (Lane, Down, 2010) Despite this fact, the market of intermodal road and rail transport services in Poland is currently well developed.

The aim of the article is to define and describe main trends that have contributed to the current state of intermodal transport market in Poland. The results of research carried out at the example of enterprises involved in the provision of intermodal transport services, ensured authors that the operations of companies that are present on the market, has been one of primary factors.

Method adopted for the purposes of empirical part was case study. While making usage of this tool, the researcher may use several sources of data: interviews, observation, documents, analysis etc. (Bennett, 2015). Authors refer mainly to the results of observation and informal (targeted) interview with the representatives of the management forces of the selected entities. The introduction to the considerations is an approximation of the conceptual apparatus in the field of intermodal transport as well as description of modern state of road and rail intermodal transport market in Poland. This part was based on a bibliographic and theoretical query. The authors referred there, among others to scientific journalism on the subject of intermodal transport and to reports prepared by the Office of Rail Transportation. Selection

of this entity's studies results from the fact that it is subordinate to the Minister of Transport, the superior authority regulating issues related to carrying out rail transport activities in Poland (OECD, 2016).

Rail intermodal Transport Market in Poland

Among the terminology of intermodal transport, in addition to the concept of multimodal transport, the term - combined transport is also used (ECMT, 1998). Interchangeable use of these three terms is often visible in journalism, as well as documents or reports (Garrett, 2014). There are many official definitions of the intermodal transport in the literature, but the best concepts are described in the glossary of Combined transport terminology published in 1993 by the European Conference of Ministers of Transport: ECMT (Mindur, 2002). It follows that, in its assumptions, intermodal transport has the useage of one and the same loading unit on the entire transport route, in changing, at least two modes of transport. „Between the points of origin and destination the load unit is neither loaded nor unloaded. Load units will usually be martime containers, continental containers, swap bodies and semi- trailers of various sizes" (Kreutzberger, 2008). M. Hoeks stresses that in the case of intermodal transport, the entire transport process is organized on the basis of a contract signed between the customer and the service contractor: „the carriage is based on a single contract concluded by a carrier […] endowing him with a carrier's liabilities" (Hoeks, 2010)**.** In case of intermodal transport, there may be combinations of various branches' means of transport. In case of intermodal rail and road transport on the main path a mean of road transport (e.g. truck with/or without semi-trailer) along with the load placed in it, uses the rail transport service (Mindur, Gąsior, 2003).

In Poland, described type of transport is developing dynamically. According to the newest report developed by the Office of Rail Transportation, in 2019 already, intermodal rail and road transport reached the level of 17 million tons of cargo, which in comparison with 2017 means a jump of over 15%. Office of Rail Transportation calculated that the mass of loads in intermodal transport increased by 2.3 million tons. This is an excellent result because the increase in the whole mass of goods transported by rail in 2018 was 4 percent. It shows out that intermodal transport is growing much faster than the rest of the market (Urząd Transportu Kolejowego, 2019).

Already noticeable increase in tonnage being transported in an intermodal way was, among others, the effect of a gradual increase in the number of carriers who offer this type of services (Kadłubek, 2016). The amount of intermodal licensed rail transport operators in Poland have changed significantly. Increase in the number of carriers, up to nowadays is shown in figure 1. Currently, PKP Cargo still remains the main player on the market, with a share in transport, according to transport performance, at the level of 52,3%. However, the company's share in described market has been decreasing for a long time (e.g. in 2012 it was as much as 64.7%), what is accompanied by the increasing role of other market leaders. The trend of increasing market shares of smaller entities in Poland is illustrated e.g. by the case of a company Captrain Polska, which in 2019 reached a share of 12.5 percent in the transport work performed. This is a good result compared to 2017, when the company had only 7.3 percent of total share (www.utk.gov.pl).

Figure 1: Change in the number of intermodal carriers in the last four years (data from the Office of Rail Transportation)

DB Cargo ranks third among the largest operators from the point of view of transport performance (≈10.2%). PCC International and LTE have also a significant share- in total, it exceeds 13%. It should be noted that the intermodal transport market in Poland is generally divided between the four carriers mentioned above. The percentage market share of individual companies is shown in Figure 2.

Figure 2: Current share of carriers in intermodal transport according to transport performance (Urząd Transportu Kolejowego, 2019)

In Polish intermodal transport containers are mainly transported. Their share in the total number of units in 2019 was 96.3%. Mostly transported were 20- and 40- foot units, which respectively constituted 47.8 and 43.8 per cent of the total number. The share of other containers was as follows: 25-foot - 0.2%, 30- foot - 1.6%, 35- foot - 0.5% and eventually 45-foot - 2.3%. Car trailers and semi- trailers accounted for 1.5% of the units being used, and swap car bodies 0.6% (Urząd Transportu Kolejowego, 2019).

Figure 3: The share of carriers in intermodal transport by transport weight in 2019 (Urząd Transportu Kolejowego, Warszawa 2019)

In relation to the transported mass of intermodal containers (on the background of the total mass of rail transported tonnage), it amounted in 2019 almost 4.7 million tons and was higher compared to the previous year by 1.4 percentage point. The leader in this category is, similarly to transport performance, PKP Cargo with the result of ≈ 46.5%. However, it should be noted again that six years earlier the share of this company achieved a much higher level, significantly exceeding 60%. Captrain Polska is in second place (13.73%), while PCC Intermodal is third with one- tenth of the market share. The share of intermodal transport carriers according to the transported weight is illustrated in Figure 3.

Method

Research problems relate to the attributes of the subject of the study, their changes, conditions in which they occur, the relationships between the features of objects, the significance of variables and their interactivity, their joint or individual interaction. In the literature on the methodology of conducting scientific research, the research problem is interpreted as a question (Walliman, 2001). Obtaining answers to them (through in-depth studies and research) serves to exhaust the state of ignorance in a given issue. "A research problem is as much as a certain question [...] that the study is to answer" (Łobocki, 2007). For the need of this article, research problem was articulated in the form of a decisive interpellation: what are the main trends that have shaped the development of intermodal transport market in Poland? The anticipated answer to the question contained in the research problem, formulated with a significant degree of - satellites that orbit at an altitude of ca. 20180 km above the earth's surface, and conviction of the researcher about its veracity, is the research hypothesis. The authors' response to the observed research problem was the thesis that the development of intermodal transport in Poland have been due to the impact of three basic factors: the European Union's Transport Policy, development of so called: New Silk Road as well as appropriate orientation of companies operating on the market. Verifying the hypothesis formulated in this way was the main aim of the undertaken cognitive effort.

In order to verify the thesis, the authors used, inter alia, a case study of two companies. The method chosen for the purposes of case study's creation was an observation and informal (targeted) interview with the representatives of the management forces of selected entities. The research on a sample of managers was inspired by the work of W. Lyon, G. Lumpkin and G. Dess, who recommend as

extraordinary useful three methods to study issues related to management practice. One of them is so-called: managerial perception, consisting in verification of theses based on consultations with managers. Thanks to managerial perception, the material for in-depth analysis is obtained through personal or questionnaire interviews from people who know best about issues related to the topic (Lyon, Lumpkin, Dess, 2000). In preparing practical part of the work, the authors also looked through selected companies' materials and reports developed e.g. for the purpose of internal reporting.

Accepted criteria for selecting enterprises for research was the desire to select units that are characterized by high operational dynamics on the intermodal transport market. The first selected entity: Laude Smart Intermodal (for the sake of brevity referred later to as: x) is an example of an organization using innovations. Among other things, it introduced and patented 20- feet containers that have universal adhibition. Their important advantage is that, in one direction one can load loose goods on them, and then palletized ones back in the door-to-door and just in time system which should be understood as a management philosophy or toolbox of techniques, that is based on performing a significant improvement in operating efficiency through reduced inventory levels, lead times and overheads (Kee-hung Lai, Cheng, 2009). Thanks to the use of such containers, empty runs are significantly reduced: economic analysis carried out later shows that even if the containers return in an empty state to the operator, such transport is still competitive compared to the road transport. The second company: PCC Intermodal (marked: y) has a high growth dynamics on the intermodal transport market. It has been operating for over 12 years in the intermodal sector. Currently owns an established position on the market also its prospects for further development seem promising. This is mainly because of its own intermodal terminal, where every year the number of serviced trains from China increases. This terminal has a chance to become the main intermodal "crossdocking" centre for Western Europe.

Transport companies' operations as a trend loading to the development of modern intermodal market in Poland

A Company X- Laude International

Surveyed unit is among the fastest growing intermodal rail and road transport companies on the market. The company's main scope of activity is intermodal rail transport abroad. It launches regular connections between Poland and the East. In addition to regularity, these connections are characterized by the delivery of shipments in the "door to door" and "just in time" options. The company is implementing a unique project that involves the use of an innovative container for transport, which allows palletized products to be transported one way and dedicated products, in the other. The company also provides an innovative service in the form of delivery container weighing up to 28 tons to the final recipient, who does not have its own railway siding. The company has specialized in the transport of steel coils by an innovative method of coil transporting. It takes place in specialized 20- foot HTCOIL containers (figure 4). Transport in innovative containers allows to eliminate packaging costs and protect transported coils. The biggest advantage of the container, in comparison with the wagons for transporting steel coils is a fact that after unloading the containers can be loaded on the way back along with other goods. In contrast, traditional wagons usually return empty, which significantly increases costs of transport. The tare weight of the container is about 3 tons, and the maximum total weight closes in 33 tons.

Figure 4: Container 20' HTCOIL (corporate website)

The company, in order to meet the expectations of customers also designed and patented another, innovative container: type HTSYP. Thanks to its usage, costs in the field of packaging, handling and dumps are reduced during loading operations. The biggest innovation of this container is the possibility of spilling the goods through the rear "flap door". None other of the wagons available on the market for bulk cargo is used for the transport of palletized loads. On the contrary, the container of a company being described has a standard door opening wide, which enables efficient unloading. The container has a capacity of 43m^3, while the standard one has only 32m^3. The permissible total weight is 33 tons, with the container tare that is equal to 3 tons. The goods can be loaded into through the loading hatches on the top, e.g. from the so-called: sleeve, without removing the roof. As part of a comprehensive service, in the case of transporting the entire train composition, the company provides the substitution of a truck (type: Reach Stacker) with a lift, for transhipping containers onto a car trailer and then transporting them to the final unloading site (http://www.laude.pl/index.php).

Table 1: Categories of railway lines in Poland (with operational parameters) on which carriers' trains may travel. Own elaboration based on: (Towpik, 2009); (Wojciechowski et. al., 2009)

Lines' category	Radius of arcs	Transport load T [mln t brutto/year]	Maximum speed of freight trains v_{max} [km/h]
Magistral	≥ 1200 m	T ≥ 25	$80 < v_{max} \leq 129$
First class	≥ 1200 m	10 ≤ T < 25	$60 < v_{max} \leq 80$
Second class	≥ 600 m	3 ≤ T < 10	$50 < v_{max} \leq 69$
Of local significance	≥ 300 m	T < 3	$v_{max} \leq 50$

The company has a fleet of 120 (including 30 own) four-axle wagons. These wagons are designed for a maximum speed of 120 km/h and the permissible total weight is 90 tons, with a length of 13.5 meters. The tare of wagons being used is 17 tons, which means that two 20-foot HTSYP containers with their maximum load can be loaded on one wagon. Then the total weight of the loaded wagon will be equal to 83 tons, which is within the maximum load range on most Polish railway lines, which is 21.5 tonnes per axle. The types of lines constituting the Polish railroad system on which the wagons of the described carrier can travel are listed in Table 1.

Comparative analysis of transporting bulk cargo in HTSYP containers made by x company.

In order to carry out comparative analysis for transport carried out by the company in question as well as for traditional road transport, cost data collected from the market was used. For the purposes of calculations, average rates were adopted. Cost analysis was made with the assumption that only the delivery prices affect the profitability of the service. It was also assumed that both the sender and recipient of the shipment have a terminal/rail siding that can be used within a 20km radius of the place of loading and unloading. In the cost table (table 2), are included separately: the costs of transport and costs of delivery and drop off together with loading and unloading of the parcel. The presented analysis does not include: fixed costs of the company, costs of personnel, average costs of rolling stock maintenance (unforeseen repairs, insurance, etc.). This assumption is correct because each company bears similar maintenance costs. Three routes were selected for the analysis, described later.

Table 2: Cost statement for intermodal rail transport and road transport (own elaboration)

Intermodal rail transport								
Track	Distance [km]	Train weight [tn]	Cost of transort [pln]	Cost of delivery and drop off [PLN]	Cost of loading and unloading [PLN]	Total price [PLN]	Price for 1 km [PLN]	Price for 1 ton of cargo [PLN]
Krakow-Katowice	94	800	7135	12400	9920	29455	313	15,56
		2600	11235	12400	9920	33555	357	17,78
Krakow-Medyka	244	800	13585	12400	9920	35905	147	19
		2600	23175	12400	9920	45495	186	24,10
Krakow-Terespol	435	800	27175	12400	9920	49495	114	26,20
		2600	46320	12400	9920	68640	157	36,4
Road transport								
Track	Distance	Cost for transporting 26 tons to destination and back	Cost for transporting 1887 tons to destination and back				Price for 1 km [PLN]	Price for 1 ton of cargo [PLN]
Krakow-Katowice	94	564	41172				438	21,82
Krakow-Medyka	244	1464	106872				438	56,64
Krakow-Terespol	435	2610	190530				438	101

It has been assumed that the maximum load of the intermodal train will be 2600 kilograms gross, because such a load is acceptable on most railway lines. Goods that are assumed to be transported is grain. 1m^3 of grain weights an average 700 kg. Given that the HTSYP container has a capacity of 43m^3, one can load about 30 tons of grain into it. So if we put 2 containers with a gross load of 33 tonnes each on a 40-foot wagon, our wagon will weigh 83 gross tonnes, because its tare is equal to 17 tonnes. Therefore, we can form train of 31 wagons. The above table includes the costs of transporting the loaded and empty storage. There is not always a return load (trains often return empty), so it will be objective to include the cost of returning the train.

In order to get the total price for comprehensive intermodal service, it is necessary to add up the price for transporting up to 800 tons and up to 2600 tons. In relation to road transport, for the comparison to be meaningful, the return of empty trucks to the loading place was also taken into account. This is in accordance with the principle that the price of service includes kilometres travelled in both directions. For the needs of calculations it is accepted that the average price on the market for transporting by dump truck in the full/empty combination is 3 PLN. For the road transport service, a universal dump truck with a permissible total weight of 40 tons was selected, with the vehicle's tare equal to 14 tons, which translates to the opportunity of loading 26 tons of grain.

Figure 5: Comparison of shipping costs (own elaboration)

It means that 73 dump trucks should be fully loaded with 1887 tonnes in order to perform the same transport work as if using one train. The table includes cost of transporting one dump truck and the total price for transporting 1887 tons forward and back for each of individual routes. In addition, the price of 1 ton was calculated for both intermodal rail and road transport.

Comparing comprehensive rail and road transport on the first short route from Krakow to Katowice, it is clearly seen that rail and road option is more expensive than road transport alone (figure 5). Although one can point out, that if we counted the external costs generated by road transport and we loaded onto the return train (e.g. palletized loads), the price would be comparable. What's more, flexibility speaks for intermodal transport, because the train can be formed and sent faster than hiring 73 dump trucks in a short period of time.

Train transport of merchandise 1887 tons: 33555 pln + 29455 pln = 63 010 pln.

Rail transport price for transporting 1 ton of goods: 63010 pln/ 1887 tons = 33,38 pln.

Road transport of 1887 tons of goods: 94km * 438 pln = 41172 pln.

Road transport price for transporting 1 ton of goods: 41172 pln/1887 ton = 21,82 pln.

Comparing rail and road transport on an average distance (from Krakow to Medyka – 244 kilometres), one can observe that intermodal rail transport looks attractive from the price point of view in comparison to road transport. It is needed to pay PLN 81400 for the whole train composition, while for road transport: PLN 106872. It means that combined, rail and road transport is cheaper by 24%.

Comparison of transport costs on the longest, Krakow - Terespol route, confirms the theory that intermodal transport is the most cost-effective over the longest distances. For intermodal rail and road service the client will pay only 118135 PLN, while for road transport has to pay as much as 190530 PLN. It means that intermodal transport compared to the road one is cheaper by PLN 72395 (as much as 37% in percentage terms). It is worth adding that in road transport, in terms of weight, the price exceeded PLN 100 per ton, thus exceeding the value of the merchandise itself.

Currently, there can be heard an opinion, that on the transport market in Poland, intermodal road and rail transport is profitable only over the longest transport distances. Thanks to the innovative solutions in the organization of intermodal processes introduced by the considered company, this transport becomes attractive not only on long, but also on medium distances. This is confirmed by the comparative analysis being carried out previously. Intermodal rail and road transport performed by company x over a section of 244 km is cheaper by as much as 24% in comparison to road transport alone. Containers implemented by the company in question have brought new quality and new opportunities in intermodal transportation processes.

Company Y (PCC Intermodal) - Analysis and Assessment of The Company's Strategy

Company under considerations is an intermodal transport operator. It exists in Poland since the beginning of the new millennium, when it launched first regular intermodal rail connection from Brzeg Dolny to the coast. Then in 2007 the company launched another regular connection between the terminal in Brzeg Dolny and the sea terminals in Gdańsk and Gdynia. A year later, a connection between Brzeg Dolny, Szczecin and Frankfurt an der Oder has been launched (http://www.pccintermodal.pl/).

Compared to the other intermodal operators on the market, company Y stands out by offering a well-developed network of regular and punctual intermodal connections. Nowadays the company offers a regular intermodal connection (takes place 6 times a week) from Poland to Rotterdam. In addition, it has a regular 5 times a week connection from Hamburg to Poland, 4 times a week from Duisburg to Poland and 3 times from Poland to Brest. However, the largest number of connections in the weekly statement is launched from polish ports to Kutno, Brzeg, Gliwice and Kolbusow. In total, the company launches 400 regular intermodal trains in a month and carries out 200 container returns from its terminals per day. It should be emphasized that the company does not have its own rolling stock. Uses the services of external carriers.

When analysing company's Y strategy at the time of its presence in Poland, it should be stated that the construction and equipment of 5 terminals together with the creation of a network of regular connections is impressive. This is particularly significant if one consider the high level of capital absorption and the long payback time from investments that characterize intermodal transport. Probably, the above mentioned successes are primarily influenced by the fact that Y is a subsidiary of the parental holding company, which is present in 17 countries and employs more than 3,000 employees. Therefore, it can afford a long-term return on expenditure without significant impact on current financial liquidity. The best example is the implementation of terminal construction in Kutno. While planning this investment in the last decade, the company was convinced that it would be a strategic terminal because would become a gateway for daily intermodal connections in the Baltic and Adriatic corridor as well as in the East-West corridor. The terminal was officially opened in 2011, and in 2014 decision to expand it was undertaken. From the terminal in 2016, the first train to China, to Chengdu, was launched. The train arrived on place in 11 days, covering 9,800 km and delivering 41 forty-foot containers. This connection was launched in cooperation with company that previously acquired 13.94% of the shares in Y. Key terminal in Kutno was chosen by investors from China because it gives the possibility of spreading throughout entire Europe goods imported by rail. Currently it is considered to be the starting station of the New Silk Road. If the increase in rail transport to China continues in the future, this terminal will be re-expanded.

Another Trends Affecting Development of Modern Intermodal Transport in Poland

In addition to the operators' proper actions, a very important trend that has shaped the Polish intermodal transport market was a support from EU funds. Millions of PLN have been allocated for the development of intermodal transport from, so called, new perspective of the European Union for the years 2014-2020.

The European Union's Transport Policy is strongly focused on the growth of intermodal transport. One of its main assumptions is that by 2030, 30% of road freight transport, at distances greater than 300 km, would be transferred to other means of transport, e.g. rail or water transport. By 2050 it should be over 50% of this types of transport. European support have been provided to selected carriers and intermodal operators in response to requests from companies applying for them. All of these funds have been used to finance construction and equipment of logistics centres, intermodal terminals and the purchase of transport units used in intermodal transport. In connection with the aforementioned EU perspective and announcements of the government it is planned that by the 2023 the modernization of the most important railway routes will be completed.

Next, significant factor supporting the growth of intermodal transport in Poland is the development of, so called: the New Silk Road (NSR), which runs through the territory of Poland. The main assumption of this initiative is to create new, alternative rail-road routes from China to Europe. As S.A. Kashmeri points out: "China is building a twenty-first-century version of the Silk Road in which high speed trains […] will replace the long caravans of ancient times that trudged across Eurasia to barter and exchange goods" (Kashmeri, 2019) . China's economic policy is determined by five-year plans approved at the meetings of the Communist Party of China. In the plan for 2016-2020, one of the main assumptions is to reduce social inequality between the eastern and western part of the country. This eastern one is at a much higher economic level. The economic plan has assumed a number of infrastructural investments and the creation of new communication routes on the western wall, so from these regions there can be a systematic increase in exports and imports to Asian and European Union countries.

Already, around 50 countries declare their participation in the NSR (Nazarko et.al., 2016). This is also a great opportunity for Poland to increase the level of exports to China. The first train to Europe from the Asian country entered Poland in 2005. However, the dynamic development of these transport has occurred in the last 2-3 years. Poland plays an important role in NSR as a logistics centre for European countries. The company's Y container terminal in Kutno is particularly important in this case. Rail transport is definitely cheaper than air transport (about 3 times) and much faster than the sea one (Grohman, 2016). Transport processes by rail from China to Europe takes about 14 days, and by ship about 35 days, which makes the first option attractive to many customers. However, the price is three times higher compared to sea transport. Rates vary because some Chinese provinces subsidize rail exports to Europe as a result of the economic program mentioned previously. The rail route from China is through Kazakhstan, Russia and Belarus. Trains reach Malaszewicze, Łodz, Kutno and Pruszkow after 12-14 days. The advantage of rail transport over sea and air options is, without doubt better service for Chinese factories far away from ports and airports. There are currently 8 regular connections from China to Poland. From Zhengzhou or Chengdu provinces, trains run several times a week. Every now and then new directions are also tested ("Transport kolejowy do Chin", 2016)**.**

Conclusion

In the literature it is emphasized that intermodal rail and road transport is widely considered to be far more ecological than the road transport itself (Grohman, 2016). Therefore one can enjoy the fact that the market of intermodal car and rail transport in Poland is growing more and more dynamically. There have been a steady increase in the number of operators since 2015. The volume and weight of merchandise transported is also gradually increasing. In addition, several dozen intermodal terminals are active in Poland.

In addition to the market description, main factors that have led to the current state of intermodal transport in Poland have been listed in the article. Authors noted, that progress was mainly done due to the European Union Perspective for 2014-2020. In addition to the European Transport Policy, the creation of the NSR should be also mentioned. Companies operating on the Polish market has also significantly contributed to the progress. The results of research carried out in the example enterprises confirmed that

companies involved in the provision of intermodal transport services are already introducing innovative solutions (HTSYP container from company X) or shape their strategy in terms of significantly expanding networks of intermodal connections (company Y).

Awareness of the factors that have shaped the development of the industry is important, because allows to properly shape further pro-development policy. For example, it seems that it is worth providing broader support to enterprises operating in the industry (e.g. of a fiscal nature), so that they can continue to undertake valuable activities. At the same time, however, the authors are aware, that the undertaken topic do not fully exhaust the issues related to the determinants of the development of intermodal rail transport in Poland. However, it can be a good starting point and inspiration for further studies and research. The impact of factors other than those considered in the work, such as the role of governmental bodies can be the area of further exploration.

Abstract

Aim: Recession and green thinking force manufacturers to reduce their losses. SME's successfully use lean to increase efficiency and performance. Despite the wide variety of literature, practical application is not widespread. The question arose: can the successful German lean method also be employed by Hungarian SME's? The purpose is to review international literature and to compare them with the lean knowledge of Hungarian SME's. It explores the impact of lean on the German parent company and the Hungarian SME, while conducts an asset research. *Methodology:* The literature review is followed by statistical and empirical elements to discover the relationship between the Hungarian and German markets. Hungarian SME's (processing and tourism industry) are the subjects of the primary research. Out of the potential 9683 SME's, 1315 were contacted online or personally, from the 223 questionnaire responses, 158 (12%) were filtered. The results obtained were supported by qualitative interviews. *Findings:* The results show that even though Hungarian SME's use lean elements, they are not lean businesses. It must be noted that this is not done consciously and a deeper analysis is required. The performance of supplier companies has a positive impact on the widespread of lean. Exploring lean practical knowledge is relevant from a scientific and practical point of view: it supports executives in the implementation of lean in order to maintain and develop their positions. In addition, it also shows the application of lean and achievement of efficiency. Furthermore the research suggests that lean could be the answer to labor shortage.

Keywords: SME's, Lean, Management

Introduction

Global recession and green-thinking affect manufacturers in reduction of their losses. The SME sector plays a significant role in the economy in the EU, as well as in Germany and Hungary. Lean manufacturing has been successfully used to increase efficiency and performance. It raises the question whether the lean method of German parent companies can be applied to Hungarian SMEs. According to this paper, with the right adaptations, it can.

In the last decade, Hungary has focused on improving efficiency along the lean, especially at foreign companies with German parent companies, and thus optimizing processes. Studies show that, despite the wide variety of specialist literature, practical application is not widespread.

The purpose of this publication is to review the literature and to compare it with the lean knowledge of Hungarian SME's, as well as to explore the use of lean in the German parent companies and in the Hungarian SME's. The lean device is conducting awareness research. The study attempts to draw attention to the fact that the situation of Hungarian SME's have become problematic in areas that could be a source of their competitiveness.

Literature Review

The Small Business Act for Europe (SBA) is the EU's flagship policy initiative. Hungary lags behind the EU average in most SBA areas. *Szerb* has attributed the weakness of the SME sector to the generally low level of corporate competitiveness. The weakest link analysis often shows significant shortcomings, even in the best performing companies. There is a critical gap in innovation, supply and networking. *(Szerb et al, 2016)* In the GEI study Hungary lagged far behind in Central Europe in terms

of opportunities, ability to start a business, product innovation and venture capital. The average value added of Hungarian SME's is less than half of the EU average *(Sasvári, 2014)* The development of the neighboring countries has led to the fact that by 2017 Hungarian competitiveness has become the driving force of the V4 countries. Competitiveness problems include aging, lack of language skills, SME operating conditions, corporate innovation capacities and the VAT rate. *(Molnár-Udvardi, 2016)* SME's with outstanding competitiveness can be found only in an island-like manner - especially in the areas on the Vienna-Budapest axis. Out of 15 competitive "Hungarian" SMEs, five are foreign subsidiaries, typically belonging to German multinationals. *(Szerb, 2010.)* European trends expect the growing importance of medium-sized companies in small open economies like Hungary. *(Kovács et al, 2017)*

Walton, author of the Deloitte & Touche study, pointed out the increasing vulnerability in terms of global competitiveness of the 100 Eastern European production companies that had been surveyed. Production companies must meet the key factors of production strategy, speed and flexibility. Companies are currently compensating for the lack of skills with the lower costs of cheap labor. Accession to the European Union tends to mean a significant risk for countries with low-cost production capacities. "As labor becomes more mobile and living standards rise, EU integration means the erosion of Central Europe as a low-cost geographical area," stated by *Walton*.

Several government programs have been launched to catalyze this process, but none have produced breakthrough results. According to *Koloszár and Pankotay*, the management tools used in the Hungarian SME sector are tight, which also affects the competitiveness of enterprises. *(Koloszár-Pankotay, 2017)*

Lean thinking is considered the gold standard for modern production management, but there are also skeptics in the field of SME's. An analysis of 425 Indian SMEs showed that lean thinking has a positive impact on operational performance *(Yadav et al, 2019)*. Competitiveness is influenced by young people who are becoming entrepreneurs, the use of new methods (lean), but also the effective use of intellectual capital *(Pankotay, 2013, 2018)*. *Szóka (2014)* notes that process thinking, production cycles and production processes must be simplified, standardized and shortened, and strategic orientation must not be overlooked. *Hines et al. (2008)* highlight organizational and cultural factors such as commitment, strategy and fit, and leadership. *Chong et al. (2013)* emphasize that cultural change is the primary aspect of the sustainable realization of lean. The importance of culture and knowledge have been emphasized by *Aboelmaged (2011), Maleyeff et al (2012), Bamber et al (2014), Tanik and Sen (2012), Albliwi et al (2014), Shokri et al (2016) and Sayer, Williems (2012).*

Hammer et al (2004) emphasized the priority of intellectual capital, while *Pankotay (2017)* emphasized the assessment of education and knowledge. *According to Achanga (2006), Dora et al. (2013), Arul-Arumugam (2015) (Koloszár 2018),* the focus should be on the people and learning process, while *Clarke et al (2006)* believes that the willingness of SMEs to learn is the key.

In 2011, *Spann et al* saw SME's becoming more competitive in a lean approach to technology and management. They identified the need for regular training for SME's. *(Spann et al 2011.) Ulewich-Kuceba (2016)* emphasized the learning process from the other side: lack of knowledge induces resistance. In addition to presenting national culture and good practices, *Netland (2016)* highlights the involvement of external experts in the SME sector. Organizational culture and behavior are key factors in TQM, LM or LSS, and the boundaries overlap. *((Antony et al(2014) Standon et al (2014) Bamber et al (2014) Dora and Gellynck (2015) Shokri et al (2014))*

Netland (2012) states that despite the various success factors of the 30 companies surveyed, they are struggling to achieve lean production. *Bhamu and Singh Sangwan (2014)* discuss different definitions and contents of reports. *Azlina Mohd Salleh, et al (2012)*, by definition, discuss the combination of LM and TQM as an integrated approach not yet discovered by the Malaysian automotive industry.

Hernandez-Matias, J., et al (2019), in a survey of lean managers of Spanish production units of international companies, describes the sequence of lean implementation. He points out that management, employee and operational performance are closely linked by the lean culture. *Belhadi et al (2017)* discuss 5 important barriers to SME lean deployment and how to overcome them. Value Analysis can help SME'S to improve their efficiency and market position. Value Analysis is a

development methodology that examines the cost-function relationship. The aim is to reduce costs and to improve functions in order to ensure customer satisfaction in the fields of quality and efficiency. It is a challenge to interpret this cost-function relationship and risk management from the perspective of sustainable development *(Szóka, 2017)*.

Methodology / Approach

Firstly the literature review had been carried out to be supported by the Hungarian and German market relations with statistical and empirical elements.

Finally, for the SME lean knowledge survey – along with the EU standards -, small and medium-sized enterprises in the manufacturing and tourism industries had been used for the primary data collection. The questionnaire was developed by pre-validation and use of relevant literature. Professional questions focused on the degree of the use of lean methods and the identification of the lean tools which are already in use. Out of the potential 9683 SME's, 1315 were contacted either online or in person, and after 223 responses, 158 (12%) were filtered. The results obtained were supported by qualitative interviews in order to identify trends and patterns of thinking.

Findings

The strong economic relations between Hungary and Germany were further strengthened after the economic recession, which is well represented by the economic indicators of the two countries. *(Table 1.)*

As an emerging science, lean still has a vast array of knowledge that is expanding almost on a daily basis. This is supported by the heterogeneous use of technical terms in the processed literature and the results of the survey: the lean elements, in some cases, are used consciously or unconsciously by Hungarian SME's, but we cannot talk about lean businesses. Lean is not an independent initiative, a business customer insists on implementing lean as their development program. The performance of supplier companies has a positive impact on the spread of the lean application. The success of the foreign parent company and the subsidiary is not based on the different national cultures, it is rather the outcome of the harmonization and application of the core cultures of the mother and subsidiary company. Culture, trust and relationship capital are the cornerstones of cross-border work organization today. *(Figure 1.)*

The relevant literature emphasizes the importance of lean in the human and cultural dimension of learning, which was also confirmed by the survey. Comparison of tools and methods is not relevant due to the cultural differences, but it may provide a point of reference.

Practical Consequences

It had been found that even though the lean elements could be used unconsciously, they are still being applied. However, the results require deeper analysis.

The research on the lean knowledge of Hungarian SME's highlights the impact of German parent companies on Hungarian SME's. Exploring lean practical knowledge in Hungarian SME's is also relevant from both a scientific and a practical point of view: it enables executives and leaders to understand the importance of lean and helps them in the implementation of lean in their businesses in order to maintain and develop their supplier position. The paper also demonstrates the applicability of lean elements to skeptics of SME lean use.

The survey confirms Benner's statements: Hungary is a success story for the German industry due to the cheaper labor. In addition, the employees in Hungary are well-educated, trade unions have little rights and logistics connections are highly developed. The government provides them with a number of tax advantages *(T Benner)*, and since Hungary is a member of the European Union, it has access to the common market. German economic operators have the largest capital stock in Hungary.

The vast majority of Hungarian SME's were unable to take advantage of the new opportunities of EU accession, on the contrary: the pressure exerted by foreign companies and imports increased

competition and made it difficult for companies to develop further. Lean could mean the solutions, which was also supported by the survey.

Lean awareness has shown that SME's are particularly vulnerable to sudden and drastic changes in the external environment. Companies that are unable to radically alter their business strategy in a rapidly changing environment will be left out from the competition and permanently excluded from the market. *(Fischer et al, 2004.)*

Originality

The study supports theoretical literature from a practical point of view. It recognizes the findings in the processed literature on human value, culture, learning, and behavior. The survey confirms or refutes the awareness of each lean element. It helps to understand the lean thinking of Hungarian SME's and its impact on performance.

It also highlights core philosophy of lean and the difference in unity across parent and subsidiary companies. It draws the attention to the "two-speed Hungarian SME's": a developing, foreign-based and/or supplying company and a lagging domestic servicing enterprise. This, in one way or another, affects the whole economy. In the future, lean thinking could be the answer to the problem of labor shortage.

Table 1: Lean Knowlege

Notion	**Knowledge of responders in %****
Toyota/ lean philosophy	60,5%
Kazein	45,9%

Evaluation of Motivation and Remuneration in the Czech Corporate Environment Based on Factor Analysis

Kateřina JANČÍKOVÁ

Brno University of Technology, Faculty of Business and Management, Brno, Czech Republic, xpjanci01@vutbr.cz

Abstract

This paper aims to define the motivational preferences of employees at large concerns in the Czech Republic. The paper presents the results of empirical research at the level of employee motivation. The research was conducted at the end of 2018. Four hundred and forty-four companies were addressed. A questionnaire was distributed to companies in the manufacturing industry. The methods of data processing used were statistical mathematical methods, specifically the Chi-squared test and factor analysis. The study demonstrates that the possibility of career education and the transparency of remuneration have a large effect on the motivation of employees in the Czech environment; these results are subsequently compared with extensive theoretical research. The findings made by this study may be used as a tool to increase employee motivation, which has a direct influence on both employee performance and the performance of the company as a whole.

Keywords: employee motivation, the role of salary in remuneration, motivation theory, benefits, employee performance

Jel Classification: J24, L19, L25, M54.

Introduction

A highly competitive environment influences the success of a company, though this success is dependent on many factors that the company cannot influence. First and foremost, these are macro-economic and micro-economic factors that, taken together, we may call external factors. These include the political situation, the legislation, public opinion, the media and so on. Secondly, factors that the company influences itself have an effect on the success of the company, such as the standard of human capital, organisation within the company, the company's subject of business, its technological maturity, etc. In spite of the fact that the market is currently changing, and a new form of industry – Industry 4.0 – emerging, the human factor is indisputably the most important factor in any business. Although the new age will be characterised by robotisation and automation, many employers cannot imagine that robots will replace the human factor in their company (PWC, 2019). The principal role of personnel managers will, therefore, be not merely to find qualified staff, but first and foremost to motivate them appropriately and keep them at the company. And this is a process that is continually living, changing and developing, and one that is greatly influenced by the composition of the workers on the labour market. In global business, human resource management is considered a tool that helps the development and growth of both the company and the market as a whole (Gottwald et al., 2017).

Staff motivation and stabilisation has an interdisciplinary nature, since it is the result of the combination of a number of academic fields. Its thematic focus falls within the area of micro-economics, though it is also part of the theory of companies and company management. It also makes use of knowledge of the psychology of Man, and in particular applied psychology. It goes without saying that it also touches on macro-economics in the area of unemployment (during high levels of staff fluctuation due to inadequate motivation) and the creation of GDP (an adequate wage level guarantees staff the satisfaction of their needs by means of purchases). A productive working environment helps in attaining the goals of the company, for which reason motivation is an essential part of human resource management (Burma, 2014; Javorčíková, 2017).

The term motivation indicates the internal incentives for each individual to do something that leads to the satisfaction of his or her needs. Motivation expresses an internal stimulus for a particular behaviour (Zafar et al., 2014), and can also be defined as an endeavour to achieve a certain goal (Richman, 2015), while the authors Eshun and Duah (2011) describe motivation as the willingness to take efforts to achieve organisational goals, which is conditional to the ability to satisfy the particular needs of the individual.

Theoretical Background

The first theoretical approaches to the motivation of employees date back to the nineteenth century. A number of theories of job motivation have been defined, from classical theories to contemporary modern approaches that see the worker as a scientific model. One of the first theories concerning worker motivation is the instrumentality theory which is based exclusively on external control and entirely neglects other human needs. It also gives no consideration to the influence of the informal relationships created among the staff of the organisation. In contrast, Maslow's hierarchy of needs, evidently the most famous theory of motivation, does consider human needs. This theory states that as soon as a worker achieves the satisfaction of his or her needs at a given level, he or she moves a level higher. The highest need is the need for self-actualisation (Armstrong and Taylor, 2015).

Modern theories of motivation see the worker as a scientific model. Approaches of this kind include the theory of goal setting created by Locke and Latham. This theory states that the performance of a worker increases with growing goals. A great many authors have followed up from this theory, which has been used in many studies (e.g. Erez and Judge, 2001; Erez and Isen, 2002; Landy and Conte, 2010). Motivation as a process is based on two basic types of motivation – internal and external.

When studying motivation, it is also important to consider two other areas – worker performance and remuneration. Worker performance is influenced by the size of the remuneration he or she is entitled to, and this in turn influences his or her motivation. Worker motivation and satisfaction is then reflected in the worker's performance. These three terms are, for this reason, extremely closely related and cannot be seen in isolation. The dependency between working performance and motivation is undeniable (Cherian and Jacob, 2013; Khan, 2012); motivation is not, nevertheless, the only factor to influence working performance. Each company tries to be successful and competitive, for which reason a motivational strategy must be defined at each company. An integral part of this is a motivational programme that elaborates a specific system of work with people and contains specific rules, measures and procedures (Němečková, 2015).

When we consider worker stability, we must not neglect worker satisfaction, high-quality staff leadership and management, a feeling of fairness, an open approach to staff, career growth, the variability of work, the corporate culture, and transparency. Great attention is devoted to staff motivation in companies in developed market economies. Companies use the services of external firms that help with the appropriate configuration of motivational strategies, or employ experts in this area in-house. Reducing the costs associated with a high level of employee fluctuation connected with dissatisfied staff can be achieved by effective motivation, which is not, of course, focused on dissatisfied members of staff who want to leave the company, but on future members of staff (Němečková, 2015).

Staff motivation and remuneration is a key process at any company, as its functioning is always dependent on the human factor. The current situation on the labour market in the Czech Republic is imbalanced, since there are a large number of job vacancies and a lack of qualified staff. Companies are, for this reason, trying to offer new staff members benefits and advantages of many various kinds and a talent war is gradually beginning to break out (Businessinfo, 2019).

For a company to be attractive to employees on the labour market, it cannot neglect their needs. These needs change both over time and in dependence on change to hierarchical position within the company. Remunerations are generally divided into material and non-material rewards. The first are made up of monetary rewards, while the second are comprised of value rewards. This set of rewards has a

considerable influence of whether a staff member will seek a new job or not. Czech Business (2019) writes that monetary rewards resolve merely the basic needs of a company's employees. Overall staff satisfaction and motivation is, of course, also comprised of another two pillars. The second pillar is comprised of the company culture, while the third pillar is the work itself. Only a good balance between all three pillars leads to staff satisfaction. Research into employee satisfaction conducted by Gallup in 2017 indicates that the second and third of these components contribute as much as 87 % to a higher level of commitment among employees and their growing productivity, and a consequent increase in company productivity of as much as 30 % and an increase in company profit of 20 %. The management of employee satisfaction and commitment has been moving to the level of an improved employee experience in the last two years in the Czech Republic under the influence of "design thinking" (Czech Business, 2019).

Many studies demonstrate that motivated staff are more orientated towards independence, are more responsible and are typified by greater engagement in the company (e.g. Ryan and Deci, 2000; Thomas, 2002; Kuvaas and Dysvik, 2009; Vansteenkiste et al., 2007). Many managers presume that a material system is the best possible employee motivation. While it is a key element in keeping employees at the company, mere financial reward does not, as has been stated above, suffice to ensure the complete satisfaction of employees. An acceptable level may be achieved by managing employee motivation by means of financial reward alone, though truly excellent results cannot be achieved in this way (Mura et al., 2017; Strachová et al., 2018).

Motivation also differs by gender. Women and men build their careers differently, and education, profession and the selection of work are limited by stereotypes and social standards (Knapcova and Kucharcikova, 2015). Environment, tradition and society also have a significant influence on employee motivation. In their study, Ližbětinová and Hitka (2019) point to the difference in worker motivation in the Czech and Chinese environments. The employees of Czech companies are more demanding in obtaining the desired level of motivation, while Chinese employees are less demanding in all key areas – the atmosphere at the workplace, team leadership, pay conditions and the approach taken to employees. Preconditions for this difference can be found in the differing level of economic maturity (Poór et al., 2018) and the approach taken to workers.

Employee motivation, their performance and, consequently, the performance of the company are increased by the education of employees. In their study, Jones et al. (2009) point to the fact that training and the development of skills have a positive relationship with job satisfaction, which is subsequently interconnected with employee performance. Training can be considered a tool both to keep employees at the company and to increase competitiveness on the market (Kauffman, 2010; Khan, 2012). Open communication at the company also contributes towards greater employee motivation. This relates particularly to adequate communication in the assignment of tasks, feedback, communication regarding remuneration, and the strengthening of formal and informal relationships at the workplace (Abolade, 2015). Where there is inadequate communication, employees are not capable of meeting their tasks properly and the company does not achieve its goals, while inadequate communication within a working team reduces its performance. All these factors contribute towards weakening the corporate identity and, most importantly, reduce the performance of employees and their satisfaction and motivation (Rudd and Mills, 2015; Syallow et al., 2017; Robbins et al., 2010).

Methodology

This paper aims to find key indicators in group factors in the area of motivation for the top management of large concerns in the manufacturing industry in the Czech Republic. Motivation is a key area in the remuneration of employees as it makes it possible to retain employees at the company, to increase their productivity, and to ensure growth in the performance of the company and the management itself. The paper further aims to identify important latent variables that influence motivation in a company's top management as a select group of employees. Empirical data for the research was obtained by means of a structured questionnaire survey. Necessary conditions to the selection of companies were the number of employees, which had to be higher than 250 in order for them to count as large concerns, and the company's principal subject of business being the manufacturing industry according to CZ NACE

classification in category C. Only financially healthy companies, i.e. those not categorised as bankrupt or insolvent, were included in the research. The appearance of such bankrupt or insolvent companies in the research could lead to significant distortion of the results, since their remunerations could be purposefully reduced. A total of 444 companies were selected for the research.

The data obtained was evaluated by the program IBM SPSS Statistics. The mathematical and statistical dependence of selected variables was assessed by the use of the Chi-squared test and factor analysis. The primary function of factor analysis is the reduction of variables. Reduction can be performed only under the condition of the mutual dependencies of variables and the given dependencies being the result of the action of a certain smaller number of unmeasurable quantities in the background, known as factors. Numerical results or visualisation by means of a scree plot can be used for the evaluation of factor analysis. Such a scree plot depicts the scatters of all factors. The curve is a falling curve and the limit determining the appropriate number of factors is found where there is the largest fall in the scatter between two factors (Cattell, 2012).

The essence of factor analysis lies in the selection of correlation and partial correlation coefficients. The aim is to uncover the correlation structure of the group of manifest variables on the basis of a lower number of latent variables that cannot be measured. Two tests are used to assess suitability (Tarnanidis et al., 2015; Conti et al., 2014):

- The Kaiser-Meyer-Olkin Test (KMO) – the determinant is its coefficient located within an interval of <0;1>. The closer the value is to the number 1, the more suitable the given group of variables is for the use of this analysis.
- Bartlett's Test of Sphericity – the basis is the definition and testing of the null hypothesis that the correlation matrix of variables is unitary, and therefore that the variables are not mutually correlated.

Results and Discussion

The theoretical part of this academic research focused on the remuneration of employees and their motivation. These two areas are extremely closely interconnected, and remuneration is of key importance to the motivation of employees. The variability of remuneration of top management is higher than it is among other employees, since the nature of their work is also more variable. Since the top management is critical to any company, emphasis must be placed on its motivation and, thereby, its increased loyalty to the company. This paper focuses, then, on determination of the factors that influence the motivation of this select group of employees.

The following factors were defined by factor analysis:

- X_1 – the fixed amount of the gross monthly salary of the employee
- X_2 – the development of personal skills and knowledge
- X_3 – the fairness of remunerations
- X_4 – the variability of work
- X_5 – the transparency of remuneration
- X_6 – the communication of remuneration

The chosen variables can be interpreted as a preliminary result, since this research also has its statistical limits that are later described in the article. The barriers to the research and the possibilities for subsequent future research are also defined.

The KMO test is used for the purposes of factor analysis; its value should not be lower than 0.5, while the resultant value of this test falls within an interval of <0;1>. In addition to the KMO test, Bartlett's Test of Sphericity was also used to assess suitability. A KMO test value of 0.594 was recorded for the selected variables and the research conducted, while the significance of Bartlett's Test of Sphericity was 0.000. The hypothesis of the sphericity of the correlation matrix (or the fact that this is not a unitary

matrix) can be rejected thanks to this result. The chosen methodology would, therefore, seem to be appropriate for the assessment of the data obtained.

The total scatter of performance indicators is defined according to values that represent the scatter explained by the individual factors. The results presented demonstrate that only two factors attained the minimum required limit, which is the number 1. The factor analysis performed therefore extracted two factors that explain the differences of all the individual cases at a level of almost 52 %. The main result of factor analysis is a rotated matrix showing the strength of the individual variables. The Varimax method is used for rotation, and was also used in this case. The selected factors are defined as follows:

$$I1 = 0.769\ X_2 + 0.648\ X_3 + 0.722\ X_4 + 0.546\ X_6 \quad (1)$$
$$I2 = 0.849\ X_1 + 0.4358\ X_3 + 0.486\ X_5 \quad (2)$$

The indices determine important factors that affect the motivation of top managers and contribute to the greater loyalty of these employees and the performance of companies and management itself.

Table 1: Extraction of variability into new factors

	Initial Eigenvalues			**Extraction Sums of Squared Loading**			**Rotation Sums of Squared Loadings**		
Components	Total	% of VAR	% of Cumulative	Total	% of VAR	% of Cumulative	Total	% of VAR	% of Cumulative
1	2.017	33.621	33.621	2.017	33.621	33.621	1.908	31.801	31.801
2	1.096	18.272	51.893	1.096	18.272	51.893	1.206	20.092	51.893
3	0.956	15.925	67.818						
4	0.831	13.842	81.661						
5	0.701	11.682	93.342						
6	0.399	6.658	100						

Source: The authors

The first two components contribute most to explaining the variability of the original factors (variables). The first of these explains 33.62 % of the variability and the second 18.27 %. Both these factors together then explain 51.89 % of the variability of the original model. The number of factors is selected according to its value, which determines variability. This value should be higher than 1. It is clear from Table 1 that the value of the third factor is extremely close to 1 and could, therefore, be theoretically included among the group of factors explaining the variability of the model as a whole. This factor was not, however, included for reason of the improved interpretation of the results, since the overall variability would increase by just 15.92 %.

Visualisation of the results by means of a scree plot also serves for the assessment of the suitable number of factors. The number of factors at which an “elbow” occurs should be chosen. A visualisation of the results is given in Figure 1.

Figure 1: Scree plot of the number of factors. Source: processing by the authors in the program IBM SPSS Statistics

Comparison of the results of the empirical research performed with the theoretical research confirmed that the employees at the Czech concerns addressed see the possibility of further education and career development as a tool for increased motivation (factor X_2). These results are also confirmed by the research by Jones et al. (2009), Kauffman (2010) and Khan (2012). The research confirmed that the openness of communication and transparency of remuneration is also a motivational factor, and this was defined as factors X_5 and X_6; this motivational factor is supported in the theoretical research by the works by the authors Abolade (2015) and Syallow et al. (2017). Factors such as the fairness of wages, their fixed amount and the variability of work are, however, also important factors for employees in the Czech Republic.

The indices created may serve company owners in particular. The limit to this research is the engagement of a low percentage of the managers addressed, for which reason these results cannot be applied across the board for all concerns. Future research could focus on various forms of benefits and specific remunerations for top management and their relationship to the increased motivation of these employees.

Conclusions

At a time of ever-increasing company competitiveness, and with the coming digitalisation in the form of Industry 4.0., it is now more essential than ever to assure and satisfy the needs of one's employees by means of their motivation and a wide range of benefits. Financial valuation in the form of a salary is no longer entirely sufficient, though it remains a strong motivational factor (Mura et al., 2017; Strachová et al., 2018). Economic development and the situation on the labour market are forcing companies to come up with new forms of remuneration in order to assure the loyalty of employees, who are an increasingly important production factor in the company (Gottwald et al., 2017; Zameer et al., 2014). As the study by Hitka et al. (2017) states, motivational factors in the Czech Republic are comparable with those in the business environment in Slovakia and Hungary. The paper presented here points to six important factors that increase the motivation of employees in the Czech Republic, and thereby contribute to their greater satisfaction and, subsequently, performance.

Abstract

Key factors of successful activity in the modern world are the learning, innovation and cooperation. Identification of abilities in the early age is necessary for further development and success of human activity in the future. The aim of the study is to highlight the results of the empirical study aimed at motivational factors that influence the identification and formation of the personality of pupils with special abilities. To study motivation of pupils, questionnaires and methods were used of personality diagnostics on motivation to success of T. Elers. The Questionarie of creative behavior KANE of S. Popek was applied for the study of pupil's creativity level and the peculiarities of their cognitive and characterological spheres. In the theory of multiple intelligences was indicated that success depends on the extent to which the person is using intelligence, and the goal of the school should be to develop the intellect and help the young person to achieve a professional and unprofessional goals that corresponds to a specific spectrum of intellects.

Keywords: Immanent Motivation, Emotional-Motivational Training, Spiritual and Moral Training

Introduction

Creativity, which is a fundamental characteristic of human nature, can be manifested in any activity, attitude to work, etc. There is a direct relationship between the development of creativity and the acquisition of competence as the ability of a person to perform a certain type of activity, which is expressed through knowledge, skills and other personal qualities. Creativity, as an expression of the health of the person, makes more interesting all the activities in which a person is involved. Formation of a creative person is preparation for self-development, management of one's own life, perfection in the chosen branch, self-realization, creation of one's own personality. Key factors for successful activity in the modern world are the learning, innovation and collaboration.

The purpose of the study is to highlight the results of the empirical study aimed at motivational factors that influence the identification and formation of the personality of pupils with special abilities.

Objectives for the goal of the study:

1. To reveal the informative characteristics of identifying abilities and the dynamics of their formation in pupils with special abilities.

2. To analyze the motivational factors influencing the formation of the student's personality with special abilities.

3. To reveal methods of revealing motivational dispositions of the person, which were developed in certain conditions of social environment.

Research Methods

The problems of creating appropriate systems of motivational-emotional programs for students with special abilities have been studied by a large number of scientists (A. Aubert, S. Molina, T. Shubert, A. Vidu, 2017; R. Kershner, 2016; L. Simpson, Y. Bui, 2017; A. Mez, L. Puigvert, R. Flecha, 2011).

The connection between intellectual and non-intellectual features in the structure of abilities drew attention D. Renzulli (1977). His model of abilities shows the interaction between the three main groups of personality characteristics, in particular creative ones. D. Renzulli (1977) assumes that human abilities develop through the interaction of the triad: intellectual abilities, creative abilities and motivation, which is integrated through the person and the environment of human life. It is about the cognitive and motivational spheres of the individual that were developed in a particular social environment.

