The authors identify the structural components of the company's labor potential to achieve the goals of this study:1) psycho-physiological potential, that is, the aptitudes and abilities of employees, their state of health, type of nervous system, the quality of their performance and endurance; 2) qualification potential as a reflection of the volume, depth and diversity of general and special knowledge, as well as professional skills that determine the ability of employees to work with a given content and level of complexity; 3) socio-personal potential, including the level of civic awareness and social maturity, the degree of employee recognition of the established labor standards, its value orientations and the needs of self-realization of employees in the labor process. This structuring of labor potential is necessary to improve the efficiency of its development and the effectiveness of the company's management as a whole. It allows us to present the company's labor potential as an integral characteristic of the aggregate ability to work (in its qualitative and quantitative terms), which determines the ability of both individual and collective employees to participate in socially useful activities (Odegov et al., 1991).

In this study, the company's labor potential (LP) is represented as a function of the quantitative (X) and qualitative (P, Q, S) characteristics of labor resources, taking into account the specific organizational, technical and socio-economic reality:

LP = f (X, P, Q, S), where

X - the number of labor resources, the size of the working time fund of one employee, as well as the coefficients of use and intensity of working time; P – qualitative indicators of the company's psycho-physiological potential (loss of working time due to diseases and injuries; frequency and severity of diseases per 100 employees, etc.); Q - quality indicators of the company's qualification potential (average category of workers; product quality; costs for professional development, etc.); S – qualitative indicators of the company's socio-personal potential (relationships between employees; losses from conflicts; job satisfaction; staff constancy coefficient, etc.).

The company's labor potential changes over time due to scientific and technological progress, digitalization, and transformation of working conditions (Torrington et al., 2008). Therefore, the more complex multi-level structure of the company's labor potential, which has its own socio-economic specifics, will also be subject to changes.

Research methods: methods of logical and theoretical studies (analysis, synthesis, comparison, generalization) was used to identify risks of digitalization for of the labor potential of the company, the graphical method was used to demonstrate the dynamics of the index of online employment, systematic method applied in the analysis of the risks of digitalization affecting employment potential, system approach applied to form a model of the development of labor potential of the company in terms of digitalization.

Results

1. Digitalization is changing the future workforce and forcing many companies to rethink how they design jobs, organize work, and plan for future growth (Schwartz et al., 2017). What trends in digitalization most strongly transform the labor market and conditions for the development of the labor potential of companies?

First, the formation of an open talent economy as a trend, as well as the development of non-standard forms of employment (Schwartz et al., 2016).

Non-standard employment is considered as an employment relationship that deviates from the standard model of full, regulated and open employment for a single employer for a long time based on one or more of the following criteria: length of working hours, payment terms, duration of the employment relationship, location of the workplace, social security, and so on (Gimpelson and Kapelyushnikov, 2006). The most common forms of non-standard employment are: temporary contracts, temporary agency work, self-employment, part-time work.

Temporary contracts have grown significantly in many European countries since the late 1970s, with periods of strong growth in individual countries concentrated in different decades until the 2008 recession. In the EU as a whole, the level of temporary employment (the number of temporary workers as a percentage of total employment) was 14.5% in 2006, 14.6% in 2007, and in the post-recession period, its maximum value of 14.2% was recorded in 2016 (Eurofound, 2018).

Since the early 1980s, self-employment, which was in long-term decline, has slowly gone up in some States. Between 2006 and 2016, the number of self-employed workers fell by almost 0.5 million. In total, the decline was 1.8 million people in Greece, Spain, Croatia, Italy, Portugal and Romania, due to a decline in agricultural employment. The largest absolute increases were observed in the UK (750,000) and the Netherlands (320,000). The level of self-employment in the EU-28 in 2017 for those who have employees (employers) is about 4.5%, and for those who do not have (their own employees) - about 10% (Eurofound, 2018).

Temporary agency work appeared in most European countries in the late 1990s and grew quite rapidly (according to the European survey of working conditions (EWCS), temporary agency work is the most unreliable of contract forms), but never accounted for more than 3% of all employment (CIETT, 2015), and it is currently about 1.9%. In 2015, the highest rate was in the UK (3.8%), the

Netherlands (3.0%) and France (2.1%); the lowest rate was 0.1% in Greece (World Employment Confederation, 2017).

New forms of non-standard employment (employee sharing; exchange work; temporary management; casual work; ICT-based mobile work; voucher-based work; portfolio work; mass employment; co-employment) are associated with digitalization (Eurofound, 2015). The economic efficiency of work mediated by digital platforms is becoming obvious, previously potential exchanges of low economic value relative to the transaction cost were not economically feasible (Eurofound, 2018). The Online Labour Index (OLI) is one of the indicators that measure the supply and demand of online employment in different countries and professions, as well as tracking the number of projects and tasks on different platforms in real time (Kässi and Lehdonvirta, 2018).

Fig. 1: Dynamics of the Online Labour Index in the world (compiled by the authors according to Ilabour, 2020).

The dynamics of the index shows how the use of the online workforce changes over time in different countries and professions. The index is normalized so that 100 index points on the y axis represent the average daily number of new projects in May 2016. Depending on the value of the Online Labour Index, Asia is the leading region in the world where online employment in 2020 is distributed as follows: 45.1% software development and technology, 32.7% creative and multimedia, 9% sales and marketing support, 6% writing and translation, 5.3% clerical and data entry, 1.8% professional services. The European region follows next, where the distribution of online employment by sector has an almost identical structure. North America is ranked third in the world, Africa is fourth, South America is fifth, and Oceania is sixth (Ilabour, 2020).

The emergence of new forms of non-standard employment is one of the most complex changes in the field of human capital: there is a transition from hiring and managing full-time employees to an expanded workforce (supplemented by technology and groups of people). This radical transition changes the usual ideas about the nature of work, staff training, workforce selection and workplace design.

If we consider non-standard labor relations through the interests of their participants, we can distinguish two groups of risks that are important for managing the company's labor potential. First, on the part of the employee, non-standard labor relations are realized in obtaining a temporary, part-time or informal workplace. This carries risks of losing social security guarantees and career prospects, increases employee insecurity, and creates problems with occupational safety and health (a combination of poor induction, training and supervision, communication failures, and work disruptions) (ILO, 2016). At the same time, a high level of employment is provided, which helps to reduce unemployment. Second, non-standard labor relations give employers flexibility in employment, which reduces labor costs, increases competitiveness, and opens up opportunities to reduce standard jobs and create new ones with already non-standard working conditions. However, on the other hand, this contributes to an increase in the share of non-standard employees, which

eliminates incentives to invest in human capital, and also negatively affects the labor motivation of employees (Blokhina and Blokhin, 2016). The effect of such negative factors can probably lead to a decrease in the quality of products and, consequently, loss of competitiveness (Titov, 2008).

In general, new forms of employment may be insecure due to weak contractual rights or market forces. By definition, temporary contracts are expected to have a limited duration, with low or even zero termination costs for the employer. The security of self-employment, usually in very small companies and with limited financial resources to deal with shocks, depends directly on the demand for services provided, so such work is highly susceptible to market fluctuations (Eurofound , 2018).

Second, the growing power of robotics and labor-saving technologies to restructure jobs (Schatsky and Schwartz, 2015).

Progress in technologies aimed at improving skills and saving labor is associated with the development of ICT, automation (artificial intelligence and machine learning technologies), new service networks, organization and management. The emergence of such labor-saving and skilled technologies changes the nature of work. Lower prices for investment goods encourage the employer to replace labor with capital, that is, to use labor-saving technologies that increase productivity and reduce labor costs. For example, according to the International Federation of Robotics, orders for industrial robots increased fivefold between 2001 and 2017, and this trend is projected to accelerate even further (IFR, 2019) when combined with a growth of the share of national income attributable to capital (OECD, 2019). The use of labor-saving technologies affects the share of national income that workers receive and the composition of the labor force (United Nations, 2020). On the one hand, technological progress can lead to the loss of some jobs due to automation and increase income inequality, and, on the other hand, it displaces low-skilled workers, creates demand for new jobs, especially for highly skilled workers, and contributes to the polarization of jobs (Salikov et al., 2019).

Automation can have a positive impact on both productivity and employee engagement and customer value. For example, Amazon effectively uses automation during the holiday seasons to quickly scale warehousing and shipping, reducing employee training time and maintaining its reputation (Stevens, 2016). At the same time, the rapid introduction of robotics and labor-saving technologies creates conditions when companies do not have time to repurpose employees and reorganize new jobs.

The results of a study by the University of Oxford and the Net job database show that while tasks are automated, the human attributes and skills (empathy, communication, persuasion, personal service, problem solving, and strategic decision-making) that determine the work process become more important (Knowles-Cutler and Lewis, 2016). Therefore, the company's strategic goal is to rebuild workplaces and rethink the necessary human skills in order to combine the capabilities of cognitive systems and robots and human abilities.

Third, the development of a shared consumption economy based on the collective use of goods and services (Schwartz et al., 2016).

Huber (2017) described sharing as a situation where at least two community members engage in direct interaction and use the same units of material goods or services to perform practices. In contrast to the traditional model, the economy of shared consumption has a fundamentally new way of creating and capturing value: the idea of sharing is realized through access to resources, rather than through their acquisition and consumption. This allows to effectively save resources while reducing consumption, preserve the environment, reduce transaction costs for consumers, and adapt products for users (Botsman and Rogers, 2010; Heinrichs, 2013; Allen and Berg, 2014; Kathan et al., 2016). The shared consumption model is most applicable in industries with access to distributed technologies and other forms of distributed fixed capital (for example, in the automobile transport industry), as well as where the design process can be separated from physical production. Companies like Airbnb and Uber are implementing the idea of a sharing economy. They actively attract freelance workers as a regular, manageable part of their workforce. The other part of employees are involved remotely and temporarily. Some companies prefer to pay for purchase orders instead of wages (Schwartz et al., 2016). Overall, the shared consumption economy is growing exponentially:

according to PwC's forecast, the revenue of companies in the shared consumption economy will increase 22 times by 2025 and reach 335 billion us dollars (PwC, 2015). According to the World Bank, China is the world's leading economy of shared consumption: in 2018, its volume was estimated at more than 230 billion US dollars, or 1.67% of the country's GDP. It is expected that by 2020 the share of the economy of shared consumption will be 10% of GDP, and by 2025 — 20% (Daxueconsulting, 2017).

The development of the economy of shared consumption causes a number of risks for the management of the company's labor potential. Some risks arise from employees and are associated with uncertainty about the future, instability of employment conditions and wages, as well as the distribution of benefits. For the company, the clear advantages of the sharing model (flexibility, reduced costs and tax charges) are accompanied in practice by problems related to hiring the best employees at the best price regardless of the type of employment relationship, consistent management of mixed labor resources, ensuring productivity growth, as well as ensuring accurate information about time, labor procurement, planning and management of personnel contingents (Brynjolfsson and McAfee, 2011). Companies are facing new and much more sophisticated competition for talent, especially as unemployment in some markets is falling and voluntary turnover is increasing (Erickson et al., 2012), as well as a problem of trust (Lacan and Parguel, 2017). To sum up, we will reflect the impact of digitalization on the development of the company's labor potential in the form of systematization of risks (table 1).

Table 1: Risks of digitalization for the development of the company's labor potential (compiled by the authors)

The trend of digitalization	Component of labour potential	Risks for employees	Risks for the company
1. Formation of an open talent economy, development of non-standard forms of employment.	Psycho-physiological potential	• Risk of disability due to health problems and stress • The risk of job loss and prospects of development • Risk of loss of social security guarantees	• Reduced incentives to invest in human capital • Reduction of labor motivation of employees • Reduced product quality • Reduced competitiveness
2. The growing power of robotics and cognitive computing for the restructuring of jobs.	Qualification potential	• Risk of job loss • Underestimation of human skills • Lack of opportunities for re-profiling and obtaining new positions	• Risk of inefficient re-profiling and reorganisation around automation • Risk of inadequate release of human resources • The risk of reducing the competitiveness
3. Development of the economy of sharing and cooperation.	Socio-personal potential	• Risk of loss of socialization • Lack of prospects for career growth and professional self-realization	• Risk of separation of the work team and its loss • Reducing the involvement of employees in achieving the company's success and productivity • Loss of high-potential employees • Elimination of corporate culture • The risk of reducing the competitiveness

2. A system approach to the development of the company's labor potential in terms of digitalization.

Let's build a model for the development of the company's labor potential in terms of digitalization based on a system approach. The system approach allows us to present development as a management process, i.e. a set of input, direct operation, and output (Fig. 2).

Fig. 2. Model of applying a system approach to the development of the company's labor potential in terms of digitalization (compiled by the authors)

In accordance with the authors' proposed component structure of the company's labor potential, the risks of digitalization were systematized. In the proposed model, they form the input conditions: a decrease in employee labor motivation and a decrease in incentives to invest in human capital (as a risk to the psycho-physiological component of the company's labor potential); inefficient re-profiling due to automation and inappropriate release of a person (risk to qualification potential) and separation/loss of the workforce and loss of high-potential employees (risk to socio-personal potential). Representing the development of labor potential as a management process requires defining the content of the impact operation in order to adapt to internal and external conditions that are undergoing changes. In our case the operation is identified with a set of the most effective risk leveling tools: 1) stress management, HR innovations; 2) development of skills of "extended workforce", design thinking; 3) team building, gamification.

Let's look at the specifics of the proposed tools.

1) Stress management and HR innovations are aimed at creating a favorable psychological situation for employees to adapt to new working conditions, reducing stress due to the risk of job loss and employee vulnerability in the future, as well as creating motivation to work. Organizational measures aimed at managing stress include changing the organizational climate and providing appropriate assistance to staff in the framework of special programs for stress monitoring, identifying possible negative consequences and implementing prevention measures, as well as mitigating or reducing the effects of stressors. The CDC estimates that depression is worth about 200 million lost work days in the United States, meaning about $ 17 billion to $ 44 billion in lost productivity (Forbes, 2017). For example, Unilever, which employs 172,000 people, has a global health initiative

for all employees, regardless of their form of employment, which includes a comprehensive program specifically designed for mental health. The company conducts mental health training for managers and senior managers, internal campaigns to raise awareness of mental illness, and regular seminars for employees on sleep, mindfulness, and exercise to improve psychological well-being (Huffpost, 2016). Employers ' concerns about hiring remote workers boil down to whether they will be able to do the job without supervision or will be out of control when they are needed. HR innovations help organize a remote workforce. For example, specialized applications such as Trello and Slack help organize remote workgroups, and hardware such as interactive displays ensures that teams can interact even if they are not all in the same place (Avocor, 2019). Productivity platforms allow to integrate applications that employees already use directly into the workflow and meet the unique business needs of a particular company.

2) The development of "extended workforce" skills and design thinking are aimed at maintaining regular demand for human resources in an automated environment, creating a new employee's qualification base for the digital economy. In the new environment, we need to rethink the limits of applying basic human skills, such as creative and ethical thinking, and the non-essential tasks that machines can manage. Research by Deloitte in the UK shows that the future workforce will need "a balance of technical skills and more general skills, such as problem-solving skills, creativity, social skills and emotional intelligence" (Knowles-Cutler and Lewis, 2017). Therefore, it is important for the company to evaluate the potential of robotics, cognitive technologies and artificial intelligence technologies for future development and establish critical human skills for the future workforce (analytical thinking, problem solving, creativity, project management, listening and ethical decision-making, communication, leadership, culture) as an investment object. In addition, an important aspect of the development of the company's qualification potential is the use of the possibility of selecting the ' best of the best' through remote recruitment (Avocor, 2019). Companies can hire people from anywhere in the world, thereby improving their competitive position.

Design thinking is a design methodology that is applied when rethinking a complex problem with human interests in mind, when creating a variety of ideas during brainstorming sessions, and when taking a practical approach to prototyping and testing. One of the main advantages of design thinking is that knowledge gained at later stages can have feedback from earlier stages. Specialists get new ideas in an endless cycle, develop new ways to create a product and its possible use, and develop a deep understanding of consumers (Rikke and Yu Siang, 2020). Design thinking by describing and documenting actual work, as well as analyzing tools, people, and work-related information, helps understand where tasks can be outsourced, and where human empathy can be further enhanced (Davenport and Kirby, 2016).

3) Team building and gamification are effective practical tools for building a company's socio-personal potential. A corporate team is a microsocium that is subject to constant changes and lives through different periods of life. Even if employees work remotely or part-time, they have channels to influence the life and work of the company. While remote work usually has a reputation for being unsocial, virtual connections can be established with people around the world. Although a virtual workplace is a place to work, a company can maintain friendly relationships, increasing employee satisfaction and, in turn, productivity. It is important to pay attention to maintaining healthy social relationships between employees and improving the effectiveness of team interaction during critical periods of the company's life, such as automation and workplace reorganization. In practice, the method of team building can be based on the principle of team building by M. Belbin - non-ideal people can form ideal teams. This perfection is achieved through a balanced approach to analyzing the weak and strong traits of each team member, which allows you to combine team members in such a way as to form a perfect team in terms of stability and productivity.

The gamification method, in our opinion, is ideal for maintaining a comfortable atmosphere in the company, strengthening corporate spirit, socialization, and increasing motivation, including for personal growth. Many large companies successfully create cloud platforms for corporate portal with integrated game mechanics that allow employees (regardless of their form of employment) to get involved in tasks. You can make your employees ' work more cohesive and productive by using gamification mechanics (coins, personal ratings, team ratings, prize shop, achievements, missions,

and quests). For example, the company Yota is using the game battle of the Republic against the Dark side to work on the implementation of the sales plan. The Track2Win service used the principle of car racing to gamify work in the office. Corporate Fitbit turns employee Wellness into a game by collecting statistics on daily physical activity (number of steps, distance traveled) and employee sleep quality.

The practical application of this set of tools will ensure the effectiveness of the company's labor potential development by optimizing quantitative and qualitative indicators $LP_1 = f(X_1, P_1, Q_1, S_1)$.

We suggest evaluating the effectiveness of the company's labor potential development (E_d) by applying a systematic method using the formula:

$E_d = E_{ey} / V_m$, where

E_{ey} – economic effect for the year;

V_m – the amount of money spent on the operation, that is, the implementation of management measures.

Conclusions

First, the authors analyzed the company's labor potential in terms of its structural components – psychophysiological, qualification, and socio-personal potential. Second, the authors identified the impact of key trends of digitalization (the formation of an open talent economy as a trend and the development of non-standard forms of employment; the growing power of robotics and labor-saving technologies for job restructuring; development of the economy of joint consumption based on the collective use of goods and services) on the conditions for the development of the labor potential of companies, as a result, the risks of digitalization for a specific structural component of the company's labor potential were systematized. Third, the article offers the author's model of applying a system approach to the development of the company's labor potential in terms of digitalization: the input conditions form the risks of digitalization for the psycho-physiological, qualification, and socio-personal potential; management impact / operation includes a set of the most effective tools for leveling risks; the output is achieved by the effectiveness of the development of the company's labor potential.

Abstract

The article considers the importance of education in enhancing the political and legal culture of citizens, and increasing electoral activity. For decades, both the school and higher education systems and the electoral system in the United States have evolved towards the consistent implementation of the principle of equal rights regardless of gender, race, nationality, religion, age, or disability. In this regard, not only voter education during the election campaign, but also general civic education is of great importance. The article examines the "Bill of Voter Rights" fixed at the level of state law, analyzes education programs in the field of voting in the Russian Federation both at the federal and regional levels. The need for more active, open and widespread involvement of local youth in various forms of political participation, as well as the possibility of using the American model of the "Bill of Voter Rights" at the level of federal law is noted.

Keywords: Elections, Education, Civic Culture, Legal Culture, Electoral Legislation and Practice

Elections are the central institution of modern democratic governments, which provides for the formation of the state mechanism, at least its highest representative structures, the legitimization of state power and its decisions, the relationship between political power and civil society, and contributes to establishing a certain level of political socialization of individuals.

However, one of the most precarious trends is the complete formalization of the electoral process, which can lead to the political alienation of voters (potential and actually participating in the vote) from the results of the people's will. The growth of absenteeism and political apathy is dangerous both for civil society (due to the loss of control over state power and leverage over it in order to ensure the interests and protection of the rights of civil society entities), and for state power (poor relationship with the population, and a lower level of legitimation and activity). Another negative tendency in the development of election practice in the modern world is an increase in manipulation of various social groupings, various methods and technologies of information pressure and even programming of voters.

At the same time, the education system plays a crucial role in "producing" active citizens that share considerable political and legal culture. In this case, not only cognitive learning that helps to "consume" the concepts effectively is important, but also value learning that forms value and normative things necessary for politically active and responsible citizens.

Electoral law has traditionally been given a significant place in the system of constitutional and legal regulation in the United States (Nikolaev, 2018). A number of laws directly provide for specific education programs to enhance the legal culture of citizens in the context of education. Thus, the Uniformed and Overseas Citizens Absentee Voting Act (UOCAVA) of 1986 (PL 99-410) provides for the right of such persons to register for elections and vote by mail, as well as launching a program of assistance to military personnel under the US Department of Defense.

The Help America Vote Act of 2002 (P.L. 107–252)) was the result of a sharp social and political response to the mixed results of the 2000 presidential election, in which George W. Bush won after complicated recounting procedures had been performed and massive disputes had been litigated in the court. The law not only established unified standards for the electoral process, providing for the creation of a voter registration database in each state, and requiring the submission of a driver's license or voter's social insurance certificate for inspection at first registration, but also provided for voters to be informed about the places of voting, as well as providing the required amount of voting machines and election forms and materials required.

The importance of the education system for the development of electoral culture is not limited to an aspect that includes the preparation of ordinary voters or members of election commissions for responsible participation in elections.

The education system ensures the formation of basic values and principles of a developed civil society: maintenance of dialogue, legal competition, but not confrontation and, in particular, tolerance, and recognition of the equal rights of all citizens regardless of gender, race, national and social background, language, religious and political beliefs, health status and age (Nikolaev, Pavlova, 2016). Ensuring the constitutional principle of equality for decades has become one of the main trends in the development of the American education system (Nikolaev, Pavlova, 2018).

An important element of the legal framework for elections was the adoption of the "Bill of Voter Rights" by state constitutions, created in the same way as the Bill of Rights (the first ten amendments to the US Constitution). So, the California Election Code contains chapter 5 "Voter Bill of Rights", which includes the following rights:

(a) All voters, pursuant to the California Constitution and this code, shall be citizens of the United States. There shall be a Voter Bill of Rights for voters, available to the public, which shall convey all of the following to voters:

(1) (A) You have the right to cast a ballot if you are a valid registered voter.

(B) A valid registered voter means a United States citizen who is a resident in this state, who is at least 18 years of age and not in prison or on parole for conviction of a felony, and who is registered to vote at his or her current residence address.

(2) You have the right to cast a provisional ballot if your name is not listed on the voting rolls.

(3) You have the right to cast a ballot if you are present and in line at the polling place before the close of the polls.

(4) You have the right to cast a secret ballot free from intimidation.

(5) (A) You have the right to receive a new ballot if, before casting your ballot, you believe you made a mistake.

(B) If at any time before you finally cast your ballot, you feel you have made a mistake, you have the right to exchange the spoiled ballot for a new ballot. Vote by mail voters may also request and receive a new ballot if they return their spoiled ballot to an elections official before the closing of the polls.

(6) You have the right to receive assistance in casting your ballot, if you are unable to vote without assistance.

(7) You have the right to return a completed vote by mail ballot to any precinct in the county.

(8) You have the right to election materials in another language, if there are sufficient residents in your precinct to warrant production.

(9) (A) You have the right to ask questions about election procedures and observe the election process.

(B) You have the right to ask questions of the precinct board and elections officials regarding election procedures and to receive an answer or be directed to the appropriate official for an answer. However, if persistent questioning disrupts the execution of their duties, the precinct board or elections officials may discontinue responding to questions.

(10) You have the right to report any illegal or fraudulent activity to a local elections official or to the Secretary of State's office.

(b) Beneath the Voter Bill of Rights there shall be listed a toll-free telephone number to call if a person has been denied a voting right or to report election fraud or misconduct.

(c) The Secretary of State may do both of the following:

(1) Develop regulations to implement and clarify the Voter Bill of Rights set forth in subdivision (a).

(2) Revise the wording of the Voter Bill of Rights as necessary to ensure the use of clear and concise language free from technical terms.

(d) The Voter Bill of Rights set forth in subdivisions (a) and (b) shall be made available to the public before each election and on election day, at a minimum, as follows:

(1) The Voter Bill of Rights shall be printed in the state voter information guide, pursuant to Section 9084, in a minimum of 12-point type. Subparagraph (B) of paragraph (1) of subdivision (a), subparagraph (B) of paragraph (5) of subdivision (a), and subparagraph (B) of paragraph (9) of subdivision (a) may be printed in a smaller point type than the rest of the Voter Bill of Rights.

(2) Posters or other printed materials containing the Voter Bill of Rights shall be included in precinct supplies pursuant to Section 14105. (Elections Code of the State of California, 2018)

Despite the consolidation of basic electoral rights, the polarization of both the political establishment and the electorate as a whole has become a dangerous trend in US elections. A similar situation is likely to be typical for the general election in the USA in 2020. The bipartisan system in the United States, which has long served as a factor and means stabilizing the political system, is increasingly becoming a source of its polarization and even radicalization.

The low level of political and electoral culture of citizens, and a significant dependence on the media propaganda machine in terms of determining political preferences play an unenviable role in this process. For example, Thus, a study by the Pew Research Center points to an obvious separation of information sources for voters of the Democratic and Republican parties. So, of those who receive news primarily from Fox News, 93 percent are Republican supporters. In contrast, voters who draw information from media such as the MSNBC (an American cable television channel that provides NBC News coverage as well as its own reporting and political commentary on current events), the New York Times, National Public Radio (NPR), and Cable News Network (CNN) (95, 91, 87, and 79 percent, respectively) identify themselves as supporters of the US Democratic Party (Grieco, 2020). More than 65 percent of Republican supporters trust Fox News, while 67 percent of Democrats have confidence in CNN's information. All this not only shows "media polarization" due to the deep separation in the sources of information and the degree of trust in them, but also raises the question of a divided nation. (Jurkowitz, Mitchell, Shearer, Walker, 2020)

Although the Russian political agenda does not currently show such fierceness of the competing parties in terms of elections, it remembers the experience of the 1990s, when, in conditions of extreme polarization of the population and lack of knowledge and experience in the new competitive electoral system, manipulation of voters' minds and the radicalization of the election campaign reached their climax. The election campaign did not represent a positive program for the implementation of state policy, but only "counter-propaganda", the main task of which was to blacken and remove a competing candidate from the ballot, even at the expense of unethical and controversial methods of struggle.

The current stability of the political situation should not be misleading, since external factors of destabilization (the COVID 19 pandemic or the global economic crisis) can significantly aggravate internal contradictions in the face of a decline in the standard of living of the population.

The most important guarantee of a critical but responsible attitude of voters to the existing political situation and rational electoral behavior is the high level of political and legal culture of citizens, provided by an effective education system. The number of voters participating in the referendum in the Russian Federation as of January 1, 2020 amounted to 108 648 120 people (outside the territory of Russia the number is 1 903 406), and the number of voters in the region of Penza is 1 064 393. (CEC of the Russian Federation, 2020)

On November 30, 1994, in accordance with the decree of the President of the Russian Federation of November 1, 1994, the Central Election Commission of Russia established the Russian Center for Training in Electoral Technologies under the Central Election Commission of the Russian Federation in order to organize, coordinate and ensure work on improving the legal culture of voters (referendum participants) , training election and referendum organizers, other participants in the election and referendum processes in the Russian Federation. The Center organizes and coordinates the training of all categories of participants in the electoral process in the Russian Federation, is engaged in publishing and analytical activities aimed at improving and developing electoral technologies. The center is focused on cooperation with state authorities, education, social and political organizations, including youth organizations.

From November 1, 2019 to March 20, 2020, the Central Election Commission of the Russian Federation together with the Ministry of Education of the Russian Federation, the federal state institution "Russian Center for Training in Electoral Technologies under the Central Election Commission of the Russian Federation", election commissions of the entities of the Russian Federation, state authorities of the entities of the Russian Federation, carrying out public administration in the field of education organized the All-Russian Olympiad for schoolchildren on issues of suffrage and the electoral process.

Every year, the Russian Center for Training in Electoral Technologies under the Central Election Commission of the Russian Federation develops an action plan. So in 2019, 1,937.6 thousand rubles were allocated for the events aiming to improve the legal culture of voters; 13 514.7 thousand rubles were allocated for training personnel of election commissions and other participants in the election process in the Russian Federation. For comparison, in 2020, 12 951.8 thousand rubles were scheduled for the training of election organizers and other participants in the election process, 6 576.2 thousand rubles for improving the legal culture of voters. There is no doubt that there is a positive shift in the cost of educating voters.

The center organizes online YouTube classes on topical issues of the electoral law and the electoral process with broadcast on the channel "Just about the elections". So, in 2019, lectures were held by the associate professor at the Department of political science and political management at the Institute for Social Sciences, the candidate of political sciences M.Yu. Pavlyutenkova (PR in the public sector); the associate professor at the Department of political science and political philosophy at the Diplomatic academy of the Russian Ministry of Foreign Affairs, the candidate of philosophical sciences A.V. Borisov (Public opinion surveys in the activities of election commissions); by the associate professor at the Department of administrative law and process at Kutafin Moscow State Law, candidate of legal sciences M.M. Polyakova (Combating corruption in the election commissions of the entities of the Russian Federation); by the professor at the Department of the Russian language and literature theory at Moscow State Linguistic University, candidate of philological sciences I. V. Kosmarskaya (Linguistic difficulties in the language of documents).

The Center also offers webinars for members of election commissions in preparation for the Single Voting Day, training programs for observers at polling stations, training for the first time elected chairmen and secretaries of election commissions of the entities of the Russian Federation, classes

on topical issues of election law and the electoral process for federal state civil servants of the Central Office election commission of Russia, employees of the Federal Center for Informatization, the Russian Training Center in electoral technologies under the Central Election Commission of the Russian Federation.

The activities of specialized bodies and organizations in the regions of the country are even more significant for educating voters on matters of suffrage and the process. So, by the Resolution of the Penza Region Election Commission of January 24, 2020, No. 87 / 561-6, the 2020 annual activity plan to improve the legal culture of voters was approved. In particular, this year events are planned for all categories of voters. The local election commissions, educational institutions, universities, city and district libraries, culture houses will hold training events, quizzes, and competitions to improve the legal culture among young voters living in cities and regions of the region of Penza. The Legislative Assembly of the region of Penza, the Youth Parliament under the Legislative Assembly of the region of Penza, the Ministry of Education of the region of Penza, the Ministry of Culture and Tourism of the region of Penza, Penza Regional Library named after M.Y. Lermontov will hold joint events to improve the legal culture of young and voters voters-to be. They plan to hold events for people with disabilities (the contest on electoral topics among voters with disabilities "Long live, the country!"; the conference "Electoral Rights of Persons with Disabilities"); for high school students (the regional Olympiad for 10th and 11th formers on the basics of the electoral law and the electoral process; training lectures, excursions; electoral law quests for 9 to 11th graders).

Particular attention is paid to the political and legal education of young people. Currently, more than 250 thousand young people aged 18 to 30 live in the region of Penza. Such an direction is necessary for the formation of a civic habit of active participation in election events, the formation of a steady interest in political life, the development of one's own political position, a broad political outlook and sufficiently deep and solid knowledge in the political and legal areas. All of the mentioned above will ensure not only the intensification of youth participation in political processes in general and in the electoral process, in particular, but will also give greater stability during "whispering" campaigns and radicalization of the media.

Specialized youth bodies play an important role in involving young people in the daily political life of the region. So, the Youth Parliament under the Legislative Assembly of the region of Penza is a collegial deliberative body and operates on a voluntary basis. Its activities are based on the principles of legality, voluntariness, equality, transparency, free discussion regarding the intended and adopted decisions. The main objectives of the Youth Parliament are:

1) participation in the preparation and discussion of draft regulatory legal acts;
2) providing young people with true information about the activities of public authorities and local authorities of the region of Penza;
3) submitting proposals for consideration by state authorities and local authorities;
4) the promotion of social, legal, educational, cultural, moral, patriotic and physical development of youth.

The parliament is made up of 36 deputies each time after the election of the Legislative Assembly of the Penza region of the appropriate convocation for the term of its powers by delegating candidates to the Legislative Assembly of citizens of the Russian Federation aged 16 to 30 years old, permanently residing in the region of Penza. Each deputy of the Legislative Assembly delegates one deputy to the Youth Parliament taking into account recommendations of youth public associations, public associations of working youth, student self-government bodies, trade union organizations of students, student councils, youth advisory bodies established under the representative bodies of municipal districts and urban districts of the region of Penza. It is important to note the importance of the activities of the youth parliament as a communication link between public authorities, on the one hand, and youth organizations, both pupils and students associations, on the other. At the same time, in order to ensure a more open, competitive and effective activity of this body, the role of youth organizations in the formation of the Youth Parliament should be increased by allocating quotas for the corresponding representation.

Another important body is the Penza Region Youth Government, which acts as an advisory body to the Penza Region Government, training political and managerial personnel, involving the region's youth in the implementation of the most important agendas of state policy.

The main objectives of the Youth Government of the region of Penza are the following:

1) the work of the departments of the youth government of the region of Penza ;
2) discussions and proposals on social and economic issues of the region;
3) representation of socially significant interests of young citizens when solving issues of social and economic development;
4) attracting young citizens to participate in the formation and implementation of the social and economic policy of the region.

The framework of the Youth Government is built in the same way as that of the Government of the region of Penza. It consists of the chairman, vice-chair people, heads of the departments of the Youth Government, as well as other assistants to the listed persons who are part of the staff and working groups. The role of the Youth Parliament in the formation of the Youth Government of the Penza Region should be strengthened, which will increase the transparency, competitiveness and democratic character of this structure.

Finally, the Penza Region Youth Electoral Commission is a specialized body in terms of political and legal education of young voters in the region. It acts as a permanent advisory body to the Electoral Commission of the region of Penza.

The youth commission regularly monitors and analyzes the electoral activity of youth (visits to voting places in the region of Penza, their participation in elections as candidates; their participation in election commissions at all levels as members of the commission with the right of decisive and deliberative vote). The commission develops recommendations on behalf of the Penza Region Election Commission, prepares proposals and is directly involved in the implementation of measures to improve the legal and political culture of young voters. The Commission provides assistance to the Penza Region Election Commission on the implementation of activities related to the training of personnel; carries out interaction of youth and youth public associations with the Electoral Commission of the region of Penza on issues of improving the legal and political culture of youth; organizes and participates in conferences, round tables and other events; exercises other powers on behalf of the Election Commission of the region of Penza.

In particular, in 2020, the Youth Election Commission aims to interact with the Ministry of Culture and Tourism of the region of Penza, the Youth Parliament under the Legislative Assembly of the region of Penza, the Youth Government and other youth organizations of the region of Penza to improve the legal culture of young people. The commission will organize the work of volunteer youth groups to help the territorial and district election commissions, interacting with older voters and people with disabilities for the Single Voting Day; will participate in meetings of the Electoral Commission of the region of Penza and meetings with representatives of territorial bodies of federal executive bodies in the region of Penza , state authorities, territorial election commissions of the region of Penza and other organizations. The Commission will organize and conduct seminars, meetings, round tables on improving the legal culture of voters, conduct training lectures. It will also conduct electoral quests for 9th to 11th graders in the city of Penza; will participate and conduct regional Olympiads for 10th and 11th graders on the basics of electoral law and the electoral process; prepare information on the work of the Youth Electoral Commission and post it on the website of the Electoral Commission of the region of Penza and on the official Vkontakte page.

It is not for nothing that the official data of the Penza region Election Commission and the VTsIOM exit poll data show the highest percentage of turnout for the 18-34 age group (69.5 and 65.6 percent, respectively, with average figures of 67.5 and 63.7 percent).

Thus, significant prerequisites have been created for an effective education system in the field of electoral law in Russia. Appropriate resources are used at all levels of the Russian education system: secondary and higher education, as well as continuing education. Of special importance are specialized programs implemented under the auspices of the Central Election Commission of Russia and the election commissions of the constituent entities. The development of active forms of youth political participation is especially significant in the regions. This allows to adapt the activities of public authorities directly to the needs and interests of the youth environment of a particular region. Despite the existence of various organizational forms of youth participation in the life of the region (Youth Parliament, Youth Government, Youth Election Commission), elitization and secrecy of such interaction should be avoided. To this end, it seems appropriate to expand the participation of various youth organizations and youth groups in nominating their representatives to such youth political bodies and organizations.

In addition, in order to increase the political and legal culture of voters, it seems possible to use the American model of the “bill of voters' rights”, in particular, to consolidate a separate chapter containing a list of basic electoral rights and freedoms of citizens in specialized legislation (Federal Law "On Basic Guarantees of Electoral Rights and the right to participate in the referendum of citizens of the Russian Federation")

Abstract

Revolutionary transformations in industry and the informatization of society, the rapid development of science, the introduction of high technologies in production, technological and service processes entail the need to improve the quality of education of young professionals in the IT sphere. The purpose of the article is to describe the algorithm for preparing and organizing the research work of students, the interdisciplinary integration of the subjects being studied and the research activity of students. The algorithm includes innovative ways of organizing the educational process, the possibility of using new educational technologies for the preparation of popular IT-specialists, focused on the creation of high-tech products. The article presents the algorithm developed by the authors for organizing the research work of students of IT specialties, taking into account promising pedagogical approaches. The algorithm orients future graduates to a phased preparation for innovation, continuous self-education and self-development, taking into account the changing market needs, opportunities and limitations of specific industrial enterprises, IT-companies. The model of organization of research work with students can be used by leaders of research work and teachers of professionally-oriented disciplines of higher educational institutions. The main directions for further research may be issues related to the approbation of the algorithm in practice, amending its structure and content according to the results of practical implementation.

Keywords*:* higher education, integration of education, educational technologies, algorithm, research work, Industry 4.0.

Introduction

In the last decade, we have seen the change of technological structures, the so-called fourth industrial revolution, which is marked by the merger of technology and the blurring of boundaries between the manufacturing, biological and digital spheres. Integration of such elements as big data, machine learning, artificial intelligence, robotics, additive technologies, virtual and augmented reality, industrial Internet of things, cloud computing, cybersecurity, protection of information in industrial networks in an integrated system will develop the concept of “Industry 4.0” and reach a new level of economic efficiency of production. The modern world is changing, the advantages in the international arena will be enjoyed by countries that actively invest in the development of high technologies. The economy needs to expand its competitive potential by increasing its advantages in science, education and information technologies (Kurnitskaya, 2018).

Analyzing the changes produced by the fourth industrial revolution, it can be argued that the labor market is also transforming. The production will require workers of a new type, with other qualification characteristics, organizational and social skills and abilities that are able to independently obtain and integrate knowledge from various fields that have an opportunity for the creation of innovative science-intensive products.

All the above mentioned significantly changes the requirements both for the content of training future graduates of higher educational institutions, and for organizing this training.

Research work is becoming one of the significant activities of university students, providing continuous improvement of the teaching and upbringing process and helps training a highly qualified specialist, a creatively active person who is able not only to acquire knowledge independently but also to generate new ones, to offer and develop innovative ideas, implement cost-effective projects.

Students research work acts as a mandatory form of students independent work in the framework of the curriculum, studying the content of the basic professional educational program and is conducted in 5-7 semesters.

The objectives of the research work in accordance with the requirements for bachelor's mastery (competence) are:

- intellectual development of future bachelors;
- preparation of future bachelors for independent research work;
- development and increase of motivation for professional activity;
- consolidation and deepening of theoretical knowledge, when studying disciplines, and the skills of using modern information technologies and software, including domestic production, in solving problems of professional activity;
- learning to manage your time, build and implement a self-development path based on the principles of lifelong learning;
- formation of new competitive ideas in the framework of innovative activity and their implementation in projects.

The main objectives of the students research activities:

- familiarization with the basics of research;
- formation of skills to justify the relevance of the chosen topic; independent setting of the research work goals; the definition of the tasks range within the stated goal; the choice of the best ways to solve them, based on existing legal norms, available resources and limitations;
- development of practical skills in search, critical analysis and information synthesis with the use of a systematic approach for solving the tasks;
- deepening the search skills of literary sources with the involvement of modern information technologies;
- expansion of knowledge gained in the study of fundamental and special disciplines, development of practical skills in the use of methods of mathematical analysis and modeling, theoretical and experimental research in professional activities;
- formation of skills to choose the necessary research methods, based on the tasks of the specific study;
- gaining experience in developing algorithms and programs suitable for practical application;
- formation of skills in processing results, analyzing and processing them in the form of reports, scientific articles and reports at the scientific and practical conferences.

Consequently, the students research work provides for the systematization, consolidation, expansion of theoretical and practical knowledge in a certain area of training and their use in solving specific scientific, production, economic, organizational and managerial tasks. Research work should be carried out by the student on an actual topic, have a sufficient theoretical level, be of an investigative nature (Sabinina, 2018).

Based on the scientific papers we studied and personal experience, the main problems were formulated:

a) the selection of actual practical-oriented research topics, corresponding to the beeing formed competencies and the specifics of the training area;

b) lack of knowledge at the required level of students' knowledge, skills and research skills;

c) low internal motivation of students, formal attitude to research activity, disinterest in the proposed topic;

d) absence of classroom hours, high workload of teachers, inability to sufficiently acquaint students with the research directions of the department; methods of research work; requirements for the design of a scientific article and other scientific and research documentation;

e) insufficient level of scientific and methodological competence of teaching staff.

Thereby, the aim of our research is to develop an algorithm for the research work preparation and organization, taking into account the revolutionary transformations taking place in the industry and

society, and including the possibilities of applying new educational technologies for the highly-demanded highly skilled IT specialists training focused on the science-intensive products creation.

Therefore, the question of developing an algorithm for the research preparation and organization using the new educational technologies is relevant.

Literature Review

The considering problematic is not new. Throughout the entire existence of engineering education, many teachers and researchers paid great attention to the problems of organizing the research work of students during their studies at the university.

Taking into account the current requirements for a graduate of higher education, the introduction of digitalization into the social sphere, including education (Shchurov and Vaulin, 2018; Scardamalia and Bereiter, 2014; Block, 2018), the latest technological achievements and challenges of "Industry 4.0", the tasks of effective organization of research work are relevant and require a new approach in their decision.

In the modern pedagogical literature much attention is paid to the students of higher educational institutions research work (Houseal, Abd-El-Khalick and Destefano, 2014; Avargil, Spektor-Levy and Zion, 2017; Scardamalia and Bereiter, 2014; Ary, Jacobs, Sorensen and Walker, 2018), its relevance is noted, but a number of problems of the preparation and organization of the research work are also indicated.

The research work of students is considered to be an obligatory and integral part of the training of specialists in the South Ural State University and is one of the priority tasks of the educational institution, which are solved on the basis of the unity of the educational and research processes (Dobichina, 2017; Prokhorova. and Ovsyanitskaya, 2015).

Various aspects and issues of improving the quality of research work are described in detail in the work (Shein and Tsai, 2015; Pickering, Grignon and Steven, 2014; Demchenko, 2015; Pochestnev and Kuzmicheva, 2016). Often scientists focus on individual problems, so there is a need for an integrated approach to overcoming the identified shortcomings in the preparation and organization of students research work (SRW). Such an approach can be realized only if innovative methods of organizing the educational process are used and new educational technologies are taken into account.

Particular attention should be paid to the work (Shadchin, 2012; Astanina, Shestak and Chmyhov, 2012; Nuzhnova, 2012), which describes the formation of new significant for modern life qualities: perseverance, professional mobility, thanks to the participation of students in research work. It is proved in the works that the acquired knowledge and skills lay the foundation for the future research activities of the future specialist, form the ability to independently obtain the necessary knowledge. The implementation of research work requires a change in the format of the pedagogical interaction of the teacher and the student. In the work (Proshkin, Glushak and Mazur, 2018) the results of the introduction of new pedagogical approaches to the organization of SRWS are given.

Modern education implies the availability of its receipt through the introduction of MOOC. The current situation and prospects for the development of MOOC are given in (Penalvo, Francisco and Fidalgo-Blanco, 2018; Karnouskos, 2017; Watted and Barak, 2018; Larionova, Brown and Bystrova, 2018). We agree with the authors of the articles; however, these papers do not pay attention to conducting NIRS among students using the distance method of students. Therefore, we have developed a technology that allows you to combine the advantages of the MOOC form with the mandatory research part.
In our studies, we relied on the work (Martyushev, Sinogina and Sheremetyeva, 2014; Karabalina, Yesengulova and Kulbayeva, 2018), which analyzed in detail the importance of organizing independent work of students. We are in solidarity with the authors of these works, but we believe

that any independent work should include elements of the research part. Our developed technology allows you to combine independent work with the scientific work of students.