S.Popek (2004) believes that the theoretical basis for the development of creative abilities is the interactive theory of abilities, which takes into account the appearance and influence on the human abilities of several equal spheres of the personality of man. The general model of abilities should take into account the interaction of the genotype with the environment. but within these factors, on the one hand, different spheres of personality that determine (intellectual, creative and special) abilities on the boundary of the genetic environment.

G. Gardner (2004) built the theory of multiple intelligences by distinguishing linguistic, logical and mathematical (as a set of logical, mathematical, and also scientific abilities), spatial (as the ability to create a mental model of the spatial world and the ability to maneuver and operate with such a model) musical, interpersonal (as the ability to understand other people, motivation of actions), physical-kinesthetic and intrapersonal (as a relative introverted ability, the ability to formulate an exact and actual model of oneself and ability to efficiently operate this model in real life) intellects. G. G. Gardner (2004) interprets intelligence as the only ability that helps in any problem situation. In particular, bodily-kinesthetic intelligence is the ability to solve problems or simulate the effects of using the whole body or its parts. As G. Gardner notes (2004) success depends on the extent to which the person is using intelligence, and the goal of the school should be to develop the intellect and help the young person to achieve a professional and non-professional goal that corresponds to a specific spectrum of intellect. In the theory of multiple intelligences, the biological origin of each skill is taken into account in solving problems.

To study the motivation of students, questionnaires and methods of personality diagnostics were used to motivate T. Ehlers' success (Practical Psychodiagnostics, Methods and Tests, 1998). To study the level of creativity of students and the peculiarities of their cognitive and characterological spheres, the Pitalnik of the creative behavior of KANE S. Popek (2004) was used.

Results

We attracted teachers working with teaching young people with special needs. We selected teachers from more than 30 educational schools from different countries of Eastern Europe. Ultimately, we wanted to establish whether teachers use non-standard teaching methods or only traditional ones (Figure 1).

Fig 1: A survey of leading teachers in Eastern Europe on the use of non-standard methods of teaching the pupils with special abilities (created by authors)

Identifying one of the types of intelligence (abilities) at an early age is necessary for its further development and success of human activity in the future. The modern school is more oriented towards the development of logical and linguistic intelligence. According to G. Gardner (2004), this may inhibit the development of other intellectuals, in particular bodily-kinesthetic, which is often important for the development of personality, especially for achievements in sports. The goal of the school is to help young people achieve their chosen life goal, which is appropriate to their range of abilities and educational needs. The search for and implementation of non-standard teaching methods for the development of students in order to identify and develop individual enrollments are the following phases:

• information, which consists in the selection or creation of organizational forms for implementation in practice and search-creative training schemes, forecasting of the results of activity;

• motivational, which means to form a creative and supportive learning environment;

• strategic, aimed at introducing innovative teaching methodologies into practice. In this phase, the teacher's readiness for creative activity and the search for ways to implement the planned learning outcomes and personality development are required the ability to reorient in the course of the activity;

• diagnostic, in which the analysis of the learning outcomes and the planning of the system of appropriate pedagogical influences is carried out in order to correct the educational activities.

Development is the result of the genotype - environmental interaction (Aleksandrov, 2004), and factors hereditary and environment are interrelated. The group influences all its participants,

normalizes educational, cognitive standards. Creativity is impossible if there is no definite (creative) environment (Druzhinin, 2007). The thrust to creativity begins in a group of people - real or potential associates (followers). For children with special abilities there are two models of behavior in a group, namely:

• be like everyone; then there is a danger of losing their creative potential;

• develop in accordance with their capabilities, that is, as a creative personality.

In the first case, the adaptive ways of developing the creative individual are possible on the condition of solving the problem associated with the adaptation, which means to find the appropriate favorable environment. Creative people are non-conformist, and personal standards are more important to them than group standards.

Young people need to be able to anticipate changes and adapt to them on the personal and social levels, creative activity helps to adapt to the changes in modern life to increasing they spiritual and moral training. Every person has an individual set of interests, therefore the presence or absence of an incentive for their development and implementation is decisive. The definitions of abilities relate to individual psychological peculiarities, which are subjective conditions for the successful implementation of a certain type of activity and peculiar qualities (a combination of certain features, characteristics, peculiarities) which allow to reach a certain level of creative activity.

The development of creativity can take place by this way: on the basis of general giftedness, under the influence of social microenvironment, imitation and training, a system of motives and personal qualities is formed (non-conformism, independence, and motivation for self-actualization). Then it is ambitious and stubborn, enduring and principled, creative people are indifferent to the critique of young people.

In the motivational-emotional sphere, the activity of the teacher is aimed at helping students open their own creative abilities, increasing their self-esteem and overcoming obstacles that complicate activity, and develop optimistic approaches to problem solving (Vişan, 2017).

Immanently motivated person brings joy to the very activity, while a person motivated by the need for achievements is satisfied with the results of this activity. Voltage and nervous experiences, increased mental activity accompany the process of studying at school. The lessons of physical culture and sport are a way of relieving stress, gaining callous emotions and motivating to study and train, gain social qualities and form a personality.

Human creativity in the chosen industry can be motivated in many ways. Different stages of the individual development of the creator will require different motivational factors. External motivation associated with a reward or its expectations may be a stimulus to the activity of a particular type. Subsequently, along with the pleasure received through the performance of creative activity, personal motivation appears. Then the value of external awards and praises diminishes. This phenomenon T. Amabaill (1996) calls motivational synergy. The motivation and emotional training of creativity is offered for the formation and development of the student's motivational and emotional-volitional fields (endurance, readiness for risk, non-conformism, will, ability to overcome obstacles). Trainings of creativity are the way to stimulate, support and develop special abilities of the person to perform a certain type of activities. One of the basic features of creative thinking is an active approach. The need to demonstrate their own preferences does not, in the majority, contribute to creativity, and the need to achieve a higher level of mastery and professionalism in the chosen industry will contribute to this. The need for excellence is close to the so-called "hubristic" motivation as an attempt to confirm and enhance the importance of one's own person (Tokarz, 2007). The purpose of the motivational-emotional type of the training of creativity is the development of motivational dispositions. They are needed to form, if necessary, the ability to stimulate the motivation process

(for example, interest, initiated creative activity, the desire to successfully perform a certain type of activity, the desire to win).

Examples of training tasks:

Exercise "Auction of motives". Exercise is needed, first of all, to determine the rating of factors that support activity or an obstacle to active activity.

The teacher invites students to write what encourages them to perform a certain type of activity, preparation for something, the desire to improve the result, the desire for success and victory, that is, the motives of their activity. The following options were obtained:

1) interesting because pupils learn something new, get new knowledge, interesting information;

2) an attempt to prove that it is possible to overcome difficulties, to win the competition, the desire to be useful to society, that is, social motivation;

3) demonstration of its significance, the desire to take a worthy place in the classroom, in a team, that is, positional motives (hubristic motivation);

4) the desire to be interesting for peers, to develop and improve, to succeed, to win, that is, the motives of own growth, improvement;

5) awareness that certain achievements at a young age are welfare and recognition in the future, high-paying work;

6) need to work, parents and trainers require high results, ashamed before teacher, coach, that is, narrow educational motives;

7) fear of being threatened to be mocked, fear of criticism, fear of losing;

8) excessive motivation as a consequence of a lack of time and external pressure;

9) fear of risk, fear of a new one;

10) reluctance to identify their own activity, generate their own ideas or lack thereof;

11) the continuous desire to criticize the achievements and behavior of others without their own achievements and constructive suggestions;

12) learning and achieving something in life does not make sense, do not need.

The teacher holds an auction at the lesson where pupils can buy training motives. The auction consists of two parts. At first, purchases of motives-stimulators of creative activity are carried out, and then - inhibitors (obstacles) of creativity. The "buy" motives the teacher stimulates in various ways (given the situation moments, conditions, features of the class, teams, proposals, etc.). Conducting a didactic game sets the teacher with certain requirements, namely: emotional maturity and personal creativity.

Students give out a certain number of "conditional units" to participate in the auction, for which a motive can be obtained. It is clear that the corresponding motive will be received by someone who will pay more for him. After the "sale" of motive-stimulants go to the second part of the auction, there is a "sale" of motives-inhibitors. The meaning of their acquisition is the finding the stimulant

content in the motive-inhibitor, one can get the same number of "conditional units" as previously expended. While the buying a motive-inhibitor, they need explanations, for example, the activity because of fear does not justify the hopes you have on your victory in the competitions forming the ability to overcome oneself, overcome their weaknesses, which will help to achieve success. The winners of the auction are determined by the final amount of each of the participants, which the teacher can reward at his discretion.

The result of the auction, in particular, is the discovery and research of the motives that dominate the students, on the basis of which it is possible to make correction if necessary. The motives that have a direct impact on the development of special abilities of the child are desirable. To do this, among other things, you need a corresponding social order for the results of work and the belief that high qualifications and a high standard of living - things are interconnected. Significantly influence the process of forming the motives of the dominant set-ups in society, that is, what society is guided by, parents, mentors, what is the position of teachers and trainers.

• Exercise "Overcoming the stressful situation". Discussion of difficult situations that arise or may arise during training, conflicts with teachers, mentors, classmates, parents at home. The conflict situation, ways of overcoming it are analyzed. Students are encouraged to submit suggestions on ways to remove internal tension or poor health. To do this, you can use the method of brainstorming.

• Exercise "Ability to listen". Exercise to develop the ability to listen to the arguments of others, the ability to conduct a dialogue with mentors and peers. Several students together choose an object or phenomenon, describe their characteristics, the principle and result of action, the possibility of application, not naming the object itself or phenomenon. The rest of the students should disclose them by description and explanation.

• Exercise "Naive Questions". One of the students plays the role of a naive person who does not understand the simplest tasks, and in this regard puts unexpected but logical questions that must relate to problems that are, at first glance, obvious.

A series of such "naive" questions makes it possible to obtain two effects, namely: firstly, it becomes clear how some of our beliefs and positions are somewhat obvious, and therefore can be changed if necessary; and secondly, it turns out that our solutions are built on non-verbalized knowledge, and therefore so little can be changed if we adhere to standard and ill-informed statements and assertions.

In the motivational-emotional sphere, the activity of the teacher is aimed at helping students open their own creativity, increasing their self-esteem and overcoming those obstacles. which complicate activity in any activity, development of optimistic approaches to problem solving.

Discussion

Studies have shown that after completing the tasks of motivational-emotional training, the number of students with moderately high and very high levels of motivation increased and the number of pupils with low and moderate levels decreased accordingly (as shown in Figure 2).

Fig. 2: A survey of leading teachers in Eastern Europe on the use of non-standard methods with teaching the pupils with special abilities (created by authors)

For the same functional readiness for the competition wins the one who has the best emotional and psychological readiness. Sometimes in sports the winner is not the one who has a higher level of training, but the crash of psychological readiness for the competition is better motivated. Although too much motivation can become an obstacle to creativity lead to burnout before the start of the competition, start.

Studies have shown that teachers, mentors with greater pleasure work with students with a higher level of intelligence, but not creative, than with a relatively lower level of intelligence, but creative and active, at their same level of achievement. The teacher must adhere to psychological and pedagogical principles in his creative methodological work, which relate to the conditions of the development of the individual, to take into account the various aspects of the learning environment.

Conclusions

Every person is born with certain instincts, has certain abilities that need to be identified, stimulated and developed in context of spiritual and moral training. It is a guarantee of successful activity in the future. It is important to identify the abilities of the child in preschool and early school age, in order not to lose them. Knowledge of laws that have an impact on the processes of change can be an instrument for improving the innovation in education. General knowledge of this type helps to understand what different forms of change differ, their course and what will be pedagogical and social consequences.

The psychological state of a person, his mood for success, his motivation, the confrontation with external pressure, and the ability to overcome stressful situations are important for successful study and achievement of good results in studying and sports. The goal of the school is to help young people to achieve their chosen life goal, which is appropriate to their range of abilities and educational needs.

For the formation and development of the pupil's motivational and emotional-volitional fields (endurance, willingness to risk, non-conformism, freedom, ability to overcome obstacles), motivational-emotional training of creativity is offered. The teacher must adhere to the psychological and pedagogical principles in his creative methodological work, taking into account the various aspects of the learning environment. For a successful study and the achievement of good results in

education and sport, the psychological state of a person, his or her determination to succeed, the confrontation with external pressure, and the ability to overcome stressful situations are important.

Human creativity in the chosen field can be motivated in many ways. Every person has an individual set of interests, therefore the presence or absence of an incentive for their development and implementation is decisive. Different stages of the individual development of the creator will require different motivational factors. External motivation associated with a reward or its expectations may be an impetus for the activity of a particular type. Subsequently, along with the pleasure received through the performance of creative activity, personal motivation appears. Then the value of external awards and praises diminishes. The objective of the school is to help young people to achieve their chosen life goal, which is appropriate to their range of abilities and educational needs. Road Signs Evaluation and Improvement of Effectiveness Using Mobile-Eyetracking Method - Conteptual Framework

Jacek WACHOWICZ

UTP University of Science and Technology in Bydgoszcz, Poland, jacek.wachowicz@utp.edu.pl

Abstract

According to World Health Organization, motor vehicle accidents on raods cause more than 1.2 million deaths worldwide. This isseriousproblem,whch requires serious concern. One of main primary sources on causes of road accidents may be police reports of road accidents. According to them, one of important primary factors may be connected with road signs readibility and ease of understanding. To improve that author proposes use of eyetracking technique,whichmay helptounderstand how drivers see and perceive road signs. This may lead to better ways of informing drivers on roads. Inthis paperpreliminary research has been done for future research.

Keywords Safety on Roads, Eyetracking, Road Signs Effectiveness

Introduction

According to World Health Organization, motor vehicle accidents on raods cause more than 1.2 million deaths worldwide (World Health Organization, 2015) This isseriousproblem,whch requires serious concern. One of main primary sources on causes of road accidents may be police reports of road accidents. According to them, one of important primary factors may be connected with road signs readibility and ease of understanding.

The quality of ways how road sign inform drivers how to drive may influence traffic, and futher its safety. City of London, drove research that phas proven that anything which facilitates consistency and predictability would result in smoother traffic flow. However, this seems to be very often not take into consideration. The same report indicated that drivers in central London feel particularly strongly that existing signage is inadequate and does not help them to navigate. A sample roadsigns that make it difficult to understand has been shown on Fig.1. This has a detrimental impact on consistency because people who are having difficulty finding their way will often be travelling more slowly. Respectively, a large number of traffic signs can result in the same problem [Smoothing… 9]

Fig. 1: Sample road signs overuse

Therefore it is essential that, when installing traffic signs, road authorities should make sure that the signage provides a service readible and useful information to the user and does not gerenate unnecessary confusion. This means first and foremost, avoiding an 'over-population' of traffic signs which, apart from confusing users, is also an ineffective use of public resources.

This may be confirmed by police reports. Which place among most frequent traffic colision sources such factors as Eyesight problems, physical problems, slow driver reaction, fatigue, weather, inattention, road conditions, poor driver judgement.

Table1: Main sources of traffic collisions in police reports

Police	Male drivers			Female drivers		
	Younger	Middle age	Older	Younger	Middle age	Older
Other driver (third party)	3.90	6.49	3.90	2.60	3.90	2.60
Unfamiliar with road (layout, route)	1.30	2.60	2.60	3.90	0.00	6.49
Drugs or alcohol	80.52	74.03	45.45	63.64	70.13	29.87
General driving ability (skills)	6.49	2.60	9.09	7.79	9.09	10.39
Excessive speed	80.52	72.73	32.47	72.73	59.74	24.68
Inexperience	61.04	3.90	2.60	62.34	6.49	7.79
Dangerous driving (peer pressure, showing off)	31.17	9.09	5.19	11.69	1.30	2.60
Distraction (phone, friends, kids, outside)	68.83	55.84	19.48	88.31	67.53	22.08
Driver error (poor judgement)	14.29	11.69	36.36	15.58	22.08	40.26
Road conditions (road layout, road hazard)	20.78	28.57	20.78	28.57	29.87	28.57
Inattention (concentration)	15.58	20.78	25.97	20.78	27.27	15.58
Careless, reckless or in a hurry	12.99	11.69	9.09	15.58	11.69	9.09
Vehicle defects (mechanical failure)	22.08	16.88	12.99	14.29	14.29	9.09
Weather	25.97	29.87	23.38	20.78	31.17	28.57
Overconfidence	7.79	3.90	1.30	1.30	3.90	0.00
Failed to look properly (poor observations)	6.49	9.09	10.39	5.19	5.19	11.69
Traffic	2.60	2.60	2.60	3.90	1.30	3.90
Fatigue	12.99	32.47	19.48	15.58	28.57	19.48
Driving too slow for conditions or slow vehicle	0.00	0.00	0.00	0.00	0.00	3.90
Slow driver reaction	0.00	0.00	20.78	0.00	2.60	22.08
Medical condition (physical impairment, medication)	10.39	35.06	77.92	10.39	23.38	67.53
Poor visibility	5.19	5.19	9.09	6.49	7.79	16.88
Eyesight (uncorrected or defective)	0.00	7.79	57.14	0.00	6.49	53.25
Dazzling light (headlights or sunlight)	1.30	5.19	2.60	0.00	5.19	2.60
Nervous or uncertain (hesitation, confusion, lack of confidence)	0.00	1.30	11.69	2.60	9.09	15.58

The influence of most of them may be reduced through effective road signs system, which would be helpful not only in good driving conditions.

Dr. Rune Elvik, "General overview on Road Safety", 1999, has interpreted these basic requirements. They reflect the main goal of road safety, whichmay be measured by reducing road accidents rates. It should be interpreted as a sequence of all 4 basic requirements that must be met, in a cascading flow, in order for the road sign to be effective. This may be presented ason Fig.2

Fig. 2: Cascading flow of sources for effective road sign compliance

Eyetracking method

Modern technologygave researchers chance to observe what people look at. This was enabled due to human eye properties, which require people to point the yellow spot at an object that one want to see clearly. Equipement that allows tracking tese movements are Eyetrackers. Usually they use infrared radiation, which allows to determine what is currently being watched by the respondent. Very often it is used to track what is viewed on a websites as the monitor screens have a fixed position in space, and therefore are relatively easy to process data collected during the eye movement study. However, Eyetracking technique advances allowed to build portable devices, which maily are used inmarketing research. Both of them collect data very quickly (usually determined 25 in simple and static research and up to 500 times per second in a precise and dynamic ones). The result data determine the location in space that personunder research looks at, so they are very difficult to understand. Therefore, it became necessary to create methods for imaging the collected results so that they were readible and possible to be interpreted ina simple way by people. [Manhartsberger, M.; Zellhofer, N. (2005)]. Currently, inEyetracking, the most common and used techniques are: Hetamaps and Gaze-plot charts. Additionally, these methods are often accompanied by Think Aloud method, in which beside of eye movements, researchers note all statements and thoughts said by participants.

Heatmaps

Heat maps (heatmaps) were created as the application of the imaging technique known from cartography - where the height is imaged using colors. Originally, the red color on the maps was determined high altitudes, yellow - medium and green smallest. This scale has been adopted - and in the heatmap technique, the points of his focus are applied to the image viewed by the respondent. It is assumed that in the image viewed the areas in which the view was the most concentrated are illustrated in red, those which on average attract attention are shown in yellow, those that have only a minimal focus - they are illustrated in green. Areas that were not directly watched are left with the original filling. The respondents' attention may be calculated differently in this technique - the measures used are most often used [Bojko A.. (2009), O. Špakov, D. Miniotas (2007)] They may illustrate the number of times that a given area has attracted the subjects' eyesight, the time that the area was directly watched. In addition, the shape of the heatmap is influenced by the factors that shape the way of calculating the area of attention - the most important of which is the radius around the central point, which is affected by vision Sample heatmap is presented on Fig. 3 [Świerczyńska-Kaczor, U.; Wachowicz, J. (2012)]

Fig. 3. Sample Heatmap

Gaze plots

Gaze plots allow you to track the movement of the focus point for a given person. They are an illustration of observation that people do not look continuously. The movements of the eyeballs are of rapid nature - they move quickly from point to point, in which points the conscious reception of the image takes place. These points are called saccades, and paths are between them - transits. The gaze-plot charts illustrate both saccades and transitions. [Salvucci, D.D., Goldberg, J.H. (2000)] The first ones are depicted as circles whose radius is directly proportional to the time of focusing attention (thus allowing to differentiate the significance of observed points). The second one illustrates the path of eyeballs movement between the saccades. [Räihä KJ., et al. (2005), Sav Shrestha; Kelsi Lenz (2007)] In addition, numbers are placed on the sacraments indicating the order in which the given point was observed. An exemplary gaze-plot chart is illustrated on Fig. 4 [Świerczyńska-Kaczor, U.; Wachowicz, J. (2012)]

Fig. 4: Sample Gazeplot

The Research Framework

Use of modern mobile eyetracking technology allowing observation of eye movements may help understand how drivers perceive road signs which factors are crucial for effective understanding information necessary for a safe trip. This would require research done with mobile eyetracker hardware with dedicated software allowing readible presentation of obtained data, preferably in a form of heatmaps, which show which parts of visible area were mostly observed or as gazeplots which illustrate eye movements of a person under research. Such data should be colleted in different conditions (day/night, good/poor visibility, a lot of/moderate sign density etc.) as well as preferably for different drivers (e.g. men/women, young/elderly).

Conclusion

Safety on roads is one of points of interest in European Union. One of influencing factors is quality of road signs and its understandibility and ease of perception by drivers. Presented research concept is tryig to find answers in this important field with a concept of use of modern mobile eyetracking toolset.

Abstract

To reduce the losses caused by diseases and pests, weeds and other plant pathogens, in addition to the agro-technical measures used, pesticides are widely used in agricultural production both preventive and curative. The paper proposes an analysis of the quantities of plant protection products, at the country level as well as at the level of Brăila county, between 2012-2018. To carry out the work, official statistical data were analysed and processed. The results of the researches highlighted the fact that by withdrawing from the market of several plant protection products and by approving some plant protection products that are used in much lower concentrations, the consumption of these products decreased slightly in recent years.

Keywords: Agriculture, Agricultural Technologies, Plant Protection Products

Introduction

The challenges generated by the global increase in the demand for food, mainly due to the demographic evolution of the last years, have required that at global level the traditional agriculture to be gradually replaced by an intensive agriculture, in which, through efficient agricultural technologies, the plants shall be provided with the optimum water requirement, nutrients, light, heat, density - space for nutrition, protection against diseases and pests, factors with direct impact on production (Stanciu, 2017). This production system has brought many economic benefits to agriculture, but in the longer term it can create imbalances in the environment. Production of agricultural crops is particularly sensitive to the weather conditions prevailing at key times of the year, as well as to the attack of diseases and pests, which imposes plant protection procedures against weeds and pests. (ICPA, 2019) According to Braicoop cooperative specialists, about one third of the potential crop is destroyed by harmful organisms, so plant protection is an important technological link that can help increase agricultural production and improve crop quality (http://braicoop.ro). For example, in lower temperatures in spring, the growth rate of maize plants is slowing down, which may favour the attack of pests, especially the maize leaf weevil *Tanymecus dilaticollis* which can

completely destroy the crops. Research conducted at NARDI Fundulea in this regard, under field and laboratory conditions, highlighted the need for maize seed treatment to combat this pest (http://www.incda-fundulea.ro/anale/82/82.22.pdf). Also, spring-summer droughts and heat waves can cause significant production losses, and weed development and pest attacks can increase in size, making harvesting difficult and reducing crop quality (Stanciu, 2018). Therefore, the meteorological and hydrological conditions play an important role in the level of crop production, the plants need a number of favourable growth factors and actions to reduce pests. For the reasons presented above the control of weeds, diseases and pests, by applying treatments with plant protection products is necessary for the cultivation of plants (Stoica (Dinca) et al, 2017). Applying plant protection procedures against harmful organisms is a major component of GAP, guidelines for Good Agricultural Practices. According to the Report on the Implementation of Directive 2009/128/EC, the use of pesticides has been steadily increasing in Europe since 1996, although there has been much discussion about the sustainability of agriculture and despite the introduction of pesticides that can be used in small doses, average use has not decreased significantly in recent years. The total volume of annual sales of pesticides at European level amounted to 400,000 tons in 2015, the vast majority of them being used in agricultural production. (http://www.europarl.europa.eu). The use of these products, which must be officially approved and officially recommended or authorized by the competent national authorities for the purpose of effective and safe control of the harmful agents for human health and environment, must be done in compliance with the good agricultural practices which stipulate among others that they must not exceed the authorized doses or to be applied in such a way as to lead to a minimum residue quantity (ICPA, 2019). According to the Association of the Plant Protection Industry of Romania (AIPROM), during the last 60 years' pesticides have become less toxic and persistent in the environment, but much more efficient (Stoica (Dinca) et al, 2017). Under these conditions farmers can apply to the crops lower doses of pesticides having similar protective effects. Pesticides currently used in agriculture are less toxic and have greater safety in use. (https://www.aiprom.ro).

Materials and Methods

In order to carry out the work, the quantities of pesticides used as plant protection products at the national level and in Braila county were analysed, between 2012-2018. In this respect, official statistical data from Tempo online, the database of the National Institute of Statistics (NIS) in Romania, were taken and processed. The results obtained were analysed, graphically represented and interpreted, the conclusions being correlated with the information from the specialized literature. Scientific papers were used to obtain bibliographic information, from the databases Clarivate Analytics and Google Academic, respectively the collection of legislative documents available at the level of the European Commission, the Directorate-General for Agriculture and Rural Development.

Results and Discussions

Pesticides are used as a control measure when other agricultural production strategies cannot reduce the population of pests below an acceptable threshold, are too expensive, time consuming, or when quality or yield effects are unacceptable to the farmer. Pesticides are products for plant protection against pests and diseases that contain at least one active substance. Pesticides are classified, depending on the effects and the pests controlled, in herbicides, insecticides, fungicides, acaricides, nematicides, molluscocides, ratacids and with mixed action, insecto-funcicides. (Https://chemicalsinourlife.echa.europa.eu/ro/chemicals- in-agriculture). The main effects of the application of pesticides are the positive influence on the growth rate of the plants, the conservation of useful components from the plants, the stripping or preventing the growth of unwanted plants (ECHA, 2018). At the national level, herbicide-treated crops hold the highest share in the application of plant protection chemicals. During the analysed period we can see a slight decrease of the herbicide-treated surfaces from 49% in 2012, to 41% in 2018. The surface treated with fungicides, from 27% in 2012 increased to 30% in 2018, and the surface treated with insecticides increased from 27% in 2012 to 29% in 2018 (Figure no. 1).

Figure 1 : Agricultural surfaces treated with pesticides at national level
Source: Authors, processing data from NIS -Tempo online 2020

Regarding the weight of the application of the different classes of pesticides, the herbicides are used in the greatest quantities for the protection of the plants, being followed by fungicides and insecticides. According to the data presented by NIS (2019), we can see a slight decrease from 3.678 tons of active substance, in 2012 to 2.739 tons in the year 2018. The quantity of fungicides used decreased slightly in 2018 and the quantities of insecticides used had an oscillating evolution during the analysed period, with a slight decrease in 2018. This decrease is due, on the one hand, to the approval of products that it is used in smaller doses, but probably also the increase of the ecologically certified areas from 182,706 ha in 2010 to 326,259 ha in 2018 (https://www.madr.ro/agricultura-ecologica/) (Figure no. 2)

Figure 2: Pesticides used at national level
Source: Authors, processing data from NIS -Tempo online 2020

Herbicide treatments applied to agricultural crops at national level, expressed in tons of active substance (s.a.), show significant differences at the level of the 4 macro-regions of development, depending on the analysed period and the weight of the agricultural surfaces related to them. Thus, a significant reduction of the herbicide doses used in Macro-region I, from 991,672 kg s.a. in 2012, at 460,571 kg s.a. in 2018 and in Macro-region III from 582,036 kg s.a. in 2012 to 399,790 kg s.a. in 2018, while in Macro-region II the quantity increased from 1,055,838 kg s.a. in 2012 at 1,118,639 kg s.a. in the year 2018 (Figure 3).

Figure 3: Herbicides used nationally, by years and by macro-regions of development
Source: Authors, processing data from NIS Tempo online 2020

Fungicides are plant protection products used for both curative and preventive purposes to combat plant diseases. The quantity of fungicides used nationally, by years and by macro-regions is shown in Figure 4.

Figure 4: Fungicides used in the period 2012-2018 on Macro-regions of development
Source: Authors based on NIS tempo online data 2020

Insecticides are chemicals used against pests both in seed and in vegetation or in stored crops. Figure 5 shows the quantity of insecticides, expressed in kg of active substance, used at national level on macro-regions of development.

Figure 5: Insecticides applied to agricultural crops, on macro-regions of development
Source: Authors, processing data from NIS tempo online 2020

During the analysed period, the largest quantities of herbicides and fungicides were used in the Macro-region II located in the east and south-east of Romania, the area in which there are also the largest land areas used in agricultural production. (Figure no. 6).

Figure 6: Agricultural area for crops, by macro -regions

Source: Authors, processing data from NIS tempo online 2020

Brăila County is part of the South-East region of Macro-region II of development. Analysing the quantities of pesticides used in the county it can be seen that herbicides were used mainly, followed by fungicides and insecticides. The data shown graphically in figure 6 show an increase in the quantities of herbicides and fungicides, and in the insecticides we can see a decrease from 10 tons s.a. in 2012 at 7 tons s.a. in 2018. This variation in the quantities of herbicides, fungicides and insecticides is due to the crop structures set up at the farm level, as well as the decrease of the labour force engaged in the agriculture of the county (Stanciu et al., 2017) (Figure 7)

Figure 7: Pesticides used in Braila county

Source: Authors, processing data from NIS tempo online 2020

The quantity of herbicides used in Brăila county during the analysed period is lower compared to Vrancea and Galaţi counties, but at the county level there was a slight increase in 2018 compared to 2012 (Fig.8).

Figure 8: Herbicides used in the South East Region, by counties

Source: Authors, processing data from NIS tempo online 2020

The analysis of the quantities of fungicides used in the counties of the South-Eastern Region of Romania revealed that Braila county has a moderate consumption compared to the other counties of the region. (Fig. 9)

Figure 9: Fungicides used in the counties of the South East Region
Source: Authors, processing data from NIS tempo online 2020

The quantities of insecticides used in the counties of the South-East Region are presented in Figure no 10. From the analysis of the data presented the county of Braila was in an average position, compared to the other counties.

Figure 10: Insecticides used in the counties of the South East Region
Source: Authors, processing data from NIS tempo online 2020

Compared to the Macro-region of which it belongs, the most used pesticides in Braila County in 2018 were fungicides, about 44% of the total, followed by herbicides 34% of the total and insecticides 22% of the total. (Fig. 11)

a) b)

Figure 11: Pesticides used in the Macro-Region II (a) and in Braila County (b) in 2018
Source: Authors, processing data from NIS tempo online 2020

In table no 1 the quantities of pesticides applied in Brăila County, by main categories, in kg of active substance applied per ha over a period of 7 years were calculated. The result showed that, with regard to herbicides, this quantity has increased in recent years. It may be a consequence of the fact that the availability of agricultural labour force is declining, and farmers are increasingly resorting to herbicides to keep the land clean of weeds. (Stanciu et al., 2017) Regarding the quantities of insecticides and fungicides, they showed a slight decrease that may be the result of the approval of some plant protection products that are used in increasingly smaller doses (Table 1).

Table 1: Pesticides used in Braila County agricultural production (kg/ha)

Pesticides (kg/ha)	2012	2013	2014	2015	2016	2017	2018
Herbicides	0.4746	0.3698	0.3648	0.3610	0.4059	0.4557	0.4876
Insecticides	0.085	0.085	0.085	0.085	0.084	0.081	0.081
Fungicides	0.3230	0.3243	0.3242	0.3242	0.3199	0.3135	0.3174

Source: Authors, processing data from NIS tempo online 2020

Conclusions

In the context generated by the growth of the global population and the necessity to increase the food need, the use of plant protection products is an essential factor for obtaining rich crops (Nicula and Stanciu, 2019). At national level, herbicide-treated crops have the highest weight in the application of plant protection products, followed by fungicide-treated crops and then by insecticide-treated crops. In the period 2012-2018 there was a decrease of the surfaces on which the herbicides were applied but the surfaces treated with fungicides and insecticides increased slightly during this period. Regarding the quantities of plant protection products used, herbicides are used in the greatest quantities followed by fungicides and insecticides. In the seven years analysed in all three categories of plant protection products, there is a slight decrease in the quantities used at national level, which means that the quantity applied per ha has decreased. In Braila county, as in the whole country, herbicides and fungicides are the most used pesticides. The data shown graphically indicate an increase in the quantities of herbicides and fungicides, while in the insecticides there is a slight decrease. Comparison of the quantities of active substance applied per hectare, in these seven years, showed that herbicides are used in larger quantity, while insecticides and fungicides have decreased the doses applied. Compared to the other counties of Macro-region II, Braila county has a moderate total pesticide consumption. This variation of the quantities of herbicides, fungicides and insecticides consumed is due to the structures of crops set up at the farm level, the pressure of pests, diseases and weeds during the vegetation period, as well as the reduction of the workforce in agriculture. Also, the decrease of the quantities of fungicides and insecticides consumed, the decrease of the quantities of active substance per ha are a consequence of the approval of the products that use lower doses, as well as the actions undertaken through the national policies in the field of agriculture.

Abstract

High-tech enterprises, possessing advanced technologies, are able to play a strategic role in ensuring the long-term, sustainable development of the national economy. This role is determined by the contribution of scientific, technical, production and personnel potentials of high-tech enterprises. A distinctive feature of these enterprises is the dominance of research activities and the related need for regular updating of used production factors. The effectiveness of high-tech enterprises depends largely on the quality of the intellectual resources used. The paper presents the results of an analysis of the effectiveness of two Russian high-tech enterprises using a modified production function. Cognitive capacity is calculated as the efficiency of using intellectual resources. As well as this, an interpretation of the results is also given. The proposed modified function can be used in practical activities to support the adoption of managerial decisions on the strategic development of industrial enterprises and increase their economic efficiency.

Introduction

In the modern economy, the place of an intellectual product rises in the hierarchy of social values, and high technologies and high rates of technological renewal of industrial production are highlighted (Innovative Development: Economics, Intellectual Resources, Knowledge Management, 2013; Gokhberg et al, 2018; Bukhvalov, 2016). As a result, long-term economic development is determined by the quality of intellectual resources and the developed information infrastructure available to high-tech enterprises (Frolov, Shirov and Gusev, 2018). The intellectual and information resources convergence leads to the new type of production factors emergence, i.e. the cognitive ones. By which we mean the totality of knowledge, abilities, and skills embodied in an economic entity that ensure the growth of employee productivity in creating an intellectual product that is in demand by the market.

The analytical dependencies used at the enterprise level do not fully reflect the efficiency of using cognitive production factors. On the one hand, traditional approaches to assessing the effectiveness of the production factors make it possible to take into account all possible effects, and on the other hand, the assumptions that underlie economic and mathematical models are constantly criticized. There is a need to develop a modified production function and model the effectiveness of high-tech enterprises using open data as an example. The aim of this work is an empirical analysis of cognitive production factors dependence and high-tech enterprises performance.

The structure of the article is as follows:

- Part 1 provides an overview of the main approaches using the economic-mathematical mechanism of a production factor (or PF);
- Part 2 proposes a model of a modified production factor;
- Part 3 focuses on modeling performance based on available data;
- Part 4 presents the results and conclusions.

Theoretical Review

Economic growth research has repeatedly attracted the attention of scientists (Bhagwati, 2006; Zamulin and Sonin, 2019; Mamonov and Pestova, 2015; Acemglou et al., 2018, Makarov and Varshavsky, 2012). In theories of economic growth, two major stages can be distinguished during the second half of the 20th century and the first two decades of the 21st century:

- Theories of economic growth, taking into account scientific and technological progress (1950 - 1960 of the 20th century);

- Theories of economic growth taking into account human capital (from 1980 to the present).

The most famous model of exogenous growth is the Solow R. model (Solow, 1957), which is based on investments in fixed assets and a corresponding increase in capital capacities per employee until a stationary state is reached. Labor productivity in this model is explained, first of all, by the capital-labor ratio per employee. A modification of this theory allows one to take into account 'technological progress', providing comparable rates of steady-state economic growth with the speed of technological progress.

Despite the relative simplicity of the Solow R. model (Solow, 1957), it allows one to explain many phenomena. Therefore, the model explains why developing countries are growing faster than developed ones. Considering that they have a small stock of capital capacities, but a large amount of labor, these capacities give a greater return, with little resources being spent on replenishing them. However, as capacities accumulate, the return on them decreases, and more and more resources are spent on maintaining them, i.e. the economy is growing at a declining rate.

To describe the growth in developed countries, Solow R. introduced a parameter of technological progress, which, multiplying the capabilities of the labor force, allows you to get away from the problem of a diminishing marginal product; and continuing to invest in new capital capacities. The main limitation of the Solow R. model relates to exogenously given parameters. Economic growth in his model occurs on its own.

The key idea of the second generation theories is that the skills and technologies created in one industry are transferred to others and that the return on investment in technological development ceases to be diminishing for the economy as a whole. An illustration of this idea is presented in the work of Nordhaus W. (1997).

Among endogenous growth models, Ramcey F. (1928), Cass D. (1965), Koopmans T. (1965), Diamond P. (1965), Romer P. (1990), Aghion F. (2015), Howitt P. (1992) models can be distinguished, Acemglou D. et al. (2016). Some of these models consider economic growth at the country level, i.e. are macroeconomic.

The works of Romer P. (1990), Aghion F. (2015), Acemglou D. (2016) explore the sources of growth at the enterprise level. Let us consider them in more detail.

The Romer P. model is the basis of the economic growth study at the company level, the so-called A-model. The production function in it is defined by the $Y = AK$ formula, where output is equal to productivity multiplied by the stock of capital capacities. Such a function does not have the property of a decreasing marginal product, therefore, investments create new capacities at a constant speed,

and while this speed is higher than the rate of disposal of the capital, output will increase. The higher the savings rate in such a model, the higher the growth rate. This result creates in the Romer P. model (1990) endogenous growth, depending on the players' decision, and which is not given exogenously. Although the A-model explores endogenous growth, it is implausible both in terms of its premises and in terms of conclusions, representing only a conceptual illustration of overcoming the trap of a diminishing marginal product.

However, avoiding the problem of a diminishing marginal product, Romer P. encountered the problem of non-competitive technologies (or the free-rider problem). Technologies act as a public good, which, in addition to non-competitiveness, also has non-exclusivity, i.e. a consumer cannot be forced to refuse to consume a given good. The merit of Romer P. can be considered as the fact that in his model he made technology temporarily excluded, since there is a monopoly on the use of technological developments. Conceptually, the model is formulated as follows: each period, the enterprise makes a decision on investments in physical capital and in Research and development (or R&D), taking into account the current level of technology. investments in capital give the enterprise greater production capabilities that are limited by the marginal product. Investments in Research and development give certain opportunities not only to the enterprise, but also to have a positive external effect, i.e. an increase of total in technology level in economy for the next period. Everything repeats during the periodt_1, enterprises make decisions on investments again, but already taking into account the greater technological capabilities. The general level of technology no longer has the property of a diminishing marginal product. Thus, enterprises receive steady economic growth.

The formal scheme of the model is as follows. Along with labor, not one type of capital, as in the standard model, but a whole set of intermediate capital factors is involved in production. The production function is as follows:

$$y = \left(\int_0^A x_i^{\alpha}\, di\right) l^{1-\alpha} \tag{1.1}$$

x_i – amount of intermediate factor $i \in [0, A]$
A – a parameter denoting the number of different capital factors is determined in equilibrium by the amount of total capital k

Capital factors are produced by different monopoly enterprises, and in order to produce x_i of factor i, need to bear the costs $\frac{1}{2}(1 + x_i^2)$. If the A parameter is responsible for the variety of production factors and the number of factors are optimally selected, then$A = (2 - \alpha)k$, $x_i = \bar{x} = \sqrt{\frac{\alpha}{2-\alpha}}$ for each $i \in [0, A]$. In equilibrium, the volume of production is:

$$y = (2 - \alpha)k\bar{x}^{\alpha} l^{1-\alpha} \tag{1.2}$$

α – parameter of a production function an exogenously given constant
$\bar{x}$, l – the costs of each capital factor and the total volume of labor are fully determined
α

By producing a new industrial product, an enterprise not only earns profit, but also promotes technological progress. The main merit of Romer P. was not so much his own theory as the fact that it served as a kind of impetus to a significant number of studies on this topic and renewed the interest of economists and researchers in the factors of economic growth at the enterprise level. Among the followers of Romer P., the most interesting models are Aghion F. - Howitt P. and Acemglou D. We shall consider them briefly. Therefore, in the theory of Aghion-Howitt, technological progress occurs due to the replacement of old goods with new ones. Each enterprise, developing a new technology, not only raises the overall technological level, but also crowds out companies producing obsolete products from the market. Since the basis of this model is based on the ideas of Schumpeter J. (1995) like 'creative destruction', seeing this, the authors called this model Schumpeterian.

The Aghion-Howitt model also attempts to combine cycle and growth theories. Researchers noticed that the presence of innovations strongly depends on the country's position relative to the technological border, i.e. from the world technological level. In a country that is close to the technological frontier, new technologies have to be invented. Developing countries have an advantage, i.e. they can import technology, greatly increasing their productivity. For economic policy, these results are significant.

First, the theory postulates the importance of antitrust law. Monopolies are harmful not only because they produce low-quality goods and sell them at inflated prices, they just have no incentive to innovate, because there is no market loss threat.

Secondly, the theory emphasizes the importance of education quality. The imitation of existing technologies and the invention of fundamentally new ones require a different level of education. In the first case, secondary and applied engineering education is important, in the second, fundamental science plays a much larger role.

Thirdly, the theory focuses on the macroeconomic policies stabilization for sustainable economic growth. In economic studies, it is customary to distinguish between the rates of long-term growth and short-term fluctuations, which stabilization policy is aimed at smoothing. Prior to the Aghion-Howitt model, it was believed that long-term growth is provided by the growth of economy production capabilities due to technological progress and the accumulation of capital capacities, and fluctuations around the trend are caused by short-term shocks and do not affect long-term growth. Aggregate demand shocks of can be offset by stabilization economic policy, i.e. a drop in aggregate demand can be stopped by expanding demand from the state or lowering the interest rate in the framework of monetary policy.

Aghion has shown that cyclical fluctuations are detrimental to long-term growth, as technological progress requires investments in Research and development, which are formed either from earned profit, or from borrowed funds. In the event of a recession, the profits of enterprises are reduced; their own funds are not enough. With well-functioning financial markets, you can use borrowed capital. With poorly functioning markets, this source becomes inaccessible. As a result, investments in Research and Development (R&D) are falling; technological progress and economic growth are slowing. An important feature is that in the event of an economic boom, the opposite effect is not observed: enterprises are in no hurry to invest in Research and Development due to temporarily high profits.

Thus, the recession suppresses technological progress, and the economic boom does not stimulate it, therefore, the economy volatility is a deterrent to its economic growth.

An important consequence of the economic growth theory by Romer P. was the study of scientific and technological progress at the enterprise level. In this sense, it is necessary to note the work of Acemglou D. Having examined the data on American enterprises for the period from 1982 to 1997, he concluded that the share of the costs of Research and Development in the total costs of the enterprise is not determined by its size. Acemglou D. identified the key mechanism for the emergence of innovation or ‘selection effect’. Small enterprises are less likely to survive than larger ones, but if they survive, they grow faster, ensuring permanent replacement in the list of leading enterprises. At the same time, the selection process changes enterprises, but not their distribution by scale in the industry and this indicator remains stable.

A current theories review has shown that economic growth is more based on endogenous factors. Productivity gains come from investments in Research and Development; continuous improvement of the product and production technology is distributed throughout the economy, creating the prerequisites for long-term sustainable development.

Modified Production Function

From the point of view of system analysis, high-tech enterprises are characterized by a heterogeneous structure, non-linearity of characteristics, asymmetric distribution of parameters and multi-loop interactions. The solutions leading to the optimal control of the production system are found in the study of empirical laws by constructing the appropriate mathematical models. Production functions (PF) are used as a useful tool that allows you to carry out analytical calculations, determine the efficiency of resource use and the appropriateness of their additional involvement in production, predict the volume of output and monitor the feasibility of investment projects.

Currently, the production functions are divided into classes depending on the characteristics of production relations and the tools used. Micro and macroeconomic PFs are distinguished as theoretical and applied, optimization and equilibrium, statistical and dynamic, deterministic and stochastic ones.

In the economy of production, traditionally used PF type $Y = F(K, L)$, characterizing the relationship between the maximum possible output and the amount of applied resources of accumulated labor in the form of production assets (capital) K, and real labor L.

To model the results of the activities of an individual enterprise, a two-factor multiplicative function of the form is often used $y = a_0 x_1 x_2$, where x_1, x_2 – are parameters of PF. This PF is known as the Cobb-Douglas function. The Cobb-Douglas PF was widely used due to its structural simplicity. Analysis of PF showed that four concepts of PF could be distinguished (table 1):

Table 1: Basic concepts of production function

#	PF CONCEPT	AUTHORS	CONTENTS
1	Probabilistic	Demidenko E.Z. (1989)	PF is considered as the mathematical expectation of a random value of output for given resources
2	Majority (optimization)	Granberg A.G. (2004)	PF expresses the maximum possible output for a given amount of resources
3	Probabilistic majority	Gladyshevsky A.I. (1977)	PF used to obtain the probable upper limit of output
4	Deterministic	Kleiner G.B. (2000) Makarov V.A. (2007)	Rigid functional relationships between model variables are investigated as arguments to PF.

Thus, the PF structure allows solving the following problems:

- Effectiveness determination of resources use and the feasibility of their additional involvement;
- Substantiation of the formation and improvement of scientific and technical groundwork;
- Capital and labor ratio optimization;
- Management decisions on the production development.

However, in modern conditions, the concept of labor is significantly differentiated not only in the aspect of accumulated and current, but also in the aspect of simple and complex. Considering the

cognitive factors of production as a production resource, the concept of 'intelligence' will be interpreted by us as the ability of human thinking to transform perception into knowledge, to analyze a priori knowledge in the process of their development. We will understand the capitalization of mental abilities as the use of knowledge, labor skills, and professional experience of corporate personnel for the purposes of production activities.

Thus, capitalization means the transformation of an individual human resource into a corporate means of achieving the production activity goal. In this regard, the value PF is determined not so much by the personal potential of knowledge, skills and experience of employees as by the value of the results of its use, crystallized in the products of the entire corporation. From this, the need for a commodity form of these abilities becomes clear, i.e. this form ensures the transformation of the intellectual abilities of a human resource into a corporate means of achieving commercial goals; the prevalence of these funds leads to their further transformation into necessary production conditions.

The productive power of cognition lies in its ability to turn the initial form of knowledge into information, then into the active form of knowledge, then into expedient activity. Consequently, the modern value of human capital lies in its cognitive nature, i.e. the ability to transform information into knowledge, knowledge into productive activity and activity into a marketable product. Cognitive activity transforms knowledge from a resource into a means of production by imparting new meaning and content to information by linking it to a commercial goal, i.e. establishing teleological certainty. The above considerations allow us to reveal the cognitive basis of modern production activity, which includes the unity of knowledge, experience and creativity.

For the production process, the cognitive nature of personnel makes it possible to carry out high-tech productive activities. In the form of expedient activity (i.e. production activity), cognition becomes a necessary condition for obtaining a result, i.e. from a resource it is transformed into a production factor. The cognitive factor becomes an element of the production process. Its quantitative side determines the necessary level of mental abilities of human capital, which correspond to the needs of a particular production.

In the production field, 'cognition' is a single concept of knowledge and methods of their industrial application. The concept of knowledge, which, under the influence of cognitive production processes, grows constantly and is verified by practice. Obviously, the production process in its constancy and innovative development contains an equally constant process of cognitive growth. This process is a constant change in the quantity and quality of 'cognitions', i.e. solidly mastered and fixed by labor activity knowledge and skills necessary for continuous development and improvement of modern and future production processes.

The necessary level of 'cognitions' saturation of human capital will be called the cognitive capacity of the production process. Cognitiveness becomes a factor not only because of the causality and because of conditionality of its relationship to production. The main sign of its attribution to factors is its transformation into a measure of cognitiveness, i.e. the unity of the qualitative and quantitative sides of this production means. The qualitative side of cognition is cognitive polymorphism, expressed in the form of experience, knowledge, creativity, which in different proportions are conditions for the practical application of this resource to technology, organization, and production management.

Given that classic PFs do not take cognitive factors of production into account, their modification is necessary. Based on the production function, Solow R. developed a modified production function, which is used to analyze the performance effectiveness of two high-tech enterprises with positive and negative profit dynamics. Data for modeling were taken from open sources. The modeling period is 8 years from 2011 to 2018.

Developed modified production function including cognitive production factors (1.3):

$$Y = AK^{\alpha} L^{\beta} Cog^{\tau} e^{\gamma(t-t_0)} \quad (1.3)$$

Y – output volume;
K – capital;
L – labor;
Cog – cognitive factors of production;
$A, \alpha, \beta, \tau, \gamma$ – model parameters;
t - time

Figures 1 and 2 show the results of modeling a modified production function for enterprises A and B.

Fig. 1: Production function including cognitive factors of production for a high-tech enterprise A

Fig. 2: Production function including cognitive factors of production for a high-tech enterprise B

In both cases, the slope of the curve becomes sharper. This indicates that enterprises could earn more with the available resources and technologies. However, this does not happen in the analyzed period. The Solow model also allows the study of consumption and accumulation rates. Manufactured products can be used either for consumption $C(t)$, or on investments in expansion of production. Then the share of income spent on investments will be:

$$Y(t) = C(t) + I(t); Y(t) = (s + q)Y(t) \quad (1.4)$$

s – share of investment income from traditional factors of production;
q - share of investment income from cognitive factors of production.

Given that the capital wears out over time, we assume that the depreciation rate (the share of capital lost per unit time interval) $\sigma \in (0,1)$ is constant.

Then gross investment over a period of time Δt will be equal to the sum of depreciation expenses and net capital gains from traditional and cognitive factors of production:

$$I(t) = \delta K(t) + \Delta K \tag{1.5}$$

whence

$$I(t) = \Delta(s + q)Y(t) \tag{1.6}$$

If divided (1.6) by L

Given the homogeneity of the production function, we shall get:

$$\frac{1}{L}\frac{\partial K}{\partial t} + \frac{1}{L}\frac{\partial Cug}{\partial t} + \delta\left(\frac{K}{L} + \frac{Cug}{L}\right) = (s + q)\frac{1}{L}F(K, Cog, 1) = \tag{1.7}$$

$$= (s + q)F\left(\frac{K}{L}, \frac{Cog}{L}, 1\right) = (s + q)f(\eta, \omega)$$

Quantities η, ω – represent factor performance.

Calculations based on real data have shown that for the studied enterprises, consumption norms exceed the norms of investment accumulation (figures 3,4).

Fig. 3: Accumulation and consumption rates for a high-tech enterprise A

Fig. 4: Accumulation and consumption rates for a high-tech enterprise

Such a situation may lead to a further decrease in efficiency, since untimely updating of existing funds will not allow producing competitive products and relying on super-profits in the form of intellectual rent.

The production function also allows you to analyze the relationship between cognitive factors and make informed decisions on the development of measures aimed at improving the efficiency of the information use and intellectual resources. We use the indicator of cognitive capacity, which reflects the contribution of information and intellectual resources to traditional factors of production.

For an enterprise A, the following data were received (table 2). Figures 5-7 show the relationship of cognitive factor of production with traditional factors of production and with output based on the calculation of the cognitive capacity coefficient.

Table 2: The relationship of cognitive factor of production with output and traditional factors of production.

Year	Cog/L	Cog/K	Cog/Y
2011	0,018883	0,00201	0,006881

2015	0,007694	0,001744	0,001414
2016	0,008309	0,001961	0,001692
2017	0,008147	0,001925	0,001719
2018	0,045331	0,008485	0,008855

Fig. 8: Cognitive capacity for an enterprise B

Fig. 9: Cognitive capital capacity for an enterprise B

Fig. 10: Enterprise cognitive output capacity B

The graphs presented show that for the cognitive capacity coefficient of the enterprise B is higher, and despite the negative dynamics of profit, it is used more efficiently than in activities of an enterprise B.