Materials and Methods

The main materials for the proposed study were numerous scientific and pedagogical publications on the problems of research in Russian and English languages, normative and program-methodological documentation and the authors' own research and teaching experience. During the preparation of the article, general methods of analysis, synthesis, induction and analogy were applied.

Experimental base of the research was the South Ural State University (SUSU) and the university educational portal “Electronic SUSU” based on the Moodle environment. The educational site “Electronic SUSU” is a joint development of the Department of Global Network Technologies and the Institute of Open and distance learning, the structural units of the South Ural State University. As a part of the study, four electronic courses were created on the educational portal “Electronic SUSU”.

The result of the work has been the developed author's technology of preparing and organizing the research work of students.

The algorithm of preparation and organization of the research work of students

We have developed an algorithm for the research preparation and organization. The created algorithm can be used by heads of scientific works of the higher educational institutions students as a step-by-step guide.

The first stage. The determination of the students research work contents and the formation of a base for research directions and topics.

The content of research is determined by the graduating department on the basis of the list of scientific topics of the department; grants implemented at the department; works performed by the department in the framework of contracts with educational institutions, research teams, industrial enterprises, companies; priority directions of research in the field of digital industry, covered in scientific, scientific and practical conferences of the department, higher school, university; in-depth study of separate sections of specialized disciplines.

The second stage. The students acquaintance with the directions of scientific researches of the department.

On the portal “Electronic SUSU” an electronic course “Directions of the Information Technologies in Economics department research” is created, to which all the students of the department are connected. In the course, students have the opportunity to get acquainted with the topics of this department research work with the help of video lectures, presentation materials, published scientific articles of the staff of the department, selection of links to thematic Internet resources. The presented materials allow the student to consciously approach the choice of the topic of future research, proceeding from their own interests. This approach takes into account the propensities and preferences of the student, forms interest and internal motivation for research activities (Shadchin, 2012).

The third stage. The statement of the problem and the choice of the research topic. Formulation of goals and objectives of research. Development of a working hypothesis.

The students independently or with the participation of the scientific adviser chooses the topic of their future research, discusses the essence of the forthcoming work.

The fourth stage. The acquaintance with the scientific research methods.

The following the results of the list on the distribution of students for research and the signing of a calendar plan, the supervisor connects students to the electronic course “BF17-18-Methods SRW” on the portal “Electronic SUSU”. By analogy with the second stage of the algorithm, students have the opportunity to get acquainted with the methods of primary information search on the problem of research, selection, processing and critical analysis of the information received, methods of system analysis and mathematical modeling, theoretical and experimental research using video overviews, presentation materials, practical works with examples of the use of scientific research methods (including those studied in disciplines at senior courses). Also on the resource is a compilation of links of thematically suitable courses on the leading foreign and domestic MOOC-platforms (Coursera, EdX, Khan Academy, Open Education, Universarium, Lectory, Stepic, etc.).

Due to the presence of mobile versions in most MOOC platforms, the student has the opportunity to study “anytime and anywhere” on the model 24/7 (Dobichina, 2017). At the same time, the acquired knowledge and skills lay the foundation for further research activities of the future specialist, form the ability to independently obtain the necessary knowledge and readiness for professional mobility.

The fifth stage. The studying of the literary sources and the selection of Internet resources on the problems of scientific research.

The student independently (the scientific adviser provides consulting support) searches, studies, selects and analyzes the literature sources (textbooks, monographs, theses, scientific articles) on the problems of scientific research, performs a selection of Internet information resources. Search should be carried out including using domestic and foreign abstract and full-text electronic databases, access to which provides the university. Particular attention is paid to literature published over the past 5 years. The study of sources ends with the preparation of an analytical review, which highlights the state and degree of study of the problem posed in the work, its relevance, articulates unresolved problems of interest for further research, suggests ways of solving the tasks posed.

The sixth stage. The correction of the research plan. The collection of the factual material. Evaluation of the reliability of the collected data, their sufficiency for completing the research work.

Based on the analytical review and methodological guidelines on the SRW organization, the student clarifies the problem (topic), the content of the research, the working hypothesis. The student develops a methodology for data collection and collects factual material for research work, assesses the reliability of the collected data, their sufficiency for completing the research work.

The seventh stage. The discussion and the selection of the scientific research methods to solve the tasks, based on existing legal norms, available resources and limitations. The processing of the actual material. The testing the working hypothesis.

Based on the goals, objectives and expected result of the study, the student chooses the method of processing the actual material, negotiates the chosen method with the supervisor. Selects software environments for data analysis (calculation), performs a comparative analysis of their characteristics, justifies the choice of a particular software product. Processes the collected material. Analyzes the received data. Checks and corrects the working hypothesis. Formulates preliminary conclusions on the work done.

It should be noted that at stages 5-7 of the algorithm, emphasis is placed on the independent work of the student. At these stages, the supervisor acts as a moderator, consultant in educational and research activities. The search for arguments to solve the problem posed, the application of previously acquired knowledge in solving practical problems, stimulate the students to be ready for constant replenishment and deepening of knowledge, search and development of new methods for processing (calculating) data, technical means for processing the results of the study. Synthesis of obtained theoretical knowledge and practical skills and skills contributes to the formation of special research

skills, the development of critical thinking, the gradual transition from training to self-education (Prokhorova and Ovsyanitskaya, 2015).

The eighth stage. The preparation of the research report. The presentation of the results of the work done. The formulation of conclusions and proposals on the results of the study.

The student presents the results of the self-completed work in the form of a report on research, drawn up in accordance with the requirements of the state standard. Formulating the general conclusions on the results of the study. Preparing a report and presentation for the public presentation of the results of work, makes proposals for further research on selected issues.

During the defense and discussion of their work, students learn to logically, unequivocally, concisely expound their thoughts, competently and correctly discuss, defend their point of view (Demchenko, 2015).

The ninth stage. The preparation of reports for scientific and practical conferences, the writing of the scientific articles.

The research work does not always end with the ninth stage. Students can complete the results of the independent research work in the form of completed scientific works (articles, reports) and use them for presentation in annual exhibition events organized by the department, higher school, university, conferences of various levels, for publication in collections of scientific papers students and graduate students.

The tenth stage. The checking of the reporting documentation for the amount of borrowing.

In order to exclude non-independent execution of scientific research and formal approach to writing a report, scientific article and other scientific works, appropriation of other people's ideas, results, fragments or whole work without indicating the source of borrowing, the student's report documentation is checked in the special system. The eleventh stage. The completing of the base of scientific research directions and topics according to the results of the SRW (return to stage 1).

Results

In connection with the revolutionary changes in industry and the informatization of society, the rapid development of science, the introduction of science-intensive technologies in production, technological and servicing processes, there is a need to improve the quality of education of young professionals in the IT field. Before the teacher of the higher school there are new tasks and problems that can be solved only when addressing to active methods of teaching and modern educational technologies. The result of the research is the algorithm developed by the authors for organizing the research work of IT specialties students, which is a complex solution of the problems presented in the introduction and taking into account perspective pedagogical approaches. The presented algorithm directs future graduates to stage-by-stage preparation for innovative activity, constant self-education and self-development, taking into account changing market requirements, opportunities and limitations of specific industrial enterprises, IT companies.

The authors of the article believe that the described algorithm solves the problems of preparation and organization of scientific activity of higher educational institutions students, announced in the introduction. It should be noted that the proposed algorithm assumes that the university has a distance learning site. The above model can be used both by the heads of research work of students and by teachers of professionally-oriented disciplines of higher educational institutions, which is the practical significance of the research performed.
The main directions for further research in this area may be issues related to approbation of the algorithm in practice, introduction of changes in its structure and content based on the results of practical implementation.

Acknowledgements: The authors of the article express their gratitude to the teachers and students of the Department of Information Technologies in Economics of the South Ural State University who took part in the development and testing of materials for electronic courses. The authors are also grateful to the reviewers of the journal for a careful reading of the article and constructive criticism.

Annotation

In modern conditions of instability characterized by the rise of competition, differentiation of profitability, depending on the belonging to the industry, and the decline of investment attractiveness, there is a need for market actors to combine methods and tools of cost management at various stages of the organizing process: production, raw material supply, and implementation. The goal of all transformations is to increase balance and stability. The main tool for achieving system budgets, which are based on the classical pricing rules for a perfect market structure. It should be noted that the ideal model of the market process in the greater degree of artificial, entirely dependent on the scope and methods of cost accounting, external factors. Currently, the role of social relations, which is an important feature of competition and the administrative system of prices. So, the theory of value and prices can only be based based on a particular ethical system. Currently, issues of diversification and competitiveness of industries, and defines the required institutional changes in the economy associated with the increase of its competitiveness. On the other hand, in the framework of institutional solutions developed routines, the implementation of which will ensure the creation of sustainable, structurally balanced industry base on the basis of the system of cost accounting. All of this requires business entities to develop a strategic model of the formation and management of gross, marginal and average cost organization in the long term. The paper systematizes the main theoretical and methodological approaches in the field of cost management of the organization in modern conditions taking into account the sectorial SPE-civic and strategic development of the organization.

Keywords: Cost, Price, Segment of The Economy, Competition, The Conditions of Profit Maximization, Managerial Accounting.

INTRODUCTION

Pricing rules, as we know, are different in a variety of market structures. Market structure is the environment in which market competition occurs. There are many market structures, but pricing rules are based on ideal structures. Ideal types of market structures that are presented in table one. For a market of perfect competition, the pricing rule looks like this:

$$P=AR=MR=MC \quad (1),$$

Where, the price is equal to the average revenue is equal to the marginal revenue is equal to the marginal cost;

P-price;
MC-Marginal costs;
AR-marginal revenue.
The authors use ideal market models for price modeling and forecasting.
Table 1-Market structures and their characteristics[1]

[1] McConnell. Economy. - Moscow: Delo, 1992

Characteristics of the market structure	Perfect competition	Monopolistic competition	Oligopoly	Monopoly
Number of enterprises on the market	Infinite set	Plenty	Several	One
Barriers to entry into the industry	no	Few	significant	blocked
The presence of non-price competition	no	Significant	There are	No
Type of products sold	standardized	Individualized within very narrow boundaries	And those and others	Unique goods

For other market structures, the pricing rule (maximizing profits) explain the following:
MC=MR (2),

Where the flat marginal cost marginal revenue.

For the purposes of marginal cost pricing is important to the family costs. Marginal costs of gross and cross variables at their point of minimum defining the optimal output that maximizes profit. The next most important indicator-rum in pricing is the index of A. Lerner (1969), which determines the rationality of the pricing:

$$L = \frac{P - MC}{P} = -\frac{1}{\varepsilon_P}, \qquad (3)$$

Where L is the Lerner index, it can vary from minus infinity to plus infinity. However, if L<0 then this is the perfect competition market, or polyposis. In this case, to control prices is impossible; if L→1 then this is a market of imperfect competition with price controls;
Ed - demand elasticity price;
P-price;
MC-marginal costs.

The process of making financial decisions is directly linked to budgeting, a key element of the system of financial planning and cost control in management accounting. Budgeting relates to the planning processes. Budgets are the key tool of management accounting and control. The primary budget in the system of forecasting of financial results is the sales budget. The financial information provided in the sales budget, forecast of price, production volumes, and projected revenues can be further used to predict the value of the company's net profit allocated for payment dividen-ing and implementing investment decisions based on the strategy self-financing activities of the company. This budget is closely linked to the budget cost (budget cost of production budget and distribution costs).

The establishment of an adequate level of prices requires forecasting of profitability, in particular:
gross margin, defined as the ratio of gross profit to revenue from sales, calculated excluding excise taxes and value added tax;

Gross profitability of expenditures, defined as the ratio of gross profit to cost of goods sold (works, services);

return on sales, defined as the ratio of net profit to revenue from sales, calculated excluding excise taxes and value added tax;
Profitability ratio, defined as the ratio of profit from sales to the amount of cost of goods sold (works, services), commercial and management costs related to the sale of goods (works, services);

the profitability of commercial and management costs, defined as the ratio of gross profit to commercial and management costs related to the sale of goods (works, services);
Return on assets, defined as the ratio of profit from sales to the current market value of assets (non-current and current) used directly or indirectly in the analyzed transaction. In the absence of the necessary information about the current market a hundred -, the physical volumes of assets return on assets may be determined based on data of accounting (financial) statements.

The cost is the sum of current costs of production and sales. Costs are the money spent by the organization to purchase resources at market prices. Comparing these two categories, we can say that they are homogeneous, but the first "cost" is a broader concept. Determine the cost of goods is the desire as accurately as possible, preferably 100% to assess all the expenses of the organization. Cost accounting does not allow achieving such precision, but with their help, it is possible to use rules to maximize profits for different market structures, the definition of bringing to pass the optimal price and assessing the level of competition. Cost is a from-total net expense for acquisition of objects of labor and means of labor for the implementation of the company's operations. The cost is an economic category that characterizes the amount of resources consumed now[Prikhodko S. E. 2016.].

Cost (overhead) is the most important economic category. All management decisions are made based on cost analysis. For example, to start or to close business, buying, selling organizations (enterprises), the definition of the strategy of personnel management, marketing strategy and many other questions require careful analysis of costs. Are the following external environment factors influencing the unit cost of production: the demographic component; the changing age of the population and fluctuations in fertility; change in ethnic ratio; the political, technological and legal component; public impact; technological innovation and standards; the business cycle and other?

Cost control involves the use of instruments in the form of a developed budgeting system, involving the effective use of resources and control mapping execute strategic objectives in the development of budgets, organization of their implementation, monitoring and results analysis.

The role of the cost of the company in the formation of solutions is that the price level allows determining the estimated amount of revenue from sales, and as a result, the planned volume of production. That is especially important in the preparation of the sales budget of the company, which is the starting point of the entire budgeting system in the company [Skornyakova I. V. 2018].

STATEMENT OF THE PROBLEM

The costs they must be properly classified and taken into account to correctly account for. Many authors suggest different classifications of costs depending on methods and accounting purposes. For example, the authors identify the following classification, as shown in table 2.

Table 2: Classification of costs [Glukhova I. M., Kushnerova O. N. 2015]

Purpose: calculation of the cost of production, analysis of the cost of inventory and profit received	Goal: decision making and planning	Goal: control and regulation
* Costs at the beginning of the period and at the end of the period; * direct and indirect; • basic and applied; * production and recurring costs; * single-element and complex; * current and one-time	* Constants and variables; • accepted and not taken into account in evaluations; • non-refundable costs; * imputed costs; * marginal and incremental; * Planned and unplanned.	Regulated; unregulated

There are many options for organizing expenses of the organization, but in this case, we are interested in the pricing process (table 2). We will focus on the classification of the costs, reflected table 2. In the

process of pricing often, allocate main technical parameter. It is this property of goods, and bought at a specified price (the Approach A. K. Lancaster). For example, the fat content of milk, the quantity of enzymes in cosmetic cream, the magnitude of the shear crank, etc. Those costs that create the main technical parameter, referred to as primary, others patch.

The next item in table 2 (direct and indirect costs) shows, if the costs can be directly, economically, and directly attributed to the product, that is direct costs, if the costs cannot economically and directly attributed if you write off the product you are creating, this is an indirect cost. The division of costs into direct and indirect is carried out in the accounting organizations in Russia since 2006; the Organization itself carries out the classification based on technological rationality. Direct costs have two main largest group: direct labor costs (PTZ) and direct material costs (DMC). Direct labor costs (PTZ) include all costs of operation of forces that can be directly and economically to carry on a certain kind of ready-products. Wages of machine operators and other workers engaged in the direct manufacturing of products. However, with the associated production and maintenance workers, managers and craftsmen, and support staff. The cost of their labor should also be included in the composition of production costs. However, these costs are labor and cost cannot be directly attributed to a specific form of finished products, they are treated as an indirect (indirect) labor costs. Indirect labor costs, like indirect material costs are considered as part of overhead costs. The division of labor costs into direct and indirect largely depend on specific situations. If the company produces one product, the monthly wages of not only production workers, but wages of management personnel can be classified as direct costs.

Direct material costs are costs of raw materials and basic materials. Basic materials are materials that become part of finished products, their cost directly and economically, without extra costs apply to a certain product. The magnitude of direct material costs can be calculated by multiplying the number of materials that can be definitely attributed to a specific product, the unit price of materials. Virtually all the norms of consumption of resources are called direct costs. This division of resources is conditional, personalized for each organization. The classification is based on the technological possibilities of production.

The following item classification. Fixed costs (FC) do not depend on production volumes and provide fixed costs, such as salaries of top management, the costs of buildings, structures, and Variable (VC) costs are almost directly proportional to depend on the volume of production, these include the costs of raw materials, wages of production workers, and other similar costs.

The main production costs are the costs of the company that are directly attributable to the production process (operating activities) of the company. Legal regulation of accounting and reporting in relation to the formed-term production cost per unit and total issue volume is based about the Ministry of Finance.

For accounting and generalization of information on availability and movement of finished products produced by an "output (works, services)". Account "output (works, services)" is intended to summarize the information about released products, delivered to Ketchikan works and services rendered during the reporting period, and identifying deviations of the actual cost of production of these products, works, and services from normative (planned) costs.

The next step in cost accounting is to sell products. In this case, there are two groups of costs that form the cost of the product:

-cost of sales;
-cost of goods remaining in the warehouse.

The organization's desire to reduce the volume of goods remaining unsold is directly related to the basic principles and methods of work of the companies based on commercial profit. To prevent the formation of excessively large amounts of production costs of companies seek to accurately determine the potential and real volume of effective demand of your target audience and choose the pricing method that is appropriate for a particular market segment. An additional competitive advantage in this

case, the own company working on a contract basis. As the system of contractual relations in institutional Economics provides the implementation of the planned volume of production in full.

Indirect (overhead) costs are the costs of the company in the emerging service process the production process of the company.

To summarize the information on costs resulting from the organization of the mechanism for the implementation and promotion of goods on the market use the account "selling Expenses". This account displays the costs of the following activities:

Organization of the system of warehousing goods;
Packing and packaging of goods in the warehouse;
Loading unloading works;
Commissions paid to marketing and other intermediary organizations;
The cost of advertising.

The financial aspect of the classification costs of the company, the formation of production unit cost of the product and total costs of the organization, accounting and analysis of actual cost of sales is realized through the development of the following management systems:

Cost control in the centers of formation costs;
Managing profit centers of formation of profit;
Inventory management, particularly inventory;
Inventory management, in particular the volume of work in progress;
Inventory management, in particular finished products in the warehouse.

It unit variable cost per unit of output are increased in a factor analysis in the formulation of flexible budget.

Gross fixed costs do not change when you change the volume of production of goods, but when calculating the per unit becomes variable (AFC).

Example. The determination of the proportion of fixed and variable costs in total costs, using method "mini-Maxi", the original data are presented in table 3.

Table 3: Source data on total costs and the company's production

The volume of production, Q	Grand Total cost, TC.
10	1000
12	1120
13	1230
15	1350
18	1400
20	1480
22	1500
25	1580
27	1670
29	1900

When determining specific variable costs, use the "mini-Maxi" method»:

$$AVC = \frac{TC_{max} - TC_{min}}{Q_{max} - Q_{min}} \quad (4)$$

$$AVC = \frac{1900-100}{29-10} = 47\text{т. р} \quad (5)$$

$$FC = TC_{max} - Q_{max} * AVC \quad (6)$$

$$FC = 1900 - 29 * 47 = 530\text{т. р.} \quad (7)$$

Thus, the company's gross cost formula will be written as follows:

$$TC = AVC * Q + FC \quad (8)$$

When structuring costs and determining production volumes, it is necessary to conduct a break-even analysis and an analysis of costs per unit of product, an analysis of assortment and quality.

The cost structure (variable and fixed costs) is particularly important when forming a flexible company budget. A flexible budget is a company's budget that is based on the company's gross cost function. The economic essence of a flexible budget is to determine the deviations of actual costs from planned costs when the volume of output changes. When organizing the planning system in the company, determining production volumes, costs are a key condition for the rational use of production factors and ensuring the normative value of profitability.

When developing resource expenditure standards, the following indicators are introduced:

norms of consumption of raw materials used in the production of goods, determined on the basis of developments in the field of R & d;
Norms of labor costs, determination of expenses for its payment in accordance with the system of remuneration in the company;
Norms of indirect costs of labor and materials, expressed as General production costs.
Consider a hypothetical example. Initial data on the company's planned costs for the production of 500 units of goods and actual costs for the production of 550 units of products, table 4.

Table 4: Initial data on actual costs and output volumes: planned output volume and actual output volume, RUB

Cost items	**Cost structure**	
	500 unit	**550 unit**
Variable costs:		
Raw	7000	7800
Semi-finished products (bushings)	1000	1100
Wages of production workers	1500	1700
Payment for electricity and water consumption (variable part)	2000	2100
Constant flow:		
Salary of management personnel	3000	3400
Lease payment	1800	2000
Payment for electricity and water consumption (permanent part)	1200	1300
Total production costs	17500	19400

If you find a deviation of actual costs from the planned amount of costs from the source data, you will get an incorrect version of determining the deviation in the volumes of actual and planned costs, depending on the volume of output. Therefore, we calculate the unit costs per unit of planned output, table 5.

Table 5: Unit costs per unit of planned output, RUB

Cost items	**Cost structure**		
	500 unit	VC	550 unit
Raw	7000	14	7700
Semi-finished products (bushings)	1000	2	1100
Wages of production workers	1500	3	1650
Payment for electricity and water consumption (variable part)	2000	4	2200
Salary of management personnel	3000	const	3000
Lease payment	1800	const	1800
Payment for electricity and water consumption (permanent part)	1200	const	1200
Total production costs	17500		18650

As you can see from table 5, the increase in costs in value terms for the actual volume of sales is 1,150 rubles, or 6.57%. The result of planning the volume of production costs of the company are indicators:

Planned expenditure in absolute terms for output;
The cost per unit of output (ATC);

The volume of costs per unit of commodity production.

Accounting and analysis of the company's cost structure is an important factor in making effective management decisions. For example, in diversified industries with a wide range of both raw material suppliers and consumer groups, there is often a question of accepting or rejecting an offer to supply components, parts, and components of the product. In the search for additional competitive advantages, minimizing production costs while maintaining the achieved level of quality is a strategic goal of planning and developing the company in the long term. In this case, it is necessary to structure all the company's production costs for pricing purposes. As we can see, the production cost of a single product with a production volume of 500 units of the product has developed at the level of 21.7 rubles. Let us assume that we received an offer from a partner company to supply this product at the sale price of 19 rubles per piece. We justify the economic efficiency of accepting (rejecting) this offer using the category of gross expenses of the enterprise and margin income, table 6.

Table 6: Justification of the economic efficiency of the offer

Cost groups	Input cost			
	Total costs for own production	Total costs associated with purchasing components from an external company	Unit costs for own production	Unit costs with the purchase of components from an external company
The cost of purchasing a component part	0	9500		19
Main materials	650	0	1.3	0
Labor costs of production workers	5500	0	11	0
Overhead (variable part)	2000	0	4	0
Overhead (permanent part)	2700	2700	5.4	5.4
Total costs	10850	12200	21.7	24.4
Deviation		+1350		+2.7

As we can see, buying a product from a third-party partner company is a non-effective management decision for us. Since the structure of the company's production costs implies a large share of fixed costs in the total production costs of the company, namely 24.88%. An acceptable variant of the price level of the component is at a level not higher than 16.3 rubles per unit, which is located as a difference of 19-2. 7=16.3 rubles per unit.

The main cost-oriented pricing models include:
Method of pricing based on variable costs;
Method of pricing based on full costs;
Return on sales method;
return on assets method.

Whatever method you choose, the final price for each method is the same, and there is a different distribution of costs and profits. Consider the mechanism for setting the sales price using a pricing model based on the unit cost calculation using the variable cost category. The formula for determining the company's profit when using the variable cost model has the following form:

Profit = (P – ATC) * Q - TC (9)
Where, Profit-profit;
P-product price;
AVC-specific variable costs;
Q - Volume of production;
TC-total costs;
r-profitability of a unit of production;
VC-variable costs.
In this case, the formula for the price of a product using the variable cost method has the form:
P =VC* (1+A))

Unit costs with the purchase of components from an external company

$$AVC = \frac{FC+Prfit}{VC} \quad (10)$$

According to the structure of the parameters of the formula for finding the price based on the method of accounting for transferred costs, it can be noted that the determination of the cost of a unit of goods is based on the summation of specific variable costs. While the value of specific fixed costs is applied

to the entire volume of product output and is included in the profit category. Thus forming a measure of the company's margin profit and margin income.

Let's consider the mechanism for setting the sales price using the pricing model based on calculating the cost of a unit of production based on full costs.

P = ATC (1+Rtotal) (11)
Where, ATC = AVC + AFC;
AVC-specific variable costs;
AFC-specific fixed costs.
In sum, variable and fixed costs per unit of production are the total cost per unit of production or the cost per unit of production.

LITERATURE REVIEW

Theoretical and methodological prerequisites for the emergence and development of current theories of value have served as the scientific works of the largest researchers of the theory of value, such as W. petty, D. Ricardo, A. Smith, J. B. Say, John. St. Mill, K. Marx, V. Lenin, Macconnel, C., Brue S., A. A. Cournot, W. Pareto, W. S. Jevons, A. Marshall, K. Menger, O. Boehm - Bawerk, F. von Wieser, L. Walras, J. B. Clark, K. Vexilla, John. Hicks, M. I. Tugan-Baranovsky, A. N. Bogatko. Subsequently, the main provisions of the classical school of monetary theory, to appear in theoretical concepts of Russian and foreign scientists studying the issues of formation and transformation of co-temporary theories of value, theories of value management in the post-industrial economy: E. K. Vasilyeva, N. And. Vedernikova, A. L. Dmitriev, T. G. Evdokimov-ing, V. E. Esipova, I. A. Jeltkovo, S. A. Kotlyarova, A. D. Krikunova, G. A. Mahovikova, E. E. Pavlova, S. V. Pereverzeva, N. Yu. Puzyna, M. S. Abryutina, Kapelyushnikov R., There Bulava V. L., V. M. the Galperina, Elster J.,North D., Davis L., Eggertsson T., John. Com-Mons, Stigler J., Williamson, O. E. Clay, George. Itwell, M. Milgate, And P. Newman.

CONCLUSION

In modern market conditions, characterized by different degree of competitor-Noah wrestling depending on the belonging to the industry, and the decline of investment attractiveness, there is a need of constituent entities of national economy of various legal organizational forms in the combination of methods and tools of cost management in your organization at different stages of the life cycle: production, raw material supply, marketing and retail network. It should be noted that the level of competition is completely dependent on scale, pricing methods, types of market structure, the category of goods. So, now enhanced status of social relations, which is an important feature of competition and the price system. So the theory of value and prices can only be based on the basis of a particular ethical system. Currently, issues of diversification and competitiveness of industries, and defines the required institutional changes in the economy associated with the increase of its competitiveness.
On the other hand, in the framework of institutional decisions are designed the information platform for cost accounting, the implementation of which will ensure the creation of sustainable, structurally-balanced industry. All this requires the economic entities of strategic formation models for the formation and management gross expenditure in the long term.

Abstract
The study is devoted to the problem of youth unemployment and entrepreneurship. The study has revealed an increase in unemployment in low- and middle-income countries, which is a driver of business development, including youth entrepreneurship. It is facilitated by government projects that are less popular in high-income countries than assistance in job creation and job search. The problem of unemployment in low-and middle-income countries is solved by the shifting of priorities from reducing unemployment to increasing employment. The high level of unemployment among young people prevails in the developed countries with a high share of industrial production in GDP. This is due to the need to get an excellent education and qualifications for tech-intensive sectors of the economy. Limited educational opportunities in low- and middle-income countries are not an obstacle to self-employment and entrepreneurship.
The exceptional position of the problem of youth unemployment and entrepreneurship in modern world order is associated with consistent high values of indicators of poverty rate dynamics of working youth, which depends on gender characteristics. High unemployment is observed among young people, both men and women, but employment among young men is significantly higher.

Keywords: Entrepreneurship, Youth, Unemployment, Poverty, Employment, Growth Rates.

Introduction

For a holistic analysis of youth unemployment and entrepreneurship in the current world order, we will explain their essence. From the point of view of ontology, unemployment is perceived by our consciousness as an abstract availability of people of working age in the economy who have no job, but fit for it and looking for it. The concept of employment is close to the functional characteristics of

a person and links the specific activities of people with satisfaction of their personal and social needs through earnings received and labor income.

Therefore, unemployment is understood as absence of a permanent job, and employment is a purposeful activity of a person focused on obtaining a stable and high income. Thus, an increase in the level of employment is more associated with self-employment and entrepreneurship, and a decrease in the unemployment rate is associated with government measures to promote job creation and help to find a job.

Giving the concept of unemployment and entrepreneurship the attribute "youth" does not change their essence, but only highlights the gender area of the problem.

The immediacy of the problem of youth unemployment and entrepreneurship in modern world order is related to a peculiar position of young people in the structure of the poverty rate among working people, and in accordance with the sustainable development goals (SDG) of the International Labour Organization (ILO). The SDG indicator shows the poverty rate of working people living below $US 1.90 at purchasing power parity.

As a result of the study of the predicted 2000-2022 data dynamics according to Human Development Reports, ILO has revealed an almost synchronous positive decrease in the poverty rate among the working population in the world, whereas high values of the poverty rate among working youth hold true.

At the same time, withdrawal of the youth from the "poverty structure" among working people often leads to an increase in unemployment. On the one hand, this is due to interruptions in work caused by the search for a new source of income, and on the other hand, the transition to alternative income in the form of receiving state unemployment benefits.

Consequently, the growth rate of unemployment among young people is an invariant of the entrepreneurial activity indicator, as it generates incentives for employment and self-employment. The results of the assessment of unemployment growth rates among young people have allowed us to form a conditional hierarchy of countries (table 1), that makes it possible to distinguish by: high median indicators and variance:

Pakistan (Me = 38.5%; σ^2 = 2310.1), Thailand (Me = 15.4%, σ^2 = 582.0) and Luxembourg (Me = 8.1%, σ^2 = 516.1);

low variance:

Swaziland (Kingdom) (σ^2 = 0.3, Me = 0.2%), China (σ^2 = 3.3, Me = 1.0%,) and Oman (σ^2 =3.7, Me = 1.1%).

Table 1: Hierarchy of countries by growth rates of "Me>0" youth unemployment (% aged 15-24), 2011-2017

Country	**Median, Me>0**	**Variance 6^2**
Pakistan	38.5	2310.1
Thailand	15.4	582.0
Luxembourg	8.1	516.1
Burkina Faso	6.7	15.1
Trinidad and Tobago	6.3	334.1
Mongolia	5.9	873.1
Palestine, state	5.4	57.3
Dominican Republic	5.4	298.8
Brazil	5.2	316.6
Jordan	5.2	38.8
Rwanda	4.9	357.5
Argentina	4.9	58.0

Country	**Median, Me>0**	**Variance 6^2**
Italy	4.6	105.8
Paraguay	4.5	96.4
Turkey	4.1	68.7
Kyrgyzstan	4.0	113.6
Bangladesh	3.9	59.3
Bahamas	3.8	103.6
Bahrain	3.8	44.9
Iran (Islamic Republic)	3.6	66.8
Maldives	3.1	25.9
Austria	2.9	38.3
Iraq	2.9	137.5
Honduras	2.8	222.7
Uruguay	2.8	77.9
Peru	2.7	181.0
Lesotho	2.6	65.4
Algeria	2.3	203.5
Morocco	2.3	28.4
Panama	2.2	157.8
Sierra Leone	2.2	14.2
Nepal	2.0	154.5
Cuba	2.0	113.8
Brunei Darussalam	1.9	53.7
Korea (Republic)	1.9	26.4
Barbados	1.7	61.0
Guatemala	1.7	468.9
Bosnia and Herzegovina	1.4	50.0
Sudan	1.4	4.1
Costa Rica	1.4	36.4
Indonesia	1.3	69.2
Suriname	1.3	121.0
El Salvador	1.2	98.5
Afghanistan	1.1	11.7
Oman	1.1	3.7
Armenia	1.0	121.3
Bhutan	1.0	272.3
Mali	1.0	2458.8
China	1.0	3.3
India	1.0	8.0
Haiti	0.8	26.3
France	0.8	15.1
Fiji	0.8	52.7
Saint Lucia	0.8	72.7
Namibia	0.7	162.0
Saudi Arabia	0.3	66.1
Swaziland (Kingdom)	0.2	0.3
Russian Federation	-1.8	66.1

Source: calculated using the data from Human Development Reports. ILO (International Labour Organization) (2018a). ILOSTAT database. www.ilo.org/ilostat (Accessed 13 April 2018).

The distinctive characteristics of these countries (according to the IMF) are: Pakistan – the population density is 258.45 people/km^2, GDP per capita – 5084 US dollars, HDI – 0.562 (average); Thailand – the population density is 130.5 people/km^2, GDP per capita is 7187 US dollars, HDI – 0.755 (high);

Luxembourg – the population density is 233.7 people/km^2, GDP per capita is 125364 US dollars, HDI – 0.904 (very high).

Thus, high median indices of youth unemployment growth rates are associated with high population density. Swaziland (Kingdom) – the population density is 68.4 people/km^2, GDP per capita is 3400 US dollars, HDI – 0.588 (average). China – the population density is 146.3 people/km^2, GDP per capita is 9380 US dollars, HDI – 752 (high). Oman – the population density is 12.3 people/km^2, GDP per capita is 45168 US dollars, HDI – 0.821 (very high).

Low variance in youth unemployment growth rates is determined by the high ratio of population density to GDP per capita.

Thus, the basic conditions for emergence and development of entrepreneurship in modern world order are quite simple and easy to evaluate. At the same time, in order to fully understand the possibilities of overcoming unemployment and developing entrepreneurship among young people, it is necessary to evaluate, in addition to density, the ratio of population density to GDP per capita, such indicators as: dynamics of the share of young people without education, work or professional training; self-employment; private indicators of employment and unemployment – employment ratio, total employment in industry, employment rate, the percentage of employees working more than 48 hours a week, etc.

The UN defines "youth" as people between the ages of 15 and 24. The definition appeared in the context of preparations for the International Year of Youth (1985) and was approved by the UN General Assembly in resolution 36/28 of 1981 (A/36/215). In the UN General Assembly Resolution (A/RES/70/1) "Transforming our world: the 2030 Agenda for Sustainable Development" of 25 September 2015, the interests of young people are taken into account in all goals and objectives.

Today, there are 1.2 billion young people aged 15 to 24 – 16% of the world population. For youth, the problems of unemployment, underemployment and low quality jobs remain unresolved. Young people are three times more likely to be unemployed than adults (in 2017, the youth unemployment rate in the world was 13%). Many young people are employed in low-paid, unstable or unofficial jobs.

The problem of youth unemployment. The ILO highlights youth unemployment as a global problem. More than 64 million unemployed young people worldwide and 145 million young workers live in poverty.

The ILO's multilateral approach to reducing youth unemployment rate is based on (O'Higgins, 2017(a)): economic policy of youth employment; possibility of getting education, training and skills, and transition from school to work; labour market policy; youth entrepreneurship and self-employment; and the right of young people to work.

It should be emphasized that one of the reasons for the development of the youth labour market is aggregate demand. A long period of youth unemployment is connected with a recession in the economy, and a decline in GDP leads to an increase in youth unemployment (Matsumoto, Hengge and Islam, 2012), (O'Higgins, 2012), (Choudhry, Marelli and Signorelli, 2012).

The implementation of the discretionary countercyclical fiscal policy (fiscal expansion based on an increase in public investment spending) in most OECD countries during the 2008 recession reduced the growth of youth unemployment (Gechert, 2015). Countercyclical fiscal policy is a tool for reducing youth unemployment during recessions. Under certain conditions, measures that increase budget deficit (or reduce budget surplus) can mitigate the negative impact of insufficient aggregate demand for labour of both youth and adults, restraining any reduction in employment and growth of unemployment (O'Higgins, 2017(b)).

Over the past century, there has been a gradual transition of young people from agriculture to industry, and especially into the service sector. Currently, the agricultural sector accounts for more than half of youth employment in low- and middle-income countries (LMICs). Low indicators of labour productivity in the economy contribute to the growth of youth employment. For LMICs agriculture is the dominant sector in terms of GDP formation and employment share (Loayza and

Raddatz, 2010). The growth in agricultural production has a positive effect on the reduction of unemployment among young people and their employment (O'Higgins, 2017(a)).

The review by the economist of the data preparation and analysis department of the ILO Statistics Department Rosina Gammarano on the problem of labour market access for youth around the world, based on global estimates for youth labour market indicators (Gammarano, 2019) showed that in 2018 21% of the world's youth were not employed and did not study. The future situation of youth labour market depends heavily on their initial experience, including how quickly and how well they can access labour market, as well as skills and competencies acquired through education and training. If you look at the proportion of young people who are not employed, do not study or are not taught separately for women and men, you find a striking gender picture – in 2018, more than 30% of all young women in the world were not involved in employment, education, or training, compared to 13% of young men.

Young women are more than twice as likely as young men to become unemployed and not to get an education. While 44% of young men in the world were employed in 2018, only 29% of young women had jobs. Similarly, 43% of young men got an education or training exclusively self-employed, compared to 40% of young women.

The situation is particularly alarming in the Arab States, where 29% of all youth in the region did not work, study or train in 2018, as compared to 23% in the Asia-Pacific Region and Africa, 19% in North and South Americas, 14% in Europe and Central Asia. The gender gap in the labour market is most impressive in the Arab States, where in 2018 45% of young women did not have work, education or training (compared to 15% of young men), in the Asia-Pacific Region 35% of young women did not have work, education or training (compared to 12% of young men).

In 2018, 37% of all young people in the world were employed, as compared to 64% of adults. In addition, 58% of all youth were outside the workforce, as compared to only 33% of all adults. These two facts are not surprising, since many young people are expected to get an education while staying out of the labour force. However, the analyses of the unemployment rate and the overall level of unemployment and potential labour force of youth and adults are very eloquent: in both cases, the percentage of youth approaches threefold the level of the adult population. While the adult unemployment rate in 2018 was 4%, the youth unemployment rate was 12%, and although the overall level of unemployment and potential labour force among adults was 7%, the corresponding rate among young people was 20%.

Recognizing the urgency of the problem of youth unemployment, the ILO has committed itself to significantly reduce it by 2020 as part of the SDG programme goals.

Assistance in job creation for young people. The SDG ILO goal is to reduce youth unemployment in the context of ensuring a sustainable, comprehensive economic development through productive and effective employment and decent work for all.

In modern world order, the common practice of promoting youth employment is to subsidize wages. Youth wage subsidy programmes, including cost reduction for youth recruitment firms, have become the backbone of the active labour market programmes/policy (ALMP) in high-income countries (HICs), especially since the beginning of the global recession. ALMPs are less common in LMICs, where they focus more on teaching of skills and promoting entrepreneurship.

ALMPs are state-funded programmes aimed at improving prospects of the participants. They include the following elements (O'Higgins, 2017(a)):

1) employment services and job search assistance (ESJSA). This is usually done by public employment services, which act as an intermediary between firms and job seekers;

2) subsidized employment takes two main forms:

- public employment projects (programmes) (PEPs), such as infrastructure construction, community service, etc.;

- assistance in job creation in private business through wage subsidies for young people;

3) training young people in professional skills at work or outside work.

Particular provisions of ALMP offer a series of support measures that cover more than one of the elements outlined above. Consequently, ALMP participants receive a combination of support forms, such as ESJSA combined with a wage subsidy from a private employer, on condition that the employer provides training.

The main rationale for introducing a wage subsidy is that it will increase employment for target groups, reduce labour costs and, as a result, increase the demand for labour resources. At the same time, two ALMP factors can lead to an integration effect after the end of the subsidy period due to the fact that: the subsidized pay period can act as a screening device, providing direct information about the performance of a young person; subsidized wages help to form skills through "training in practice" (Heckman, Lochner and Cossa, 2002), (Kluve, Puerto, Robalino, Romero, Rother, Stoterau and Weidenkaff, 2016).

Self-employment and entrepreneurship. In the context of a decrease in world trade growth rates and an increase in global competition, the development of self-employment and entrepreneurship is becoming a key element of the strategy for promoting youth employment in LMICs.

The increase in self-employment reflects "latent" unemployment, when it acts as a temporary alternative to unemployment (Tatomir, 2015). Self-employment may also indicate that people are employed part-time, for example, in the case of people who receive a certain income from formal work but want to work extra hours to increase their income. The increase in self-employment reflects long-term demographic trends, technological development, or institutional changes that encourage people to create independent firms.

The prevalence of self-employment is closely related to income level per capita in the country. In LMICs, the vast majority of the economically active population is self-employed, concentrated in sectors such as construction, agriculture, and street trading (Gindling and Newhouse, 2014). Most self-employed people in LMICs work in sectors of the economy with low productivity and income, and as a result, many of the self-employed and their families remain poor.

The self-employed in HICs also have few rights to paid sick leave, leave, maternity leave or parental leave, or compensation for dismissal. Within the EU, self-employed workers tend to work longer hours and have lower earnings as compared to full-time workers (D'Arcy and Gardiner, 2014).

Self-employment is not always a favourable employment status for young people. Self-employment promotion is not necessarily an effective mechanism for increasing social mobility or reducing poverty. In many cases, self-employment can be seen as the only way to generate income in economically depressed areas.

So, self-employment becomes a survival mechanism both on the part of a person and his family. Self-employment among young people is often rooted in the family where parents or other family members are self-employed. Self-employment is less advantageous than permanent employment. Instead of receiving a constant guaranteed income in the formal sector, many career paths of young people are stuck in a cycle between self-employment and unpaid family work, which in itself is considered a much more negative phenomenon (O'Higgins, 2017(a)).

Method and Results

To assess the possibilities of reducing unemployment and developing entrepreneurship among young people in modern world order, we apply the methods of descriptive statistics, including processing of empirical data, their systematization, visual representation in the form of graphs and tables, and their quantitative description by means of basic statistical indicators. Using descriptive statistics, we estimate the data set by statistical indicators – median and variance.

To identify the "stimulus-response" in relation to "unemployment-entrepreneurship", we apply statistical and cluster analysis. Statistical analysis will serve as a method of collecting, studying and presenting large amounts of data on properties (Lazar, Feng and Hochheiser, 2017) and data relationships (Schofield, 1993), correlation relationships of spatial and time series of indicators, which will allow us, while maintaining the research methodology, to create an analytical platform for applying cluster analysis. Cluster analysis will make it possible to justify the significance of the reasons for changes in money supply (monetary aggregate), to identify the main schemes of their

grouping, to formulate hypotheses (Adolfsson, Ackerman and Brownstein, 2019), (Favero and Belfiore, 2019).

Analysis

A multi-faceted review of literature on youth unemployment and entrepreneurship in modern world order allows us to conclude that young people who are not involved in the current structure of economic activities are forced to create new forms of gaining income, both legal and illegal. Within the framework of legal forms of income generation, the choice of young people is limited to entrepreneurial activity – entrepreneurship.

In view of the fact that there are many regulatory restrictions on entrepreneurial activity in the world, and the subject of the study is the analysis of the dynamics of youth entrepreneurship in the world, the presence of Russia as a certain regulatory benchmark is necessary, even if it is not included in the hierarchy of countries in terms of growth in youth unemployment. Relatively stable

median values of youth unemployment growth rates (Me = -1.8%, $\sigma^2 = 66.1$)

allow Russia to be included into the study as a determinant of youth unemployment and entrepreneurship in modern world order.

Relative to Russia, Pakistan and Thailand show high median rates and variance in youth unemployment. Pakistan is a developing agro-industrial country, and agriculture is the basis of the economy. The main crops are wheat, sugar cane, cotton and rice, which together make up more than 75% of the total value of exported crops. Pakistan's largest food crop is wheat, which in 2017 was produced more than in Africa and almost as much as throughout South America.

Thailand is an agro-industrial country too. The share of agriculture in GDP is more than 10%, it employs a third of the working-age population of Thailand.

Despite the fact that Pakistan and Thailand are agro-industrial countries, and according to the ILO SDG concept, the development of low-productive sectors of the economy (agriculture) in LMICs will significantly reduce the unemployment rate among young people, in reality we see the opposite effect.

In the structure of the hierarchy of countries by growth rates of youth unemployment (see table 1), one should single out a high level of youth unemployment in developed countries with a high share of industrial production in GDP such as Austria, Italy, Luxembourg and France. First of all, this is due to the need to get an excellent education and, secondly, to off-the-books employment, when young people do not seek to register their income, usually realizing their potentials in the service sector.