Conclusion

Thus, the modeling of the production function taking into account the cognitive production factor (or CPF) revealed the problems analyzed high-tech enterprises inefficiency, which are related to the excess of consumption norms compared to the norms of accumulation and investment in production resources, both information-intellectual and material. Using the cognitive capacity coefficient allowed us to analyze the relationship of CPF with traditional factors of production, as well as to determine the contribution of CPF in the total output. The data obtained allowed us to conclude that an enterprise with positive dynamics of profit does not use the available CPFs efficiently enough, while an enterprise with negative dynamics of profit is vice versa.

Abstract

To eliminate potential financial risks and determine the level of financial sustainability of an enterprise, prediction models are used. The development of digital technologies creates a platform for managing risk and improving the competitiveness of companies. The method of fuzzy sets in addition to taking into account the specifics of the enterprise is focused on Russianreality and gives more accurate results. The developed software for predicting financial distress is simple and easy to use. It is notable for its visibility of the results, the ability to change the number and significance of the indicators involved in the assessment, the ability to take into account the analysis period and the industry specialization of enterprises.

Keywords: Modelling, Analysis Of Financial Distress, Financial Risk, Fuzzy Set Theory, Program Model

Introduction

The manufacturing sector has undergone significant changes in terms of scale, complexity and technology over the past decades. Increased competition, growing uncertainty of the business environment, a variety of goals of economic entities and market participants increase the level of risks that can lead to the risk of effective development of industrial enterprises. Planning and forecasting will allow the manufacturer to gain visibility and control over all aspects of the activity. The development of digital technologies creates a platform for managing risk and improving the competitiveness of companies. To eliminate potential financial risks and determine the level of the financial health of an enterprise, forecasting models of bankruptcy are used, perceived as systems of timely warning of impending problems. Their task is to assess the financial condition of the company based on the selected financial indicators or other characteristics of the company or the environment in which they operate (Svabova, 2016). Accurate prediction of a bankruptcy of companies in various industries causes great concern of investors and creditors since it is possible to reduce the risk of creditors (Lee, 2013). Analysis of the most important financial indicators makes it possible to evaluate the results of the financial activity of an enterprise, it becomes possible to competently, scientifically-based management of business processes that ensure the achievement of the planned strategic goals (Foster, 1986).

Literature Review

For a comprehensive assessment of the financial condition of the enterprise and the probability of bankruptcy risk, a number of models are used, including the method developed in 1968 by E. Altman

(1968), the models by J. Connant and M. Golder (2014), U. Beaver (1966), and Taffler (1984), J. Fulmer (1984), Zmijewski (1984), Horrigan (1996), and others. Russian scientists are also involved in developing methods and criteria for analyzing financial condition: I. Ya. Lukasevich (2013), M. A. Fedotov (2018), R. S. Saifullin, G. G. Kadykov, O. P. Zaytseva, L. V. Dontsova (2008), and others.

Theoretical Part

In the course of the study, a comparative analysis was carried out and a test of the adequacy of the common models of comprehensive assessment of the financial condition based on the reporting data of a number of industrial enterprises. Of the eleven models considered, an adequate assessment of the current financial condition of the company was obtained only with the use of six: the five-factor original and improved Altman models, the Connan and Golder, Tafler, Springgate models, the O. Zaitsev six-factor model and the rating method for assessing the financial condition of the company R.S. Sayfulin and G.G. Kadykov (Table 1).

Table 1: Test results for bankruptcy prediction models

Indicator	2014	2015	2016
Two-factor Z – model Z = – 0,3877 – 1,0736 K1 + 0,0579 K2			
Value Z	–1,119	–1,304	–1,980
Probability of bankruptcy	less than 50%	less than 50%	less than 50%
Four-factor bankruptcy risk assessment model R = 8,38 K1+1,0 K2+0,054 K3+0,63 K4			
Value R	0,8025	-5,0759	1,7687
Probability of bankruptcy	minimal	maximal	minimal
Five-factor Z – E. Altman model Z = 1,2 X1 + 1,4 X2 + 3,3 X3 + 0,6 X4 + 1,0 X5 – original			
Value Z	2,51	–1,8	–0,44
Probability of bankruptcy	low	high	high
Five-factor Z – E. Altman model – refined Z = 0,717 X1 + 0,847X2 + 3,107X3 + 0,420 X4 + 0,998X5			
Value Z	4,29	– 2,71	– 2,44
Probability of bankruptcy	low	high	high
Four-factor model of R-invoice R = 8,38 K1 + K2 + 0,054 K3 + 0,63 K4			
Value R	–0,167	–2,414	0,206
Probability of bankruptcy	minimal	high	medium
Credit-men method N = 25 R1 + 25 R2 + 10 R3 + 20 R4 + 20 R5			
Value N	185,8466	93,2452	138,992
Probability of bankruptcy	low	high	low
Solvency indicator of J. Conan and M. Golder Z = – 0,16X1 – 0,22 X2 + 0,87X3 + 0,1X4 – 0,24X5			
Value Z	– 0,08	0,263	0,284
Probability of bankruptcy	50%	90%	90%
Four-factor model of Taffler Z = 0,53 K1 + 0,13 K2 + 0,18 K3 + 0,16 K4			
Value Z	0,613634	0,14987	0,18732

Probability of bankruptcy	low	high	high
Six-factor model of Zaitseva K = 0,25 K1 + 0,1 K12+ 0,2 K3 + 0,25 K4 + 0,1 K5 + 0,1 K6			
Value K	2,103166	1,43927	77,3856
Probability of bankruptcy	low	low	extremely high
Method of rating the financial condition of the company of R.S. Saifullin and G.G. Kadykova R = 2 K1 + 0,1 K2 + 0,08 K3 + 0,45 K4 + K5			
Value R	0,133867	-7,1268	0,54791
Probability of bankruptcy	high	extremely high	high

The high probability of error when using the remaining models may be due to the fact that they do not take into account the possibility of a negative value of the equity capital of the enterprise, due to retained loss from the activities of the enterprise. In the models of Tafler and Fulmer, in order to obtain a negative value of the Z indicator, which indicates the company's proximity to bankruptcy, it is necessary to have very high losses from the funds raised, therefore the results of the assessment on this model are close to reality.

Studies by a number of authors: D. Olson (2012), S. Balcaen (2006), H. A. Alaka (2018) also indicate inconsistency of the results obtained using these discriminant models. Thus, the studied models have several disadvantages:

1. Some indicators cannot be determined on the basis of published financial statements only.

2. The values of the weights in some models are not balanced, reflect not all aspects of the financial and economic activities of the enterprise.

3. There is no consideration of industry specifics and, accordingly, differentiation of threshold values of integral indicators.

4. Models based on the methods of linear progression and multidimensional discriminant analysis only state the current financial condition and are deprived of the possibility of its dynamic prediction.

With all the advantages of the models of E. Altman, J. Connant, M. Golder, U. Biver, G. Springgate and D. Fulmer, it should be noted that they are based on the study of the behaviour of firms in the conditions of economic development of Western countries. Building such models for the Russian economy is problematic, firstly, because of the imperfection of the regulatory framework for the bankruptcy of Russian enterprises; secondly, due to the lack of consideration of many factors affecting the financial sustainability of enterprises. In addition, along with the professionalism and intuition of an analyst who studies the economy of an enterprise, the quality of financial reporting documents and the degree of the information content of the statistical data and coefficients on which the models rely play a significant role. Many of the Western models are applicable only for wealthy enterprises and cause different, often opposite, opinions about the possibility of their application in specific country conditions (Peres, 2016; Jones, 2017; Deakin, 1972).

Foreign and domestic scientists are actively developing methods for assessing the financial condition and bankruptcy risk using neural networks (Odom, 1990; Anandarajan, 2001; Alfaro, 2008), using a hybrid approach based on precedents and genetic algorithms (Back, 1996; Ahn, 2009), based on the integration of decision tree classification and logistic regression (Chen, 2011; Cho, 2010), as well as using the apparatus of the theory of fuzzy sets (Chaudhuri, 2011; Mamdani, 1974; Zadeh, 1983) . The main difference between the theory of fuzzy sets is that this theory determines the belonging of some elements to the set not in binary values, as in the classical theory, but allows the gradation of the degree to which the element belongs to the set. This process is implemented using membership functions (Zadeh, 1965). The method for solving the problem of comprehensive assessment of the

financial condition of an enterprise and the related task of assessing bankruptcy risk on the basis of a fuzzy-multiple approach was described by A.O. Nedosekin (2017).

Comparing the effectiveness of neural network tools with methods of fuzzy logic and discriminant analysis showed that the neural network model cannot select any indicators that the analyst considers necessary, which is acceptable for models based on fuzzy logic. The use of models based on fuzzy logic is also supported by the fact that when analyzing the financial condition of an enterprise, a situation may arise when some explanatory indicators included in the discriminant model can be very low for a particular enterprise compared to their "normal" values, while others, on the contrary, are too high, which is also unacceptable. However, the combination of these indicators may indicate a stable financial condition of the enterprise, since it is the calculation of one integrated indicator based on all input factors at the same time. The solution of this issue can be accomplished by forming a base of decision-making rules when assessing the financial condition of enterprises, achieved using models built on the basis of fuzzy logic methods (Abdoulaeva, 2015). If we compare the values of the financial condition obtained with the help of a point estimate and the value of the financial condition obtained using fuzzy sets, we can conclude that the second method gives a more accurate estimate, because takes into account the specifics of the enterprise. In addition to taking into account the specifics of the enterprise, this method is focused on Russianreality and gives more accurate results than other methods.

Practical part

The method of solving the problem of comprehensive assessment of the financial condition of an enterprise and the associated task of assessing bankruptcy risk based on a fuzzy-multiple approach is used in the "Master of Finance: Analysis and Planning" program model developed by the Voronov and Maksimov consulting group. The program is implemented in the form of a template for Microsoft Excel, which includes a sheet with tables of initial data and results and about a dozen sheets of charts. As one of the branches of the Alt-Finance program, it has much in common with it. The main differences are a tidier design, many more options, however, the latter also turns out to be drawbacks - the program is easy to get lost. Among the shortcomings of this software, it can also be noted that the spreadsheet is not the most successful medium for developing large applications; working in this format with the results of the analysis is not very convenient. But the authors of the Master of Finance managed to get rid of many potential problems and make their template look like a real program (Abdoulaeva, 2015).

For a comprehensive analysis of the financial condition of the company during the study was developed software based on fuzzy logic. Based on the calculated financial indicators from the financial statements for the period, selected by a group of experts so that they best characterize the enterprise, at the same time form a complete set, a conclusion is made about the financial condition and risk of bankruptcy.

The number and names of indicators depend on the selected area. In the proposed version of the program uses six factors. However, you can specify their significance on a scale from 0 to 10. For example, a coefficient with a significance of 3 will be three times more significant than with a significance of 1. A coefficient with a significance of 0 will not be taken into account in further calculations.

To create a calculation, it is necessary that all fields for indicators be filled in and at least one indicator has a significance not equal to 0.

Information about the selected indicator is displayed in graphic or digital form. In digital form, a table of the boundaries of the membership functions for the selected coefficient will be presented. The graph shows the graph of the membership function.

If the entered parameters do not satisfy any conditions, the program will report this. The report displayed on the basis of the entered indicators contains a calculation table, a textual and graphical representation of the state of the enterprise.

In the main window of the program, you can also select the area for which the complex indicator of financial condition will be calculated.

Each region has its own coefficients, the number and membership functions of which can be changed. The presented model allows taking into account no more than 10 indicators.

When creating a new area, a window will open in which you must enter the name of the area and the number of coefficients. In the fields on the right side should be entered the names of the coefficients. Next, you should specify the boundaries of the subsets of states for each coefficient or the so-called T-numbers for the values of the linguistic variable, by setting which experts can take into account the industry sector and other qualitative parameters of the enterprise (for example, hidden or explicit options, image, reputation, enterprise personnel, etc.).

Using the developed software product, an assessment of the financial condition of a number of industrial enterprises was carried out. Comparison of the values of the complex indicators of financial condition obtained using common models with the results of calculations of a program using fuzzy sets led to the following conclusion: the developed model, takes into account the specifics of the enterprise and allows you to qualitatively assess the risk of bankruptcy of the enterprise.

Findings

Thus, the advantages of the proposed software product are simplicity and ease of operation, visibility of the calculation results, the ability to change the number and significance of the indicators involved in the assessment, take into account the period of analysis and industry specialization of enterprises. The developed program offers a solution to a fairly generalized problem. However, it has the flexibility to customize to the needs of the user, taking into account the specifics of the enterprise and the ability to solve new goals and objectives of the analysis. It is planned to establish the interaction of this program with other common software products, such as Microsoft Excel or 1C Enterprise, 1C Accounting, as well as to create the ability to integrate the report into Microsoft Word, which will increase the practical significance of the program.

Abstract

The problem of the size premium for small capitalization listed on Warsaw Stock Exchange is the main subject of this paper. We find that abnormal returns from small capitalization stocks are not properly explained by standard CAPM approach. The main thesis is that for small capitalization stocks it takes more time to reflect current information in their prices. Therefore, the additional explanatory variable is return realized in the preceding periods. The results are statistically valid, and the additional variable helps to explain the realized return. The importance of this result is that the size premium defined as the increase of beta coefficient should be applied to majority of Polish public and non-public enterprises.

Keywords: CAPM, small capitalization companies, beta coefficient, Warsaw Stock Exchange

Introduction

One of the leading models used to estimate the expected rate of return on investment in shares is the CAPM (capital asset pricing model) model. This is a one-factor model in which the size of the expected rate of return depends on the changes taking place on the capital market. The choice of the explanatory variable indicates that the investor examines exposure to market risk, and his investment portfolio might be well diversified.

The exposure to market risk can be related with financial features of companies, e.g., the size of debt, the operating leverage, the cost structure. In the paper, the financial parameter which explains the size of the beta parameter is the company's capitalization. It is assumed that the lower capitalization of the company means greater exposure to market risk. The following example can explain the impact of the required rate of return on the company's capitalization. Two companies with the same amount of expected cash flows have different standards of performance required by owners. A higher discount rate of expected cash flows will determine smaller goodwill. This means that companies which activities are riskier should be smaller and vice versa. The higher business risk for small businesses will require a beta adjustment - a measure of financial risk in the CAPM model. Pioneering research on the effect of small companies and how to include it in the CAPM model was carried out by RW Banz in 1981 [Banz, 1981, pp. 3-18] and the effect itself was observed in many markets [Arzac, 2008, p. 52]. The introduction of company capitalization could possibly improve the results obtained while using the CAPM model, as there is a reasonable suspicion that the beta coefficient for small companies are underestimated. The company's capitalization can be a good approximation of the influence of factors omitted in the calculation of the "classical" CAPM as well as compensate for the error of parameter estimation [cf. Berk, 1995, pp. 275-286]. The aim of this article is to estimate the premium for the size of companies listed on the Warsaw Stock Exchange. The main research problem is to determine the premium of small companies' exposure to changes in market risk.

There are several possible explanations of small capitalization. The increased risk of small business operations may be due to the low liquidity of shares, the higher risk of breaching the contractual condition and another way of organizing the market of trading in shares of small companies. Besides,

the size of the company is correlated with the difference (spread) between the buy and sell offers in the order book [see Ibbotson, Kaplan, Peterson 1997, p. 105]. The rate at which new information is included in the share price may depend on the size of the spread. Shares of high spread companies may reflect future information slower because an investor will decide whether to buy or sell a stock if the impact of the new information on the valuation exceeds the transaction costs. For this reason, shares of companies with a high spread will most likely show a positive autocorrelation of monthly returns in the portfolio [Mech 1993, 307 - 344].

The effect of small companies may result from the fact that not all shares of companies can be listed at the same time. The problem does not seem to be so important when one takes into account the monthly rates of return [Pratt, Grabowski, 2014, p. 227]. Ultimately, the delay in reflecting new information in share prices may be due to a limited number of analysts valuing the company. The speed at which further information is included in the price increases with the number of analysts performing stock analysis [see Brennan, Jagadeesh, Swaminathan 1993, pp. 799-824].

Description of the Research Model

In the literature describing the problem, determining the required rate of return of small-capitalization companies, the importance of the impact of low turnover on sensitivity to market changes is emphasized. One of the proposals to solve this problem was to use annual (instead of monthly) rates of return in determining the beta parameter [Kothari, Shanken, Sloan 1995, pp. 185 - 224]. It was assumed that within one year, most of the information that may affect the listing of the company's shares would be taken into account. An attempt to determine the required rate of return in this approach is limited for Polish companies, due to the small number of annual returns for companies listed on the Warsaw Stock Exchange.

Another way to make adjustments related to a low turnover on the securities market is to determine the exposure to market risk in two consecutive periods. This procedure was proposed by E. Dimson [Dimson 1979, pp. 197-226; Dimson 1983, pp. 753-783]. E. Fama adopted this solution, and K. French [Fama, French 1992, pp. 427-466], and the research results were developed and commercialized thanks to [Ibbotson, Kaplan, Peterson 1997, pp. 104-112]. This approach assumes that the estimation of the regression equation coefficients for the rates of return on the market and shares for the next two months:

$$R_t - R_{ft} = \propto + \beta\left(R_{mt} - R_{ft}\right) + \beta_{-1}\left(R_{mt-1} - R_{ft-1}\right) + u_t. \quad (1)$$

Where:
R_t- rate of return on shares in period t,
R_{tf}- the risk-free rate in period t,
R_{mt}- rate of return on the market portfolio in period t,

Most financial services publish β data calculated based on two weeks or monthly rates of return. The β coefficient better describes large companies (due to their higher share in market capitalization), and the factors of a small capitalization company will need to be adjusted for two reasons: the size and estimator's accuracy. The adjusted measure of the exposure of shares to market changes is SUMβ. This is the sum of the directional coefficients from equation 1.

$$SUM\beta = \beta + \beta_{-1} \quad (2)$$

The β factor measures the periodic correlation between return on shares and profits on the market portfolio. The portion of the performance obtained in the current period that reflects the correlation of rates of return represents the rate of return on the market portfolio in the previous period are additive, which allows the entry shown in Equation 2.

In studies conducted on the NYSE / AMEX / Nasdaq market [Ibbotson, Kaplan, Peterson 1997, pp. 104-112], the size of the coefficients increases as the size of the company decreases. Therefore, the

share of the coefficient in SUMβ change with the size of the company. The article presents the calculation of the SUMβ for companies listed on the Warsaw Stock Exchange.

The beta coefficient is commonly used in finance to determine the cost of capital. The basic model, that uses this factor is the CAPM model. This model does not exclude the use of modifications to the adopted beta coefficient [Feldman, 2005, p. 70]. The beta is also used as a risk measure. The full information beta can be used to determine the sector's risk premium [Pratt, Grabowski, 2014, p. 181].

Description of the Research Sample

The survey covered companies listed on the Warsaw Stock Exchange. The analysis covered the period from January 2002 to December 2017. The companies listed on the Warsaw Stock Exchange were divided into deciles with respect of their capitalization. For the analysis, companies listed on alternative market (i.e. New Connect) market were excluded. The average monthly rates of return of companies listed in the first and last deciles were calculated. The rate of return in decile is the weighted average capitalization of individual companies. The choice of the period was determined by the relative stabilization on the capital market at that time. The capitalization limits for each decile have changed over time. The minimum value of the lower limit for the first decile observed in February 2002 amounted to PLN 593 million, and the maximum value for the lower limit of this decile was observed in June 2007 and amounted to PLN 5,077 million. The capital of the companies gathered in the first decile ranged between 86.55% and 67.05% of the capitalization of the main trading floor. The special focus is put on the decile 9 because the results for the result of the decile 10 were inconclusive. For that reason, it was omitted further in the analysis.

In the analyzed period, for the data from the ninth decile, the maximum and minimum values of its upper limit were at the level of 217 million and 6 million, respectively. The size of companies in the ninth (last representative) decile did not change significantly. The capital of companies gathered in the ninth decile represented barely a maximum of 0.74% and a minimum of 0.07% of the capitalization of the main trading floor.

Figure 1 shows the change in the lower limit of companies in the first decile and the change in the upper limit in 10 deciles in the analyzed period.

Figure 1: The limits of the first and ninth deciles for companies listed on the Warsaw Stock Exchange in the years 2002 2017, Source: own study

In decile 9, in the period under review, the companies generated a monthly arithmetic average rate of return of 0.36% based on logarithmic monthly rates of return with a standard deviation of 5.27%. Similarly, to the arithmetic average of the rates of return and the standard deviation for the WIG index, the values were 0.39% and 2.72%, respectively.

Research method and the result of the analysis

The reflection of company size on the rate of return was analyzed as follows. Beta coefficients were calculated for companies in the first and ninth deciles following equation 1. Then, using the factors and SUMβ were calculated. The power of explaining the rate of return, taking into account market risk exposure for companies in the 9th decile increased.

Table 1: Strength of explaining the model dl for β and SUMβ coefficients for companies from decile 9

	β	SUMβ
Adjusted R^2	0,2095	0,2283
Standard deviation of an estimate	0,1249	0,2533
Number of observations	191	190

Source: own study

For the companies from the first decile, the adjusted R^2 for the model taking into account β was 0.9632, and for the model taking into account SUMβ was 0.9635. Thus, the introduction of an additional variable in the first decile did not significantly improve the regression estimates.

Table 2 presents the quantities and SUMβ together with data describing the level of significance of regression estimates for companies in deciles 1 and 9.

Table 2: The size of the coefficients β, β_{-1} and SUMβ for companies from decile 1 and 9 listed in the years 2002 – 2017

	Decile 1	Decile 9
β	1,0415***	0,8927***
β_{-1}	-0,0238	0,2964**
$SUM\beta$	1,0177	1,1890

The numbers in brackets denote t-statistics. (***), (**), (*) reflect the 1%, 5%, 10% level of significance respectively.
Source: own study

This means that in calculating the betas for entities the size of companies from Decile 9 (the maximum value of the range is PLN 217 million), a beta factor of 1.1890 should be used. The coefficient value is underestimated by 0.2963, or 33%!

Figure 2: Comparison of beta and sumbeta for 9 deciles

Source: own study

The figure above presents the beta coefficient determined as in CAPM without taking into account the possibility of autocorrelation, and the sumbeta coefficient resulting from the use of multiple regression. The aggregated returns in decile 10 provides no statically valid regression results. Nevertheless, the study shows that for 9 out of 10 deciles, as the capitalization of entities decreases, the sumbeta coefficient increases. This can be explained by the occurrence of the autocorrelation of rates of return, which would indicate market inefficiency because information shaping the value of the entity would be included in the valuation slower in case of objects with lower capitalization than in case of objects which shares are highly liquid. Another argument for usage of the sumbeta coefficient instead of beta may be the increase in the standard deviation of rates of returns as the companies' capitalization decrease (from 2,88% in first decile to 5,27% in ninth decile). The following differences between the rates of return from the examined deciles were observed:

Table 3: The differences in the standard deviations of return in deciles

Decile 1	Decile 2	Decile 3	Decile 4	Decile 5	Decile 6	Decile 7	Decile 8	Decile 9	Decile 10
2,88%	2,68%	3,10%	3,29%	3,40%	4,01%	4,02%	4,35%	5,27%	7,15%

Source: own study

The trend of the standard deviations of the rates of return presented above corresponds to the sumbeta levels calculated for individual deciles, which may mean that the sumbeta coefficient better reflects the risk of small companies than the CAPM-related beta coefficient. This would indicate that the smaller companies are "overactive" to signals from the market.

Conclusions

The study observed the occurrence of significant differences between the sumbeta coefficients and the beta coefficients, which increase inversely to the capitalization.

Changes in the size of the companies forming deciles were significant in the analyzed period. Thus, the results can only be interpreted on the assumption that investors' expectations for the companies in the

decile (relative size of companies) are the same. The result of the analysis is a premium for companies with lower capitalization. The size of the premium is indirectly dependent on the size of the sumbetas coefficient. In contrast, the premium does not correspond with the rates of returns generated in particular deciles, but rather with the standard deviations of these rates of returns as a measure of risk.

In similar studies conducted on the US market, the size of premium was calculated based on very long time-series. As the data series describing small companies on the Polish market will extend (especially those listed on the New Connect market), they will allow for a confirmation of results achieved so far and enable the analysis of the volatility of the size premium over time. The next step in the small capitalization effect is to identify factors that determine the premium value.

Women's Health in Precarious Work: A Review of Existing and Conceptual Framework for Future Research

Anastasiya PESHA

Ural State University of Economics
Yekaterinburg, Russia
myrabota2011@gmail.com

Abstract

The growth of interest in research on women employment in the last two decades is largely due to the spread of modern information technologies (the Internet, artificial intelligence, software, etc.), which led to large-scale changes in the labour market, providing women with additional opportunities for precarious work, but, at the same time, increased the requirements for the professional level of labour market participants. In addition, the large-scale changes and dynamism of the modern economy leave their imprint on the institution of family and marriage, the role of women and men in the family is increasingly blurred, women take on the responsibility of providing the family on an equal footing with men. Competition in the labour market leads to an increase in the number of employees working on a temporary basis, under flexible conditions of employment, which is often associated with a decrease in their income level and the emergence of health problems. The article is based on an analysis of Russian and foreign authors publications included in one of the bases: Web of Science, Google Scholar, RINC, which discuss issues of precarious work, and its impact on the physical and psychosocial health of women. The reasons for the negative impact of precarious work on women's health are analyzed. The results of the analysis show the state of scientific knowledge of the context of the impact of non-standard forms of employment on women's health.

Keywords: Precarious Employment, Female Employment, Flexible Employment, Distance Employment, Employment and Health of The Woman

Introduction

Employment instability and non-standard forms of employment are a social determinant that affect the health of the employee, his family and society as a whole. The intensification of the popularity of research on precarious work is caused by three main trends: the surge in “flexible employment” and the changing demand for labour, as well as the transformation of working conditions since the mid-1970s; increased interest in social aspects of health, including working conditions; introduction and development of new information technologies and systems.

Despite the growing interest in the problem of precarious work, not a large number of domestic studies are devoted to the gender aspects of the impact of precarious forms of employment on the health of workers (Kislicyna, 2015; Pesha, 2018; Pinchuk, 2018; Shal`, 2007). Russian researchers are more concerned about the transformation of the labour market as a result of the global and active spread of precarious forms of employment, as well as the insecurity of youth and rural residents in these new conditions (Cygankova & Telyatnikova, 2012; Gimpel`son & Kapelyushnikov, 2006; Kolot, 2013; Kotlyarov, 2015; Shkaratan, et all, 2015).

The term “precarious work” has been widely used for decades in various sciences and disciplines: sociology, economics, political sciences, and the media (Kalleberg, 2009; Rodgers & Rodgers, 1989; Tonkikh, et all, 2019). Over the past decade, interest in precarious work in research has increased (Vankevich, & Zajceva, 2015; Kamarova, 2015; Benach, et all 2016; Campbell, 2016; McDowell, et all, 2009). For example, a search for the key definition of “precarious work and women's health” at Google Scholar shows that between 4,560 works and 19,000 between 2001 and 2010 were published between 1970 and 1980. From 2011 to 2015, 17,500 articles appeared, and from 2019 to February 20,

2020, 16,900 new scientific articles and books have already been published.

The ongoing transformation of labour relations has led to an abundance of terms characterizing non-standard forms of employment: “precarious work”, “flexible employment”, “temporary employment”, “part-time employment”, “self-employment”, “home employment”, “distance employment”, “informal” employment ”,“ random employment ”(Benach, et all 2016; Campbell, 2016; McDowell, et all, 2009; Benach at all, 2014; and others).

The purpose of this paper is to analyze the problems of researching non-standard forms of female employment, to review the reasons highlighted by the authors for the negative impact of non-standard forms of employment on women's health, and also to highlight the main methodological issues of future studies.

Analysis method - content analysis of publications on the impact of non-standard forms of employment on women's health in Google Scholar, WoS, E-library.

The analysis is based on the most cited publications of the authors (according to Google Scholar, WoS, E-library) on the impact of non-standard forms of employment on women's health, published from 1991 to 2019. Articles and other kinds of scientific publications were selected by title, keywords and annotations of the definitions “precarious work, women”, “precarious employment and women's health”, “flexible women's employment”, “remote women's employment” (teleworking and gender). For the most part, publications in scientific databases intersect with each other. The sampling totaled 120 publications, with minimal citation for Russian-language publications - 6, for foreign ones - 30 (the difference in the selection criteria for citation is explained by the relatively small and only growing interest in the research problems in Russian publications, and the corresponding number of citations for publication). And also, relevant publications over the past two years - 2018-2019. When analyzing the RSCI base, priority was given to publications in peer-reviewed journals; nevertheless, works that met the search criteria published in collections of scientific papers, including those based on the results of conferences, and dissertation research were also added to the review. All descriptive works after analysis were excluded from the sample. The paper provides links to the most cited publications.

It should be noted that the entire sample body of work on non-standard female employment and its impact on women's health has several characteristics:

- Most of the publications reflect the results of empirical studies, which were carried out mainly with the help of interrogation techniques and refinement of statistics. This phenomenon emphasizes the importance of using along with methods that provide a subjective assessment of objective data and deepening research with a detailed understanding of various aspects of precarious female employment, their explanation and prediction of development trends at the local, regional, national and global levels.

- The dominant part of the research was carried out in Europe and the USA, in Russia, research is mostly concentrated on regional aspects and a small part of them, regarding foreign studies reflected in publications, deals with the impact of non-standard forms of employment on women's health.

- The most cited are works that reveal non-standard forms of employment and their impact on the labour market, the interaction of workers and employers, on the health of workers and on the institution of parenthood from an empirical point of view, work based on long-term and massive ones in terms of a sample population. Most of the popular studies include a deep methodological study of the existing scientific base on precarious work.

Research Directions on The Negative Impact of Precarious Forms of Employment on Women's Health

As a part of research in this direction, questions of legal and psychological safety of flexible and non-standard forms of employment, advantages and disadvantages, the effectiveness of these forms of employment for the economy of the family and the state are raised (Clarke, et all, 2007; Gerasimova,

E et all, 2017; Pyataya chast, 2015; Tonkix & Kamarova, 2015; Zlobin, 2011). For example, some researchers express concern about the physical and psychological health of women who are precariously employed in the economy (Amable, 2006; Ferrie, et all, 1995; Gerasimova, et all, 2017; Huws, et all, 2015; Virtanen, et all, 2005 ;). Empirical studies in various countries show that precarious work can lead to adverse health effects, including the development of low self-esteem, musculoskeletal diseases, injuries and mental health problems, family disorder, problems with raising children, smoking, alcohol abuse, anesthesia (Amable, 2006; Benach & Muntaner, 2007; Ferrie, et all, 1995; Huws, et all, 2015; Kim, et all, 2012; Virtanen, et all, 2005). Most studies supporting the hypothesis of the harmful health effects of precarious work are the result of studies of unsecured employment and temporary employment. Of course, not all non-standard forms of employment negatively affect women's health, in particular, temporary jobs can serve as a transition to permanent employment, and distance employment brings women satisfaction due to the availability of free time.

Researchers of the influence of non-standard forms of labour relations and forms of employment identify a number of reasons for their negative impact on women's health. Benach J., Muntaner C. (2007) (Benach & Muntaner, 2007, p. 276), who study temporary employment and work under fixed-term employment contracts, identify the following reasons for the negative impact of non-standard forms of employment on women's health:

- Non-standard forms of employment (flexible) have much in common with unemployment. Workers are offered low-skilled, low-income labour.

- non-standard forms of employment can be as adverse to health as unemployment;

- there is a mismatch between the level of work safety that a person experiences and the level at which he expects;

- transfer to a non-standard form of employment due to the closure of enterprises, insecurity in work leads to violations of self-esteem, chronic stress;

- temporary work associated with the implementation of heavy, tiring work, with repeated movements;

- temporary and intermittent work does not give an idea of the working environment, have less autonomy in work and are subject to closer monitoring.

These reasons, for the most part, are also noted by other researchers: Letourneux, (1998), Amable et al., (2006), Quinlan et al. (2001), Virtanen et al. (2005) (Amable et al., 2006; Letourneux, 1998; Quinlan et al., 2001; Virtanen et al., 2005). Lucı´a Artazcoz et al. (2005), based on a study of 8,400 people employed in Spain, confirmed that health problems are more likely to occur in women than in men with flexible employment patterns; dissatisfaction with work is greatest among women employed in low-skilled manual labour under flexible employment conditions; temporary contracts are positively associated with poor psychological health, regardless of gender. In this study, flexible employment was understood as: conclusion of a fixed-term contract, fixed-term temporary contract with an unlimited period and work without a contract.

Furthermore, because of these multiple forms of gender-based discrimination, women are more likely to accept precarious work that is precarious, unsafe, dangerous, and low paid (Huws, et all, 2015, p. 778; 65). One of the reasons for the negative impact of precarious work on women's health is also the inequality of the rights of precarious workers and permanent workers and the lack of social protection (Amable, 2006; Bloom, et all, 2012). The lack of training in the workplace is also indicated by researchers as one of the reasons for the negative impact of precarious work on health (Benach, 2016).

Orpen S. (1993) in his empirical study showed that although perceived flexible employment is associated with anxiety and depression among all employees, these mental health indicators do not differ between employees in the workplace who are objectively protected or unsafe. Thus, a feeling of insecurity in work is not always associated with objective conditions reflected in labour or other forms

of contractual relations (Walby, 1997).

Most studies confirm the negative impact of precarious work on the psychological health of workers (both sexes) (Orpen, 1993; Walby, 1997); part of the research focuses on the effects of precarious work on physical health (De Witte, 1999; Huws, 2015; Sverke, et all, 2002). Analysis of the studies revealed a lack in the depth of study of the topic of the direct impact of various non-standard forms of employment on women's health, since both women and men were present in the sample. In this regard, subsequent studies, in our opinion, should be carried out using conceptual models, which will include analysis of indicators of macroeconomic processes, welfare factors of the country and various regions, the development of non-standard forms of employment in various fields, followed by their correlation with an empirical study on women's health.

Results

Traditional employment covered all types and fields of activity in the World during the first industrial revolution, but already in the 20th century, the strengthening of state regulation of labor and the impact of political transformations on world labor markets, as well as technological changes led to the emergence of precarious work, which is widely distributed in economically developed countries and begins to spread in countries with developing economies. In addition, the development of “flexible employment” was facilitated by the fact that in the late 1970s “flexible production” was considered as a positive and necessary innovation to ensure sustainable economic growth. The need for “flexibility” was proposed for technical systems, schedules and salaries in the workplace, and “flexibility” was even recognized as a positive personality trait of the employee. In the last 20 years, with the advent of new technologies, new flexible forms of employment have appeared. A number of key areas can be distinguished in the studies, the dynamics of publications on which is presented in Figure 1. There are no publications on the selected issues until 1991 in the Web of Science (English-language works) E-Library (publications in Russian). The data reflect a growing interest in research issues and the main focus of scientists.

Figure 1: Dynamics of publications in the areas of research of non-standard forms of employment and their impact on women's health (% of the average annual indicators of the previous period, according to the Web of Science, E-Library)

Among the most cited studies on research, Kalleberg, A. L., 2009 (1634 citations) can be distinguished; Quinlan, M., et al., 2001 (694 citations); Benach, J., et al., 2007 (292 citations); Artazcoz, L., et al., 2005 (185 citations); Shkaratan, O.I. et al., 2015 (64 citations). The problems under study are devoted to the work of a wide range of researchers; of the most cited Russian-language publications, we can

distinguish the works of Aivazova S. G., 1998 (273 citations); Temkinoi A.A., 2002 (134 citations); Romanovsky N.V., 2000 (80 citations); Yarskaya V.N. and Yarskaya-Smirnova E.R., 2002 (56 citations) [2, 18, 19, 24] The most cited works in English on the topic of female employment: Sainsbury, D. (Ed.)., 1999 (2003); Kalleberg, A. L., & Leicht, K. T., 1991 (1236); Goldberg, P., 1968 (1,176 citations), England, P., 2017 (1,038 citations); Ridgeway, C. L., 1997 (946 citations); Bailey, D. E., & Kurland, N. B., 2002 (909 citations); Mandel, H., & Semyonov, M., 2006 (445 citations).

An analysis of the areas of research on issues of female employment showed that the largest number of published works have economic problems (about 20%), about 10% of the work in the field of sociology, psychology and management, at the same time, a fairly large number of studies are carried out by the authors within the framework of such sciences. like economic geography, demography, medicine and education.

Given the previously presented trends in research on the issues of precarious female employment, we present the following methodological principles for developing a conceptual framework for future research:

1. Consideration of non-standard female employment, taking into account all the components of this phenomenon: woman's employment in the family and domestic work, woman's activity in the economy and her competitiveness with respect to men; physical and socio-psychological health and well-being of women and marital and parental relationships.

2. The study of modern trends in the field of precarious female employment: the impact of innovative and modern information technologies on the position of women in the labour market, their entrepreneurial activity and family roles.

3. Reliance on the definition of flexible employment as including two aspects: the use of labour by the employer using non-standard forms and conditions of employment (flexible working hours, temporary, seasonal work, etc.); self-employment, as well as types of employment that allow a greater degree of freedom of action, decision making and choice of tools, place and time for the implementation of these decisions.

4. The use of an interdisciplinary and multidisciplinary approach to research on issues related to the effectiveness and impact of non-standard forms of employment on women, their health and economic and social satisfaction, their microsocium, as well as global processes in demography, economics and politics will allow us to more deeply study current trends in the field of employment of women.

5. Consideration of non-standard female employment issues from "private to general" and from "general to private" to confirm / refute research forecasts.

6. Consideration of issues of non-standard female employment is inseparable from male employment, in order to trace the correlation and general trends in relations in the labour market and employment.

7. The construction of a conceptual model for the study of modern aspects of female employment based on an analysis of the demand and supply of women's jobs and labour force, the distribution of female jobs by field of activity and form of employment, contribution to corporate / family outcomes and mobility.

Based on the analysis of studies for the period 1991-2019, the author proposes a conceptual model of the study of female employment, which demonstrates the influence of factors on the opportunities and prospects of women in the economic and social sphere, as well as the risks of modern transformation (Figure 1).

All changes in employment from a gender perspective are closely interconnected and research in this area, as we see it, should be carried out with a multidimensional analysis. So, if we study the issues of distance women's employment, it is necessary to trace the trends in distance employment in general,

the role of the female part of the population in them, the factors that contribute to its distribution (after all, all the factors from Figure 1 affect the distribution of distance employment), what are the prospects distance employment and what it can lead to, and what are the risks of its spread.

Environmental factors, economic and social policies have a significant impact on the employment and health status of modern women. In the conceptual model, the author formulated key risks caused by these factors - from forced informal employment of women to lower fertility and changes in parental functions. At the same time, we assume that there are opportunities for economies and politicians of states and companies that allow women to avoid the risks associated with precarious work in the future.

Fig. 1: Conceptual model of research on female employment

Conclusion

Women's employment and precarious work is a relatively new area of interdisciplinary research. But, in the era of large-scale digitalization of the economy, in the era of the economy of knowledge and innovation, and the growing number of precariously employed people in the countries, there is an

intensification of the interest of scientists in the world in protecting the health of workers, families and society, prone to these trends.

In the work, we presented the circle of the most exciting researchers on the issues of precarious work and its impact on women's health, reflected in scientific publications from 1991 to 2019, described key points and research results, as well as directions for future in-depth study.

Conclusions regarding the study of the problems of the influence of non-standard forms of employment on women's health:

- the question of the influence of non-standard forms of employment on women's health requires a deeper empirical study. But it is clear that a number of forms of temporary contracts are associated with adverse health and psychosocial consequences, in the first place, this relates to low-paid physical seasonal and temporary work;

- the question requires a deeper study also in that the number of precariously employed in the economy is constantly growing and can lead to negative consequences not only for the health of working women themselves, but also for family health, parental and marital relations, and the health of nations. Knowing the possible consequences of precarious work on workers, it is possible to prevent the development of serious social problems;

- as questions for further research in this direction, we propose to consider the impact of distance employment of some employees of organizations on the achievement of team (group) labour results, its reflection on the behavior of professional communities, the transformation of the communicative space in conditions when a third of the world's population has switched to flexible forms employment;

- It would be interesting to analyze the reasons why women of working age prefer flexible forms of employment to traditional ones on a global scale. Research can be aimed at studying the influence of flexible forms of employment on the autonomy of labour organization and control, job satisfaction and labour productivity.

In this review and the conceptual model of the study, as its summary, we tried to take into account and combine interdisciplinary achievements in the study of precarious female employment, as well as its impact on women's health.

From the point of view of the gender passport and the formed social portrait of the country, Russia has a female face. The changes taking place in the field of female employment in our country relate to new opportunities and obstacles to their integration and adaptation to new living conditions. Focusing on the prospects and dynamics of technology development and the introduction of innovations, it is necessary to make a qualitative forecast and create conditions for reducing the gender gap in the national labour market. This is a global and serious task, which must be solved in a comprehensive manner, with the active role of strengthening state policy, modernizing the education system, diversifying employment at the enterprise level and softening the stereotypes of the population regarding “male” and “female” labour.

Abstract

The purpose of this paper was to add to existing research by exploring the importance of external factors on successor's commitment into a family business. It was done by performing comparative analysis of the culturally distant countries: Indonesia and Poland. The empirical survey was carried out among potential successors of family businesses. The hypotheses were based on four types of successor's commitment: affective, normative, calculative and imperative. The survey revealed numerous clear differences in successor commitment between the cultures under study. In particular, Indonesian successors commitment is basically an affective one, as opposite to calculative commitment of successors in Poland. We found strong first-hand support for cultural embeddedness of FB succession. That brings us closer to understanding of the commitment mechanism in particular and succession efficiency in general. We also point at stimulating niches for further study.

Keywords: Family Business, Succession, Successor, Commitment

Introduction

Due to the confirmed significance of the next generation perspective for the effectiveness of succession of family business, the investigations of the successor-related factors have been numerous. And, quite many elements of the successor predispositions for the succession have already been identified. However, there is still a visible gap in our knowledge on the conditions that influence the successor's approach to the issue and on the external determinants of the willingness of the successor.

In order to gain deeper understanding of successor approach development within family business, the study is to identify factors that affect willingness of the successor to take over the family business. Cultural embeddedness of successor commitment is selected for detailed investigation. Commitment of a successor is influenced by cultural context is hypothesised. To verify the supposition, a detailed examination of four kinds of commitment identified by Sharma and Irving (2005) in comparative analysis of two culturally distant nations is performed. The research is based on an empirical investigation made among the potential successors of the family businesses.

The significance of the issues under study comes from the importance of family business in every economy and the delicate issue of succession as an important element of business development. The findings reduce the gap in our knowledge on the family business succession determinants with special reference to cultural embeddedness. Moreover, this study adds to general knowledge on business and signs into discussions on far-strategic planning in family business.

Successor-Related Factors – Hypothesis Development

The matter of succession has long been an area of interest in the family business literature (Bozer, Levin, and Santora, 2017; Evert et al., 2015). And, the perspective of next generation on taking over family business is quite popular in FB research (De Massis et al., 2016). Chrisman, Chua and Sharma (1998) identified as many as 30 desirable successor features. Venter, Boshoff and Maas (2005) pointed at three groups of main successor related factors:

- **the preparation level of the successor (or readiness**) – defined as an ability or competences of the successor – managerial skills, personality and business experiences;
- **the quality of the relationship between the incumbent and the successor** – it is not surprising the literature suggests that the harmony and consensus between the incumbent and the successor are both essential for succession;
- **the willingness of the successor to take over the business** – a family's commitment to the business refers to the extent to which family members desire the perpetuation of the business in the family; as far as the successor is concerned the commitment is also defined as successor's willingness to take over the business.

In search for the explanation of the successor commitment phenomenon Sharma and Irving (2005) have identified four types of motivation that can be the fundament of successor's approach to take over the FB and that put some light on the successor approach to the issue (ANCI model):

- AFFECTIVE – based on desire,
- NORMATIVE – based on obligation and tradition, and/or under pressure,
- CALCULATIVE – based on opportunity costs,
- IMPERATIVE – based on need/necessity.

Table 1 summarizes determinants of the successor commitment that have been recognized in the literature. One can identify an important niche in the understanding of the problems of succession: the knowledge on the mechanism of both operation and importance of culture as a determinant of successor approach to FB is highly unsatisfactory because there is hardly any research done on the issue. Paradoxically, cultural references are very often mentioned in the succession literature, but the issue is rarely studied thoroughly. In other words, culture is one of those elements that is scarcely carefully incorporated into the investigation of the issue.

Table 1: Determinants of successors' commitment

Individual aspects	
affective commitment may be influenced by personal factors such as age, gender, birth order, skills, trust, abilities, career perspectives;	Cabrera-Suárez, and Martín-Santana, 2012; Cadieux, 2007; Fox, Nilakant, and Hamilton, 1996; Pyromalis, and Vozikis, 2009; Sharma, and Irving, 2005.
affective commitment is based on family member's strong desire to contribute to their family business' success;	Sharma, and Irving, 2005; Karima, and Habib, 2012.
commitment depends on self-efficacy of a successor;	Agarwal, Kumar, and D'Souza, 2016.
Family and business-related factors (microenvironment)	
the will of the successor to take over the FB is proportional to the degree of responsibly exhibited by them;	de Pontet, Wrosch, and Gagne, 2007; Pyromalis, and Vozikis, 2009.
the relationship between the owner-manager and the successor is important for the willingness of the	Chaimahawong, and Sakulsriprasert, 2013; Chrisman, Chua, and Sharma, 1998;

successor to take over the business;	Goldberg, and Wooldridge, 1993; de Pontet, Wrosch, and Gagne, 2007.
commitment depends on potential benefits for the future successor as they weigh the benefits and costs of assuming the leadership of the family firm;	Agarwal, Kumar, D'Souza 2016; American Family Business Survey, 1997; Handler, 1994; Sharma et al, 2001.
the fit between the career interests of a successor and opportunities in the family firm is important in determining if the potential successor joins family business;	Bozer, Levin, and Santora, 2017; Zellweger, Sieger, and Halter, 2011.
the cultural patterns of the family (patriarchal, collaborative or conflicted) might be important for succession;	Dyer, 2009.
education of a leader is important as predecessor plays a vital role to prepare the potential successor;	Amran, and Ahmad, 2010; Richards, Kammerlander, and Zellweger, 2019.
Macroenvironment	
succession is a social and family process influenced by cultural circumstances;	Le-Breton-Miller, Miller, and Steier, 2004; Karima, and Habib, 2012; Ward, 2000.
cases of areas of culture manifestations in FB succession related with gender and birth order;	Barnes, 1988; Friedman, 1991; Wang, 2010.
competitive environments play a very important role in the process of family business succession;	Marceau, Aldrich, and Aldrich, 1991; Stavrou, 1999.
changes in macro or micro business environment can influence the succession process;	Chaimahawong, and Sakulsriprasert, 2013.
uncertainties and contingencies in the business environment affect the distribution of power and control within family business and this distribution, in turn, influences selection and replacement of successors;	Wang, 2010; Nordqvist et al, 2013; Stavrou, 1999; Venter, Boshoff, and Maas, 2005.
as FB professionalizes the issue of succession it is far less emotional;	Afghan, and Wiqar, 2007.

Source: own elaboration.

The extensive studies of the family businesses all over the world made it clear that family business operations are deeply rooted in cultural context. And, uniqueness of family business is based on solid networks between private and professional life, and the social structure is strongly reflected in business culture (Dyer, 2009; Sułkowski, 2013). However, a vast majority of the research on firm succession carried out so far are single-region studies (Nordqvist et al., 2013) and they relate to Anglo-Saxon countries (Van der Merwe, Venter, and Ellis 2009). Moreover, international perspective in empirical studies of the determinants of FB succession is still limited. The identified importance of cultural embeddedness provokes reservations about possible generalization across countries. In other words, it implies doubts if mechanisms identified in one country might work in other countries as well. Therefore, it seems reasonable to expand our geographical area of investigation and suggest a comparative study of culturally distant countries. Such an approach seems to offer an opportunity to enrich our understanding of cultural background of succession. It also follows Morck and Yeung's (2003) suggestion that FB in the formerly planned economies may have their specificity and that studies in developing countries might bring important insights. Asia Pacific region seems to be relevant here as it is dominated by family-controlled businesses (Globerman, Peng, and Shapiro 2011).

The literature survey provides a conceptually sound framework which helps to improve the understanding of successor development in family businesses in general. Accordingly, this examination is to add to existing research by exploring the importance of external factors on successor approach to the issue in different cultural context and provide insight into how culture influences the succession in family business. Further hypothesis derived from ANCI model by

Sharma and Irving (2005) is to answer questions regarding the importance of culture for the successor's commitment to family business. The operationalisation of culture is based on Hofstede's (1980) dichotomies.

Following the aim of the study the following hypothesis was put to examination:

H. Commitment of a successor towards a family business depends on cultural embeddedness.

H1. Affective commitment is stronger in a collectivist culture that in an individualistic one.

H2. Normative commitment is more important in collectivist cultures than in individualistic ones.

H2a. Normative commitment is weak in individualist cultures.

H3. In individualist societies successors are driven mostly by calculative commitment.

H3. There is no cultural impact on imperative commitment.

Research Methodology

The purpose of the research was to find out whether there were any differences in the commitment of potential successors to family businesses among cultures. We applied comparative analysis as a basic research method. There is a number of frameworks for comparative investigation of factors influencing entrepreneurial behaviour in diversify of regions (Bouncken et al, 2008; Ozarall, and Rivenburgh, 2016). Patrickson, and O'Brien, 2001; Stehle, and Erwee, 2005). In the study we followed those patterns to compare the two countries under study, considering cultural issues following Hofstede (1980). An interviewing technique was used to collect empirical data on successor commitment with the measuring instrument developed on the basis of questionnaire offered by Hewitt, van Rensburg, and Ukpere (2012). The research instrument consists of three parts: SECTION A – the questions related with biographical data on a respondent and SECTION C – the demographical data on family business – these sections are to bring data that allows us to compare groups of respondents and to build up a company profile. In SECTION B (Q15-Q33) is an attempt to gather data on potential successors' commitment in FB. Respondents rated their orientation on a 7-point Likert scale. The following items have been developed here:

15. How involved are you with the strategic decision making in the family business?

16. To what degree do you believe and support the goals of the family business?

17. To what degree do you support the following statement: "It's our business; that is what we do"?

18. To what degree do the goals of the family business align with your own personal goals?

19. How important is it to keep the business in the family?

20. How important is it to pass the family business on to the OLDEST SON?

21. How important is it to the FAMILY to continue to manage the family business the same way it has been done by the previous generation?

22. How important is it to YOU to continue to manage the family business the same way it has been done by the previous generation?

23. To what degree do you feel FORCED to work in the family business by your parents?

24. To what degree do you feel OBLIGED to work in the family business?

25. I will earn a higher income being employed in the family business than I will get anywhere else.

26. By being part of the family business I ensure my inheritance in the family estate.

27. By being part of the family business I get access to the family networks.

28. By being part of the family business I nurture my relationships with family members.

29. To what degree were you employed in careers other than those available in the family business?

30. To what degree did you want to follow in the footsteps of your family member(s) who is/are controlling the family business?

31. My skills are in high demand in businesses other than the family business.

32. I will be more successful outside the family business.

33. My best career option is to be employed in the family business.

In order to catch context-related factors that might be important for FB succession, two culturally distant countries have been selected for comparative analysis. The case of Poland is interesting if only because as an emerging economy it does not have much experience in transferring leadership in private businesses (Bhalla, Orglmeister, and Tong, 2016). Indonesian case is worth attention – among others – due to its cultural heterogeneity and dynamic socio-economic development. Following Hofstede Insights Indonesian culture is collectivist, with both power distance and seniority importance high. And, Poland's national culture is an individualist one, with both power distance and seniority importance low (Hofstede Insights, 2020).

The results of the survey

The Sample: Respondents

This survey focused on investigating the perspective of university students with regard to their involvement in FB succession. The empirical data were collected among the university students of management, economics and finances coming from the families that run their own family business. The students declared to be real or at least potential successors. The respondents were interviewed in October 2019 at the universities in Jakarta and Warsaw. Simple random sampling was used to identify the survey's respondents. The questionnaire was successfully administered to n=52 students in Jakarta and n=90 students in Warsaw.