Limited educational opportunities in most LMICs are not an obstacle to self-employment and entrepreneurship, for example, in countries such as Armenia, Afghanistan, Bangladesh, India, Iraq, Mali, Namibia, Pakistan, Sudan, Trinidad and Tobago, Turkey.

The problem of the high proportion of young people without education, work or training is gradually taking hold in Europe. This is a critical problem, since the highly developed European labour market cannot "digest" the excess supply of unskilled labour. There are significant negative median values of the growth rates of youth self-employment in Luxembourg, Greece, Croatia, Poland, Serbia, Iceland, Belgium, Malta, Italy, Portugal, etc.

Let us analyze the growth rates of employment and unemployment indicators in Russia (table 2).

Table 2: Clusters of the growth rates of employment and unemployment indicators in Russia, 2010-2018

Cluster		Squared Euclidean distance
Proportion of adult population with higher education	Employment rate, men	24.240
	Total employment in industry	43.215
	Youth employment rate	82.672
	Level of employment	106.859
	Percentage of employees working more than 48 hours a week	537.914
	Unemployment rate	593.918
	Non-fatal industrial injuries per 100,000 employees	728.196
Level of employment	Population employment	2.675
	Employment rate, women	11.180
	Total employment in agriculture	89.115
Employment rate, men	Employment-to-population ratio, men	3.270
Total employment in industry	Employment-to-population ratio, women	2.706
Total employment in industry	Total number of people engaged in services	9.821
Total number of people engaged in services	Average number of actual hours worked per week per employed person	3.146
Unemployment rate	Unemployment rate, women	20.897
	Unemployment rate, men	32.527
	Youth unemployment rate	491.689
Youth employment rate	Youth employment rate, men	1.426
Youth employment rate	Youth employment rate, women	5.961
Youth unemployment rate	Youth unemployment rate, men	6.462
Youth unemployment rate	Youth unemployment rate, women	32.235
Non-fatal industrial injuries per 100,000 employees	Lost days on occupational injury	79.294
Non-fatal industrial injuries per 100,000 employees	Fatal industrial injuries per 100,000 employees	302.640

Note: Hierarchical cluster analysis – the average distance between clusters, squared Euclidean distance.

Source: calculated in "SPSS Statistics" according to the Russian Federation. ILOSTAT Country Profiles. https://www.ilo.org (Accessed 01 November 2019).

The analysis has revealed significant clusters:

1) adults with higher education, mostly men, are employed in industry;

2) opportunities to increase the employment rate mainly among women are related to agriculture;

3) high unemployment rate among adult men;

4) high youth unemployment among women.

5) loss of basic income is caused by non-fatal industrial injuries (lost days on occupational injury).

The resulting clusters allow us to highlight the gender component of the problem of Russian unemployment and entrepreneurship. High unemployment is observed among young people, both men and women, but employment among young men is significantly higher. At the same time, we notice low unemployment of the adult population "25+" among men, high employment among women.

The current economic situation in Russia indicates a significant enhancement of the role of entrepreneurship as a strategic resource that can provide an increase in national welfare (Smirnov, Talanova, Zakharova, Dulina, Getskina and Huraskina, 2018), (Smirnov, Semenov, Kadyshev, Zakharova and Perfilova, 2019), (Smirnov, Zakharova, Talanova, Dulina, Gubanova and Getskina, 2019).

The study results in complementary proposals and measures to improve youth unemployment situation:

- formation of social capital as a special economic environment and state institutions that increase the associative activity of functioning of entrepreneurship factors;

- the solution to the problem of population urbanization lies in the synchronization of small business management processes and the development of the urban economy;

- formation of industrial capital as part of financial capital will contribute to the development of the small and medium-sized enterprises sector;

- development of the mechanism of industrial cooperation and social stabilization, typical for the Russian craft of the past, will maintain a favourable institutional climate for corporate business, etc.

Conclusion

The immediacy of the problem of youth unemployment and entrepreneurship in modern world order is related to a peculiar position of young people in the structure of the poverty rate among working people. The dynamics of the poverty rate among working people in the world shows persistently high values among young people. This negative phenomenon is compounded by a high percentage of young people in the low-income group.

Unemployment growth in LMICs encourages the development of entrepreneurship, including youth entrepreneurship. This is facilitated by PEPs less popular in HICs than ESJSA measures. For example, the shift in emphasis on entrepreneurship in Russia (a country of LMICs) is linked not only with raw materials-based economic structure, unable to respond to ESJSA government measures, but also with well-developed PEPs implemented within the framework of National projects. Thanks to PEPs, Russia demonstrates significant and stable dynamics in reducing the growth rate of youth unemployment.

Generally, in LMICs the solution to the problem of unemployment as a lack of permanent work for the population is carried out by changing priorities towards employment, where personal interests dominate – stable income generation. At the same time, an increase in income is associated with self-employment and entrepreneurship.

In HICs unemployment growth leads to significant problems in the economy caused by additional costs for implementing ESJSA government measures. High youth unemployment rate is prevalent in HICs with a high share of industrial production in GDP. First of all, this is due to the need to obtain an excellent education and qualifications for tech-intensive sectors of the economy. Limited educational opportunities in LMICs are not an obstacle to self-employment and entrepreneurship.

The study has revealed a long period of high median values of growth rates for the proportion of young people without education, work or training, not only in underdeveloped countries, but in developing countries as well. The importance of the problem of employment and unemployment also depends on gender characteristics. High unemployment is observed among young people, both men and women, but employment among young men is significantly higher. In general, the growth of youth unemployment can reflect their decision to continue education.

Abstract

Social media marketing is a phenomenon which has become an important aspect of the marketing mix and revolutionize the way companies interact with their customers. It is a new field of research and literature quick scan revealed that not many studies exist on social media marketing on SMEs in UAE. Quantitative methodology was employed in this research and 350 questionnaires were distributed to the target respondents and 245 were used for the analysis in this research work. SPSS and Smart-PLS were employed in data analysis. The findings indicate that email and twitter have negative effect on organisational culture while Facebook and WhatsApp showed positive effect. However, only the effect of twitter shows significant effect ($\beta = -.606$, $t = 17.49$, $p = .000$) while the remaining variables did not show any significant effect. Altogether, the four social media tools explained about 36 percent change in organisational culture. In addition, the effect of the four's social media tools and SMEs performance indicated that Facebook have negative effect on SMEs performance even though the effect is not statistically significant. The most influential determinant of SMEs performance is shown to be organisational culture ($\beta = .922$, $t = 40.70$, $p = .00$), this is followed by WhatsApp which returned a significant effect ($\beta = .193$, $t = 5.306$, $p = .000$), overall, email, Facebook, twitter, WhatsApp and organisational culture collectively explain about 77 percent variation in SME performance.

Keywords: Social Media, Organizational culture, SMEs, UAE.

Introduction

Over the past few years, social media has gained an enviable position in the life of many people and it has become a topic for discussion across different sections of our society and has gained widespread acceptance in today's busy life. The freedom and the level of interaction one can have in the various social media platforms have also influenced the way business is carried out these days. One can safely assume that in many organisations different platforms of social media has been playing a very important role in business development and better performance (Ahmad *et al.,* 2019). There has been a fundamental shift in the strategy of conducting business amongst the ever-evolving business community all over the world and the people who have not yet got into the bandwagon are forced to come on board due to the rapid spread and acceptance of social media among the general public and the consumers in particular. As social media has become a part of consumers' everyday life a lot of organizations have started exploring the positive qualities of the internet and have now shifted their attention to e-commerce and online trading (Daou et al., 2018).

One of the many advantages of social media is that it allows an organization to communicate closer to its target audience while it enhances the organization to increase its brand visibility (Gilbert, 2017). "Many organizations active on the social networking scene have direct links from their corporate websites to their social networking sites like Facebook, LinkedIn, Instagram, YouTube and Twitter, and use these social media sites to promote brands and support the creation of brand communities" (Prasad et al., 2019).

The advancements of the internet technologies in recent years have made new systems available to business of social media is one of the examples of such as online communities evolved with the advent of internet technologies. The general availability of the internet has allowed individuals to use social media, from email to Twitter and Facebook, and to interact without the need for physical meetings (Negoiţă *et al.* 2018). Web 2.0 applications have facilitated this, Web 2.0 is a new advancement, which has transferred the internet to a social environment by introducing social media, where individuals can interact and generate content online.

In today's business "environment, social media has become a new marketing tool that is available to all businesses, that instantly develops relationships with potential customers. Traditionally, large companies had the power of reaching their markets through the colossal advertising budget, which small companies found it difficult to fight the stiff competition from these large companies (Leung et al., 2019). Social Media, today, is among the 'best opportunities available' to a brand for connecting with prospective consumers. Social media is the medium to socialize (Ahmad *et al.,* 2018). These new media win the trust of consumers by connecting with them at a deeper level. Social media marketing is the new mantra for several brands since early last year. Marketers are taking note of many different social media opportunities and beginning to implement new social initiatives at a higher rate than ever before. Social media marketing and the businesses that utilize it have become more sophisticated. One cannot afford to have any presence on the social channels if the competitor is making waves with its products and services (Khasawneh, 2017).

Decisions of purchases are normally inspired by the persons who the customers trust and familiar with. Furthermore, several shoppers who shop online encourage to read and get familiar with the thoughts of expert bloggers before finalizing their buying choice to decrease the possibility of purchasing a bad product. Internet-based social groups, dynamically nurtured by Electronic business companies, permit customers to share their familiarities by rating reviews, writing reviews, and talking between trusting affiliates. They drive the number of visitors to shopping" sites and turn out to be an opening point for Web customers. Electronic commerce companies have captured data on the social contact among customers in their websites, with the possible objective of leveraging and understanding the social effect in customers' buying decision process to increase purchaser's attention and ultimately upsurge their sales (Kumar *et al.,* 2020).

Using e-commerce, the "decision-maker trying to concern costs and revenues at the same time, and seeking to follow all the means that lead to the improvement that serves as an goal sought by most of the companies that will contribute to the help the administration in the process of planning and sales policy-making of the company and facilitate the process control of those costs and help the administration in making sound decisions that relate to the marketing activity and being significantly effect on the company's sales and the level of profits (Fahad *et al.,* 2019).

Social media are online platforms that facilitate global collaboration and sharing amongst users. New social media applications in e-commerce appear on a daily basis and result in enormous shocks to the ecosystem of individuals and businesses. One of the most significant trends in the past decades is the growing use of the Internet and communication technologies (ICT). Internet and associated technologies have a major impact on the way organizations conduct business (Hollensen et al., 2017). Internet technologies provide new opportunities for companies to compete in the global market and play a major role in the world's economy. Even though the significance of several studies in the field of online business, the area of this kind of study requires more studies to be done (Taiminen, 2016). SMEs according to the State of Small and Medium Enterprises in Dubai is any company that fits the

thresholds of turnover" and headcount of an employee**,** as suited to the sector that lies into (services, trading and manufacturing). Figure 1 below represents Dubai SMEs' definition of SMEs.

Figure 1: SMEs definition according to Dubai SMEs by the sectors and businesses' size
(Source: www.sme.uae, 2015)

Today, they are around 95% of the businesses and the reason for 90% of employment in the UAE. The report indicated that in Abu Dhabi for example, SMEs represent 74% of firms' total number. Moreover, in a similar report conducted by Dubai Small and Medium Enterprises, 95% firms in Dubai were considered SMEs (Nuseir, 2018). The majority of them are operating in trading sector estimated by 57% while 7% and 35% respectively are operating in manufacturing and services sectors. In addition, the report also stated that the contribution of SMEs to Dubai's GPD% and the total employment by 42% (Atienza, 2019). These findings confirmed by another report conducted by Emirates NBD in 2014. Those reports provide us with clear picture for the significant role of SMEs to UAE' growing economy and its main function to provide business and work opportunities for investors and job seekers which in turns shall grant a maintainable source for investments reaching to the region.

A study conducted by Alaa (2016) revealed that 58% of SME managers stated that they are planning to invest in social networks marketing due to the potentials and full benefits abound in the sector. These online business opportunities are available in the UAE business sector. Example of this businesses are the textiles industries, the electrical and electronics, the capital market and many other sectors. SMEs' top three priorities in digital marketing are increasing the use of social media.

Figure 2: Future Digital Marketing Channel SMEs looking to invest in U.A.E (Alaa, 2016)

Similar a study conducted by Cader and Al Tenaiji (2013), they found that the primary purposes for social media marketing utilization by companies in UAE were as follows: to advertising; improve awareness of the brand: feedback on services or products; directing to the company web site; promotional offers and low-price reach of customers and gathering of market intelligence. Furthermore, they stated that Facebook, YouTube, Twitter, Flicker, Linked in and My Space were probably the famous sites used for marketing activities.

This study will discuss how Small and Medium Enterprises (SME) can leverage social media to penetrate their markets, reach their customers and develop relationships in a personal and direct manner that can catapult their brand and raise their awareness as successfully as any large business. The study also discloses the influence of social media on consumers' online buying decisions.

Methodology

The study employed a quantitative approach to achieve the research objective. The use of quantitative methods provides a concrete manifestation of the findings in an actual setting (Basias et al., 2018). In the same light, the use of this type of research allows the researcher to measure the parameters held in the objectives of this research paper (Brannen, 2017). Using survey research strategy and a convenience sampling technique, a total of 350 questionnaires were self-distributed to the target respondents which were employees of the SMEs in UAE (Quinlan et al., 2019). A total of 245 questionnaires were used for the analysis. The sample size was calculated to guarantee a sufficient number of respondents. Thus, the following formula has been used to estimate the population sample size (Queirós et al., 2017):

Where:

n = Required sample size (minimum size)
t = Confidence level at 95% (standard value of 1.96)
p = Estimated fractional population
m = Margin of error at 5% (standard value of 0.05)

The number of respondents in each subgroup was calculated based upon the collected data from the 263 respondents. Similarly, the questionnaire constituted of two sections A and B. Section A sought information about the respondents' socio-demographic data while section B contained questions with respect to the research constructs. The question format in the section B was designed in a Likert-scale format in a scale of 1 (strongly disagree) to 5 (Strongly agreed). Table 1 presents the factors, number of measurement items, scale and sources for each of the constructs used in the study. The data analysis was conducted using SPSS and AMOS software.

Result and Findings

Measurement Model Assessment

Figure 3 below shows the measurement model for SMEs performance. The model consist of six constructs measured in reflective-reflective mode (Hair, Ringle, & Sarstedt, 2011). The six constructs are linked with one-headed arrows which indicate causal effect among them. Being a reflective-reflective model, the assessment of the measurement model involves testing the validity of the model, the indicator loadings, Average Variance Extracted (AVE, composite reliability and discriminant validity needs to be computed (Hair, Ringle, & Sarstedt, 2011). The main purpose of assessing measurement model is to test for construct validity. According to Hair, et al (2017) construct validity is the degree to which the indicators of a latent construct represent it.

Construct validity is assessed through testing the convergent and discriminant validity. The convergent validity measures the extent of correlation among the indicators of a latent construct. On the other

hand, discriminant validity test the degree of uniqueness of a construct relative to other constructs in the research model (Henseler et al., 2015).

Figure 3: Measurement model for SMEs Performance

Convergent validity

Hair, et al (2014) defined convergent validity as the extent to which the indicators of a latent construct correlate. Hair, et al. (2011) recommended the use of indicator loading and AVE as criteria for judging convergent validity.

Indicator Reliability

Indicator reliability measures the absolute importance of individual measurement items in defining the latent construct. It shows the relationship between the latent construct and the measurement items (Hair, et al., 2014). A factor loading of .70 is considered sufficient (Becker et al., 2012) although Hair, et al. (2014) pointed that values less than .70 are also acceptable provided that the AVE is achieved.

Average variance extracted (AVE)

The second criteria for establishing convergent validity is the AVE. It is defined as the overall mean value of the squared loadings of the indicators of a latent construct (Hair, et al., 2014). According to Fornell and Larcker (1981) the AVE measures the amount of variance a latent construct explained from its measurement items in relation to the amount explained by measurement error. Hair et al. (2014) recommended that AVE should be .50 and above which indicates that at least more than half of the variance in the indicator is explained by the construct.

Composite reliability (CR) measures the internal consistency of the measurement model. Hair, et al. (2014) described it as the degree of inter-correlations among indicators of a latent construct. The recommended value is .70. However, Hair et al. (2011) pointed that .60 is equally acceptable especially in exploratory research.

Table 1 shows the outer loading of the indicators, AVE and composite reliability of the measurement model. All the parameters meet the recommended thresholds for model's convergent validity. Specifically, the outer loadings ranges from .593 to .946 and they are all statistically significant. Similarly, the AVEs reported values within the acceptable threshold of .50. The composite reliability values also reported values within acceptable benchmark of .70. The CR values range from low of .898 to a high of .952This indicate that construct validity is achieved.

Table 1: Construct validity

Discriminant Validity

Discriminant validity as defined earlier measures the uniqueness of latent construct with respect to other constructs in the model. Discriminant validity is assessed using the Hetrotrait-Monotrait (HTMT) criterion. Henseler, et al. (2015) recommended it as the most conservative measure of discriminant validity. The criterion is to compare the calculated result with a value of .85 and .90 in such a way that any value in the table above the recommended threshold implies that discriminant validity is not achieved. Table 2 show the result of the HTMT test. The correlation matrix indicates that no value exceeds the recommended benchmark of .85 and .90. This implies that discriminant validity is achieved.

Table 2: Discriminant validity

Structural Model Evaluation

After assessing the measurement model, next stage is to evaluate the research framework. The structural model is evaluated using collinearity assessment, test of significance of path coefficients determination of r-square and effect sizes (Hair, et al., 2014). Figure 4 shows the structural model extracted from the PLS software.

Figure 4: Structural model evaluation

Path Coefficient and R^2

The path coefficient is the estimate of the hypothesized relationships among the model's constructs. According to Hair, Black, Babin and Anderson (2010), the path coefficient ranges from +1 to -1 where values tending towards 1 indicate stronger relationship. Apart from magnitude of the path coefficient, it is equally important for the estimates to be statistically significant.

R^2 is considered the overall measure of model performance. It is an indicator of the combined effects of all the independent variables in explaining the variation in the dependent variable in a model. Hair, et al. (2014) provided a threshold for interpreting the R^2 value where R^2 of .75, .50 and .25 are considered to be of substantial, moderate and weak effect respectively. However, in behavioural research, consumer satisfaction studies and other related areas in management and social science fields, R^2 value of .20 are considered of high effect (Hair et al., 2014). Table 4.11 presents the path coefficients for the relationships among the six constructs in the model. All the reported path coefficients are positive which indicates that the variables in the model are positively related. The R^2 value is also reported.

Table .3 shows the path coefficients of the relationship among the constructs in the model. The table shows that email and twitter have negative effect on organisational culture while facebook and whatsapp showed positive effect. However, only the effect of twitter shows significant effect (β = -

.606, t = 17.49, p = .000) while the remaining variables did not show any significant effect. Altogether, the four social media tools explained about 36 percent change in organisational culture.

In addition, the effect of the fours social media tools and SMEs performance indicated that facebook have negative effect on SMEs performance even though the effect is not statistically significant. The most influential determinant of SMEs performance is shown to be organisational culture (β = .922, t = 40.70, p = .00). This is followed by whatsapp which returned a significant effect (β = .193, t = 5.306, p = .000). Overall, email, facebook, twitter, whatsapp and organisational culture collectively explain about 77 percent variation in SME performance.

Table 3: Path coefficients and R-square

	Path coefficients	T Statistics	P Values	R^2
Email -> Org_Culture	-0.011	0.147	0.883	.364
Facebook -> Org_Culture	0.020	0.318	0.751	
Twitter -> Org_Culture	-0.606	17.491	0.000	
Whatsapp -> Org_Culture	0.005	0.129	0.897	
Email -> SME_Performance	0.017	0.363	0.717	.768
Facebook -> SME_Performance	-0.065	1.667	0.096	
Twitter -> SME_Performance	0.026	0.706	0.480	
Whatsapp -> SME_Performance	0.193	5.306	0.000	
Org_Culture -> SME_Performance	0.922	40.700	0.000	

Effect Size (f^2)

The effect size measures the relative importance of individual construct or variable in the overall performance of the model (Hair, et al., 2014). It indicates the change in R^2 resulted from the removal of one of the independent variables in a model. The Cohen (1992) guideline is used to assess the relative importance of an exogenous construct where f^2 values of .02, .15 and .35 are considered small, medium and large respectively. Table 4 shows the effect sizes of the exogenous constructs in the model. The result shows that twitter has large effect size on R^2 in the relationship between twitter and organisational culture while it has no effect on R^2 in the relationship between twitter and SME performance. On the other hand facebook has a marginal small effect on R^2 in the relationship between facebook and organisational culture. In the relationship between organisational culture and SMEs performance, OC showed a very large effect on R^2, thus indicative of its importance in explaining the variation in SMEs performance.

Table 4: effect sizes of the constructs

	Org_Culture	SME_Performance
Email	0.000	0.001
Facebook	0.001	0.018
Twitter	0.453	0.002
Whatsapp	0.000	0.127
Org_Culture		2.332

The analyses conducted provided answers to the research questions as well as help to achieve the research objectives. It also provides empirical evidence that validate the research conceptual framework.

Conclusions

The successful implementation of social media marketing tools depends on its impact on the SMEs performance in UAE. Based on the survey data, the researcher has concluded that organizational culture has a significant influence on the relationship between social media marketing tools and SMEs performance in UAE. This study has addressed a significant gap in the literature pertaining to the social media marketing tools and performance of SMEs in UAE. This was done by formulating and examining a research model linking the multidimensional social media marketing tools and organizational culture as a mediating relationship between social media marketing tools and SMEs performance. The results of this study indicated that organizational culture has a mediating effect on the relationship between social media marketing tools and performance of SAMEs in UAE.

Abstract

Research background: Nepotism is one of the forms of favouritism occurring at people's workplace. This is the reason why it creates a problem for managers in charge of organizations, ethicists, and psychologists. Although nepotism as such is in principle negatively assessed, the employment of family members, especially in family businesses, is often considered natural and it can benefit the organization if certain conditions have been met.Purpose of the article: The goal of the article is to analyse the perception of nepotism occurrence in Polish small and medium family businesses, as well as to identify nepotism related factors, both beneficial and unfavorable ones. Methods: A qualitative study aiming at enhancing the knowledge concerning nepotism range in family businesses in Poland, followed by a quantitative study, performed to verify the information obtained in the qualitative study and to compare the nepotism perception of employees in family businesses and employees in other organizations. Findings and Value added: In Poland there is noticeable paucity of empirical research concerning the nepotism phenomenon. As a result of the studies which have been carried out, identification and stratification of positive and negative factors connected with nepotism in family businesses will be possible.

Keywords: Nepotism, Family Business, Recruitment Process

Introduction

Nepotism is one of the forms of favouritism occurring at people's workplace (Riggio and Saggi 2015, p. 19). Although it is in principle negatively assessed, the employment of family members, especially in family businesses, is often considered natural and it can benefit the organization if certain conditions have been met (Bellow, 2003, pp. 50-79).

At the same time, there is a clear lack of empirical research on the phenomenon of nepotism in Poland (Sroka and Vveinhardt 2018, pp. 31-45; Ignatowski et al., 2020, pp. 15-19; Vveinhardt and Sroka 2020, pp. 11-18). Therefore, the authors of the article decided that its objective will be to examine the opinions of business owners and employees on the phenomenon of nepotism in small and medium-sized family businesses. The implementation of the goal is possible through a research program that is based on a mixed method. In the first stage, qualitative research was conducted in the form of individual interviews with several entrepreneurs running family businesses. Their main goal

was to deepen the knowledge of nepotism in family businesses in Poland. In the second stage, a quantitative study was carried out to verify the information received in the qualitative study.

The result of the research will be the identification and stratification of positive and negative factors related to nepotism in family businesses. This will allow not only to gain in-depth knowledge of this phenomenon, but also to determine the direction of further research. In addition, the research results and their analysis will have practical value. They can be used by the owners of small and medium-sized family businesses when making rational decisions related to the employment of family members.

Nepotism in family businesses – literature review

Enterprises belonging to the family and managed by its members are the most common form of running a business and constitute an extremely valuable element of the economy that significantly affects the stability of economic development. Analyzing the essence of their functioning and development, it is noticed that they constitute an interesting example of relations between a family having a dominant influence on running the business and a company as well as a type of relationship with society and the economy that constitute a significant context for running a business. The functioning of a family enterprise is based on two logics - an emotional one based on the need to care for relatives and a business one based on economic rationality (Sułkowski et al., 2018, pp. 225-270). Undoubtedly, family enterprises have a number of features that distinguish them from other entities and decide on their specificity (Hoy, 2014, pp. 620-628). One of them is the issue of nepotism.

Nepotism in family businesses is a natural phenomenon, morally justified by the family ownership of the company's assets. At the same time, its impact on family businesses is one of the least studied and researched areas. In the case of family enterprises, the use of nepotistic practices is not always criticized, although it may cause huge problems for their functioning and succession (Sugundan et al., 2018, pp. 764-765).

Nepotism is not a homogeneous phenomenon. It covers a wide range of family relationships that connect with professional relationships. I-Pang Fu, referring to the works of Padgett and Morris (2005), talks about two forms of nepotism: "cross-generational nepotism" and "paired employees". Cross-generational nepotism refers to the employment of family members who come from the first two or earlier generations. Such a situation is often encountered in family businesses. The nepotism called "paired employees" raises greater controversy. The term refers to a dual career and relationship between husband and wife in the office. Controversies are associated with situations when married couples apply to work in the same workplace. The aforementioned Padgett and Morris question anti-nepotistic policy. They believe that married couples can better balance work and link family responsibilities when they become significant actors in the workplace (Fu, 2015, p.1).

Bearing in mind the nepotistic practices of family businesses, it should be noted that they may discredit some family members and support others. Applying nepotistic practices, families use their control to employ family members, which allows them to sustain family involvement in the company over time and for generations. Nepotistic practices in family businesses can be seen in two ways. Peter Jaskiewicz, Klaus Uhlenbruck, David B. Balkin and T. Reay (Jaskiewicz et al., 2013, pp. 121-139) talk about "reciprocal nepotism" and "entitlement nepotism".

The first of them, reciprocal nepotism, takes into account family conditions and interdependencies, relationships within the family, cultural norms as well as competences and obligations of people employed in relation to other family members.

The entitlement nepotism does not take into account the family ties and determinants, it may ignore the potential benefits resulting from them. Employment is based on family ties, but does not take into account the competences of the candidates. When it is deeply embedded in practice, it can be dangerous and even detrimental to the functioning of the business. Persons appointed for high

positions do not always feel obliged to achieve the results expected by the family and the reasons for their employment may be based on altruistic considerations (Jaskiewicz et al., 2013, pp. 121-139). Where nepotism, which does not take into account family conditions and is based on a simple intergenerational management transfer, is practiced in family businesses, the results achieved earlier are reduced and the employees' confidence in the management in the family's possession is lower (Keles et al., 2011, pp. 11-14).

The level of nepotism in family businesses is influenced by the requirements faced by company managers. The lower they are, the level of nepotism is higher. The managing director, who is derived from the family, is most often employed in small companies with low RandD expenditures and high expenditures on promotion and advertising (Lin and Hu, 2007, p. 1349).

The employment of a nepotistic candidate, if he is properly qualified, can be positively evaluated by his superiors. In addition, the employment of competent and properly prepared family members translates into an increase in the scope of family power in the organization and higher employee loyalty (Popczyk, 2017, p. 49; Ewing, 1965, p. 27).

Professional family businesses face a serious dilemma when there are no innovative and qualified people among the closest family members. In such a situation, they may look for a qualified manager outside the family circle (Miller et al., 2015, p. 35). There is also a second option for family businesses, namely postponing succession in time and making every effort to educate a successor who will acquire the necessary qualifications to run the family business (Liu et al., 2015, pp. 419-435).

An important factor related to nepotism in employment, which can positively affect the functioning of family businesses is the specificity of the relationship between family members. Mutual social connections of such candidates are higher than in the case of people from outside the family, which promotes the construction of the company's social capital that can be used for better knowledge management in the organization, which translates into strengthening competitive advantages (Jaskiewicz et al., 2013, pp. 128-130).

The family, having the power in the company, has a sense of self-worthiness that it brings to the organization, which translates into motivating its members to work for the development of the organization. Members of the family employed as a manager will place material benefits on the second plane, and the first one will be occupied by social, emotional and ethical security (Popczyk, 2017, p. 49). In the case of family members, flexible employment contracts are often used, where the provision of such services often goes beyond the formal responsibilities of the manager. The leader of the family does not need to be monitored so much (Lin and Hu, 2007, p. 1350). Persons employed on the basis of family connections are characterized by a higher level of loyalty and involvement in the organization. Growing up in a family running a business, they are often adapted from their youth to fulfill the future roles of managers, which naturally creates a team of highly competent and educated people who are an important social resource of the organization (Gibb Dyer, 2006, p.262).

When they are positively evaluated by the environment, they also manage to gain greater trust and involvement from other members of the organization (Padgett et al., 2014, p. 284, Ewing, 1965, p. 37). It can contribute to the formation of so-called communal organizations with a more holistic attitude of employees (Padgett et al., 2014, p. 285). This will rearrange into positive social capital of the organization (Sułkowski and Chmielecki, 2017, pp. 23-24). The high level of trust in families has also contributed to the development of small and medium-sized family businesses in Poland (Marjański et al. 2019, pp. 280-304).

If the family has large control over the company, this situation may result in limiting the manager's freedom of action. If the manager comes from the family, the probability of conflicts with the owners of the company is reduced (Lin and Hu, 2007, pp. 1359-60). In the case of limited ability to monitor by business owners, the risk resulting from the so-called "agency" phenomenon, where an external

manager with full access to information acts as an agent in relation to the owners is lower (Popczyk, 2017, p. 51).

The issue of employment and the functioning of a family business also applies to the lower level of employees. Companies that use specialized employee selection and have clear salary criteria achieve better results than those that did not implement such practices. The introduction of professional practices (referred to as high-performance work systems) in family businesses leads to disciplining unfair relatives and increases the involvement of other employees (Stewart and Hitt, 2012, p. 62).

Nepotism in family businesses is associated with a number of factors that are unfavorable to the organization. If employees from lower levels know that promotion decisions are not directly dependent on work performance, then they have less motivation to work and tend to be less inclined towards loyal life in the company. As a consequence, there is a loss of talented employees. All this reduces the value of the company (Bertrand and Schoar, 2006, pp. 78-79).

Managers employed according to nepotic practices usually have lower competencies. This leads to a reduction in the company's investment due to their lower qualifications. Which in the long run can lead to loss of competitiveness (Parise and Leone 2018, pp. 15-22).

Other disadvantages of nepotism include the perception of a person employed in this way. The subordinates, regardless of their competences, will perceive them as less competent and inferior (Padgett and Morris, 2005, p. 36). Some researchers claim that such people are stigmatized by the environment (Padgett et al., 2014, pp. 285-287). The subordinates of a person employed as a result of family connections experience lower job satisfaction and willingness to get involved in the organization as well as lower motivation (Padgett and Morris, 2005, pp. 39-42, Padgett et al., 2014, p. 283; Padgett et al., 2019, pp. 110-117; Abdalla et al ., 1998, p. 569; Pearce, 2015, pp. 41-44; Ignatowski et al., 2020, pp. 15-19). Nepotism can cause jealousy and bad emotions among employees (Padgett et al., 2014, pp. 285-287; Ewing, 1965, p. 37). Their trust in the organization is decreasing (Keles et al., 2011, p. 13), which weakens its social capital (Chmielecki and Sułkowski, 2018, pp. 99-103). The willingness of employees to leave the company also increases (Padgett et al., 2014, p. 283), and also, if information about nepotism practices gets into the environment, the willingness to hire outsiders decreases (Ewing, 1965, p. 37) . Such employees also note that they are treated worse than family members (Uygur , Ã‡aÄŸatay, 2015, p.144). The negative perception of nepotism is higher when employees are managed in an authoritarian manner (Ugurluoglu et al., 2018, pp. 165-176). At the same time, such a superior has less chance of getting support from his subordinates (Padgett et al., 2014, p. 286). All of the above negative factors weaken the social capital of the organization, contributing to the weakening of the organization's competitiveness (Sułkowski, 2017pp. 155-171).

The large role of nepotism in recruitment processes results in less employee involvement in raising their qualifications (Ponzo and Scoppa, 2010, p. 17). However, we meet studies that show that as the importance of nepotism in the functioning of the organization increases, the willingness to invest in social capital decreases as well as the willingness to improve qualifications in educational processes decreases (Perez-Alvarez and Strulik, 2018, pp. 26-27). This negative effect is strengthened in the case of educational processes of family members of the company's owner. Research conducted on students in Turkey showed a strong correlation between being a child of a parent running their own business, and weaker results in learning, smaller willingness to graduate, and less entrepreneurship (Gevrek and Gevrek, 2008, pp. 26-29). Only in the case of free professions, a reverse tendency was observed, in which parents performing a free profession had a positive impact on their children's learning outcomes, and also transferred skills and professional competences (Aina and Nicoletti, 2014, pp. 24-25). The problem may also have a broader perspective. If nepotism becomes widespread in a given country, the described negative phenomena may affect the entire economy, which, as in the case of Russia, will result in a "brain drain" from that country (Safina, 2015, pp. 631-634). This will result in a decrease in the competitiveness of the entire economy, and thus also of enterprises operating within it.

Research Methodology

The main objective of the study was to analyse employee opinions on the phenomenon of nepotism in small and medium-sized family businesses and to compare them with the opinions of other organizations' employees. The following specific objectives have been formulated for the purposes of the study:

- to determine the understanding of the phenomenon of nepotism by owners who manage the family businesses,
- to determine the scale of the phenomenon of nepotism,
- assessment of the phenomenon of nepotism both by entrepreneurs and employees,
- assessment of the impact of nepotism (both positive and negative) on the functioning of the family businesses.

On the basis of the research objectives mentioned above, the following research hypotheses were formulated. The first two relate to the very understanding of nepotism. By definition, it takes place when there are family connections between the beneficiary of nepotism and the person applies this practice. In the absence of such links, there is a similar phenomenon called cronyism (Keles et al., 2011, pp. 9-16, Arasli, and Tumer, 2008, pp. 1237-1250, Jaskiewicz et al., 2013, pp. 121-139)). Therefore, it is important to check if the respondents notice this difference. Hence, the first two hypotheses are as follows:

H1. Nepotism is properly understood by family entrepreneurs
H2. Nepotism is properly understood by employees in family businesses

It is equally important to determine the scale of the phenomenon of nepotism. Previous studies indicate that it is a common phenomenon (Sroka and Vveinhardt 2018, pp. 31-45; Ignatowski et al., 2020, pp. 15-19; Vveinhardt and Sroka 2020, pp. 11-18). At the same time, it seems that it is more frequent in family businesses, which results directly from their specifics, hence two further research hypotheses sound as follows.

H3. Nepotism is a common phenomenon in family businesses
H4. Nepotism is a significantly more frequent phenomenon in family businesses than in others

For the analysis of the phenomenon of nepotism, its assessment by both the employed as well as the owners themselves, is important. The analysis of the literature allows us to state that the former assess it negatively, the owners of companies - positively. At the same time, the competences and skills of the employed person influence the assessment of nepotism. Based on the above knowledge, two further research hypotheses were put forward.

H5. Nepotism is positively evaluated by family entrepreneurs
H6. Nepotism is negatively assessed by employees in family businesses

In the course of literature studies, the influence of nepotism on a number of factors related to the functioning of the company was identified. The next two hypotheses aim to verify the collected information and evaluate this impact based on research carried out on the same research sample. They sound as follows:

H7. Nepotism in family businesses has a negative impact on:
- o satisfaction,
- o motivation to work,
- o involvement,
- o trust in the organization,
- o willingness to work in the organization.

H8. Nepotism in family businesses, if it is related to the relevant competences of the manager employed due to the family connections, has a positive impact on:

- reducing the scale of conflict at the owner-manager level,
- employee engagement,
- employee motivation,
- employee satisfaction.

To verify the above research hypotheses, the study included both qualitative and quantitative methods. As part of the quality method, an in-depth individual interview was used. Its main goal was to identify the manifestations and effects of nepotism in the surveyed companies. Interviews were conducted between February 2019 and September 2019 with 19 owners of small and medium family enterprises. The selection of the qualitative approach at this stage of the research made it possible to reach specific cases and gave an opportunity to understand the specifics of the surveyed enterprises (Toften and Hammervoll 2010, pp. 108-121). Individual in-depth interviews were based on a repeatable research scenario, which gave the opportunity to ask respondents additional questions, thanks to which it was possible to refine the research issues. Prior to the research, the interview scenario was consulted with external experts dealing with family enterprises. Two experts came from the academic community, and one from a non-governmental organization dealing with family entrepreneurship. Interviews were recorded, then transcribed and subjected to qualitative analysis.

The selection of respondents was purposeful. The survey was targeted to owners of small and medium-sized enterprises, who considered their company as a family business and meeting the conditions resulting from the adopted definition of a family business treated as an economic entity based on family ties and dependencies, which seeks to sustainably maintain a decisive influence on family business through participation in the future. in ownership, management and responsibility with the intention of transferring it to the next generation.

In this study, it was intended to identify the understanding of the phenomenon of nepotism by owners of small and medium-sized family enterprises, to determine the importance of nepotism and to assess the impact of nepotism on the functioning of the enterprise.

In the second stage of the study, a quantitative survey was carried out in the form of an auditory survey. The survey is aimed at verifying information received in the interviews with entrepreneurs and learning the phenomenon of nepotism from the employees' perspective. The survey involved both employees in family businesses and employees in other organizations, which made it possible to compare opinions on nepotism among employees of various organizations and the frequency of this phenomenon. Comparative analyses were conducted using standard statistical inference methods, including significance tests for mean values and structure indicators.

The survey study was conducted using a group of 510 respondents, employed by Polish firms and service companies, and at the same time enrolled in an extramural programme at a prestigious Polish university. The surveyed group are all business faculty students, familiar with the principles of nepotism occurring in the employment procedure. In the course of their studies, they participate in lectures devoted to the issues of professional ethics and problems faced by family businesses. Thus, they have a fully formed image of how family businesses function in society. Consequently, they have sufficient background needed to be able to address the survey questions competently. Let it be noted that similar studies concerning nepotism, involving groups of student participants, have already been carried out by Padgett, Padgett and Morris (Padgett *et al.*, 2014, p. 287; Padgett & Morris, 2005, p. 36). The structure of respondents is presented in the table 1:

Table 1: Respondent structure

Characteristics	Percentage of valid answers
Gender	
Female	64.3%
Male	35.7%
Age	
Below 19 y.o.	1.0%
20-29 y.o.	56.6%
30-39 y.o.	28.1%
40-49 y.o.	11.7%
Above 50 y.o.	2.6%
Labour market situation	
Working in a family business	10.1%
Running one's own business	4.2%
Working in a private enterprise	41.6%
Working in a state or local government institution	29.4%
Not working	14.7%
Net income of the household	
Below 2700 PLN	16.1%
2701-5000 PLN	36.1%
5001-9000 PLN	25.5%
9001-15 000 PLN	17.5%
More than 15 000 PLN	4.8%

Source: authors' own calculations

A questionnaire with four compound main questions basic and five metrics-type questions was used for the study. All questions, except one, were closed, complex measurement scales were used.

Results of Qualitative Research

The research confirmed that the owners of the interviewed companies were mostly reluctant to approach the issue of nepotism. This resulted from the sensitivity of the issue as well as the dual impact of family and enterprise systems, which always causes the need to reveal sensitive information related to family members. The respondents pointed out that one of the factors related to the family-owned enterprise is the retention of key information among family members involved in running a business.

The study showed that the understanding of the phenomenon of nepotism was differently understood. 14 entrepreneurs surveyed were able to determine the nature of this phenomenon. It was pointed out that it was a favour of family members in the casting of positions regardless of their competences. However, 5 subjects were unable to identify the phenomenon of nepotism that may occur in a family business. Only after explaining the essence of the phenomenon of nepotism during the interview they were able to refer them to the realities of functioning of one's own company.

In the opinion of all respondents, employing family members in an enterprise is a completely natural phenomenon and is related to the family character of the subject and cannot be described as nepotism. It was pointed out that it is an inalienable right of the owner family and that the family is the basis of the family business.

Thus understood, nepotism has a positive impact on the functioning and long-term development of a family enterprise. The construction of the family social capital allowing for the competitive advantage of the company was indicated as positive. It was emphasized that the family social capital allows for a high level of trust and standards in internal relations in the enterprise as well as external relations with the environment. The respondents also noticed a positive impact on the high level of flexibility and undertaking joint actions by family members during the period of downturn.

It was also pointed out that nepotism could have negative effects if family members would be privileged without taking into consideration their competence. Five respondents indicated that such a situation took place in their company. It was also pointed out that emotional ties with family members employed in the enterprise, in the case of conflict situations, sometimes make it difficult to make rational decisions that take care of the company's interest. This fact was indicated by 11 respondents.

Most of the respondents indicated that nepotism understood as the use of social capital in the enterprise has a positive impact on the functioning of the entity by building trust, identity, reputation and commitment. These types of activities also allow to create a succession plan. On the other hand, 7 respondents also pointed to the possibility of negative effects of nepotism, nepotistic practices in the selection and treatment of human resources in the enterprise were given as an example. Managers are aware of this issue.

As it can be seen from the study, the influence of factors resulting from the family nature of the surveyed entities causes that the approach to the issue of nepotism must take into account both positive factors and threats. The mere employment of family members cannot be treated as a manifestation of nepotism because this situation results from the very nature of the family firm. The involvement of family members in family business activities increases the company's chances for its development and business continuity.

Results of Quantitative Research

In the following report presenting the results of the quantitative survey the responses of employees in family businesses (study group) are compared with the responses of employees in other organizations (in private non-family enterprises, in a state or local government institution), treated as comparative group.

The first question used in the study examined the degree of understanding of nepotism by the respondents. It consisted of five statements, in which five situations related to nepotism in employment were described. Two of them concerned the employment of a family by ordinary managers, not family-related with the company, and three situations when the relationship is between the owner and the person employed. The results show (Table 2) that the above all respondents considered the situation in which the manager hired a relative for a managerial position as nepotism (more than 63% of the respondents both from the group of employees in family businesses and in other organizations were rather in agreement or strongly agreed with the naming this nepotism). About 50% of respondents agreed that the remaining of the listed in Table 2. situations are the forms of nepotism. Most respondents did not agree (strongly or rather disagree) that employment by the owner of a person related to him / her on a regular position should be treated as nepotism (about 56%). Although the cumulated shares of employees in family businesses who rather agree or strongly agree are bigger than these shares of employees in other organizations, significance tests for structure indicators show no statistical significance of differences between them. An important reason for this insignificance is the small sample size of study group (51 units).

Table 2: Defining nepotism by the respondents

In your opinion, is the phenomenon mentioned below nepotism?					
		Strongly disagree	**Rather disagree**	**Rather agree**	**Strongly agree**
Employment by the recruiting manager of a person related to him / her on a managerial position	A B	9.8% 14.3%	23.5% 22.7%	21.6% 29.4%	45.1% 33.6%
Employment by the recruiting manager of a person related to him / her on a regular position	A B	13.7% 16.2%	35.3% 33.9%	31.4% 35.3%	19.6% 14.5%
Help of any company employee in employment for a person related to him in this company	A B	12.0% 16.4%	34.0% 38.4%	36.0% 35.0%	18.0% 10,2%
Employment by the owner of a person related to him / her on a managerial position	A B	17,6% 20.4%	29.4% 26.6%	21.4% 30.0%	31.4% 22.9%
Employment by the owner of a person related to him / her on a regular position	A B	17,6% 24.4%	39,2% 33.7%	25.5% 28.1%	17.6% 13.8%

A – employees in family businesses (study group); B – employees in other organizations (comparative group)
Source: authors' own calculations

The purpose of the next question was to assess the occurrence of the frequency of nepotism in employment and other areas of the organization's functioning. This question consisted of eight items in which respondents assessed the frequency of occurrence of the above phenomena using the five-point scale. The first part of the question was about the phenomenon of nepotistic employment. As a reference point, one situation was also given to present cronyism (employing a friend for a managerial position). The phenomenon of nepotism is more common when employing people for ordinary positions (Table 3). At the same time, in the case of the cast of managerial positions, nepotism was more often indicated (47,1% of respondents from study group and 42,9% respondents from comparative group meet this situation often or very often) than in the case of cronyism (37,2% in study group and 38,2% in comparative group). .

Table 3: Frequency of occurring nepotism in recruitment

How often in your career do you meet the following						
		Never	Sporadically	Rarely	Often	Very often
Employment for a managerial position of a person related to the business owner or a recruiting manager	A B	9.8% 14.0%	15.7% 21.6%	27.5% 21.6%	31.4% 29.7%	15.7% 13.2%
Employment for a regular position of a person related to the business owner or a recruiting manager	A B	8.0% 6.5%	16.0% 20.8%	28.0% 22.5%	32.0% 33.4%	16,0% 16.9%
Employment for a regular position of a person related somebody in the company	A B	9.8% 12.7%	21.6% 21.2%	27.5% 29.9%	27.5% 27.4%	13.7% 8.8%
Employment for a managerial position of a friend of the business owner or a recruiting manager	A B	3.9% 12.1%	17.6% 22.6%	41.2% 27.1%	23.5% 31.4%	13.7% 6.8%

Questionnaire scale description: 1 –never; 2 – sporadically (1-2 during all professional career); 3 – rarely (a few times in a year); 4 - often (1-2 times in a month); 5 very often – common phenomenon

A – employees in family businesses (study group); B – employees in other organizations (comparative group)Source: authors' own calculations

As with the previous question, the small sample size makes it difficult to carry out significance tests for the structure indicator (all differences between structure indicators for study and comparative groups, as well as between indicators for manifestations of nepotism and cronyism seem to be statistically insignificant). In connection with this limitation a synthetic measure of the frequency of nepotism in recruitment was calculated based on average scale values. The synthetic measure takes values from 1 to 5 (according to the scale adopted in the survey questionnaire), where 1 means that the respondent has never met any of these 4 situations and 5 means that every situation encountered very often. In the studied group the average value was equal to 3.23 (for 50 units) while in the comparative group 3.09 (for 350 units). Significance test for means indicates that the difference between average values of frequency of nepotism in recruitment is insignificant. This does not allow a positive verification of the hypothesis that nepotism in recruitment is a significantly more frequent phenomenon in family businesses than in others.

In the second part of the question assessing the frequency of nepotism, the respondents were asked about other nepotistic situations that may occur in the organization (Table 4). In this case, the most common form of nepotism was a better treatment of a related person and its milder assessment. 52.9% and 62,7% of respondents from study group indicated it as a frequent and very frequent phenomenon respectively (47.1% and 46.3% of respondents from comparative group). Promoting relatives and paying them a higher salary was much less common, although it was still a frequent phenomenon.. The percentages of respondents from the study group who often or very often met all nepotistic situations listed in Table 4 were higher than in the comparative group. Despite this, all differences between the structure indicators are statistically insignificant. As in the case of frequency of occurring nepotism in recruitment analysis, a synthetic measure of the frequency of the situations listed in Table 4 was calculated. Unfortunately, as before, the difference between the average values of these measures in the study group (3.19) and comparative group (3.01) turned out to be statistically insignificant.

Table 4: Frequency of occurrence of nepotism in other selected areas of the organization's functioning

How often do you meet with the following phenomena in your professional career?						
		Never	Sporadically	Rarely	Often	Very often
Promoting a person related to the business owner or that person's (direct or indirect) supervisor	A B	19.6% 14.3%	13.7% 21.6%	21.6% 28.0%	33.3% 25.8%	11.8% 10.4%
Paying higher salary to a person related to the business owner or that person's (direct or indirect) supervisor	A B	21.5% 23.0%	17.6% 20.8%	19.6% 27.2%	25.5% 22.2%	13.7% 6.7%
Better treatment of a person related to the business owner or that person's (direct or indirect) supervisor	A B	9.8% 10.9%	13.7% 17.4%	23.5% 24.6%	35.3% 33.9%	17.6% 13.2%
Milder assessment of a person related to the business owner or that person's (direct or indirect) supervisor	A B	13.7% 10.1%	9.8% 18.5%	13.7%% 25.2%	43.1% 35.9%	19.6% 10.4%

A – employees in family businesses (study group); B – employees in other organizations (comparative group)
Source: authors' own calculations

The results of significance tests both for structure indicators and average values of synthetic measures of the frequency of nepotistic situations do not allow a positive verification of the hypothesis that nepotism a significantly more frequent phenomenon in family businesses than in others.

In the next question, the authors examined the evaluation of nepotistic phenomena among respondents. There is a noticeable difference in the perception of these situations depending on the type of organization (Table 5). In the case of employees in family businesses, i.e. those who are most affected by nepotism, the employment by the recruiting manager of a person related to him on a managerial position was rated negatively (as unacceptable or improper) by 84.3% of respondents (study group), whereas only 69,6% of respondents from comparative group rated it negatively (the difference between these structure indicators is statistically significant, p-value=0.015). Other manifestations of nepotism were negatively assessed by higher percentage of respondents from study group but those differences between structure indicators were statistically insignificant. Employment by the owner of a person related to him on a regular position got the mildest assessment in both groups of respondents, more than 3/2 considered such a situation as neutral, appropriate or desired.

Table 5: Assessment of situations related to nepotistic employment in companies

How do you assess the following situations in the company?						
		Unacceptable	Improper	Neutral	Appropriate	Desired
Employment by the recruiting manager of a person related to him on a managerial position	A B	25.5% 20.3%	58.8% 49.3%	9.8% 24.8%	3.9% 5.1%	2.0% 0.6%
Employment by the recruiting manager of a person related to him on a regular position	A B	7.8% 8.4%	35.3% 28.7%	41.2% 47.5%	15.7% 14.6%	0.0% 0.8%
Employment by the recruiting manager of his friend on a managerial position	A B	25.5% 17.7%	45.1% 43.8%	21.6% 31.5%	5.9% 5.6%	2.0% 1.4%
Employment by the owner of a person related to him on a managerial position	A B	12.0% 14.1%	44.0% 33.2%	22.0% 33.2%	18.0% 15.5%	4.0% 3.9%
Employment by the owner of a person related to him on a regular position	A B	2.0% 7.9%	31.4% 23.1%	35,3% 42.5%	29.4% 22.8%	2,0% 3.7%
Employment by the owner of his friend on a managerial position	A B	10.0% 12.7%	46.0% 34.6%	28.0% 36.1%	14.0% 13.5%	2.0% 3.1%

A – employees in family businesses (study group); B – employees in other organizations (comparative group)

Source: authors' own calculations

In addition to employment, respondents also assessed other nepotistic situations in the organization (promotion, higher salary, better treatment and a milder assessment). Each of these situations was negatively rated by 74-84% of respondents (Table 6). There are very small differences between the evaluations of employees in family businesses and in other organizations. In the case of paying the better salary there was no significant difference between a friend and a relative noticed.

Table 6: Assessment of selected situations related to nepotistic activities

How do you asses the following situations?						
		Unacceptable	Improper	Neutral	Appropriate	Desired
Promoting a person related to the owner of the business	A B	28.0% 29.3%	50.0% 49.3%	12.0% 12.7%	4.0% 7.6%	6.0% 1.1%
Paying higher salary to a person related to the owner of the business	A B	49.0% 45.6%	33,3% 33.0%	7.8%% 15.5%	3.9% 4.5%	5.9% 1.4%
Paying higher salary to a manager's friend (direct or indirect)	A B	52.9% 42.4%	21.6% 37.6%	15.7% 13.3%	5.9% 5.4%	3,9% 1.4%
Better treatment of a person related to the owner of the business	A B	42.0% 33.8%	42.0% 44.2%	14.0% 15.2%	0.0% 4.2%	2.0% 2.5%
Milder assessment of a person related to the owner of the business	A B	36.0% 30.4%	42.0% 47.6%	18.0% 15.8%	4.0% 5.1%	0.0% 1.1%

A – employees in family businesses (study group); B – employees in other organizations (comparative group)
Source: authors' own calculations

In the last question, the authors asked the respondents about the influence of nepotistic phenomena on the functioning of the organization. The first part of the question referred to phenomena that have a negative impact. On the basis of literature analysis, the areas influenced by nepotism were identified. These are: motivation, job satisfaction, commitment to work, trust in it and willingness to be employed there. The highest percent of respondents who indicated negative impact on the discussed phenomena was recorded for motivation to work in the family business – 74,5% of respondents in study group (Table 7). More than half of respondents agreed with the statement that motivation to work, job satisfaction, commitment to work and trust are reduced when direct manager is employed due to family relation with the owners of the company. Similarly, more than half of respondents would not start working in the company in which it is preferable to employ family members in managerial positions. Only in the case of reduced motivation to work the percentage of employees in family businesses who agree with the statement was significantly higher than the percentage of employees in other organizations (p-value=0.021 in the significance test for structure indicators).

Table 7: Negative impact of nepotism on the functioning of a family business

Do you agree with the following statements?					
		Strongly disagree	Rather disagree	Rather agree	Strongly agree
Direct supervisor employed due to family relation with the owners of the company reduces motivation to work in the family business	A B	3.9% 10.1%	21.6% 30.1%	54.9% 39.6%	19,6% 20.2%
Direct supervisor employed due to family relation with the owners of the company reduces job satisfaction in the family business	A B	9.8% 7.9%	29.4% 37.6%	45.1%% 42.1%	15.7% 12.4%
Direct supervisor employed due to family relation with the owners of the company reduces the commitment to work in the family business	A B	9,8% 10.4%	27.5% 36.5%	43.1% 40.2%	19.6% 12.9%

Direct supervisor employed due to family relation reduces the trust in the family business	A B	11,8% 10.7%	37,3% 38.0%	37,3% 36.9%	13,7% 14.4%
If I knew that in a given family company it is preferable to employ family members in managerial positions, I would not start working in this company	A B	7.8% 10,5%	35.3% 30.7	33.3% 33.8%	23.5% 25.0%

A – employees in family businesses (study group); B – employees in other organizations (comparative group)
Source: authors' own calculations

As it was pointed out in the literature that if a candidate in the family has appropriate competences, nepotism can have a positive impact on the organization, in the second part of the fourth question respondents were asked about the benefits that may arise in the case of positive nepotism. Based on the analysis of the literature, the following phenomena have been selected which may result from it: increased employee engagement, increased satisfaction and motivation, and reduced risk of conflict with owners. In the case of each of these factors, the majority of respondents (51-61%) agreed that the above-mentioned positive phenomena occur (Table 8). Moreover, in every cases the percentage of respondents from study group who do not agree with the statements was higher than in comparative group. This outcome could suggests that positive assessment of nepotistic phenomena depends on the respondent's workplace, since the employees of family businesses in the sample were the least likely to point to such phenomena as positive. Unfortunately, the differences between structure indicators were not statistically significant..

Table 8: Positive influence of nepotism on the functioning of a family business

Do you agree with the following statements?					
		Strongly disagree	Rather disagree	Rather agree	Strongly agree
Direct supervisor, being a member of the owner's family, possessing the required competences to work in his position, increases the commitment of other employees	A B	7,8% 7.0%	39.2% 33.5%	31.4% 42.3%	19.6% 17.2%
Direct supervisor, being a member of the owner's family, possessing the required competences to work in his position, increases the satisfaction of the work of other employees	A B	7,8% 6.8%	41.2% 36.1%	35.3% 42.8%	15.7% 14.4%
Direct supervisor, being a member of the owner's family, possessing the required competences to work in his position, increases motivation for the work of other employees	A B	13.7% 6.5%	33.3% 31.8%	37.3% 45.9%	15.7% 15.8%
Direct supervisor, being a member of the owner's family, possessing the required competences to work in his position, reduces the risk of conflicts with the owners of the company	A B	17.6% 11.0%	31.4% 29.6%	31.4% 42.0%	19.6% 17.5%

Discussion

After the research, both qualitative and quantitative, the authors come to the following conclusions. The first two hypotheses (H1 and H2) related to the definition of nepotism have been partially confirmed. In qualitative research, most respondents were able to accurately define what nepotism is. However, five entrepreneurs had a problem with it. At the same time, it was noticed that proper

definition of nepotism depends on the type of enterprise and the place of its occurrence in the company's organizational structure. The lower the person responsible for nepotism is in the organizational structure of the company, regardless of whether he was the employer or the employed, the more rarely nepotistic phenomena were considered as such. At the same time, nepotistic situations related to employment in family businesses are less often called nepotism than in ordinary enterprises. This suggests that some respondents, due to being the owner of the company, give permission to do so. Quantitative research shows that the vast majority of respondents (including employees of family businesses and running their own business) correctly understand the concept of nepotism.

The third hypothesis (H3) was also confirmed. Nepotism is a common phenomenon in family businesses. The vast majority of respondents employed in family businesses encountered this phenomenon often and very often. The results of comparison of responses of employees in family businesses and in other organizations do not allow to confirm the second hypothesis that the nepotism is more frequent in family businesses than the others was not confirmed. Quantitative research has shown a slight, more frequent occurrence of nepotism in family businesses, compared to non-family companies. At the same time, the level of nepotism in the public sector was similar to that of family businesses.

The hypothesis about a positive assessment of nepotism by family entrepreneurs (H5) has not been confirmed. Although, the results of qualitative research suggested that the employment of family members in the enterprise is a completely natural phenomenon and has a positive impact on the functioning and long-term development of the family enterprise and the construction of family social capital, and allows to obtain a high level of trust and standards in internal and external relations, still such situations have been assessed negatively three times more often. So despite the fact that the evaluation of nepotistic phenomena in employment issued by entrepreneurs running their own business was milder in comparison with employees of family and non-family enterprises, negative evaluations of this form of recruitment were still predominant. In the case of other nepotistic situations, most entrepreneurs rated them negatively, and the differences in assessments with other groups were small.

The sixth hypothesis (H6) indicating a negative assessment of the indicated nepotistic phenomena by the employees has been fully confirmed. The vast majority of respondents assessed all cases of nepotism as inappropriate or unacceptable in the organization. In the case of employment of relatives in a family, there is a clear difference in assessments between those working in family businesses and entrepreneurs running their own business. But even they assessed these phenomena negatively more often.

The seventh hypothesis (H7) indicating the negative impact of nepotism on: satisfaction, motivation and commitment of employees, as well as trust in the organization and willingness to work there was also confirmed. Over half of the respondents indicated that nepotism has a negative impact on the above-mentioned factors. Also in a qualitative study in interviews, entrepreneurs indicated that if family members would be privileged without taking into consideration their competences, their impact on the functioning of the organization is negative. Thus, research results obtained were similar to those of other researchers (Padgett and Morris, 2005, pp. 39-42, Padgett et al., 2014, p. 283, Abdalla et al., 1998, p. 569, Keles et al. 2011, p. 13, Ewing, 1965, p. 37).

At the same time, the eighth hypothesis (H8), which says of the positive influence of nepotism on subordinates, has not been fully confirmed. On the one hand, employees in family businesses were divided in these assessments in half, which means an ambiguous assessment of this situation. On the other hand, two-thirds of the surveyed entrepreneurs conducting their own business agreed with the above statements. At the same time, in qualitative research, nepotism was indicated as a natural tool used to effectively manage family businesses. Perhaps a large discrepancy in the assessment of the impact of nepotism results from the phenomena of stigmatization of nepotism described by Padgett

and Morris (Padgett et al., 2014, pp. 285-287). Therefore, a study dedicated to this problem would be needed to get a clear assessment of this hypothesis.

Conclusions

Nepotism means favouritism of family members in their employment, promotion and remuneration at the workplace. Research on nepotism began only in the mid-1960s (Ewing, 1965, pp. 22-160). It does not change the fact that it was always practiced, as long as the business and service activities are carried out by people. Its occurrence, not only in family businesses, is confirmed by research carried out in this study. Low job satisfaction, reduced level of trust, commitment and motivation to work are mentioned among the negative effects of nepotism. This is clearly reflected in this research. In order to better understand the phenomenon of nepotism, further research should take into account the cultural context and the customs prevailing in the society in which the company exists and wants to develop. One cannot overlook such conditions as the economic situation and standards existing in organizations, also state legislation. Therefore, the phenomenon of nepotism will never be homogeneous and depends on the context of its occurrence. In addition, despite the negative effects that adversely affect the development of any organization, nepotism is widely practiced in family businesses, which is reflected in the conducted research. In this context, attention should be paid to two things. First of all, there is still a lack of satisfactory research on the values of nepotism. It is also not possible to say in advance that they have incomparably less importance compared to negative impacts. Let us remind that enterprises managed by the family are a widespread form of running a business and have a positive impact on the stable development of the economy. It should therefore be postulated to pay more attention to research on the phenomenon of nepotism in these companies. The conclusions can be used not only for the functioning of family businesses, but also for all sectors of the economy.

Ratna DJUWITA
Faculty of Psychology, Universitas Indonesia, Depok, Indonesia, christinarahayu.w@gmail.com

Abstract

Waste sorting behavior among "XYZ" University's students has the urgency to be intervened. Results of the baseline study showed that students were not sorting waste properly. It caused the waste management to be ineffective. Using the theory of planned behavior as the theoretical framework, the author found that perceived behavioral control (PBC) was the significant predictor of waste sorting behavior. The author designed an intervention using a video, containing information (knowledge) about waste sorting, which was expected to increase student PBCs and encourage them to perform waste sorting behavior. It was contructed based on social influence theory and social modelling. The hypothesis was waste sorting literacy through video can improve waste sorting behavior of the student. The author used an experimental (between-subject) design and divided the participants into two groups (waste sorting literacy vs. control group) using randomization. Participants were undergraduate students from various faculties which recruited by spreading posters and prospective participants registered through an online application. Waste sorting behavior was measured by observing whether participants sorted or not sorted their waste during the intervention. The results showed that video-based waste sorting's literacy significantly increased the accuracy of the waste sorting behavior of organic waste, but not with inorganic waste. Based on this finding, video-based waste sorting interventions can be adapted to increase waste sorting behavior in university context.

Keywords: behavior, intervention, students, waste-sorting

Introduction

"XYZ" University is a state university in Indonesia which has been implementing waste sorting program. In contrast, the survey result showed that their students, as the biggest population in campus, still sorted waste incorrectly. This matter would influence Green Matrix index of "XYZ" University and also caused waste management program in "XYZ" University became ineffective. It was because the cleaning service staff should sort out the waste which mixed from the trash bin. It would add work load for the them even though it was not necessary as if civitas academia would have sorted their waste correctly. It is clear that waste sorting behavior among students at "XYZ" University has the urgency to be intervened. This research is an intervention research developed based on the results of a baseline study. The aim of the intervention is to demonstrate that video-based literacy program can increase waste sorting behavior of "XYZ" University's students.

The baseline study consists of qualitative and quantitative method (Cresswell, 2009). Its purpose was to explore issues about waste sorting which are relevant for "XYZ" students. The qualitative method was conducted through interview toward students, cleaning service staffs and others staffs related waste management in "XYZ" University. The data was coded into categories related factor influencing waste sorting behavior among students. The quantitative method was conducted by surveys using questionaires relating waste sorting behavior of students and their knowledge about waste management at "XYZ" University.

Results of the baseline study showed that "XYZ" University students were not sorting waste properly. The qualitative study also found that factor influencing student to sort their waste were varies, such as knowledge about benefit and availability waste sorting program, knowledge about how to separate waste correctly, availability of time and opportunity to sorting waste, and also availability of waste sorting facilities. Support this finding, the quantitative study showed that most of participants did not know about waste sorting program. Furthermore, using the theory of planned behavior as the theoretical framework (Gadiraju, 2016; Stoeva & Alriksson, 2017; Zhang, Zhang, Yu, & Ren, 2016), the author found that perceived behavioral control (PBC) was the significant predictor of waste sorting behavior. PBC itself was individuals' perceived ability to perform such of a behavior (Ajzen, 2014). The higher individual's PBC to perform waste sorting behavior, the higher individual's intention to do waste sorting framework (Gadiraju, 2016; Stoeva & Alriksson, 2017; Zhang et al., 2016). When individual's intention to perform a behavior increase, the probability of the behavior to be performed would be increase as well (Ajzen, 2014). Besides, PBC to do waste sorting, also correlated with knowledge how to sort waste, benefit of behavior[2] and knowledge of availability waste management program (Kirakozian, 2015).

Based on those findings from the qualitative and quantitative study, the author designed an intervention to increase knowledge that "XYZ" University had waste sorting program, its benefit and also knowledge how to sort the waste. Video was chosen as media intervention in this study. It was seen as cheap, effective as media champaign, and easy to Access (Chung, 2015). It was also found to be effective increasing knowledge about environmental issues (Lalmuanpuii, Zagade, Mohite & Shinde, 2015; Pearson, Dorrian, & Litch, 2011). Furthermore, when people know what to do to reduce enviromental risk, it could increase their PBC to perform it. Beside PBC, video was found effective to increase people's intention to do something reducing environmental threat such as global warming (Kurisu, Kimura & Hanaki, 2019). Those finding gave consideration to the author to use video as intervention tool to increase knowlege about the benefit and how to sort waste, also knowlege of availability of the waste sorting program in "XYZ" University. It was expected that by increasing student's knowledge, it would increase their PBC's to sort the waste and encourage them to perform waste sorting behavior. The video was constructed based on social influence theory (Baumeister & Finkel, 2011) and social modeling (Bandura, 1977), which was found as effective technique to promote pro-environmental behavior (Varotto & Spagnolli, 2017). The hypothesis of this intervention study were:

H1: the organic sorting behavior of the intervention group (with video literacy) will significantly higher than the control group.

H2: the inorganic sorting behavior of the intervention group (with video literacy) will significantly higher than the control group.

H3: the waste sorting behavior of the intervention group (with video literacy) will significantly higher than the control group.

Method

For the intervention study, the author used an experimental (between-subject) design. Participants were divided into two groups (waste sorting literacy vs. control group) using randomization (Field, 2009). Participants were undergraduate students from various faculties. Participant's recruitment was done by spreading posters a week prior the intervention study and prospective participants registered through an online application.

A total of 51 participant became participant of this study, but only 29 participant (14 students in intervention group and 15 students in control group) were valid to be analyzed due to measurement's criteria.

Materials

There were two videos used in the experimental study. The first video was waste sorting literacy which gave information related waste sorting program in "XYZ" University, its benefits, and how to sort waste correctly. The content was given by students and social models who was responsible for the waste management in "XYZ" University and also by models who has authority in "XYZ" University.

The second video did not related to waste sorting behavior and was given to the control group. The video was washing hand literacy at "XYZ" University.

Procedures

There was deception in this intervention study. At the online registration form, the author told that this study was about pro-environmental behavior and they were expected to give review about the video they were going to watch. There was no information explaining that the study was intent to measure their waste sorting behavior. Its purpose was to let the participant showed their waste sorting behavior as natural as posible.

The intervention study conducted on April 13, 2019 at "XYZ" University, from 9.30 am until 11.30 am. All participants, which registered and confirmed that they were willing to be participant of this intervention study, were divided into two groups (waste sorting literacy vs. control group) using randomization. Each group was in different room with similar condition and was given the same procedures. They were accompany by three facilitators who helped the author conducted the study. Before entering the room, all participants were given snack.

After the participants came in the room, the facilitator gave introduction and gave deception of the study. All participants were given informed consent form and approval sheet for being participant. After it was filled and signed, they were asked to watch the video. Each of participants was asked to answer several question about the video. It was used to be a manipulation check for the author to know whether participant watch the video or not. Then the participants were asked to gather in short discussion and were given permission to eat their snack. The discussion was held for half an hour and asked the participants what they thought about the video as feedback, aligning with the deception of this study, which told the participant that their feedback about the video was useful for the author. After discussion, one of the facilitator closed the study, while the others observed their waste behavior. The authors also provide several bins with categories label on each bins (figure 1) so the waste behavior could be measured. The participant then could leave the room. All participants were given transport fee for came and being participant of this study. Debriefing was given 3 weeks after the intervention study by email to each participants. All participants were given information about the aims of the study that this study was not to get their feedback about the video, but to see whether waste sorting video's effect to their waste sorting behavior.

Fig. 1: Trash Bin with Different Waste Categories (inorganic and organic waste)

Fig. 2: Organic Waste (banana leaves)

Fig. 3: Inorganic waste (Plastic wrapping)

Measurement

Waste sorting behavior was measured by observing whether participants sorted or not sorted their waste based on its categories after they watched the video. The waste sorting behavior is classified by counting the waste of the snack given in the study by its categories: organic/banana leaves of a snack (figure 2) and inorganic waste/plastic wrapping (figure 3). Each snack item was given a code or mark for each participant, so it could be easily categorized whether each participant put their waste in the right bin. If a participant correctly sorted his/her waste in to the right bin, his/her behavior will be coded as 1, or 0 if the participant put it incorrectly. If the waste sorting behavior of the participants could not be observed during the intervention study, the data would be coded as missing data.

Data Analysis

A total of 29 participant were observed for their waste sorting behavior and were analyzed using non-parametric test, Fisher's Exact test (Field, 2009; Kim, 2017; Tomczak & Tomczak, 2014).

Result

A total of 29 participants were being analyzed for their waste sorting behavior. The author only counted the snack's waste whose mark could be detected come from different participant. Manipulation check also showed that all participant in each group watched the video.

The statistic descriptive of waste sorting behavior is showed by table 1. The data was tested using Fisher's exact statistical test (for categorical data).

Table 1: Waste Sorting Behavior's Statistic Decriptive of Participant

No	Waste	Intervention Group		Waste's Observed Amount	Control Group		Waste's Observed Amount
		Correct	Incorrect		Correct	Incorrect	
1	Organic waste (banana leaves)	93%	7%	14	45%	55%	11
2	Inorganic waste (Plastic wrapping)	100%	0%	14	92%	8%	13

H1: the organic waste sorting behavior of the intervention group (with video literacy) will significantly higher than the control group.

The Fisher's exact statistical test shows that H1 was supported by the data. It means the participants which were given waste sorting literacy more likely to sort their organic waste correctly than participants in the control group (df = 1, n = 25), $p < 0.05$, $V = 0.52$.

Effect size for Fisher's exact analysis method (2x2 table) can be seen from *phi* value or odds ratio (Kim, 2017; Tomczak & Tomczak, 2014). The Fisher's exact test for H1 showed the value of phi, $\Phi = 0.52$ and the odds ratio = 15.6. For the degree of freedom (df = 1), the value of $\Phi = 0.52$ is categorized as large effect (Kim, 2017). In addition, the odds ratio also shows that the possibility of participants sorting organic waste compared to not sorting out is 15.6 times higher if they are given a waste sorting literacy intervention compared to the control group.

H2: the inorganic sorting behavior of the intervention group (with video literacy) will significantly higher than the control group.

Hypothesis test results for inorganic waste showed that the hypothesis (H2) was not supported by data (df=1, n =27), p>0 .05, V=0.20. By this finding, the author answered that the sorting behavior of the intervention group (with video literacy) will significantly higher than the control group (H3) was partially supported by the data. It means video-based waste sorting's literacy significantly increased organic waste sorting behavior, but not with inorganic waste.

Discussion

The results of the intervention showed that video-based waste sorting's literacy significantly increased organic waste sorting ratio accuracy, but not with inorganic waste. It could be explained by several reasons. First, the information about the waste sorting program at the University of "XYZ" and the importance of separating organic waste from inorganic waste were only given to those who watched waste sorting literacy's video (intervention group). There was also information about the journey of the waste in "XYZ" University from the trash bin until it was recycled or became compost (for organic waste). It might give vicarious experience to the participant to know the real benefit of waste sorting, that their action to separate their waste would not be useless. The video also gave information how to sort their waste based on its categories. Those reasons might made video literacy significantly increase organic waste sorting behavior in the intervention group compared to the control group.

The author also conducted interview to several participant in the intervention group. They stated that kind of information change their attitude toward waste sorting behavior to be more positive. It

supported social learning theory (Bandura, 1977) which stated that when the observer could feel the outcome of the observed behavior, the observer could perceive themselves could perform such a behavior to get similar outcome. This study gave new finding to the literature that video not only could increase individual's PBC and intention to performed waste sorting behavior, but also increase the probability of the behavior to be performed. Besides, the organic waste used in this intervention was banana leaves, which might easily distinguished and categorized as organic waste by the participants.

However, the video literacy did not significantly increase inorganic waste sorting behavior, and this might caused by several factors. First, there is the possibility that participants already recognize and know to sort inorganic waste (plastic wrapping). It might also show the possibility that knowledge and PBC scores are already high, although the author could not provide data to support this statement. When knowledge related to inorganic waste is high, literacy is no longer able to increase their PBC, so it does not significantly increase inorganic waste sorting behavior of the participant (ceiling effect). But, because of the absence of pre-post tests related to knowledge in participants, the authors were unable to ascertain whether there was a ceiling effect in this intervention study or not. This can be suggestion for future research to conduct pre-posttest without give hint to the participant about the aims of the study (e.g. used filler question).

Furthermore, there were another finding from the interview conducted two weeks after the intervention study. While their attitudes were change positively toward waste sorting and they have higher intention to separate their waste, but if the facilities were not available, the behavior would not be performed. For examples, two of the students in the intervention group stated that they usually want to sort their waste. But they tend to not perform sorting waste behavior, simply because they found it was hard to find trash bin with several categories. This supported previous research which stated that availability of the facilities might became a gap that inhibit the intention to manifest into real behavior (Zhang et al., 2016). It also happened when they have no time to sorting the waste. Inconvenience factor, such as availability of time and chance, could influence someone whether they would sort their waste or not (Gadiraju, 2016). Personal values, such as individual's habit relating waste sorting, could become another factor which could encourage or inhibit the intention became a behavior. Unfortunately, those factors (inconvenience factor and personal values) were not variable of the study. Also, the interview was not part of this study and was only done by the author to help explaining the result of the study. Nevertheless, future research can add such of variables (inconvenience factor and personal values) to be investigated its correlation with waste sorting behavior.

This intervention study also had limitations. First, the sample size was small (less than 30 participants). Second, the author did not conduct pre-posttest related knowledge and waste sorting behavior of the participants during the study. For future research, the researcher could use filler questions to avoid participant knowing the aim of the study and then collect the pre-posttest data. Another limitation was all participant were undergraduate student in "XYZ" University. The result cannot easily be generalized into another population which have different criteria. But, in the "XYZ" University context, this study still valid because undergraduate student was the biggest population in the campus. This video can be environmental campaign to encourage waste sorting behavior for their students.

The author also realized that behaviour change could not be happened instantly by one-time intervention. There should be integrated system from many factors to make a behaviour sustain, from the availability of the facilities, good waste management system and clear regulation, socialization of the waste sorting program and education to all civitas academia in the campus. However, video-based waste sorting literacy has been shown to partially improve the waste sorting behavior of University "XYZ" students. Hence, this intervention can be adapted to increase waste sorting behaviour in university context, especially in Indonesia.

Acknowledgments

This research was supported by a grant from Universitas Indonesia (Hibah PITMA-B UI 2019).

Abstract

The article discusses the implementation of digital technologies in the forestry sector of Russia. The results of a study of the state forest management system at the level of Russian regions for the application of digital technologies are presented. It has been established that the digitalization and implementation of ICTin forestry is hampered by the lack of national information systems and digital platforms and a unified approach to standardization of processes, forms of collection, storage and transmission of complete and relevant information on forest resources and forest areas. The need for digital technologies in the forestry business is growing, and the most demanded are mobile applications, online services, cloud services and distance learning technologies. To support forestry entrepreneurship, it is necessary to create a mobile application «Personal account of the tenant» with the characteristics of the leased forest plot, forest resource (timber stock, species composition, productivity, etc.) and economic characteristics (rental payments, expected income, rental period). Digitalization of the Russian forest complex should be carried out on the basis of standardization; reliability; unification; distribution of information; openness; information security.

Keywords: Management, Digital Technology, Forestry

Introduction

Digital technology is a set of methods and tools used to collect, store, process and disseminate information. Modern digital technologies today determine the level of technological development of industries and industries, regions and countries. Accelerated implementation of digital technologies in the economy and social sphere is an important goal that is being successfully implemented only in very few countries. The development of the digital economy is one of the priority areas for countries that are economic leaders, including the USA, Great Britain, Germany, Japan, etc. While in the developed countries the main goal of introducing digital technologies is to improve the quality of information, digitalization is oriented in developing regions with economies in transition on economic development and stabilization of individual business processes (Limani Y. et al., 2018).

Despite the existing cross-country differences, the need for the use of information and communication technologies both at the level of government and in business management is beyond doubt.

A huge number of enterprises use digital tachology, such as electronic data exchange, blockchain and big data to increase productivity, process efficiency, increase the amount of information. The technology of «digital doubles », combining the industrial Internet of things and digital modeling, is actively implemented in developed countries at all stages of the product life cycle - from development to operation (Huang S. et al., 2020; Kitain L. 2018).

Digital technologies increase the speed of information exchange, increase the flexibility of business processes and increase the efficiency and reliability of business networks.

The importance of the transition to digital technologies, designated as «Industry 4.0» in developed countries, is emphasized in the writings of researchers who consider various models of digital transformation of business processes, factors that determine the success of their application and problems (Laudante E. 2017; Schröder C. 2016).

Среди них готовность бизнеса и общества к цифровой трансформации, наличие развитых информационных технологий и спрос на них со стороны стейкхолдеров (Arvidsson, V. et al., 2018; Elia G. et al., 2020).

Russia is actively introducing digital technologies in industries and sectors of the economy. Managers of Russian enterprises have mastered basic digital technologies, in some cases they have automated and restructured business processes to advanced digital technologies.

Today, 83% of Russian organizations already use broadband Internet, 63% - have mastered the technology of electronic data exchange (Polyanin A. et al., 2019).

To assess the development of digitalization at the country level, the ICT Development Index is used, which is a combined indicator characterizing achievements in terms of the development of information and communication technologies. According to the index of the development of information and communication technologies, in 2017 Russia ranked 45th in the world.

At the same time, the demand for digital technologies in Russia from the side of state management and entrepreneurship is characterized by positive dynamics. Progress in the field of big data analysis, cloud computing has created a demand for innovation, both in management and in business. Today, 83% of Russian organizations already use broadband Internet, 63% - have mastered the technology of electronic data exchange (Morkovina S.S. et al., 2019).

However, the digitalization of sectors of the Russian economy is uneven. In some industries (mechanical engineering, chemical industry), the cost intensity of digitalization is similar to that in the United States. However, in such large sectors of the Russian GDP as trade and the forest sector, significantly lower digitalization costs are observed (Abdrakhmanova G.I. et al., 2019). Despite the uneven distribution of digital technologies in industries and complexes, the Russian forest complex, like no other, now feels the need for digitalization (Morkovina S.S. et al., 2016). In recent years, the interests of the Russian forest sector are related to the intensification of forestry, which is impossible without reliance on new information technologies (Nordberg M. et al., 2013; Petrov A.P. et al., 2019).

Methods

In the course of the study, an integrated approach to the study of the use of ICT in the Russian forest complex was implemented. As scientific methods, methods of content analysis, detailing, and a comparative approach were used. Sources of information were: federal and regional information resources, monitoring data from print and electronic business and specialized publications, analytical reviews. The application of analytical, logical research methods has made it possible to develop recommendations aimed at creating a unified digital platform to provide state power with information in forest management.

Results and Discussion

The forestry sector of the Russian Federation is significantly inferior to the world forest powers in digitalizing forest management processes, the reason for this is the lack of strategic documents and digital transformation programs. In the countries of Europe and America (USA, Canada, Great Britain, Serbia, Finland, Belarus) there is a stable legislation and there are a large number of developments related to the implementation of ICT, in particular, there are strategies for informatization of the forest industry.

Most countries use ICTs for forest inventory, monitoring and mapping of forest lands, and accounting and tracking of wood. Sustainable Internet in European countries and developed technical means have provided a breakthrough in the field of digitalization of forestry. In this case, the most popular ICTs are in forest inventory processes, which use modern GIS and RSE technologies, as well as various applications for automating the processes of mapping and maintaining forest resource databases.

At the same time, ICT in forestry can solve a significant number of problems and ensure a qualitative improvement in a number of processes (Figure 1).

Fig .1: ICT Opportunities in Forestry

In all countries, at the level of departments (departments and services) of forest management, structural units have been formed responsible for the implementation of ICT. By analogy with European countries, a state policy in the field of forestry informatization should be developed in the Russian Federation.

According to the results of a study of the sites of state forest management at the level of Russian regions, it was determined that ICT implementation processes are haphazard, and informatization as a whole is fragmented, with one third of all state forest management bodies of the regions having dedicated websites (Figure 2).

Fig. 2: Capabilities of existing websites of state forest administration authorities of the regions of the Russian Federation

The largest amount of information presented on the websites of state forest management bodies of the regions of the Russian Federation relates to the organization of activities.

There is little information for individuals and public organizations, and feedback is not effectively organized.

The following factors impede the digitalization and implementation of ICT in forestry, as well as the digitalization of state forest management processes:

– lack of a unified approach to standardization of processes, forms and formats for collecting, storing and transmitting complete and relevant information on forest resources and forest plots;

– a high level of deficit in the industry labor market for specialists who are able to work effectively with innovative digital technologies;

– lack of a regulatory framework and practice of interagency cooperation at the regional level;

– incomplete data on cadastral registration of all forest plots;

– lack of national information systems and digital platforms that provide forest users and regional bodies of state forest management with a set of spatial data and cartographic materials containing up-to-date information on the state of use of Russian forests.

The main use of forests in Russia is lease under the terms of the contract and as a result of the auction. At the same time, the most profitable type of forest use is logging (Table 1).

The use of ICT in entrepreneurial activity is increasing, and studies have shown that the most popular are digital solutions for forest users - the Internet, mobile applications, online services, cloud services and distance learning technologies. We performed an analysis of the demand for ICT among entrepreneurs operating in the forestry sector (Morkovina S.S. et al., 2019).

The channel for transmitting and storing information with the maximum coverage of entrepreneurs is corporate mail: more than 50% of entrepreneurs use it. Also, systems for automating the operation of the enterprise are quite in demand.

Table 1: Dynamics of forest use (forest use) in the Russian Federation

Indicators	Year end value							
	2010	**2011**	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**
Number of lease agreements for timber harvesting (pcs.)	10217	10481	11811	13735	15098	15112	11965	13379
Forest area for timber harvesting (thousand ha)	155680	166983	177377	175798	173896	167448	166557	166986
The number of lease agreements for hunting (thousand ha)	888	939	1022	1132	1347	1492	1553	1595
The area of forest land for hunting (thousand ha)	33725	33506	37086	54248	44182	49876	55357	53883
Number of lease agreements for recreational activities (pcs.)	9834	12028	13237	13359	13804	14 295	14753	15050
Forest area for recreational activities (thousand ha)	83	49	37	36	35	33	76	34,1

The use of communication channels to receive forms and provide completed forms is the least developed ICT. The number of entrepreneurs using cloud services as a means of storing and transmitting information has grown significantly (Figure 3).

Fig. 3: Уровень востребованности ИКТ технологий у бизнеса, %

The vast majority of entrepreneurs (98%) use the Internet to conduct business. At the same time, entrepreneurs noted the need to create specialized mobile applications for the forest business. Training employees to use digital technology, according to entrepreneurs, is necessary.

As a conclusion, we note that forestry needs the creation and implementation at all levels from forestries to the federal level of a single industry digital platform in which all data on forestry will be accumulated and systematized.

In this digital platform, it is advisable to create a service « Personal account of the tenant», which will reflect the full information:

– characteristics of the leased forest plot and its location on the map;

– characteristic of the forest resource (timber stock, species composition, productivity, etc.);

– economic characteristics (rental payments, expected income, rental period, etc.).

All this will make it possible to efficiently manage forests and ensure the investment attractiveness of forestry through visualization of entrepreneurial activity.

When creating a digital platform and its mobile applications, both general and particular rules imposed in such objects must be taken into account. The general principles in our opinion are:

– standardization - the establishment of standard forms and data sets for individual events in forestry life, processes and interfaces of information systems, common standards and reference books to achieve orderliness, and the possibility of analytical processing, modeling and visualization of industry information, as well as technical and information compatibility of components of information systems;

– reliability - ensuring uninterrupted access in real time and remotely (without access to the information and communication network «Internet») to a single database of primary documents;

– unification - the establishment of common approaches to the development of technical and software solutions for information systems in the forest industry, common standards for the exchange of information, common unique sets of rules and processes that determine the interaction between users on different sides of ITP;

– distribution - the use of distributed information systems and resources, components of information and computing infrastructure, including a distributed cloud platform that allows you to store, protect, process and deliver data from / to all ITP users in the Russian Federation, at a high data transfer rate with minimal delays, as well as offline (without access to the Internet);

– openness - the availability of data established by law from primary documents on the forest industry to citizens, representatives of business entities and other interested parties in open access on the geoinformation portal in the Internet information and telecommunication network;

– legal significance - the exchange of primary documents between authorized persons and organizations should be based on the principles of building a distributed platform using the existing infrastructure of electronic document management operators, including those widely used by state organizations and business entities in the Russian Federation. At the same time, for ITP participants who do not use the specified infrastructure, the implementation of the corresponding functionality as part of ITP is provided;

– information security - ensuring the security of information, data and supporting infrastructure from accidental or intentional influences of a natural or artificial nature, including the use of information protection technologies using Russian cryptographic standards and Russian technologies to ensure the integrity, confidentiality, authentication and accessibility of transmitted information and its processing processes.

Conclusions and Recommendations

An analysis of the current state of informatization in the sphere of state forest management in Russia indicates that in the forest sector there is still no comprehensive approach to create a unified information system of state forest management bodies at all levels. There are many gaps in the regulatory system.

The forestry sector of the Russian Federation is significantly inferior to the world forestry countries in the field of ICT, which determines the need to accelerate the transition to digital technologies that are most in demand at the level of state forest management and the forest business. By analogy with European countries, a state policy should be developed in the field of forestry informatization, as well as the creation of a digital forestry platform.

Measures to digitalize forestry in Russia must be carried out in order to:

– a technological breakthrough in forestry and the achievement of a significant increase in the productivity of forest users through modern digital technologies, robotics, the use of artificial intelligence, big date and blockchain;

– transformation of state forest management processes and ensuring the effectiveness of decisions based on a single information space that ensures the completeness and consistency of information;

– digitalization of the forest sector in Russia and the creation of a single industry digital platform will contribute to the achievement of the following results;

– improving the quality of control and supervision of the forest business;

– unification and standardization of documents and rules for the organization of forest use;

– transparency of the results of work in forestry;

– lower costs for the production of forest products;

– increasing the efficiency of activities, including through the growth of labor productivity;

– reducing the time taken for managerial decisions, including due to the relevance of the information;

– increasing openness of information and increasing activity of the population and citizens in forest management processes.

Abstract

In modern conditions of Russia, the implementation of federal projects of the national program «Digital Economy of the Russian Federation» is especially relevant. Particular attention in the scientific community is paid to discussing the modern concept of the "digital economy" and the practice of developing regional digitalization processes. The paper provides a critical analysis of foreign and domestic approaches to assessing the level of development of the digital economy. The possibility of their application in the conditions of modern Russia at the regional level is investigated. The authors have proposed an approach to building the digitalization index of the Russian regions, which allows a comprehensive assessment of the digital economy development level in regions. This tool is especially relevant as a tool for analyzing the implementation of the digitalization strategy for the constituent entities of the Russian Federation in the framework of federal projects as a part of the national program «Digital Economy of the Russian Federation».

Keywords: Digital Economy, Digitalization Strategy, Subject Of The Russian Federation, Digitalization Index.

Introduction

The relevance of the research problem is due to the fact that the regional authorities in Russia today do not have tools to adequately assess the implementation of regional projects in the framework of federal projects of the national program "Digital Economy of the Russian Federation". Therefore, monitoring progress in the field of digital development of regions, as well as a comparative analysis of problematic issues in the implementation of the strategy of the constituent entities of the Russian Federation, is not yet possible.

In the course of data processing and analysis, a complex of economic research methods was used, united by a systematic approach to studying the digitalization problem, analytical, economic-statistical, abstract-logical, comparative methods were used.

The work states the existence of objectively existing problems that, on the one hand, impede the process of implementing tools for managing the process of implementing the digitalization strategy of the constituent entities of the Russian Federation within the framework of federal projects of the national program "Digital Economy of the Russian Federation", and, on the other hand, determine the relevance of research on the development of methodologies and tools to adequately assess the implementation of regional projects, and focused on their practical usefulness. Developed within the framework of the integrated (integral) approach that has prevailed over the past few years, methods, procedures and tools are not yet sufficiently clearly systematized, often contradictory, and in some

cases (this primarily relates to comprehensive diagnostics of progress in the field of digital development of the regions of the Russian Federation) very unsuitable for use in practice.