The respondents were aged 19–26 with dominant age of 21 in both countries and of the balanced sex structure. The study findings show a significant involvement of students in family firm operations in Indonesia (67%), evidently more than in Poland (53%). However, in both cases roles played by respondents in FB have been ranging from simple duties of cleaning and office administration to supervision and managerial tasks. Second, almost 60% of Indonesian respondents are to take over the business compared to less than 30% in the case of Polish students. The latter is probably related with the differences in having the succession plan between the countries (see section 4.2.). Third, it is worth mentioning that the way the questionnaires were filled in suggests that potential successors in Indonesia knew much more about the family business than it was in the case of Polish students.

The Sample: Family Businesses

The characteristics of family businesses represented in the sample are summarised in Table 2. The vast majority of businesses in the sub-samples from both countries have been created by parents – fathers and/or mothers of the respondents. The age of these family firms ranges from start-ups of 1 to 3 years up to well established firms that are over 20 years old. The median age in both sub-groups is the same and is 10 years. The businesses represented in the sample are mostly micro and small in size measured by number of employed. However, in Indonesian sub-sample the median size is 10 compared to 4 in Poland. Nevertheless, being small in size the business might be potentially equally attractive to potential successors, in comparison to big business that are definitely more desirable by younger generation. The businesses in both samples operated in many sectors (from the largest): wholesale and retail trade; services, transport, construction, manufacturing, tourism and hospitality, agriculture. Slightly more than a half of FBs in both countries represented in the sample operate on local markets, the rest range national markets, with a few operating on global scale. Polish FBs derive their key competences on price (60%) and flexibility (40%) compared to Indonesian businesses that mostly choose quality and price (46% and 36% respectively).

As far as succession is concerned in both countries the firms are still managed by their founders – they have not passed any succession yet. Nevertheless, one can easily notice the visible differences in approach to succession between the two countries as the majority of Indonesian firms (92% – compared to 13% in Poland) have their succession plans, they have already pointed the successor (87% – compared to 40% in Poland) and have already initiated the succession process at least through the implementation of the initial stages (85%, compared with only 13% in Poland). What is more, the strategy building and the succession planning in Indonesian firms covered by the survey have been much more far-reaching and mature than in the case of Polish firms. It was found that in both cases major strategies in succession planning that favour multigenerational outlook were primarily family discussions, mentoring and early participation in the family businesses. Moreover, in Indonesia the successors have been usually pointed quite early, their education has been subordinated to succession plans, and the other children in the family have been prepared for other career paths. This is not the case in Poland as the majority of families do not make such regular arrangements.

Despite these differences the responses to our questionnaire were irrespective of industry of operation, age or size of a business.

Table 2: The family business in Poland and Indonesia, the survey sample, numbers, (%)

age of family business							
	1-5	6-10	11-15	16-20	21-25	26-30	31-

Successor's approach to the FB

The comparison of the sub-samples covered by the survey yields the following results. There are not many similarities as far as an approach to family business of students from Indonesia and from Poland is concerned. First, the identification of the younger generation with the FB (Q17) is moderate in both countries: 48% of Indonesian students and 50% of the Polish ones agreed that: "This is our business". Second, in both countries, students are moderately convinced that by being a part of FB they ensue themselves an inheritance in the family estate and get access to family networks (Q26: Indonesia 48% and Poland 44%; Q27: Indonesia 58% and Poland 52%). Third, 58% students from Indonesia and 59% students from Poland believe that their skills are in high demand in businesses other than the family business (Q31). Also, their belief that their best career option is to be employed in the family business is similarly moderate (Q33: 54% in Indonesia and 56% in Poland). As far as slight differences between the countries are concerned it appeared in the survey that both in Indonesia (10%) and Poland (17%) the younger generation is not so much involved in strategic decision making in FB, and in Indonesia the decision making is more concentrated in the hands of older generation. (Q15)

Comparison of the two groups of students brings quite a number of evident differences as far as successors commitment is concerned. The dissimilarities are summarized below.

1. Potential successors believe in and support the goals of the family business much stronger in Indonesia (90%) than in Poland (50%) (Q16).
2. For potential successors in Poland it is quite important (65%) to keep the business in the family, but in the case of the Indonesian successors it is extremely important (95%) (Q19).
3. For the successors in Indonesia the takeover of the company by the eldest son is rather important (56%), apparently more than in the case of Poland (32%) (Q20).
4. The Indonesian potential successors would like to continue to manage the family business the same way it was done by the previous generation more (58%) than in the case of the ones in Poland (29%) (Q22).
5. Higher share of potential successors in Poland (47%) than in Indonesia (23%) claim that the goals of the family business do not align with their own personal goals (Q18).
6. Indonesian potential successors were employed in careers other than those available in the family business to a lesser extent (46%) than successors in Poland (56%) (Q29).
7. Students in Poland believe that they will be more successful outside the family business (56%) and the Indonesian students are not so optimistic about that (40%) (Q32).
8. Correspondingly, the Indonesian students present moderate belief that they will earn higher income being employed in the family business than they will get anywhere else (46%) and the opinion has a rather small acceptance among the Polish students (32%) (Q25).
9. The Indonesian students feel forced to work in the family business by their parents (44%) and the Polish students can hardly feel any pressure (9%) (Q23).
10. Similarly, the Indonesian students usually feel the obligation to work in the family business (64%) and the Polish students typically feel free from this kind of obligation (12%) (Q24).
11. The Indonesian students believe strongly that by being part of the family business they nurture their relationships with family members (73%) compared to moderate approach of the Polish students (53%) (Q28).
12. In Indonesia, the potential successors attach much more attention (60%) than in Poland (26%) to the family to continue to manage the FB the same way it was done by the previous generations (Q21).

13. Indonesian students would like to follow in the footsteps of their family member(s) who is/are controlling the family business to a higher extent (54%) than in the case of the Polish students (41%) (Q30).

The observable differences between Indonesia (as a collectivist culture) and Poland (as an individualist culture) regarding the potential successors approach to family business suggests that the main hypothesis of this paper might be true. In other words, the reported survey supports the premises that H: "commitment of a successor towards a family business depends on cultural embeddedness".

As far as the power of affective commitment is concerned, the results show that the Indonesian students are much more emotionally involved in the FB than the Polish students. That would advocate the statement H1: "Affective commitment is stronger in a collectivist culture that in an individualistic one". What is more, the tradition and social norms seem to be much more important for the Indonesian students for their approach to family business than for students from Poland. That would support the hypothesis: H2: "Normative commitment is more important in collectivist cultures than in individualistic ones" and H2a: "Normative commitment is weak in individualist cultures". For the students from Poland the calculative commitment seems to be more important than for the Indonesian students. That would go along with the H3: "In individualist societies successors are driven mostly by calculative commitment".

Discussion

In general, the results of the study go along with the previous knowledge on the importance of cultural embeddedness for the family business operations, succession planning included. In particular, the significance of the study is that it sanctions the legitimacy of comparative analysis of the topic. The empirical results confirm that culture determinants are important factors to successor commitment to the family business. Also, the researchers have not seen any empirical work which goes so deeply into successors' commitment nor its importance for the succession efficiency. What is more, the study shows the rationality of successor commitment understanding following the ANCI model. Moreover, a long list of identified important differences between the two subsamples from distant cultures is a substantial input into our understanding of succession mechanism.

The imperative commitment has been weakly presented in data on both sub-samples. It may come from the specificity of the respondents, i.e the students who are working on their future professional paths and are aware of the importance of education, and for them the FB takeover does not have to mean a necessity. One can also suppose that the method used in the research is not efficient as far as imperative commitment is concerned – a field study and qualitative research among actual successors seems to be more reasonable here. Thus, further research is necessary to learn more about the importance of culture and other external factors for successor's commitment to family business.

The wider scope of research survey seems to be justified to verify quantitative strengths of the relation between culture and commitment. We still operate in the area of suppositions that definitely need verification.

Conclusions

The comparative analysis of potential successors in Poland and Indonesia gave strong premises that justify our hypothesis. The evident differences between successors' commitment in Indonesia and Poland point at the specificity of the commitment depending on culture. However, study has not provided enough information on the activities of potential successors in relation to possible succession, and the real outcome of the succession process remains unknown. Moreover, the information in not enough to explain all the dissimilarities between the two sub-groups surveyed. What is more, as a special "by-product" of the survey quite meaningful suppositions on succession

planning in two countries under study emerged. That is why further study is necessary to explain the observed differences and root them deeply in cultural environment.

Abstract

Motivation to deal with the problem of managerial kitsch was the natural consequence of our previous research about crossing the borders of art and management. Our own – both practical and theoretical – experience in the fields of art and management was the main argument for combining these areas with benefits to the science and practice of management. This approach in management literature is rare and fragmentary; we try to establish the main routes for the future research. The delicate edging and features of art lead to the phenomenon of kitsch as something opposite to art or. Applying the well-developed theory of aesthetical kitsch into management area was vital for understanding the real nature of the phenomenon of kitsch in management. The research methodology bases on a qualitative review of the literature; the methodological approach bases on interdisciplinary and multi-paradigm approach taking into account the publications from areas of art (aesthetics theories) and management (organisational kitsch). The main research questions were: 1) is there any set of factors/features constituting the management kitsch and 2) what type/types of organisational roles are main for kitsch transfer? After the broad review of the literature, a synthetic description of management kitsch forms (one best way claim, simplification, grandiosity, organisational cynicism functional stupidity, bullshit jobs, seeming management) and the main carriers and propagators of organisational kitsch (management gurus, narcissistic managers, mendacious CEOs and owners) were described and the management kitsch was defined. Management kitsch should be defined and reduced for quality improvement of organizational life.

Keywords: Kitsch in Management, Kitsch in Aesthetics, Critical Management Studies

Introduction: Taste and Disgust, Aesthetic Theory of Organization

It is not an easy task to define the concept of kitsch. We may find many definitions of it, but each one leaves us with the feeling of insufficiency. Kitsch is easier to feel than to describe. By transferring the theory of kitsch from the field of aesthetics to the field of management, depending on the definition of kitsch, we get a kind of scale which we may put an aesthetic assessment of the manager's activity on: from the artist/virtuoso management to kitsch-method-producer imitating management (Szostak and Sułkowski, 2020). Since each assessment is the basis of improvement, the field of Critical Management Studies (CMS) opens itself as a theoretical canvas for the collision of aesthetics with management.

A positive change – as the basis of the CMS – is the purpose of constructive criticism: diagnosis, leading to therapy. This approach involves the use of humanistic management methods, within which nine pragmatic and methodological objectives (characteristic of the CMS cultural trend) can be distinguished (Alvesson and Willmott, 2003): 1) creating organizational cultures based on real intra-organizational democracy; 2) removing all forms of violence from the organizational culture by: rejecting false consciousness, reflectiveness, creating meaning (managing sense making),

humanization and moral and ethical sensitivity; 3) improving the social position of disadvantaged groups through the use of emancipation methods such as: empowerment, parities, political correctness; 4) implementing an emancipatory culture both at the level of relationships between organizations, within the organization and between employees; 5) rejection of the functionalist paradigm and instrumental reason in cultural interpretations; 6) developing qualitative, interpretative and engaged methods of researching organizational cultures; 7) the transformation of professionalism and technocratism of the academic community and management practitioners into critical methodological pluralism; 8) creating a reflective and critical organizational culture that will guide the development of organizations, society and people towards an increase in humanization; 9) developing humanistic management projects by radicalizing methods. Referring critically – in the spirit of the theory of art – to some of the above-mentioned CMS goals, one could say that they are unreal, or in themselves they are closer to kitsch than the immanent values of real artistic activity. The basic argument on the ground of aesthetics is that democratization – by its statistical nature – means lowering the bar to a level accepted by the majority, and this isn't associated with high quality. We can even find some of these goals to move towards kitsch methodically. Nevertheless, CMS is vital approach in our study.

The second half of the 20th century broadly transposed the phenomenon of kitsch scientifically from the field of art to other areas of life. Kitsch in management can be considered in two ways: literal and metaphorical. Literal reasoning is based on "bad taste" – question of a taste, i.e. the ability to recognize good from evil (Herbert, 1968; Eco, 1989); "golden recipes" of the management gurus, rhetoric of some of the guidebooks on management and leadership, shallow management concepts (like Maslow's pyramid of needs). In turn, the metaphorical understanding of kitsch is "any management", that is: non-creative and flattering low motives, deprived of mission – senseless and pointless, founded on the cynicism of organizational managers (Selznick, 1948), present in scientific area as Bullshit Management, BSM (Sułkowski, 2019). Using aesthetic optics, we can talk also about "taste and disgust in management": in some actions of managers we can find universal values, while in others – quite the opposite. In this theoretical framework – art-kitsch and taste-disgust – we'll be moving in this work.

Methodology and Theoretical Framework

The research methodology was based on a qualitative review of the literature taken from databases: EBSCO, Google Scholar, JSTOR and Scopus. The methodological approach based on interdisciplinary and multi-paradigm approach taking into account the publications from areas of art (aesthetics theories) and management (organisational kitsch). The main research questions were: 1) is there any set of factors/features that constitutes the kitsch in management and 2) what type/types of organisational roles are main for kitsch transfer? An additional goal was to define the kitsch phenomenon in management.

Literature Review

Analysis of the kitsch phenomenon in art is necessary to transpose the kitsch concept into management, that's why the literature review is divided on two groups: aesthetics and management. Both areas are firstly described separately to prepare the base for drawing the conclusions of the research.

Kitsch in Aesthetics

Although the kitsch phenomenon has always existed in art, it was named only at the end of the 19th century and it is only from this period that the development of its theory dates. This development of theory went hand in hand with the practical intensification of kitsch in the art of the 19th and 20th centuries, when the emphasis was placed on satisfying mass taste through mass (cheap and fast) production (Greenberg, 1985; Calinescu, 1987); it was a way to increase the material profits of artists who – putting aside the issue of loyalty to the ideals of art – focused on producing artefacts that found crowds of recipients, and thus enabling easier earning of livelihood. Kitsch, as a consequence of commodification, expresses problems inherent to high capitalism. If art becomes an extension of daily life it loses itself; it becomes a commodity among commodities, kitsch (Rosenberg, 1959: 267). Although kitsch was defined in of the second half of the 19th century in the Munich painting school, the phenomenon of kitsch is associated with human artistic creativity from its very beginning. The birth of the word "kitsch" shouldn't be equated with the birth of the phenomenon it describes. This thesis

results from the fact that kitsch lies on the opposite – to purely artistic creativity – pole of scale. Therefore, every creator, consciously or unconsciously, moves between these poles of ideal states.

Dictionary definitions of kitsch focus mainly on the meaning of a kitsch artefact instead of a kitsch phenomenon as a whole. The kitsch artefact means "something that appeals to popular or lowbrow taste and is often of poor quality (Merriam Webster, 2019), considered by many people to be ugly, without style, or false but enjoyed by other people, often because it's funny" (Cambridge Dictionary, 2019b). Synonymous words are: crap, debris, detritus, down-cycle, dross, effluent, influent, jetsam, jumble, junk, recycle, refuse, rubble, scrap, spoil, tat, upcycle, upcycling, waste product. Kitsch common features are: fundamentality, secondary nature, exaggeration, hysteria. The most popular themes of aesthetical kitsch are: patriotism, religion, erotism and politics. Starting from this point, we can conclude that kitsch likes primal instincts, which need primal fulfilment also. Kitsch answers for eternal need of emotion. From word "kitsch" there is close to the word "putty", which refers to filling the gaps with easily adhering mass. It can be said that the essence of kitsch is "special quality, which evokes emotions in a sure and easy way, effective in human creations, with stereotypical features". Because it isn't an easy task to define what kitsch is, that's why contemporary aesthetics theoreticians prefer the overview method of the kitsch artefact's features (Banach, 1968: 24, 34-38).

Adorno perceived kitsch in terms of the "culture industry", where the art is controlled and formulated by the needs of the market and given to a passive population which accepts it — what is marketed is art that is non-challenging and formally incoherent, but which serves its purpose of giving the audience leisure and something to watch. It helps to serve the oppression of the population by capitalism by distracting them from their alienation. Contrarily, art is supposed to be subjective, challenging, and oriented against the oppressiveness of the power structure. Kitsch is parody of catharsis, and a parody of aesthetic consciousness (Adorno, 2002). An important contribution to the kitsch definition process was adding ethics into the discourse: kitsch wants to act on the base of beauty (more "prettiness" than real beauty), not – like an art – on the base of the truth. Kitsch arises as a result of giving up the truth for the sake of prettiness. Kitsch isn't a bad art; kitsch is an evil in art – it creates its own reference system. On the base of this approach, there is no possibility to use a previous-mentioned scale where on one side there is an art and on other side there is kitsch; art and kitsch can be perceived as the separate levels (Broch, 1969a).

Aesthetical theory created a concept of kitschification, which means the phenomenon of departing in the work from artistic values in favour of the features belonging to kitsch. Kitschification, as an aesthetic defence against reality, "normalizes" the painful episodes in history, neutralizing that history, trivializing that history, commercializing that history, and exploiting that history in such cases as Nazi history transformed into a consumable commodity (Saltzman, 2001: 55). It consists, instead, in a sentimentalised unreflective emotional appeal that manipulates emotions, distorts perceptions, reduces rationality and understanding, and avoids or suppresses unpleasant or disturbing aspects of reality (Kulka, 1996). On sufficient scale, and with a sufficient permeation of societal sectors, kitsch not only disables people's capacity for aesthetic judgment, but also for political and moral judgement (Solomon, 1997). Kitsch is predominantly figurative, drawing on the conventions of 19th-century romanticism or socialist realism rather than abstract or cubist styles. One of its most characteristics traits is its use of the most conventional, standard, well-tried, and tested representational canons (Kulka, 1996: 29), rather than esoteric, idiosyncratic, original or innovative styles, since it must achieve an unchallenging, and effortless identifiability. Kitsch is aesthetically conservative and stylistically reactionary. It is universally accessible and easily understood. It is explicit and one-dimensional, lacking ambiguity, uncertainty or hidden meanings, and, by allowing for only one interpretation, is fundamental and dogmatic. It is pre-digested and pre-packaged "art" for the spectator, sparing effort and providing a short cut to pleasure without having to deal with the interpretive difficulty of genuine art; kitsch is mechanical and operates by formula. Kitsch is vicarious experience and faked sensations; it changes according to style, but remains always the same. Kitsch is the epitome of all that is spurious in the life of our times; it pretends to demand nothing of its consumers except their money (Greenberg, 1985: 25).

Kitsch origins are located in romanticism, in debased form emphasising dramatic effects, pathos and sentimentality (Broch, 1969b), a hackneyed form of romanticism (Calinescu, 1987: 240). Some researchers dispute its modern origins: poor aesthetic taste of classical-period Roman merchants – the universal access to and proliferation of kitsch were only made possible by the economic conditions and

mass culture of modern industrialism. The individual in a money economy becomes a mere cog in an enormous organization of things and powers which tear from his hands all progress, spirituality and value. Acquisition becomes one of the central motives of modern capitalist society, resulting in a sensory numbing from mass production (Greenberg, 1985). Money, while serving to measure the relative value of objects, relegates human activity to an alienated margin; cultural objects increasingly evolve into an interconnected enclosed world that has increasingly fewer points at which the subjective soul can interpose its will and feelings; this trend is supported by a certain autonomous mobility on the part of the objects; both material and intellectual objects today move independently, without personal representatives or transport; objects and people have become separated from one another. In this manner, economic modes of interaction replace socially embedded ones, transforming every facet of life to fit into the logic of market exchange through commodification.

Based on the theory of "aesthetic situation" by Maria Gołaszewska (1984, Szostak, 2020; Szostak and Sułkowski, 2020), we can present the problem of the kitsch experience by showing its opposition to the aesthetic experience. To distinguish it from an artwork, we will call the kitsch product as "kitsch artefact", whereas the kitsch creator as "kitsch producer/manufacturer". The synthesis of the discussed phenomena is presented in the Table 1.

Table 1: The Kitsch Experience vs the Aesthetic Experience

Element	Aesthetic Experience	Kitsch Experience
Creator/Producer	focus on universal values	focus on mass recipient
	creative reliability	duplication, copying
	opened for criticism and discussion	closed for criticism and discussion
Work/Artefact	it has an advantage over the receiver	it is dominated by receiver's (patriotic, religious, sexual, political) desires and needs
	it extends the recipient's existence	confirms the recipient's habits
	coherence	pretentiousness
	it fills the future based on the past	it fills the present
Receiver/Recipient	submission to a work of art	willingness to interfere with an artefact
	exclusivity	egalitarianism, mass scale
	willingness to consider the work from all sides/dimensions	choosing items to consider from the recipient's desires
	share of thought, awareness and will	avoidance of thought, consciousness and will (lack of reason, gullibility, irrationality)
	deep emotions, feelings	shallow and fleeting experience, sentimentalism
	internal contemplation	external experience
	need of loneliness	need of community
World of Values	dominant: truth	dominant: beauty (prettiness) and pleasure
Real World	source of creative inspiration	source of impulses to satisfy

Source: Authors' own elaboration.

Creator of artwork – being reliable in his creativity – focuses on universal values and is open for criticism and discussion about his work. Kitsch producer – copying own or other's ideas and patterns – focuses on mass recipient avoiding criticism. One motivation of the kitsch producer is to make something appear more valuable than it actually is. Kitsch is essentially deceptive – an artistic imposter, camouflaged as art: the whole concept of kitsch clearly centres around questions as imitation, forgery, counterfeit, and what we may call the aesthetics of deception or self-deception; it is a specifically

aesthetic form of lying (Calinescu, 1987: 229). Unreflective and uncritical, kitsch lends itself easily to the injection of propaganda and groupthink. It is confused with entertainment, attractiveness or fame, camouflages personal flaws, and is used to ingratiate. As dogma it is used to distract from important underlying realities, particularly those of contradiction and conflict, producing compliance and maintaining the status quo.

A work of art is coherent, it has an advantage over the receiver and – filling the future based on the past – it extends the recipient's current existence. Kitsch artefact is most often dominated by receiver's patriotic, religious, sexual and political desires and needs; it likes to confirm recipient's habits, to fill the present only shining with its pretentiousness. Artwork receiver is submissive to contemplated work, which gives him exclusivity and willingness to consider the work from all sides/spectrums; he needs to use his thought, awareness alone and will to contemplate deep emotions and feelings internally. The kitsch artefact lacks basic criteria of aesthetic values: unity, balance or harmony comprised of an inner logic of structure and style; complexity, multidimensionality, repleteness, combinations of heterogeneous forms, and elaboration of structures and detail; and intensity as vitality, forcefulness and vividness of presentation. The kitsch artefact also lacks the artistic value of creative and innovative contribution to the history of art – that is, opening new possibilities and suggesting solutions to topical artistic problems (Kulka, 1996), presenting an 'original' concept. It doesn't enrich our associations relating to the objects or themes, but rather is parasitic in nature since it doesn't create a beauty of its own. Essentially, kitsch artefacts lack provenance – they are disconnected from the original from which they are derived and lack considerations of sociohistorical context that in part add to their complexity but also their meaning.

Kitsch consumer wants to interfere with kitsch artefact by feeling egalitarianism of mass scale; he chooses items to consider from the recipient's desires avoiding his own thought, consciousness and will keeping his attention on external, fleeting and sentimental experiences preferably in the community of people in the same situation. Kitsch is easily understood by the consumer, doesn't question socio-political reality or vested interests, requires no great intellectual effort, reinforces our prejudices, avoids unpleasant conflicts, and promises a happy ending. We embrace images, popular actors, actresses, and musicians who, above and beyond their talents, have been given charismatic status despite – or perhaps because of – certain flaws in their character or theatrical skills. The appeal of kitsch to consumers resides not in the kitsch producer, its provenance, its contribution to the development of the arts, or even its social status. Kitsch is purchased as an end in itself because it satisfies an immediate desire and doesn't disturb our basic sentiments and beliefs. It also aims at universal rather than individual emotions, playing on the most common/lowest, denominator (Samier, 2008: 8-9). It is stirring but empty, serving primarily as a distraction. Kitsch, unlike art, doesn't accept the nature of things in the light of their critical or revelatory attributes, but to the extent which they cover and protect, relieve and console (Gregotti, 1969: 276). Kitsch mustn't question the basic metaphysical and moral assumptions of human existence the meaningfulness of our endeavours, the accepted moral code, and the meaning of life as such (Kulka, 1996: 97). It omits conflict producing the kitsch-man (Broch, 1969a).

Considering the world of values, in aesthetic experience we find domination of truth, but in kitsch experience – domination of prettiness and pleasure for the kitsch consumer. It can be said, that ethics is a distinguisher of kitsch. Real world is a source of creative inspiration in aesthetic experience, but a source of impulses to satisfy in experience of kitsch.

The development of the theory of kitsch phenomenon in aesthetics has been creatively adopted by management theory. The essence of the kitsch remains still the same: trivializing phenomena and reality, building appearances and moving away from the truth. As in aesthetics, kitsch in management is a departure from the truth. Management literature avoids answering the question of what organizational kitsch is; it focuses mainly on the description of its phenomenon. Trying to reach management area from the widest level, we collect kitsch manifestation in society, politics, religion, public administration, and education – finding management as the main denominator of all above levels.

Kitsch in Human Activities

McDonaldised (kitschified) society consists in four principles (Ritzer, 1996): 1) efficiency (the fastest way to satisfy a need); 2) calculability (an emphasis on the quantitative aspects of products, thereby

simplifying them); 3) predictability (the universal standardisation of products and services resulting in utter routinisation of thought and action); 4) control (the technological substitution of the non-human for the human). The primary purpose of kitsch socially and politically is in creating and perpetuating ideology and power structures: kitsch becomes totalitarian kitsch when it is a state policy, an approved way of understanding reality – dangerous not to admire it, more dangerous still to view it with irony. In this ideological context, kitsch takes on the status of dogma (Sabonis-Chafee, 1999: 365). Even in non-totalitarian contexts, kitsch has affected public policy. Public arts policy was used in the USA by liberals in the 1950s and 1960s to recruit art to support individuality, freedom and the superiority of the American way of life (Howard, 2004: 297). Similarly, the public art policy of Detroit that resulted in 'easily assimilated' imitative works posing as art. The new public 'art' was accepted as unproblematic by the citizens of Detroit since it lacked the provocative character of art, kitsch having substituted 'user friendly' installations that are unnoticeable elements of the urban environment aimed at covering, protecting, relieving and consoling (Hall, 1989: 328-329). The purpose of the policy was to beautify and ornament rather than challenge; if art becomes an extension of daily life it loses itself; it becomes a commodity among commodities (Rosenberg, 1959: 267). The preference for kitsch – exhibited by totalitarian regimes and, through extension, by authoritarian, top-down management styles – is that they can ingratiate themselves inexpensively with their subjects, and, unlike art, kitsch lends itself easily to the injection of propaganda (Greenberg, 1985: 30).

Kitsch can be found in all types of political systems. Socialist realism not only sanctioned but imposed kitsch, creating a "perfect world" of extravagant and socialist-realist theme parks, spectacular military parades, organised rallies, and gala atmosphere of party congresses. Capitalism requires kitsch exemplified in advertising using class distinctions and status symbols to create artificial needs and illusions to foster the ideology of the consumer society (Freidin, 2000: 134-135). Examples are buildings that imitate objects of desire: McDonald's stands masquerading as hamburgers or gas stations as mushrooms, houses imitating the style of ancient Greece, and buildings in gambling resorts modelled on the Taj Mahal or the great pyramid of Cheops (Kulka, 1996: 104-105). Despite the fact that politicians are often bearers of ideals and ideologies, political kitsch is like box-office attractions in the field of entertainment. Political symbols – being often manifestation of kitsch – allow to serve a mobilising function in totalitarian regimes. Political kitsch symbols: 1) are easily understood; 2) call for an unreflective emotional response; 3) handle core values of a political regime or ideological system as a closed, harmonious entity endowed with beauty to make them more effective and 4) link truth and beauty leading to a stylisation capturing mythical patterns (Friedländer, 1990: 203).

Religion, as a manifestation of the spiritual life of man, is also not free from the kitsch phenomenon. Benoit Mathot (2015), based on the philosophical and aesthetic concepts of Hermann Broch, Milan Kundera and Slavoj Žižek, shows kitsch's specific manifestations. Kitsch points to a blind path towards the external manifestations of the sacraments or liturgical rituals, which – without understanding their meaning based on the truths of faith – they are a blanket of empty gestures that lead to nothing (Pawek, 1969).

Kitsch is also an effect of globalisation: another mass product of Western industrialism, it has gone on a triumphal tour of the world, crowding out and defacing native cultures in one colonial country after another, becoming the first universal culture (Greenberg, 1985: 26). This process also describes the kitschified version of public administration, the New Public Management (NPM), a private-sector-style managerial ideology for the public sector adopted in the 1980s internationally (regardless of its lack of relevance in many jurisdictions). The NPM subjects public organisations to market concepts and forces that both theoretically and practically have been criticised and deemed highly problematic if not a failure (Samier, 2008: 7-8).

In a consumer society predicated upon instant gratification – expectations of success without hard work or without facing resistance and conflict – educational administration is transformed into a practice that comforts and reassures its audience. Leadership and policy kitsch's preferential characteristics as providing psychological comfort, reinforcing mythologies, predictability, and creating a sense of history, culture and reality that constitutes the 'beautiful lie'. It is the same underlying principles that are at the heart of the corporatisation and commercialisation of education, which has led to the transfer of authority from faculty to administration, conflict between Senates and Boards of Governors that erodes collegial governance, and a community of scholars based primarily on the vagaries of the

intellectual market (Lugg, 1999). Educational administration analogues are the leadership books that provide easy guidelines for becoming an effective leader, the many claims of leadership for all (reducing the qualifications to a mediocre level achievable by anyone), and superficial professional workshops that reduce complex moral theory to simplified rules. Intellectual kitsch – just as kitsch religion provides spirituality without the requirement of orthodox belief and action (Klinghoffer, 1996: 259) – kitsch administration gleans only the most superficial aspects of social reality. Organisationally it produces a total or comprehensive kitschification. Such principles pervade many teaching approaches aimed at making learning entertaining and effortless, including many of the learning organisation models promising a painless and conflict-free path to organisational improvement. The teaching of educational politics substituting anecdotes and war stories for political theory and analysis produces a course lacking foundational theory and rigorous examination of empirical studies. Without a scholarly foundation even the more insightful and penetrating use of war stories as a complex and sophisticated form of narrative, phenomenological and hermeneutic source is lost – it requires no knowledge, understanding, critique nor analysis.

Kitsch in Management

Looking for sources of kitsch in management, we can consider the growing pace of life and conducting business as one of the most important factors. A fast pace of functioning requires quick decisions; managers have less and less time for relevant analyses, hence the search for universal and simple rules is becoming a natural solution. These rules – often far from the "truth" – act as a remedy for problems and fill the features of kitsch. Analysis of kitsch in area of management created many own optics/metaphors of kitsch, f.eg.: Kitsch as Eternal Return, Kitsch as Human-Centred, Kitsch as Mass Sentiment or Kitsch as Defence Mechanism (Linstead, 2002: 662). Because management concerns various types of organizations – from small teams to entire societies – so descriptions of the kitsch phenomenon in management to date are rather selective and treat selected topics analytically.

Bullshit is unavoidable whenever circumstances require someone to talk without knowing what he is talking about: businessmen, politicians, PR specialists and consultants, forced to talk about any topic, can produce bullshit. Bullshit undoubtedly constitutes the concepts of many management gurus, promoted through their consultancy work and by offering the philosopher's stone of business, the frequent purpose of which is flattering the managers' egos. Sources of the expansion of Bullshit Management (BSM) include attempts to comment on every issue, attempts to dominate the discourse, repeating the same fashionable concepts, and lack of criticism in the scientific discourse (Sułkowski, 2019). BSM can draw on CMS theory by drawing on the definition of BSM as regular and instrumental manipulation of recipients using communication and social actions. But BSM should be exposed both within the theoretical discourse and in managerial practice. This is part of the revealing of false consciousness and symbolic violence that conceal the structures of power (Waring, 1998). Ways of resistance against managerial bullshit are: demystification and resistance that could be described as weapons of the weak (Scott, 2008).

We can distinguishes between two types of kitsch: 1) common kitsch that tends toward universality, and 2) uplifting kitsch which is rooted, symbol-centred, and emotionally linked to the values of a specific group – much like decontextualized leadership training programmes (Friedländer, 1990: 203). Contrived and inauthentic kitsch is found in organisational practices like creating mascots and company songs through executive decision rather than emerging naturally from the culture. Kitsch sanitises socio-political reality: kitsch excludes everything from its purview which is essentially unacceptable in human existence; a categorical agreement with being is a world in which shit is denied and everyone acts as though it didn't exist; it dilutes meaning (Kundera, 1990).

We need to mention here the bureaucracy also. Bureaucrats follow laws and rules without much thinking if these make sense or not. Followers willingly let their leaders do the thinking for them. Employees habitually avoid negative thinking and look on the bright side. People adapt to norms and expectations of others. They often jump on new fashions and fall for seductively formulated solutions. In each of these cases, people are thinking – but only in the most narrow and circumscribed ways. People are often competent, intelligent and clever within these established limits (Alvesson, 2018).

Results of the Research

We can distinguish two results of our research, which answer the basic initial questions. The first result are characteristic forms kitsch in management. The second result are carriers and propagators of organisational kitsch. Finally, the management kitsch definition is established.

Discussion and Interpretation of Results

This part is divided on three groups: 1) description of characteristic forms of kitsch in management; 2) description of carriers and propagators of organisational kitsch; and 3) definition of management kitsch.

Characteristic Forms of Kitsch in Management

There are characteristic forms of kitsch in management such as: 1) one best way claim; 2) simplification; 3) grandiosity; 4) organisational cynicism; 5) functional stupidity; 6) bullshit jobs; 7) seeming management.

Management belongs to social disciplines because the object of analysis are organizations created by people who, knowing the results of the research, adjust their behaviour reflectively; it means that the research subject itself is constantly changing. The ability to influence the directions of these changes is a powerful ideological tool that allows to manipulate the society. That is why there is a subtle and hidden pressure to conduct some research directions and limit others. In management, there are less frequent threads of rationalization of ownership and management, instrumental treatment of human resources, manipulative aspects of marketing, total organization or symbolic violence (Bourdieu, 1985: 93-94; Sułkowski, 2003). On the other hand, research areas and publications legitimizing the existing social order are exposed and financed. We can observe two trends that significantly limit the possibilities of communication consensus. On the one hand, we are dealing with an increase in the capacity and ambiguity of basic concepts, and on the other, with a growing terminology specialization in management sub-disciplines. Many basic management terms are ambiguous and resemble a "family of words". This is the case with organization, enterprise as well as management, structure, strategy or organizational culture. At the same time, management has its own specialized terminology within each sub-discipline. The language of reflection is increasingly condensed and less transparent, and thus the discourse is encapsulated. An additional language problem is the abundant use of terms from other disciplines and from life, which is a jumble of difficult rhetoric and phraseology. Fractal, learning, intelligent, vibrating, virtual and organic organizations are useful metaphors that are, however, difficult to define. Management, hiding behind the smoky curtain of jargon, is becoming more and more hermetic and instead of demanding openness of communication, we are dealing with the closure of small circles of specialists within our own sub-disciplines (Andreski, 2002: 66). On the other hand, we have "management shamans" who, rejecting the theoretical achievements of the discipline, use simple and colloquial language categories, which allows them to attract crowds of followers; they found their place and publicity with simple diagnosis for all organisational problems perfectly.

The problem arising in connection with the increase in the importance and popularity of management is confrontation with the values of post-industrial society. The area of management is increasingly dominated by the rules of the "mass intellectual goods" market. The demand for "recipes for market success" has been created. Management gurus, consulting companies and managers promote management ideas and works aimed at achieving the highest possible sales rate. Therefore, commercial criteria are beginning to prevail over cognitive values. This doesn't mean that outstanding managers or advisers don't create management achievements, but only that it loses its scientific character by becoming an area of mass culture (scientific truth gives way to superficial "prettiness"). When analysing the problem of the management idea commercialization, it's worth paying attention to the popularization issue. Dissemination of science is a process of bringing complex theories and discoveries to researchers so that they become accessible to society (Kozłowski, 2003: 18). In management, the sphere of creation and popularization of science are completely mixed. The mass goods market has created conditions in which the "production" of overly simplified ideas is a substitute for real discourse. And yet scientific cognition isn't egalitarian, so by definition the results of scientific work are of an academic/specialist nature, and only later should they be simplified and popularized. Meanwhile, in managing the standard is the creation of science as "mass theoretical products", which

are the intellectual equivalent of fast food, which by their simplicity and obviousness are to appeal to all interested parties (researchers, students, managers). It is no wonder that the problem of producing scientific banality corrupts the reputation of management. Critics point out the terminology based on colloquial terms and the lack of in-depth research, which creates room for "management shamans" (Micklethwait and Wooldridge, 2000a: 19-20). This leads to the sad conclusion for the academic community that management is at the stage of epistemological development comparable to tribal medicine, while at the stage of social development it is approaching show business. Management serves as an example of science, which too strong connection with the market and commercial categories can lead to cognitive pathologies (Amsterdamski, 1994). Simplification, as a way of social standardisation can be seen in many types of fiction organisations: communist organisations of youth, totalitarian organisations or artificial West-capitalist organisations always happy and ready to action while singing their company's hymn (Kostera, 1997).

Grandiosity refers to delusions of grandeur, characteristic of individuals with severe disturbances regarding their own qualities and significance. It can be observed in obsessions of dictators and other leaders constructing monuments to commemorate themselves or to leave a lasting legacy. Grandiosity is linked the narcissism of our times and a generalized craving to enhance self-esteem. The appeal of grandiosity and the social pressures to enact it create significant obstacles for management learning. Topics and methods signalling something glamorous and narcissistically satisfying attain great currency, uncritically seducing students into naïve acceptance of superficial and dubious knowledge (Alvesson and Gabriel, 2015). The ethos of grandiosity is one of the factors that has led to a fundamental re-evaluation of the functions and nature of management in today's organizations. Instead of a preoccupation with efficient production and rational administration, management is seen as increasingly seeking to bewitch the consumer with the magical, the fantastic and the alluring (Ritzer, 1999). Narcissistic individuals seeking to enhance their self-image easily embrace an employing organization's glamorous image and allure as a means of supporting and nurturing their self-identities. Today's organizations, imbued as they are with an ethos of grandiosity, are very liable to be led by narcissistic leaders. They can easily inspire their followers with their visions and can turn around moribund organizations and groups. The ethos of grandiosity brings organizations much closer to their consumers (Gabriel, 2005). Far from being outsiders to the world of organizations, consumers are being drawn into each organization's corporate fantasy, invited not only to purchase goods and services but a wide range of glamorized images, signs and symbols (Alvesson and Gabriel, 2015). The inflation of grandiosity labels is common: groups have become teams, groups with senior managers become "executive teams" or "top teams"; rationalization is "business process engineering" and management training takes the form of "executive development programmes". A whole new vocabulary of buzzwords and euphemisms has emerged, fuelled by the activities of management gurus and disseminated through MBA programmes, where simple tasks are elevated to heroic status and mundane calculations are turned into glamorous undertakings (Collins, 2000; Jackson, 2001). Grandiosity involves representing or loading phenomena in a way that makes them appear to be as attractive and extraordinary as possible, without being perceived as obviously fake. Issues of substance are marginalised.

Stupidity is often associated with low intelligence, but in a social context there is no clear link between people's IQ and their actual thinking and action. Clever people may do stupid things: in private life and at work, where social forces may be in operation. Functional stupidity involves narrow thinking, where established frameworks are accepted uncritically. Most workplaces seek to encourage and cultivate critical thinking, reflection and 'out of the box' ideas, yet they often remain better at doing the opposite. Managers and subordinates follow organisational and professional templates and cultures without paying much attention to assumptions and beliefs. In the kitsch context, the main aspects of functional stupidity are: 1) an absence of reflexivity: stop asking questions about the assumptions; rules/routines/norms are seen as completely natural; 2) not seeking cause or a good reason: stop asking 'why'; a rule is a rule and it must be followed, even if no one is clear why it exists; 3) lack of substantive reasoning: stop asking about the wider consequences of actions (Alvesson, 2018).

The Cynics – back to fourth century Greece – very openly questioned the existence of government and religious institutions. Cynicism was revived as a school of thought and propagated the idea of mockery of convention and tradition and prevailing beliefs and modes of behaviour. Organizational cynicism emerged as the new paradigm of employer-employee relations. A significant percentage of employees

are highly cynical about their organizations. Organizational cynicism arises when employees lack confidence in their organization and feel that the organization cannot be trusted. Definitions of organizational cynicism are associated with emotions such as disillusionment and anger. Organizational cynicism is divided into five distinct structures: 1) personal cynicism, 2) societal cynicism, 3) cynicism towards change, 4) work cynicism, 5) employee cynicism. Organizational cynicism comprises of three distinct dimensions: 1) cognitive cynicism, 2) affective cynicism, 3) behavioural cynicism (Durrah and al, 2019).

Bullshit job is a task (workplace, profession) whose disappearance wouldn't cause any noticeable change in the environment and would be accepted with indifference of the employee. There are five types of bullshit jobs: 1) making someone (client, boss) feel important: assistants, porters, elevator operators; 2) absolute solicitation of the interests of their principals: lobbyists, corporate lawyers, telemarketers, PR/marketing specialists; 3) solving problems that could be avoided with better organization: programmers with difficulty improving prematurely sold software, people accepting complaints; 4) generating documents, procedures and rituals instead of the real, needed action: performance managers, creators of magazines distributed among the company's employees, authors of intranet blogs; 5) managing people who do not need management or setting additional responsibilities that don't make sense but take time: medium level managers, leadership specialists (Graeber, 2019).

When a manager has no goals/plans for the future of the organisation, and the organisation is running with its own speed and direction, we can speak about the seeming management. Kitsch manager tries to keep his top position artificially, on the surface only. Seeming management connected with narcissistic personality of the manager can be very dangerous situation for the organisation, creating delusion situations (Sismondo, 2018).

Carriers and Propagators of Organisational Kitsch

Based on the phenomena presented in the review of the literature, we can distinguish three types of management process participants, which can be called as carriers and propagators of organisational kitsch or just as management kitschists: 1. management gurus; 2. narcissistic managers, 3. mendacious CEOs and owners. Guru is a concept derived from Sanskrit and signifies "a spiritual master who gives advices" (Cambridge Dictionary, 2019a), but in science the emphasis should be placed not on trusting the guru but on critical cognitive reflection. Guru is a role that means a distortion of both cognitive and practical management trends (Pinnington, 2001). One can ask the question, where did the role of the guru come from, which unfortunately is becoming more and more widespread in "home-grown" management. The reasons are varied and are rooted in both the subject of the discipline and its social environment (Andreski, 2002). Management, as a discipline, is extremely susceptible to the occurrence of the guru phenomenon for several reasons: 1) it concerns – in the vast majority – organizations focused on financial profit, so guru's "prescriptions" are an easy investment with a potentially high rate of return in a short time; if ready and simple solutions are applied, the profits will begin to flow in a wide stream; 2) concerns a phenomenon occurring commonly: everyone manages something and struggles with problems in the managed area, so simple solutions come with great interest; 3) verifying the guru's theses isn't easy: it is enough for the guru to have above-average wealth, which justifies his role and theories he proposes; in this case, scientific justifications aren't required. The guru role in the comparison to social roles of scholars in management is shown in

Table 2.

Table 2: Social roles of scholars in management

Social Role	Researcher	Teacher	Practice	Guru
Subject of Study	organization as an object of scientific cognition (finding out the truth)	organization as a place of social knowledge transmission	organization as a subject to change	organization as an object of intuitive cognition and changes
Approach to the Achievements of Discipline	building on management achievements (theorizing)	popularizing management achievements	adaptation of the pragmatic methodology of discipline	declaration of rejection of achievements
Seeking Confidence	pursuit of high probability	striving to pass the canon of probable knowledge	operating in conditions of uncertainty	suggesting certainty
Concentration Cognition vs Action	concentration on cognition	concentration on communication	focus on activities	focus on activities
Professional Ethos	scientist and researcher	academic teacher	consultant	shaman and prophet
Perfect Auditorium	the scientific community	students	employees, managers and clients	followers – businessmen

Source: Authors' own elaboration.

Management guides are popular on the publishing market and in cyberspace, whose authors are "management gurus" focusing more on self-marketing than on the transmission of reliable knowledge. They break with the tradition of real masters of management (Drucker, Kotler, Ansoff), who combined popularization with reliable theory skilfully. On the other hand, however, an advisory sector has emerged between the business sectors and other organizations and business schools, which makes little use of academic output and research, which deepens the gap between management theory and practice. The concepts promoted in consulting are – for marketing purposes – presented in an uncritical way, which in the long run reduces the authority of management sciences. F.eg., a non-reflective approach to reengineering, value management and organizational culture, and unsuccessful attempts to apply these concepts have aroused the distrust of many managers and have distanced them from the research community. Multiplying management guru concepts that pretend to be a philosopher's stone for managers are usually not of a scientific nature. They are characterized by tautological construction, excessive simplification of complexity, inability to verify, in which they resemble concepts of pseudoscience such as astrology (Wilson, 2000). Management gurus often exploit utopian motives by referring to the vision of an ideal organization leading to perfect social order (Reedy, 2002: 175-176); as an example we can use Senge's concept of "learning organization" described as the basis for a "knowledge-oriented society" (Senge, 1993). The management guru focuses on the process of intuitive

cognition that is supposed to cause changes (Peters, 1994). Managerial culture is based on authorities that are socially produced and reflect the structures of power. Some influential management representatives occupy the position of gurus instead of reflective and critical researchers. Gurus are therefore "heroes" and the most important promoters of oppressive culture and managerial ideology. Gurus "producing" the most widespread guides and simple and "practical" management concepts focus on a clear, "contagious" idea combined with effective marketing. Gurus are read because their concepts "seduce", so: 1) they don't require deeper reflection, 2) they are simple in understanding and remembering, 3) they have an element of "shocking" news, 4) they are lectured in a simple, non-academic language. Contrary to appearances, the gurus aren't rebels destroying existing power structures, but on the contrary they support them. They play the role of "cultural industry" in management. They create media interest in management concepts and structures, sanctioning the obvious and natural nature of this order. They bother their minds with peculiar "memes" of contagious concepts, at the same time postponing reflection on fundamental issues for organizations such as power and justice. Gurus try to "program the minds" of managers in accordance with the interests of those in power (Micklethwait and Wooldridge, 2000b: 9). The "cultural industry" of the guru is supported by mass advertising, PR and scientific marketing activities that lead to building the position of "idols" for managers. Gurus are treated in a special way in management, because their publications are of a popular nature and don't meet scientific rigors, and therefore they are relatively rarely criticized by the scientific community. It is also worth noting that because relationships with practice, the consultancy sector are an inherent feature of management understood as a practical scientific discipline, writing for practitioners and managers is a value in itself. Some management gurus from the past (Drucker, Kotler, Ansoff) also popularized research results and created valuable scientific achievements, sometimes constituting the foundations for entire sub-disciplines of management. Concluding this area, we can say, that there is a need of translation of science but in understandable way for untrained readers, otherwise this field will be (still) filled naturally by management kitschists.

The second group of carriers and propagators of organizational kitsch are narcissistic managers who build self-centred and professional-centred constructs in management practice. Putting the truth/merits of processes aside, they focus on the superficiality of actions and creating their own role in the organization. In this case, the organization becomes a means to build and fuel its own myth, not a tool to achieve business goals. The myth of Narcissus is permanently present in the history of mankind, because it opposes the phenomenon of self-worship, which is an immanent feature of human nature. The problem begins when narcissism becomes a significant or dominant personality trait. The need for narcissistic confirmation is not a new phenomenon, nor does it necessarily lead to grandiose delusions, disproportionate emphasis on image and presentation or constant craving for recognition, approval and praise. What is new is the generalized culture of narcissism (Lasch, 1980) which suffuses late-capitalism's where people become obsessed with trying to build a positive self-image, often through consumption of objects, experiences and brands. The effects of narcissistic attitudes on managers can be many: from deteriorating organizational efficiency, through demotivating employees, to creating fiction and artificial reality that can put the organization's vigilance and credibility to sleep.

The third group of carriers and propagators of organizational kitsch consists of mendacious CEOs and owners who – pretending to create and implement a mission in the organization – focus exclusively on revenue and profit maximisation. It can be said that efficiency (profitability) is a natural goal of any organization, but in this case we emphasize the element of false mission building, which is a fraud, giving up the truth (the basic feature of art) in favour of pretending to be external "prettiness" (the basic feature of kitsch). The presence of professional ethics can be here an important factor of distinction (Callahan, 1988).

Definition of Management Kitsch

After analysing the phenomenon of kitsch in aesthetics and based on the concept of an aesthetic situation (Gołaszewska, 1984), which concept is deformed by the kitsch-practitioners stripping off an element of universal values, kitsch in management – according to us – can be defined as "behaviours/manifestations/activities/attitudes in the organization deviating from an universal value of truth (understand as intended action) in favour of appearances and external forms".

Conclusions, Limitations and Perspectives

Kitsch in aesthetics – in relation to art – is clearly perceived negatively; even literally as an evil (Broch, 1969a). Kitsch in management is commonly perceived much less negatively, more mildly because the argument about the basic financial goal of business (profitability) acts as a justification for all (even unethical) methods of operation. BSM – on the flow of CMS – acts against kitsch in management. On the base of this research, it can be concluded that well developed aesthetical theory of kitsch can be used for understanding and developing of the kitsch phenomenon in management. Management kitsch features, kitsch carriers and propagators in organisations need to be clearly defined and possibly reduced for better effects and quality of organizational life.

Limitations of the research are as follows: 1) the matter of art is ephemeral and the matter of management is very real; not all kitsch features in aesthetics are applicable in the field of management; 2) as in the case of aesthetics, one shouldn't moralise over kitsch in management nor validate it; the kitsch phenomenon was, is and will be always; it should be studied and understood to the widest extent possible – assessing kitsch can affect the reliability of tests; 3) positive effects of kitsch in management can be found (e.g. creating myths around newly created businesses to facilitate market access) – although they are not long-term (life verifies all myths) and shouldn't be recommended as intentional methods of action.

Perspectives of the research are as follows: 1) deep studies in aesthetics as a possibility to next comparisons and conclusions in management; 2) development of kitsch in aesthetics as predictions for kitsch in management; 3) constant mix of kitsch and art gives the eternal perspective for the area of management kitsch studies.

Abstract

The article analyzes the impact of digitalization on the relationship between an enterprise and its stakeholders. The analysis of transformations in the economic mechanisms of the enterprise due to digitalization and the conditions for the emergence of new economic entities - digital enterprises. The stakeholders of the enterprise are analyzed and the directions of their influence on the activity and sustainable functioning of the enterprise are shown. The impact of digitalization on the relationship between stakeholder groups and the enterprise is evaluated. An approach to the analysis of the relationship between stakeholder groups and the enterprise is proposed. It is shown that digitalization has a bi-directional effect on the relationship between stakeholder groups and enterprises, while the negative actions of stakeholders in relation to the enterprise can be successfully compensated.

Keywords: Digital Enterprise, Sustainable Development, Stakeholders

Introduction

Today, new digital technologies, innovative business models penetrate into all spheres of the economic life of society and begin to influence the economy and contribute to the formation of qualitative structural changes in it (Plotnikov, 2018). Digital technologies are acquiring a decisive role in the economic development of many countries of the world. A single digital economic space, formed in the global space, contributes to economic growth and labor productivity, creating innovative jobs and digital assets, expanding the opportunities and rights of citizens, improving access to global markets and increasing the competitiveness of micro, small and medium enterprises, improving the quality of public services (Pirogova, Makarevich, Ilina, Ulanov, 2019).

The contribution of the digital sector, namely the production and trade of IT equipment, digital services and services, software and digital products development, and telecommunications to the Russian economy is relatively small in comparison with the economies of developed countries. So, in 2018, the share of the digital sector in the Russian economy amounted to 3% of GDP. At the same time, in most developed countries, the size of the digital sector averages 6–7% of GDP, for example: in France – 5,7%, in Germany – 6,3%, in the UK – 7,1%, in the USA - 7,4%, Sweden – 8,6%. At the same time, in many other indicators related to digitalization, Russia practically does not lag behind developed countries (Aleksandrov, Fedorova, 2019).