The interest of the research lies in the formation and scientific substantiation of theoretical, methodological and practical directions for the development of a mechanism for assessing the digitalization process in Russian regions, which allows for comprehensive monitoring and assessment of the level of development of the digital economy at the regional level.

The research results are in improving the process of managing the implementation of the digitalization strategy of the constituent entities of the Russian Federation in the framework of federal projects of the national program "Digital Economy of the Russian Federation".

Methodology

The main goal of the study is to develop an approach to building the digitalization index of the Russian regions, which allows a comprehensive assessment of digital economy development level in regions. This tool should contribute to the comprehensive monitoring and evaluation of the level of development of the digital economy at the regional level, as well as the analysis of the implementation of the digitalization strategy of the constituent entities of the Russian Federation within the framework of federal projects of the national program "Digital Economy of the Russian Federation".

To achieve this goal, the possibilities of applying a new system of indicators (rating) of the National Index of the Development of the Digital Economy of the Regions of the Russian Federation were investigated. The rating implies a balanced assessment of the development of digital transformation in the regional and sectoral aspects. The formation and selection of indicators takes into account state requirements established in regulatory legal acts governing digitalization processes in the Russian Federation, as well as taking into account the analysis of requirements and expectations from the business environment and citizens of the Russian Federation.

Literature Review

In the course of the work, the scientific works of domestic and foreign authors on the study of the problems of the digital economy were studied. Here are some definitions of the digital economy that are used in the scientific and professional communities:

- The economy is based on digital technologies, but we understand this to a greater extent as the implementation of business operations in markets based on the Internet and the World Wide Web by British Computer Society (2013).
- Use of digital technologies to change a business model of Banu Dawood Gani and Fernando (2018).
- Integration of digital technologies into everyday life by the digitization of everything that can be digitized – defined by Ochs and Riemann (2018).
- Is the process of converting information into a digital (bits - 0,1) format (i.e., readable by computers). This allows any information to be stored, processed, and transmitted easily by using a network of computers. Gupta (2019).
- The integration of digital technologies into everyday life. Digitalization also means the process of making digital everything that can be digitized and the process of converting information into digital format by Croon Fors (2013).

Obviously, the diversity of opinions presented on the essence of the digital economy gives rise to different versions of its description.

We agree with the opinion of L. Gokhberg (2019) that the digital economy is the creation, dissemination and use of digital technologies and related products and services - Gokhberg (2019).

The question of the relationship between digital and conventional activities remains open, and it also requires specifying the types of digital technologies by Polozikhina (2018).

In Russia, the term "digital economy" is defined in the "Strategy for the Development of the Information Society in the Russian Federation for 2017 - 2030." as “an economic activity in which the key factor of production is digital data, the processing of large volumes and the use of analysis results which, compared with traditional forms of management, can significantly increase the efficiency of various types of production, technologies, equipment, storage, sale, delivery of goods and services " in Decree About the Strategy for the Development of the Information Society (2017). At the same time, the specification of the directions of measurement and evaluation of the digital economy is not given.

Following Polozikhina (2018), we believe that the digital economy is segments of the market where added value is created using digital (information) technologies.

Thus, by the digital economy (digitalization) we mean a level of implementation of digital technologies at which they become a key factor in production and significantly increase the efficiency of various fields of economic activity and the quality of life of people. At the same time, a digital space is being formed in which, thanks to the accelerated progress of telecommunication technologies, a new basis is being formed for the development of the economic and social sphere by Antipina (2018) and Demura (2019). The digital economy is turning from a strategic priority for the state into reality for business, municipal organizations and the population of Russia. Decree of the President of the Russian Federation of May 7, 2018 No. 204 (2018) and the National Program “Digital Economy” define key areas for the development of the information society (2019).

Today, there is an urgent need to develop a new system of indicators (rating) of the National Index of Development of the Digital Economy of the Regions of the Russian Federation, which would take into account the initially existing “digital inequality” of the Russian regions and allow tracking the development dynamics of specific regions taking into account the specifics of their functioning.

Analysis

Today, the digital economy is turning from a strategic priority for states into a reality for business, municipalities and the public. At the same time, the current formation (change, concretization) of digitalization requirements must be taken as an opportunity to transform (specify) the tools taking into account new challenges and requirements that are formed at successive phases of the development of digital transformation (the principle of flexibility in building the Rating).

Decree of the President of the Russian Federation dated May 7, 2018 No. 204 and the national program “Digital Economy of the Russian Federation”, approved by the Presidium of the Presidential Council for Strategic Development and National Projects dated December 24, 2018 No. 16, set a new vector for the development of the information society.

To ensure the continuity of state policy and the “soft” transition of the stage of building the information society to the stage of formation of the digital economy, it is necessary to develop a new system of indicators for the National Index of the Development of the Digital Economy of the Russian Federation (hereinafter - the Rating). Continued use of the monitoring and rating tool will provide a timely assessment of the pace of regional digital development, and will provide an opportunity for flexible development management of the constituent entities of the Russian Federation. Information society building in Russia was executed in accordance with National program “Information society (2011-2020)”. Stages were as follows: digital technologies to legal bodies – by 2015 and trend towards fully electronical government with elements of infrastructure and cyber-security investments.

The peculiarity of regional rating and its difference from the all-Russian (country) rating is that initially the subjects of the Russian Federation are in unequal conditions from the point of view of

forming the potential for the development of digitalization in them. Therefore, the final rating should take into account the initially existing “digital inequality”, but it is advisable to lay the basis for its calculation methodology on the principle of assessing the development dynamics of a particular region taking into account its specific functioning features. Therefore, before the full-fledged use of the Rating as a monitoring and management tool, it is necessary to evaluate the starting positions of the regions, that is, measure their current state and development dynamics.

At the same time, when constructing the Rating, it is advisable to take into account the following three interrelated premises:

- the uniqueness of the region, including its industry structure;
- degree of mobility of the digital environment;
- maturity stage of digital technology.

The uniqueness of the region is connected with the fact that each region has a different level of development of the basic institutions necessary for launching digital transformation processes (infrastructure, human resources, etc. - the basis for the formation of the first index component).

The degree of mobility of the digital environment. The development of digitalization is largely determined by the degree of penetration of existing “end-to-end” digital technologies into the internal operations of a particular industry. Consequently, the ability to get the effects of digitalization varies across industries. At the same time, the trajectory of the socio-economic development of the region is largely determined by the existing sectoral structure, which should be perceived as an important variable in the rating process of the constituent entities of the Russian Federation. It is necessary to take into account not only the possibility of an integrated assessment, but also the qualitative and quantitative characteristics of the digital transformation of the economies and social spheres of the constituent entities of the Russian Federation by tracks, industries and fields of activity - tracks (the basis for the formation of the second index component).

It should be borne in mind that various industries have different digitalization potentials because the third-wave digital technologies, including artificial intelligence, big data analysis and storage, distributed registries, the Internet of things and other end-to-end technologies, have an impact on industry development opportunities in varying degrees and form fundamentally different prospects for creating added value.

At the same time, the degree of mobility of the digital environment also determines the level of activity of the main participants in the region's digitalization processes.

The maturity stage of digital technologies influences the intensity and efficiency of development of industries and fields of activity. New digital technologies dynamically penetrate the country's economy and thereby have a significant impact on the development of its infrastructure. These trends are becoming a key element in international economic competition; therefore, control and stimulation of these processes at the state level is becoming particularly relevant. The increasing use of modern information and communication technologies is becoming a prerequisite for the emergence and development of new effective management technologies and entrepreneurial practices.

Accounting for all three components will ensure the implementation of a systematic approach to assessing the development of digitalization of regions from a position of ensuring integrity, which will allow:

- monitor the conditions of system development over time;
- evaluate the evolution of the passed stages of development;
- prevent the occurrence of imbalances in digital transformation (balanced development of the system);
- set the vectors of managerial decision making at the regional level.

To increase the effectiveness of public administration and make informed management decisions, it is advisable to provide for a channel of social diffusion, the possibility of feedback, reflecting the degree of public reaction to digital transformation, including at the regional level. Thus, the index can carry not only an information-analytical function, but also be an interactive tool through which the main participants in the process of digital transformation of the region can influence the adjustment of state policy, including reform, in this area through their direct involvement in evaluating effectiveness (basis for the formation of the third index component).

Results

In the proposed methodology for determining the index, three upper-level index components are identified that are focused on key areas of the digitalization process in a particular region. Together, they form a common framework model for this process.

The first index component is "Perception of the processes of digital transformation of the subject of the Russian Federation. It is built in a regional context on the basis of taking into account the public opinion of citizens of the Russian Federation regarding state and regional digitalization programs. The information basis for this index component is the data of special sociological studies, the uniqueness of which is a feedback tool, due to which further adjustment of state policy is possible. Assessment of population satisfaction with digitalization processes is based on three components: trust, motivation and expectations, which allows maintaining parity between economic, political and social aspects when implementing state policy in the field of regional digitalization.

The second index component, "Factors for the development of regional digitalization," reflects the willingness and ability to transform the digital environment of the region. These factors are, in our opinion: the availability of appropriate human capital, innovative and investment potential of the environment, the level of development of information systems in state authorities, the level of development of information and communication culture, the willingness of subjects of the digitalization process to use domestic software. It demonstrates the degree of digitalization of the priority directions of the region's development (urban economy, industry, public administration, healthcare, transport, education, agriculture). When forming the index, we took into account important methodological aspects: the mandatory inclusion in its composition of indicators reflecting the degree of achievement of goals in the framework of the Digital Economy of the Russian Federation program; the implementation of the continuity between the previous assessment of the level of development of the information society in the constituent entities of the Russian Federation. For analysis, data from official authorities are used. Within the framework of this index, two subindexes are identified:

1. Readiness of the digital environment - at the level of the region's economy (macro indicators). They are considered in three sections: the readiness of the digital environment for the population, for business and for government.
2. Readiness of the digital environment - at the industry level (meso-indicators). These are target indicators of relevant sectors of the economy, which are enshrined in federal and regional projects as defining the development of regional entities.

The third component index characterizes the final effects of the digital transformation of the economy and social sphere of the region - for the population, business, government and key sectors of the economy.

The third index component "Effects of digital transformation for the economy and social sphere of the region" reflects the final effects of digital transformation for the economy and social sphere of the region (along the tracks) for the population, business, government and key industries identified in the second index component.

Currently, the main effects of digitalization are associated with the fact that the introduction of new ICTs allows to improve technological processes and improve product quality, optimize organization

in various fields of activity, and finally contribute to improving people's health and quality of life (Polozikhina, 2018).

Conclusion

Thus, the proposed methodology for determining the index allows you to carry out several areas of analysis: individual analysis of the selected index components; comparative analysis of regions; as well as analysis of the impact of digitalization by industry and by target groups. This analysis will be useful for developing policies in the field of digitalization in the region, as well as for analyzing the impact of digitalization by industry and by target groups, taking into account the specifics of their functioning.

When constructing the Rating, it is taken into account that the set of indicators and indicators of the digital development of the regions reflects the interests and involvement of all the main subjects of the digitalization process of the constituent entities of the Russian Federation, including aspects of the involvement of representatives of the business community and citizens of the Russian Federation outside the regulatory sphere. At the same time, the formation and selection of indicators takes place not only taking into account state requirements for the digital transformation process established in the main regulatory (regulatory legal) acts regulating the digitalization processes in the Russian Federation, but also based on an analysis of the requirements and expectations of business representatives community and citizens of the Russian Federation.

The proposed index allows for several areas of analysis, such as a comparative analysis between regions, an individual analysis of the selected index components, which is useful for developing policies in the field of digitalization in the region, as well as an analysis of the impact of digitalization by industry and by target groups.

The limitation of the proposed index at present is comparability with previous years, since many indicators have been calculated in Russian statistics with the introduction of the National Digital Economy Program.

Abstract

This study contains an analysis of the main determinants of the inflow of foreign direct investment to Poland between 2010-2017. The first section outlines the theoretical framework of the problem at hand, while the second part contains the results of own research whose scope covered identification of motives for FDI location in Poland. The aim of the study is to pinpoint the most important motives for locating FDI in Poland between 2010 and 2017, in a both national and regional perspective. This study focused on determining the cause-and-effect relationship between the scale of inflow of foreign direct investment (response variable) and selected macroeconomic parameters of the economy (explanatory variables). In the search for significant relationships between the inflow of capital in the form of FDI to particular regions and the factors determining that inflow, a regression model was used. The choice of explanatory variables in the model was dictated by an attempt to include the most frequently researched determinants of foreign direct investment. The dependent (response) variable, which represents the level of inflow of foreign direct investments to Poland between 2010-2017, was expressed by the number of active foreign-invested enterprises in a given year. Meanwhile, the independent (explanatory) variables are indicators that illustrate the most important determinants for the location of foreign direct investment in Poland. The following variables were assumed as explanatory: market size, labor costs, and the quality and availability of labor. A regression model was used in the search for significant relationships between the inflow of capital in the form of FDI to particular regions and the factors determining that inflow. The research was conducted for 16 Polish provinces (voivodeships) in the period between 2010 to 2017. The time range of the analysis was entirely conditioned by the availability of statistical data in the GUS database (Statistics Poland, Local Date Bank). The obtained estimation results did not provide grounds for rejecting the research hypotheses. The proposed regression model indicates that the main factors that encourage foreign investors to invest in Poland were the search for an absorptive market and an efficient workforce.

Keywords: Foreign Direct Investment; Investment Location; FDI In Poland; Statistical Analysis.

Introduction

International capital flows are one of the most important forms of relationships between entities in the modern global economy. From among the different forms of capital transfer conducted on an international scale, foreign direct investment (FDI) deserves special attention, having for years remained the largest external source of financing for developing economies. The lack of internal accumulation of capital in many developing countries forces them to seek various sources of financing for their economy, with foreign direct investment playing here a particularly important role according to E. Frejtag-Mika (2009, p. 165). Modern technology, knowledge and investing in people have grown to become important, if not crucial, factors of long-term business development and therefore of a country's economic growth. Investments aimed at boosting these aspects of corporate value growth largely determine such companies' domestic competitive advantage. The connections and cooperation of domestic companies with enterprises with foreign capital are not without

significance here. It is precisely their expansion that is believed, among others, to fill the gap of capital shortage, transfer of modern technologies, knowledge and skills, or diffusion of modern organizational solutions. FDI is most often associated with the influx of innovative technologies and modern solutions, breaking the barrier to the development of lagging economies. FDI also creates jobs directly related to the area of the investment and its surroundings, which may in turn trigger permanent changes in the social and economic structure of regions and therefore national economies at large.

Foreign direct investment is a widely discussed topic within economic literature (Skawińska 2018). It is generally believed that the advantages that FDI brings to the standard of living and prospects for economic growth of the host country, largely outweigh its disadvantages (Janicki and Wunnava, 2004, p. 505; Bobenič Hintošová, Bruothová, Kubíková, and Ručinský, 2018, p. 223). In the global economy, most FDI is located in highly developed countries (World Investment Report. Investment and New Industrial Policies, 2018). However, for several years there has been an increase in the inflow of FDI to developing and transforming countries, among them Poland, which has become one of the largest recipients of foreign capital from among the countries of Central and Eastern Europe (Czech, 2016, p. 36; Cieślik, 2018, p. 33-34; Jirasavetakul and Rahman, 2018; Wyrwa, 2018). By embracing the influx of foreign direct investment in the late 1980s and early 1990s, the economies of Central and Eastern European countries have managed to better lure foreign investors to this region. Over the past twenty-five years, Poland has seen a significant increase in FDI inflows, being currently one of the most important recipients of foreign capital from among the new EU member states. Poland has been relatively successful at confronting the global financial crises of the last decade - recording one of the highest economic growth rates in the EU, one of the lowest unemployment rates in the EU, and all this while avoiding "major financial turbulence" (SpotData, 2018, p. 3). In addition, Poland is the only country in the EU to not have been affected by the de-industrialization process which took place in 2007-2017. In that time, the percentage of persons employed in the industrial sector rose in Poland by 0.1 p.p. (according to Eurostat data, it stood at 24% in 2017, compared to 23.9% in 2006) - Poland was thus the only EU country in which an increased share of industry in employment was reported (SpotData, 2018, p. 7). Industrial enterprises operating in Poland benefited primarily from the development of supply chains by West European manufacturers, especially German. This is clearly reflected, among others, in Germany's increased share in Polish exports (from 25% on the eve of the financial crisis to around 28% at present). In some sectors, the entire Central European region serves as the EU-15's manufacturing base (SpotData, 2018, p. 7).

The favorable conditions for doing business in Poland, also highlighted by the *Strategy for Responsible Development* (Ministerstwo Funduszy i Polityki Regionalnej, 2017), are reflected in the opinions of reputable international centers. Last year the World Bank published its *Doing Business 2019* report, where Poland was among the countries with the best business conditions. Poland's relatively stable rank in this report is a sign that the reforms introduced in the last decade have been effective. The dynamic change of Poland's economy over the years has given rise to entirely new conditions for economic development, also in the context of the inflow of foreign capital. An important element of FDI analysis is identifying the motives guiding foreign investors in the choice of a location to inject capital. This is especially important because it allows assessing the level of development of a country's economy. A review of research studies on factors determining the size of involvement of international enterprises in Poland shows that economic determinants play a key role in the process of choosing Poland as a place to locate capital in the form of direct investment. Among these, market and resource motives have been of major significance (Wilson, 1990, p. 29; Tatoglu and Glaiser, 1998, p. 214; Karaszewski, 2001, p. 274, 280; Johanson, 2006, p. 17; Bitzenis, 2007, pp. 83-111; Gorynia, Nowak, Trąpczyński and Wolniak, 2015, p. 94; Shukurov, 2016, p. 87). While market motives have remained equally relevant over time, there has been quite a noticeable evolution in the area of resources. In the initial period, their cost advantages dominated, i.e. efficiency determinants (mainly labor costs), but soon, quality determinants (qualifications, skills of employees, etc.) would gain increasing importance (Jaworek and Karaszewski, 2018, p. 45).

The changing nature of the size and structure of FDI over time justifies efforts, both theoretical and empirical, to clarify the determinants of these changes. This study builds on previous research

exploring the determinants of international enterprises' activity in Poland. The first section outlines the theoretical framework of the problem at hand, while the second part contains the results of own research whose scope covered identification of motives for FDI location in Poland. The aim of the study is to pinpoint the most important motives for locating FDI in Poland between 2010 and 2017, in a both national and regional perspective. To achieve that goal, the following research hypotheses have been set out:

Hypothesis 1: The number of international enterprises is positively correlated with the size of the Polish market.

Hypothesis 2: Lower labor costs lead to an increase in the number of international enterprises in Poland.

Hypothesis 3: Higher quality and availability of workforce contribute to an increase in the number of international enterprises in Poland.

The article attempts to answer the question whether Poland is still perceived as a country whose main asset is low operating costs, including low labor costs (as was the case in the 1990s), or perhaps resource factors, including high qualifications of the workforce, are now of more importance to investors. The article presents the results of own research whose objective was to identify the motives for locating FDI in Poland. The assessment of the determinants was based on the results of the causal relationship between the scale of FDI inflow (response variable) and selected macroeconomic parameters of the economy (explanatory variables).

Research Methodology

Assuming that direct investors are driven by identical motives in the location of FDI, both in relation to individual Polish provinces and the country as a whole (Heller and Warżała, 2005, p. 797), the strength of correlation between the inflow of capital in the form of FDI to particular regions and the conditions of its location in Poland was examined. To test this assumption, a regression analysis was performed which enables – through the development of econometric models – the determination of the influence of individual explanatory variables on the dependent variable. The research was conducted in 16 Polish provinces (*voivodeships*) in the period between 2010 and 2017. The time range of the analysis was entirely conditioned by the availability of statistical data in the GUS database (Statistics Poland, Local Date Bank).

The aim of the study was to determine the factors that influenced the volume of FDI inflow to Poland between 2010-2017. To this end, simple- and multiple-regression models were used. An important part of the model-building process was its verification. The developed models were tested substantively and statistically. Substantive verification was based on the assessment of signs (characters) standing by the structural parameters of individual variables. This evaluation was to check the compatibility of signs with the expected correlation between an independent variable and an explanatory variable resulting from economic theory. Statistical verification, meanwhile, consisted of assessing the quality of the model using appropriate parameters and statistical tests. A statistical correlation between the level of inflow of foreign direct investments to Poland and the investors' motives between 2010-2017 was examined using regression analysis. Regression coefficients were estimated using a traditional method of least squares, the significance of which was determined by Student's t-test, while the significance of all variables in the model was estimated by variance analysis, i.e. the F-test. The coefficient of determination (R^2) was assumed as a measure of the regression model fit.

The choice of explanatory variables in the model was dictated by the attempt to include the most frequently researched determinants of foreign direct investment. The dependent (response) (y) variable, representing the level of inflow of foreign direct investment to Poland between 2010-2017, was expressed by the number of active foreign-invested enterprises in a given year. Meanwhile, the independent (explanatory) (x) variables are indicators that illustrate the most important determinants

for the location of foreign direct investment in Poland. The following variables were assumed as explanatory: market size, labor costs, and the quality and availability of labor.

Empirical studies employ several different measures to determine the size of the market, although these are most commonly GDP and GDP per capita. Some researchers also try to obtain the value of this variable by referring to the size of the population of a studied area (Resmini, 2000; Wei, 2000; Habib and Żurawicki, 2002; Johnson, 2006). As noted by A. Chakrabarti (2001, p. 98), GDP and GDP per capita show two different aspects of market size. While absolute GDP reflects the total size of the population, GDP per capita represents the level of income and the related quality of demand (the higher GDP per capita, the greater should be domestic demand for more advanced goods and better quality) (Johnson, 2006, p. 17). Thus, GDP per capita reflects not only the level of income, but also the quality of demand in the sense of increased demand for more advanced and higher-quality goods (Wawrzyniak, 2010, p. 92). A. Chakrabarti (2001) additionally points out that the variable representing the size of the host market appears almost in all empirical studies related to FDI determinants.

In this study, market size was reflected in the value of GDP at current prices, and its absorptivity – in the population, GDP per capita, and the gross household income per capita. A larger host market enables the simultaneous operation of a larger number of business entities (both domestic and foreign), thereby achieving economies of scale and increasing the likelihood of breaking even in terms of investment costs. In view of the above, a positive impact of the size of a host market on FDI is anticipated (Zhang, 2001; Erdal and Tatoglu, 2002; Janicki and Wunnava, 2004; Buch, Kleinert, Lipponer and Toubal, 2005; Clausing and Dorobantu, 2005; Kirkpatrick, Parker and Zhang 2006; Bellak, Leibrecht and Riedl 2008).

However, in relation to the variable reflecting labor costs, a negative impact on FDI is expected (Carstensen and Toubal, 2004; Janicki and Wunnava, 2004; Bellak, Leibrecht and Riedl, 2008). Higher labor costs mean a decrease in the profitability of a potential investment and therefore discourage FDI. A higher unit labor cost means a higher marginal cost, and consequently, a lower FDI inflow (Bellak, Leibrecht and Stehrer, 2008). Having said that, empirical studies reach markedly varied conclusions. They indicate both the existence of negative and positive correlations, but also the lack of a statistically significant influence of labor costs on FDI (cf. e.g. research overview presented in: Chakrabarti, 2001; Zhang, 2001; Hilber and Voicu, 2006; Wawrzyniak, 2010). Labor costs are the most controversial of all potential FDI determinants. This is because, although in theoretical approaches there is agreement on the importance of cheap labor in attracting transnational corporations, a large disparity is nevertheless observed in empirical research findings – some argue that higher labor costs in a host country reduce the size of FDI (Bellak, Leibrecht and Riedl, 2008; Sakali, 2013), others suggest a lack of correlation whatsoever, while still others find there is a positive correlation (Bénassy-Quéré, Fontagné and Lahrèche-Révil, 2005; Boudier-Bensebaa, 2005).

In the study, labor costs were expressed by the average monthly gross wage and labor productivity per employee, and a positive relationship was established between FDI inflow and labor costs.

Another factor taken into account in the analyses is the quality of the workforce. When high, workforce quality not only leads to increased production, but also enables the implementation of activities that use advanced technologies. This is particularly important for capital-intensive FDI, targeted at a qualified workforce. Therefore, areas marked by higher workforce quality should expect higher inflows of FDI compared to those where the quality of the workforce is low. In the study, the number of students per 10,000 residents in a region was used as the measure of workforce quality. The availability of qualified employees can significantly increase competitiveness of a host country in the international market, which is pivotal in attracting foreign direct investment (Quazi, 2007, p. 60). Given that the majority of empirical studies support the concept that higher workforce quality attracts FDI, a positive impact is anticipated.

Having said that, availability of labor force is an FDI determinant that is relatively rarely considered in empirical research. To measure it, the unemployment rate is used. However, there is no agreement in the literature on the direction of the influence of this variable on FDI. On the one hand, higher

unemployment means easier access to manpower resources, making employees value their current employment more and being more willing to work for lower wages (Billington, 1999, pp. 66-67). On the other hand, high unemployment may lead to an erosion of skills (Billington, 1999, p. 67), be a symptom of labor market rigidity for international enterprises (e.g. related to minimum wages or low spatial mobility) (Boudier-Bensebaa, 2005, p. 615), or signal the existence of less competitive conditions and a lower quality of life (Hilber and Voicu, 2006, pp. 13-14; Wawrzyniak, 2017, p. 58). In the study, the unemployment rate was to reflect the availability of the workforce. Despite the previously indicated disagreement in the literature with regard to the direction of the influence of this variable on FDI, it was assumed that a lower unemployment rate attracts FDI. Therefore, a negative impact is anticipated.

A set of indicators was compiled on the basis of available data for the years 2010-2017, using the ranks denoting:

x1 – GDP (market-related),
x2 – population (market-related),
x3 – GDP per capita (market-related),
x4 – nominal gross household income per capita (market-related),
x5 – unemployment rate (resource-related),
x6 – average monthly gross wage (resource-related),
x7 – number of students per 10,000 residents in a region (resource-related),
x8 – labor productivity per one employee (resource-related).

Explanatory variables (x1–x8) were selected in line with the guidelines on the substantive relationship, multidimensionality, accessibility and reliability of data.

The calculations were made using the statistics software suite PQStat v.1.6.6.202. Test probability at $p < 0.05$ was considered as significant, while test probability at $p < 0.01$ was considered as highly significant.

Results and Discussion: Determinants of the take-up and location of foreign direct investment – Research Findings

In this section, the results of empirical research obtained using the linear regression model are discussed. These results are included in the annex. The modeling procedure consisted of three stages. In the first stage, the degree of correlation of explanatory variables (x1–x8) with the explained variable (y), and of the explanatory variables (x1–x8) with each other, were assessed. This assessment was performed by estimating the R^2 and tolerability coefficients. The R^2 coefficient indicates the percentage of variability of a given independent variable translated by the remaining independent variables. The closer the R^2 coefficient is to 1, the more strongly a variable is correlated with the other independent variables, which indicates its redundancy. The tolerance ratio expresses the percentage of variability of a given independent variable not translated by the remaining independent variables. The closer this coefficient is to 0, the stronger a variable is correlated with the other independent variables, which indicates its redundancy.

In the second stage, the correlation was estimated using a linear regression model:

$$y = a + bx + [e]$$

where:
y – dependent variable,
x – independent variable (predictor),
a – intercept term (Y-intercept coefficient),
b – slope coefficient (directional),
e – standard error of the estimate.

The number of simple linear regression equations is determined by the number of adopted motives for the location of direct foreign investment in Poland. As a result of the estimation of regression coefficients, the following equations were obtained:

$$y = 1.4393 + 0.8307x1 + [2.5898]$$
$$y = 1.65 + 0.8059x2 + [2.754]$$
$$y = 0.8325 + 0.9008x3 + [1.9942]$$
$$y = 0.8269 + 0.9037x4 + [2.0068]$$
$$y = 14.5643 - 0.7134x5 + [3.2593]$$
$$y = 1.7929 + 0.7891x6 + [2.8574]$$
$$y = 3.425 + 0.5971x7 + [3.7314]$$
$$y = 1.5643 + 0.816x8 + [2.689]$$

In these regression equations, the number of active foreign-invested enterprises in a given year (y) depends in a statistically significant way ($p<0.01$) on all analyzed predictors. Among these variables, there are both stimulants and destimulants. For x5, which is the unemployment rate, this impact is negative, i.e. it is a destimulant, because a higher level of unemployment indicates a lower value of the share capital at the disposal of foreign-invested companies. However, attention should be paid to the previously indicated disagreement in the literature with regard to the direction of the influence of this variable on FDI. Higher unemployment facilitates access to labor force resources, but it can also lead to a decrease in skills, indicate labor market rigidity, or signal a lower quality of life. As far as other predictors are concerned, the regression coefficients were found to be positive, i.e. higher values triggered an increase in the number of foreign-invested enterprises (Table 1).

In the third stage, the obtained results were further explored by conducting a multidimensional regression analysis. To determine the strength and direction of the influence of selected factors affecting the level of inflow of foreign direct investment to Poland between 2010-2017, a multiple regression equation was constructed with all explanatory variables (x) that showed a statistically significant relationship with the explained variable (y) and their combinations (the best-subset method). The estimated model is as follows:

$$y = -2.3846 - 0.6529x1 + 1.0971x2 + 0.3447x3 + 0.0212x4 + 0.0959x5 - 0.035x6 + 0.0067x7 + 0.4024x8 + [1.4452]$$

The obtained results in the form of the value of coefficients describing the number of active foreign-invested enterprises in a given year are shown in Table 2.

The parameters in the estimated multidimensional Model I are logical and consistent with previous studies and theory. The model's coefficient of determination was R = 0.9537, (95%), R^2 = 0.9096, whereas the adjusted factor was at R^2 = 0.9026 (90%). These values indicate good agreement, as more than 90% of *y*'s variation was explained by the explaining variables. The model as a whole is highly statistically significant ($F = 129.55$, $p<0.0001$), with the standard error of the estimate at 1.4452. Noteworthy, however, is the fact that tolerance values are low, which means a high redundancy of predictors in terms of their mutual correlation. Given the standardized values of the regression coefficients, the following should be considered the main factors of FDI inflow to Poland: GDP, population, GDP per capita, labor productivity per one employee. The first factor has a negative directional coefficient, i.e. a region's higher rank in terms of GDP leads to a decline in the number of foreign-invested enterprises. The sign of estimating this parameter is opposite to that anticipated. The other three predictors have positive directional coefficients, i.e. a higher rank in terms of population, GDP per capita, labor productivity per one employee leads to an increase in the number of foreign-invested enterprises.

The most relevant description of the relationship between the level of inflow of foreign direct investment and the determinants of its location in Poland was adopted for multiple regression models with the highest determination coefficient.

Model II with four explanatory variables is expressed as follows:

$$y = -0.8587 - 0.3847x1 + 0.8154x2 + 0.2506x3 + 0.4194x8 + [1.4391]$$

Model II (four-dimensional) was found to be highly significant (F = 260.55 p<0.0001), with the standard error of the estimate at 1.4391. The coefficient R = 0.9523, R^2 = 0.9069, whereas the adjusted coefficient of determination is R^2 = 0.9034 (Table 3). The research reveals that a region's GDP value is not an important factor in this model, which is why the predictor was removed from the model.

Model III with three explanatory variables is expressed as follows:

$$y = -0.7597 + 0.4637x2 + 0.221x3 + 0.4044x8 + [1.4549]$$

Model III (three-dimensional) was found to be highly significant (F = 338.80 p<0.0001), with the standard error of the estimate at 1.4549. The coefficient R = 0.9508, R^2 = 0.9039, whereas the corrected coefficient of determination is R^2 = 0.9013 (Table 4). All three predictors in this model are highly significant (p<0.0001). The calculated value of the determination coefficient (R^2) showed good agreement between the model and the empirical data. Predictor tolerances are already higher here than in Model II which contains four predictors.

Conclusions

The purpose of this study was to examine the determinants of FDI in Poland between 2010 and 2017 using to this end the linear regression model. The obtained estimation results did not provide grounds for rejecting the research hypotheses. The proposed regression model indicates that the main factors that encourage foreign investors to invest in Poland were the search for an absorptive market and an efficient workforce. The adopted multiple regression model is interpreted as follows: the inflow of foreign direct investment to Poland between 2010-2017 is positively influenced by the market's absorbency measured by population and GDP per capita, and labor costs expressed by labor productivity per employee. The direction of the impact in both variables is as anticipated, i.e. these factors may lead to an increased inflow of FDI to Poland. However, the conducted analysis is not exhaustive, and in order to formulate detailed conclusions, it is necessary to conduct in-depth research that goes beyond the model adopted in this study.

Financial Reporting for Financial Instruments in Individual Investors' Decisions

Jarosław PAWŁOWSKI

Nicolaus Copernicus University in Toruń, Toruń, Poland
jpawlowski@umk.pl

Abstract

The observed development of financial markets and growing importance of financial instruments entail increasing investors' interest in relevant financial information. Consequently, in the current economic situation, the significance of financial reporting and financial instruments in individual investors' decisions is an interesting research problem. In this regard, the purpose of this paper is to assess the use of financial reporting for financial instruments by individual investors in their decision-making processes. The following research methods have been applied to achieve the assumed research goal: descriptive, comparative, subject literature analysis and survey among individual investors. The paper starts with an introduction to financial reporting and informative needs of investors. It is followed by a discussion concerning the results of own study. The final part of the paper contains the conclusions. These indicate that in individual investors' opinion financial reporting is an important source of information on financial instruments. However, a number of issues have been identified regarding the current solutions in this scope.

Keywords: Financial Reporting, Financial Statements, Financial Instrument, Individual Investor

Introduction

In current times of intensive growth on financial markets, business entities are more and more interested in financial instruments. The risk is indispensable in this kind of investments (Kurek, 2011). There is a large spectrum of identifiable types of risk related with investing in financial instruments. The basic ones include the risk of non-performance, market risk (interest rate, currency, prices), liquidity risk, political risk, inflation risk and management risk (Wasilewska, 2004). That is why proper risk judgment of financial instruments is an important issue in the investors' decision-making processes. Therefore, a wide interest in information on financial instruments from this group is identified. However, the way entities prepare relevant information, as well as the scope and form of their presentation, complicate the correct assessment of this risk and limits their decision-making usefulness (Koonce, et al. 2005).

The problem of informative needs of investors in their investment processes has been the subject of analyses for a long time. The first studies in that field were conducted in the 1970s by Slovic (1972), who focused on investors' behaviours concerning data processing and selection of investment strategies. A pioneer study in the field of general informative needs of individual investors was conducted by Baker and Haslem (1973). Investment decisions made by individual investors are determined by a number of various conditions. The major importance in this regard is attributed to economic factors. But there are also non-economic issues that count, including willingness to take risk, emotions, tradition, financial culture, knowledge and experience (Bielawska, Kordela, 2014, p. 30). In such conditions, individual investors need various information for the purposes of their decisions (Beyer et al., 2010). However, considering the specificity of financial instruments, a number of difficulties occur concerning the presentation of adequate financial information adjusted to the investors' expectations (Koonce et al.

2005). In this regard, this paper aims at evaluating the significance of financial reporting for financial instruments in individual investors' decisions. For the purposes of the assumed goal, the following research methods have been used: descriptive, comparative, subject literature review, analysis of results of third party research and analysis of results of own survey.

Literature Review

Financial reporting is currently deemed a major source of information used in investment processes. It gives investors access to a lot of information allowing to determine the property and financial situation of the company, as well as to financial results of business entities operating on financial markets (Toma et al., 2015). In the recent years, financial reporting rules have undergone significant transformations. It was mainly influenced by popularisation of the International Accounting Standards (IAS) and International Financial Reporting Standards (IFRS). The observed changes focus financial reporting on providing information consistent with the informative needs of the users, especially investors. This underlines the importance shareholder-based orientation in international regulation of accounting (Devalle, et al., 2010). It is reflected in the conceptual assumptions of the IAS/IFRS, which define the goal of financial reporting as providing financial information regarding the entity, that is useful for investors, lenders and other creditors in their decision-making processes (Kobiela-Pionnier, 2013). In this connection, the introduction of the IAS/IFRS had a major effect on the operation of financial markets, as well as on the decision-making processes of investors (Onali et al., 2017).

The findings of the recent analyses confirm that individual investors use financial reporting information in their decisions (Lerman, 2018). Additionally, the research concerning this group of investors in Poland indicated that financial report is considered as an important source of information (Pawłowski, 2018; Błażyńska, 2015; Adamczyk, 2014). However, the observed changes in financial reporting, that mainly result in an increase in the amount of disclosed information, method of presentation and degree of complexity cause that individual investors encounter difficulties in proper analysis and interpretation of such information (Kelton, Murthy, 2016). These problems are also seen in accounting for financial instruments. Investors indicate incompatibility of prepared financial information regarding financial instruments with their informative needs. Due to the specificity of financial instruments, including derivatives, the difficulties identified in this area mainly concern their recognition and valuation, as well as presentation of relevant information (Garstecki, 2014). The introduction of the rules of measurement of financial instruments based on fair value has long been a subject of controversy. On one hand, it is emphasised that due to the character of the instruments and informative needs of investors, using fair value is reasonable. But in certain situations using this parameter may affect reliability of financial reports, and also limit their usefulness in decision-making processes (Kunz, 2015). It is noteworthy that investors are critical of combinations of valuation of financial instruments in financial reporting. They react negatively to opacity of the information in this regard (Ballas, 2012). Another area of serious difficulties are disclosures on the risk exposure from financial instruments. Simultaneously investors consider this kind information essential in their decisions. That is why they require more relevant and transparency information that allows to evaluate the character and the extent of risks, and also the importance of the financial instruments to the firm's financial position. (Adznan, Nelson, 2014). The identified expectations in this regard concern both qualitative and quantitative disclosures of different types of risks of financial instruments, especially credit risk, liquidity risk and market risk (Malaquias, Lemes, 2013). Despite the significance of information concerning risk exposure for investors, certain issues have been identified regarding the current solutions in this field (Nadia, Rosa, 2014). The outcomes of the research indicate that some companies only partially complied with the regulations in this field, omitting other requirements (Othman, Ameer, 2009). Moreover, IAS/IFRS disclosure practices in this regard differ in particular countries. The main reason behind that is varied scope of enforcement and interpretation of international regulations (Adznan, Nelson, 2014). In view of this, the role of

financial reporting for financial instruments in individual investors' decisions is an important and complicated research problem.

Research - Results

For the purposes of this paper, the findings of an own survey, conducted on the author's demand in 2015 by the Individual Investors Association, have been used. It encompassed 408 individual investors from Poland. The research tool was an electronic survey questionnaire, published on the website of the association.

Individual investors participating in the survey have been categorised as natural persons investing their savings in various assets (Dziawgo, 2004). The assumed definition made it both a large and varied group. It is noticeable e.g. in the area of education, age, investment experience, capital owned and knowledge. Therefore, survey participants have been characterised in terms of selected features. Figure 1 presents the respondents' division according to the field of education.

Fig. 1: Respondents division in terms of education (%)

Source: own work

When analysing the outcomes, it is noticeable that the majority of survey participants had economic education (47.3%). A relatively high number of investors had technical background (17.6%). The rest of the surveyed group was quite varied in this aspect. It is worth pointing out that persons with IT education (5.7%) and legal education (3.4%) were smaller groups.

Another feature that differentiates individual investors is investment experience. Based on this criterion, and with reference to considerations included the subject literature, survey participants have been divided into three categories (Dziawgo, 2016):

- investors with small experience, up to 3 years,
- investors with medium experience, 3 to 10 years,
- investors with high experience, more than 10 years.

This division is illustrated in Figure 2.

Fig. 2: Respondents division in terms of investment experience (%)

Source: own work

The major group, constituting almost half of the respondents, were investors with medium experience, from 3 to 10 year (48.8%). Participants with small experience - up to 3 years and high experience - longer than 10 years appeared as a minority (25.0% and 26.2%, respectively).

The basic assumption of the survey was to determine the degree of usage of financial reporting for financial instruments in individual investors' decisions. The analysis of the problem started with a check whether survey participants consider involvement of the entities in financial instruments in their decisions. The replies are presented in Figure 3.

Fig. 3: Percentage of answers to the question: "Do you consider involvement in financial instruments while making decisions on buying assets of a given business entity?" (%)

Source: own work

The analysis of the findings brings to a conclusion that the majority of survey participants considered entities' involvement in financial instruments in their investment processes (54.2%). Additionally, it has been determined that some of them paid particular attention to derivatives (20.3%). The rest of the respondents claimed that they were not interested in such information (45.8%). In the following part of the survey, participants indicated the sources of their information concerning financial instruments used by business entities. Respective data are presented in Figure 4.

Fig. 4: Percentage of answers to the question: "Where do you find information regarding financial instruments used by companies?" (%)

* FI means financial instruments.

** Respondents could choose more than one answer to this question. The total number of indications was 1266.

Source: own work

Based on the findings presented above, it has been determined that yearly financial statements was the major source of information regarding business entities' involvement in financial instruments for individual investors (61.8%). Furthermore, the respondents indicated special significance of company analyses (50.7%), current reports (48.3%) and web portals (32.6%). It needs to be pointed out that some survey participants indicated other financial reporting tools as well. These included management board report on the activity (26.2%), interim financial statements (24.3%) and statutory auditor's statement and report (20.8%). Additionally, there was a group of investors who did not search for information in the discussed field (11.5%) .

Another analysed issue concerned the degree of usage of financial reporting for financial instruments by individual investors in their investment decisions. Survey participants evaluated such information, using the scale from 1 to 5. As a rule, higher grades indicated greater significance. Additionally, it has been agreed that grade 1 meant irrelevance of a given source of information, while grade 5 meant its relevance. Results are presented in Figure 5.

Fig. 5: Percentage of answers to the question: "Please specify the degree of usage of reporting information on financial instruments in your decisions, use the scale from 1 to 5 (1 - irrelevant source of information, 5 - relevant source of information)." (%)

Source: own work

Based on the results, it has been concluded that for a large group of survey participants reporting data on financial instruments was a significant source of information (grade "4" or "5", 42.2%). A relatively smaller group of investors admitted that such information was not useful at all (grade "1", 14.7%) or hardly relevant (grade "2", 13.0%). These answers were given by 27.7% of respondents. The remaining group of survey participants indicated medium relevance (grade "3") of this type of disclosed information (30.1%).

At the following stage, individual investors' use of individual financial reporting elements in search for information on financial instruments was analysed. The findings are presented in Figure 6.

Fig. 6: Percentage of answers to the question: "Which elements of financial statements do you use while searching information on financial instruments in your investment decisions? Specify the extent." (%)

Source: own work

Based on the survey results it has been concluded that investors usually support their decisions with the profit and loss account (49.6%), balance sheet (45.3%) and cash flow statement (33.2%). Answers indicating irrelevance of these reports in the analysed aspect occurred less frequently. Other types of reports were apparently less significant for the respondents. Most often, survey participants admitted that they sometimes used these sources of information, i.e. management board report on the activity (42.4%), notes (42.0%) and statement of changes in equity (42.0%). Additionally, there were quite a lot of answers indicating that these information is not used in the decision-making processes at all.

The following part of the study aimed at determining the reasons behind the fact that individual investors do not perceive reporting data on financial instruments as a relevant source of information in their decision-making processes. For this purpose, the respondents who previously admitted irrelevance of financial reporting in this field (ratings 1 to 3), were asked to explain the grounds of their opinion. The findings are presented in Figure 7.

Fig. 7: Percentage of answers to the question: "If you find reporting information on financial instruments irrelevant in the decision-making processes, please explain the reasons." (%)

* Respondents could choose more than one answer to this question. The total number of indications was 453.
** The letters IF in the figure indicate financial instruments.
*** A small group of respondents selected the answer "Other reasons", without specifying any details.
Source: own work

After the analysis of the findings, certain basic issues concerning reporting information on financial instruments can be identified. These claims relate to two problematic aspects. The first concerns the shape of financial reporting rules, that in investors' opinion is too complex (39.5%) and does not guarantee a clear way of presentation of relevant information (39.2%). It affects the possibility of proper understanding and practical use in investment processes. Other repeating claims concerned the scope of disclosure related to financial instruments. In the respondents' opinion, it is not only excessively limited (36.7%), but also descriptive information is insufficient (22.4%). The identified informative restrictions confirm the incompatibility of the portfolio of presented information with the investors' needs.

Conclusions

In general, on the grounds of the literature review and the analysis of the outcomes of own study, a number of conclusions have been formulated concerning the relevance of financial reporting for financial instruments in individual investors' decisions. It is noteworthy that this study was limited. It was conducted on a purposive sample of individual investors from Poland, therefore the obtained results and the conclusions drawn concern only the surveyed group. Therefore, they cannot be generalized to their entire population. However, they have theoretical and practical cognitive value.