In order to develop the digital economy in Russia, a number of measures are being implemented. So, for example, the decree “On the Strategy for the Development of the Information Society in the Russian Federation for 2017-2030” defines a program of measures to develop the economy in Russia for the coming years. In 2017, an order was issued by the Chairman of the Government on the approval of the Digital Economy of the Russian Federation program (Ananyin, Zimin, Gimranov, Lugachev, Skripkin, 2019), in which the main objectives are to create conditions for the development of high-tech industries and increase the competitiveness of national economy sectors and strengthen it on the world market.

The introduction of new digital technologies, of course, has an impact on the development of enterprises, making it possible to make cardinal improvements at all stages of its production cycle (Rappaport, 1986). Digitalization allows to reduce production costs, optimize supply management, which contributes to a faster response to any new consumer needs, including in real time (Stern, Stewart, Chew, 1995). Customers have a feedback system with the manufacturer, consumer properties and the safety of goods and services are significantly improved due to the digital component, the contribution of which to the cost can reach up to half its value (Plotnikov, Pirogova, 2018).

The development of the digital economy leads to the emergence of new phenomena. More and more often in economic practice the term "digital enterprise" or "digital organization" sounds. The term "digital enterprise" was first proposed in 1996 in the book Being Digital by the director of MIT Media Lab Nicholas Negroponte, but it was possible to transfer to the practical implementation of the idea of a digital enterprise quite recently thanks to the development of appropriate technologies (Makovkina, Semeykina, 2016).

Digitalization and The Concept of Digital Enterprise

Various attempts are currently being made to define the term "digital enterprise". So at McKinsey they believe that an enterprise is digital if it is undergoing cultural digital transformations. Accenture claims the digital enterprise offers the opportunity for new operating models and business processes, connected product platforms, analytics, and teamwork to increase productivity. In the works of V. Ananyin (Ananyin, Zimin, Gimranov, Lugachev, Skripkin, 2019) it is proposed to call the "digital organization" the one in which the assets of computer capital are the most volatile complementary asset. In general, the authors adhere to the following definition of "Digital Enterprise" - a company that uses information technology (IT) as a competitive advantage in all areas of its activity: production, business processes, marketing and customer interaction.

According to most researchers, we are currently witnessing the Digital Transformation of traditional enterprises into enterprises with "digital thinking". A product or service created by a digital enterprise also becomes digital. The main features of a digital enterprise (Gurkov, 2011):

- most of the most important processes of relationships with customers, suppliers and employees are digital and supported by digital technologies;
- main business processes or logically interconnected business tasks, are implemented using digital networks;
- key assets (intellectual property, core competencies, financial assets and personnel) are managed digitally;
- business response to environmental changes is accelerated and enhanced through digital communications, which allows you to adjust the work in time and space (business can be conducted outside traditional geographical boundaries).
- not only the conditions but also the fundamental foundations of the enterprise are subject to change
- for a digital enterprise, information becomes one type of resource or raw material.
- digital technologies enhance the depth of penetration and impact of information on all areas of activity and relations of the enterprise.
- digital enterprises are becoming more flexible with expanding reconfiguration capabilities.
- focus on resource conservation: resource conservation, environmental conservation, energy saving, labor saving and capital saving.
- expanding the use of new materials or materials with new properties (including nanomaterials) that have predefined properties necessary for the final product, taking into account adaptation to additive technologies.

The positive and negative aspects of the impact of digitalization on the activities of enterprises are presented in table 1 (Gurkov, Avraamova, 2011).

Table 1: The positive and negative aspects of the impact of digitalization on the activities of enterprises

The positive impact of digitalization on the activities of service enterprises	The negative impact of digitalization on the activities of service enterprises
- decrease in the role of intermediaries, since digitalization enables enterprises in the service sector to independently promote and advertise their services.	- exclusion of government participation in the development of the digital economy
- reduction of costs for searching and processing information, reduction of transaction costs, promotion costs, etc.	- reduction in the share of investments, both in fixed assets and in the development of the hardware base of digitalization in enterprises
- optimization and acceleration of business processes of enterprises	- increased costs due to low investment attractiveness and the introduction of digitalization tools in enterprises
- reduction of time for promotion and implementation of new products and services, market adaptation	- low qualifications of personnel capable of effectively implementing and using digitalization tools
- increasing the flexibility and responsiveness of marketing strategies of enterprises	- inadequate security and the risk of digital fraud

Using digitalization tools, enterprises also change their behavior model, i.e. their organizational structure, mission and goals are changing, and the speed of these changes is so great that the current level of development of the digitalization infrastructure does not keep pace with the changing economy (Gurkov, Avraamova, 2011).

Digital enterprise stakeholders and their classification

Digitalization significantly affects the relationship with the organization's stakeholders. The stakeholder approach, being one of the leading areas of management over the past 30 years, suggests that the company should build relationships with its surrounding parties taking into account their interests, namely, create for them some values that may lie in the material, financial, social and other spheres. Currently, the stakeholder approach has spread not only in the field of pure management, which includes the classic works of I. Ansoff, E. Freeman, but also more modern studies, for example, I. Ivashkovskaya, which proposes the concept of managing the value of the company based on the interests of stakeholders, as well as the work of B. Kleiner and I. Gurkov, where relations with stakeholders are put at the heart of the mechanism for ensuring the sustainability of the enterprise (Ivashkovskaya, 2012, Gurkov, 2011, Freeman, 1984).

In accordance with the classification of J. Harrison and C. John, all stakeholders can be divided into three large groups: a wide environment, an operational environment, and an internal environment (Harrison, John, 1998).

Depending on the level of environment, the influence of the enterprise changes. The enterprise has the least influence on the wide environment, at the same time, this environment sets the context and changes in the conditions of existence and development of the enterprise. The wide circle includes sociocultural forces (society), technological changes (technologies), global economic forces (economics and economic trends), and global political and legal forces (politics) (Pirogova, Plotnikov, 2019).

The enterprise has a more significant influence on stakeholders in the operating environment. They, in turn, also have a significant impact on the enterprise. This includes suppliers, competitors, buyers, financial intermediaries, public authorities and the administration, as well as trade unions, activist groups, and local communities. The classification of stakeholders in accordance with their goals and objectives is presented in table 2 (Ivashkovskaya, 2012).

Table 2: Classification of stakeholders in accordance with their goals and objectives

Stakeholders:	Objectives:	Goals:	Expenses:	Win:
Owner	self-realization	Getting maximum profit, functioning and business development	Time, mental and other efforts, risks	Entrepreneur's rent
Investors	Provide financial flows for the development of projects	Profit from the sale of the final product	Risks, including loan defaults	Income
Customers & Buyers	Grow into a regular customer	Get a quality product at an affordable cost	The price of a product or service	The quality of the product or service
Supplier	Sales	Regular payment of orders	Quality of supply of goods or services	The price of the supply of goods or services
Staff	Performance of professional duties	Decent pay	Working hours, efforts, moral discomfort	Material and moral reward
State	Create the most correct relationship	Timely taxes paid	The cost of balancing the satisfaction of interests of all groups of stakeholders	Benefits of various stakeholders from the activities of the enterprise
Supervisor	Coordinates activities throughout the project life cycle, leads the team	Revenue generation and business operations	Working hours, efforts, moral discomfort	Material remuneration or a share of the company's income

The internal environment of the enterprise is the owners, board of directors, managers and employees. The internal environment has the greatest impact on the functioning and development of the enterprise and vice versa. In addition, various stakeholders can influence other stakeholders in the internal environment.

In the works of I. Gurkov (Gurkov, 2011), the crucial point is that the enterprise interacts with the labor, capital, finance, material resources, goods, as well as information and information solutions markets not directly, but indirectly, through specific entities that are actually stakeholders. Depending on whether these stakeholders have competitors, what is the level of completeness of information that is used when interacting with a particular stakeholder, the level of dependence of the enterprise on the stakeholder: all this determines the strength of its influence, as well as the value that the enterprise generates in the process its activities in the interests of a stakeholder.

In accordance with the approach of I. Gurkov (Gurkov, 2011), he classifies all stakeholders into 4 categories: key players, sleeping monsters, hostages, random companions. Key players or key stakeholders are stakeholders whose relationships are built on the basis of minimizing the level of acceptable solutions for the enterprise. The enterprise, on the contrary, holds hostages in a black body and can impose decisions on them at the lower limit of acceptability. For casual companions, the company does not try.

Transforming Digital Enterprise Stakeholder Relations

Currently, in the era of the development of digitalization, relations between stakeholders of a digital enterprise are undergoing a profound transformation (Greiner, 1972). This transformation is associated with the following factors:

1. Increasing the speed of transmission and dissemination of information, as well as reducing barriers to the distribution of confidential information, increasing information openness (what previously could be hidden or concealed, now it becomes almost impossible to hide).
2. The appearance of information or digital doubles, which are digital copies of processes, phenomena of objects, including enterprises. In fact, you can learn a lot about the enterprise from information networks.
3. The introduction of digital standards for transaction processing and technological processes in all areas of the enterprise, crowding out a person (employee) from the field of routine, simple, often repeated operations by information robotic systems.
4. A multiple increase in the amount of information collected, processed and stored about interactions with stakeholders (the transition to the so-called multidimensional big data), which reduces the risk of operational decisions.

The factors listed above can significantly affect the relationship of a digital enterprise with stakeholders and, as a result, require a change in the way they work with them.

In some cases, digitalization can lead to a change in the type of markets. For example, a buyer's market may turn into a seller's. And then the enterprise will lose the ability to impose a pricing policy on suppliers. The opposite is the case - the seller's market can turn into the buyer's market, where he determines the level of prices for products depending on their quality, functionality and level of support.

To analyze the sustainable development of an enterprise, it is necessary to determine what aspects of its functioning and existence can be affected by digitalization in relations with stakeholders. In our opinion, the following aspects can be distinguished:

1. Raising the awareness of stakeholders and strengthening the so-called "negotiating power", as a result of which the boundaries of acceptability of current decisions are shifted and, as a result, the potential profit for the enterprise is reduced.
2. Reducing the lifetime of the competitive advantage, which allows the company to extract additional rents. As a result, a decrease in the time for obtaining additional income and a reduction in the period of high growth rates of the enterprise value, and a decrease in investment efficiency.
3. Transformation (changing the requirements for a set of key competencies of stakeholders). First of all, it is necessary to note the employees and managers of the digital enterprise, who, competing with informational robotic systems, are forced to demonstrate new competencies, namely the ability to create innovations.

Digitalization Crises and Ways to Overcome Them

Directions for overcoming the indicated features of the functioning of digital enterprises and their interaction with stakeholders should be based on the understanding that, in principle, there are no insurmountable contradictions between the interests of stakeholders. If they existed, then in the end the enterprise would become unstable and collapse, which contradicts, first of all, the observed trends in the economic situation.

The next important aspect of crisis management is the understanding that digitalization is an expansion of opportunities not only for stakeholders, but also for the enterprise itself (Ivashkovskaya, 2009).
Let us consider in more detail, using the example of several stakeholders, how the interaction between them and the enterprise is changing in the context of digitalization.

Workers want to maximize their remuneration while minimizing effort. As a result, this leads to an increase in unit costs on the one hand, and a minimization of competencies, while minimizing efforts. On the other hand, digitalization, which allows automating some routine processes of personnel activities, leads on the one hand to increase competencies (the employee must solve tasks of a higher level), and on the other hand, allows to save money by reducing the excessive number of lower-level

staff and increasing higher salaries qualifications. Thus, digitalization compensates and even blocks the negative trends in the influence of the interests of workers on the activities of the enterprise.

Consumers are forcing the company to improve quality and reduce price. Improving the quality is due to the growth of the competencies of the enterprise, which leads to an increase in unit costs, and subsequently, to a loss of profitability of financial stability. Digitalization, accelerating the exchange of information, expands the consumer's ability to find the perfect combination of price and quality of the required product, on the other hand, it also allows the company to more flexibly and accurately meet consumer needs through the use of an individual approach, a system of discounts, personal offers, as well as optimizing its assortment based on the conditions of maximizing income for a given volume of sales or other gross indicators.

A similar analysis can be performed for all pairs of group of stakeholders - the enterprise. Based on this, strategic matrices can be built that allow one to evaluate where the enterprise will be moved in the coordinates of "price - quality" and "unit costs - competencies".

Conclusion

An analysis of the interaction of the enterprise with stakeholders in terms of digitalization showed that the introduction of digitalization in most cases can successfully compensate for the benefits of stakeholders. The winnings in the current situation are received by enterprises that earlier manage to transform into digital ones, which will allow them to compensate for the negative interests of stakeholders much faster, as well as offset the costs of introducing digital solutions into operational and strategic activities.

Abstract

This paper is aiming to analyze the influence of media exposure, environmental performance, type of industry, company size, profitability, and leverage on carbon emission disclosure. The dependent variable in this research is carbon emission disclosure that was measured by scoring a checklist of carbon emission disclosure. The independent variables are media exposure, environmental performance, type of industry, company size, profitability, and leverage. This research used secondary data with the population of all non-financial sector public companies that joined PROPER from 2014 – 2017. The 21 samples of companies were selected by using purposive sampling technique. This research used multiple linear regression using Eviews 10. The results proved that media exposure, type of industry, and profitability have positive and significant influence on carbon emission disclosure, whereas environmental performance, company size, and leverage have no influence on carbon emission disclosure. This research contributes to the development of green accounting in Indonesia and expects that related parties can develop a better evaluation and planning in increasing carbon emission disclosure of companies in Indonesia.

Keywords: Carbon Emission Disclosure, Media Exposure, Environmental Performance, Type of Industry, Company Size, Profitability, Leverage.

Introduction

The global warming caused by greenhouse gas emissions (GHG) has been a politics and business issue which has become more important in many countries (Bae, Lee, & Psaron, 2013) facing a lot of challenges resulting from this matter. One of the countries is Indonesia. According to *World Resources Institute* (2016), Indonesia was the sixth largest emitter of carbon emissions which released up to 1.98 million tonnes of CO_2 emissions every year based on its 2016 report. In 2017, Indonesia contributed 5,3% to the total global GHG in which Indonesia's GHG per capita reached 10,5 tCO_2e/cap compared with the average of G20 countries with 8,3 tCO_2e/cap (Climate Transparency, 2017).

Indonesia had ratified the Kyoto Protocol on December 3rd, 2004 by the enactment of Law No. 17 Year 2004 to participate in the efforts to reduce global GHG emissions. As a follow-up action, the president issued Presidential Decree No. 61 Year 2011 which stated Indonesia's National Action Plan for Reducing GHG (RAN-GRK). In 2015, Indonesian government submitted its post-2020 climate pledge

known as Nationally Determined Contributions (NDCs) to the United Nations. In its NDCs, Indonesian government promised to reduce the GHG emissions by 29% up to 41% in 2030. This pledge has been implemented in the national development plan 2015-2019 by determining several climate mitigation and adaptation targets, such as moratorium for new forest concessions and peatlands, peatland restoration, renewable energy mix targets, social forestry, and degraded forest land rehabilitation (Chrysolite, Juliane, Chitra, & Ge, 2017).

In the Indonesian National Action Plan for Reducing GHG (RAN-GRK), it was revealed that the industry sectors were the largest GHG emitters. The industry sectors or businesses undeniably had the biggest potential to increase the economy growth and became the development priorities in various provinces in Indonesia; however, the activities of the industries had the potential to release GHG emissions and contributed to global warming and climate change (Utama, 2014). Therefore, the related companies must support the measures to reduce GHG emissions and cope with the global warning effects as their corporate social responsibility efforts known as *carbon emission disclosure*.

The main objective of applying carbon emission disclosure is to reduce carbon emission produced by the industries as a part of the agreement within the Kyoto Protocol. Through the disclosure, each company can measure the amount of carbon emissions it produces, create a strategy to reduce it, record the results, and report them to the company's stakeholders (Dwijayanti, 2011). Carbon emission disclosure is a type of climate change disclosure covering the GHG emissions intensity and energy use, corporate governance, and strategy in relation to dealing with climate change (Cotter & Najah 2012). Carbon emission disclosure is also a form of contribution from the related parties to environmental changes, particularly global warming (Akhiroh & Kiswanto, 2016).

To measure the implementation of carbon emission disclosure, a non-profit organization based in England, called CDP, has issued a Carbon Disclosure Project (CDP) in the forms of information request sheets or questionnaires which have been submitted to the companies which need to be measured. CDP has functioned as the spearhead for the implementation of global disclosure system which has been useful for investors, corporations, cities, states, and regions to control their environmental effects. The CDP questionnaires was adopted and developed into a carbon emission disclosure checklist with 18 indicators by Bae et al. (2013) who used them to measure carbon emission disclosure in Australian companies.

In Indonesia, the carbon emission disclosure is still a voluntary act. A voluntary disclosure is a provision of information voluntarily by a company beyond the mandatory requirements which exceeds the minimum requirements of the existing stock exchange regulations (Nuswandari, 2009). Thus, companies have considerable discretion as to the amount of information they want to disclose. This creates variations of carbon emission disclosure stated in the companies' annual reports, and the carbon emission disclosure has been rarely implemented by companies involved in economic activities. The voluntary disclosure will urge the companies to consider the costs and benefits of the disclosure. For companies emitting GHG, the carbon emission disclosure can be advantageous to obtain legitimacy from the stakeholders and to avoid serious repercussions such as increased operating costs, reduced demands, reputational risk, legal proceedings, fines, and penalties (Berthelot & Robert, 2011).

In the discussion on carbon emission disclosure, there are some factors which can influence the extent of the disclosure. Several previous studies revealed the determinants of the carbon emission disclosure, including carbon emission levels, the size of the firms, the type of industry, profitability, growth opportunities, legal systems, environmental performance, financial market pressure, economic pressure, and other factors (Bae et al., 2103; Luo, Tang, & Lan, 2013; Jannah & Muid, 2014; Kalu, Buang, & Aliagha, 2016). Factors such as media exposure, environmental performance, and the company's characteristics measured by its type of industry, its size, and its profitability are still interesting to be studied as an attempt to reconcile the conflicting results found among the researchers in the area.

Media exposure is one of the factors that can influence the coverage size of carbon emission disclosure. The rapid advancement in information and technology has encouraged media to be a crucial part in carbon emission disclosure. This media exposure compels the companies to publish its activities related

to the protection of the environment to obtain positive responses from their stakeholders (Jannah & Muid, 2014). Companies which have more online media coverage from external parties tend to disclose their GHG emissions voluntarily because those companies have become more motivated in making a social and environmental disclosure (Majid & Ghozali, 2015). On the other hand, some researchers are of the opinion that the media presence does not always give the motivation for the companies to perform carbon emission disclosure in their annual reports (Pratiwi & Sari, 2016). In this case, companies have lacked explorations on the media visibility which is directly associated with the level of carbon emission disclosure due to the excessive anxiety or fear about the environmental control or retribution they will face if the information was disclosed openly in media, especially for the companies which cannot control the environment optimally (Cahya, 2017).

Within the environmental management issue, the environmental performance becomes the determinant of the carbon emission disclosure. The environmental performance of a company is the result of environmental management as an attempt to push the company to manage the environment. The Indonesian Ministry of Environment and Forestry has put some efforts to promote the management of the environment through the Program for Pollution Control, Evaluation, and Rating (PROPER) which has been in effect since 1994. The objective of this environmental performance rating (PROPER) is to encourage the company to comply with the laws and regulations by means of giving reputation incentives and disincentives and by compelling the practice of cleaner production. It is expected that the increase in the companies' environmental performances can encourage the disclosure of environmental issues such as the carbon emission disclosure.

Most of the publicly listed companies in Indonesia which have high environmental performance tend to encourage the companies to disclose the GHG emissions so that the public can give full supports (Prafitri & Zulaikha, 2016). However, companies with high PROPER ratings have indirectly represented the companies' commitment to cope with the climate change, and this has lowered the companies' motivation to disclose their carbon emissions voluntarily (Jannah & Muid, 2014). Conversely, companies with low PROPER ratings incline to make efforts to obtain the public trust through their voluntary GHG emission disclosure (Majid & Ghozali, 2015).

In the implementation of the companies' carbon emission disclosure, the characteristics of the companies' can encourage the extent of the coverage and the companies' motivation level in implementing the carbon emission disclosure. The characteristics of the companies can be measured from the type of industry, the company size, their profitability, and leverage. The type of industry can be grouped into high profile industry and low profile industry which can be differentiated from the intensity of their operational activities which can affect the environment. The high profile industry type is more intensive in producing emissions which bring negative effects on the environment, whereas the low profile industry includes companies which are not intensive in producing emissions (Bae et al., 2013). The high profile companies whose operational activities can bring negative effects on the environment have the tendency to disclose more corporate social responsibility (CSR) information than the low profile companies (Wang, Song, & Yao, 2013).

Bae et al. (2013) conducted a research on 100 Australian largest companies showed that the type of industry which is more intensive in producing emission will disclose carbon emissions more extensively. Companies in energy sector, transportation, materials and utilities which are more intensive in producing carbon emissions tend to disclose information related to environmental aspects compared with companies which do not produce carbon emissions intensively like the companies in financial sector (Jannah & Muid, 2014). In contrast to the statement above, Cahya (2017) is of the opinion that companies producing carbon emission intensively do not fully disclose their carbon emissions because the disclosure is still voluntary and this makes the companies incline to disclose their corporate social responsibility from other perspectives.

Subsequently, one of the characteristics of companies is their size. Large companies will actively involve in voluntary carbon emission disclosure because they have a lot of resources to prepare comprehensive disclosure (Bae et al., 2013). On the contrary, small companies tend to avoid this voluntary carbon emission disclosure because the quality of their human resources is not sufficient for

implementing the disclosure, not to mention their lack of other resources (Majid & Ghozali, 2015). Larger companies are more transparent in disclosing the carbon emissions information, so that they can maintain their environmental legitimacy (Gonzáles-Gonzáles & Zamora-Ramírez, 2016). Kalu et al. (2016) conducted a research on Malaysian listed companies, and the results showed that the more awareness and education the public has on carbon emissions, the higher the public consideration will be on the corporates' contribution towards the carbon emission threats. Consequently, the public will give more social pressure on companies which motivates them to increase their participation in carbon mitigation through voluntary carbon emission disclosure. Contrary to the previous statement, the results of Cahya's research (2017) on Indonesian *sharia* companies showed that the company size does not influence the extent of *sharia* social responsibility to disclose carbon emissions because large *sharia* companies still have not taken into considerations the positive effects of disclosing information for their companies, particularly the carbon emission disclosure.

In developing countries, financial resources play more significant roles in making decisions related to the companies' carbon emission disclosure (Luo et al., 2013). A company's profitability level is its financial resource which can indicate the company's performance to take some measures to reduce emissions and disclose the measures in its annual report. Companies with high profitability show that they can react well to the environmental pressure effectively, and they are willing to solve problems promptly (Jannah & Muid, 2014). Conversely, profitability does not correspond with the carbon emission disclosure which is caused by irrelevant benefits and disclosure costs. When a company discloses its carbon emissions, but the disclosure creates problems for the stakeholders in understanding it, the disclosure gives little contributions to the company (Irwhantoko & Basuki, 2016). Companies with high profitability do not need to extend the scope of the disclosure related to their environment because they are afraid that the disclosure can disrupt the information about the company's financial achievement (Prafitri & Zulaikha, 2016).

Leverage is another characteristic of a company. A higher leverage level in a company can increase the creditors influence in exerting pressure on the company. The higher the leverage level in a company is, the greater the creditors' expectation will be on the company's performance (Roberts, 1992). This shows that the credibility of GHG emissions has a directly proportional relationship with the company's leverage level (Rankin, Windsor, & Wahyuni, 2011). On the other hand, a higher liability level of a company than the company's debt and expenses can place restrictions on its carbon emission disclosure. A high leverage level reduces the tendency for the company to conduct social and environmental disclosure (Jannah & Muid, 2014). A company with high leverage level will be very careful in reducing and disclosing expenses related to carbon emission prevention action (Luo et al., 2013). The higher the leverage level is, the more obvious it will be that the companies tend to settle their liabilities rather than making disclosures which can result in an increase in the company's expenses (Majid & Ghozali, 2015).

Based on the reviews of previous research, it is found that there are some conflicting results from the previous studies. These different results motivate this present study which attempts to examine the relations between media exposure, environmental performance, and the characteristics of a company (e.g. the type of industry, the company size, profitability, and leverage) and carbon emission disclosure to obtain empirical evidence for this study.

Through development and testing of models, this present study can yield certain contributions. First, this study provides new empirical evidence for the relations between variables such as media exposure, environmental performance, and the characteristics of the company (e.g. the type of industry, the company size, profitability, and leverage) and carbon emission disclosure. Second, this present study can contribute to the development of green accounting, particularly its application in Indonesia. Third, this present study can enrich the existing empirical research on carbon emission disclosure which is still rare in Indonesia.

Literature Review

The Influence of Media Exposure on Carbon Emission Disclosure

Based on the legitimacy theory, media has a role in increasing pressures which come from public demand on the companies. Media exposure has a major role in the efforts to encourage companies to publish their activities, especially those related with environmental aspects. When the media publish the information related to the companies' activities which involve the environment, the information will become one of the considerations taken by the public in making pressure to the companies to legitimize their activities by disclosing their carbon emissions.

Based on the stakeholder theory, media plays a role in compelling the companies to fulfill various social contracts with various stakeholders of the companies. Media exposure on the companies' carbon emission policies encourages the companies to make necessary measures related to the environment. These measures to preserve the environment can help the companies obtain supports from various parties.

The high intensity of media attention on a company can increase the company's motivation to disclose information. The more intense the media attention on the company's environmental policy is, the more extensive the carbon emission disclosure will be. This is in line with the results of research by Jannah & Muid (2014) and Kusumah, Manurung, Oktari, & Husnatarina (2016) showing that media exposure has positive influence on the carbon emission disclosure. Thus, it can be assumed that media exposure can affect the carbon emission disclosure positively.

The influence of Environmental Performance on Carbon Emission Disclosure

The legitimacy theory asserts that to obtain public legitimacy, the companies must conduct environmental preservation which can create harmony between the environment and the company. The companies' efforts to bring this harmony are the results of their environmental preservation measures which can be reflected on their environmental performances. With a good environmental performance, a company can disclose more extensive carbon emission information as its attempt to create harmony between the environment and the company.

A company with high level of environmental performance can disclose the information on its carbon emissions to obtain legitimacy from the public in the surrounding areas. Thus, companies use carbon emission disclosure as one of the means to obtain public legitimacy. In this case, the better the environmental performance of a company is, the better the company's carbon emission disclosure will be. This is in line with the results of a research by Prafitri & Zulaikha (2016) and Dawkins & Fraas (2011). Prafitri & Zulaikha (2016) did a research on 298 listed companies in Indonesia and revealed that higher environmental performances can motivate the companies to disclose their GHG emissions including carbon emission disclosure. Similarly, Dawkins & Fraas (2011) who studied companies within S&P 500 also showed that environmental performances influence climate change disclosure positively. Accordingly, it can be assumed that environmental performances have positive influence on carbon emission disclosure.

The Influence of Type of Industry on Carbon Emission Disclosure

Corresponding to the legitimacy theory, companies operating in industries which intensively produce carbon emissions can receive greater demands from the public. The public demand that the companies make adjustments to their environmental management as the companies' activities which can potentially affect the environment becomes higher. With this demand, the companies can take some measures to restore the environment by decreasing their carbon emissions and publishing their carbon emission disclosure.

Business activities of a company involve various stakeholders. Each stakeholder will consider whether or not a support will be given to those business activities. Naturally, a company's business activities influence the provision of the stakeholders' interests. Each activity must yield value added to the stakeholders. When a company conducts business activities which have impacts on the decrease in the environment quality, the stakeholders can consider the measures taken by the company to restore the quality of the environment. Hence, companies which are active in producing carbon emissions will publish their carbon emissions disclosure more extensively to obtain the supports from the stakeholders who become more active in assessing the company.

The more intensive a company's contribution towards the increase of carbon emissions is, the more extensive its carbon emission disclosure will be. This is similar with the results of research by Bae et al. (2013), Jannah & Muid (2014), and Pratiwi & Sari (2016). Bae et al. (2013) which showed that the type of industry which produces carbon emissions intensively will disclose their carbon emissions extensively. Similarly, Jannah & Muid (2014) showed that the type of industry has positive influence on carbon emission disclosure, and they are significant for carbon emission disclosure. A similar result was also found by Pratiwi & Sari (2016) who studied non-industrial companies which are listed in Indonesian Stock Exchange. Therefore, it can be assumed that there is a positive correlation between the type of industry and carbon emission disclosure.

The Influence of Companies' Size on Carbon Emission Disclosure

The legitimacy theory and the stakeholder theory show that companies which have great resources can receive public attention and high demands for each of their business activities which are conducted to fulfil the interests of the stakeholders involved in those companies. Subsequently, companies with great resources are demanded to do extra measures to restore the environment.

The company size can influence its ability to report its carbon emission disclosure with its resources. It is in line with the fact that the size of the company's resources can affect its ability to conduct activities to mitigate carbon emissions. With great resources, a company can be more unimpeded in disclosing the mitigation activities. Studies done by Bae et al. (2013), Jannah & Muid (2014), Majid & Ghozali (2015), Gonzáles-Gonzáles & Zamora-Ramírez (2016), Kalu et al. (2016), and Hermawan, Aisyah, Gunardi, & Putri (2018) showed that the company size has positive effects on carbon emission disclosure. Thus, it can be assumed that the company size affects its carbon emission disclosure positively.

The Influence of Profitability on Carbon Emission Disclosure

Profitability reflects the ability of a company to fulfil the interests of its stakeholders from the financial aspect. A high level of profitability indicates that a company is able to give value added to its shareholders and creditors. Based on the legitimacy theory and stakeholder theory, a company must be able to satisfy the public demands related to the environment and to other social contracts. With a high profitability, a company is demanded to be capable of implementing the necessary measures to reduce the carbon emissions, in addition to increasing the wealth of the shareholders and fulfilling various social contracts with the stakeholders. Profitability can boost the company's ability in increasing its carbon emission disclosure.

Studies on the relation between profitability and carbon emission disclosure have been conducted by, among others, Bae et al. (2013), Luo et al. (2013), Gonzáles-Gonzáles & Zamora-Ramírez (2016), all of which show that profitability has positive and significant influence on carbon emission disclosure. The better the company performance in making a profit is, the better the company's contribution in reducing the carbon emissions will be, including in making carbon emission disclosure. Accordingly, it can be assumed that profitability affects carbon emission disclosure positively.

The Influence of Leverage on Carbon Emission Disclosure

Based on the stakeholder theory, the management will increase value creation to minimize losses suffered by the stakeholders. In this case, the stakeholders who become the center of attention from the management are the ones who provide debt financing to the company. To minimize the losses suffered by these stakeholders, the company will put more efforts into reducing any disclosure which can worsen the company's image. If the company's image becomes worse in the public eye, the company will weigh the disclosures which are considered as ineffective in increasing the company's image. Moreover, a high leverage level reduces the company's ability to publish its non-financial disclosure.

A high leverage level can motivate the company to limit the level of carbon emission disclosure to the public. A company with high leverage will prioritize the policy related to the fulfilment of the company's liabilities rather than its efforts to reduce its carbon emissions. This puts a restriction on the company's carbon emission disclosure. The results of studies by Jannah & Muid (2014), Luo et al. (2013), and Majid & Ghozali (2015) share the same opinion that the leverage level has a negative effect on carbon emission disclosure. Therefore, it can be assumed that leverage affects the carbon emission disclosure negatively.

Methodology

In this present study, the research objects focused on the level of carbon emission disclosure published in the annual reports or sustainability reports of listed companies in non-financial sectors which had joined PROPER over a four-year period from 2014 to 2017. These companies became the objects of research because the non-financial sector is closely related to the environmental issues, and the companies in this sector contribute to the increase in carbon emissions. The scope of this present study is constrained by variables influencing carbon emission disclosure, namely media exposure, environmental performance, type of industry, company size, profitability, and leverage.

This present study is a quantitative research using multiple linear regression to analyze secondary data. To assess carbon emission disclosure, the secondary data were obtained from the companies' annual reports uploaded to official website of Jakarta Stock Exchange (JSX) and other additional reports taken from the official websites of the companies.

All the listed companies in non-financial sector which had joined PROPER during 2014 – 2017 became the research population of this present study. The samples were taken by using purposive sampling technique in which the samples were taken based on certain considerations or certain criteria. The criteria used in taking the samples were as follows: 1) A listed company in non-financial sector which had joined PROPER from 2014 – 2017; 2) A listed company in non-financial sector which had published its financial reports and annual reports consecutively from 2014 – 2017; 3) A listed company in non-financial sector which has disclosed its carbon emissions implicitly and explicitly (covering at least one policy or one disclosure item which was related to carbon emissions or greenhouse gas emissions) in various published documents, such as annual reports, sustainability reports, and financial reports from 2014 – 2017; 4) A listed company in non-financial sector which had made positive profits from 2014 – 2017.

The Dependent Variables ini this research is Carbon emission disclosure, used the checklist scoring to operationalizing it. The scoring which is developed by Bae et al. (2013) based on the information request sheets distributed by CDP (Carbon Disclosure Project). The calculation of carbon emission disclosure index in this present study was conducted by following these steps (Jannah & Muid, 2014): 1) Give a score to each disclosure item by using a dichotomous scale; 2) Each disclosure item in a report was worth 1 point and vice versa; 3) the total score for each disclosure item (carbon emission disclosure by a company) was calculated using this formula:

$$CED = \frac{\sum di}{M} \; x \; 100\%$$

Notes:

CED = Carbon Emission Disclosure
$\sum di$= Total of the entire score 1 obtained by the company
M = Total items for maximum disclosure (18 items)

The Independent Variables in this study are Media Exposure; Enviromental Performance; Type of Industry; Company Size; Profitability; and Leverage. Media Exposure was calculated by using a dummy variable in which score 1 was given to a company which had had positive and negative news coverage from external parties or from internal parties with regard to the company's efforts in dealing with carbon emissions. The news coverage here was referred to the online media coverage. However, score 0 was given to companies which has received no publication on any types of media from external parties concerning the company's efforts in handling its carbon emissions.

In the operational description, the environmental performance was measured by using the ranking scores as stated in Program for Pollution Control, Evaluation, and Rating (PROPER). The PROPER rating puts the companies in gold rank, green rank, blue rank, red rank, and black rank. In this present study, each rank was given a score from 5 to 1 respectively. The table below illustrates the ranking scores for environmental performance based on PROPER ranking.

Table 1: PROPER Ranking of Environmental Performance Variables

Color	Ranking Scores	Notes
Gold	5	Excellent
Green	4	Very Good
Blue	3	Good
Red	2	Poor
Black	1	Very Poor

Source: proper.menlh.go.id

The type of industry was measured by using the ranking scores based on the ranking of three industrial sectors which had been the biggest contributors to carbon emissions in Indonesia as revealed by the Indonesian Ministry of Industry (2013). Each listed company was classified into one of the sectors, and they were given score 3 to 1 respectively. The table below shows the ranking score for the three sectors which constitute the type of industry variable.

Table 2: The Ranking for Carbon Emission Contributors in Indonesia

Sector	Ranking Score
Energy Sector: Mining and Energy Industry.	3
Industrial Processes and Product Use (IPPU) Sector: cement industry, steel, pulp and paper, textile, electronic and electrical appliances, petrochemicals, ceramics, food and beverage.	2
Agriculture, Forestry, and Other Land Use (AFOLU) Sector: Agro-industry, plantation, livestock, forestry, property, real estate, building construction, pharmaceutical and cosmetic.	1

Source: the Indonesian Ministry of Industry

The company size was measured by using the natural logarithm of total assets.

SIZE = Ln(Total Assets)

The level of profitability in this present study was measured by using ROA formula as stated in Gitman & Zutter (2013, p. 81):

$$ROA = \frac{Earnings\ available\ for\ common\ stockholders}{Total\ Assets}$$

This ROA formula had also been used in several previous studies, such as Bae et al. (2013), Jannah & Muid (2014), and Pratiwi & Sari (2016).

The leverage was measured by using the *debt to assets ratio* formula:

$$Debt\ to\ Asset\ Ratio = \frac{Total\ Debt}{Total\ Assets}$$

This formula had also been used in Jannah & Muid (2014).

The multiple linear regression analysis was done to measure the degree of influence from the factors which affected the carbon emission disclosure (CED). The multiple linear regression model was conveyed in the following equation:

$$\mathbf{CED} = \propto_o + \boldsymbol{\beta_1}\mathbf{MEDIA} + \boldsymbol{\beta_2}\mathbf{PROPER} + \boldsymbol{\beta_3}\mathbf{TIPE} + \boldsymbol{\beta_4}\mathbf{SIZE} + \boldsymbol{\beta_5}\mathbf{ROA} + \boldsymbol{\beta_6}\mathbf{LEV} + \boldsymbol{e}$$

Notes:
CED = Carbon Emission Disclosure
α = Constant
$\beta_1 - \beta_6$ = Regression Coefficient
MEDIA = Media Exposure
PROPER = Rating to Measure Environmental Performance
TIPE = Type of Industry
SIZE = Size of the company
ROA = Return on Total Assets
LEV = Leverage (Debt to Asset Ratio)
e = Error

Results and Discussion

Seventy-four (74) companies from non-financial sector became the research population in this present study. From the population, 21 companies were selected as the samples by using purposive sampling technique with several criteria. Thus, the total number of observations were 84 observation from a period of four years from 2014 – 2017.

The Results of Hypothesis Testing

After all the data were assessed using the classical assumption test and regression model evaluation, the next step was to test the multiple linear regression model on Eviews 10. The significant t-test results can be seen in Table 3 below.

Table 3: Results of Statistical Tests

Variables	t-statistic	Prob.
Constant	-0,948501	0,3459
MEDIA	3,240314	0,0018
EP	1,466138	0,1468
TYPE	3,054248	0,0031
SIZE	0,749745	0,4558
ROA	2,689701	0,0088
LEV	0,523496	0,6022
F-Statistic	12,18502	
Prob(F-Statistic)	0,00000	
R-squared	0,565167	
Adjusted R-squared	0,518785	

Source: Output Eviews 10

The results of multiple linear regression and significant t-test for each independent variable are explained briefly as follows:

1. First Hypothesis
The table above shows that *media exposure* (MEDIA) has positive and significant influence on carbon emission disclosure. This can be seen from t-value of 3,240314 > 1,992 t_{tabel} with p-value below 0,05, which is at 0,0018. Since it can be concluded that media exposure has positive and significant influence on carbon emission disclosure, The hypothesis which is stating that media exposure has positive influence on carbon emission disclosure is accepted.
2. Second Hypothesis
The environmental performance variable has p-value of 0,1468 which is higher than 0,05, and the t-value stands positively at 1,466138. This means the environmental performance variable has no significant influence on carbon emission disclosure. Thus, The hypothesis which is stating that environmental performance has positive influence on carbon emission disclosure is not accepted.
3. Third Hypothesis
The type of industry variable has positive and significant influence on carbon emission disclosure. This can be seen from t-value of 3,054248 which is higher than t_{tabel} of 1,992, and p-value stands at 0,0031. Therefore, the third hypothesis stating that type of industry variable has positive and significant influence on carbon emission disclosure is accepted.
4. Fourth Hypothesis
The company size variable does not affect carbon emission disclosure. This can be seen from t-value of 0,749745 which is lower than t_{tabel}, of 1,992 with *p-value* of 0,4558. This proves that the company size has no positive and significant influence on carbon emission disclosure. Consequently, H_4 stating that the company size has positive influence on carbon emission disclosure is not accepted.
5. Fifth Hypothesis
The profitability variable measured by ROA shows positive influence on carbon emission disclosure. This is because p-value of 0,0088 stands below 0,05 with t-value of 2,689701 > 1,992 t_{tabel}. Therefore, the fifth hypothesis stating that profitability has positive influence on carbon emission disclosure is accepted.
6. Sixth Hypothesis
The leverage variable measured by DAR has no significant influence on carbon emission disclosure. This variable has p-value of 0,6022 with positive t-value of 0,523496. As a result, the six hypothesis stating that the leverage variable has negative influence on carbon emission disclosure is not accepted.

7. Based on the test results above, the regression model equation in this present study shows that the independent variables simultaneously have significant influence on the dependent variables. This is proven from the probability F-value which is below the significant level of 0,05.
8. Coefficient of Determination
Based on the table above, the coefficient of determination value can be seen from *adjusted r-square* value of 0,518785 (51,88%). This value means that the independent variables used in the multiple linear regression model has 51,88% influence in explaining the dependent variables. The percentage is more than 50%; thus, it can be indicated that the independent variables in this present study have strong relations with the companies' carbon emission disclosure. In other words, these independent variables has high level of ability to explain factors which can influence carbon emission disclosure.

Discussion

The Influence of Media Exposure on Carbon Emission Disclosure

Media exposure (MEDIA) has positive and significant influence on carbon emission disclosure. This can be seen from t-value of 3,240314 > 1,992 t_{tabel} with p-value of 0,0018 which is below 0,05. Thus, it can be concluded that media exposure has positive and significant influence on carbon emission disclosure. Accordingly, the first hypothesis stating that media exposure has positive influence on carbon emission disclosure is accepted.

This result is in line with those of Jannah & Muid (2014) and Majid & Ghozali (2015) which showed a positive relation between media exposure and carbon emission disclosure. Jannah & Muid (2014) studied non-financial companies listed in Jakarta Stock Exchange from 2010 – 2012. During that period, it is found that media can motivate the companies to disclose their carbon emissions. However, this results are in contradiction to those of Pratiwi & Sari (2016) in which media exposure does not always motivate the companies to publish their carbon emission disclosure in their annual reports.

Companies which have continuous coverage from external media tend to publish carbon emission disclosure more extensively. For example, PT Bukit Asam (Persero), Tbk is one of the state-owned enterprises (SOEs) which often receives media coverage with regard to the company's policy in reducing carbon emissions. During the period of research (2014 – 2017), PT Bukit Asam (Persero), Tbk always received news coverage from external media related to its carbon emissions. Because of this considerable media exposure, PT Bukit Asam (Persero), Tbk published extensive carbon emission disclosure which covered 94,44% (17 items) from the total of 18 disclosure items. PT Bukit Asam (Persero), Tbk published a comprehensive carbon emission disclosure in its sustainability report which started from the company's experience in implementing carbon emission disclosure to its development and the results of its efforts to mitigate its carbon emissions.

The directly proportional relationship between media exposure and carbon emission disclosure was also proven from the companies which did not get media exposure during the research period. For example, PT Asahimas Flat Glass, Tbk which did not receive media exposure from 2014 – 2017 published only 22,22% to 22,78% from the total of 18 carbon emission disclosure items. The extent of carbon emission disclosure published by PT Asahimas Flat Glass, Tbk was not as extensive as those published by companies which constantly received media exposure. In other words, the less frequent the companies receive media exposure, the more restricted their carbon emission disclosure will be.

The results of this present study are in line with the legitimacy theory and the stakeholder theory which are applied in this present study. For example, PT Astra Agro Lestari, Tbk was one of the companies which received news coverage from external media regarding its policy in reducing the carbon emission level. As a crude palm oil (CPO) producer, PT Astra Agro Lestari, Tbk published 77,78% to 83,3% of its carbon emission disclosure in its efforts to obtain public legitimacy amid negative issues attacking palm oil producing companies. Not only did PT Astra Agro Lestari, Tbk contribute in the efforts to reduce carbon emissions nationally, but it also gained supports from its stakeholders in running its business activities.

The rapid advancement of information and technology has encouraged companies to be more active in responding to the media exposure. Various media have also become more active in criticizing the policies and issues striking the companies. By doing this, media can motivate the companies to extend its carbon emission disclosure in order to build and maintain their images in public who have become more aware of the companies' activities. It seems that the more frequent media exposure to a company is, the more extensive its carbon emission disclosure will be. Based on the theories, statistic test results, and facts, it can be concluded that media exposure has positive and significant influence on carbon emission disclosure. Hence, the fourth hypothesis is accepted.

The Influence of Environmental Performance on Carbon Emission Disclosure

The environmental performance variable has p-value of 0,1468 which is higher than 0,05, and it has a positive t-value of 1,466138. This means the environmental performance variable has no significant influence on carbon emission disclosure. For this reason, H_2 stating that environmental performance has positive influence on carbon emission disclosure is not accepted.

This result is conflicting with that of Prafitri & Zulaikha (2016) who are of the opinion that environmental performance has positive influence on greenhouse gas emissions (including the carbon emissions). The research by Prafitri & Zulaikha (2016) shows that the disclosure has been in line with the companies' commitment on the environment to obtain legitimacy and supports from their stakeholders.

On the other hand, the test results in this present study confirm some previous studies such as Jannah & Muid (2014), Majid & Ghozali (2015), Akhiroh & Kiswanto (2016), and Cahya (2017). Furthermore, the publication of high PROPER rating has indirectly represented the companies' commitment to cope with climate change problems (Jannah & Muid, 2014); thus, the increase in PROPER rating does not correspond with the companies' motivation to publish their carbon emission disclosure.

In this present study, there are some reasons (or facts) why the environmental performance has no influence on carbon emission disclosure. First, companies with high PROPER rating lack the motivation to publish carbon emission disclosure. They are more motivated to disclose their other environmental responsibilities in their annual reports. For example, PT Indofood CBP Sukses Makmur, Tbk received green PROPER rating in 2016, but its carbon emission disclosure only reached 22,22%. In its annual report, PT Indofood CBP Sukses Makmur, Tbk was more inclined to disclose its social responsibilities within the farmers' social welfare and the environment domain rather than to disclose its carbon emissions. With high PROPER rating, the company's motivation to extend its carbon emission disclosure was still less than expected although the company itself has been promoting the efforts to create alternative energy conversion which was environmentally friendly in which the program implied an effort to reduce the company's carbon emissions.

Second, although companies already have good environmental performance, they still lack the motivation to disclose their carbon emissions because they think they have fulfilled some of the rating criteria in PROPER. In green rating criteria, the companies think that if they can fulfil the air pollution and clean production aspects in PROPER, these two aspects can be considered as the alternatives in their efforts to reduce their carbon emissions. In the air pollution aspect, the companies which have air pollution emissions below 50% of the air pollution control standards have met one of the criteria in green PROPER rating. Within the clean production aspect, the green rating criteria include the application and conversion of efficient and environmentally friendly energy. Consequently, companies with green PROPER rating feel that it is unnecessary for them to extend carbon emission disclosure because the companies have already passed the evaluation criteria concerning air pollution and clean production which are two important aspects in carbon emission disclosure. Statistically, the environmental performance variable with other independent variables can simultaneouly have significant influence on carbon emission disclosure (the dependent variable) as revealed in the significant F-test value of this present study. For example, PT Indofood Sukses Makmur, Tbk has a green PROPER rating, and this company is aware that it does not belong to the type of industry which

is more intensive in producing carbon emissions; therefore, PT Indofood Sukses Makmur, Tbk becomes less motivated in publishing its carbon emission disclosure. Based on the statistic test results and facts found in this presen study, it can be concluded that the second hypothesis is not accepted. In other words, this present study states that the environmental performace has no significant influence on carbon emission disclosure.

The influence of Type of Industry on Carbon Emission Disclosure

The type of industry variable has positive and significant influence on carbon emission disclosure. This can be seen from t-value of 3,054248 which is higher than t_{tabel} of 1,992, and p-value stands at 0,0031. Therefore, H_3 stating that the type of industry variable has positive and significant influence on carbon emission disclosure is accepted

The observation in this present study applies to the three sectors of industry which include carbon emission contributors from the Ministry of Industry, and it is in line with previous studies by Bae et al. (2013), Jannah & Muid (2014), and Pratiwi & Sari (2016) In general, these three previous studies are of the opinion that the type of industry which intensively produces carbon emission tend to publish the carbon emission disclosure more extensively.

The results of this present study show a positive and significant relation between type of industry and carbon emission disclosure. Out of eight companies in energy sector, three companies had scored more than 90% of the total carbon emission disclosure items. They are PT Indocement Tunggal Prakarsa, Tbk, PT Bukit Asam (Persero), Tbk, and PT Semen Indonesia, Tbk, all of which operate in mineral mining industry which contributes rather enormously to the carbon emission increase in Indonesia. However, the three companies had made some efforts to mitigate carbon emissions by applying various policies and reporting the progress of their efforts publicly through their sustainability reports uploaded in their official websites. This confirms the legitimacy theory and the stakeholder theory in which companies must focus not only on the financial aspects, but also on the environmental aspects, particularly in the environment where the companies conduct their business activities.

The more intensive the companies produce carbon emissions, the bigger their efforts in publishing carbon emission disclosure will be. This has been done by PT Semen Indonesia, Tbk. In order to reach the target of reducing its carbon emissions, PT Semen Indonesia, Tbk. has done a lot of things, such as cooperating with Japanese companies in developing an environmentally friendly technology, implementing a pollution prevention program, environmental conversion, greenhouse program, and using biomass fuel in its plant in Tuban. All of the programs and their progress have been reported in a comprehensive carbon emission disclosure covering every segment of the company. This carbon emission disclosure of PT Semen Indonesia, Tbk is published in its annual report and sustainability report.

On the other hand, companies which are not intensive in producing carbon emission only reveal a small number of items from the total carbon emission disclosure items. For example, PT Kalbe Farma, Tbk operating in pharmaceutical industry did not publish carbon emission disclosure extensively although the company had been aware of the on-going climate change and carbon emission issues. Nevertheless, PT Kalbe Farma, Tbk only revealed its general strategies on reducing carbon emissions. Therefore, based on the statistic test results and described facts, it can be concluded that the third hypothesis stating that the type of industry has positive and significant influence on carbon emission disclosure is accepted.

The Influence of the Company Size on Carbon Emission Disclosure

The company size variable does not affect carbon emission disclosure. This can be seen from t-value of 0,749745 which is lower than t_{tabel}, of 1,992 with *p-value* of 0,4558. This proves that the company size has no positive and significant influence on carbon emission disclosure. Consequently, H_4 stating that the company size has positive influence on carbon emission disclosure is not accepted.

The results of this present study are not in line with several previous studies such as Jannah & Muid (2014), Majid & Ghozali (2015), Bae et al. (2013), Luo et al. (2013), Kalu et al. (2016), and Gonzáles-Gonzáles & Zamora-Ramírez (2016), all of which state that company size has a directly proportional relationship and significant relationship with carbon emission disclosure. Jannah & Muid (2014) are of the opinion that company size has positive and significant influence on carbon emission disclosure. Majid & Ghozali (2015) further explained that big companies are confident in publishing carbon emission disclosure because they have the necessary human resources which are highly capable in publishing the disclosure.

Based on the statistic test results, the direction of the relationship between company size and carbon emission disclosure is the same with that of H_4. However, the influence between company size and carbon emission disclosure is not significant yet. One of the reasons for this phenomenon is the presence of big companies which have not published their carbon emission disclosure optimally. For example, PT Indofood Sukses Makmur, Tbk which had a total asset of Rp 91.381.526.000.000,- in 2015 revealed only 22,2% (4 items) from the total of 18 carbon emission disclosure items. This implied that the company's resources have not been used optimally to decrease carbon emissions. The extent of the company's resources is reflected on the company's total asset value which has been obtained from various contracts made to increase the fixed assets. However, the fixed assets have been used to develop plantation crops which are valuable for PT Indofood Sukses Makmur, Tbk to increase the abilities of its business segments.

PT Indofood Sukses Makmur, Tbk also puts a lot of efforts to mitigate the risks of global warming and climate change which can endanger its business segments. The company's mitigation acts include maintaining the inventory level of raw materials, building good partnership with the suppliers, establishing contingency plans to anticipate disaster, and ensuring the provision of sufficient insurance protection against financial losses. However, these mitigation measures have less impact on extensive carbon emission disclosure because the mitigation efforts have not been focused on the measures which can potentially reduce the company's carbon emissions. Big companies with great resources have not been aware of the importance of reducing carbon emissions with more focused and continuous action. Consequently, the company size as reflected in its resources has no influence on the extent of carbon emission disclosure published by the company.