One of the fundamental insights is that for surveyed investors, yearly financial statements was the most frequently used source of information on business entities' involvement in financial instruments (62%). Additionally, a large group of them emphasised that it was a significant source of information in investment processes (42%). After the analysis of the use of individual financial report elements in the considered aspect, it has been concluded that investors most frequently used the information included in the profit and loss statement (82%), balance sheet (81%) and cash flow statement (72%). Despite the interest in this type of reporting information, a number of claims appeared pertaining the current financial reporting rules. These issues mainly concerned complex accounting rules (40%), lack of transparency in the methods of presentation (39%) and limited scope of disclosed information (37%). To sum up, it has to be mentioned that the analysed findings of the research contain a lot of various opinions concerning the rules of financial reporting in terms of financial instruments, expressed by the basic group of users of financial information, i.e. individual investors. Therefore, these remarks and recommendations undoubtedly form an interesting and important material that is worth being considered in the context of further work on improve solutions in the field of accounting for financial instruments. The importance of this issue and many reservations of respondents indicate the need for further study in this scope. One of the basic further directions of future research should include determining of detailed information requirements of individual investors in the analysed aspects. Another interesting area of research would concern assessment of the significance financial reporting for financial instruments in the opinion of institutional investors.

The Importance of Cultural Intelligence In International Human Resource Management - A Pilot Study

Agnieszka KNAP-STEFANIUK

Jesuit University Ignatianum in Krakow, Faculty of Education, Institute of Political and Administrative Sciences, Department of Law, Management and Economics, Krakow, Poland, agnieszka.knap.stefaniuk@ignatianum.edu.pl

Abstract

At present cultural intelligence is a topical issue of great significance. It is widely discussed in subject literature, especially in the context of international business and management of multicultural teams. The special role and importance of cultural intelligence stems, first of all, from the fact that it affects the ability to notice, understand and accept attitudes, behaviours, norms, principles and values of representatives of other cultures. Cultural intelligence (CQ) understood as a set of skills and qualities necessary to effectively function in culturally diverse environment, plays a vital role in international human resource management. The pilot study (individual in-depth interviews) discussed in the article was conducted in international companies.

Keywords: cultural intelligence (CQ), International Human Resource Management, intercultural teams, multicultural environment.

Introduction

Operating on an international scale necessarily implies operating in multicultural environment - with reference to both employees and clients - which creates an opportunity to exploit the potential of culturally diverse employees and managers, their competences and experience, to implement new solutions, to take up new international challenges, and to improve the competitiveness of the company on the basis of effective ways of human resource management. The ability to effectively cooperate in different cultures has, therefore, become crucial in today's global business world.

Cultural intelligence (CQ) is nowadays of growing interest to researchers, which, to a great extent, results from globalization and a subsequent marked increase of intercultural interactions. Therefore, in order to function effectively in the international arena, managers and employees must possess cultural awareness and display sensitivity in intercultural contacts.

Cultural intelligence, i.e. the ability to adapt effectively to diverse cultural contexts enables employees and managers not only to quickly adapt to culturally diverse work environment, but also to act more efficiently and to achieve the organizational goals on the international market.

The theoretical part of the article explains the concept of cultural intelligence and its significance, defines international human resource management, and discusses the role of cultural intelligence in multicultural work environment.

The qualitative study whose results are reported in this article (6 individual in-depth interviews) was a pilot study and serves as an introduction to the more extensive study the author is planning to conduct in the future on the role of cultural intelligence in international human resource management among employees of international companies in Poland, the Czech Republic and Spain.

The aim of the article is to demonstrate the significance of cultural intelligence in international human resource management. Considering this aim and the above premises, the following research question was formulated: Are employees of international companies familiar with and do they understand the concept of cultural intelligence and are they able to determine the impact of cultural intelligence on various areas of human resource management?

Cultural Intelligence (CQ) – Definitions and Meaning

Cultural intelligence first appeared in articles and study reports at the beginning of the 21st century (Earley, 2002; Earley and Ang, 2003; Earley and Peterson, 2004; Thomas and Inkson, 2004; Earley and Mosakowski, 2004; Ang, Dyne, Koh, andNg, 2004; Earley, Ang, and Tan, 2006; Earley and Mosakowski, 2007; Ang, Van Dyne and Rockstuhl, 2015).

Cultural Intelligence or Cultural Quotient (CQ) is a relatively new concept (Brancu, Munteanu, et al., 2016; Engle, Nehrt, 2012), and subject literature provides its numerous definitions, whose brief outline is presented below.

Earley and Ang (2003) define cultural intelligence as a multidimensional construct that includes the individual's ability to function effectively in culturally diverse contexts. Piwowarczyk describes cultural intelligence as "a specific form of intelligence, connected with the ability to properly understand situations characterised by cultural diversity and to reason and behave adequately in such situations" (Piwowarczyk, 2016, p. 5).

Creque and Gooden define CQ as "an individual's cognition or knowledge that influences his perception to a cultural environment or state and which leads to how he behaves in that environment" (2011, p.143), while according to Khodadady and Ghahari, it is "the ability to interact effectively in multiple cultures" (2012, p. 22).

Engle and Nehrt (2012) define cultural intelligence as the person's ability to effectively engage in relationships in different cultural contexts. Brancu and Munteanu emphasise that "cultural intelligence (CQ) is a concept which explains why certain individuals can adapt to different cultural contexts more efficiently than others" (Brancu, Munteanu, et al., 2016, p. 336).

Cultural Intelligence (CQ) is also interpreted as the ability of managers, employees and other persons involved in intercultural interactions to act efficiently in the globalized world (Fang, Schei, et al., 2018). According to other authors, cultural intelligence refers to the individual's ability to recognize foreign cultural contexts, and then effectively function in culturally diverse environment (Shepherd, Willis-Esqueda, et al., 2019).

Another approach to cultural intelligence treats it as a feature which helps the individual to adapt to foreign cultural contexts, i.e. different cultural environment marked by different ways of doing things, different values and norms (Piwowarczyk, 2016). As Ang and Van Dyne observe, cultural intelligence is the individual's ability to function effectively in situations characterized by cultural diversity (Ang and Van Dyne, 2008).

Subject literature offers also other interpretations of cultural intelligence. "Peterson (2004) defined cultural intelligence as the aptitude to use skills and abilities appropriately in a crosscultural environment" (Brancu, Munteanu, et al., 2016, p. 337). For him, this kind of intelligence is: "the ability to engage in a set of behaviours that uses skills (i.e. language or interpersonal skills) and qualities (e.g. tolerance for ambiguity, flexibility) that are tuned appropriately to the culture-based values and attitudes of the people with whom one interacts" (Peterson, 2004, p.89). Moon sees CQ as "an organization's capability to function and manage effectively in culturally diverse environments" (Moon, 2010, p.458).

Emphasizing the need to understand how an individual adapts to new, unfamiliar social environment, cultural intelligence is defined as the individual's ability to successfully adapt to new cultural contexts (Lovvorn and Chen, 2011).

Recapitulating the above considerations on the definitions of cultural intelligence, it should be noticed that this term is used with reference to the individual's ability to successfully adapt to new and unfamiliar cultural contexts and to effortlessly and effectively function in situations characterised by cultural diversity (Nunes, Felix, et al., 2017). Therefore, cultural intelligence is particularly important in international human resource management, i.e. in managing multicultural teams.

Cultural intelligence comprises four distinct but interconnected components: metacognitive, cognitive, motivational, and behavioural (Ang, Van Dyne, et al., 2006; Ang, Van Dyne and Rockstuhl, 2015; Brancu, Munteanu, et al., 2016). Researchers and authors of publications devoted to cultural intelligence observe that these components shape the individuals' ability to learn about other cultures, their ability to learn how to learn about other cultures, their willingness to interact with other cultures, and their ability to modify their behaviour to behave appropriately and efficiently when faced with representatives of other cultures.

The metacognitive component (Metacognitive CQ) is defined as the individuals' mental capacity to acquire and evaluate their own cultural knowledge. It refers to one's awareness and monitoring of the cognitive process which takes place during interactions with representatives of other cultures with reference to one's own and their culture and cultural identity (Simpson, 2017). Metacognitive CQ means that managers and employees of multinational companies should acquire cultural knowledge not only about their own culture and cultural identity but also about the culture and cultural identity of their co-workers in order to better understand their relationships and the causes of possible failures. "People with high metacognitive CQ are able to question cultural assumptions, to adjust their mental models in intercultural situations. They are aware of others' cultural preferences before and during interactions" (Brancu, Munteanu, et al., 2016).

The cognitive component (Cognitive CQ) is connected with the individual's general knowledge of cultures and their differences (Simpson, 2017). It refers to the knowledge of norms, practices and rules present in various cultures, which are acquired through learning and personal experience. Individuals with high cognitive CQ know and understand a wide range of economic, legal and social aspects of different cultures (Nunes, Felix, et al., 2017). They are familiar with and accept cultural models, possess and understand information about values, norms, and traditions specific to the cultures with which they interact (Brancu, Munteanu, et al., 2016).

The motivational component (Motivational CQ) refers to intrinsic motivation of an individual who makes an effort to effectively function in culturally diverse contexts (Simpson, 2017). It is the ability to direct one's attention and energy to act successfully in face of cultural diversity. Motivational CQ is an important element of cultural intelligence, especially in the field of adaptive behaviours in intercultural environment.

The behavioural component (Behavioural CQ) is based on the individual's ability to respond appropriately - verbally and non-verbally – while interacting with representatives of other cultures (Simpson, 2017). Individuals with high behavioural CQ can communicate and react to a given situation appropriately. Therefore, if an organization is to overcome challenges posed by intercultural exchanges in the global business operations, culturally intelligent behaviour of its managers and employees is of vital importance (Solomon and Steyn, 2017).

Managers and employees must possess all four components of cultural intelligence if they want to achieve its high level, as all four of them are indispensable in successful development of intercultural relationships in international work environment, in achieving teamwork goals and organizational objectives, and in communicating with clients from different cultures and co-workers from outside the organizational structures.

"Cultural Intelligence (Bailey, 2004) is a basis for comprehending and learning the cognitive, motivational, and behavioural components of effective intercultural adaptation" (Mukherjia, Jainb, et al., 2016, p. 9). Moreover, "CQ allows an individual to appreciate the diversity of experiences to formulate rapid, accurate, and situationally sensitive responses to emerging issues" (Lovvorn and Chen Jiun-Shiu, 2011, p. 277). Managers and employees with a high level of cultural intelligence are able to adapt their behaviours, thinking and communication strategies to culturally diverse clients, which can contribute to better performance of teams and the whole company (Hartini, Fakhrorazi, et al., 2019).

It should be noticed here that, as a result of globalisation and the expansion of businesses to international markets, the role and importance of cultural intelligence as an essential skill in modern management is definitely growing (Day, 2017).

Summing up, cultural intelligence is a set of skills that are indispensable to successful international human resource management and to employees' effective functioning in multicultural teams.

International Human Resource Management - Managing Intercultural Teams

Looking for new ways of expansion and development, contemporary organizations increasingly expand their business activity to international markets. In order to improve their competitive position on the global market, they apply various strategies in building their competitive advantage (Tiwarai, 2013).

Both theoreticians and practitioners have been emphasizing the role of changes in the modern world and their impact on the functioning of business organizations for years. Effective human resource management, which adequately responds to the contemporary challenges, also those faced by international organizations, is essential if companies are to become and remain competitive on the market (Lima, 2016).

In today's business world, the internationalisation of the company's activity is becoming a decisive factor in its future expansion and development. However, internationalisation requires introducing numerous changes in the way it functions, especially in the area of human resource management (Đorđević, 2016).

Strategic international human resource management is nowadays a challenge for many companies which develop their business activity on the global scale (Alharthey, 2018). Therefore, both business theoreticians and practitioners emphasise the vital role played by human resources in the achievement of organizational strategies and objectives.

International resource management is a concept widely discussed in academic studies and publications, most of which are devoted to the direction of changes in the functioning of contemporary organizations (Knap-Stefaniuk and Karna, 2017).

International human resource management is defined in many ways. One of the shortest definitions is given by R. Boxall, who points out that international human resource management refers to the ways of managing employees in a situation where an enterprise conducts its business activity on an international scale (Beardwell and Holden 2001).

International human resource management is defined as "the human resource management issues and problems arising from the internationalization of business, and the human resource management strategies, policies and practices which a firm pursues in response to the internationalization of business" (Scullion, 1995, p. 352).

Gomes believes that the IHRM is the process of acquiring, allocating and effective using of human resources in international business (Gomes, 2012).

Human resource management in enterprises conducting business activity on an international scale differs from human resource management in enterprises which operate on a national scale. The differences include a greater number of tasks faced by human resource departments, especially in the area of preparing managers and employees sent to work abroad and in the area of building personal, team and organizational relationships in international work environment. They are also connected with coordinating employees' transfer within the structures of the company in the international dimension (Zając, 2012, pp. 44-45). It is worth mentioning here that the complexity of processes and tasks faced by human resource personnel working in international companies to a great extent stems from cultural diversity of their employees.

International human resource management is based on the same techniques of recruiting, motivating, training, and promoting employees as national human resource management, the difference being determined by cultural factors (cultures and languages used within the organization), geographical expansion of the company, and characteristic features of the home country (Dowling, Festing, et al., 2008). International human resource management focuses primarily on the formulation and implementation of strategies based on planning, recruitment and selection, training and development, remuneration, appraisal and long-term career management of employees in the context of international human resources.

International companies often adapt their human resource management solutions to practices implemented in various countries (Tiwari, 2013). In the author's opinion, human resource management in international companies which recruit employees from diverse cultures must take into account a range of various solutions adequate to given cultures and recognised by employees of given nationalities.

International human resource management should focus on achieving organizational goals and performing tasks in such a way that enables employees and managers to follow a global way of thinking while implementing the company's strategy. Therefore, successful cooperation between members of multicultural teams and the ability to influence the attitudes and behaviour of employees from different countries are among key challenges in contemporary management (Story, Barbuto, et al., 2014).

In the author's opinion, human resource management is an extremely important aspect of contemporary international organizations. The implementation of effective solutions related to human resource management is a crucial condition of the company's success (Agarwal and Saif Al Qouyatahi, 2017). However, many managers find managing multicultural employees, both within teams and within the whole organization, a demanding task (Devine, Baum, et al., 2009).

"The international organizations can use culturally sensitive and adaptive HRM practices for creating competitive advantage in overseas operations" (Tiwari, 2013). International teams are commonplace today and are part of the global operations of contemporary companies. In order to achieve organizational objectives and successfully implement its strategy, the organization must be pro-active and involved (Drach-Zahavy, 2011).

"To improve the effectiveness of employees in cross-cultural interactions, global organizations should focus their efforts on hiring the right people, matching them with the right managers and providing the right training to them" (Day, 2017, p. 11). Employees and managers should possess a high level of cultural intelligence in order to successfully function in international, i.e. culturally diverse work environment. Organizations, on their part, should organise training aimed at increasing employees' cultural competence in order to develop their cultural awareness and sensitivity, which are crucial factors in working in intercultural teams.

Summing up, human resource management in the globalised, international business context is a great challenge today (Agarwal and Saif Al Qouyatahi, 2017). In the author's opinion, it is a challenge for both managers and employees. Moreover, even though the concept of international human resource management is defined in many different ways, all definitions share certain elements which shape the

activities undertaken by mangers of culturally diverse employees. One of them is the multicultural structure of teams, which makes it necessary to develop employees' awareness of cultural differences with reference to teams and whole organizations.

Globalisation, technological progress, and changes in contemporary work environment create new challenges for management (Grabara, Cehlar, et al., 2019). Undoubtedly, cultural intelligence (IQ) is such a challenge in international human resource management, in which managers and employees work at the intersection of diverse cultures.

It should be emphasised that managers who operate in international environment must possess the qualities and skills which allow them for successful functioning in multicultural environment and facilitate efficient and effective management of culturally diverse teams (Karna and Knap-Stefaniuk, 2018). Cultural intelligence is indispensable for effective management of culturally diverse employees.

Cultural Intelligence and Its Importance in Multicultural Environment

Constant and dynamic changes taking place in today's global world, which affect the operation of organizations, especially those international ones, create such work environment in which managers and employees interact with people with various cultural backgrounds on a day-to-day basis (Rand, Cultural Intelligence, 2015).

Globalisation and international expansion of organizations have a significant impact on their intercultural interactions and commercial contacts, which makes it necessary for their employees to acquire knowledge about different cultures and to develop competences essential for their effective functioning in intercultural work environment. The success of modern managers responsible for international operations depends on their cultural intelligence (Sozbilir and Yesil, 2016)

Cultural diversity and intercultural dialogue are highly topical and widely discussed issues. Cultural diversity covers a wide range of phenomena, including symbols, heroes, rituals, values and practices (Albu, 2015). Therefore, employees and managers working in international companies, i.e. in multicultural work environment, should possess adequate knowledge about the cultures of their co-workers.

Positive aspects of cultural diversity among team members include the exchange of knowledge and experience between them, which can lead to better results and the achievement of objectives (Mukherjia, Jainb, et al., 2016, p. 9). However, if cultural diversity is to bring positive results, managers of multicultural teams must possess a high level of intercultural competence, manifested in their ability to adapt to culturally diverse work environment, in their openness and sensitivity to other cultures, and in their ability to negotiate and apply management tools suitable to multicultural environment and to build and manage international teams.

"Intercultural competence includes attitude, knowledge, interpretation and relating skills, discovery and interaction, as well as critical cultural awareness" (Byram, 1998, in: Gonçalves , 2014, p. 34). Intercultural competence also covers such treatment of people coming from other cultures that is not offensive or contemptuous.

Intercultural competence is defined as the individuals' ability to notice, understand and accept differences in their own cultures and those of other countries, and to respond adequately to differences through appropriate behaviour and communication (Gonçalves 2014). This competence also includes their systems of values and the ability to communicate effectively across cultures (Dimitrova and Chakarova, 2015).

International human resource management should be based on good practices and be part of strategies built around specific competencies of a given organization, which are key to achieving its competitive advantage on the global market (Edwards and Kuruvilla, 2005). Nowadays it is cultural

competence – with a particular role of cultural intelligence discussed in the article – that is considered to be the most important of these competences.

It is worth mentioning that, although it seems obvious that cultural intelligence is so crucial, especially in the context of the international activity of contemporary enterprises, so far certain aspects of the significant role it plays in contemporary companies have not been fully acknowledged (Stening, 2006).

Cultural intelligence understood as the ability to quickly adapt to and effectively act in diverse cultural environments (Piwowarczyk 2016) is essential for employees' and managers' functioning in multicultural environment and aiming at achieving the goals of their teams and the company. In the organizational context, cultural intelligence is simply the ability to deal effectively with cultural differences within an organization (Hu, Wu, et al., 2019).

The success of international companies to a great extent depends on cultural intelligence (CQ) of its employees who interact with people from other cultures (Ang, Van Dyne and Rockstuhl, 2015). Managers' cultural intelligence is particularly important, as it enables them to effectively operate in culturally diverse contexts, helps them to understand the norms, principles and values recognised in different cultures, and facilitates their understanding of different cultural principles in terms of working style, team leadership, communication and interactions with employees. Cultural intelligence exerts a significant impact on intercultural adaptation, the quality of performance, trust and cooperation in teams, team performance, and global leadership skills necessary to operate in international environment (Engle and Nehrt, 2012).

Moreover, cultural intelligence affects the relationships between employees and managers sent to foreign branches of their companies and their local co-workers, facilitates the resolution of intercultural arguments and ethical dilemmas, supports preparation of effective training courses and development programs for employees working in various cultural environment, enables the formation of effective intercultural teams and cooperation of their members, the development of managers' global thinking, and their ability to do business and build relationships with foreign clients (Stening, 2006, pp. 76-77).

Cultural intelligence of managers working in international organizations should help them develop openness and tolerance of cultural diversity within their teams. Managers should be more flexible and able to apply appropriate management styles and communication patterns in relation to different cultures. Their cultural intelligence should facilitate the implementation of activities that bring together culturally diverse employees.

Theoretical and practical knowledge of managing cultural diversity and first-hand experience in working with multicultural teams are essential for managers who want to support the operations of their companies on the global market (Agarwal and Saif Al Qouyatahi, 2017).

"Demonstrating culturally intelligent behaviour is therefore vital if individuals and organizations are to overcome the challenges presented by cross-cultural exchanges" (Solomon and Steyn, 2017), and that is why practitioners and theoreticians continue their efforts to identify and define individual characteristics that facilitate the individuals' successful functioning in different cultural contexts, especially as members of multicultural teams (Engle and Nehrt, 2012).

It is worth emphasising that "in order to function effectively, individuals need to be socially apt in deciding on the most appropriate behaviour suitable in a cross-cultural interaction" (Hartini, Fakhrorazi, et al., 2019, p. 217).

It is cultural intelligence (CQ) that allows managers and employees to function successfully in international environment, to deal with various - sometimes difficult - intercultural situations, and to anticipate and respond to the needs and expectations of culturally diverse employees and clients (Sozbilir and Yesil, 2016).

From the point of view of a manager who manages a multicultural team, it is important to create such work environment in which employees from various cultures can openly express their opinions, suggest solutions, and analyse problems from the perspective of their different knowledge and cultural experiences.

The crucial role of training courses organized by multinational companies for their managers and employees in the area of cultural sensitivity and awareness must be mentioned here. Such courses should aim at shaping attitudes and behaviours that lead to the acceptance of cultural diversity and the development of cultural intelligence of all employees. An international, multicultural, friendly workplace is the one in which all employees are accepted and treated equally, regardless of their cultural background.

Methodology

The pilot study, which was a qualitative one, was based on an interview method. The technique used in it was an individual in-depth interview, based on an interview scenario with open questions developed by the author.

The criterion for recruiting respondents was their employment in international companies and membership in international teams (in which at least 2 members were of different nationalities). The study was conducted in Kraków in 2020 among 6 persons (without dividing them into employees and managers) working in 4 international companies from the IT sector and 2 international branches of companies that operate as shared services centres in the area of accounting, payroll, and human resources).

Not all the respondents agreed to have their interviews recorded on a voice recorder, that is why the answers to the interview questions of 3 of them were handwritten by the author. The empirical material collected during all 6 interviews was transcribed, coded and categorised, and its quantitative analysis was also conducted.

All the respondents participating in the interviews were Polish, aged between 25 and 42 (4 women and 2 men), who worked as: Senior Developer, Product Manager, Event Marketing Specialist, Team Leader, Business Development Manager, HR Business Services Specialist.

The aim of the interviews was to obtain information whether the respondents are familiar with and understand the concept of cultural intelligence, whether, in their opinion, CQ has an impact on international human resource management in the organizations in which they are employed, and whether they are able to indicate those areas in which they believe CQ is important in human resource management. The author also wanted to discover whether and why, in the respondents' opinion, CQ is important for employees who work in international organisations and for managers who manage international teams, and whether they have ever taken part in training courses devoted to working in culturally diverse environment.

Cultural intelligence – the results of the pilot study

The pilot study consisted of 6 individual in-depth interviews, and can be treated as a preliminary step to the further study the author is planning to conduct in Poland, the Czech Republic and Spain among employees of international companies.

The respondents who took part in the pilot study were people working in international environment (4 international companies operating in the IT sector and 2 international branches of companies that operate as shared services centres in the area of accounting, payroll, and human resources).

The questions the respondents answered during the interviews included the following aspects: how do they understand the term "cultural intelligence"?, does CQ exert, in their opinion, an impact on international human resource management in the organizations in which they work?, is cultural

intelligence important for members of teams consisting of people of different nationalities?, is it important for managers of international teams in their organizations and why?, have they participated in training courses devoted to working in multicultural teams?.

The respondents included 4 women aged between 25 and 42 and 2 men aged between 28 and 35. All of them worked in international companies and were members of intercultural teams consisting of employees of at least 2 nationalities.

Due to the qualitative nature of the empirical material, the respondents' answers concerning their understanding of the concept of cultural intelligence, are presented below literally, as quotations of their answers. Respondent 1 (female, aged 25) - "cultural intelligence is the ability to understand and accept diversity; it is about cultural diversity; it is about accepting employees from other cultures, even if we are very different". Respondent 2 (female, aged 29 old) - "in my opinion, cultural intelligence is simply the ability to accept that people come from diverse cultures and are different in terms of behaviour, communication, how they work, what values they adhere to, even how they dress, what they consider important or irrelevant". Respondent 3 (female, aged 35) - "I think it's sensitivity to other cultures and the ability to work well with people from other cultures; cultural intelligence is the ability to accept cultural differences, e.g. in a team when there are people of various nationalities". Respondent 4 (female, aged 42) - "cultural intelligence is the ability to feel comfortably in environment where diverse cultures meet and also the ability to perceive people from other cultures in a positive way". Respondent 5 (male, aged 28) - "it is the ability to accept culturally diverse people. Understanding that people from other cultures think differently, work differently, behave differently in various situations". Respondent 6 (male, aged 35) - "cultural intelligence is the ability to communicate easily with people from other cultures, it is the ability to understand cultural differences and to cooperate easily in diverse environment where there are people from different cultures".

All respondents agreed that cultural intelligence plays a vital role in international human resource management, which is evident in the different dimensions of employee management in their organisations. During the interviews, the respondents indicated the areas in which, according to them, cultural intelligence is particularly important. These were: recruitment and selection - 4 respondents; appraisal interviews - 5 respondents; employee training and development - 4 respondents; talent management - 4 respondents; motivating and engaging employees - 6 respondents; conflict resolution - 5 respondents; the ability to respond to emotions of people of other nationalities - 6 respondents; building positive relationships between employees - 5 respondents; and the quality of team work (how fast teams work and achieve organizational objectives) - 5 respondents.

All respondents participating in the study emphasised that cultural intelligence is particularly significant in international work environment, for both employees who work in international teams (6 respondents) and for managers who manage such teams (6 respondents).

As far as international team members were concerned, the respondents were of the opinion that cultural intelligence greatly affects effective cooperation between people from various cultures (6 respondents), an effective way of building relationships in a team (5 respondents), effective communication (6 respondents), the ability to share knowledge (4 respondents), and the ability to resolve conflict together (5 respondents).

As far as managers were concerned, the respondents were convinced that cultural intelligence allows them, first of all, to manage people of various nationalities and cultures in a more conscious and sensitive way (6 respondents) and to adapt human management solutions to employees' diverse needs and expectations (5 respondents). Four respondents had participated in training courses addressing such issues as cultural diversity of the teams in which they worked or positive and negative aspects of working in multicultural teams. Participation in these courses undoubtedly increased their knowledge of cultural intelligence. Two respondents had not participated in any training related to working in culturally diverse teams.

Summing up, the pilot study revealed that all respondents were familiar with and understood the concept of cultural intelligence. They also notice an obvious link between cultural intelligence (for both employees and managers) and various areas of human resource management in international companies where they worked.

Discussion

It is worth repeating here that the study whose results are reported in this article was a pilot study, with small sample of 6 respondents, intended to serve as an introduction to a further, more extensive study (which will be conducted among employees of international companies in Poland, the Czech Republic and Spain). Individual in-depth interviews yielded the following results. All six respondents were familiar with and understood the concept of cultural intelligence and were able to explain and describe it. In their opinion, CQ plays a vital role in international human resource management and influences various areas of human resource management, such as: recruitment and selection, appraisal interviews, planning employee training and development, talent management, motivating and engaging employees, conflict resolution, the ability to respond to emotions of people of other nationalities, building positive relationships between employees, and the quality of team work (how fast teams work and achieve organizational objectives).

The study also revealed that, in the respondents' opinion, CQ is important both for employees and managers who work in international environment. They believe that cultural intelligence allows managers to manage people of diverse nationalities in a more conscious and sensitive way, as well as to adapt human management solutions to culturally diverse employees. The interviews provided information concerning the respondents' knowledge about and their preparation for working in intercultural teams (4 respondents had previously taken part in training courses devoted to, among others, issues related to working in a culturally diverse team).

The results of the pilot study provided the answer to the research question: Are employees of international companies familiar with and do they understand the concept of cultural intelligence and are they able to determine the impact of cultural intelligence on various areas of human resource management?

As a follow-up of the pilot study, the author is planning to conduct - in the near future - individual in-depth interviews with employees of international companies in Poland, the Czech Republic and Spain who work in culturally diverse teams (whose members are of at least 2 nationalities). The study will cover much larger sample than the one described in the article and will investigate the way in which respondents understand the concept of cultural intelligence, and its role and importance in international human resource management, but this time from the perspective of employees of different nationalities.

Conclusions

On the basis of subject literature review and individual in-depth interviews (the pilot study), the author of the article demonstrates the importance of cultural intelligence in international human resource management. Her further study investigating cultural intelligence in a wider context (separately among employees and managers of various nationalities) will be conducted on a much bigger scale among respondents from three countries.

The constantly growing role of international cooperation makes it necessary for managers and employees of international companies to pay a lot of attention to managing cultural diversity, i.e. understanding and accepting diverse ways of thinking, working style or problem solving.

The ability to successfully interact with representatives of various cultures has become a key feature of the global business world today. In order to effectively function in international work environment and manage human resources on an international scale, employees and managers must possess and develop cultural intelligence.

Cultural intelligence, especially in international human resource management, in which managers and employees work at the intersection of different cultures, helps them to notice, understand and accept behaviours, working style, communication, norms, and values adopted in various cultures. Cultural intelligence ensures faster adaptation to and smooth functioning in culturally diverse work environment, facilitates communication, and fosters positive relationships with clients, co-workers and members of other teams. It plays an important role in the process of recruitment and selection of employees from various cultures, during appraisal interviews, in planning employee training and development, in motivating employees, in resolving conflict and – last but absolutely not least – in building positive relationships.

Managers and employees with a high level of cultural intelligence understand what and why is accepted in different cultures, are able to work together with representatives of other cultures to achieve organizational goals, and to share their knowledge and experience.

Abstract

The article presents directions of creative clusters' development in Russia and prospects of their creation and activity. The authors pay special attention to improving methodological approaches to definition and characterization of «creative clusters». Authors also formulate issues of infrastructure support for creative clusters development, directions of improvement of methodical approaches and criteria for evaluating effectiveness of russian creative clusters.

Keywords: Creative Industries, Clustering, Creative Cluster, Intellectual Creative Products.

Introduction

The primary task of any state is to maintain competitiveness. Destabilizing factors of the modern economy encourage economic actors to seek new forms of economic activity to support it, including the concept of cluster development, which is implemented by the state in the framework of innovative economic policy. In modern economy clusters can serve as the most effective form of integration of financial and intellectual capital, providing the necessary competitive advantages. This is emphasized by various researchers.

Thus, M. Porter in the book «Competitive strategy: methods for analyzing industries and competitors» (2011) defined clusters as «geographically concentrated groups of interconnected companies, service providers, specialized suppliers, companies in related industries, and organizations associated with their activities (universities, trade associations, and standardization agencies) that compete in a number of areas, but work together».

In a research study «Classification of trade and local industries in the US economy. Panorama of the European cluster» (2016) mentioned that the corresponding division of the European Commission (EnterpriseDirectorate-General) refers to a cluster as «a group of independent companies and related organizations that: first, compete and cooperate; second, are geographically concentrated in one or more regions; third, specialize in specific areas of activity and are linked by common skills and technologies; fourth, are traditional or based on knowledge; fifth, may have a management body, or may not have one».

It is interesting to define Ketels K., who focuses on a geographically specific region and their interconnectedness with certain interdependencies to provide goods/services. Because the cluster components are geographically close, they can benefit from several positive externalities related to the specifics of their location. These positive effects may include: access to specific human resources and suppliers; transfer of knowledge; new knowledge gained as a result of close cooperation with specialized suppliers and consumers. Therefore, a cluster that exists within these rules is a specially organized space that allows large firms, small businesses, suppliers (equipment, components, specialized services), infrastructure facilities, research centers, universities, and other organizations to develop successfully. At the same time, it is important that the cluster achieves primarily a synergistic effect, since the participation of competing enterprises becomes mutually beneficial.

From the point of view of our research, the works of G. Mensch listed in the research named «Synthesis of cluster strategy on the basis of system-integration theory» (2019) related to the analysis of economic dynamics are of great importance. On the basis of a huge empirical material in the field of technological innovation at the industrial stage of development of society, G. Mensch established the cyclical and uneven innovation process, completed the formation of powerful clusters of basic innovations at the stage of depression (i.e., when the economy is characterized by the greatest susceptibility to innovation). Therefore, clusters themselves contribute to the launch of another large cycle of economic conditions, and due to depression, the search for survival opportunities is stimulated, whereas they can be provided by the innovation process (this phenomenon has been called the «trigger effect of depression»).

In economic science, a whole theory of clusters has been developed and widely developed, which is understood as a group of organizations that are related to each other (including companies, research and other organizations), localized by geographical principle, mutually cooperated, which contributes to the growth of the cluster's competitiveness as a whole.

The concept of creating creative clusters was first proposed in 2000 by urban development specialist CH. Landry in the work «Creative city». The researcher, in particular, mentioned the prospects of «combining the creative resources of people and communities to form an economically and socially prosperous urban environment», emphasizing the positive consequences of such integration. The terminological designation of creative clusters was first formulated by S. Evans, curator of the UNESCO program «Creative cities»; in particular, it was noted that «... a creative cluster is a community of creative-oriented entrepreneurs who interact in a closed territory». One of the main tasks of forming a creative cluster is to establish partnerships between creative enterprises that are part of it.

This problem is highlighted by the fact that in the last 10-20 years the formation of creative clusters has become an important part of state policy in the field of regional development in many countries of the world. The integrating nature of the cluster approach as a tool for regional development lies in the possibility of complex problem solving.

Further, these problems will be considered from the point of view of the experience of implementing cluster initiatives in various countries with an emphasis on the development of cluster structures in Russia. This study is carried out in the conditions of imperfection of the legal framework, insufficient domestic practice of implementing the cluster approach and lack of understanding by the majority of the population of the importance and prospects of the cluster system. To date, it is impossible to talk about the full functioning of the Russian cluster system. In order to solve the main problems that hinder the creation and slow down the development of creative clusters in Russia, the following tasks are set:

1. Consider theoretical component of creative clusters, its structure, identify characteristic features, and determine the range of stakeholders.
2. Analyze foreign experience in the development of creative clusters, identifying its advantages and disadvantages.
3. Analyze the foreign practice of the system of creative clusters and identify opportunities for introducing the most successful elements of foreign experience into Russian practice.
4. Consider the process of managing a cluster system in Russia.

As the main approach for the study, a system approach was chosen, which is based on the consideration of the object as an integral complex of interrelated elements.

Authors used the following general scientific methods in the research process: tools of deductive and inductive analysis, which allowed combining the conclusions of individual authors and formulating their vision of the problem, and the method of analysis.

The method of expert survey was also used in the research process. One of the authors worked as an expert of Working group of the results' of intellectual activity commercialization together with the InterMedia News Agency (Moscow, Russia, 2017-2018). This working group was created in April 2017 in the Council of Intellectual property in Russian Federation as part of Council's initiative to prepare a draft law on culture. The study is supported by the results obtained by CCI working group: «Preliminary results of a comprehensive study of creative industries» and «Basic block diagram of the sphere of culture» (2018).

Method

Turning to the initial stages of cluster' development abroad, it should be noted that the history of cluster development in Europe and North America began more than 70 years ago. In the second half of the XX century, according a research study by Abashkin L., Artemov S., Alenkina E., Gokhberg L. (2017), the economies of many countries on these continents faced the problem of decline existing industrial clusters on their territories. In large cities, there is a need for new jobs, sources of replenishment of city budgets, points of growth of the city economy. In order to solve this problem, the former industrial territories were reorganized into creative spaces; this is how art centers, concert and exhibition halls replaced the production facilities.

During their existence, creative clusters have accumulated vast experience in «revitalizing» (transforming, updating) industrial territories, creating infrastructure, regulating business processes, etc. Creative clusters are usually located on territory of former industrial zones or abandoned buildings; the latter stimulates innovative activity, transforms the districts and cities in which they are located. Examples of successful creative clusters abroad are Hollywood (USA), Truman's brewery (UK), Zollverein (Germany), and others; there is a significant variety of creative clusters; they can be classified by scale, by areas of activity (cinema, fashion, fine art, design, architecture, etc.), and other grounds. The activity of creative clusters is supported by the fact that currently European cluster development programs are integrated into national policies and have the following characteristics:

- most cluster development programs are priority for the state;
- programs are necessarily coordinated with the tasks of other programs, which allows the most efficient use of financial resources;
- the importance of internationalization;
- program operators are actively developing individual clusters;
- the quality of cluster management is of particular importance at present;
- monitoring and evaluation are complex, but necessary;
- the importance of cluster policy is important not only for the region, but also for the country as a whole;
- innovation development and cluster development programs are linked;
- the program strategy takes into account the development of newly formed clusters, and support for Mature clusters.

The «Strategy for innovative development of the Russian Federation for the period up to 2020» also focuses on the need to support cluster initiatives. Analysis of the number and nature of creative clusters in Russia has shown that they are mainly located (and this is natural) in large cities, centers of Federal districts and cities with millions of people according a document named «Methodological recommendations for the implementation of cluster policy in the subjects of the Russian Federation» (2008). Antonova A. (2015) mentioned that the first creative cluster was formed in 2006; since that

time, «ARTPLAY» (its specialization is architecture), «Flacon» design factory, «The Factory», «ARMA», «Vinzavod» (cluster profile – photography and fine art), «Garage», «ART Strelka» cultural center, etc. have been formed and successfully operate in Moscow; in St. Petersburg there are «The Floors», «The Weavers», «Contour Family», «Museum of street art», «More Place», «Artmuza», «Taiga», «Erarta», «Pushkinskaya 10», «Lumiere hall», «Golitsyn loft», «Mansion on the Palace Embankment». In Yaroslavl, Krasnoyarsk, Novosibirsk, Yekaterinburg, Ulyanovsk, Ufa, Kazan, Kostroma, Ivanovo, Vladivostok and Rostov-on-don there are also appear more and more creative clusters every year.

According to existing statistics, creative companies currently make a significant contribution to the Russian economy. Over the past few years, their share in GDP has been more than 5%. In addition, according to data provided in UN Reports, 7.3% of Russian population is employed in production of creative products according to Abashkin L., Artemov S., Alenkina E., Gokhberg L. (2017). However, creative and cultural industries are underestimated as full-fledged priorities for regional development, including as an object of cluster policy: while KIBS, creative and cultural industries operate in 16 industries (production of films, videos and television programs, publishing of sound recordings and music; performing arts activities; distribution of films, videos and television programs; provision of services in the field of marketing, design and publishing; distribution and e-Commerce; provision of financial services; insurance services; production of designer clothing), the number of industries with cluster initiatives is 0.2.

It seems that a characteristic feature of Russian clusters, which include creative organizations, is the order of their creation and management: clusters are created on the initiative of individuals and entrepreneurs («from bottom to up») and operate without receiving support from the state. All the more important is the work that is currently being carried out to combine existing clusters. For example, Sofia Trotsenko, Dean of the Ranepa school of design and founder of the Vinzavod creative cluster support Foundation (Moscow), announced the creation of the Union of creative clusters in November 2019. It includes «Winery», «Bottle», «ARTPLAY», «The Factory». The reasons for this Association are the situation that has developed around creative industries and creative clusters: growing interest on the part of municipal authorities and the government; unresolved issues related to the General terminology, standards for the creation and operation of creative clusters and management issues. Issues of support for creative companies are increasingly being discussed at the regional and municipal level (largely due to such «private» initiatives).

The provisions of Russian legislation, however, do not contribute to new projects in the field of development of creative clusters, since they do not contain even the minimum necessary definitions. Only the concept of «innovation cluster» is highlighted as «... a cluster in the so-called «new sectors», such as information technology, biotechnology, new materials, as well as in the service sectors related to the implementation of creative activities (for example, cinematography)». Thus, in the legal field, creative clusters were assigned to the service sector, and the categories «innovative clusters» and «creative clusters» were equated to each other. However, the following indisputable position is noteworthy: the results of innovation activities of an innovation cluster may lie in technological, product, marketing, and other areas; results of innovation activities of creative clusters contain creative products related to the activities of creative industries.

In this regard, the authors of the article suggest introducing a new concept into scientific circulation – «results of intellectual creative activity», since the results of this nature are the actual result of the activity of creative clusters. This is a significant difference between them and other innovation clusters/organizations that also produce a «creative product», but the result of their activity is not creative products in the narrow sense (products of creative industries), but creative products as a result of creative activity in the broad sense, new products, technologies or management innovations. Organizations of this type can be part of a creative cluster to provide its infrastructure, but its core must be the companies that produce the creative product. According to the authors, the list of possible results of intellectual creative activity should include: musical works, works of drama, fine art, architecture and landscape design, literary works, movies and TV series, clothing design, phonograms, web design, news releases, talk shows, reality shows, objects of decorative and applied art, objects of photography,

journalism, etc. In this way, results of intellectual creative activity will be in the legal field of copyright and related rights legislation.

The issue of classification of industries of enterprises included in the creative cluster is also significant. The identified problem is based on the absence of a generally accepted classification as a whole: both the types of activities of clusters related to creative sector of economy, and the list of creative industries whose representatives can be combined into a creative cluster. There is no single Federal law defining the concept of «creative industries» in Russian Federation at the moment.

According to the WIPO classification, creative industries are defined as «the economic sector that creates products based on creativity and cultural resources» and combine music, visual and performing arts, film, fashion, crafts, literature and publishing, advertising, design, architectural design, the Internet and multimedia.

Kutsenko E., Abashkin V., Buderkina E. (2018) mentioned that referring to the experience of foreign countries: in the United States, the creative industries are divided into six branches: 1) museums and collections; 2) performing arts; 3) visual arts and photography; 4) film, radio and TV; 5) design and publishing; 6) art schools and services.

In the UK, the following classification of creative industries is accepted: advertising, architecture, art and Antiques, craft, design, fashion, film and video, music, performances, publishing, TV and radio, computer games and video; however, many researchers consider it erroneous to include IT, software, sports, and computer games in the creative industries according to Voitova L. M., Vasilieva Yu. S., Smirnova V. R. (2019).

Results

Practical application and implementation results of intellectual activity by creative clusters is possible when developing appropriate legal support that will solve a number of problems that arise in the process of creating and commercializing intellectual property. It is important to create a favorable climate in this area - creating conditions and an atmosphere conducive to the generation of new ideas, the manifestation of initiatives on the part of creative people and their implementation.

It seems that it is necessary to highlight the problem of produce the results of intellectual creative activity. When the results of intellectual creative activity not be created within the cluster, there can be no reason to define the cluster in the «creative» terminology.

The second distinctive feature of creative cluster should be the list of subjects that make up it. These can be: a) organizations (the «core of the creative cluster») that result in the creation or replication of the results of intellectual creative activity: record labels, film studios, production centers, publishing houses, galleries, concert venues, museums related to the theme of the creative cluster, theaters and theater studios, craft workshops, workshops of artists and sculptors, photo studios, circus studios, exhibition centers, radio and television centers, dance and choreographic studios, architectural bureaus and design studios, fashion houses, writers, actors, recording studios, etc.; b) providing organizations: bookstores, publishing houses, antique stores, libraries, cinemas, ticket offices, points and shops for the rental and sale of intellectual asset, museum and exhibition facilities, printing houses, fashion industry enterprises, examination of art objects, auctions of art objects, organizations of wholesale and retail trade in discs, albums, etc.; c) infrastructure objects that are not related to creative industries: catering enterprises; trade; musical instrument stores; construction and repair organizations; enterprises that provide Internet services, security, hairdressers, beauty salons, etc. It is necessary to observe certain proportions of these types of organizations' structure in cluster.

There are certain tools, well-developed methods and experience to measure cluster initiatives, (projects, activities, programs). However, there are certain difficulties in measuring the cluster. Statistical agencies do not collect or publish any data about clusters, clusters cannot be measured, evaluated, or compared based on publicly available statistics.

A cluster is measured primarily by macroeconomic parameters that allow us to assess its scale, weight, and significance for the regional and national economy. Examples of such parameters:

- the cluster's contribution to the gross regional product (in monetary terms and as a percentage of GRP);
- cluster contribution to the region's industrial production (for industrial clusters);
- the cluster's contribution to the export of the country and region, the cluster's position in the national and global markets;
- the cluster's contribution to the region's innovative products;
- employment in the cluster.

Cluster measurement is the subject of cluster mapping. At the same time, macroeconomic parameters are supplemented by a number of microeconomic ones (cluster enterprises, regional infrastructure). It is important to measure clusters in order to assess their current and future significance for the region's and country's economy. Cluster programs and projects are measured using the program-target approach. Examples of parameters: goals, expected results and indicators of their achievement; performers and deadlines; budgets and sources of funding.