In addition to the policies implemented by a company, the characteristics of the company also influence the company size which has no influence on carbon emission disclosure. This present study also showed that actually several big companies are not the largest carbon emitters. This is because the company's characteristics such as type of industry and company size simultaneouly have significant influence on carbon emission disclosure. For example, PT Indofood Sukses Makmur, Tbk is a big company with big total assets. Nevertheless, the company does not belong to the type of industry which produces the largest carbon emissions. Because of this, the company feels unnecessary to publish extensive carbon emission disclosure. Thus, the company's total assets can be used for a more strategic policy.

To extend its carbon emission disclosure, a company must have a higher awareness of reducing carbon emissions by using the company's available resources which have not been focused on implementing carbon emission policy comprehensively. Because carbon emission disclosure is still voluntary, most of the companies still focus on their financial performance. In fact, carbon emission disclosure not only contributes to the environment, but it can also be published as value added statement which is not included in the financial statements as stated in the Indonesia Financial Accounting Standard or PSAK No.1 (Ikatan Akuntan Indonesia, 2009).

In this present study, although the direction of the relationship between the company size and carbon emission disclosure is the same with that of Hypothesis No. 4, the facts that happened in the sample companies make the influence is still insignificant. Thus, it can be concluded in this present study that the company size variable does not affect carbon emission disclosure.

The Influence of Profitability on Carbon Emission Disclosure

The profitability variable measured by ROA shows positive influence on carbon emission disclosure. This is because p-value of 0,0088 stands below 0,05 with t-value of 2,689701 > 1,992 t_{tabel}. Therefore, H_5 stating that profitability has positive influence on carbon emission disclosure is accepted. The results of this present study confirm the results of previous studies by Bae et al. (2013), Gonzáles-Gonzáles & Zamora-Ramírez (2016), and Cahya (2017). These studies showed that the increase on profitability will encourage the company to publish a more extensive carbon emission disclosure. On the other hand, some other previous studies such as Pratiwi dan Sari (2016) and Irwhantoko & Basuki (2016) showed different results. Both studies show that the increase in profitability has no significant influence on carbon emission disclosure. In other words, profitability does not affect the extent of carbon emission disclosure.

This present study used ROA to demonstrate how a company with a good profitability can publish carbon emission disclosure optimally. For example, PT Unilever Indonesia, Tbk had ROA of 41,50% in 2014, and its carbon emission disclosure reached 83,33% or 15 disclosure items (from the total of 18 carbon emission disclosure items). By directly proportional relationship similar to that of PT Unilever Indonesia, Tbk, the carbon emission disclosure of PT Asahimas Flat Glass, Tbk experienced reduction and became less extensive because its ROA value decreased drastically to 0,62% in 2017. Smaller ROA values encourage the decrease in carbon emission disclosure.

Companies with high ROA value can implement many policies which can reduce carbon emissions. This effort can bring many benefits which can increase the reputation of the company. One of the companies which has already been aware of the benefits of carbon emission disclosure is PT Semen Indonesia, Tbk which has been using carbon emission disclosure as a strategy of energy transformation. This energy transformation is implemented by using rice husk and cocopeat biomass as an alternative fuel which creates energy as the source of efficiency for the company by obtaining certified emission reduction (CER). By using alternative energy, the company has shown its commitment in managing energy, reducing carbon emissions, and increasing economic value.

Companies with high profitability tend to be active in disclosing their carbon emissions. By disclosing their carbon emissions, the companies hope they will receive positive viewpoints from their stakeholders, and these viewpoints are expected to be able to support their financial performance which had already been reported to public. Companies with high profitability can make use of this profitability to implement beneficial policies outside the financial aspect. It is expected that carbon emission disclosure can bring relevant benefits for the companies' reputation because by disclosing their carbon emissions the companies can receive public trust which can support the companies' operational activities which eventually can increase the companies' images.

The considerable cost for carbon emission disclosure corresponds with the benefits which are received by the companies from their carbon emission disclosure. The companies can focus on their social responsibilities for the environment, social, culture, and economy aspects. The companies' ability to make profits can influence the extent of their carbon emission disclosure. The higher a company's profitability is, the higher the company's awareness is in disclosing its carbon emissions which can support the results of its financial performance. Based on the statistic test results and facts found in the present study, it can be concluded that profitability has a positive and significance influence on carbon emission disclosure.

The Influence of Leverage on Carbon Emission Disclosure

The leverage variable measured by DAR has no significant influence on carbon emission disclosure. This variable has p-value of 0,6022 with positive t-value of 0,523496. As a result, H_6 stating that the leverage variable has negative influence on carbon emission disclosure is not accepted.

The results of this present study are different from those of the previous studies. For example, Jannah & Muid (2014) are of the opinion that leverage has a negative and significant influence on carbon emission disclosure. Companies with high debt financing tend to restrict its carbon emission disclosure and focus on settling the liabilities to the creditors or other financiers.

The direction of the relationship between leverage and carbon emission disclosure shows a different direction from that of the formulated hypothesis. There are facts demonstrating how leverage has positive but insignificant influence on carbon emission disclosure. For example, PT Unilever Indonesia, Tbk had a high leverage level of 71,91% in 2016, but the company's carbon emission disclosure was valued only at 77,78%. Although PT Unilever Indonesia, Tbk is aware that it should pay close attention to its expenses and discard any costs which do not add value to the consumers, the company still publishes its carbon emission disclosure extensively. Furthermore, the company still pays attention to non-financial aspects which also influence the company's good reputation. This implies that the company intends to fulfil various social contracts even though it has high leverage. However, the reduction of the company's carbon emission has not been directed optimally. This supports the claim that leverage has a positive relationship with carbon emission disclosure although it is not significant yet. Another example of companies with high leverage and restricted carbon emission disclosure is PT Indofood Sukses Makmur, Tbk which had leverage of 53,30% in 2015, but the company's carbon emission disclosure was valued only at 22,22%.

Moreover, the leverage level during the period of research tends to be high because of several factors, one of which is the increase in long-term liability. This happened with PT Phapros, Tbk whose DAR was increased from 29,57% to 40,35% in 2017. The surge was caused by an increase in liability value of 81,67% from 2016 which was mainly caused by the increase in long-term liability from Rp 215.020.000.000,- in 2016 to Rp 289.820.000.000,- or 287,47% increase in 2017. Furthermore, medium term-notes revenues which were realized in 2017 also contributed to the increase along with an increase in long-term bank loans to Rp 9.320.000.000,- or 19,59% which were used to fund investments. The increase in leverage level was also triggered by an increase in the current value of post-employment benefits which rose 20,14% from 2016 and reached Rp 80.510.000.000,-. The considerable increase in liability value did not correspond with the increase in total asset value which only rose 33,13% from 2016. Moreover, the increase in liability value also was not intended for purposes outside the company's carbon emission policies.

Similar things also happened to PT Semen Baturaja, Tbk which experienced an increase in leverage from 9,76% in 2015 to 28,56% in 2016. This surge was caused by retention receivables which reached 1030%. The retention receivables were incurred from the purchase of machinery equipment from Tianjin Cement Industry Design and Research Institute, the retention of civil construction work Phase I on DDK Joint Operation, and the retention of civil construction work Phase II plus mechanical and electrical installation from Waskita. All of the retention receivables were intended for the Construction Project of Baturaja II Plant.

The increase or the decrease of leverage is caused by funding which is used to support various company's interests in increasing the company's operations. The companies tend not to apply an optimum strategy to attract the stakeholders' attention (Ghozali & Chariri, 2007). This encourages the companies to lower their intention to publish their carbon emission disclosure. This is why leverage level does not influence the extent of the companies' carbon emission disclosure. Based on the statistic test results and facts found in this present study, it can be concluded that leverage has no significant influence on carbon emission disclosure.

Conclusion

Based on the discussion above, it can be concluded that there are three independent variables which have influenced and have the same direction of relationships with the research hypotheses. The variables are as follows: Media exposure which was measured by dummy variables to see how news coverage from external media can influence the companies' carbon emission disclosure. The results

show that media exposure has positive and significant influence on carbon emission disclosure. In other words, the more frequent news coverage from external media concerning the companies' policy on carbon emission is, the more extensive their carbon emission disclosure will be. Type of industry was measured by using the scoring based on the sector division of carbon emission contributors from the Ministry of Industry. The more intensive an industry is in producing carbon emissions, the more extensive its carbon emission disclosure will be. The results showed that type of industry has positive and significant influence on carbon emission disclosure. Profitability was measured by the companies' *Return on Asset* (ROA) values. The results showed that the company's profitability has positive and significant influence on carbon emission disclosure. Companies with good profitability will publish their carbon emission disclosure decently. The disclosure of carbon emission will become the center of attention from the companies because they are starting to realize the benefits they will have from carbon emission disclosure.

Is the context of R&D narrative contingent on R&D expenses or R&D intensity? Evidence from European biopharmaceutical companies

Joanna DYCZKOWSKA

Wroclaw University of Business and Economics, Wroclaw, Poland
joanna.dyczkowska@ue.wroc.pl

Abstract

Biopharmaceutical industry encompasses R&D-intensive companies which invest huge amounts in basic and clinical studies. Since most of R&D expenditures are expensed as incurred and the time needed to develop new medicines is long biopharmaceutical companies may generate negative financial results for years. Therefore, investors appreciate non-financial information on R&D activities which is more informative. It should be emphasized that this paper contributes to the literature by applying qualitative and quantitative approaches to investigate relations between particular words and establish the contextual meaning of the analyzed texts extracted from 65 annual reports of European biopharmaceutical firms. The study analyses how R&D narratives differed in various groups of biopharmaceutical firms in terms of a discussion context. It also examines whether the way how firms depicted their business within the R&D context was dependent on R&D expenses or R&D intensity levels. The results of the study proves that the companies which disclosed strategic aspects of their R&D activities had higher R&D expenses levels and higher R&D expense growths than the companies with operational R&D narrative context. Moreover, the group that disclosed intensively on R&D accounting policy statistically differed in terms of R&D expenses growth from the group disclosing on R&D operational aspects. The empirical evidence did not supported the conjecture that R&D intensity level might have affected R&D narrative context. The advantage of this study is that it applies an international context on the European level. However, there are also certain limitations, therefore, future research can upgrade and broaden the analyses.

Keywords: Biopharmaceutical Companies, R&D Expenses, R&D Intensity, R&D Narrative, Textual Analysis.

Introduction

The business activity of biopharmaceutical companies is affected by quickly changing technologies, need for highly skilled employees as well as intensive efforts directed at effective managing R&D expenses, launching new products and attaining marketing approvals issued by regulatory authorities. Interestingly, R&D budget managers more and more often face a problem of delivering better R&D performance with limited budgets. Whereas new products in order to gain reimbursement have to indicate a significant improvement of treatment effectiveness over the existing therapies (Deloitte, 2015).

The sector-specific conditions, various business models adopted by biopharmaceutical companies as well as long life cycles of R&D project cause that a decision on what should be disclosed becomes challenging even for experienced managers.

Investors, who attentively observe activities of high-technology companies in terms of financial and non-financial performance, expect periodic reports reflecting the actual situation of an entity. In turn, managers are on the horns of dilemmas regarding the framework of voluntary disclosures in the context of proprietary costs and possible benefits (Dye, 1985; Verrecchia, 1983). Cheng (2004) claims that R&D activities seemed to be a source of agency problems between insiders and outsiders. Aboody and Lev (2000) share that position and argue that R&D activities are significant drivers of

the information asymmetry which cause that investors can react more sturdily to the disclosure of insider trades in R&D companies than in non-R&D companies. Therefore, many researchers perceive voluntary narrative disclosure as a mechanism which aims at a reduction of the information asymmetry and agency conflicts (Jensen and Meckling, 1976; Patelli and Prencipe, 2007; Nekhili et al, 2015). It should be emphasized that disclosures made by high-technology companies refer to broader aspects, including substantial risks from openness to external organizations. In order to win the support of external parties or to obtain an access to external knowledge sources, companies may be impelled to share knowledge with other institutions.

The main objective of this study is to examine whether the way how biopharmaceutical companies depicted their business within R&D context was dependent on R&D expenses or R&D intensity. The paper contributes to the literature in applying qualitative and quantitative approaches to establish the contextual meaning of the analyzed paragraphs extracted from corporate annual reports.

This paper is organized in the following way. Firstly, it revises the empirical studies in terms of R&D narrative disclosures. Secondly, the paper introduces the research question. Thirdly it presents the research sample and elaborates on research methods. Finally, it provides the empirical evidence on contextual analysis, cluster analysis and comparisons between the identified subsamples based on content characters of the annual reports in terms of R&D expenses and R&D intensity levels.

Literature Review

Biopharmaceutical companies spend a lot of time and huge sums on its basic research and clinical trials. They expect in return effects that will contribute to a major breakthrough in a treatment of incurable diseases. Therefore, a topic of communicating R&D outcomes may be interesting not only from the viewpoint investors but also society or competitors. That is why a matter of R&D disclosures is thought-provoking in the context of proprietary costs. An issue of proprietary costs results from "disclosing information which may be used by competitors and other parties in a way which is harmful for the reporting company" whereas a lack of these costs may stimulate companies „to voluntarily disclose relevant information to the market in order to reduce information asymmetry and, consequently the cost of capital" (Prencipe, 2004). There is always a trade-off between disclosing more or disclosing less, since more disclosures decrease the cost of capital but also reduce the manager's profits from inside trading (Baiman and Verrecchia, 1996). These trade-offs may be considered as partial-disclosure equilibria, which are contingent on the information to be disclosed, the level of regulatory related costs, and the probability that a competitor will enter the product market (Wagenhofer, 1990; Cohen, 2002).

There are also several studies which refers to the nature of disclosures within R&D activities, the approaches of managers or analysts to R&D disclosures, the factors shaping R&D disclosures and the impacts of R&D disclosures on cost of equity, information asymmetry, analysts' forecasts. Entwistle (1999) interviewed analysts and executives in order to obtain an insight into disclosures of R&D intensive companies. The interview delved into the types of information the companies disclosed to communicate how they created value through mobilizing R&D expenditures. The executives were also asked about their anxiety for disclosing proprietary or bad news on R&D information, the methods of monitoring the effectiveness of R&D disclosures and overall R&D disclosure philosophy labelled as "conservative", "aggressive" or "mid-range". Moreover, Entwistle (1999) inquired the executives and analysts to identify the potential benefits from effective R&D disclosure management and to express their opinion on deferring vs. expensing development expenditures. The last part of that examination, based on a content analysis of annual reports of 113 Canadian stock-listed companies, evidenced that the ratio of R&D expenditures to total operating expenses and a listing status explained the amount of R&D disclosures provided by the high-tech companies.

In turn, Ding et al (2004) examined disclosure practices in French and Canadian high-technology companies based on 186 annual reports. They found a significant positive correlation between R&D disclosures and R&D intensity of Canadian entities. Moreover, Ding et al (2004) remarked that Canadian companies were more eager to disclose non-financial information and prospects concerning

the level of R&D expenses than their French counterparts which provided more financial and accounting information in a traditional way.

Another interesting study was carried out by Jones (2007), who examined 119 R&D intensive companies searching for their voluntary disclosures from the annual reports and the sources beyond financial reporting such as direct disclosures to financial analysts mainly in the form of conference calls. Jones (2007) focused on three types R&D information, including R&D spending, R&D projects in progress and development-stage R&D. She developed three research questions concerning: the types of information disclosed by managers of R&D intensive companies, the conditions under which managers of R&D intensive companies made voluntary disclosures, the relations between the level of voluntary disclosures on R&D activities and analysts' forecasts. Following research results she came to several interesting conclusions. Firstly, companies disclosed more R&D information when their financial statements were less informative about a market value. Secondly, no evidence suggested that companies with a higher level of information asymmetry disclosed more. Thirdly, the relation between R&D expenditures and R&D disclosures was positive but not significant, whereas the relation between analysts' forecast accuracy at the beginning of the year and the level of R&D disclosures during the year was negative.

Cheng and Zhao (2019) provided the empirical evidence that the number of textual R&D disclosures was negatively correlated with the profitability of the firm. They explained that companies with less profitability were more likely to publish more textual R&D disclosures to divert or confuse investors whereas companies with better profitability were not eager to publish too many textual R&D disclosures because there is no need to distract investors. Likewise, the study of Merkley (2014) concerned the extent of R&D narratives in annual reports and its relation to earnings performance. The results of that study evidenced that earnings performance was negatively associated with the quantity of R&D disclosures. The reason why companies disclosed more when their earnings performance was lower was not that managers used disclosures to put a positive spin on performance information, but it was rather a respond to investors' information needs. Consistently with the previous research (Jensen and Meckling, 1976; Patelli and Prencipe, 2007) the study of Merkley (2014) supported the statement that voluntary narrative disclosures aim at reduction of information asymmetry.

Most of the abovementioned findings relate to different conditions and various, though narrow, research samples including high-technology firms. Therefore, the results should not be generalized, nevertheless, they may constitute a point of reference for the research studies.

Research Question

The growing interest of non-financial narrative role in communicating topical issues to stakeholders and the empirical evidence on determinants and effects of R&D disclosures have become a motivation to take a closer look at annual reports of biopharmaceutical companies. Consequently the following research question was developed:

RQ: *Is the context of R&D narratives contingent on R&D expenses and R&D intensity?*

The empirical research studies linking R&D disclosure with R&D expenses and intensity levels have concerned mainly the extent of narrative so far. Napoli (2013) assumed that firms made more R&D disclosures when their earnings were less informative. That assumption was consistent with the earlier evidence provided by Entwistle (1999) who found that companies with higher levels of R&D expenses were more likely to provide additional disclosures. Likewise Gu and Li (2003) proved that companies made greater disclosures of innovation whilst increasing the rate of R&D expenses. Moreover they evidenced that disclosures of innovation were positively associated with the firm's R&D intensity. Positive association between R&D intensity and R&D disclosures was indicated in many studies, including: Entwistle (1999); Ding et al (2004); Nekhili et al (2012), Merkley (2014) and Mazzi et al (2019). However, R&D expenses and intensity levels have not been combined with R&D disclosure context so far. In order fill the research gap the empirical study whether the context of R&D narratives was dependent on R&D expenses and intensity levels was carried out.

Research Sample and Methods

Since this examination is motivated by the predetermined research question relevant texts for the purpose to answer it were collected. The study was based on annual reports of European biopharmaceutical companies listed in the 2500 world top companies R&D ranking (2014). The population was composed of 77 European entities, dominated by British (14) and Swiss (10) companies. The final research sample included 65 companies, since 12 entities were excluded due to a lack of access to annual reports.

The procedure applied in this study was divided into three stages.

First of all, annual reports of the selected companies were carefully examined in order to search for separate sections or paragraphs discussing R&D activities. It was clear to identify separate sections, since they were often placed on a content page. However, there were cases when R&D information was not easily noticeable. Guthrie et al (2004) point out that while analyzing the content of annual reports paragraphs' exploration seems to be more appropriate in drawing inferences from narrative statements than exploration of separate sentences or words since it enables to establish the appropriate context of the statement. Therefore, when a lack of clear separate R&D sections was identified, the overall text was decomposed into meaningful paragraphs, including the terms: „research and development", „R&D" or „research & development" which were essential to recognize and understand the meaning of R&D activities and their contextual linkages. The extracts from annual reports created an aggregated document covering narratives concerning all companies. Such document was ready to be mined, therefore it was inserted into a text mining tool (i.e. KH Coder). The applied procedure was to examine concomitance of words within the same paragraph. In order to examine the relations between particular words Jaccard's coefficient of similarity was computed. The said measure is a ratio of the number of elements in the intersection set divided by the size of the union set. In this case Jaccard's coefficient of similarity showed how frequently did two particular words occur in the same paragraph in relation to total occurrence of those words in the examined narrative.

The second stage of this study aimed at examining how the analyzed entities merged into clusters in terms of similarity of how they told the story about R&D activities. Therefore, vectors consisting of the number of Top 100 most common words were created for each company. Then agglomerative hierarchical clustering approach was applied and Euclidean distances between particular objects were established. In order to determine how particular objects merged, Ward's method was used. Ward's method does not use cluster distances to link objects (Ferreira and Hitchcock, 2009). Instead, it takes into consideration a classical sum of squares criterion and generates groups that minimize within-group dispersion. In other words, this method joins at each stage of an agglomerative procedure those cluster pairs whose fusion minimizes an increase in a total within-group error sum of squares (Rasmussen, 1992). This technique represents a mixed approach which enables processing qualitative data through clustering. Such an approach allows to manage a complexity of qualitative data while still maintaining its richness (Macia, 2015). The vertical axis displays linkage distances, whereas the horizontal axis presents observations. The tree diagram illustrates a way how clusters are created. In this procedure each object O_i (i = 1,2,…49) is considered to be a single element cluster (G_i) in the beginning. Then the Euclidean distances between all pairwise clusters are computed. If we assume that clusters G_p and G_q merge into a new cluster Gr where $Gr = G_p \cup G_q$, the next step is to specify a dissimilarity between Gr and all other objects (Oi) or clusters (Gi). The Lance-Williams dissimilarity update formula allows to establish the abovementioned distance (Murtagh and Contreras, 2012).

$$d_{ir} = \alpha_p d_{pi} + \alpha_q d_{qi} + \beta d_{pq} + \gamma \left| d_{pi} + d_{qi} \right|$$

Following Ward's method parameters: α_p, α_q, β and γ are computed as follows:

$$\alpha_p = \frac{n_p + n_i}{n_p + n_i + n_q} \qquad \alpha_q = \frac{n_q + n_i}{n_q + n_i + n_p} \qquad \beta = \frac{-n_i}{n_i + n_p + n_q} \quad \gamma = 0$$

Based on the cluster analysis and the qualitative examination of R&D narrative disclosures three subsamples with regard to their discussion character were specified.

The third stage of the research procedure consisted in checking whether the subsamples came from different populations in terms of R&D expenses level and consequently whether they significantly differed between each other. Therefore, a null hypothesis was posed that the subsamples came from populations with the same distribution. Since the ANOVA has restrictive assumptions concerning the distributions of the samples which in fact have not been met for this dataset rank-based nonparametric Kruskal-Wallis H test was applied. It is an omnibus test checking whether the mean ranks of the groups are the same. In case of the rejection of null hypotheses of the Kruskal-Wallis H tests for independent variables multiple pairwise comparisons looking for stochastic dominance or median differences between particular subsamples were planned to be carried out.

For this purpose, a post hoc Dunn's test is applied which uses the following statistic: $d = \frac{|\bar{R}_i - \bar{R}_j|}{\sigma}$,

where mean rank for the j-th sample equals $\bar{R}_j = \frac{R_j}{n_j}$

and the standard error equals $\sigma = \sqrt{\frac{n(n+1)}{12}\left(\frac{1}{n_i} + \frac{1}{n_j}\right)}$

Dunn's d-test statistic approximates the exact rank-sum test statistics by using the mean rankings of the outcome in each sample from the preceding Kruskal–Wallis test R¯_j=R_j/n_j where Rj is the sum of ranks, and nj is a size of the sample for the j-th group) and basing inference on the differences in mean ranks in each group (Dinno, 2015).

Empirical Evidence of the study

Results of Contextual Analysis

As a result of the first stage of the research procedure the co-occurrence network was developed (Fig. 1). It exemplifies 200 relations between 100 most common words and sheds the lights on the most important linkages to show explicitly the thematic modules.

The sizes of the circles exemplify numbers of particular words which appeared in the analyzed text, hence the bigger circles show more frequent words. It should be explained that although the content analysis is based on 100 most common words the said co-occurrence network does not illustrate all of them, since 24 words did not create strong linkages with the other 76 words. In order to show more words on the network Jaccard's coefficient should be decreased, what would lead to more linkages appear on the network, as well.

Based on contextual relations exemplified in fig. 1, five main modules discussed in the R&D narrative parts of annual reports were singled out.

Fig. 1: Contextual analysis based on exploration of paragraphs: 200 relations between 100 most common words (n=65)

Source: Own presentation

The first module (a yellow graph) concerned a topic of 'CLINICAL STUDIES' and was composed of the following phrases: clinical programs, clinical trial phases, clinical trial data, study result, patient therapies, cancer treatment, disease area, disease medicine. There were 12 nouns included in the module - 'CLINICAL STUDIES' - which precisely indicated a discussion framework.

The second module (a purple graph) referred to 'PROJECT DEVELOPMENT' and covered the following phrases: research activity, pharmaceutical company development, development cost and development in time dimension, as for example 2-year development. Likewise, here nouns are the most frequent words which combine with verbs, adjectives and adverbs.

The third module (a red graph) discussed on 'NEW PRODUCTS" and reflected the following phrases: new product market, technology use, new drug candidate, sale marketing, business growth and investment increase. This module shows how many issues have arisen around new product development. They entailed not only product-related aspects but also technology applied, R&D investments as well as a final phase associated with sale marketing.

The next module (a blue graph) focused on 'EXTERNAL ENVIRONMENT' and drawn an attention to the following phrases: collaboration agreement, milestone payment, regulatory approval. These issues are pivotal for continuity of business activities in biopharma industry.

The last module (a turquoise graph) referred to R&D accounting policy. The debate oscillated around the topics related with value, acquisition and impairment of intangible assets, acquisition of patent rights, future cash, recognition of revenues and income tax.

Results of Cluster Analysis

The second stage of the study focused on examining how the analyzed entities merged into clusters in terms of similarity of how they told the story about R&D activities. The dendrogram presented on fig. 2 visualizes the results of the hierarchical clustering approach. It presents how two individual entities merged together or with an existing clusters consisting of more than one observation. A visual inspection of the tree diagram allowed to identify five various groups separated through cutting off four linkages. The groups were not equinumerous. Another point is that the dendrogram clearly shows two agglomerations which had quite long distance from each other. The adopted approach allowed to distinguish five clusters which differed in terms of narrative context in the R&D area.

The first cluster covered four companies which came from the European Anglosphere[1]. The textual analysis indicated that the main discussion in this group oscillated around R&D accounting policy, product and development. The first feature distinguished this cluster from the other groups specified in this study. The R&D paragraphs provided a lot of information about intangibles and their structure, amortization and impairment. It should be noted that intangibles account for a significant part of assets in biopharmaceutical companies. They are classified into indefinite-lived (in-process R&D) and definite-lived intangibles (such as licenses, customer relationships, tradenames, developed technology etc.) for which weighted average life is established. In their narratives companies informed about reclassification of in-process R&D into to definite-lived intangibles or capitalization of expenses as a result of reaching market approvals.

The next area of interest was related with R&D expenses. The companies disclosed amounts and changes in the levels of R&D expenses as compared to the previous years. They reported on the structure of R&D expenses as well. Another issue debated in the annual reports was the recognition of R&D expenses in the financial statement following the assumed R&D accounting policy. It is expected that managers should form judgments with respect to the commercial status of products in determining whether development expenditures meet the criteria for immediate expense or capitalization.

Fig. 2: Cluster analysis (n=65)

Source: Own presentation

The biopharmaceutical companies included in the first cluster also readily discussed on acquisitions in which they sought incremental development of growth opportunities. Through acquisitions of other entities companies may not only expand their knowledge with new technologies but also increase their efforts to develop generic products with complex formulations.

The textual analysis reflected topics which appeared frequently in the R&D narratives of the first cluster. However, it is interesting to make an insight into the notions which did not appear or were rarely used. As compared to the second cluster, the companies from the first one did not discuss about medicines, diseases, therapies or patients at all or almost at all. The strategic issues of innovation and patents were also rarely disclosed. Concluding, the first cluster provided mainly mandatory disclosures related with R&D accounting policy imposed by regulators.

The second cluster was composed of seven companies[2]. A careful analysis proved that these companies intensively discussed on diseases and other contextual aspects such as patients, treatments, clinical phases or product development in their R&D narratives. In that way they made a contribution about how they pursued the mission by communicating a sense of intended directions of the whole organization and providing tangible effects of clinical trials, treatments or therapies. Such an approach is consistent with stakeholder and legitimacy theories. Stakeholder theory underlines existence various groups of interests and assumes that stakeholders have a right to know what happens in an organization (normative branch of the theory) and their needs should not be disdained (positive branch of the theory) (Deegan, 2000). In this context managers are required to contemplate the frameworks of voluntary narrative disclosure. Legitimacy theory is based on an assumption that organizations act in a manner which is consistent with "socially constructed system of norms, values, beliefs and definitions" adopted by society (Suchman, 1995). Following this theory a quality of voluntary disclosure are to be adjusted to the expectations of society, whereas narratives should legitimize business activities, efforts and performance in a comprehensive and readable way.

The companies of the second cluster stressed an importance of potential beneficiaries stating that they should be treated equivalently with shareholders. In that context the companies were searching for persons most likely to benefit from their treatments. Moreover, they examined efficacy of drug candidates in particular groups of patients and reported about the results in R&D narratives. Personalized medicine development capability is presently of growing interest in biopharmaceutical industry. It refers to identification of groups of patients with unique genetic profiles and recognition of certain biologic characteristics or biomarkers that have the potential to be more efficient and effective in treatment procedure (Haruya and Kano, 2015).

The companies also precisely described the activities' areas and specified the range of diseases they were aiming at with various treatments and therapies as well. They strengthened the importance of new technologies and a role of effective collaboration with strategic research partners. The interesting but difficult part of disclosure in this cluster concerned the results of clinical studies. The companies reported on outcomes achieved in various phases of clinical trials.

The third cluster consisted of ten companies of which six entities were from the European Anglosphere, whereas the other from continental Europe[3]. The companies included in the third cluster focused on presenting their strategic priorities related with new product development. They mentioned about that in the context of product differentiation within a product pipeline, business or operating models, product licensing or acquisition.

The majority of companies in the third cluster disclosed information on sales performance. They reported about the changes in sales volumes and factors affecting thereof. Some organizations provided detailed information on sales in segments across the various markets all over the world. Another issue discussed broadly concerned the achievement of marketing approvals which was a key step in strengthening and broadening product portfolios. It should be noted that business activities of biopharmaceutical companies are subject to extensive regulations by various institutions such as FDA, EMA and other regulatory authorities which impose several requirements on manufacturing, labelling, packaging, storage, advertising, promotion, sale, distribution and R&D activities. Due to

these requirements product development, marketing approval and commercialization processes are very often expensive and time-consuming.

The fourth cluster was the most numerous one and consisted of twenty three objects of which fifteen came from the Western Europe and Scandinavia[4]. The cluster included also four companies from the European Anglosphere and the same number from Central and Southern Europe. The discussion included in the annual report of these companies oscillated around product development, cost and research and had operational context. It should be noted that the topic of research was quite intensively debated in terms of research alliances stimulating new research projects, active involvement in clinical trials and partnerships with researchers, patient organizations and research centers.

The last cluster covered twenty one objects of which nine came from the Western Europe and the same number from Scandinavia[5]. There were also three companies from the European Anglosphere and one from Central and Southern Europe. The R&D narratives in this cluster had definitely operational character since they referred mainly to financial effects of activities carried out in the reported period. The companies rarely discussed on patients, therapies, clinical studies or collaboration with external partners in the R&D context which may be explained by their less strategic orientation due to the lower R&D expenses as compared to the other clusters.

Dependence of R&D narratives' context on R&D expenses and R&D intensity

Both the results of the cluster analysis and the qualitative examination of R&D narrative disclosures enabled to distinguish three subsamples differing with regard to content characters of the annual reports. It should be emphasized that the content of the examined annual reports referred to R&D accounting policy context (cluster 1), R&D strategic context (clusters 2-3) and R&D operational context (cluster 4-5). Such a division was consistent with the agglomerative hierarchical clustering approach which results were demonstrated on dendrogram (Fig. 2). In this case only two linkages were cut following the established character of R&D narrative.

The procedure applied in this stage of the research study consisted in checking whether the abovementioned subsamples came from different populations in terms of R&D expenses level and consequently whether they significantly differed between each other (Table 1).

Table 1: Analysis of R&D expenses mean ranks across the subsamples

Group no	Description	Obs. no	Mean ranks		
			R&D expenses (t-1)[1]	R&D expenses (t)[2]	R&D expenses growth (t/t-1)
1	R&D accounting policy context	4	45,0	46,75	52,25
2	R&D strategic context	17	41,9	44,12	42,65
3	R&D operational context	44	28,5	27,45	27,52
Kruskal-Wallis test			H(2,N=65) =7,96 p = 0,019	H(2,N=65) =11,78 p = 0,003	H(2,N=65) =12,26 p = 0,000
[1] 2013, [2] 2014					

Source: Own presentation.

The results of Kruskal-Wallis H test for independent variables related with R&D expenses indicated that there existed statistically significant difference (at 0.05 or 0.01 levels) in each median variable among the three subsamples which differed in terms of R&D narrative context. Due to the rejection of all null hypotheses of the Kruskal-Wallis H tests for independent variables multiple pairwise comparisons looking for stochastic dominance or median differences between particular subsamples were carried out.

The results of post hoc test evidenced that there were significant differences (at 0.05 level) between groups 2 and 3 (strategic versus operational R&D narrative) in terms of R&D expenses levels as well as R&D expenses growth in (t) and (t-1) analyzed periods (Table 2).

Table 2: Dunn's post hoc test

Pairwise comparisons	***std err***	***x-crit***	**R&D expenses (t-1)**		**R&D expenses (t)**		**R&D expenses growth**	
			d-stat	***sig***	***d-stat***	***sig***	***d-stat***	***sig***
Groups 1-2	10,51	25,15	0,29	no	0,25	no	0,91	no
Groups 1-3	9,87	23,64	1,68	no	1,95	no	**2,50**	**yes**
Groups 2-3	5,40	12,93	**2,50**	**yes**	**3,09**	**yes**	**2,80**	**yes**
k=3, d-crit = 2,39, α=0.05								

Source: Own presentation.

The conclusion is that companies which disclosed more strategically on their R&D activities had higher R&D expenses levels and growths than companies with operational R&D narrative context. Moreover, the group which reported intensively on R&D accounting policy differed with statistical relevance from the group reporting on R&D operational aspects in terms of R&D expenses growth. In this case companies which orientated on R&D accounting policy discussion had higher R&D expenses growths over the years of 2013 and 2014 than companies reporting on operational aspects.

Similar analysis was carried out in reference to R&D intensity which is measured as a ratio of R&D expenses to sales revenues (Table 3).

Table 3: Analysis of R&D intensity mean ranks across the subsamples

Group no	**Description**	**Obs. no**	**Mean ranks**	
			R&D intensity (t-1)	**R&D intensity (t)**
1	R&D accounting policy context	4	17,00	19,75
2	R&D strategic context	17	27,59	27,65
3	R&D operational context	44 (*42)	36,55	34,93
Kruskal-Wallis test			H(2,N=65)=5,80 p = 0,055	H(2,N=63)=3,82 p = 0,148
*Two companies were excluded in (t) due to a zero level of sales revenues				

Source: Own presentation.

In this case Kruskal-Wallis H test allowed to accept the null hypothesis that the subsamples came from populations with the same distribution with reference to independent variables. It means that mean ranks of the groups were the same. Therefore, there was no reason to proceed with post hoc Dunn's test. Concluding, it was proved that the subsamples did not differed statistically significant between each other in terms of R&D intensity levels.

Conclusion

It should be noticed that despite the growing significance of R&D information knowledge on how companies disclose R&D related information is limited (Merkley, 2014). Although R&D narratives often constitute an important part of annual reports of high-technology companies, in fact, they may be difficult to capture. The reason is that, with minor exceptions, R&D narratives are not well distinguished as separate sections of annual reports.

The research question developed in this study referred to relationships between the content of R&D narratives, R&D expenses and R&D intensity. In order to obtain an answer whether R&D narrative

context was related with R&D expenses or R&D intensity a non-parametric Kruskal-Wallis test was applied for searching a difference between medians and post hoc Dunn's test for pairwise multiple comparisons. The results of the study proved that the companies which disclosed strategic aspects of their R&D activities had higher R&D expenses levels and higher R&D expense growths than the companies with operational R&D narrative context. Moreover, the group that disclosed intensively on R&D accounting policy statistically differed in terms of R&D expenses growth from the group disclosing on R&D operational aspects. The empirical evidence did not supported the conjecture that intensity level may affect the R&D narrative context.

This paper contributed to the existing body of literature by applying a qualitative approach to establish the contextual meaning of the analyzed R&D paragraphs extracted from corporate annual reports. Moreover, an in-depth text analysis allowed to create of a co-occurrence network which exemplified the relations between the words in the examined text. The advantage of this study is that it applies an international context on the European level. However, there are also certain limitations, therefore, future research can upgrade and broaden the analyses. Firstly, the study focuses on biopharmaceutical companies only which was an intended limitation due to idiosyncrasy of R&D activities. The concentration on a specific sector of high-tech companies due to relative uniqueness of their R&D activities facilitates to some extent formulation of final inferences. Secondly, the study refers to R&D disclosures provided in annual reports and ignores R&D information revealed voluntary through other media such as corporate websites or press releases. Finally, a separation of R&D content from the annual report when it is not clearly distinguished in text depends on a researcher's approach and may raise a questions concerning objectivity.

Concluding, future research may search for an answer how to improve R&D disclosures transparency while balancing stakeholder needs with the protection of sensitive R&D information at the same time.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland under the programme "Regional Initiative of Excellence" 2019 - 2022 project number 015/RID/2018/19 total funding amount 10 721 040,00 PLN.

Abstract

Motivation behind conducted research was the analysis of significant international society problem, which is the effectiveness of Europe's national healthcare systems actions. To estimate this effectiveness quality, traditional analysis based on adequate indexes and measures with Data Envelopment Analysis were used. Evaluation has been performed according to objective and subjective data. It was shown that comprehensive view of the problem, which is given by DEA, is a significant amplification of fragmentary analysis performed by index analysis.

Keywords: DEA, Effectiveness, Healthcare Systems.

Introduction

The main objective of this research is to present an evaluation of the quality of national healthcare systems. For this purpose, three fundamental dimensions were analysed: praxeological (the effectiveness of therapies and treatment procedures), personal (individual health state satisfaction observed in general population), and economic (effectiveness expressed as a quotient of the product volume – in this case, the general health state – against total per-capita cost of the service rendered. Multidimensional assessment of health security systems is similar to WHO (2018) quality definition which is: "Quality health services across the world should be: Effective: providing evidence-based health care services to those who need them. Safe: avoiding harm to people for whom the care is intended. People-centred: providing care that responds to individual preferences, needs and values. In order to realize the benefits of quality health care, health services must be timely, equitable, integrated and efficient". Recently, public health state is analyzed depending on variety of environmental factors. Samut and Cafri (2016), besides DEA analysis method, investigated dependency of health status of population and Education expenditure in tertiary and incomes also. Dhaoui (2019) analyzed national health status according to Literacy rate, which is HDI component, and urban population percentage. Aside from the unidimensional analysis of the above, the last part of this paper presents a comprehensive analysis of effectiveness of selected national healthcare systems based on the DEA method (*Data Envelopment Analysis*). Most studies evaluating hospital efficiency have performed an efficiency analysis, using DEA. Mobley and Magnussen (1998), Retzlaff-Roberts et al. (2004) and Spinks and Hollingsworth (2009), are among such studies. Retzlaff-Roberts et al. compared health care results in OECD countries by DEA. For the national healthcare systems performance assessment as inputs were used: Number of beds, MRI – Magnetic Resonance Imaging, Physicians, Expenditure, Social environment inputs (School expectancy, Gini of income distribution, Tobacco). For the Health status outputs: Infant mortality and Life expectancy. Or (2001) measured population health status by the premature mortality counted by PYL.

Analytical evaluations were conducted for a selection of 20 European countries, divided into four groups. The first group, labelled as Postcom, included selected representatives of the Visegrad Group (Poland, Hungary, Slovakia, and Czech Republic) accompanied by several other countries of the former Eastern Bloc, namely: Latvia, Lithuania, Estonia and Slovenia. The second group included countries of the so-called Old Europe: France, Spain, Germany, Portugal, Great Britain, and Italy – labelled as Old EU. The third group included Nordic states typically associated with high level of social welfare: Denmark, Finland and Sweden. The last group was that of small and affluent countries of the Western Europe: the Netherlands, Austria and Switzerland. Data on the remaining countries of the European geographic area was not adequate enough to allow for their inclusion in the study.

Theoretical Framework

"The most fundamental problem in determining the 'satisfactory level of healthcare services' and the requirements of the strategic decision-making process within the analysed sector depends a lot on the environment. Modern healthcare systems operate in an unstable environment resulting from the following social transition factors (Walshe and Smith 2006):

- Demographic changes (ageing societies),
- Fast pace of technological innovations,
- Changing (more demanding) expectations of patients and society,
- Increased costs as a consequence of previous factors.

In addition, the problem's complexity is further enhanced by the scarcity of budget support for the operation of healthcare institutions, evident particularly in the post-communist states. In effect, the effectiveness of national healthcare systems will be strongly influenced by the quality of solutions offered by the respective governments, particularly by their accord with the principles of economic effectiveness, operational efficiency, and social justice (Fukuyama 2005).

In a strictly economic approach, the state of human health is perceived both in terms of capital goods (or, more specifically, an element of human capital that may affect their economic welfare) and consumer goods (with potential to directly affect their well-being). For the majority of global human population, health remains one of the most fundamental constituents and determinants of a happy life." (Biernacki 2017).

The responsibility for maintaining a satisfactory level of public health rests with public healthcare service systems. In accordance with WHO recommendations, the primary purpose of activities conducted by these systems is to 'promote, restore and/or maintain health'. After H. Laframboise (1973), M. Lalonde (1974), general condition of public health is determined by the following: genes, environment, life style, and public health system organization. Badura (1995) provides evaluations of the relative impact of the above factors, measured by mortality rates related to various health conditions. For example, in the group of cardiovascular conditions, mortality rates attributed to each of the factors were as follows: 25% (biology), 9% (environment), 54% (life style) and 12% (healthcare); for cancer, the findings were: 29%, 24%, 37% and 10%, respectively. While the above estimations are based on statistical data from the 1990ies, the fact of the matter remains: public health is affected by the organization and the effectiveness of the public healthcare system; and this impact, while not decisive, is fairly significant. Khaew et al. (2008) showed strong dependency between lifestyle and mortality by analyzing healthcare data of a group over twenty thousand English citizens, men and women. Colpani and others (2018) by analyzing health data of sick women received similar results.

The main task faced by health economics is to determine whether public healthcare services on offer are effective in improving the general state of public health in entire populations. Apart from the attribute of effectiveness, the services are also examined from the viewpoint of social justice, to ensure that distribution of general public health benefits across various segments of population is fairly equal.

The Praxeological Dimension – The Effectiveness of Treatment

The effectiveness of treatment is best measured by outcome indices, i.e. measures regarded as the best approximations of quality evaluation. Two separate measures were selected for this purpose, namely: EHCI and HLY.

The Euro Health Consumer Index (EHCI), a measure calculated and reported annually by Health Consumer Powerhouse since 2004, was used for assessing the effectiveness of national healthcare systems in Europe. The idea of the measurement is to assess the efficiency of healthcare service provision from a patient's viewpoint. In 2012, the assessment included five categories: 1. Patient's rights and information, 2. Waiting time for treatment, 3. Effects of treatment, 4. Scope and range of the provided services, and 5. Pharmaceuticals. There were a few or even a dozen or so subcategories distinguished in each category. For instance, the 'effects of treatment' category included the following subcategories: 3.1. Real mortality caused by heart failure, 3.2. Infant mortality, 3.3. Number of deaths caused by neoplastic disease in relation to the associated incidence rates, 3.4. Potential years of life lost, 3.5. MRSA infections, 3.6. Suicide rate decrease index, 3.7. Percentage of diabetic patients with high diagnosed levels of glycated haemoglobin HbA1c[1].

Average values of the EHCI index in analysed groups of countries are presented in Fig. 2.

It may be worth noting that all the groups under examination displayed a marked increase of the EHCI index over the period under study, suggesting a noticeable improvement of effectiveness in the operation of national healthcare systems. In addition, and over the entire period under examination, national healthcare systems of post-communist countries received markedly lower scores from patients compared to those in the remaining groups of countries.

Fig. 2: Average values of the EHCI index in analysed groups of countries

Human well-being is, to a large extent, a function of good health. Moreover, health condition largely determines human performance at work and in education-related tasks. One of the most adequate measures of health condition is the healthy life years index (HLY). To a certain degree of simplification, it may be observed that – while the life expectancy index measures life longevity – the HLY index can be seen as a gauge of life quality (Jagger 2008). Therefore, the authors decided to employ the HLY as a measure of general health condition in societies under study. Table 1 provides an overview of HLY scores and dynamics indices obtained in the study.

Table 1: Healthy life years in absolute value at birth

Group of countries	2006	2009	2012	2015	2017	2017/2006
Post-communist	55.89	57.59	58.25	57.41	58.41	1.045
Old EU	62.43	61.54	62.68	62.79	64.48	1.033
Nordic	62.62	63.22	62.23	63.58	62.67	1.001
Small affluent	62.88	61.72	63.55	58.83	57.87	0.920

Source: own research using Eurostat data.

General health condition in large and affluent countries of Europe, including the Nordic group of social welfare countries, is ostensibly superior to that observed in the remaining countries of the analysed sample. It must be noted, however, that the most pronounced dynamics of HLY growth was observed among the least affluent countries of Europe (Postcom). This trend can be attributed to the radical lifestyle improvements brought about by systemic transformations and to mass popularisation of modern methods of prevention against civilizational diseases (cardiovascular and neoplastic).

Effectiveness of treatment is strongly correlated with the total expense assigned in support of the national healthcare system (Leigh, Jencks and Smeeding 2011). Figs. 3 and 4 present the respective ratios of EHCI and HLY to national health costs for each of the analysed group of countries, to serve as gauges of the systems' effectiveness. For our purpose, national healthcare costs (total expenditure volumes) were backdated by 2 years in relation to their corresponding EHCI and HLY values.

Fig. 3: The effectiveness of national healthcare systems – EHCI/cost

Source: own research using online data published by the OECD and the Eurostat.

Fig. 4: The effectiveness of national healthcare systems – HLY/cost

Source: own research using online data published by the OECD and the Eurostat.

The observed prominence of effectiveness values for the Postcom group attests to a decidedly lower level of financing received by their national systems in relation to the levels registered in other European countries. This effect is produced by the markedly lower share of GDP directed to healthcare services in this group of countries. For a detailed analysis of national healthcare systems' effectiveness, see section four below.

Fig. 5 presents total per capita cost of national healthcare services in the analysed groups of countries. It must be remembered that per capita values registered in Postcom countries are significantly lower compared to the other groups.

Fig. 5: Total per capita cost of national healthcare services in $ PPP

Source: own research using online data published by the OECD.

The Personal Dimension

To evaluate the effectiveness of resource utilization by national healthcare systems, the findings related to improvement of social health (measured by EHCI and HLY) should be examined against those

related to equity in social distribution of health (i.e. in general health condition) (Morris, Devlin and Parkin 2007). This aspect of social justice has long been emphasised in the British NHS (National Health Service). According to some experts in health economy (Williams and Cookson 2000), equity of health has to be distinguished from equity in access to healthcare protection, as excessive focus on health protection may result in poor representation of other effective methods of health improvement, such as disease prevention and propagation of healthy lifestyle choices. For the above reasons, this study employed a measure of general health condition – an analogue of the abridged Sen's social welfare function (1973) $\mu \cdot (1 - G)$, where μ represents average subjective state of health, and G – the Gini coefficient of the distribution of public self-perceived health.

The problem of equity and justice in relation to health is associated with the principle of inequality decrease in the distribution of health across populations. The Gini coefficient served to evaluate the degrees of inequality in our study. Since 2009, the Eurostat has published annual updates of *Self-Perceived Health* surveys, measured on a scale from 1 to 5. Based on these records, Fig. 6 presents subjective distribution in public self-perception of health, and Fig. 7 – values representing inequality in public distribution of subjective health for the analysed groups of countries.

The largest distance of inequality in the distribution of public self-perceived health between analysed groups was observed at the onset of the period under study (i.e. in the year 2009) and amounted to 6 percentage points; at the end of the analysed period (i.e. in the year 2018), it was reduced to 4 percentage points. This represents a clearly positive trend, particularly in the light of the relatively constant inequality in the distribution of income in Europe (between 0.303 – 0.31, according to the Eurostat).

Fig. 6: Public self-perceived health

Source: own research using online data published by the Eurostat.

Fig. 7: Inequality in public distribution of subjective health
Source: own research using online data published by the Eurostat.

Similarly to the procedure described in the earlier section, the final stage of the process involved analytical evaluations of healthcare systems' effectiveness, measured as a quotient of public self-perceived health divided by total expenditure volumes (backdated by 2 years), as presented on Fig. 8.

Fig. 8: The health/expenditures quotient
Source: own research using online data published by the OECD and the Eurostat.

The economic dimension – total effectiveness of national healthcare systems

As already noted in an earlier section, total expenditures assigned to national healthcare systems are strongly correlated with effectiveness of treatment measured on national levels by the EHCI index. This observation raises a question whether such cost can also be related to general health condition (as measured by the HLY index) or to public self-perceived health (expressed by $\mu \cdot (1 - G)$). This question

is particularly important in the light of the fact that evaluation of national healthcare systems is commonly examined on the basis of relations between these measures (EHCI, HLY and μ·(1 – G)) and the aforementioned total expenditures (cf. Figs. 3, 4 and 8).

Another question arising in association with the above dilemma is whether public expenditures in support of national health systems affect the aforementioned measures in an immediate fashion or is this effect delayed in time? And to what extent, if the latter holds true? Studies of professional literature have yet to provide a satisfactory answer to this question (Or 2001). This study aimed to tackle both questions by means of an analytical evaluation of correlations between the collected data segments[2]. For this purpose, the authors analysed Pearson's linear correlation coefficients between total expenditures and each of the data segments (EHCI, HLY and μ·(1 – G)), both for the same period and for periods representing a delay of one, two, and three years, respectively. The procedure also involved segmentation of total expenditures in two segments, representing two principal sources of healthcare funding, namely: private and public expenses. This step was designed to improve the depth of subject analyses.

This part of the study revealed that the findings had been of comparable quality, suggesting that the strength of correlations between the respective values had been largely unrelated to changes in the calculation of correlation coefficients (immediate vs. delayed)[3]. Based on this observation, the authors gained a greater degree of freedom in selecting a suitable approach to the task at hand. One other question remains: are the coefficient values significantly departing from zero values. Or in other words: are the correlations strong enough? Ultimately, the authors decided to adopt values representing expenses in private and public dimension, with a delay of two years in relation to the respective EHCI, HLY and μ·(1 – G) values, in line with the course of action previously adopted for the construction of effectiveness measures of national healthcare systems presented on Figs. 3, 4 and 8. Due to gaps in data, this level of delay offered the broadest available period of analytical evaluation[4]. Values of the resulting Pearson's linear value coefficient are presented in Tab. 2. In addition, a KPSS test was performed to test stationarity of EHCI, HLY, μ·(1-G) and of the private and public expense time series and the result is that all these time series are level-stationary on significance level equal to 0.05.

Table 2: Coefficients of correlation between private/public expenses taken with a delay of two years and the respective values of EHCI, HLY and μ·(1 – G)

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
r(w_priv,EHCI)	0.652	x	x	0.519	0.663	0.611	0.658	0.643	0.597	0.614
r(w_publ,EHCI)	0.915	x	x	0.853	0.907	0.845	0.842	0.825	0.843	0.853
r(w_priv,HLY)	**0.360**	0.387	0.394	0.491	**0.127**	**0.116**	**0.155**	**0.065**	**0.032**	x
r(w_publ,HLY)	0.562	0.544	0.475	0.510	**0.299**	0.402	0.492	0.384	**0.267**	x
r(w_priv,μ·(1-G))	**0.369**	**0.357**	**0.307**	**0.219**	**0.213**	**0.163**	**0.233**	**0.162**	**0.301**	**0.243**
r(w_publ,μ·(1-G))	0.456	0.442	0.386	0.389	0.428	0.423	0.446	0.418	0.528	0.479

*Note: x – missing data, **bold** – statistically insignificant coefficients (at a significance level of 0.1).*
Source: own calculations, based on collected data.

It may be useful to note that all the correlations are positive, in line with economic intuition and suggestive of a trend that values of EHCI, HLY and μ·(1 – G) increase significantly with increases of expenditures from both sources. This seems to satisfy the precondition for further analyses of effectiveness of national healthcare systems conducted on the basis of the DEA method. It must be emphasised, though, that in some cases the values of coefficients are statistically insignificantly different from zero. This applies in particular to correlations between private expenditures and HLY and μ·(1 – G), respectively. In view of their values being insignificantly different from zero, coefficients of correlations between private expenditures and HLY for the years 2016-2017, the authors decided to remove the category of HLY from further examination[5]. In addition, due to the unavailability of EHCI index data for the years 2010-2011, the initial period of effectiveness analyses was reduced

to include the years 2012-2018 only (cf. Fig. 2). In the earlier sections, the effectiveness of national healthcare systems was analysed in relation to total levels of health expenditure (i.e. without division into those funded from private and public sources) and separately for each of the selected measures of EHCI, HLY and $\mu \cdot (1 - G)$. In this context, it may be valuable to examine the total effectiveness of all the studied systems in relation to each of the statistically significant categories. As already mentioned, the category of HLY had ultimately been rejected as practically unrelated to the level of private health expenditures.

For the task at hand, an output-oriented BCC model in the envelopment form was employed (Banker, Charnes and Cooper 1984), representative of the DEA methodology. DEA models are classic examples of input-output models, therefore our method required proper attribution of input and output roles among each of the studied categories. In line with earlier observations, the group of inputs will be represented by public and private health expenses, while outputs will be populated by the respective EHCI and $\mu \cdot (1 - G)$ values.

The analytical evaluations were based on a model construed on the assumption of variable returns to scale, to allow for analyses of national systems of varied scale and on varied stages of development. With the adoption of an output-oriented model, main analytical focus was placed on the examination of potential for increases in the values of EHCI and $\mu \cdot (1 - G)$ at a predetermined volume of both types of expenditures (taken with a two-year delay). If such potential exists, it would mean that the effectiveness of the associated national system is not yet fully realized. The degree of ineffectiveness will then be expressed un our measure by a value in excess of 1, calculated from the above model. When the value of the measure equals 1, the associated system is deemed as fully effective.

Table 3 presents values of our measure of effectiveness over the period under study (the years 2012-2018). In order to retain proper correspondence with the previous segments of the study, the results were aggregated to represent each of the four groups of countries. Geometric mean was selected for the purpose, due to the multiplicative and ratiometric character of the utilized measure.

Table 3: Average measures of effectiveness of national healthcare systems for each of the four studied groups of countries

	2012	2013	2014	2015	2016	2017	2018
Postcom	1.0252	1.0229	1.0193	1.0324	1.0203	1.0235	1.0243
Old EU	1.1200	1.0568	1.0578	1.0729	1.0492	1.0430	1.0346
Nordic	1.0235	1.0188	1.0110	1.0213	1.0231	1.0206	1.0103
Small affluent	1.0502	1.0305	1.0381	1.0370	1.0347	1.0279	1.0244

Source: own calculations, based on collected data.

Analytical findings suggest that, over the studied period, the most effective national healthcare systems were those in the Nordic group of countries, which may come as no surprise given their renowned status of social welfare states. Post-communist countries came as second in terms of their system's effectiveness, and even placed on the top of the ranking in the year 2016. However, in the authors' opinion, the reasons behind their 'good score' are quite distinct, as the group is characterised by the lowest level of total healthcare expenditures (cf. Fig. 5), while at the same time retaining the highest level of effectiveness, measured separately for each of the studied categories (cf. Figs. 3, 4 and 8). This means that the high effectiveness in this group may be attributed to the fact that – at such low funding – higher values of both EHCI and $\mu \cdot (1 - G)$ taken with two-year delay are quite simply unachievable.

The third position on the effectiveness ranking is occupied by 'small and affluent' countries, with average effectiveness scores improving significantly over the analysed period and remaining – in authors' opinion – on a relatively high level. Even in the most adverse period (that is: in the year 2012), values of both the EHCI and $\mu \cdot (1 - G)$ may potentially be improved by not more than 5%, at a predetermined level of public and private healthcare expenditures recorded for the year 2010[6].

The last place on the ranking is occupied by countries of the Old EU, but also in this case notable improvements can be observed over the analysed period. It must be noted, however, that this score is quite distinct from the one determined on the basis of separate evaluations of EHCI, HLY and μ·(1 – G) indices (cf. Figs. 3, 4 and 8), where Old EU placed second, right behind the Postcom group. This means that analytical evaluations of joint effectiveness of a national healthcare system produced on the basis of all significant categories may provide results quite diverse from those produced separately for each category, in line with the approach presented in previous sections of this study. Regardless of our selection of the second-degree delay between inputs and outputs, decided on the grounds of separate analyses of correlation, it leaves us with the still unresolved question on the aptitude of our decision, this time in the context of the findings. Would our procedure yield significantly different results if the inputs were delayed in relation to outputs by a different degree or with no delay whatsoever?

To address this question, the last part of the study was devoted to analytical evaluation of the results' susceptibility to the degree of delay between expenditures and the values of EHCI and μ·(1 – G). Results of this part of our inquiry are presented in Tab. 4.

Table 4: Values of effectiveness measures for analysed groups of countries, in relation to the degree of delay between inputs and outputs of the model employed in the study

	2012a	**2012b**	**2012c**	**2012d**		**2015a**	**2015b**	**2015c**	**2015d**

Small affluent	1.0313	1.0311	1.0305	1.0300	Small affluent	1.0360	1.0360	1.0347	1.0325
	2014a	2014b	2014c	2014d	Note 1: Letters a, b, c, d are used to represent models with: no delay, and delays of the first, second and third degree, respectively.				
Postcom	1.0147	1.0164	1.0193	1.0201					
Old EU	1.0525	1.0535	1.0578	1.0623					
Nordic	1.0094	1.0093	1.0110	1.0113	Note 2: **Bolded** values represent measure values in the distance of less than 0.01. Comparisons were made in rows, i.e. between models.				
Small affluent	1.0398	1.0373	1.0381	1.0387					

Source: own calculations, based on collected data.

First of all, it must be noted that, due to the already noted gaps in source data, the period of effective analysis was narrowed down to the years 2012-2016. It is evident that average values of measures within each group only sporadically display variance of more than 0.01 when the only differing value is the degree of delay between the model's inputs and outputs[7]. The case in question is evidenced by values for the Postcom group (years: 2013 and 2015-2016) for Old EU (years: 2012-2013). Furthermore, differences of more than 0.01 do not apply to all four of the analysed groups, but are only observed for two or (in one case) three groups.

To sum up, the adoption of the second degree delay between inputs and outputs does not seem to impose any significant impact upon the results, at least in these authors' opinion and with a few exceptions. In closing, it may be useful to note that the significant gaps in source data, as already

mentioned, had the effect of ruling out the prospect of broader analyses of both the initial correlations and the resulting susceptibility of results to degrees of delay in excess of the three-year margin.

Conclusions

On the basis of the available data provided by the EUROSTAT and POWERHOUSE in relation to general health condition of European societies and data related to national levels of healthcare expenses (OECD) it can be observed that European countries, just like the majority of countries on a global level, seem to fall in line with the trend where increases in health expenditures correlate with increased satisfaction from the service (as evidenced by EHCI values presented on Fig. 2, by per-capita expenditures – Fig. 5, and by public self-perceived health – Figs. 6 and 7). This leads us to the observation that the increase in spending does not necessarily produce a comparable improvement in perceived health, as measured by the HLY index. This is, without doubt, evidence of the M. Lalonde's (1974) effect, where public self-perception of health is believed to be mostly affected by lifestyle, environment, and genetic predisposition, with national healthcare system regarded as the least important factor in this context. It is also worth noting that the post-communist countries, characterised by the drastically lowest level of healthcare spending, display the highest dynamics of HLY growth, in consequence of their rapid transformation, increased awareness and lifestyle improvements, accompanied by effective prevention of modern civilizational diseases (cardiovascular and neoplastic). While this group also displays the most pronounced disparities in public self-perception of health, the present trend shows significant improvement in this respect.

Joint effectiveness of national healthcare systems in the European countries included in this study is of a fairly high level. The least pronounced effects in this context can be observed among representatives of the Old EU, but their effectiveness has also showed a steady increase over the studied period. It must be remembered, however, that the reasons for the increased effectiveness observed in the Postcom group are quite different from those observed in other groups, as the Postcom countries are characterised by a radically lower level of healthcare spending. At such low levels, higher values of both the EHCI and of the self-perceived health adjusted by differences in health as measured by $\mu \cdot (1 - G)$ are quite simply unachievable. For this reason, national health systems of the Postcom group were deemed as effective at their present level of healthcare expenditures.

Future research should conduct national healthcare systems performance analysis depending on manner of funding and its amount. Additionally, it is planned to investigate the impact of environmental factors on quality, work of healthcare system (it's effectiveness) and its productivity. The time of a worldwide pandemic has shown that for public healthcare condition we are responsible personally.

[2] That is: not in general, but in relation to the specific empirical study discussed in this paper.
[3] Results of this part of the study are available upon request.
[4] These include missing data for the volumes of private and public expenses in the years 2017-2018, EHCI values for the years 2010-2011, and HLY values for the year 2018.
[5] It may also be useful to note that the HLY category was found to be insignificantly correlated with public expenses in the years 2013 and 2017, respectively. In addition, due to missing data, calculations of correlations and effectiveness for the year 2018 could not be performed.
[6] This can be seen as evidence of clear interpretation of this measure, and a source of information of supplementary value for analyses of economic effectiveness.
[7] The threshold value 0.01 was set in an arbitrary fashion. In these author's subjective opinion, and with the given set of values, differences in the range of 0.01 and below can be regarded as negligible, particularly in view of the fact that the employed measures of effectiveness represent *average* values for the studied groups of countries.

Acknowledgment

Abstract

The article analyzes the key technologies of Industry 4.0, as well as their role in resolving the contradictions of socio-economic development. An integral indicator of the density of implementation of Industry 4.0 technologies is proposed for ranking the studied countries of the world. The ranking results indicate that the world's economies are differentiated by the level of implementation of Industry 4.0 technologies. This carries the risk of further strengthening the multipolarity of the global economy and increasing inequality. It is proved that the further development of Industry 4.0 may cause the appearance of new environmental restrictions and the emergence of cyber threats. Research methods: methods of logical and theoretical research (analysis, synthesis, comparison, generalization), methods of systematization, method of calculating an integral indicator based on the analysis of the standard deviation from the maximum values in each group of indicators.

Keywords: Industry 4.0, socio-economic development, contradictions, demographic problems, multipolarity of the global economy

Introduction

Each new stage of scientific and technological progress leads to a change in the paradigm of social development and the emergence of new contradictions of a socio-economic nature. Thus, the first industrial revolution caused a complete technological replacement of machines and equipment, the second industrial revolution led to the mass introduction of technologies based on the production and use of electricity, the third industrial revolution was based on automated technologies that provided almost complete replacement of industrial equipment. Industrial revolutions also caused significant changes in the structure of society, rapid urbanization of the population, growth in labor productivity, global change and re-profiling of labor resources and, as a result, an increase in the living standards of the population.

The next stage in the development of the world economy was the fourth industrial revolution or Industry 4.0, associated with the emergence of digital control systems, as well as the increased integration of "cyberphysical systems" in production processes.

These technologies probably have a great potential that can solve numerous problems of socio-economic development at the current stage. However, according to Klaus Schwab, the President of the World Economic Forum, "the problems associated with the fourth industrial revolution coincide with the rapid emergence of new environmental restrictions, the strengthening of the multipolarity of the international order and the growth of inequality» (Schwab, 2018). This allows us to make an assumption about the possible negative consequences of the impact of Industry 4.0 technologies on the global economic system.

Thus, the study of the nature of the impact of Industry 4.0 technologies on the world economy is currently becoming particularly relevant.

Methodology

The research hypothesis is based on the assumption that the development of Industry 4.0 is a natural stage in the evolution of the world economy in response to the existing contradictions of socio-economic development associated with global demographic changes (population aging and urbanization), as well as with a decrease in economic stability due to a slowdown in labor productivity and inefficient use of resources. The existing potential of Industry 4.0 technologies, on the one hand, makes them a tool for overcoming these contradictions, and on the other hand, it can cause the emergence of new environmental restrictions, the strengthening of the multipolarity of the global economy and the growth of inequality, as well as the emergence of cyber threats.

Schmidt and Cohen (2013) introduced the concept of the "digital age", which is associated with the active development and implementation of information and communication technologies (ICTs), covering a variety of software and hardware and related processes. Boyd and Crawford (2012) note that digitalization is changing the way people interact with each other and with their natural environment. Zuboff (2015) points to the transformation of the corporate landscape under the influence of new technologies.

Initially, the concept of Industry 4.0 (I40) appeared in Germany as a national strategic initiative of the government (European Commission, 2017). This concept was aimed at advancing digital manufacturing by increasing digitalization and interconnection of products, services, value chains and business models. The concept was designed for 10-15 years (starting in 2010). In the future, this concept was taken as the basis for implementing digital transformation in various countries of the world. The concept of Industry 4.0 is based on the use of information and communication technologies for intelligent networking of machines and processes that ensure the needs of industry through flexible production convertible factory (modular building production lines to improve performance), customer-oriented solutions (convergence of consumers and producers), optimized logistics, use of data and resource-efficient circular economy (Davies, N. And Schwab K., 2018, Haberer, S. et al., 2017). The success of implementing the new industrial Industry 4.0 will be based on the flexibility and sensitivity of national economic institutions to the upcoming transformations, which will require widespread changes in the legal regimes for the use of new components of the industry (Gokhberg et al., 2017).

Issues of digital security and information protection, as well as the creation of powerful technological bases for the development of components of new technologies are reflected in the works Smit et al. (2016).

Researchers have different assessments of the impact of new technologies on the socio-economic system and its security. Some scientists see the positive potential of information and communication technologies in solving problems of socio-economic development of society (Gijzen, 2013, Hampton et al., 2013). Others emphasize the growing vulnerability of the system and the possibility of information, economic and social threats (Helbing, 2012, Karpunina et al., 2019).

Research methods: methods of logical and theoretical research (analysis, synthesis, comparison, generalization), methods of systematization, method of calculating an integral indicator based on the analysis of the standard deviation from the maximum values in each group of indicators.

Results

Contradictions of socio-economic development as a condition for the development of Industry 4.0.

1) Global demographic changes, which consist of a process of continuous population aging, especially in developed countries, as well as continuing urbanization.

Thus, the share of the world population over 60 years of age from the total population is (in%): 1950-8%, 2000-10%, 2050 (according to forecasts) - 21% (PwC, 2017a). If we analyze the ratio of the old population (65 years or more) to the population of 15-64 years, we can see the trend of population aging. If the global average was 0.113% in 2005, it was 0.137% in 2018, meaning that the global aging trend is not so disastrous. However, an analysis of the dynamics of this indicator by country shows a more negative picture (table 1).

Table 1: Assessment of population ageing through estimation of changes in the ratio of dependents in the old age (65 years and older) to the population of 15-64 years (OECD Data, 2019)

Country	Old age dependency ratio (65 and over/15-64)		Assessment of population ageing through assessment of changes in the dependency ratio in old age (65 years and older/15-64)
	2005	2018	
Japan	0,305	0,472	0,167
Finland	0,239	0,347	0,108
Czech Republic	0,199	0,3	0,101
Netherlands	0,21	0,292	0,082
Portugal	0,259	0,336	0,077
Canada	0,181	0,257	0,076

Greece	0,276	0,344	0,068
Poland	0,188	0,255	0,067
United States	0,185	0,245	0,06
European Union (28 countries)	0,248	0,307	0,059
OECD - Total	0,207	0,264	0,057
Italy	0,297	0,354	0,057
Sweden	0,264	0,318	0,054
China	0,106	0,157	0,051
Germany	0,284	0,33	0,046
Australia	0,193	0,239	0,046
United Kingdom	0,241	0,287	0,046

Austria	0,239	0,281	0,042
Switzerland	0,234	0,276	0,042
Norway	0,224	0,262	0,038
Brazil	0,098	0,133	0,035
Belgium	0,262	0,293	0,031
Turkey	0,102	0,127	0,025
World	**0,113**	**0,137**	**0,024**
Russia	0,194	0,218	0,024
Mexico	0,089	0,109	0,02
India	0,076	0,093	0,017

This problem is most relevant for Japan (an increase in the aging rate by 0.167%), Finland, the Czech Republic, and the Netherlands. The population is aging at an accelerated rate in the countries that are leaders in terms of national economies – the United States, China, Germany, and the United Kingdom. The aging population of developed countries significantly affects the global economy, creating prerequisites for the active introduction of new technologies and modernization of production processes.

The dynamics of the indicator "the share of the world's urban population in the total population, %" helps to characterize the process of urbanization: in 2010, the value of this indicator was 50%, by 2050 it is expected to increase to 72% (PwC, 2017a). The process of urbanization leads to an increase in current market segments, as many companies not only expand the geography of their market presence due to the emergence of large infrastructure projects, but also form new market segments.

2) The reduction of labor productivity in industrial production and the presence of fragmented demand for its products requires the modernization of production, including through the introduction of high-tech innovative innovations.

Let's analyze labor productivity and its dynamics, and use the GDP per employed person indicator from 1978 to 2018 (in US dollars, in constant prices in 2015) (OECD Data, 2019). We will select countries at random in order to maximize coverage of highly developed countries and a number of developing countries (table 2).

Table 2: Dynamics of labor productivity based on the analysis of GDP per employed person from 1978 to 2018 (in US dollars, in constant prices in 2015) (created by the authors, source: OECD Data, 2019)

Country	GDP per person employed Dollars USD, constant prices, 2015 PPPs					
	1978	1988	1998	2008	2018	GDP growth per employed person for 2018 to 1978 as a percentage
China	1 445,6	2 803,2	6 030,9	14 836,3	31 021,8	2 046,0
Korea	14 605,1	27 141,2	43 603,6	65 013,5	78 609,5	438,2
Turkey	30 565,4	39 036,9	48 672,6	67 076,5	79 884,9	161,4
Finland	45 040,6	59 926,9	79 935,6	95 044,3	95 313,9	111,6
Sweden	51 138,0	60 223,9	76 902,9	93 270,7	100 965,5	97,4

Japan	41 194,5	58 573,7	66 795,7	74 694,7	77 073,5	87,1
United Kingdom	49 332,4	61 832,4	74 165,1	86 603,6	89 848,6	82,1
Norway	64 920,5	77 848,2	102 239,3	113 335,9	117 552,9	81,1
United States	69 506,0	78 523,8	94 226,8	110 676,0	123 570,7	77,8
Austria	58 974,2	72 729,7	89 536,9	102 066,7	102 891,0	74,5
Denmark	58 544,3	68 664,6	83 617,6	91 611,4	101 493,7	73,4
Portugal	39 158,5	47 285,2	56 878,0	64 017,9	67 644,0	72,7
Belgium	67 157,9	82 081,5	96 577,1	108 381,0	113 583,7	69,1
France	61 557,2	74 903,9	87 059,7	96 177,8	101 715,7	65,2
Australia	58 815,8	65 992,7	79 199,8	86 853,0	93 993,5	59,8
Germany	61 961,8	68 874,7	81 292,2	89 065,8	92 354,4	49,1
Netherlands	67 791,9	74 030,8	83 686,6	94 323,9	98 154,6	44,8
Canada	63 246,8	67 414,3	75 107,6	82 903,7	89 074,5	40,8
Italy	65 528,5	81 390,7	95 407,6	94 926,8	91 765,0	40,0
Switzerland	85 045,3	89 148,8	97 436,0	108 836,2	111 479,4	31,1

According to the authors, the table data shows that the largest growth in labor productivity over the past 40 years was observed in China (20 times growth), South Korea (4.4 times growth), Turkey (1.6 times growth), Finland (1.1 times growth), as well as in Sweden, Japan, United Kingdom, Norway and the United States. The lowest growth in labor productivity is typical for Germany, Netherlands, Canada, Italy, and Switzerland. In addition, it can be argued that the US economy has the highest labor productivity (123 thousand us dollars per employed person) and Norway (117 thousand US dollars). China has the lowest indicator (31 thousand US dollars).

We will conduct an additional analysis of this trend and divide the GDP per employed person indicator into ten-year cycles (OECD Stat, 2019) (table 3).

Table 3: Dynamics of GDP per employed person in term of ten-year cycles (created by the authors, OECD Data, 2019)

Country	GDP growth per employed person from 1978 to 1988 as a percentage	GDP growth per employed person from 1988 to 1998 as a percentage	GDP growth per employed person from 1998 to 2008 as a percentage	GDP growth per employed person from 2008 to 2018 as a percentage	Change in the dynamics of GDP growth per employed person for the period 2018 to 2008 and for the period 1988 to 1978, % growth
China	93,9	115,1	146,0	109,1	15,2
Canada	6,6	11,4	10,4	7,4	0,9
United States	13,0	20,0	17,5	11,7	-1,3
Switzerland	4,8	9,3	11,7	2,4	-2,4
Australia	12,2	20,0	9,7	8,2	-4,0
Netherlands	9,2	13,0	12,7	4,1	-5,1

Denmark	17,3	21,8	9,6	10,8	-6,5
Germany	11,2	18,0	9,6	3,7	-7,5
Turkey	27,7	24,7	37,8	19,1	-8,6
Sweden	17,8	27,7	21,3	8,2	-9,5
Portugal	20,8	20,3	12,6	5,7	-15,1
France	21,7	16,2	10,5	5,8	-15,9
Norway	19,9	31,3	10,9	3,7	-16,2
Belgium	22,2	17,7	12,2	4,8	-17,4
United Kingdom	25,3	19,9	16,8	3,7	-21,6
Austria	23,3	23,1	14,0	0,8	-22,5
Italy	24,2	17,2	-0,5	-3,3	-27,5
Finland	33,1	33,4	18,9	0,3	-32,8
Japan	42,2	14,0	11,8	3,2	-39,0
Korea	85,8	60,7	49,1	20,9	-64,9

This approach confirms the conclusion that productivity is declining in most countries, with the exception of China and Canada. The decade of maximum productivity growth in most of the analyzed countries is observed from 1988 to 1998, and the lowest efficiency was in the last decade from 2008 to 2018. Germany allowed labor productivity to fall from 18% of GDP growth per employed person in the growth decade (1988-1998) to 3.7% in the decade of weak labor productivity (2008-2018). In the US, productivity declined from 20% to 11.7% of GDP growth per employed person, in the UK-from 20% to 3.7 %, in Sweden-from 27.7% to 8.2%, in Norway - from 31.3% to 3.7%, in Finland - from 33.4% to 0.3%, in South Korea - from 61% to 21%, in Canada-from 11.4% to 7.4%.

Industry 4.0 technologies and their role in resolving the contradictions of socio-economic development.

Industry 4.0 is represented by the following key technologies: Internet of things technologies; 3D printing technologies; artificial intelligence interfaces; cloud computing technologies; mobile devices; virtual and augmented reality technologies; location technologies; big data analysis technologies; distributed registry technologies-blockchain; quantum computing technologies; detection and authentication tools; smart sensors; drones, etc. (PwC, 2018).

The above-mentioned technologies of Industry 4.0 ensure the transformation of production due to the following technological trends: network integration, intellectualization and flexible automation of the technological process (Haberer et al., 2017). At the same time, network integration technologically provides communication between individual network nodes or production facilities, as well as facilitates access to information. Intellectualization helps to automatically track the occurrence of specified events and provides prompt provision of information for decision-making, and flexible automation, in turn, includes response mechanisms in the production process - automation and remote control of the technological process. In turn, the transformation of production processes using Industry 4.0 technologies leads to the restoration of positive trends of stable productivity growth in the world economy and should help to solve old problems of economic security – resource scarcity, population aging, reducing the overall efficiency of economies and reducing the human resources potential of many developed countries (table 5).

Table 5: Key technologies of Industry 4.0 and their role in resolving contradictions of socio-economic development (created by the authors)

Key Industry 4.0 technologies	Applications of Industry 4.0	The role of technology in resolving the contradictions of socio-economic development
Blockchain is a distributed database system that uses algorithms to reliably record transactions without the ability to replace or edit them	* Identification and access control • P2P transactions •Supply chain management • Smart contracts • Traceability and permanence of information • Secure login asset / property rights	According to experts, the introduction of blockchain in the financial industry can reduce losses associated with fraud by $ 15-20 billion per year (Santander, 2015). According to Bain & Company, blockchain can effectively reduce the size of the trade Finance deficit and lead to an increase in global trade by $1.1 trillion. Mass adoption of blockchain technology can increase exports of the Asia-Pacific region by $ 257 billion per year (World Economic Forum, 2018).
Drones are flying or water-based devices and vehicles piloted remotely	• Validation of insurance claims • Infrastructure Test •Cargo delivery • Intelligent management of construction sites in other industrial facilities •Forestry • Check the condition of the equipment	Analysts at IDC expect global spending on solutions in the field of robotics and unmanned aerial vehicles to reach $ 115.7 billion next year. This is 17.6% more than in the current year. For 2022, analysts forecast a figure of 210.3 billion dollars, corresponding to an average annual growth of 20.2%. The cost structure is dominated by robotics. It will cost 103.4 billion dollars next year (IDC, 2019). Research and markets analysts predict that by 2025, the market for unmanned aerial vehicles will grow to $ 51.85 billion, which is significantly more than in 2016 ($11.45 billion) (Research and markets, 2020). Tractica predicts that global revenue from services provided by unmanned aerial vehicles will grow from $ 337.6 million in 2017 to $22.7 billion by 2026 (Tractica, 2019). According to PwC calculations, the global market for business services using unmanned devices exceeds $ 127 billion. PwC highlights promising sectors: infrastructure, where the market for using unmanned devices is estimated at $ 45.2 billion; agriculture, where the potential for using drones is $ 32.4 billion; transport ($13 billion); security services ($10 billion); media and entertainment ($8.8 billion); insurance ($6.8 billion); telecommunications ($6.3 billion); mining ($4.4 billion). The market for unmanned aerial vehicles, including helicopters, could grow to $615 billion by 2040 (PwC, 2017b)
Three-dimensional printing is a method of creating three-dimensional objects in	• Health and smart medical devices • Production tools and parts • Prototyping • Optimization of the supply chain	Research by the McKinsey Global Institute shows that by 2025, the volume of three-dimensional printing can bring up to 550 billion dollars a year. Approximately $ 6 billion was accumulated by three-dimensional printing in 2017. This figure is projected to increase to $ 11 billion in 2020 (McKinsey Global Institute,

layers based on a digital model by applying material sequentially and using plastic, glass, and wood	• Customization of goods • Remote Production	2013). ING employees believe that after 40 years, 50% of the products produced will be created using 3D printers (ING, 2018).
Virtual reality is a computer simulation of a three-dimensional image or a full-fledged environment in a given and controlled space, with which the user can actually interact to provide an immersive effect	• Virtual jobs • Manufacturing / product development • Design and construction • Education / training • Entertainment • Health • Merchandising	According to Goldman Sachs, there are about 230 million consoles and 150 million computer players in the world. The total sales of VR/AR is 1.5 trillion US dollars. by 2025, 315 million users are projected with sales of 35 billion dollars. In 2018, the AR market was $ 11.1 billion, and the VR market is estimated at $ 7.9 billion. By 2020, 100 million customers will make online purchases using AR technologies (VC, 2016).
Augmented reality is an overlay of graphics / audio for a more detailed introduction to a task or product	• Virtual exhibition •Education •Travel and tourism •Game industry • Print and Advertising •Retail •Marketing	
The Internet of things (IoT) is a network of devices equipped with sensors, software, and network hardware that can collect and exchange data over the Internet	• Tracking the movement of goods and materials • Monitoring of assets • Remote data collection • Self-Service • Remote services • Obtaining market data real-time • Flexible pricing models	The total amount of global investment in the Internet of things will be $ 1.4 trillion by 2021. By 2020, the number of devices connected to IoT in the world will reach 21 billion units. A combined annual growth rate (CAGR) of 19.6% over 2020-2025 is needed for the market to grow from US $ 14.5 billion in 2020 to us $ 35.5 billion by 2025 (Marketsand, 2020b).
Artificial intelligence is software algorithms that implement visual	• Trading system • Risk management and combating fraud real-time • Automated virtual assistants	The use of artificial intelligence can provide additional growth of the world economy by 16 trillion dollars by 2030, or lead to an increase in total GDP by 16% compared to today's level. This represents about 1.2 percent of additional GDP growth per year (PwC, 2017b).

perception, decision-making, and so on.	• Underwriting of loans and insurance	The growth of automation through the introduction of AI will reduce about 75 million jobs by 2025, while new technologies and AI will drive the creation of new jobs to 133 million over the same period. Up to 60 percent of professions may be automated or robotic in the future. 375 million workers, or 14 percent of the world's workforce, will have to change their profession, and most workers will have to adapt to working together with robots and AI (McKinsey Global Institute, 2018).
	• Data analysis and advanced analytics	
	• Merchandising	
	Marketing and sales analysis of network traffic, analyze the quality of customer service, and in order to network automation	
	Autonomous vehicles, mobile communications there between	
	Personalization of service based on the history of purchases of financial services, and other intelligent services	
	Enhanced control and automatic correction of the production processes, analysis of supply chain optimization and production, the product optimization, predictive analytics	
Robots are devices or virtual agents that autonomously or according to instructions automate, improve, or support human actions	•Production	Robots will complete 42% of current work tasks by 2022, and 52% of current work tasks by 2025. More than half of current employees will either have to change jobs or go through a global digital reforging, but at the same time, at least half of today's professions will remain by 2022 (McKinsey Global Institute, 2018). Automation will affect 1.2 billion people with a total salary of 14.6 trillion dollars. The introduction of Robo-cars will bring $ 3.1 trillion annually to the global economy by reducing the number of accidents and reducing CO2 emissions. by 2050, the market for self-driving cars will generate $ 7 trillion annually (WSJ, 2018).
	• Harmful production	
	• Hospitality and Tourism	
	•Services sector	
	• Automation predictable operations	
	•Data management	
Cloud computing is a model for providing convenient on-demand network access to a shared pool of configurable computing resources (for example, data networks,	Cloud technologies in the educational process	Markets and Markets forecast that the global cloud database and database as a service (DBaaS) market size will grow from us $ 12.0 billion in 2020 to us $ 24.8 billion by 2025, with a combined annual growth rate (CAGR) of 15.7% over the forecast period (Marketsand, 2020a). The growing demand for processing requests with low latency is one of the main factors driving the growth of the market.
	Cloud technologies in the process of implementing blockchain technologies	
	Cloud-based technologies in medicine and banking business	

servers)		
Big data refers to structured and unstructured data of huge volumes and significant diversity that horizontally scalable software tools efficiently process	Transport telematics has been used by automakers for many years, but now a more sophisticated method of data collection is being lobbied that makes full use of Big Data.	According to expert estimates, by 2019, the turnover of the connected car market will reach $ 130 billion (Marketsand, 2020d).
	The implementation of Big Data technologies in the medical field allows doctors to study the disease more carefully and choose an effective course of treatment for a specific case. Understanding user requests and targeting is one of the largest and most widely publicized areas of Big Data tools. Big Data helps you analyze customer habits in order to better understand customer needs in the future.Data analysis is also used to improve a number of aspects of the life of cities and countries. For example, by knowing exactly how and when to use Big Data technologies, you can optimize transport flows.	According to MarketsandMarkets, the global size of the big data market will grow from us $ 138.9 billion in 2020 to us $ 229.4 billion by 2025, with a combined annual growth rate (CAGR) of 10.6% over the forecast period (Marketsand, 2020c).
	The introduction of Big Data tools helps to increase the transparency of industrial processes and implement "predictive production", which allows you to more accurately predict the demand for products and, accordingly, plan the use of resources.	Frost & Sullivan estimates that in 2021, the total global market for big data Analytics will increase by more than 2.5 times compared to 2016, to $ 67.2 billion, with an annual growth rate (CAGR) of 35.9% (Tadviser, 2019).

The data in the table shows that most expert companies predict a significant economic contribution of Industry 4.0 to the global economy, which should provide solutions to major problems, including reduced productivity and a lack of qualified and young personnel.

Comparative analysis of the implementation of Industry 4.0 technologies in countries around the world

Let's analyze the level of technology implementation of Industry 4.0 in 14 countries with different levels of digital and economic development: Australia, Denmark, USA, Netherlands, Germany, Sweden, France, Portugal, Belgium, UK, Canada, Italy, Japan and China. The choice of countries is justified by the possibility of maximum coverage of data in open sources in the context of implemented technologies.

To determine the country's rating by the level of implementation of the described Industry 4.0 technologies we propose to introduce an integral indicator of the density of implementation of Industry 4.0 technologies – D_{ti} (Density of Technology Imlementation).

The calculation of this indicator is based on comparing and ranking countries for each indicator with a conditional reference country that has the best results for all the indicators being compared. This approach corresponds to the practice of market competition, where each country strives to "look better than its competitor in all indicators of this type of activity" (Karpunina, 2011). The rating value for each analyzed country is determined by a summary calculation of integral (generalizing) indicators. An integral indicator of the density of implementation of Industry 4.0 technologies, calculated by the formula:

$$D_{ti}=\sqrt{\sum_1^i (1-xi)^2},$$

xi – standardized indicators for the implementation of Industry 4.0 technologies (where $xi=X_i / X_{max}$), $i = 1 \ldots .10$.

As initial indicators, we suggest taking:

X_1 - number of IOT devices per 100 inhabitants (units)

X_2 - number of installed industrial robots per 10,000 manufacturing workers (units)

X_3 - the share of high-tech and medium-tech products (as a % of total manufacturing output) in 2019 (based on the OECD technology intensity classification)

X_4 - the composite index of the penetration of artificial intelligence

X_5 - gross expenditure on research and development, % of GDP

X_6 - GDP/unit of energy use

X_7 - share of high-tech and medium-tech manufacturers in total, %

X_8 - number of samples contained in industrial design applications submitted to a given national or regional office (per billion PPP $ of GDP)

X_9 - computer software expenditures, % of GDP

X_{10} - high-tech exports minus re-exports (% of total trade).

The values of the baseline indicators for the analyzed countries are presented in table 6.

Table 6: Initial indicators for calculating the integral indicator of the density of implementation of Industry 4.0 technologies (compiled by the authors, HAI (2019), WIPO (2019))

Country	Internet of things devices per 100 inhabitants in 2017	Number of installed industrial robots per 10,000 employees in manufacturing industry, 2016	High-tech and medium-high-tech output as a percentage of total manufactures output, in 2019 years, %	Composite AI Index Scores, 2015-2018	Gross expenditure on R&D, % GDP	GDP /unit of energy use	High- & medium-high-tech manufactures, %	Industrial designs by origin/bn PPP$ GDP	Computer software spending, % GDP	High-technology exports minus re-exports (% of total trade)
China	6,20	68	59,4	32,56	2,1	6,6	0,5	26,3	0,4	27,90
Australia	7,90	83	35,5	23,3	1,9	8,5	0,3	2,3	0,3	1,70
Belgium	15,60	184	47,4	21,69	2,6	8,5	0,4	2,4	0,7	8,10
Canada	11,60	145	49,8	27,45	1,7	5,5	0,4	0,5	0,7	4,90
Denmark	32,70	211	55,2	20,17	3,1	15,6	0,4	6,8	0,6	5,20
France	17,60	132	58,9	27,55	2,2	10,3	0,5	6,3	0,6	12,80
Germany	22,40	309	73,8	30,44	3	11,6	0,6	14,5	0,6	11,50
Italy	10,20	185	48,6	20,99	1,4	13,5	0,4	16,6	0,6	5,30
Japan	8,20	303	70,5	17,83	3,2	11,2	0,5	4,5	0,3	12,10
Netherlands	24,70	153	38,8	26,91	2	10,9	0,3	3,8	0,6	11,20
Portugal	16,20	58	32,7	17,27	1,3	12,3	0,3	7,2	0,6	2,70
Sweden	21,90	223	58,6	22,1	3,4	9,7	0,5	4,1	0,6	7,30
United Kingdom	13,00	71	52,8	26,83	1,7	14,7	0,4	7,9	0,7	9,00
United States	24,90	189	66,8	57	2,8	8,1	0,5	1,2	1,1	5,80
Maximum value of each indicator in the group	**32,7**	**309**	**73,8**	**57**	**3,4**	**15,6**	**0,6**	**26,3**	**1,1**	**27,90**

Standardized indicators are found by dividing the values of each of the given initial indicators by the maximum number of this indicator for the countries under study (table 7).

Table 7: Calculation of the integral indicator of the density of implementation of Industry 4.0 technologies (compiled by the authors)

Country	x_1	x_2	x_3	x_4	x_5	x_6	x_7	x_8	x_9	x_{10}	Integrated indicator of the level of density of implementation of Industry 4.0 technologies
China	0,657	0,608	0,038	0,184	0,146	0,333	0,028	0,000	0,405	0,000	2,399
Australia	0,575	0,535	0,269	0,350	0,195	0,207	0,250	0,833	0,529	0,882	4,624

Canada	0,416	0,282	0,106	0,269	0,250	0,419	0,111	0,962	0,132	0,680	3,627
Denmark	0,000	0,101	0,064	0,417	0,008	0,000	0,111	0,550	0,207	0,662	2,119
France	0,213	0,328	0,041	0,267	0,125	0,115	0,028	0,578	0,207	0,293	2,195
Germany	0,099	0,000	0,000	0,217	0,014	0,066	0,000	0,201	0,207	0,346	1,149
Italy	0,473	0,161	0,117	0,399	0,346	0,018	0,111	0,136	0,207	0,656	2,624
Japan	0,561	0,000	0,002	0,472	0,003	0,080	0,028	0,687	0,529	0,321	2,683
Netherlands	0,060	0,255	0,225	0,279	0,170	0,091	0,250	0,732	0,207	0,358	2,625
Portugal	0,255	0,660	0,310	0,486	0,381	0,045	0,250	0,527	0,207	0,816	3,937
Sweden	0,109	0,077	0,042	0,375	0,000	0,143	0,028	0,713	0,207	0,545	2,239
United Kingdom	0,363	0,593	0,081	0,280	0,250	0,003	0,111	0,489	0,132	0,459	2,762
United States	0,057	0,151	0,009	0,000	0,031	0,231	0,028	0,911	0,000	0,627	2,045

The calculations make it possible to distinguish two groups of countries depending on the density of implementation of Industry 4.0 technologies (table 8).

Table 8: ranking of countries according to the value of the integrated indicator of the density of implementation of Industry 4.0 technologies (compiled by the authors)

Country	Integrated indicator of the level of density of implementation of Industry 4.0 technologies	Rank by level of the integrated indicator of the level of density of implementation of Industry 4.0 technologies	The country is a leader or outsider in terms of the density of implementation of Industry 4.0 technologies
Germany	1,149	1	leader
United States	2,045	2	leader
Denmark	2,119	3	leader
France	2,195	4	leader
Sweden	2,239	5	leader
China	2,399	6	leader
Italy	2,624	7	outsider
Netherlands	2,625	8	outsider
Japan	2,683	9	outsider
United Kingdom	2,762	10	outsider
Belgium	2,784	11	outsider
Canada	3,627	12	outsider
Portugal	3,937	13	outsider
Australia	4,624	14	outsider

Thus, the leaders in the implementation of Industry 4.0 technologies are: Germany, United States, Denmark, France, Sweden, China (the value of the D_{ti} indicator is in the range of 1-2.5). Italy, Netherlands, Japan, United Kingdom, Belgium, Canada, Portugal, Australia are outsiders (the value of the D_{ti} indicator is in the range of 2.5-5).

Conclusions

The results of the study allow us to conclude that the level of development, penetration and use of Industry 4.0 technologies in the analyzed countries is significantly differentiated. This probably carries a certain risk of further dividing the economic world by the rate of economic development and economic well-being. For example, a study by the McKinsey Global Institute and WEF points to the emergence of a significant gap between countries and companies that are actively developing new technologies and countries and companies that are outsiders who remain aloof from new technological trends. The leaders are projected to have a combined cash flow growth of 122% over 5-7 years, while the outsiders will have a more modest growth rate of 10% (Weforum, 2019).

The available data highlight the growing multipolarity of the global economy: the centers of economic leadership are shifting from developed countries to the developing world. Thus, according to economists ' forecasts, up to 66% of the middle class and 59% of their consumption will be concentrated in Asian countries by 2030 (an increase of more than 2 times the volume of 2009). This process will consist in accelerated growth of the GNP of the developing E7 countries (China, India, Brazil, Russia, Indonesia, Mexico, Turkey) over the economic growth of the developed G7 countries. So, in 2015, the GDP of the G7 countries was $ 34 trillion, the GDP of the E7 countries was $19

trillion, according to forecasts by 2050, the GDP of the G7 countries will be $ 69 trillion, and the GDP of the E7 countries will grow to $ 138 trillion (that is, GDP growth (2050 to 2015) will be 7.26 (while in developed countries 2.03) (PwC, 2017a).

Another risk for the development of Industry 4.0 technologies may be the emergence of new environmental restrictions due to the increased burden on the industrial sector of the world economy. ICT estimates that for every 1% increase in global GDP, CO2 emissions will increase by about 0.5%, and resource intensity by 0.4% (GeSI, 2015). Current business practices will contribute to a global gap of 8 billion tons between supply and demand for natural resources by 2030, resulting in a loss of $ 4.5 trillion in economic growth by 2030 (Accenture, 2015). In addition, research by the Global Footprint Network indicates a shortage of available resources, and also shows that today the level of global consumption exceeds the available resources by 1.7 times (Footprint Network, 2018). The solution to this problem requires the development of new cyclical business models, their acceptance by customers and the impact on the environment of the digital technology itself.

The introduction of Industry 4.0 technologies also leads to the emergence of cyber risks and the updating of digital security issues due to the growth in the number of new devices connected to the Internet (in 2018, there were about 50 billion of them) (McKinsey Global Institute, 2018).

Abstract

The threat of viral epidemics is a factor of economic security of the state. Its manifestation damages the life and health of the population, as well as the normal functioning of the economic system. The authors reveal the dialectical nature of the impact of epidemic threats on the economic security of the state. They prove that the destructive impact of the epidemic threat is manifested in the form of economic damage at all levels of the economic system (a decrease in economic activity of economic entities, a reduction in the volume of markets, a fall in real GDP). The authors note that there is also a creative impact of epidemic threats, which is manifested in the growth of incomes of enterprises specializing in medical products, as well as the development of new digital forms of economic activity that contribute to improving the economic security of the state. The authors proposed a formula for calculating the amount of reduction in the economic security of the state as a result of the introduction of quarantine measures. The formula can be adapted to calculate the value of a country's GDP loss over the entire period of the epidemic. The authors proposed the directions of state policy that can increase the level of economic security of the state in the face of the threat of epidemics (preventive, reactive and proactive), as well as measures for their implementation.

Keywords: Economic Security of The State, Epidemic Threat, Economic Damage, Digital Technologies

Introduction

In modern conditions, the countries of the world face new challenges that focus their interest on issues of economic security and search for mechanisms to strengthen and improve it.

Digitalization and increasing the technological efficiency of production processes, as well as the penetration of information and communication technologies into the daily life of people shift the emphasis towards preventing, first of all, anthropogenic threats and risks to economic security.

Nevertheless, with a certain regularity, real threats of a natural nature arise in the world, they cause significant damage to humanity. One of these threats is viral epidemics, which damage the health of the population, increase mortality, and have economic consequences that undermine the security of states: a reduction in GDP, an increase in unemployment, an increase in the cost of social programs, and so on.

For example, the World Bank estimated the total economic damage from the Spanish flu pandemic during world war I (1918-1919) at 6.6% of world GDP. The economic consequences of SARS in 2002-2003 were reflected in a slowdown in economic growth from 11.1% to 9.1%. At the same time, direct damage to Asian countries was estimated at $12-18 billion, while indirect damage to the world economy amounted to $30-100 billion (The Bell, 2020).

Research on the economic consequences of the largest viral epidemics in world history shows that epidemics can also have a positive impact on the economic security of a state, for example, lead to an increase in per capita income or the development of new forms of economic activity (Brainerd and Siegler, 2003; Qiu et al., 2018). What is the dialectic of the relationship between the epidemic threat and the economic security of the state? Can modern digital technologies correct the impact of epidemic threats on the state of economic security of states? Our research is dedicated to finding answers to these questions.

Methodology

Research hypothesis. In the modern world, countries face new challenges and threats that reduce their level of economic security. The epidemic threat is one of the security threats that determine the development of the global economic system. Its impact on the economic security of the state is dialectical: on the one hand, the economic consequences of the epidemic threat have a destructive effect on the economic system, reducing the level of economic security of states; on the other hand, the emergence of an epidemic threat contributes to the development of new digital forms of economic activity, which are both a source of future sustainable development and a permanent tool for ensuring economic security.

The basis for the hypothesis is researches that reveal the essence of economic security of the state. According to Huber et al. (2010) economic security reflects the readiness of the economic system to ensure decent living conditions and personal development, socio-economic stability, and the implementation of the military and political potential of society and the country to eliminate internal and external threats.

The complexity and dynamism of economic security is determined by a variety of economic, social, financial, and political processes (Kesternich and Schnitzer (2010); Bordo et al. (2009); Busse and Hefeker (2006); Schwimmer (1995); Sercu (1980); Wilson (1979)).

Researchers define economic security as a factor of national security that provides resources and dynamic balance of other components of the economic system to eliminate poverty, hunger, social and economic inequality between individuals and between regions of the country (Rehm and Schlesinger (2013); Quadrini (2011); Ausloos and Miskiewicz (2010); Besten den (2007); Estrada (2000)).

Economic security includes many aspects, such as income security, housing security, health security, and so on. Guaranteed income is one of the most important aspects of people's lives. All basic necessities and commodities in a market economy have a monetary or price value, and people's perception of their own economic insecurity depends largely on their purchasing power. Maintaining a certain level of income is a critical security issue for human well being (Yang, 2014).

A complete list of indicators of economic security of the state includes more than 150 indicators, including GDP; share of investment in fixed capital; the share of defense spending; the share of expenditures on science; the share of innovative products in total volume of industrial production; the proportion of persons with cash incomes below the subsistence level in the whole population; the

decile coefficient of income differentiation of the population; the unemployment rate; foreign debt and other (Grigoryeva et al., 2017).

Violation of the normal functioning conditions of the economy is associated with the emergence of natural threats (when threats arise from the natural environment) and anthropogenic threats (when threats provoked by human activity), which are reflected in the form of lowering the threshold values of indicators of economic security.

Threats of a natural nature, including ecosystem parameters, are least affected by the economic security system, and are usually unpredictable and extensive (Fay, 2011). Conditions and factors that are fraught with danger may arise either by themselves or under the influence of certain circumstances. A common feature of threats and dangers is their destructive nature and negative impact on the subsystems of the state.

In the Global Risks Report 2019, the global risks are primarily man-made (the trade conflict between the US and China; US corporate debt problems; a large-scale crisis in emerging markets; a prolonged economic downturn in China; a devastating jump in oil prices; territorial disputes in the South China or East China sea; cyber attacks and data integrity problems; a military confrontation on the Korean Peninsula; the UK's exit from Brexit; the Italian banking crisis). However, the emergence at the end of 2019 in China, a new form of viral infection "coronavirus", which led to a world-class epidemic, actualizes the significance of threats of a natural nature for modern society (The Economist Intelligence Unit, 2019).

A number of studies are devoted to the study of the economic consequences of the world's largest epidemics. According to most of them, the spread of infectious diseases is considered one of the main global economic threats. Analysis shows that most economic losses are usually caused not by the disease itself, but by consumer responses, labor shortages, and cascading failures in the economic and financial sectors.

Researchers focus primarily on the negative consequences of epidemics in the form of increased costs for the health system associated with medical treatment of infected people and the control of disease outbreaks. Epidemics reduce the efficiency of the labor process, destroying labor productivity. Measures related to the introduction of quarantine during epidemics, as well as psychological instability of the population caused by fear of infection, lead to social distancing and disrupt the normal functioning of the economy (Bloom et al., 2018). The decline in trade, the decline in tourism, and the decline in foreign direct investment are also seen as negative economic consequences of epidemics (Fan et al., 2016).

However, a number of alternative studies also focus on the positive impact of epidemics on the socio-economic development of society (Brainerd and Siegler, 2003; Qiu et al., 2018). This allows us to make an assumption about the dialectical nature of the impact of epidemic threats on the economic security of the state. The study uses a qualitative approach to case studies, including a literature review, document analysis, and in-depth interview results. It relied on a wide range of data sources, including books, journal articles, government documents, policy reports, and conference proceedings. The method of economic and mathematical modeling was used to develop a formula that estimates the amount of reduction in the economic security of the state as a result of the introduction of quarantine measures. The dialectical method, the method of induction and deduction, and the systematic approach were used to form conclusions and conclusions.

Results

Let's turn to research on the economic side of epidemics and note that their consequences are distributed unevenly throughout the economy. For example, pharmaceutical companies that produce vaccines, antibiotics, or other products needed to respond to virus outbreaks are potential beneficiaries. So, according to RoboForex, Alpha Pro Tech's shares have always responded to outbreaks of various epidemics: in 2003, during the epidemic caused by the SARS-CoV virus, the company's share price increased by 300%; in 2009, the swine flu outbreak triggered a 700% increase in the share price; in 2014, the Ebola epidemic provided a 500% increase in the share price%

(RoboForex, 2020). Another example is the behavior of Roche Holding Ltd., the manufacturer of the drug Tamiflu, which sold $ 388 million worth of Tamiflu stocks during the swine flu outbreak (previously produced for the US and UK to fight avian flu) (Mercola, 2009). However, the pharmaceutical company Roche was not the only one that received large revenues during the epidemic. Thus, GlaxoSmithKline Plc. earned $ 364 million during this period, Sanofi-Aventis – $ 382 million, and Baxter International Inc. - $ 123 million (Kaushik, 2009).

At the same time, insurance companies face unexpected costs, at least in the short term. Epidemic risks are difficult to predict and even harder to insure. For example, in early 2020, Singapore company NTUC Income offered customers whose trips are affected by the new coronavirus outbreak the flexibility to cancel their travel insurance plans to any destination and receive a full refund of premiums. Japanese insurance company Tokio Marine said that holders of Tokio Marine life insurance policies can receive $ 5,000-limited to the first 50 submissions - if they have contracted the virus to help them "get through difficult times» (Straitstimes, 2020).

Inequality also affects different groups of the population: vulnerable segments of the population are most vulnerable to the impact of epidemics, because they have fewer opportunities for quality health care and fewer savings to protect them from financial disaster.

In general, the amount of economic damage caused by an epidemic threat consists of the cost of medicines, doctor calls, hospitalization and treatment of complications; and the loss of working days. The economic consequences of epidemics for employees are a decrease in income for the period of disability, an increase in medical expenses (doctor's consultations, purchase of medicines, hospital treatment), and an increase in the risk of losing their jobs. Indeed, falling productivity in poor health reduces earnings, and in response, people start working less, preferring leisure, which reduces the supply of labor. Skipping work due to illness entails direct costs of paying for sick leave and indirect costs due to reduced productivity during the employee's absence. For example, in the UK in 1994, productivity losses due to absence from work due to illness were estimated at more than 15.8 billion euros, while sickness payments in 1993 amounted to about 30.6 billion euros in Germany and 15.8 billion euros in the Netherlands (EFILWC, 1997). The occurrence of health problems in employees has many negative consequences for the companies in which they work: the quality and productivity of labor decreases, there is a failure to fulfill obligations, and, as a result, a decline in production, a reduction in profits, and a decrease in competitiveness.

Over the past thirty years, the number of epidemic threats of an infectious nature has increased significantly. The World Bank estimates that the annual global cost of moderate to severe pandemics is approximately $ 570 billion, or 0.7% of global income (Candeias and Morhard, 2018).

Let's analyze the consequences of epidemic threats and their impact on the economic security of the state (table 1).