Abashkin L., Artemov S., Alenkina E., Gokhberg L. (2017) mentioned that in Russia, following the example of European countries, specialists of the Higher school of Economics have also created a Cluster Observatory, but the mechanism for evaluating and monitoring cluster activities has not yet been set up. The publicly available information provided by the Observatory does not meet the requirements of stakeholders, and there is no direct access to cluster data. Research on clusters is carried out by various organizations, such as the Russian venture company (hereinafter referred to as RVC), the Russian Bank for support of small and medium-sized businesses, the Association of innovative regions of Russia (hereinafter referred to as AIRR), and others.

There is no aggregated information about cluster’s development in the open access. Enterprises participating in clusters analyze their own economic activities for tax reporting and internal purposes, some of the statistical data for clusters are provided by cluster development centers, but the information is collected in different time periods and according to different indicators. The Russian Cluster Observatory provides the most comprehensive and complete information on cluster pilot programs. However, this is not enough to make a conclusion about the dynamics of cluster development and their impact on the country's economy.

With regard to the introduction of creative clusters in Russia, we can say that the fundamental task is to develop a legal framework for creating and regulating activities of the above-mentioned associations, which is possible through the creation of a package of draft legal acts. In addition to preparing draft laws and draft by-laws, the fundamental task is to create and plan public management decisions for the implementation of cluster policy.

Thus, the authors propose to solve the methodological problems of creative clusters’ functioning as follows:

- to develop and approve a list of creative industries;
- to develop a methodology of creativity - interpretation of the concept, approaches to the study of creative industries, indicators, which will be studied by the industry (e.g., such as employment in the cultural sector, enterprises in culture sphere, export and import of products and services of creative industries, the spending on culture, etc.), classification of creative industries;
- to introduce the category «results of intellectual creative activity» into scientific circulation;
- to identify the distinctive features of creative clusters (first, note that the product creative cluster have to classified as an «intellectual creative activity results»; second, the list of subjects (the «core», providing and infrastructure organizations) in its composition);

– to fix the legal status of creative clusters, their main activities, rights and obligations of subjects, and the procedure for supervising their activities.

Abstract

In today's world economy, innovation is seen as the main factor of competitiveness and sustainable economic development. In developed countries, small enterprises make significant contributions to the innovative development of national economies by leveraging their competitive advantages in the flexibility and responsiveness of decision-making. The article focuses on the role of small business in sustainable development. The article considers the possibilities of development of small business in the period of innovative economic development. The foreign experience of economic policy with regard to small business was studied, key problems and risks associated with the development of small innovative enterprises were identified and recommendations were made to improve the system of state support for small and medium business, taking into account the peculiarities of its development in the current environment.

Keywords: Small Business; Innovations, Competitive Advantages, State Support.

Introduction

Small business is the most important element of the market economy, without which the state cannot develop harmoniously. Small business largely determines the economic growth rate, structure and quality of the gross national product. According to the UN, in general, small and medium-sized enterprises in the world employ almost 50% of the labour population and produce 33-60% of the national product.

The development of small businesses creates prerequisites for accelerated economic growth, promotes diversification and saturation of local markets, while at the same time compensating for the costs of market economy (unemployment, market fluctuations, crisis phenomena).

Small entrepreneurship has great potential for optimizing the way the economy and society as a whole develop. The characteristic feature of a small enterprise is the high intensity of use of all kinds of resources and constant striving to optimize their quantity, to provide their most rational proportions for these conditions. Small businesses make a significant contribution to innovative production because they are the most mobile and can react quickly to revolutionary innovations in the economy and society.

Role of small business in sustainable development

Theories about the role of small business in the economy began to be developed in the 1900s. J. Schumpeter (1908) saw small firms as a place for gathering innovations and changes included in the economic system. In the 1980s, when the demand for mass industrial products based on fourth wave technologies saturated, the emphasis shifted from mass production to - individualized. These factors have strengthened the small business sector, making it more flexible and responsive to changing conditions and consumer demands. The opinion about the decisive contribution of small business to the development of the economy is becoming more widespread nowadays, in the era of another technological revolution. For example, in the book by Schumpeter J. (1908) mentioned that the concept of "Think Small First" is common in the European Union, which implies the creation of the most favorable environment for the functioning of small businesses.

Z.Ax and D.Odrech (1988) argue that small enterprises contribute significantly to technological development, providing about half of the most important innovations of the 20th century. A. Cooper (1964) in his article "R&D is more effective in small companies" concluded that small enterprises had spent considerably less time and money on the development of a particular product because of the higher ability of technical staff, their greater interest in the cost of the project and their more effective communication and coordination. W. Baumol (1972) believes that breakthroughs are achieved by small enterprises and suggests that large enterprises, because of their inherent organizational structure, will tend to specialize in improving innovations, while small enterprises will tend to specialize in revolutionary breakthrough innovations.

G. Aldrich and E. Auster believe that small and large enterprises can benefit from mutually beneficial cooperation, which will accordingly have a positive impact on economic development. The benefit of small enterprises is to access the missing resources through close links with large enterprises (through franchising, long-term contracts, mergers and acquisitions). D. Birch (1987) points out that the most successful companies start as small firms, and many of them remain small. The following conclusions were drawn from the Dun and Bradstreet credit ratings database for December 31, 1969, 1972, 1974 and 1976. 1. On average, about 60% of all jobs in the US were created by firms with 20 or less employees, while large companies (over 500 employees) created less than 15% of all jobs. 2. After more than 4 years in the market, the company's ability to create jobs was significantly reduced.

The British scientist D. Storey in his book "Entrepreneurship and New Firm", as opposed to D. Burch, argued that large enterprises create most of the new jobs and are responsible for the elimination of most jobs. Most small firms have low growth rates and are liquidated a few years after their establishment. D. Story believes that the contribution of small business to job creation is not supported by facts, and therefore questions the desire of politicians to put small business in a more favorable environment. In the book "Basic information about the small business sector" (1994). D. Story concluded that it was the fast-growing firms that made up a small proportion of all small businesses that contributed significantly to job creation, which brought him closer to D. Birch's conclusion about the role of gazelles. In the same study (conducted in 1989-1992). D. Storey (1993) showed that small firms in the USA and England create new jobs faster than larger firms, although their contribution is not as high as he originally estimated. Moreover, small enterprises were more reliable in job creation and less exposed to macroeconomic conditions, regardless of the stage of business cycles in the economy. However, the wages and additional benefits for workers in small enterprises were lower compared to those in large ones.

D. Henrekson's (1999) study "Institutional Effects on the Evolution of the Size Distribution of Firms" ("Institutional Effects on the Evolution of the Size Distribution of Firms") provides a statistical analysis of the evolution of Swedish firms from the late 1960s to the early 1990s and the evolution of the number of employees in firms of different sizes since 1984. Since the late 1960s, the relative importance of medium-sized firms (10-199) has gradually declined. This trend can be seen in the economy as a whole, in the private sector and in manufacturing. The reduction in the number of medium-sized firms is due to the fact that the Swedish tax and pension system, credit market regulation, labour legislation, and a high degree of monopolization of the service sector do not

contribute to the development of small and medium-sized businesses. Henrexon and Davis have shown that, in Sweden, large firms tend to increase their share of the economy at least until the mid-1980s. In contrast to Henrexon and Davis, Loveman and Sengenberger (1991) argue that "there is a general trend towards small organisational forms" in the 19 six largest OECD member states, which first became prominent in the US in the 1970s and then with a slight delay in other major economies.

I. Kitov's paper describes the evolution of the size distribution of US firms from 1992 to 2002. Two approaches were used in estimating firm size: sales volume and number of employees. In the period under review, the share of medium-sized firms decreased and the share of large firms increased, as well as the return on labour in small and medium-sized firms decreased and grew in large firms. Individual industries show significant differences in the evolution of firm size distribution. The author proposes to take these trends into account when choosing industries and firm sizes for long-term investments. For the first time, K. Motokhashi (2016) conducted an extensive analysis of the innovation activity of an entire population of Japanese firms using the interrelationship between the Census and Enterprise Census and the IIP Patent Database. The results of this study showed that the innovation activity measured by patenting positively correlated with the performance of enterprises. Moreover, there is a strong correlation between patenting and survival for large firms and a strong correlation between patenting and growth for small firms. The results of a study by K. Motokhashi on the example of Japanese enterprises show that small companies face greater risks associated with patenting. Therefore, the state should provide support to small businesses for technology commercialization.

Opportunities for small business development in the period of innovative economic development

During the technological revolution, small businesses have unique opportunities to get innovative rents from the commercialization of basic innovations, recouping the costs of scientific research in emerging industries. Apple's success in delivering growth opportunities during the technological revolution is exemplified by its innovative personal computer and operating system solutions, as well as by the undervaluation of the PC market by large businesses. In other words, small business is already innovative by its nature, it turns into a key factor of transformation changes in the economy.

Small entrepreneurship provides mobility and dynamism to the economic system as a whole, promotes rapid commercialization of research and development results, as well as adaptation to changing conditions in all spheres of activity, which has a significant impact on the accelerated pace of innovative development.

Modern information technologies provide small businesses with access to new activities and increase the share of small businesses in the global market for goods and services.

In addition, information technologies create conditions for reducing production costs (Internet technologies significantly reduce the cost of processes in marketing, advertising, logistics, consulting, registration, organization of contacts with partners) and allow small businesses to increase their competitiveness.

All this indicates in favor of small business, which is becoming an important factor and enabler of dynamic business development.

Subjects of domestic small business in Russia have the most qualified staff. The share of specialists with higher education at small enterprises in 2018 amounted to 34.2% of the average number of employees, although the all-Russian level for manufacturing companies fluctuates within 20.8%. In organizations with 50 to 100 employees, the share of innovative products in the total volume of goods shipped is 16.3%, while the average figure for domestic companies does not exceed 12%.

Small companies are also leading in terms of innovative products and services. While for small businesses in 2018 the output per employee in the production sector ranges from 72.1 thousand to 115.1 thousand rubles, and for services - from 39.9 thousand to 49.2 thousand rubles, for large companies -36.9 - 51.8 thousand rubles and 0.65 thousand - 0.94 thousand rubles, respectively.

Incapacity of products manufactured by small enterprises in Russia is 3 times higher than that of large organizations, and the cost of innovation per employee at small enterprises in 2018 amounted to 64.5 thousand rubles / person, and in organizations of large businesses - 17.4 thousand rubles / person.

At the same time, according to official data, only 6.2% of the total number of organizations are engaged in the introduction of innovations in the country in 2018, while in industry it is no more than 10%. Costs of innovation do not exceed 1.5% of the value of industrial products, while in the EU countries this figure is much higher.

First place in the ranking of world leaders in the field of innovative development is occupied by Switzerland, followed by Sweden, the United States of America (USA), the Netherlands and the United Kingdom; such data are given in the Global Innovation Index (GII) 2019 report, which also indicates that India, South Africa, Chile, Israel and Singapore have emerged as leaders in their regions, while China, Viet Nam and Rwanda have emerged as leaders in their respective income grouped country categories.

Methodology

In the process of research the following methods were used: methods of historical, logical-structural and system analysis, tools of inductive and deductive analysis, which allowed to combine the conclusions of individual authors and formulate them into a single problem. A comparative analysis of small and large enterprises provides insight into the role of small business in innovation and its contribution to the world economy. Using expert survey methods and content analysis, the survey identified the main problems and risks of small innovative enterprises development in Russia. Involvement of specialists in the field of innovation activity and employees of professional Russian small business associations in the survey made it possible to focus on the emerging difficulties in the field of interaction between government and business in the framework of development of application and implementation of innovative technologies in the business environment. As a result, a three-stage analysis of small business development was carried out: the possibilities of small business development and the level of innovative development of the economy were investigated; the problems and risks of small business were investigated, and the essential role of small business in the innovative development of society and economy was defined. The methods used allowed us to draw further conclusions about the impact of small business on Russia's economic development.

Problems and Risks Associated with The Development of Small Innovative Enterprises

Small innovative companies are one of the most effective tools to successfully bring scientific developments to the market. But small enterprises face the following challenges in attempting to create innovative products:

1) the problem of recruiting and retaining qualified staff;
2) the problem of insufficient resources for large-scale research;
3) the problem of lack of resources to introduce an innovative product to the market;
4) lack of advantages of "group research" conducted by engineers who develop new products;
5) the problem of fierce competition with large enterprises even if innovative products successfully enter the market.

The peculiarities of creation and operation of small innovative companies in Russia create a number of specific risks that require assessment, accounting and management. Even at the stage of selecting an innovative development for subsequent implementation from the existing pool of ideas, there is a deferred risk of lack of market demand for the product of small innovative companies after its launch into industrial production, partially informalized relations with the "parent" institution, which negatively affects the prospect of attracting investors. In addition, the risks associated with the licensing of small innovative companies can be regarded as legislative, as the long term of the license directly affects the success of the project.

It should be noted that up to the present day remains relevant conclusions made by G. Aldrich and E. Auster (1986) that the age and size of the enterprise affect changes in the structure of organizational populations... Small and new organizations face the threat of novelty and small size. This threat is manifested, first of all, in the lack of trust of market participants due to their ignorance, in recognition and tolerance of established brands.

For Russian small production enterprises, the problem of survival is topical: only three out of one hundred small enterprises have been operating for more than three years. Among the reasons for such statistics are management errors. Many managerial mistakes at the early stage of development of small production enterprises are related to the wrong choice of business model.

The difficulties of small enterprises arise at the stage of transition to industrial output. It is difficult for small enterprises to combine the cheapness of new products with its active advertising promotion and development of service network. In the event of financial difficulties, many small businesses have to be taken over by large corporations.

The main problem of Russia's lag in the innovation sphere is related to low demand from business for new technologies and innovative products. Russia is developing a catch-up development model, which is unacceptable for a technological revolution.

Current activities of small innovative companies also carry risks, primarily related to resource constraints. Often functions on realization of the basic and providing business processes of the small innovative companies are assigned to the scientific experts who are not professionals in the field of commercial activity. The implementation of this risk is associated with a decrease in the quality of these processes and can lead to negative consequences, primarily affecting the commercial success of the project.

Results

The analysis of small business development shows that it should be oriented to the markets of technological mode, as it is a supplier of components produced with the use of new technologies for mature industries. In order to secure a place in the technological landscape, small enterprises have to intensify their research and development. The share of small enterprises in federal support of research and development is also growing (up to 16.4%).

The Russian Federation has a multi-channel system of state support for small business that includes all the main types of support: financial, property, information and consulting, and personnel. The main measures of state support to innovative SMEs include:

1) R&D funding under the programmes of the Foundation for the Promotion of Small Innovative Enterprises;
2) financing the creation and development of infrastructure to support innovative SMEs (engineering centers, shared use and innovation technology clusters);
3) subsidizing part of the SME costs:
4) tax and customs privileges for residents of the Skolkovo Innovation Centre;
5) opportunity to establish small businesses under universities

But the current state support measures for SMEs in Russia have significant shortcomings.

First of all, Russia has not developed a systematic concept of state support for small business, instead of which separate measures and declarative strategies are taken.

Second, state support to small businesses is mainly directed at mass small and medium-sized enterprises, with unreasonably little attention paid to promoting the innovation activity of small businesses.

Thirdly, state support ignores the trends in small business development.

The Government has taken legislative measures to expand the access of small businesses to state and municipal purchases (the quota of small businesses has been increased to 15%, the initial price of a contract has been increased to 20 million rubles) and to purchases by state companies (the quota of small businesses is 10%). Also, measures have been developed to ease the administrative burden - a ban on scheduled control and supervision measures for three years in respect of small businesses, which, based on the results of the previous three years, did not reveal any significant violations of the RF legislation.

However, despite all efforts on the part of the government, the share of Russian small businesses in GDP is more than twice as low as in developed countries. Small and medium-sized Russian businesses lag behind the European Union, not only from the leading EU countries (Germany, France, and the UK), but also from the average level of all EU countries. The small business sector in the Russian Federation has concentrated its activities in trade and services.

At the same time, the contribution of small businesses to the Russian economy is much greater than that of medium-sized enterprises: the share of small businesses in employment was 22.6% and 24.4% in the turnover of enterprises in 2018, while the share of medium-sized businesses was 3.8% and 4.8%, respectively.

Conclusions

The analysis of the dynamics of small and medium business in the domestic economy shows that its development is non-monotonous. Over the period 1997-2018, a significant variation in the share of small business (and a less significant variation in the share of medium business) in employment, turnover and investment in fixed capital in Russia was found. The share of small enterprises in employment has a pronounced upward trend: from 12% in 1997 to 22.6% in 2018. The share of small enterprises in the turnover of all organizations decreases in 2008-2014 and increases to 24.4% in 2018. The share of small enterprises in fixed capital investments is most subject to variation. Reduction periods in 1997-2000, 2009, 2011 are followed by growth periods in 2001-2008, 2010, 2012-2018.

At the same time, the technological multiplicity of the Russian economy should be taken into account. Russia must simultaneously address the challenges of catching-up and forward-looking development. In the latter case, through direct public funding. Innovation clusters and technology platforms can make a significant contribution to the cooperation of small and large businesses, educational and scientific institutions. The state orientation of large enterprises in these sectors towards the purchase of innovative small business products is important to expand the opportunities for this business in testing promising areas of technological development.

For Russia, it is necessary to develop a state innovation policy to modernize industries and industries that use technologies from previous years, and to create and develop industries with a new technological mode.

For this purpose it is necessary to apply a strategy of advanced commercialization of scientific discoveries and technologies, combining the development of its own research and development sector and adaptation of foreign developments.

To implement the strategy of innovation breakthrough in Russia, it is necessary to develop an effective system of state support and development of small business that takes into account the specifics of its development.

Therefore, for the successful commercialization of fundamentally new technologies, it is necessary to provide priority state support to small innovative enterprises in the following areas:

1) support for independent small enterprises created by talented scientists and innovative entrepreneurs;
2) assistance to large Russian enterprises in creating their own small organizational forms engaged in innovation activities;
3) development of venture financing in the country.

The state should also promote the widest possible cooperation between small and large businesses, educational and scientific institutions through the mechanism of territorial innovation clusters and technological platforms.

Thus, small innovative entrepreneurs need to be supported as they are able to generate better innovations, which makes a significant contribution to the innovative development of the economy. It seems expedient for the government to stimulate demand for innovative products of small enterprises through the expansion of state procurement programs and state guarantees for the purchase of high-tech products by large private businesses.

Abstract

Modern development of e-business is considered from the point of view of it as a component of information economy. Theoretical background of Internet sphere concepts definitions is investigated. The development of the Internet is considered by the authors at three levels. Levels of e-economic activity are listed too. The main goals of online business creation are analyzed. The article contains statistics on the level of electronic environment development in Ukraine. It is stressed that UAnet or Internet segment in Ukrainian is among the most common language segments on the Internet. Websites in Ukrainian make up a significant part of the global network. At the same time, among the most popular Ukrainian websites, there are only few sites which main language is Ukrainian. The authors pay attention to consideration of cloud services development. They note that the Internet provides opportunities for the development of activities that have traditionally been perceived as offline, in particular the educational field. The material of the article confirms the great potential of Ukrainian developments in the Internet environment. Examples of successful technological solutions of domestic developers are listed. The authors state that electronic environment greatly facilitates the work of businesses with potential consumers and creates opportunities for easier entry into the market for new players. The authors draw conclusions that the evolution of e-business in Ukraine has already passed a number of stages, but is still in a stage of growth. This market is ready for radical innovations.

Keywords: Electronic Business, Internet, Information Economy, Online Presence for A Company, E-Commerce, Distance Learning At University, International Electronic Trading.

Introduction

Now in the information economy, where knowledge is the most important resource, there is an active process of convergence and integration of communications and technologies in IT (Bilan et al, 2019) the full impact of information technologies on economic activity (most employees of companies operating on the principles of information economy, are IT specialists (System Administrator, SMM Manager, Internet Marketer, Content Manager, Online Consultant, SEO Specialist, Web Developer, Web Programmer, etc.), and products that are manufactured by these companies are mainly information products and services)). The active incorporation of revolutionary new technologies along with the transformation of the current system of international relations characterize the formation of the global information society at the beginning of the 21st century (Fyliuk et al., 2019). The changes in modern society are focused more on the sustainable economic growth. When reviewing the transmission from an agrarian economy towards industrial, knowledge society, organizational knowledge, intellectual

capital acquires greater importance and approval that they are some of the most valuable resources for sustainable economic future (Mikalauskiene et al., 2019). The society required new information system that would clarify the previously unexplained and intangible processes. The growing interest in the e-business and commerce coincided with the creation of information economy, movement towards the "Industry 4.0" (Krykavskyy et al., 2019). In particular, in economic activity such tendencies act as a technological platform for concepts of "digital economy", "electronic activity", "network economy".

Recent advances in technologies, fast global competition, and the increasing demand on the side of customers are forcing organizations to re-examine how they can exploit the benefits of information technology capabilities to gain competitive advantage. E-business is becoming one of the fastest growing fields in today's economy. Most scholars anf entrepreneurs predict that it would continue to expand faster and faster. Internet business is a great instrument that can assist in obtaining different competitive advantages over their rivals and improving their capabilities to compete with large firms at the world markets (Hu, 2019).

In the conditions of rapid development of modern information technologies and their use in all spheres of economic activity the approaches to solving problems of any socioeconomic processes are changing radically. These processes lead to the transformation of the marketing principles and functions and directly of the role of commerce. Each technology cycle is characterized by the existence of technological revolution and leading sectors of the economy (Osmyatchenko et al., 2019). Change of technological cycles leads to the transformation of the theory of marketing and its practical application. Particularly, approaches to business management changed due to the application of information technologies. Online business becomes leading. There is a significant development gap between different countries, which is the lack of harmonized relationship between the level of digital technology development and the time taken for introducing digital technologies into business sphere for example (Afonasova, 2019).

E-business has gained worldwide development. For example, every fifth European business make e-sales. The level of development of the modern Internet environment is demonstrated by the following data: users of the social network Instagram for a minute like about 2.5 million posts. On Twitter they send 9.7 thousand tweets in a minute. Users of YouTube hosting add 400 hours of new video in a minute. People registered in Facebook share more than 216,000 photos in just one minute. Snapchat users can watch 6 million videos in one minute online. Nearly 570,000 new images are uploaded to GIF services, 830,000 new documents are uploaded to Dropbox every day. Siri (cloud-based personal assistant and iOS-adapted question-and-answer system) manages to answer 100,000 questions in just one minute (E-commerce, 2020).

An increase of the e-business share in GDP can become an economic growth driver in every country. For example, BRICS countries today pay great attention to the development of e-commerce and plan to strengthen cooperation in this area (Revinova, 2019). For the company, the feasibility of doing business on the Internet is determined by the ability to work around the clock any day of the week, no geographical restrictions for work place, minimizing costs (including initial business investments), opportunities for business globalization, equality of access to the market for all businesses, facilitating marketing communications with customers (including interactive communication with them), increasing the speed of call ment operations within the business, reducing the risk associated with the human factor, reduced time-to-market product, no need to pay customs taxes related to electronic payments and others. Consumers also benefit from a number of benefits by using the Internet as a platform to buy goods, including 24/7 availability of business information, confidential receipt of goods and services from companies, purchase of goods and services at lower prices than at physical points of sale, availability of rare goods and services from foreign markets, unlimited opportunities for communication with representatives of companies, providing access to the purchase of goods and ordering services for people with disabilities, convenience for comparing competitive offers (saving time and financial resources).

The levels of development of the Internet approach within the enterprise can be defined in three levels:

- the first level (only the presence of the company on the Internet (presence of a web page, e-mail box, advertising on the Internet));
- second level (interaction with suppliers and consumers based on the use of the Internet);
- third level (transformation of business processes, when the main part of the action is carried out with the help of Internet technologies).

Developing people's interest towards starting a business plays a vital role in Ukraine in which, for a very long time, private property and free initiative were almost completely suppressed. Electronic technologies give opportunities for young people without huge starting finance capital to lounch their private acttvity in a market (entrepreneurship phenomenon) (Vargas-Hernández, 2013).

The increase of entrepreneurial activities is a major issue on which the sustainability of future growth depends (Belás et al., 2017).

Many businesses, at one stage or another of their development, believe that it is important to expand their presence in the eyes of the target consumer with the wide range of tools the Internet can offer. Nowadays, there is a belief that every company that wants to be successful in its customer acquisition activities should have at least a minimal presence on the Internet (having a business site, periodically launching online advertising, a company page on social networks (at least one), etc.). Separate services allow businesses to provide information about themselves to consumers, to deal with reviews (because experts estimate that consumers are about 1.7 times more likely to respond to companies who respond to reviews than those who ignore them). This service, for example, is a Google My Business service that enables businesses to present themselves on Google pages, including Search and Maps. Company representatives have opportunity to respond to customer reviews, post photos using this service.

Literature Review

With the spread of internet usage, electronic business has gained huge attention in the academic literature. Theoretical and methodological basis of the sphere of electronic business is developed in the works of a small number of Ukrainian scientists (Polivanov et al., 2018), (Malitska et al., 2018), (Zaitseva et al., 2015), (Sytnik et al., 2016), (Bashynska et al., 2019). Among the foreign scientists who have been involved in various issues of the development of e-business, can be called (Apăvăloaie, 2014; Yaser, 2013; Maureen et al., 2016; Dimitrios et al., 2014; Pilinkiene et al,, 2013; Delina et al., 2015; Roudposhti et al., 2018; Samašonok et al., 2016; Pabedinskaitė A. et al., 2012) and others. Due to its volatility, the amount of thorough and up-to-date research in the field of e-business is very small. Some aspects of e-commerce development and online projects are noteworthy and determine the relevance of this study.

Zorayda Ruth B. Andam from Philippines is of the opinion that e-coomerce encompasses wide array of the types of electronic businesses. Therefore, this author believes that online business is a component of e-commerce. In addition, the scientist notes that the definition of e-commerce is comprehensive to some extent and becomes really revolutionary phenomenon in modern business (Zorayda, 2003). Rajneesh Shahjee from India agrees with the previous scientist's view that e-business is a component of e-commerce (Rajneesh, 2016). Sahal M. Sheikh and Mehmet Basti from Turkey claim that all definitions of e-commerce can be devided in two groups – concrete and narrow. They think that narrow defntions are very simple (Basti et al., 2015). Chaffey (2009) explained e-commerce as the the exchange of electronic information between business and its external stakeholders. Harsono A. from Indonesia regards e-business as an ancillary link to e-commerce, consider it like a new link for improving physical business (Harsono, 2011). Poong et al (2006) suggest that e-commerce should be viewed from different angles according to the point of view of specialists of different specialization.

Since there is no kinship point of view in determining the relation of concepts, the authors of this article propose the idea of structuring the relations of these concepts for clarity.

Polivanov et al (2018) believe that online business covers the fields of information law, electronic money, technical and software, internet marketing, information management, online logistics, online insurance, tourism, online banking and online trading. Malitska et al (2018) consider e-business at the third level of e-commerce functioning and define it as the development and implementation of new forms of interaction between market participants. Also, it is a new way of exchanging information.

Maureen et al (2016) defined electronic business as the conduct of commerce in goods and services, with the assistance of telecommunication and telecommunication-based tools such as the Internet. E-commerce they identify as a sub component in e-business. In the research study by Yaser (2013) electronic acivity is comprised of three levels such as infrastructure, services, products and structures.

In most scientific studies, the Internet is defined as an additional channel for the effective pursuit of economic activity of various directions. Internet businesse is often identified with e-commerce, often without differentiating between these concepts of the information economy.

We agree with (Sytnik et al., 2016) that the development of online activity is influenced by a variety of factors and objective circumstances. This development is individual for each country. Therefore, it is advisable to identify trends in Internet business development in Ukraine separately from other countries. Scientists of the work (Pilinkiene, 2013) claim that electronic business improves business processes through the automation

economy such as: efficiency of public governance (Bilan et al., 2019c); macroeconomic stability (Vasilyeva et al., 2019; Lyulyov et al., 2017; Melnyk et al., 2018); country's brand (Bilan et al., 2019b); efficiency of the financial system (Vasylieva et al., 2014; Kuzmenko et al., 2014; Vasylyeva et al., 2014; Leonov et al., 2017, 2014; Vasilyeva et al., 2016; Bilan et al., 2018b; 2019a); level of shadow economy and development of creative industry (Levchenko et al., 2019; Kostyuchenko et al., 2018; Bilan et al., 2019e; 2019g; Leonov et al., 2019); information system (Bilan et al., 2019h).

Analysis of various studies shows that is a lack of investigations analyzing whether positiv electronic business impact leads to the stable competittive advantages on the market. and optimisation of usual business process.

The authors in the papers (Yevdokimov et al., 2018; Chygryn et al., 2018; Lyulyov et al., 2019; Vasylieva et al., 2019; Abaas et al., 2018; Lyeonov et al., 2019; Cebula et al., 2018; Lyulyov et al., 2015; Bilan et al., 2018a) proved that information economy boost the sustainable development and e-commerce should develop considering the green aspects (Cebula et al., 2015; Chigrin et al., 2014; Bilan et al., 2019f; GrenÄÃkovÃ et al., 2019; Shevchenko et al., 2016).

At the same time the group of the authors allocated the range of determinants which restrict the developing of e-commerce and information.

Methodology

The research methods are formed by an analysis of the scientific and business literature. The authors use quantitative method. The questionnaire was used to identify the attitude of the research participants towards ythe sphere of electronic business and advantages that it gives to entrepreneurs. Statistical analysis methods were used to process the obtained research data: commonly exploited applications worldwide, usinf of Internet by Ukrainian enterprises, volume of cloud serivises with forecast, leading e-commerce product categories purchased by shoppers in Ukraine, popularity of various sources in the Internet among Ukrainians. Statistical data analysis was carried out using Excel version 2010.

Results

The basic goals of a company transition to the Internet environment may be different. In addition, under the current conditions of rapid development of Internet technologies, the company from the very beginning of its existence can be represented exclusively in the virtual environment. It has become

commonplace, for example, for shops to sell their products without having their own warehouses, using the services of third-party carriers, placing their own storefronts on the Internet, etc. All key processes of a business are performed remotely without binding to the physical locations of goods.

Supported by that development such us invention of mobile phone and internet, caused a faster exchange of information (Amelia, 2014). Internet business is made possible by the development and continuous improvement of search engines. According to the statistics of 2019, Internet browsers have become the second most popular application in the world (Fig. 1). The market of developed countries is in its maturity phase, and the competition among eCommerce players is extremely high and cost-intensive. Marketplaces like Amazon and AliExpress are flourishing, while many stand-alone retailers struggle to find their USP as brand and store loyalty are decreasing and cart abandonment rate in the industry is at 75%. Increasing brand engagement can be achieved through community building (e.g., ASOS Marketplace), loyalty programs, and a seamless mobile and desktop user experience.

Fig. 1: Most commonly exploited applications worldwide as of 3rd quarter 2019 (formed with the use of (Statista, 2019))

The main goals of organizing an online presence for a company include:

- information support of existing non-electronic business with the purpose of creating another advertising and information channel, facilitating communication with partners, forming a positive image of a company that uses modern technologies. For example, creating a corporate site. This approach is typical for the B2B industrial market;
- organizing the sale of goods and services of an existing non-e-business through the Internet in order to use the Internet for advertising and product marketing (the so-called "new retail" was proposed by the founder of Alibaba Group, Jack Ma in 2016). For example, creating an online website with the possibility of ordering products online (such as Ukrainian Epicenter supermarket chain with their website 27.ua or the bookstore chain "Bookstore E" with the book-ye.com book ordering website. Or other example of the resource f.ua, which grew from a small kiosk to one of the most visited online stores in Ukraine;
- creation of a company that sells products exclusively on the Internet for the purpose of realization in the electronic environment of a complete business cycle of activity. That is, such a business is completely remotely implemented, including payment settlements, dealing with customer reviews and claims, consulting). Nowadays, there are more and more examples of companies entering the market within the framework of such rules of operation. On the Ukrainian market, one of the first online stores was Rozetka. In addition, examples of businesses created for this purpose include the Ukrainian online photobank Depositphotos, which mediates between photo authors and their buyers;

- business with advertising goals when creating an online resource with a segmented audience to further sell its contacts to advertisers. Site contains content of interest to the target audience in order to attract the maximum number of users (for example, if the resource is visited by at least 1 000 unique Internet users) with further search and attract advertisers who are willing to pay for contact with the audience of this site. This method of monetization is typical for many information resources, resources that provide free services, such as Ukrainian online site with publications “Na chasi”, which tells about business and entrepreneurship.

There are examples of companies in Ukraine that have expanded their presence to physical stores from the online model. For example, in contrast to Bookstore E, the bookstore Yakaboo, which started its business with an online store, also opened offline store in 2019.

Quite often e-commerce is identified with e-business, although e-business is the most generic concept. It includes any form of interaction between market actors by means of digital technologies: exchange of inform□tion; conducting m□rk□ting r□s□□rch; □st□blishing cont□cts, for □x□mpl□, b□tw□□n pot□nti□l custom□rs □nd suppli□rs; pr□- and after-sales support, such as providing detailed information on products and services, answering customer qu□ri□s, □tc .; s□l□ of goods □nd s□rvic□s; □l□ctronic p□ym□nt, in p□rticul□r using □l□ctronic p□ym□nt syst□ms; product distribution, including d□liv□ry management and tracking for physical products, direct delivery of products that can be distributed electronic□lly; □bility to org□niz□ virtu□l □nt□rpris□s (□ group of individu□l prof□ssion□ls or □v□n ind□p□nd□nt comp□ni□s for joint busin□ss □ctiviti□s); impl□m□nt□tion of busin□ss proc□ss□s jointly m□n□g□d by comp□ny □nd its tr□ding p□rtn□rs; m□n□g□m□nt of information flows within an enterprise. Online sales are in the sphere of e-commerce, and the customer acquisition and retention process already cover e-business as a whole. It is not enough for a successful sales person to have a website. It also needs to attract the attention of potential consumers. For example, if companysells home appliances online, then collectively it is an e-business, because when a visitor sees it, the first thing that catches his eye is the design of the site and the navigation that helps him find what he needs. The information provided must eliminate any doubt of the site visitor to turn it into a buyer. So far, no cash transactions have been made. It’s not e-commerce yet, it’s e-business. And only after the purchase we say that a company and a consumer have established relationships in the field of e-commerce. Levels of e-economic activity are listed in Fig. 2.

Fig. 2: Constituents of the electronic sphere in their relationship (formed using (Steblina, 2019))

E-commerce changes every year, both in terms of technology and business approach. In particular, multichannel marketing (making the most of all available customer acquisition channels), niche specialization, e-commerce festivals (Double 11 in China, Cyber Monday in the US, etc.) is gaining increasing popularity. The issue of business ethics in conducting economic activity in the electronic environment is of particular relevance today too (Kiss L. B., 2019).

The electronic environment in Ukraine is developing at a slow pace, but domestic entrepreneurs are trying to keep up with the neighboring countries in this field. The first Ukrainian site was launched in 1997 (UAnet, 2020). Currently, the UAnet or Internet segment in Ukrainian is among the 30 most common language segments on the Internet. Websites in Ukrainian make up about 0.2% of the global network (Davidaviciene, 2019). At the same time, among the 25 most popular Ukrainian websites, there are only 4 sites which main language is Ukrainian. Among Ukrainian enterprises that used the Internet, in 2017, the largest number used it for sending and receiving emails (Fig. 3a), and enterprises using social media mostly used social networks (Fig. 3b).

Fig. 3a: Using of the Internet by Ukrainian enterprises in 2017 (developed by using data from (Statistical Yearbook, 2018))

Fig. 3b: Using of social media by Ukrainian companies in 2017 (developed by using data from (Statistical Yearbook, 2018))

Social media becomes an integral part of life that helps reach modern generations of consumers. Results of scientific studies indicate that usage of social networks is effective for the formation of image of employer. This is important because there are clear links between workplace attractiveness, usage of social network and image of an employer (Most popular sites, 2019).

In 2019, trends are changing, including the popularity of cloud services and their use in business processes. According to the data, the volume of the cloud services market is growing rapidly (Fig. 4). So, we can conclude that the Ukrainian Internet has the potential for development, but there are still a lot of steps to be taken to become a leader in the global space of the Internet.

Fig. 4: Volume of the cloud services market in Ukraine, million dollars USA (built using data from (Agieiev, 2019), (Dainovskyi, 2019))

Overall, 2019 proved to be a success for the global internet startup market (according to statistics, among the IT sectors most invested in 2019 were electronic financial services, e-commerce, data analytics and SaaS). The Ukrainian startup Grammarly also stood out, attracting $ 90 million (Ukraine B2C, 2019).

In addition to Grammarly, Ukraine has already implemented a number of successful Internet startups, including:

Preply. Despite the fact that the competition in the educational projects market is high, this online tutor search service, launched in 2013, is developing successfully. Initially, it was intended as a service for learning English, but in the process of trial and error the creators changed its concept several times. It is now an online marketplace where you can find a tutor in 24 languages.

Restream. A streaming service that allows users to stream video content across multiple platforms and social networks (including the most popular video channels such as Facebook, YouTube, Twitch, Mixer, LinkedIn). The main service of it is cloud online broadcasting, which allows the author to broadcast videos to various streaming video sites.

PatentBot. Digital assistant for online trademark registration. This service checks name of a new trademark. If name is free, it helps to draw up necessary documentation. It helps to save up to 80% of the time, as well as paying lawyers.

Na'Vi (full name – Natus Vincere, which translates from Latin as “Born to Win”). Ukrainian multi-game eSports organization. The development of technologies, such as streaming services, gives the opportunity for mass viewing of competitions with greater involvement of sponsors, investments.

Prom.ua. Ukrainian marketplace, on the platform of which entrepreneurs have the opportunity to create online stores and / or place their products in the general catalog, to receive SEO promotion services, to advertise their products within the internal budget of ProSale.

Jooble. A search engine that aggregates job postings from job boards, newspapers, corporate career pages, and recruitment agencies. The search engine starts the site search by entering the city and job title. Filters allow you to sort your ads by city, date, salary, and company name. The ad search algorithm considers hundreds of parameters and selects relevant vacancies for user. By clicking on an ad, user is redirected to a relevant company page where he/she can find employer contacts and submit a resume.

TicketForEvent. An online service that enables event organizer to automate registration and questionnaire of visitors on their website, accept payment from their clients and secure them with electronic tickets / badges. The service is focused on various events by type and scale: exhibitions, conferences, forums, trainings, seminars, cultural and entertainment events.

Hubbub. An online platform that is a social network where people communicate by recording and exchanging short voicemails “bubs”.

Address.ua is a real estate portal. The site contains a complete and reliable database of homes for sale and rent. The ads go through a rigid system of control before posting on this resource.

Ukrainian startups in the field of electronic business are not inferior to European and American and have a chance to succeed and conquer the market, but their distinctive feature is that they are often implemented outside the home country of their developers, due to a number of circumstances. Despite the fact that e-business is thriving industry in Ukraine there is lack of favorable environment, expertise, mentoring, government and business support. Ukraine has strong human resources that understand future needs and what the consumer needs. However, a common problem for domestic startups is that they do not have alternative development options, that is, if a particular startup is not interesting to the audience it is aimed at when entering the market, it is necessary to have alternative ways of using it in advance. That is, most issues arise at the stage of commercialization of startups, which should be noted in the future developments.

A special place in the market of Ukraine is occupied by online stores, which now became popular not only for the purchase of goods, such as electronics, household appliances, clothing, cosmetics, but also food, baby goods, home goods and so on. Market leaders by number of visits include such projects as Rozetka, Allo, Citrus, Comfy, Make UP, Foxtrot, 27.ua, kasta.ua, f.ua, Moyo, Eldorado, Intertop. At the same time, it is natural that projects that place clothes, shoes, cosmetics, jewelry in the catalogs (Bonprix, kasta.ua, Leboutique, Make UP, zolotoyvek.ua) are leading by number of visits. The rapid development of information communication technologies has expanded the possibilities for marketing communication (Sabaitytė, 2019). In order to increase electronic business competitiveness and carry out effective marketing activities, it has therefore become important to acquire knowledge about e-consumers and to identify their preferences in purchase. Most popular categories of goods that were interested and purchased in Ukraine are shown in Fig. 5.

In general, visually buying preferences in Ukraine are similar to a triangle. The triangle shows the trend of increasing purchases in certain categories. According to this approach, if purchases in the fashion category have already reached an important maximum, and for sales growth is not projected, then significant sales growth can be expected in sales of travel services online, goods for children, furniture.In 2019, trends are shifting in favor of the increasing popularity of shopping for atypical categories in Ukranian e-market. For example, the Ukrainian medicines search and delivery service Liki24.com.

In fact, this service is not an online pharmacy. It is like a mediator between drugstore and consumer. Also, every consumer has the opportunity to order the service “I'll take it myself”. This is a good aggregator for finding the right medication.

If in 2018 the Ukrainian e-commerce market grew by 30%, showing the second growth rate in Europe, in 2019, the e-commerce market grew by 17% to UAH 76 billion. At the same time, the size of the average check of one purchase decreased by 7-10%, and the cost of delivery increased and is 5-15% of the cost of goods. However, online commerce shows faster development than regular retail (Educational institutions, 2019).

Fig. 5: Triangle of leading e-commerce product categories purchased by shoppers from Ukraine in 2018 (formed using data from (The e-commerce market, 2018)

Note: does not add to 100% due to multiple answers possible

In Ukraine, the Internet provides opportunities for the development of traditionally offline organizations such as, for example, a university. A system of distance learning is becoming more and more popular. Distance learning has already been introduced by such universities in Ukraine as the Ternopil Ivan Puliui National Technical University, Odesa National Academy of Food Technologies, Khmelnytskyi National University, State Fiscal Service University of Ukraine and others (Sumy State University, 2018). Sumy State University e-learning information system is provided by a complex of the software and information environments: automated distance learning system, Examiner open online course platform, blended learning platform, open educational resources, electronic catalog, institutional repository. The system includes online studio providing two-way audio and video communication for lecturer and student, recording and online broadcasting of training videos (Statista, 2019).

Thanks to international electronic trading platforms more and more opportunities for establishing own business for entrepreneurs in Ukraine are opened. This type of activity is especially popular for individuals as purchases in foreign online stores with the subsequent delivery of goods to end consumers. Plenty of sites such as next.co.uk, sportsdirect.com, decathlon.co.uk, hm.com, mountainwarehouse.com, lidl.de, carters.com, amazon.com, 6pm.com, calvinklein.com, zara.com provide favorable conditions for cooperation and periodic promotional offers in the case of wholesale purchases of goods. The popularity of browsing websites for reviewing goods at online stores is one of the main components in the sources used by Ukrainians on the Internet (Fig. 6).

Fig. 6: Popularity of various sources in the Internet among Ukrainians in 2018 (formed using data from (The e-commerce market, 2018)

We can conclude that the worldwide accessibility to the Internet is one of the defining phenomena of the present times reshaping the world as we know it (Kirichenko, 2017).

Conclusions

The evolution of e-business in Ukraine has already passed a number of stages, but is still in a stage of growth. The Ukrainian market is ready for radical innovations in this field. Most Ukrainian companies are "scouting" according to the classification of innovation behavior types by Miles and Snow. They try to follow trends and changes in the market to use them to improve own business.

We understand that internet technology is no longer an extension of the business, it became the main driving force of change. Modern companies operating in various sectors change their way of doing business to take advantage of the power of the internet technologies. We conclude that electronic businesses are built due to a rapid distribution of information. There is also a premise for the continuous change that, by its nature, requires constant improvement and innovation.

With regard to future trends in e-business, an analysis of a number of scientific and practical sources shows that trends in e-business will continue to intensify. Social shopping will grow at a rapid pace. Significant technological and marketing changes are expected in the B2B e-commerce sector. Consumer electronic personalization will be a common thing. In terms of radical innovation, innovations in mobile sales will be a real revolution. Voice commercialization will become a common utility.