Table 1: Economic consequences of modern world epidemics and their impact on the economic security of the state (compiled by the authors)

Epidemic threat	Negative economic consequences	Associated positive economic consequences
An epidemic caused by the H1N1 virus in 1918-1920 ("Spanish")	On average, the decline in real GDP per capita compared to the previous peak in 1918 (and sometimes in 1919 or 1920) was 6.6% (for the 24 countries with data, the average decline in real consumer spending per capita was similar to the decline in real GDP per capita). A significant decline in GDP was recorded in Canada and South Africa (by 24%) and in Italy (by 22%). From 1918 to 1921, there was a drop in GDP per capita and consumer spending by 12% and 14%, respectively (Barro and Ursua, 2009). In Spain, real consumer spending per capita fell during the epidemic. In the period 1918-1920, 11 countries experienced a stock market crash. The weakest markets during this period include Italy (minus 69%); Denmark (minus 57%); Switzerland (minus 54%); Japan (minus 52%); France and Spain (minus 46%).	The decline in the working population due to the virus caused a marked increase in per capita real income in the manufacturing sector in the United States in the 1920s (Brainerd and Siegler, 2003): the decline in the supply of manufacturing workers caused by flu-related deaths had the initial effect of reducing the supply of manufacturing labor, as well as increasing the marginal product of labor and capital per worker, and thus increasing real wages. Businesses that specialize in medical products had an increase in revenue (Garrett, 2007). The World Health Organization appeared.
SARS (2002–2003)	In 2003, business and leisure travelers sharply reduced flights. Revenue for Asia-Pacific carriers fell by $6 billion, while North American airlines lost another $ 1 billion. The tourism industry has also suffered a crushing defeat. Net income for Park Place Entertainment, owner of Caesar's Palace in Las Vegas and other gambling and hotel complexes, fell more than 50 percent in the second quarter of 2003 compared to the previous year (Reuters, 2013). By may 2003, Singapore Airlines had reduced capacity by 71 percent and placed 6,600 employees on unpaid leave. Tourism in Singapore has fallen	The epidemic triggered the rapid development of China's nascent E-commerce, mobile telephony and Internet sectors (Ghosh, 2016)[1]. Chinese suppliers have invested more in online marketing on the Alibaba platform. in 2003, Alibaba's business grew by 50% and generated daily revenue of 10 million yuan. More than half of the 1.4 million suppliers on the B2B platform saw strong sales growth (Digital Commerce 360, 2020). Taobao was also launched in 2003, and within two years, the platform surpassed eBay to become the number one C2C market in China.

[1] Bobby Ghosh (2016) China's internet got a strange and lasting boost from the SARS epidemic // https://qz.com/662110/chinas-internet-got-a-strange-and-lasting-boost-from-the-sars-epidemic/

	by 70 percent, and the country's GDP has reached $ 400 million. The global macroeconomic impact of SARS is estimated at 30-100 billion US dollars or about 3-10 million US dollars per case (Smith, 2006). An outbreak of SARS in 2003 resulted in losses of us $ 12.3-28.4 billion and an estimated 1% decrease in GDP in China and 0.5% in Southeast Asia (MacKellar, 2007).	
H7N9 virus (avian flu) epidemic in China in 2005, 2013	The direct medical cost of hospitalizing a patient with H7N9 was estimated at 71,060 yuan, which is more than an annual income for a person in a rich province of China (Huo and Chen, 2016). In April 2013, the H7N9 avian flu epidemic caused the price index for meat and poultry and their products to drop to 101.5 on an annual basis. China's poultry industry has suffered losses of more than 40 billion yuan (Huang et al., 2015). However, the economic impact in the global community was insignificant.	Creation of a system of state prevention of human infection with avian flu, operational optimization of the poultry industry, promotion of a healthy lifestyle and improvement of food culture (Ali et al., 2015). Global production and trade have demonstrated the potential for rapid recovery from severe outbreaks, which were mainly confined to East and South-East Asia (McLeod et al., 2005).
Swine flu epidemic of 2009	The 2009 swine flu epidemic was not significant for the macroeconomics of most countries, with the exception of Mexico. However, there were significant risks of depression. Perhaps 20-30% in the US, due to the global financial crisis of 2008, the potential for a flu pandemic increases the chances of depression, especially given that the strain disproportionately affects people of primary working age (Barro and Ursua, 2009). Overall, estimates of economic losses in the affected countries range from 0.5% to 1.5% of GDP (The Economist, 2014).	Investors have profited from the epidemic: sales of vaccines and drugs to fight swine flu in 2009 increased sales of some pharmaceutical companies. By the beginning of 2010, when the moderate epidemic ended, Sanofi-Aventis had a net profit of $ 10.1 billion, up 11 percent from a year earlier. The epidemic has benefited telecommunications companies, e-Commerce companies, home entertainment, and even utilities. The epidemic forced currency traders to rush to safe havens, which caused the dollar to rise (Reuters, 2013).
Ebola outbreak in West Africa (2014-2016)	The short-term (2014) impact on output is about 2.1 p. p. of GDP in Guinea (reduced growth from 4.5% to 2.4%); 3.4 p.p. of GDP in Liberia (reduced growth from 5.9% to 2.5%); and 3.3 p. p. of GDP in Sierra Leone (reduced growth from 11.3% to 8.0%). In 2014-2016, the damage	The increase in the level of food security in Liberia. In the health sector, there has been a shift from private providers back to public ones. Incentives have been created for the development of medical products for the treatment of diseases that affect the poor and have little market appeal

	amounted to $53 billion, taking into account the increase in unemployment, the cost of social programs and damage to public health (The Economist, 2014). There was a 41% drop in tourist visits to the country, and the Bank of Korea lowered its benchmark interest rate to a record low.	(World Health Organization, 2015). The foundations have been laid for well-functioning health systems that integrate public health and primary health care. Funding mechanisms needed to build rapid response capacity to outbreaks and humanitarian emergencies have been established. In Liberia, mobile communications were widely used for data collection (World Bank, 2015).

As can be seen from the above table, on the one hand, as a result of the impact of epidemic threats, the economic activity of most economic entities decreased, the volume of markets decreased, and there was a drop in real GDP per capita in many countries and regions that were both hotbeds of infection and affected by epidemics as a result of global population displacement.

We believe that to determine the amount of reduction in the economic security of the state as a result of the impact of epidemic threats, we can use the formula for GDP losses of a specific country (developed by the authors):

$\mathrm{GDPlos} = (\mathrm{GDP} * \mathrm{Dd} * \mathrm{Pq})/(\mathrm{Dw} * \mathrm{Pe})$, where

GDP – the volume of the country's GDP in current prices (according to official data of the Federal State Statistics Agency); D_d - the number of disability days; P_q - the number of people under quarantine (in the country); D_w – the number of work days per year; P_e – the number of employed people (in the country).

We will demonstrate the use of this formula for calculating the reduction of economic security in Russia as a result of the spread of the COVID-19 coronavirus pandemic.

Compliance with a two-week quarantine for persons arriving from abroad and those in contact with them was the first measure implemented by the Government of the Russian Federation to prevent the spread of coronavirus in Russia. These persons are on official sick leave.

We will calculate the amount of GDP that will be lost in 2020 due to the introduction of quarantine.

We will use the following indicators for the calculation:

1) The number of disability days (D_d):14 days
2) The number of people under quarantine (in the country) (P_q): 3.317 million people (data as of 01.04.2020 (M24, 2020)
3) Total number of disability days: $D_d * P_q$ =14*3,317 = 46.438 million days (46438 thousand days)
4) The number of work days per year (D_w): 248 days
5) The number of employed people (in the country) (P_e): 71576,9 thousand people (the average value for 2019, according to Gks (2019))
6) GDP: 110046,1 billion rubles (in current prices, according to Gks (2019))
7) The Minimum wage in 2020: 12130 rubles.

Calculate the amount of GDP lost due to the people being quarantined using the formula:

$$\mathrm{GDPlos} = (\mathrm{GDP} * \mathrm{Dd} * \mathrm{Pq}) / (\mathrm{Dw} * \mathrm{Pe}) = (110046{,}1 * 46438)/(248 * 71576{,}9)$$
$$= 287{,}9 \text{ billion rubles}$$

Thus, Russia's GDP will not receive about 287.9 billion rubles or 0.26% of GDP only due to quarantine measures (due to loss of working time).

We are confident that the proposed formula can be used to assess the reduction in economic security due to the introduction of quarantine measures not only for those arriving from abroad, but also for all categories of workers in the case of quarantine throughout the country.

On the other hand, the typical economic consequences of many epidemics were: 1) the growth of revenues of enterprises specializing in medical products; 2) the growth and rapid development of telecommunications companies, Internet Commerce companies, and home entertainment companies.

The growth of enterprises in these sectors largely compensated for the decline in GDP in many countries of the world due to epidemics and led to an increase in economic security indicators. For example, restrictions related to the epidemic threat of SARS in China have contributed to the development of the country's e-Commerce sector (primarily through the rapid growth of Alibaba), digital mobile telephony and the Internet. The epidemic has also triggered a rise in text messaging, which has boosted business for cellular companies such as China mobile. It also contributed to the development of three Chinese Internet portals Sina, Sohu and NetEase, through revenue-sharing agreements with the telecommunications company (Ghosh, 2016). Broadband Internet access has also received a huge boost, due to the need of the people under quarantine for communication, information and entertainment.

Thus, the emergence and development of new digital forms of economic activity is both the result of the impact of epidemic risk on the economic system and the source of its future sustainable development, as well as a permanent tool for ensuring economic security: 1) the economic effect of digitalization is significantly higher than that of autonomous technologies (cumulative effect, accumulation of intangible capital); 2) the economic effect of digitalization indicates a return to scale (the economic effect increases with the growth of the level of digitalization development); 3) economic growth and job creation depend on the level of technological development of the country (Katz, 2015; Katz and Koutroumpis, 2012).

The identified consequences of the impact of epidemic threats can become a starting point for determining the policy directions for ensuring economic security of the state: 1) preventive - minimizing the likelihood of new epidemic threats; 2) reactive – in the form of minimizing the consequences of economic damage; 3) proactive - creating conditions for improving the stable and safe functioning of the economic system based on the development of digital technologies.

The tool for implementing the preventive direction is to strengthen health institutions and develop the health services sector to protect countries from serious health shocks that can significantly affect human capital and hinder economic growth. The reactive approach is implemented in the event of a direct epidemic threat to limit the spread of the virus and its negative consequences (organizational, medical, social, technological, and economic measures). However, managing the epidemic threat is complicated by a number of factors. Diseases can be rapidly transmitted both within and between countries, so a timely response to initial outbreaks is essential. The epidemiological potential is enhanced by globalization and increased by climate change and urbanization: climate change expands the habitats of various common disease vectors; urbanization contributes to the transmission of infectious diseases in the context of close interaction of urban populations. The proactive direction includes a number of technological solutions that can help minimize the burden of epidemics: the use of online services, phones and other digital transactions is especially valuable, including in case of emergencies. For example, in 2015, the "Big data" project was launched to support States in the field of emergency telecommunications. The project facilitated the timely exchange of information on human mobility, including cross-border movement, and the spatial and temporal distribution of people in order to combat the Ebola epidemic (ITU, 2015). Aid agencies can track the geographical spread of viruses and save time in responding to an outbreak by turning processed and anonymized

official data into a dynamic map. Another proactive direction of economic security policy is the development of digital platforms and services to form the basis of the national economic system, ensuring uninterrupted operation and provision of goods and services in the event of an epidemic threat.

Conclusions/Recommendations

As a result of the research, the following conclusions were obtained. First, the place of epidemic threats in the system of economic security of the state has been established. Second, the dialectical nature of the impact of epidemic threats on the economic security of the state is revealed. On the one hand, epidemic threats have a destructive effect on the economic system, causing it economic damage and reducing the level of economic security of the state. The formula for calculating the reduction of economic security of the state as a result of the introduction of quarantine measures is proposed in the article. It can be adapted to calculate the country's GDP loss over the entire period of the epidemic. On the other hand, the accompanying results of epidemic threats are the intensive development of the sphere of medical goods and services, as well as the emergence of new digital forms of economic activity, which compensated for the decline in GDP in many countries of the world due to epidemics and led to an increase in economic security indicators. Third, the policy directions for ensuring the economic security of the state are defined: preventive (minimizing the likelihood of new epidemic threats); reactive (minimizing the consequences of economic damage); proactive (creating conditions for stable and safe functioning of the economic system based on the development of digital technologies).

Abstract

The authors analyzed various approaches to the disclosure of the concept of "digital transformation", presented the author's vision. The process of digital transformation is divided into three stages, depending on the dominant digital technology. The authors proved that each stage of digital transformation is associated with a certain set of social risks. It is proved that at the stage of spreading the Internet, there are risks of developing information, knowledge inequality and inequality in opportunities. The stage of intensive digital consumption provokes the risk of degradation of human relations, along with an increase in human vulnerability in front of digital environment. The stage of development of automation and robotization leads to the emergence of socio-economic risks due to the deepening of negative aspects of the psycho-emotional picture of human existence.

Keywords: Digital Transformation, Social Risks, Inequality, Automation, Internet

Introduction

The process of digital transformation has become an objective reality. For more than half a century social and economic conditions of human life have been changing under the influence of information and digital technologies. There are 3.9 billion people in the world who use the Internet, which is 51.2% of the world's population (ITU, 2018). People have the opportunity to participate in economic, political, social and technological processes thanks to new technologies.

However, many of the economic and technological benefits of digital transformation are accompanied by the emergence of new risks that threaten the well-being of modern society. Thus, digital inequality, which demonstrates differences between countries and within them in access to basic telecommunications infrastructure, cannot but affect the emergence of social risks associated with inequality in the realization of human opportunities. The result of the development of the Internet and Internet platforms is, on the one hand, the formation of production networks and the creation of conditions for the rapid satisfaction of consumer demand. On the other hand, there is likely to be a new social risk associated with the growing vulnerability of society under the influence

of the network. Thus, it is currently relevant to study social risks that have a negative impact on human well-being.

Methodology

Research hypothesis: Each stage of digital transformation is associated with a certain set of challenges and risks for modern society. The Internet distribution stage is associated with the risk of developing information, knowledge and opportunity inequality. At the stage of intensive digital consumption, there is a risk of degradation of human relations and increasing human vulnerability in front of digital environment. The processes of technological improvement of the quality of decision-making and automation of routine operations are accompanied by the emergence of economic risks and the deepening of negative aspects of the psycho-emotional picture of human existence.

In this research, we use the term "digital transformation". To identify it, we analyzed the work of Fitzgerald et al. (2013), McDonald and Rowsell-Jones (2012), which determined that digital transformation goes beyond simply digitizing resources and leads to the creation of value and revenue from digital assets. Collin et al. (2015), Gimpel and Roglinger (2015), Kane et al. (2015) Kane et al. (2015) emphasize that digitization usually reflects the simple conversion of analog information to digital, whereas the term "digital transformation" is a broader concept that affects politics, business, and social issues. In Stolterman and Fors (2004), digital transformation is concerned with the changes that digital technology causes and how it affects all aspects of human life.

Thus, in the current study, we will understand digital transformation as a process of changing social and economic conditions of human life, caused by the emergence of new opportunities and risks as a result of the development of digital technologies.

The basis for the research hypothesis was the discussion article "Social and economic impact of digital transformation on the economy" by Katz, in which the author divides the entire process of digital transformation into three waves, depending on the nature of the technologies being implemented (Katz, 2017). Similar stages in the process of digital transformation are found in the research of other scientists. Thus, Sologubova (2017) justifies that the process of digital transformation is implemented in stages: the first stage is associated with the birth of the digital economy, as well as legal regulation that promotes the development of "digital"; the second stage-the transition to the digital economy - is implemented through the formation of skills necessary for the introduction and use of digital technologies; the third stage forms effective institutions for digital development.

Alekseenko and Ilin (2018), Kulikova (2018), and Shmelev (2018) also emphasize the expediency of highlighting three stages of digital transformation: the first stage is associated with the automation of existing business processes and technologies, the second-with the global spread of the Internet and mobile communications to all spheres of public life, the third-modern-with the spread of digital currencies and distributed ledger technologies in the world economy.

There are several alternative views on the economic impact of digital transformation. Some researchers emphasize the positive impact of digital technologies on the economy: for example, Clarke (2008) cited evidence that firms in the manufacturing sector that have broadband Internet access produce 6% more foreign sales than others (Katz, 2017). The positive effect of broadband on job creation in the manufacturing sector was identified by Crandall et al. (2007). На рост выручки в результате расширенного охвата рынка указали Varian et al. (2002), Gillett et al. (2006), и Jonscher and Tyler (1982), Atkinson et al. (2009) pointed to revenue growth as a result of expanded market coverage and linked the economic benefits of digitalization to reducing trade distortions and stimulating demand for local ICT infrastructure services.

Other scientists noted the negative impact of digital transformation on the economic sphere: reduced employment as a result of the replacement of capital and labor in certain industries (Thompson and Garbacz, 2011); loss of revenue from Internet disruption due to natural disasters, cybercrime,

technological failures, or a politically motivated outage (West, 2016); reduction of jobs as a result of automation (Frey and Osborne, 2013); slowdown in economic growth in many countries, including mature economies (Ark et al., 2016; Summers, 2015), the decline in factor productivity (Gilbert et al., 2016).

However, the process of digital transformation is accompanied by the emergence of a whole range of social risks, some of which are reflected in research Katz (2012), De Los Rios (2010), Popper (1992), Molchan et al. (2019), Salikov et al. (2019).

It is the social risks of digital transformation that are of particular research interest and will be discussed in this article.

To conduct the research, we used observation, comparison, analysis and synthesis methods, logical, dialectical, graphical, and system methods.

The research is based on reports and forecasts from the OECD, ITU Statistics, Fincert of the Bank of Russia (2019), the Federal State Statistics Service of the Russian Federation (2019), McKinsey Global Institute (2017), the International Bank for Reconstruction and Development, and the World Bank (2016).

Results

Let's analyze the stages of digital transformation and the corresponding key social challenges and risks to support our hypothesis (Fig. 1).

Fig. 1: Relationship between the stages of digital transformation and social challenges and risks (created by authors)

According to the logic of Katz (2017), Sologubova (2017), Alekseenko and Ilyin (2018), Kulikova (2018), and Shmelev (2018), the digital transformation process can be divided into three stages.

The first stage of digital transformation is associated with the emergence of the Internet and the introduction of mature technologies, including management information systems aimed at automating data processing and used for monitoring and reporting business results, as well as telecommunications technologies that allow remote access to information (broadband (fixed and mobile) and voice telecommunications) (Katz, 2017). At this stage, scalability restrictions were relaxed, and conditions for further business expansion, meeting additional final demand and increasing the need for labor, and faster growth rates in traditional sectors of the economy were created (Atkinson et al., 2009; Varian et al., 2002; Gillett et al., 2006; Jonscher and Tyler, 1982). The implemented technologies had a prolonged result. They were developed and started to be implemented starting from 1960, and only by 2015 the maximum penetration of mobile telephony and the use of personal computers in households was achieved, and in 2016 the maximum implementation of fixed broadband in the world was achieved. However, some developing countries and regions of the world (for example, the African region) are still at this stage of digital transformation (TAdvisor , 2019).

This stage of digital transformation is associated with the emergence of so-called "digital inequalities", that is, gaps between individuals, households, businesses and geographical areas at various socio-economic levels, both in terms of their access to digital technologies, and in terms of their use of the Internet for professional and personal purposes (OECD, 2001).

Digital inequality results from differences in the availability of computers (or alternative access via mobile phones) and the Internet.

The universal telecommunications services indicator "number of access lines per 100 inhabitants" is used to assess digital inequality at the international level. According to the International telecommunication Union (ITU), at the end of 2018, 3.9 billion people, or 51.2% of the world's population, access the Internet. ITU estimates that 53.6 percent of the world's population, or 4.1 billion people, will be using the Internet by the end of 2019 (ITU Statistics, 2018).

Indeed, the degree of Internet penetration in the world has grown rapidly, however, it still remains uneven in the context of macro-geographical regions of the United Nations (Fig. 2).

Fig. 2: Internet penetration Rate in macrogeographic regions of the world, in 2018, in % (compiled by the authors according to ITU data (2018))

For example, in Africa, only 2.1% of the region's population used this service in 2005, while in 2018, 24.4% of the population had access to the Internet. However, compared to developed regions, African countries lag far behind in terms of Internet access. For example, in 2018 in Europe, 79.6% of the population had access to the Internet (TAdvisor, 2019). In general, in the developed world, the share of people using the Internet has increased to 80.9% (in 2005, it was 51.3%), and in the developing world, this share is 45.3% (it was 7.7%). Note that the majority of the world's inhabitants have technological access to the Internet: 96% of people live in the mobile cellular area, and 83% of families in developed countries and 36% in developing countries have computers.

Significant digital disparities in access to personal computers and the Internet exist within countries and regions. Thus, according to the Federal state statistics service of the Russian Federation, the digital inequality between the regions of the Russian Federation in terms of the use of personal computers by households in 2014 was 1.96 and increased to 2.02 times by 2018. Digital inequality in terms of household Internet access increased from 1.3 times in 2014 to 1.6 times in 2018. The gap between the regions of the Russian Federation in terms of broadband access to the Internet for households is 1.9 times in 2018 (3.3 times in 2014) (Gks, 2019).

Income, level of education, size and type of household, age, gender, racial and linguistic origin, and location (for example, Internet access is more accessible in cities than in rural areas) are factors that determine the availability of computers and Internet access (Novak and Hoffman, 2000; Wilhelm, and Thierer, 2000). The population with a higher income level has greater access to a personal computer and the Internet, despite the fact that there is also a positive trend in access growth in lower-income groups. We can see this pattern on the example of differentiation of Russian regions. Regions of the Russian Federation, which traditionally have high incomes and a high level of socio-economic development, have the highest rates of Internet access: in the Yamalo-Nenets Autonomous district, 96.3% of the population have access to the Internet, in the Khanty-Mansi Autonomous district-Yugra-88.9%, in the Republic of Tuva-87.4%, in Saint Petersburg-84.7% (Gks, 2019). In addition, people with higher levels of education have more motivation and opportunities to access and use ICT at home and in the workplace (OECD, 2001). Thus, a significant social risk of this stage of digital transformation is digital inequality in access to a personal computer and the Internet.

The existing digital inequality can lead to the emergence of social risks of the next level-inequality in knowledge and opportunities (Stiakakis et al., 2010). Howard et al. (2001), Rogers (1995), Hargittai (2002) in their research emphasize that people who have access to the Internet and have computer skills find information easier and faster, as well as have a greater willingness to use the network to expand knowledge, obtain education and develop their own potential.

At the same time, Sologubova (2017) notes that in this case, there is an inequality in the amount of knowledge mastered, as well as a gap in their interpretation, which determines the level of human capital development. For example, users from the leading countries in terms of digitalization (the United States, Canada, and European countries) have a higher number of materials indexed by the google search engine, and a higher share of publications among all scientific journals published in the world (IBRD and World bank, 2016). In addition, researchers note an increase in the average income of households with broadband access (De Los Rios, 2010), as well as a strengthening of social division (Katz and Callorda, 2014).

The second stage of digital transformation is associated with the intensive development of the Internet and its corresponding platforms (search engines, marketplaces), as well as the spread of cloud computing. These technologies began to be implemented in the 90 years of the XX century, but tangible results were achieved only by 2015. For example, the launch of the social network Facebook occurred in 2005, and only by 2015, the regular access of the OECD population to the network reached 48.05% (Katz, 2017).

The intensive development of technologies of the second stage of digital transformation causes new social risks in the form of increasing human vulnerability in front of digital environment. In particular, at the individual level, information about personal data is increasingly leaked from state and municipal information systems. According to InfoWatch analysts, in 2019, the number of registered leaks from commercial companies and government organizations increased by about 10% compared to 2018. The total number of compromised user data records (personal data and payment information) exceeded 14 billion, which is almost double the figure of the previous year. In Russia, the number of leaks has increased by more than 40% over the year, and the number of compromised records has increased by about six times to about 170 million. The share of intentional violations has increased significantly in the world – about 2/3 of all leaks were committed intentionally (about 40 of internal leaks%) (InfoWatch, 2019).

Bank card holders become the target of cyber espionage, which brings them both direct financial losses and a whole range of negative emotional experiences. New technologies, information systems used by enterprises, high-tech user behavior, as well as electronic public administration systems create prerequisites for increasing the degree of human vulnerability and their economic activity (Karpunina et al., 2019b). For example, a serious risk for a person is cybercrime using virtual wallets, virtual exchanges, selling business packages, sites that are duplicates with fraudulent details, SMS fraud, attacks on systems that are massively used in daily life (the Internet of things). Thus, according to Fincert Bank of Russia in 2018, the volume of all unauthorized transactions made using payment cards issued on the territory of the Russian Federation amounted to 1384.7 million rubles, which is

44% higher than in the same period of 2017 (961.3 million rubles). The number of such operations for 2018 was 416,933 units, which is an increase of 31.4% over the same indicator for 2017 (317,178) (FinCERT Banka Rossii, 2019). Note that the average amount of one unauthorized transaction in 2018 increased by 9.6% and amounted to 3.32 thousand rubles against 3.03 thousand rubles in 2017.

In addition, a specific social risk is Internet addiction (its officially recognized symptoms are abstinence, compulsiveness, denial, tolerance), which is associated with "electronic network non-freedom". It contributes to reducing working hours and reducing labor productivity, loss of professional characteristics, and waste of time (Karpunina et al., 2019a). Research shows that 25% of Internet addicts form Internet addiction within 6 months after starting using the Internet, 58%-within the next 6 months, and 17% — after a year (Chou et al., 2005). According to Katz (2012), this form of social risk and intensive digital consumption lead to the degradation of human relationships. The author points out that users become unable to develop personal qualities, communication, self-identification and expand the field of knowledge due to excessive use of the network. As a result, they miss opportunities for future professional growth.

Scientists attribute the beginning of the third stage of digital transformation to 2010. They associate it with the introduction of technologies aimed at improving the quality of information processing and decision-making, as well as further automation of routine tasks and widespread robotization (Katz, 2017). Changes in the nature of the labor process due to automation and robotization, as well as shifts in the labor organization system, the emergence of new forms of employment create prerequisites for the emergence of new types of social risks.

On the one hand, currently about a quarter of the world's production is subject to robotics, it is expected that by 2021 the total number of installed industrial robots will double to about 630 thousand (for comparison, in 2009, only 60 thousand devices were produced, i.e. 10 times less) (World Robotics, 2016). This growth, according to experts, will be accompanied by a further reduction in the cost of automated devices, as well as an increase in the use of "inexpensive" robots (over the past 5 years, their cost has decreased by 17%).

On the other hand, one of the new social risks may be the growing trend of increasing robotization in developed and developing countries, which will lead to the forced release of significant labor resources. In this sense, robotics and automation carry the risk of a global restructuring of the labor landscape and the displacement of man by the machine (Salikov et al., 2019). So, McKinsey analysts studied more than 2,000 tasks performed by people from 800 different professions, and they concluded that almost half of the work can be automated using current technologies (while employers spent 15 trillion us dollars on it). However, only about 5% of these professions can be fully automated using existing technologies, and another 60% of professions can be automated by at least a third. According to analysts, the processes that use monotonous physical labor, as well as data collection and processing, will suffer the most. McKinsey experts estimate that 81% of the time that employees spend on physical labor can be transferred to robots; and automation of data processing and data collection will give employees 69% and 64% of free time, respectively (McKinsey Global Institute, 2017).

This type of social risk can be associated with increased unemployment, a decrease in the overall income, reducing aggregate demand and slowing productivity growth and a decline in overall welfare of the society. These adverse economic consequences can be accompanied by an increase in emotional experiences, fear of future job loss, loss of social status and personal degradation (Molchan et al., 2019).

In addition, the use of new technologies significantly changes the nature of work, creates prerequisites for increasing temporary or part-time employment in the labor structure, as well as the development of the so-called "precariat", that is, the practice of truncating rights and social security packages. This can also be considered as a risk situation in term of social well-being.

There are problems of emotional, psychological and behavioral nature against the background of increasing disunity in society as a result of virtualization, they threaten the well-being of society,

Popper (1992) describes the emerging situation through the concept of "open society", in which people almost never meet face to face, are completely isolated and communicate with each other through letters and electronic communication. People do not have enough live communication, attention, understanding and empathy, as a result of which new psychoemotional disorders such as nomophobia (fear of being left without a smartphone) or phantom phobia syndrome (when it seems that the phone rings or a message has arrived), as well as fears of loneliness and meaninglessness of existence are increasingly appearing. In addition, the process of meeting human needs for goods and services is changing: thanks to advanced digital technologies, it becomes extremely simple and fast. In turn, the acceleration of the process of emergence of new needs leads to a reduction in the time of satisfaction with the process of consumption, the syndrome of" frustration" begins to develop in people. It triggers transformations in the mechanism of demand formation and increases the risks of psycho-emotional experiences and depression.

Conclusions/Recommendations

The authors proved that social risks differ depending on the stage of digital transformation. The authors concluded that there are three stages of digital transformation: the first is associated with the emergence of the Internet, the introduction of management information systems in business structures, and the development of telecommunications technologies. At this stage, the following types of social risks can usually be identified: risks associated with the emergence of digital inequalities between individuals and households, inequality in knowledge and inequality in the realization of individual opportunities. The second stage of digital transformation is determined by the spread of the Internet, the development of Internet platforms and cloud computing. In turn, intensive digital consumption causes an increase in the vulnerability of society under the influence of cyber threats to the information environment and leads to the main social risk - the degradation of human relations. The third stage of digital transformation is characterized by the introduction of technologies aimed at improving the quality of information processing and decision-making, as well as further automation of routine tasks and widespread robotics. There is a change in the labor landscape due to automation and robotization, as well as shifts in the labor organization system. This leads to the emergence of new types of social risks – the risk of human displacement by robots and artificial intelligence technologies, the risk of future job loss, loss of social status and personal degradation, as well as the risk of deterioration of the psycho-emotional picture of human existence.

Abstract

The purpose of the research is to identify problems of youth employment and employment, as well as to study the advantages and risks of the digital environment for youth employment. The authors analyze the dynamics of youth employment in the global space and systematize the problems of their employment (the dilemma between employment and education; low motivation for development and employment due to high status and income ambitions; employers' distrust of hiring young professionals, the choice in favor of employees with work experience; gaps in social policy to support young unemployed). The authors reveal changes in the labor market that occur as a result of digitalization (the formation of new forms of labor, cooperation and exchange; growth in the quality of labor resources and changes in employee requirements; structural shifts in professions and competencies; automation and robotization of work and displacement of people). The authors propose a "B-R" matrix that reflects the benefits and risks of digitalization for youth employment. It is concluded that digitalization can overcome many existing problems of youth employment, expands opportunities for realizing the ability of young people to adapt to more flexible forms of work and training, but without motivation for development and employment of modern youth, all options for adaptation to the changing labor market become impossible.

Keywords: digitalization, youth, employment, unemployment, labor market

Introduction

Young people are an independent socio-demographic group with specific age characteristics and qualities that distinguish them in the social structure of society. Common characteristics of young people include their low social status and a high level of uncertainty about their professional future and their desired level of well-being. Indeed, young people face problems of age discrimination, underestimation of professional qualities and distrust from employers when they enter the labor market. Thus, the level of youth unemployment according to the International Organization for Economic Cooperation and Development in 2019 amounted to 11.17 % of the working population, in addition, international organizations note an increase in the share of economically inactive youth

(located outside the labor market-NEET (Not in Empoyment, Education or Training)) (OECD, 2020b, 2020c).

At the same time, young people have a high level of adaptability to changing conditions, as well as mobility and development potential, which can give stability to the economic system during its transformations. The current stage of transformation is associated with intensive digitalization, which causes critical changes in the labor market and requirements for professional qualities of employees. What are the challenges of digitalization for young people? How much does the digital environment contribute to solving youth employment problems? What are the risks of digitalization for young workers? The study of these issues is currently particularly relevant.

Methodology

Research hypothesis .Existing problems of youth employment are finding new solutions in term of digitalization. Young people as carriers of professional skills and competencies, on the one hand, will contribute to increasing social mobility, smoothing social inequality, as well as facilitating the adaptation of the labor market to new digital conditions. On the other hand, digitalization brings new challenges for young people (the need for continuous self-education, the growth of digital skills, the presence of internal motivation for development, self-organization), which can become factors that constrain the process of youth entering the labor market.

The theoretical basis of the research is formed by the works of:

- Elhorst (2003), Nataraj et al. (2012), Zubok and Chuprov (2012), Hohlova and Hohlov (2017), Korchagina (2019), describing the situation of youth in the labor market and the problems of youth unemployment;

- Frey and Osborne (2013), Sizova and Husyainov (2017), Snell and Bohlander (2012), Sorokina (2012), Bonin et al. (2015), Dengler and Matthes (2015), reflecting changes in the labor market in terms of digitalization;

- Zudina (2019), Gbadamosia et al. (2015), Lewis and Heyes (2017), reflecting the author's vision of the challenges of digitalization for young people.

Digitalization as an objective process of modern reality is based on the transformation of information into digital form, it leads to a radical change in production processes, the structure of life and social relations. In terms of digitalization, companies “compete through people”, their success is increasingly dependent on human capital and on the effectiveness of talent management (Snell and Bohlander, 2012).

Frey and Osborne (2013) note that in the process of digitalization, a high-tech (information and network) environment is formed, many types of work are carried out using a personal computer, mobile devices and applications, which themselves become the subject and/or means of work.

The development of digital platforms will reorganize the labor market and transform employment mechanisms (Kenney and Zysman, 2016).

The Federal Ministry of labor and Social Affairs of Germany (2017) presented a new model of labor and employment “Work 4.0”, which is being intensively developed in countries with advanced economies at the moment.

Sizova and Husyainov (2017) prove that the main features of "Work 4.0" are new requirements for employee training that apply to all professional groups without exception. In terms of technological change, there is a demand for a workforce with high skill requirements, the so-called “skill-based technological change” (Spitz, 2004).

In addition, there is a blurring of the classical labor organization and the usual employment patterns, while jobs that are not tied to one place and time are created (BMAS, 2013). Strebkov and Shevchuk (2009), Sorokina (2012) explore the specifics of new forms of remote work, outsourcing, and self-employment on the Internet.

In this study, we will refer to youth as a socio-demographic group that is distinguished based on a combination of age characteristics (from 16 to 25 years), features of social status and certain socio-psychological qualities: 1) transitivity of the situation (the development of new social roles (employee, student, citizen, family man)) and a high level of mobility and adaptability (young people are subject to internal changes that are characterized by emotional awareness and flexibility, self-control and regulation, stability and the ability of the individual to maintain concentration, as well as perseverance in the process of overcoming obstacles (Di Fabio and Kenny, 2015); 2) low personal wealth and low social status (Korchagina, 2019); 3) active search for their place in life and prospects in professional and career terms (young people began to consider job search and career formation in terms of global labor mobility, competition among graduates for specific jobs (Michael, 2014)).

The logic and concept of the research is presented in the figure 1.

Fig. 1: Concept of research on the impact of digitalization on youth employment (compiled by the authors)

Research methods: methods of logical and theoretical research (analysis, synthesis, comparison, generalization), methods of systematization, system method, graphic method.

Information base of the research: materials of international reports of OECD (2020), McKinsey Global Institute (2017), Euromonitor International (2012), European Commission et al. (2014), Deloitte (2015), IMD (2019), as well as materials of international conferences and monographs.

Results

Problems Limiting Youth Employment

According to the International Organization for Economic Cooperation (OECD), the world youth unemployment rate in 2019 was 11.17 % of the working population (youth unemployment is the number of unemployed people aged 15-24 years, expressed as a percentage of the total labor force) (OECD, 2020c)).

The value of the index varies depending on the general level of socio-economic development of the country, implemented social policy, income levels, political instability, unemployment of the working population, as well as a number of other factors. The top 5 countries with the best indicators of youth unemployment in 2019 include Japan, the Czech Republic, Germany, Israel, and the Netherlands. The countries with the worst indicators are South Africa, Greece, Spain, Italy, and Turkey (figure 2).

Fig. 2: Youth unemployment rate in 2019, % (% of the total labor force aged 15-24) (compiled by the authors according to the OECD, 2020a)

This anomalous gap between South Africa and all other countries can probably be explained by the largest share of the world's young population - more than 70% of the region's population is under the age of 30. In terms of median age (average age distribution), Niger had the youngest population in 2011 at 15.4 years, followed by Uganda (15.7 years) and Mali (16.2 years) (Euromonitor International, 2012).

Of course, youth unemployment is a multi-factor process, which is caused by internal contradictions of young people, imperfections of the labor market, as well as the implemented state policy. Let's note some problems that limit the employment of young people:

1) The dilemma between employment and education. Young employees often seek higher education and find out their career direction. Young people benefit from remaining in education and training because they continue to invest in their human capital, which can lead to better jobs, higher wages and higher productivity (European Training Foundation, 2015). Conversely, young people who find themselves without education and training at an early age are "vulnerable" because they face disadvantages in the labour market at the initial stage, as well as throughout their working life, because lack of or low qualifications significantly hamper their employment and career development (European Commission et al., 2014). In addition, the needs of the labor market may change during the course of education, which creates the problem of re-profiling or professional retraining.

2) Low motivation for development and employment due to high status and income ambitions.

The main motivating factor for youth employment is the quality of the offered employment, i.e. the ratio of the employment regime, the level of income received and career prospects. On the one hand, young people between the ages of 16 and 24 are usually not highly qualified, so they can apply for jobs that do not require professional skills. These types of jobs can't offer high earnings. For example, in 2017, the daily earnings of employed youth in developing countries were less than 3 US dollars. Of course, this amount of income does not encourage young people to actively join the workforce. On the other hand, initial entry into the labor market a priori can not guarantee a high level of remuneration and, as a rule, it is a necessary step for career advancement in the future. In addition, many young people are attracted to underemployment in the informal economy, which does not require high qualifications, as well as self-employment (Korchagina, 2019). Elder notes that there is a category of young people who consider job search a futile effort. Young people do not believe in the existence of a suitable job for themselves (in the desired professional field, with the desired characteristics of work, as well as in their knowledge and qualifications that meet the requirements of employers (Elder, 2009). In addition, in recent years, there has been an increase in the share of economically inactive youth (youth who are not engaged in employment, education or training and are outside the labor market - NEET (Not in Employment, Education or Training), especially in such countries as Turkey, Italy, South Africa, Argentina, Colombia, Brazil. Young people who do not have a job, education, or training are at risk of becoming socially isolated – people with incomes below the poverty line and lack the skills to improve their economic situation (OECD, 2020b).

3) Employers ' distrust of hiring young professionals, choosing employees with work experience. This is primarily due to the low level of competitiveness of young professionals in the labor market, their lack of professional skills and experience. The employer will incur additional financial investments in the professional training of young professionals, adapting them to the specifics of their activities, as well as certain risks in the future in the case of hiring young professionals without initial work experience. For example, the South Korean Government sends unemployed youth to train in manufacturing companies in order to solve this problem. This helps to eliminate the mismatch of jobs between businesses and job seekers. As a result, applicants get "work experience", as well as opportunities to plan their career path and develop productivity through experience before actual employment (Deloitte, 2015).

4) Gaps in social policy to support the young unemployed. In many European countries, conditions are too favorable for the unemployed, including young people. The ratio of the minimum wage of a young professional to the amount of unemployment benefits often pushes young people to choose the labor exchange. For example, Belgium uses various social policy mechanisms to regulate youth unemployment: the right to receive unemployment benefits or social benefits; an employee's social contribution; requirements for finding or having a job to receive unemployment benefits or social benefits; employment assistance, advice or employment; conditional income tax credit, benefits or “make work pay” schemes. But at the same time, social policy tools include sanctions and reducing the duration of unemployment benefits. The combination of such support and incentive measures is assessed as a good incentive for young people to take measures to find work, in contrast to other European countries (Deloitte, 2015).

The transformation of the labour market in terms of digitalization.

The introduction of digital technologies into production processes and people's daily lives has triggered corresponding transformations of the labor market and social reality.

1) Formation of new forms of work, cooperation and exchange:

- digitalization is transforming the labor market and employment mechanisms (Kenney and Zysman, 2016);

- there is a new model of work and employment "Work 4.0", which is derived from the concept of Industry 4.0 implemented in developed countries of the world (Federal Ministry of Labour and Social Affairs of Germany, 2017);

- work is becoming autonomous and mobile, Gig Economy is developing, and freelance and project work is dominating the labor market (for example, in Germany, about 30 % of employees regularly work outside the office, 12 % of employees and 4% of workers perform work tasks several times a week outside of official working hours) (BMAS, 2015);

- atypical forms of work are developing (remote work, outsourcing and self-employment on the Internet) (Strebkov and Shevchuk, 2009), remote work increases the degree of social mobility of a person, helps to equalize their life chances, reduces social inequality; employee productivity no longer depends on their location (a Gallup study showed that in 2018 alone, the number of remote workers increased from 39% to 44%) (Pravkina, 2012);

- temporary employment, part-time employment, temporary loan work, multi-party employment, and dependent self-employment are becoming more common (Sorokina, 2012);

- digital technologies allow you to divide the workflow into smaller operations within the global digital production, and work tasks become more fragmented (Kergroach , 2017).

2) Increasing the quality of labor resources and changing employee requirements:
- companies are more profitable to "hire by necessity", so competition for talent is growing;
- the professional profile of a modern employee includes professional competencies, system, creative and soft-skills, ability to abstract, fast processing and selection of information, as well as digital literacy;
- identification of future leaders, their retention and adequate development, succession planning and management of the personnel reserve become the most important for organizations.

3) Structural shifts in professions and competencies:

- the professional structure has changed in many countries, the process of creating new jobs has been divided into high-and low-skilled groups, and jobs requiring average skills and performing routine operations are being eliminated first (Goos et al., 2009; Autor and Dorn, 2013).

- new jobs require new skills and competencies: the availability of digital skills and lifelong learning become the basic conditions for a successful employee (Frey and Osborne, 2013); self-organization, management, teamwork, or communication are increasingly important;

- new types of jobs are being created: digitalization and big data are driving demand for employees with analytical skills and cybersecurity specialists (according to CEB forecasts, by 2030 the market will need 298,600 specialists in machine learning and predictive Analytics, and 351,500 engineers in the field of cybersecurity), as well as specialists in the field of artificial intelligence (by 2030, the supply will be 108,600 people) (Astera, 2017).

4) Automation and robotization of work and human displacement:

- the relationship between technology and labor is twofold: on the one hand, technological changes increase labor productivity, promote economic growth and create new jobs both at individual enterprises and at the macroeconomic level (Keynes, 1930), on the other hand, in many industries and professions, new technologies have already replaced human labor, which has led to the release of workers in different sectors of the economy and regions (Kergroach, 2017);

- the development of machine learning, robotics and artificial intelligence will inevitably contribute to the automation of production and change the structure of labor demand (Brynjolfsson and McAffee, 2011);

- robotics and automation carry the risk of a global reshaping of the labor landscape: McKinsey analysts concluded that almost half of the work that employers spent 15 trillion dollars on can be automated using current technologies, while only about 5% of these professions can be fully automated using existing technologies, and another 60% of professions can be automated by at least a third (Salikov et al., 2019);

- McKinsey experts estimate that 81% of the time that employees spend on physical labor can be transferred to robots; and automation of data processing will give employees 69% of their free time, data collection-64% of the time (McKinsey Global Institute, 2017).

Changing the Position of Young People in The Labor Market in Terms of Digitalization

Dynamics of the indicator "youth unemployment rate total, % of youth labour force" shows that in a time of increased digitalization 2015-2019 most of the studied countries, Japan, Czech Republic, Germany, Israel, Netherlands, Greece, Spain, Italy - have significantly improved their performance in 1,1-2,2 times, and only in Turkey and South Africa in 2019 relative to 2015 was increased by 1.4 and 1.1 times respectively. In general, there is a decrease in the unemployment rate among young people in OECD countries, which can probably be a consequence of the ongoing digitalization (Figure 3).

Fig. 3: Dynamics of the youth unemployment rate total, % of youth labor force, 2015-2019 (compiled by the authors according to OECD, 2020c)

It can be assumed that significant achievements in the field of digital development in most of the countries studied allowed them to create conditions for improving the situation with youth unemployment. For example, according to IMD data (2019) Germany has strengthened its leadership in scientific concentration, training and education, and the introduction of digital technologies by its citizens (adaptive settings). Israel is a key regional player in the field of digital competitiveness, the country topped the ranking in areas such as talent development (a sub-factor of training and education) and R&D intensity (scientific concentration). The Netherlands has demonstrated high levels of readiness for the future (in terms of it integration, business flexibility and adaptive installations) (IMD, 2019)

Let's reflect the impact of digitalization on youth employment in the form of a matrix of "B-R" (benefits and risks) (table 1).

Table 1: Matrix "B-R": benefits and risks of digitalization for youth employment (compiled by the authors)

Manifestations of digitalization / Problems of youth employment	Formation of new forms of work, cooperation and exchange	Increasing the quality of labor resources and changing employee requirements	Structural shifts in professions and competencies	Automation and robotization of work and human displacement
The dilemma between employment and education	**B:** ability to combine work and study; possibility of employment with incomplete education	**B:** opportunity for continuous learning, self-improvement and development of professional skills during working life	**B:** youth flexibility and rapid adaptation to changes in the labor market	**B:** availability of digital skills, as well as opportunities to develop soft-skills and analytical skills that allow to enter the segments of the labor market that are not subject to automation
	R: low incentive to get an education in case of employment without a diploma	**R:** inability to find employment due to high competitiveness and shortage of professional staff	**R:** non-compliance of the chosen education profile with the needs of the labor market	**R:** lagging in the speed of response to changes in the labor market, displacement from the labor market
Low motivation for development and employment due to high status and income ambitions.	**B:** choosing a new form of employment that meets the requirements of young people (freelance, self-employment, outsourcing, etc.)	**B:** low probability of finding your own niche in the set parameters "scope of work-amount of income" with the existing level of professional competence	**B:** it is unlikely that the profile and professional competence of young people will meet the new requirements of the labor market	**B:** low probability of staying in the labor market with the existing level of professional competence
	R: lack of internal motivation for development makes new forms of work ineffective	**R:** it is impossible to improve the quality of the labor resource without internal motivation for self development and improvement of professional competencies	**R:** it is impossible to respond adequately to structural changes in the labor market without internal motivation for self development and improvement of professional competencies	**R:** it is impossible to resist displacement from the labor market due to automation without internal motivation for self-development, improvement of professional competencies and digital skills
Employers' distrust of hiring young	**B:** new forms of employment (on-demand work,	**B:** the chance of employment in conditions of equal	**B:** rapid response to structural changes will	**B:** the acquisition of soft- skills that meet the

professionals, choosing employees with work experience	self-employment, outsourcing, etc.) allow you to smooth out the problem of distrust of employers and find a job	competition with experienced employees increases if professional skills are continuously improved	allow to acquire the necessary professional profile and increase your chances of employment	requirements of the labor market will allow to become in-demand specialists and save your workplace during automation
	R: high competition for talent reduces the chances of young professionals finding employment	**R:** it is impossible to develop professional skills of a young specialist in the case of low internal motivation, employment opportunities are minimized	**R:** slow response and poor adaptation to new conditions will not allow a young specialist to find a job in the desired profile	**R:** the advantages of automation and robotics, as well as cost reduction, do not allow the employer to make a choice in favor of young professionals
Gaps in social policy to support the young unemployed	**B:** guaranteed support from the state during the testing of a new form of employment	**B:** guaranteed support from the state during the period of training and professional retraining	**B:** guaranteed support from the state during the period of professional retraining	**B:** guaranteed support from the state in case of labor release due to automation and robotization
	R: excessive incentives for unemployment benefits reduce the motivation for employment in new forms	**R:** excessive incentives for unemployment benefits reduce motivation for training and retraining	**R:** excessive incentives for unemployment benefits reduce the motivation for professional retraining	**R:** excessive incentives for unemployment benefits reduce the motivation for self-improvement, development of soft and digital skills

These tables allow you to draw the following conclusions:

- digitalization helps to overcome many existing problems of youth employment, expands opportunities for realizing the ability of young people to adapt to more flexible forms of work and training, and promotes broader self-government in the field of employment and social integration;

- professional work and its results become exclusively a zone of personal motivation and responsibility for each young person under the influence of digitalization, without motivation for development and employment, all options for adaptation to the changing labor market become impossible;

- self-efficacy is associated with status and income ambitions, the level of education of young people and their confidence that they can achieve more through effort are the strongest predictors of new forms of employment available in the conditions of digitalization;

- young people who have information and digital communication resources for new forms of work (remote) have a “value”, since remote work increases the degree of social mobility of a person, helps to equalize their life chances, and reduces social inequality (Sheler, 1994).

Conclusions

The authors obtained the following conclusions. First, we analyzed the dynamics of youth employment in the world and systematized the problems that restrict their employment: the dilemma between employment and education; low motivation for development and employment due to high status and income ambitions; employers ' distrust of hiring young professionals, the choice in favor of employees with work experience; gaps in social policy to support young unemployed. Second, we have revealed the changes in the labor market that occur as a result of digitalization: the formation of new forms of labor, cooperation and exchange; the growth of the quality of labor resources and changing requirements for employees; structural shifts in professions and competencies; automation and robotization of work and the displacement of people. Third, we analyzed the impact of digitalization on youth employment, and proposed a "B-R" matrix that reflects the benefits and risks of digitalization for youth employment.

Abstract

The purpose of the study is to determine the objective risks of digitalization for each of the components of the company's labor potential (psycho-physiological, qualification, and socio-personal), as well as to develop tools for developing labor potential based on risk management. The authors showed how digitalization transforms the labor landscape and reduces the effectiveness of traditional tools for developing the company's labor potential. The researchers systematized the risks of digitalization, which are most likely to hinder the development of psycho-physiological, qualification and socio-personal components of the company's labor potential. The authors proposed a model of development of labor potential of the company in terms of digitalization, based on system approach (input of the model - risks of digitalization for psycho-physiological, skill and social and personal potential; management impact/operation - a set of the most effective tools to reduce risks; output of the model - the efficiency of development of labor potential of the company).

Keywords: Labor Potential, Company, Digitalization, Non-Standard Employment, Economy Of Joint Consumption, Automation

Introduction

One of the most responsible and significant aspects of a modern company is its work with personnel, which includes the management of labor potential. This is due to the increasing role of human capital in production activities as the main resource of the digital economy.

The developed labor potential becomes a source of increasing production efficiency and product quality in the conditions of digitalization (Chowdhury and Mukherjee, 2015). Solving the issues of continuous development of human capital, increasing the professionalism of employees, creating motivational mechanisms largely determine the company's competitiveness and the possibility of its sustainable development in the long term. However, the introduction of artificial intelligence,

cognitive computing and robotics technologies is radically changing the entire labor landscape and provoking changes in the structure and forms of employment, professions and organization of labor activity (Brynjolfsson and McAfee, 2011).

Modern companies in the process of developing their own labor potential face the challenges of designing new jobs, finding the optimal combination of automation and the use of human skills, as well as numerous risks that threaten the loss of competitiveness and traditional social values.

Methodology

Labor potential has the character of a strategic resource for the company's development and growth of its competitiveness. Digitalization is a factor that transforms the labor landscape and reduces the effectiveness of traditional tools for developing the company's labor potential. Improving the efficiency of the company's labor potential development is possible by using a system approach to managing digitalization risks, which become the starting points for choosing new tools for developing the company's labor potential.

Issues of managing the company's labor potential are reflected in the works of Sudakova (2014), Odegov et al. (1991), Torrington et al. (2008), Joshi (2013), Chowdhury and Mukherjee (2015).

The specifics of the transformation of the labor market and labor relations under the influence of digitalization are shown in the research by Brynjolfsson and McAfee (2011), Schwartz et al. (2013, 2016, 2017), Gimpelson and Kapelyuchnokov (2006), Kassi and Lehdonvirta (2018), Blochina and Blochin (2016), Titov (2008), Schatsky and Schwartz (2015), Stevens (2016), Knowles-Cutler and Lewis (2016), Huber (2017), Bostman and Rogers (2010), Heinrichs (2013), Allen and Berg (2014), Kathan et al. (2016), Erickson et al. (2012), Lacan and Parguel (2017).

In the present study under the labor potential of the company means a set of potential capabilities of workers in the framework of the activities of a particular company over time, taking into account their qualitative and quantitative characteristics (total size of the labor force, their age structure, educational level, opportunities for optimal use in industry, vocational qualification and territorial aspects) (Odegov et al., 1991).

The state of the company's labor potential is determined by a variety of factors, including location, sphere of activity, culture of development, specifics of relationships in the workforce, and traditions (Sudakova, 2014). The task of the company's management system is to form its labor potential (based on the qualitative, temporal, spatial, and quantitative characteristics of employees) as a strategic resource that determines its competitiveness in the long term (Joshi, 2013).