Internationalisation and Competing – Evidence from The Polish Road Freight Market

Malgorzata KEDZIOR-LASKOWSKA

University of Warmia and Mazury in Olsztyn, Poland
malgorzata.kedzior@uwm.edu.pl

Abstract

Globalization influences the development of enterprises, regions and national economies. It also affects transportation markets. The air and maritime transport enable and accelerate the development of trade on a global scale. In EU, road transport plays a significant role in international trade and is responsible for ¾ of transported goods. The competition between European road carriers is strong. Polish enterprises are an important element of that process. It should be noted that the road freight transport is dominated by SME sector. In Poland, the structure is similar (although the majority are micro and small enterprises). The possibility of servicing on foreign markets, the necessity to compete with foreign competitors, the opportunity to develop intellectual resources may improve carrier's competing abilities. The purpose of that article is to indicate the role of internationalisation in competitiveness in road transport companies, to reveal the change in the perception of that role and to test if employment level has influence on perception of the role of internationalisation in shaping competitiveness of road carriers. The study was conducted in 2013 and in 2019. The respondents evaluated 6 factors that determine the internationalization process of Polish road carriers. In statistical analysis, measures of location and variability were used. To test the significance of differences between the groups (one from 2013 and the second from 2019), the Mann Whitney's U test was used. Research results prove that internationalization is important in shaping competitiveness of road carriers. Moreover, time and size of employment had an influence on research results.

Keywords: Freight Transport Market, Competitiveness, Internationalisation, SME.

Introduction

Global changes have been taking place in both spheres of production and consumption. This evolution is based on socioeconomic changes. The complementary nature of transport, whose main task is to serve the needs of the economy, determines the significant relationships between them. Development of the global economy strengthens the role of transport as an instrument used for boosting trade (Janelle and Beuthe 1997).

Internationalisation is a less advanced globalisation process. In a discussion on defining the concepts and interrelations between them (Scholte, 2002), both processes have a positive effect on economic growth. Internationalisation of technology and the development of international trade are very important elements of globalisation (Marginean, 2015; Cieślik et al., 2019; Szczepaniak, 2019). They are boosted by processes of liberalisation and economic integration. These are factors that have a considerable impact on the development of international transport services (Hertz, 1992).

Marine and air transport provide significant support to globalisation processes and trade transactions on a global scale (Rodrigue, 2007). The needs of trade in EU countries are served mainly by road freight and, to a lesser extent, by rail freight. The domination of road freight companies is determined by its competitive advantages compared to other transport branches (rail or inland waterway transport). This competitive edge can be regarded from several perspectives: technical and technological innovations, human capital or the organisation structure and management methods (see: Wang et al., 2011; Zygmunt, 2019; Świadek et al., 2019; Jakimowicz and Rzeczkowski, 2019a, 2019b; Mačerinskienė and Survilaitė, 2019).

The importance of road freight in serving transport needs in the EU makes it the main branch of transport. However, the conditions of orders acquisitions can be regarded as demanding. One of the causes is the road freight sector fragmentation in most EU countries. The decisive factor in effective competition of entities is the ability to find competition instruments in different segments of the service market, i.e. in serving the following needs (Rucińska, 2015): the native country logistics with the competition of resident carriers, domestic logistics in competition with foreign entities, foreign trade of domestic manufacturers with resident carriers, foreign trade with foreign competitors, regarding freight in foreign markets (including cabotage).

Road carriers participate in international competition processes in the domestic and foreign markets. The export of services is regarded as an opportunity for developing competitive potential (see Smallbone et al. 1998; Thrassou and Vrontis 2008). It also confirms the internationalisation of activities. It seems significant to determine the importance of internationalisation in developing the competitiveness of road carriers, which determines the objective of this study. The internationalisation process is determined by six factors (variables) referring to the market environment in which Polish road carriers operate. However, they reflect the conditions in which carriers from the Visegrád Group countries and the countries along the eastern border of the EU operate. These factors were evaluated by respondents. The study was conducted using two independent study samples in 2013 and 2019. A comparative analysis was performed whose aim was to show the change in perception of the importance of internationalisation in the development of competitiveness.

Literature Review

The main attributes of competitiveness of transport services include contents of service, time of transport, reliability, capabilities and availabilities (Žvirblis, 2003). Specific features of road freight have shaped the freight structure in the EU. The advantages of road freight in the competition between forms of movements on roads include high flexibility, service availability, door-to-door direct delivery, a relatively short time to taking up the order and completing its execution. In air, marine or rail transport, it is necessary to use road freight as a link between the employer, forwarder, cargo administrator, and the principal transport operator (rail, air, marine carrier). It is a feature of road freight that it does not need to use other branches. It enables reducing the time of delivery and helps to maintain the cargo safety (without the need for extra handling). These elements confirm the high competitiveness of road freight in the inter-branch competition.

Competitors include entities with various amounts and quality of material, financial, and human resources. Most of transport companies in Europe are SMEs. Different from large multinational enterprises, they need to create and sustain competitive advantage (Ho et al. 2016). The qualified and skilled staff is one of the most important factors in international development in small companies (Nemkova et al., 2012). Competitiveness of hauliers is an effect mainly of advertisements and promotion (creating the image of a socially responsible entrepreneur, who cares about the environment and provides high-quality services). Development of the service offer, taking into account the current needs of customers, developing customised and niche services, preferably with added value (Mallard and Glaister, 2008).

The share of road freight in cargo freight in the first decade of the 20th century was stable and amounted to approx. 70% (COM (2014) 222). This trend is not changing despite attempts at reducing road transports role to in-and-out transport. These actions are caused by the need to prevent degradation of the environment and global warming. At the level of the EU transport polity, several solutions are being implemented that favour ecologisation and decarbonisation of transport, mainly road freight (see: Jänicke et al. 1993; Jacyna et al. 2014; COM (2011) 144).

Liberalisation and development of international trade and access to new markets as a result of economic integration increases the demand for transport services. At the same time, they set different conditions of competing for orders for cargo freight. These conditions should be regarded as

demanding in the case of road freight companies. Participants in the competitive struggle include domestic and foreign entities with different levels of human and capital resources. SMEs have to face great challenges in increasing global competition. Their weakness, often lack of sufficient resources and capabilities, makes their internationalisation process more challenging (Genc, et al., 2019). The differentiation of needs, increasing expectations regarding the service quality, competition from global logistics operators - all of this necessitates some changes in the existing market strategies (Haung et al. 2019).

Internationalisation in transport activities can be regarded from a dual perspective. Studies analyse both the sources (factors) and the process of internationalisation (Fletcher, 2001). Internationalisation of companies, including small and family enterprises, can also be considered from the perspectives of (Lin, 2012):

1. pace – determined as time needed to achieve a set goal,

2. scope – the geographic area of activities; it shows the number of countries where the activities are conducted,

3. rhythm – defined as the process regularity or the time during which new branches (companies) are established.

Operating in foreign markets confirms active internationalisation – foreign expansion (Gorynia, 2000). Competing with foreign entities in the domestic market is referred to as passive internationalisation – without service provision in foreign markets. One of the forms of internationalisation of transport companies can be domestically-located service exports (providing transport services domestically on orders from foreign customers) (Andersen et al., 2000).

Economic integration was undoubtedly an impulse in the development of transport companies in the EU. Langesth et al. (2016) identified the technological factors which enabled quicker, more effective transport between trade partners. In the context of the EU law, a road freight company can be regarded as international when it conducts economic activities in international cargo transport (Dz.U.2019.0.2140). An entrepreneur is obliged to obtain a licence so that it can provide services in international markets, including in third-country markets. Offering services in foreign and global markets (outside the domestic market) is a manifestation of business internationalisation. According to Kandasaami (1998), an enterprise can be regarded as international when it operates in the global market from the start, without operating previously in the domestic market.

The freight structure in EU countries is dominated by road freight, which meets approx. 75% of the transport needs. Regardless of what kind of measure is adopted (cargo tonnage, tonne-kilometres), the freight carried by Polish road carriers makes them important actors in the EU market (see Fig. 1). Together with operators from Germany, France and Spain, they are responsible for nearly half of the freight transport.

Fig. 1: Structure of road transport of goods in the EU in 2017

Source: the author's calculations based on EUROSTAT data (https://ec.europa.eu).

The majority of road carriers in Poland are SMEs, employing under 250 people. The sector structure in the EU is similar (European Commission 2014). Moreover, micro- (up to 9 employees) and small (up to 25 employees) enterprises account for approx. 80% of the sector in Poland. Some of them are family enterprises. As in other sectors of the economy, they have limited human and financial resources at their disposal (Laufs and Schwens, 2014). The considerable share of Polish carriers in the EU transport market is proof of their effective competition in foreign markets, cross-trade services (cargo is transported between two countries by an independent carrier), cabotage (transport between two places in one country by vehicles registered in a different country) and serving the intra-community trade.

To compete for orders in international markets, company management has to be aware of the needs of potential customers and effective competition instruments. Polish carriers seem to meet those criteria. The service prices seem to be one of the major criteria in the competition. It is noteworthy that the growing cost of transport activities in EU countries did not worsen their competitive position considerably. One can cautiously assume that their well-established position is also a consequence of quality-oriented competitive factors.

Research Questions

The aim of this study is to identify the factors that affect the competitive position of road freight enterprises in international activities. An attempt was made to answer the following questions:

1. Does the internationalisation affect the competitiveness of road carriers?

2. Does the perception of the role of internationalisation in shaping road carrier's competitiveness change?

3. Does the employment level influence the perception of the role of the internationalisation in competing?

Research Design and Methodology

Internationalisation provides opportunities for creating and developing private labels, especially by access to new (intellectual, material, etc.) resources, information (conditions and instruments of competition) and knowledge on how foreign markets operate. The service provided in international trade is an important element of transport internationalisation in the context of entering new markets

on orders from domestic customers or executing orders from foreign enterprises which can trade with distant countries.

The analysis of internationalisation of transport activities took into account six factors (variables). They were determined on a basis of literature and preliminary interviews with entrepreneurs. They included: a) competition in the domestic market, b) competition in foreign markets, c) activities of big international companies, d) benchmarking, e) cabotage markets, f) personnel quality (qualifications and education). It seems that these are the areas in which road carriers should follow cautious strategies. It is beyond doubt that conducting international activities allows acquiring and developing intellectual capital, which applies especially to senior staff. Therefore, it can bring tangible commercial effects.

The internationalisation factors were evaluated by respondents. A 6-grade scale was used to evaluate their importance in affecting the competitiveness of road carriers (1 – completely unimportant; 6 – of great importance). The factors that were given $\bar{x} \geq 4.00$ were regarded as those of considerable importance to competitiveness. The statistical analysis used measures of position and variation. The significance of differences between groups was checked by the U Mann Whitney non-parametric test, as not all the variables met the criterion of matching the normal distribution and because they did not meet the criterion of the equinumerosity of comparable groups (Ključnikov et al., 2019).

The study was conducted in two stages (in two independent test samples). The first study stage was performed in 2013 (the first study sample). The data were acquired by an interview with a survey questionnaire using telephone and personal interviews conducted by the author. The study was conducted on a sample of 134 road carriers in the Voivodship of Warmia and Mazury, Poland. Owners or managers of the companies were the respondents. The second study stage was performed in 2019 (the second study sample). The study employed an electronic questionnaire prepared using Google's Form tool. The survey was sent to the owners, managers or to staff members responsible for transport in transport companies. Not all of the respondents were able to use this tool. The problems reported included difficulty accessing the questionnaire and answering the questions. Part of the questionnaires were completed with the author's support. Ultimately, 73 properly completed forms were obtained.

The respondents are entities registered in the Voivodship of Warmia and Mazury, Poland, which operated in international markets and represented the SME sector. The study samples reflect the entity-based structure of the road freight sector in Poland. The entities employed up to 25 people. In 2013, approx. 70% of respondents represented the micro-enterprise sector, with up to nine employees per enterprise. There were 56% of the enterprises representing this sector in the study sample in 2019, while 44% of the enterprises employed 10-25 people.

Research Results

The factor with the highest score in terms of its importance to the competitiveness of road freight companies was personnel quality (see fig. 2). The qualifications, education and skills of the personnel affected the development of the competition potential of enterprises in international markets. Access to (and operating in) cabotage markets was also regarded as an important element in competitiveness development. The personnel quality and cabotage markets received the highest score in both of the analysis periods, i.e. in 2013 and 2019.

Fig. 2: Mean scores for the competitiveness factors in 2013 and 2019

Source: based on the findings of the author's studies.

Table 1 shows descriptive statistics for the competitiveness factors in individual years. The shaded fields show the factors which – in the respondents' opinion – affected the possibility of competing for orders. Competition in foreign markets (61% of grades below 4) and benchmarking (42% of grades below 4) were ranked as not affecting competitiveness in the first study sample. Their importance grew in the respondents' opinions in the second study sample (2019). It is noteworthy that all the proposed factors were regarded as important for competitiveness in the second analysis period.

Table 1: Descriptive statistics

Variable	Mean ($\bar{x}$)	Median (Me)	Variance	Standard deviation (SD)	Minimum	Maximum	Range (R)	Coefficient of variation (V) (%)
2013 (n=134, 95% of the confidence interval for the mean)								
Domestic competition	4.24	5	0.995	0.998	2	6	4	20
Competition in foreign markets	3.61	3	1.472	1.213	1	6	5	40
Activities of large international companies	4.40	4	0.784	0.885	3	6	3	22
Benchmarking	3.55	4	0.851	0.922	2	5	3	23
Cabotage markets	4.72	5	0.987	0.993	3	6	3	20
Personnel quality	5.22	6	1.168	1.081	3	6	3	18
2019 (n=73, 95% of the confidence interval for the mean)								
Domestic competition	4.73	5	0.785	0.886	3	6	3	18
Competition in foreign markets	4.45	5	1.890	1.375	1	6	5	27
Activities of large international companies	4.70	5	1.130	1.063	1	6	5	21
Benchmarking	4.36	5	1.038	1.019	2	6	4	20
Cabotage markets	4.82	5	1.037	1.018	2	6	4	20
Personnel quality	5.14	5	0.713	0.855	2	6	4	17

Source: based on the findings of the author's studies.

The descriptive statistics revealed the non-homogeneity of the study samples. The competition processes in foreign markets resulted in the highest score variation (V=40%, R=5) in the first sample. A similar situation was observed in the second group (V=27%, R=5). With a high score variability, this factor was regarded as important in competing by the majority of the respondents (73% gave scores of 4 and more). The highest consistency was observed in the respondents' scores given for the personnel quality both in 2013 (V=18%, R=3) and in 2019 (V=17%, R=4).

An analysis of assessment of factors affecting the competitiveness was performed with the U Mann Whitney test. This analysis revealed groups of homogeneous and non-homogeneous scores based on the central tendency measure (median – Me). The zero hypothesis was formulated (H_0), according to which the grouping variable (study year) did not affect the internationalisation factors assessment, and an alternative one (H_1), according to which the grouping variable (study year) affects the internationalisation factors assessment, at the assumed level of significance of α=0.05. Due to the positive verification of H_0 it was possible to regard the groups as homogeneous. Its rejection was tantamount to adopting H_1, which confirmed the effect of the grouping variable on an assessment of the internationalisation factors (statistically significant differences in scores). Table 2 presents the test results.

Table 2: Results of the U Mann-Whitney test analysis (grouping variable: study year)

Variable	U Mann-Whitney test	W Wilcoxon test	Z	Asymptotic (two-sided) significance
Domestic competition	3708.000	12753.000	-3.080	.002
Competition in foreign markets	3138.000	12183.000	-4.459	.000
Activities of large international companies	3963.000	13008.000	-2.371	.018
Benchmarking	2768.000	11813.000	-5.394	.000
Cabotage markets	4587.000	13632.000	-.769	.442
Personnel quality	4228.000	6929.000	-1.752	.080

Source: based on the findings of the author's studies.

Domestic competition received significantly higher scores from the second respondent group (2019). Similarly, the conditions of competition in foreign markets, activities of large international companies and benchmarking were regarded as more important for competitiveness in 2019 compared to the scores given by the respondents in 2013. These factors determined a significant difference in scores given to the factors affecting competitiveness, which shows that the H_0 hypothesis must be rejected and the alternative hypothesis H_1 accepted. It is noteworthy that the rank of competing in foreign markets changed. This factor was not a significant factor affecting competitiveness in the first study group (Me=3 in 2013). It was regarded as an important element in competing for customers' orders in the second sample (Me=5 in 2019.

Cabotage markets and personnel quality determined groups of homogeneous scores. The H_0 indicates that there are no significant differences in perceiving these factors as affecting competitiveness – they were equally important regardless of the study year. Importantly, cabotage and personnel quality also received the highest scores in both study samples (in 2013 and 2019).

The statistical analysis was expanded, taking into account the employment level. It was an attempt at determining whether scores given by respondents employing the same number of people differ statistically during the two periods of analysis (2013 and 2019). The test results are presented in Table 3.

Table 3: Results of the U Mann-Whitney test taking into account the employment level (grouping variable: study year)

Variables	U Mann-Whitney test	W Wilcoxon test	Z	Asymptotic (two-sided) significance
Employment level **1-9** people				
Domestic competition	384.000	735.000	-2.038	.042
Competition in foreign markets	410.000	761.000	-1.641	.101
Activities of big international companies	451.000	802.000	-1.099	.272
Benchmarking	308.000	659.000	-3.039	.002
Cabotage markets	493.000	844.000	-.534	.593
Personnel quality	409.000	1270.000	-1.756	.079
Employment level **10-25** people				
Domestic competition	1282.000	7168.000	-2.383	.017
Competition in foreign markets	932.000	6818.000	-4.167	.000
Activities of big international companies	1299.000	7185.000	-2.259	.024
Benchmarking	936.000	6822.000	-4.108	.000
Cabotage markets	1614.000	7500.000	-.592	.554
Personnel quality	1464.000	1992.000	-1.420	.156

Source: based on the findings of the author's studies.

Groups of micro-enterprises (employing up to 10 people) can be regarded as homogeneous in perceiving the importance of the competitiveness factors. The H_0 should be accepted, according to which there are no significant differences in perceiving these factors – the study year did not have a significant impact on the scores given for these factors. Benchmarking was an exception and it was not a significant factor affecting competitiveness in 2013. According to the respondents in 2019, this factor increases the market attractiveness of the enterprises.

The respondents employing 10-25 people (small enterprises) should be characterised as non-homogeneous groups. The competition processes in the domestic market, competition in foreign markets, activities of large international companies and benchmarking formed groups of significantly different scores (H_0 was rejected and H_1 accepted). Significantly higher importance of these factors was observed in the study conducted in 2019. Scores for cabotage markets and personnel quality confirmed the group homogeneity. H_0 was accepted – the study year did not change the perception of their importance in affecting competitiveness.

Conclusions and Discussion

In the respondents' opinion, internationalisation affects the competitiveness. This was confirmed by the mean scores for the factors under analysis ($\bar{x}$=4.29 in 2013, $\bar{x}$ =4.70 in 2019). Most of factors are regarded as important in shaping competitiveness. The study year affected the perception of the importance of internationalisation. In second sample (2019), internationalisation is ranked at higher level which means its growing significance in international competing. The increase in the demand for road freight and the geographical expansion, resulting from the international trade development observed during the period between 2013 and 2019, was probably the source of these changes. Benchmarking was a factor whose increase in significance should be regarded as desirable. It was not significant as a factor affecting the competitive potential development in the first study sample (2013). On the other hand, according to 82% of the respondents in 2019, the possibility of copying operation strategies of large transport operators can have tangible effects on the activities of Polish enterprises.

The employment structure in the respondent enterprises provides information on their diversity. No significant differences were observed in the way different factors were perceived in the group of micro-enterprises. Benchmarking was an exception, which is a desirable trend. Most factors were regarded as significantly more important in affecting competitiveness in the group of small enterprises (employing 10-25 people) (i.e. domestic and foreign competition, activities of large international companies and benchmarking). The importance of cabotage markets and the personnel quality seems interesting against this context. These factors were equally important as factors affecting competitiveness.

In conclusion, one can say that smaller groups of enterprises are less diverse in terms of their answers, as opposed to those with a larger number of employees. There is a question of whether those opinions would be even more diverse in enterprises employing more than 25 people. This indicates the need for studies on the effect of internationalisation on the competitiveness of road carriers. Larger enterprises have better resources and – usually – a larger potential for competitiveness, although the response structure might be different than in the current study.

Internationalisation should be regarded as a development opportunity. It is an obvious threat to Polish road carriers (SME sector, with small capital) that they have to compete against larger entities in the domestic market and abroad. It is important that the respondents are aware of increasing internationalisation of transport activities and, in consequence, of the need to adapt to the market requirements. The study results have shown that the importance of competition in foreign markets is growing. It is probably caused by an increase in the costs of transport activities in Poland, increasing costs of access to roads in the EU and the growth of competitors from such countries as Lithuania and countries of the Visegrád Group. They can decrease the price-related competitiveness of Polish carriers and accelerate the development of quality-related competition factors. Equally importantly, there are changes in the legal environment concerning transport activities observed in foreign markets (German and French, among others). These changes are referred to as the new mobility package. One of the main reservations raised with respect to the package, which affects the competitiveness of carriers from Central and Eastern Europe, is an increase in the operating costs (the minimum wage in a country, the need to provide hotel accommodation for a driver after a 6-day work week, etc.) They are regarded as detrimental to free competition and are an instrument of protection of resident carriers. The need to adapt to the changes in the way transport activities are conducted in international markets is the basis for further functioning in foreign markets. These changes have their source in internationalisation of transport activities.

Study limitations

The ability to compete and development opportunities for road carriers depends on such factors as the level of internationalisation of their activities and income diversification. These, in turn, depend on the enterprise size. Taking larger enterprises into consideration in the study will provide important information. The entity-related structure of the respondents is similar to the sector structure in Poland. Moreover, the study was conducted in one of the poorest voivodships of Poland and one of the poorer regions of the EU, which prevents generalisation of the results. It would also be valuable to expand the study scope geographically. A change in the study area could be important with respect to a change of the enterprise structure. In voivodships with better linear (with priority axes of the TEN-T network) and point infrastructure (large warehouse areas, container terminals, including bimodal ones). All these limitations will be taken into consideration in the future (extending the research area and including larger entities).

The study results provide a platform for considerations on the importance of internationalisation and globalisation processes on transport markets. They should be continued in an interdisciplinary setting (including the legal environment). It is also noteworthy that studies of the road freight service supply are less developed than those concerning demand (which usually take into account the expectations, needs and satisfaction of customers).

Abstract

Purpose: The aim of the study is to investigate the association between human resource management practices and future plans of Ukrainian employees working in Poland. **Design/methodology/approach:** This paper applies a quantitative methodology. The study is based on questionnaires conducted in Ukraine and filled in by 441 people who had worked and continue work in Poland. **Findings:** The results demonstrate that there is a significant relationship between HRM practices, especially in the area of training and development as well as compensation and rewards, applied in the case of employees from Ukraine, and their future plans. **Practical implications:** The findings of this study should be beneficial for HRM specialists and managers in Poland who hire employees from Ukraine and would like to retain them longer, as they confirm the importance of certain practices and facilitate their efficient selection. **Originality/value**: This research is valuable in terms of recognising the relationship between the application of certain human resources management practices in Polish enterprises and the fact whether employees from Ukraine intend to stay for a longer period of time or permanently, as it pertains to the employment in Poland.

Keywords: Human Resources Management Practices, Ukrainian Employees, Poland, Migration, Future Plans

Introduction

The issue of labour migration has been the topic of many discussions for years now, also between academics. The reason is that it now a common aspect of labour markets all over the world. In Poland, this situation is rather quite specific, as Poles travelling to other countries (especially Great Britain and Germany) in search of work since the accession of Poland to the European Union has been rather commonplace, but foreigners started coming to Poland for the same reason relatively recently. Ukrainians represent the most numerous groups, which offers significant support for the Polish labour market. Currently, there are 665,600 employees from Ukraine who work legally and pay social insurance contributions (Błaszczak 2020), and if we also take into consideration those who work in Poland illegally, the number increases to over 2 million (ZPP, ISBNews 2018). Employees from Ukraine are not only extremely valuable for Polish organisations for economic reasons, but they also have a significant capacity for assimilation due to the similarity of cultures (Gadomska-Lila, Moskalenko, 2019), way of thinking and language. However, incentives offered by other countries, especially Germany, the Czech Republic or Hungary, which provide legal and administrative tools as well as attractive employment and working conditions, encourage some Ukrainians to leave Poland. It is estimated that 60% of employees from Ukraine are considering work in another country, particularly Germany (EWL 2018). Moreover, a better social and economic situation of Ukraine and forecasted increase of real earnings encourage some of them to think about coming back to their home country. Therefore, the outflow of Ukrainians from the Polish labour market has become an actual risk, which may be a source of numerous problems for many employers, and slow down the Polish economy in the long term. For this reason, there is a need for incentive actions addressed to this particular group of employees to retain them in Poland longer or permanently. Many actions

which could potentially increase the attractiveness of Poland as a country for Ukrainians to work and live in require an intervention at the central level – simplifying and shortening the application procedures connected with obtaining residence and employment permits, creating a migration policy which would be consistent with social policy, health protection and education, etc. However, some of the actions encouraging to take up employment in Poland may be introduced by employers. Human resources management practices may prove critical. It is necessary to ask whether there are any dependencies between human resources management practices employed by Polish enterprises towards employees from Ukraine and their future career plans. In order to answer this question, the Authors conducted quantitative research among Ukrainians who worked/work in Poland. The results offer some contribution to the understanding of the relations between human resources management practices of Polish enterprises employing Ukrainians and their plans as to their future stay and work in Poland.

Theoretical Framework

Migration of Employees from Ukraine

Dynamic globalisation and integration processes result in barriers being removed from labour markets and migrations becoming commonplace. There are many reasons for this situation – educational, religious or political (Kawczyńska-Butrym, 2009), nonetheless economic reasons remain crucial (Kuciński, 2004). People migrate in search or better conditions of life, but also looking for security and shelter from military conflicts, persecution or natural disasters (Walaszak, 2003). People emigrating from Ukraine have similar reasons. Low salaries, massive corruption and the conflict with Russia force more and more Ukrainians to emigrate (Malynovska, 2018). Estimates of the total number of Ukrainian labour migrants simultaneously working abroad would probably amount to 3 million (Libanova, 2019). Ukraine is indeed one of the biggest donors of cheap labor for the EU and Russia (Molodikova, Yudina, 2016). The major recipient countries of Ukrainian labour force are the Russian Federation (43.2%), Poland (14.3%), Italy (13.2%) and the Czech Republic (12.9%) (Drbohlav, Jaroszewicz, 2016). Historically, one of the first destinations attracting part of the broader migration outflow from Ukraine in the mid-1990s towards West-European countries was Greece (Nikolova, 2013). Flows of labour migration are also directed to Hungary (Çağlar, Gereöffy, 2008), Portugal (Fonseca, Pereira, 2016) or Spain (Stanek, Hosnedlová, Brey, 2016). Recently, Poland has become the most popular destination for Ukrainians, who choose it primarily for economic reasons (Koshulko, 2016); however, it should be stressed that non-economic factors have gained more importance in recent years, especially for the youngest generation (Rovenchak, 2012; Blyznyuk, 2017). Economic migration of Ukrainians is very profitable for the Polish economy. Changes in the Polish labour market – decreasing working-age population, reduced retirement age, low unemployment rate and dynamic development of enterprises actively searching for employees, cause Ukrainians to be perceived as a valuable asset for Polish enterprises. Geographical and cultural proximity of both countries and the perception of Poland as a geographically, politically and socially attractive country are also conducive to this situation. Employing Ukrainians allows for the gap in labour supply to be filled in and ensures continuity of economic activity. Thus, employers are faced with the challenge of creating new solutions to acquire and retain employees from Ukraine, especially, since migration legislation and entry procedures are becoming more liberal in other European countries, which only adds to the competition in terms of attracting this group of employees. The German market seems to be posing a particular threat, as it became more open to economic immigrants from outside the European Union. Thus, employers should become active participants in the "fight" for this group of employees and initiate actions and implement HRM practices encouraging them to work in Poland in the long term or even stay permanently.

Importance of HRM Practices

Human resources practices exert a significant impact on results of organisations (Becker, Gerhart, 1996) as well as the conduct and attitudes of employees (Choudhury, Mishra, 2010). They establish and maintain organisational efficiency (Enz, Sigaw, 2000) and are of utmost importance in terms of attracting employees and retaining them in the organisation, and then developing their knowledge and skills (Choudhury, Mishra, 2010). Practices related to remuneration, trainings, employee participation or flexitime motivate employees to use their knowledge, skills and talents for the benefit of the

organisation (Evans, Davis, 2005). It increases job satisfaction, performance and decreases employee rotation, which, in turn, improves the results of the enterprise (Delery, Shaw, 2001). These dependencies were confirmed empirically in terms of job satisfaction and engagement (Alzyoud, 2018; Gong, Law, Chang, Xin, 2009), civil behaviour (Sun, Aryee, Law, 2007) or quitting work (Nam, Lee, 2017). Choosing the HRM practice becomes especially significant in developing countries (Miah, Bird, 2007) due to specific characteristics of the political, economic, social and cultural environment (Napier, Vu, 1998; Budhwar, Sparrow, 2002). Therefore, the choice of HRM practices made by Polish enterprises employing foreigners, including Ukrainians, is crucial, as they may be an effective solution for retaining them longer.

The article allows for deeper understanding of how HRM practices are used in Polish organisations with employees from Ukraine. It tests the relationship between HRM practices and future plans of this group of employees. This study presents implications based on significant dependencies between certain HRM practices and decisions of Ukrainians regarding their future professional careers and staying in Poland longer or permanently. The main hypothesis, verified in the course of the empirical research, assumed that HRM practices are positively related to future plans of Ukrainian employees.

Method of Study

Research Sample

Human resources management practices, attitudes and behaviours, future plans as well as values and barriers are the subject of the research project focused on Ukrainian employees, conducted by the Authors from February to December 2018. It consists of two parts – the quantitative research carried out in Ukraine among people who worked and continue to work in Poland, and the qualitative research carried out in Poland among employers and other entities involved in actions pertaining to the employment of Ukrainians, e.g. employment agencies, labour offices, trade unions, e.g. the Association of Ukrainians in Poland. The article presents the results of the quantitative research carried out in Ukraine with the PAPI method (Paper and Pencil Interview). A total of 441 respondents were surveyed. The majority were male, aged 25-34, with higher education, working in Poland for approximately 2 years, primarily as unskilled or semi-skilled manual workers in various industries, mostly in construction or catering. The detailed parameters of the research sample are presented in Table 1.

Table 1: Characteristics of the research sample

Sex					
Male			Female		
222 (51%)			219 (49%)		
Age					
Up to 25	25-34	35-44	45-54	55 and over	
118 (27%)	181 (41%)	107 (24%)	32 (7%)	3 (1%)	
Working period in Poland					
Up to 1 year	Over 1 year	Over 2 years	Over 3 years	Over 4 years	5 and over
12 (3%)	153 (35%)	127 (29%)	60 (14%)	51 (11%)	38 (8%)
Type of work performed in Poland					
Manager of one or more subordinates (non-managers)	Vocationally trained craftsperson, technician, IT-specialist, nurse, artist or	Unskilled or semi-skilled manual worker	Academically trained professional or equivalent (but not a manager of people)	Generally trained office worker or secretary	Manager of one or more managers

Research Instruments

The quantitative research was carried out with the use of a questionnaire, prepared by the Authors of this project. The questionnaire consisted in five sections: 1. Human resources management practices, 2. Attitudes and behaviours, 3. Future plans, 4. Values, and 5. Respondents' particulars. With respect to HR, the respondents were asked to provide their opinion on statements describing certain practices and evaluate them on the five-point Likert scale, where 1 means "no" and 5 means "yes". An identical scale was used for future plans. However, in the case of attitudes and behaviours, 1 meant "very low" and 5 – "very high". The values had the scale from 1 **"**of very little or no importance" to 5 – "of utmost importance". The measures were developed for the purpose of this research. They were analysed in terms of reliability with the Cronbach's α, whose value above 0.7 confirmed the reliability recommended for exploratory research projects (Templeton, Lewis & Snyder, 2002).

Results Presentation

In order to verify the research hypotheses, we conducted statistical inference based on the regressions analysis. Stepwise regression was used as the basis for selecting key variables for the model. Then, we constructed three independent regression models. The analyses we conducted are presented in Table 2.

Table 2: Regression analysis summary

	Intention to have a professional career in Poland (N=441)	Intention to stay in Poland longer (at least a few years) (N=441)	Intention to stay in Poland permanently (N=441)
financing education, including foreign language courses	0.287 (0.046)		
offers of work creating the possibility of learning and personal development	0.494 (0.021)		
clearly defined work assignments		0.204 (0.030)	
significantly higher remuneration than in Ukraine		0.521 (0.580)	
fair assessment of performed work (not favouring Poles)		0.384 (0.036)	
respecting employees' rights, e.g. breaks at work, OSH protection, leave entitlement		0.186 (0.024)	0.195 (0.029)
opportunities to be promoted to positions with increased pay and/or responsibility within the company		0.076 (0.025)	0.224 (0.028)

opportunities to develop at work			0.398 (0.041)
participation in trainings			0.197 (0.026)
clearly defined career paths			0.203 (0.034)

Source: Own study.

The models confirm that the practices exert significant impact on future plans of employees from Ukraine and their decision whether to stay in Poland longer or permanently and whether to continue their career in Poland. The first model for "Professional Career in Poland" did not only prove to be well adjusted and reliable, but it also explains as much as 60% of result variances. The main predicates for this model are financing education, including foreign language courses, offers of work creating the possibility of learning and personal development. Essentially, it may be stated that the higher the engagement of employers in developing competences of employees from Ukraine in financial and organizational terms, the more often such employees declare their intention to develop their professional careers in Poland. The second model, pertaining to the factor of "Intention to Stay in Poland Longer", also offers effective measures of adjustment and reliability. It explains almost 70% of variances of results, and its main predicates are HR practices connected with clearly defined work assignments and fair assessment of performed work (not favouring Poles), respecting employees' rights, e.g. breaks at work, OSH protection, leave entitlement, as well as the opportunities to be promoted to positions with increased pay and/or responsibility within the enterprise. Nonetheless, the strongest predicate is remuneration, in particular, the fact that Ukrainians earn more in Poland than in Ukraine. Thus, it may be stated that the application of the aforementioned HR practices exerts a positive effect on the intention to stay in Poland longer (at least few years).

The third model is also characterised by effective measures of adjustment and reliability and explains over 80% of variances of results, confirming that the following HR practices are of importance for Ukrainians considering permanent stay in Poland: respecting employees' rights and creating opportunities for promotion. Moreover, it offers development, organising training courses, clearly determined career paths. The results of the regression analysis show that the hypothesis concerning the relation between HR practices and decisions of Ukrainians to stay longer or permanently and develop their professional career in Poland was confirmed.

Discussion

The objective of the article was to research and explain the relations between human resources management practices and future professional plans of Ukrainians employed in Poland. The key issue was to find practices crucially important for the decision regarding their future career and staying in Poland longer or even permanently.

The research shows that employees from Ukraine find training and development practices especially important. It is because they connect the decisions to develop their career in Poland with the opportunity to develop their competences. What is also important in this respect, is the offer of work which creates opportunities for learning, furthering personal development and provides financial support for education, including learning foreign languages. These findings correspond to findings of Jasniewska and Tomaszuk (2019) regarding Ukrainians, and show that the learning ability and high qualifications (comparable to the competence of Polish employees) are the strengths of Ukrainians,

who intend to continue their development working in Poland. Kupczyk and Przemyślańska-Włosek (2017) concluded that such HR practices increase efficiency and satisfaction with working in Poland among Ukrainians. It is valuable that Ukrainians want to develop their language competences, learn Polish and that they appreciate the engagement of employers who provide financial support to this end. It is an investment which they will not be able to rely on in other countries, which shows that Ukrainians consider Poland to be a valuable area of employment and that they have long-term plans connected with it.

Another important group of HR practices identified in the research is connected with compensation and rewards. The amount of offered remuneration is of particular importance in this case. Thus, it confirms the findings of such authors as Bilan, (2017) or Inshyn and Moskalenko (2018), who point that one of the primary reasons for Ukrainians is economic migration, which results from differences between wages in Ukraine and potential remuneration in the country of destination. In fact, the findings presented in the article show that the decisions whether to stay in Poland longer and develop the career significantly depends on the amount of remuneration. At the same time, the respondents stated (85% answered "yes", 10% "rather yes") that they earn much more than in Ukraine. However, it raises a question whether the amount of remuneration received in Poland is satisfactory, because it helps employees to care for their families by transferring money to Ukraine, or because it allows them to have dignified life in Poland, at a level higher than in Ukraine, or because it offers them the opportunity to bring their family to Poland. In this context, the issue of cultural proximity becomes significant – the similarity between Ukrainian and Polish cultures, languages and customs. This proximity may be conducive to Ukrainian employees staying in Poland longer or even permanently.

Practices pertaining to compensation and rewards include such significant predicates as opportunities to be promoted to positions with increased pay and/or responsibility within the enterprise. It suggests that employers should also pay attention to organisational structures and the opportunities to plan the career path as well as the principles and transparency of promotion. The decision to stay in Poland longer is connected with the fact that employees' rights are respected, the performed work is assessed fairly, without favouring Polish employees, and Ukrainians are offered opportunities for development. Training participation is also very important in this case. However, the research which was carried out shows that even though these practices are significantly connected with the decision on future professional plans of Ukrainian employees, they are implemented in a limited scope in Polish enterprises. Respondents pointed to this shortage in their answers, as 39% of them stated that there are no opportunities for development in their work, only 19% admitted that they participated in training courses and less than 15% declared that their career paths were clearly defined. It suggests that more employers should pay attention to this particular group of practices, especially because the research of Blyznyuk (2017) shows that they are of significant importance to younger generations of Ukrainians, who tend to emigrate most often.

Conclusion

The difficult situation in the labour markets of many developed countries forces them to search for solutions aimed at attracting employees from outside the European Union, which includes Ukraine. It means that Poland, which is currently the most common economic destination of Ukrainians, may soon lose its importance. Simplifying procedures of employing emigrants, offering higher remuneration or creating attractive employment conditions constitute incentives used by such countries as Germany and the Czech Republic to compete for employees from Ukraine. Therefore, despite geographical and cultural proximity, common history, similar languages, lifestyles or attitudes to life constitute important advantages of working in Poland, it is necessary to take certain measures to encourage Ukrainian employees to stay in Poland longer or even permanently. It refers to legal and administrative actions taken at the central level as well as human resources management actions taken by enterprises which employ Ukrainians. The research confirmed the impact of HR practices on future professional plans of Ukrainian employees. The findings suggest that some practices, especially in terms of training and development, and compensation and rewards, are of utmost importance to Ukrainians considering their future professional careers and longer or permanent residence in Poland. They proved especially important among the numerous practices assessed by respondents (43 practices). The findings suggest that HR departments, HR specialists and managers play an important role in the process of developing and implementing HR practices.

Therefore, it offers practical implications of the research on the selection of practices which exert positive impact on performance and satisfaction of Ukrainian employees as well as the decision pertaining to their future career in Poland.

Thanks to the findings pertaining to Ukrainians employed with Polish enterprises, the article offers contribution to the understanding of the preferences of this particular group of employees regarding human resources management practices, which will allow employers to take more appropriate choices as to tools in this area. Since the decision to take up/continue employment in a given country is affected by organisational, institutional and cultural factors, the knowledge offered by this research may also be conducive to integrating actions in certain areas. It presents the synergy of action taken by employers and institutions responsible for such areas as healthcare, educational offer or social security, which, considering the beneficial cultural context, may allow Ukrainians to move their lives to Poland for a few or several years, or even permanently.

Limitations and Future Research

One of the limitations of the research is connected with the essence of questionnaire surveys and their static nature, thus these issues should be further validated using a longitudinal data set. Another limitation is focusing on one national group. Ukrainians are of special importance to the Authors, since they constitute the biggest group of employees from abroad in Poland and their high level of assimilation capacity is an advantage for employers. Bearing in mind the fact that employees from Belarus, Moldova or Kazakhstan and, more recently, from India, Nepal, Bangladesh or Philippines are pursuing permits to work in Poland, it becomes more important to recognise human resources management practices dedicated to employees from these cultures.

As it pertains to employees from Ukraine, another interesting area of research may also be to diagnose human resources management practices in enterprises operating in Ukraine, and then compare the scope of such practices in Polish and Ukrainian entities.

Patient Safety Management in The Face of E-health Development

Malgorzata DYMYT

Faculty of Management, General Tadeusz Kosciuszko Military University of Land Forces, Wroclaw, Poland, e-mail: malgorzata.dymyt@awl.edu.pl

Abstract

The development of information and communication technologies creates opportunities to support innovation in the health services sector in the sphere of eHealth services and tools. The implementation of digital technologies in the sphere of health affects the safety of patients. The question about the possibilities of using eHealth services and tools in supporting patient safety management becomes a key issue. The aim of the article is to present the essence of patient safety and the objectives, benefits and areas of eHealth application in the process of patient safety management.

Keywords: E-health, Patient Safety Management, Health Care, Digital Health Interventions.

Introduction

The basic assumption of the article is the issue of ensuring patient safety in the era of progressive development of digital health. With the advancement of information and communication technologies, the possibilities of supporting the development of innovation in the medical services sector are expanding. Real benefits resulting from the implementation of digital technologies in the processes of providing health services, strengthening the role of the patient, involvement of patients and the community in health-related activities are recognised. The institutions of the European Union point out that thanks to the significant use of digital innovations it is possible to promote health, prevent and combat illnesses, help meet patients' needs and facilitate equal access to high quality care for citizens, and therefore recommend the implementation of priority actions in three main areas such as: citizens' secure access to and sharing of health data across borders; better data to advance research, disease prevention and personalised health and care and digital tools for citizen empowerment and person-centred care (Commission to the European Parliament, 2018).

Progress of digital technologies contributes to the dynamic development of eHealth, including services and tools for mobile health (mHealth) and telemedicine. According to Eurostat data, in 2019 already 55% of individuals aged 16 to 74 (citizens of 28 EU countries) used the Internet to search for health-related information (injury, disease, nutrition, improving health, etc. within the last three months before the survey) (Eurostat, 2020).

Digital innovations used in the health sphere can be a source of benefits in increasing the availability of health services, improving communication between participants of the health care system, providing high quality health services that significantly influence the patient safety. At the same time digital technologies can generate safety risks, especially in the area of data management, quality and reliability of the data collected and provided to patients. The key challenge for health care systems is to ensure health safety, including safe data management in the field of digital health interventions. This applies both to the recipients of health services (current and potential patients), health care providers (in the institutional dimension and at the level of employees) as well as national and local decision makers responsible for the functioning of the health system and organisations related to the information sphere.

Research Approach

The starting point in the research process was the assumption that the use of eHealth services and tools is important for the management of patient safety. The author tried to answer the following key questions:

1. what is the essence and what factors determine the management of patient safety,
2. what functions are the tools and services of eHealth in the health care system,
3. how and in what areas digital health interventions can support patient safety management.

The main aim of the article is to present the essence and determinants of patient safety and to identify the possibilities of using eHealth tools and services (digital health interventions) in the process of patient safety management. The article is conceptual and based on the analysis of literature as well as documents. The following research methods were used: a) study of literature - review and in-depth analysis of literature in the field of management, related to the patient safety management and digital health, and b) analysis of documents - review and in-depth analysis of international strategic documents on health policy, reports and legal acts.

The Essence and Determinants of Patient Safety Management

The issue of safety in the field of health is multidimensional. The complexity of the problem stems from the very definition of health, which is considered as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 2020). In a broader sense health means a "dynamic state of physical, mental, social and spiritual well-being" (Chuengsatiansup, 2003). In the considerations of the essence of health safety, the specific features of health services are important, in particular their professional character, which is usually a source of disproportions in the knowledge resources, occurring in the relations between a medical worker (a professional) and a patient (not possessing specialist knowledge). The main features of health services include: intangibility and lack of guarantee of the effectiveness of the health service, psychological complexity of the process (stress accompanying patients), constant interaction between the doctor and the patient, professional knowledge of the service provider, which enables professional performance of the service and implies the need for good communication between the doctor and the patient to build trust (Bukowska-Piestrzynska, 2009).

The concept of safety in the area of health is associated with such issues as safe health care, health safety, patient safety and concerns both the system level (health care system and society), as well as the patient's level (relations between the individual patient and the organisation providing health services).

Safety is an indispensable and desirable feature of health services. According the World Health Organisation (WHO, 2018a), a good health system should deliver quality services to all people, when and where they need them. Ensuring security is the domain of the state that is responsible for shaping such a health care system that will provide good health services to citizens. In this context, health safety is the process of continuous efforts of the state and individuals to meet their health needs and manifests itself in the certainty of action of government administration bodies, local government administration and subordinate services in the field of protection of life and health (Paplicki, (2016). These activities should lead to achieving health safety, i.e. a state guaranteeing no threats that may cause a deterioration or loss of citizens' health (Ameljańczyk and Ameljańczyk, 2012). In the general dimension health safety concerns the formal and organisational determinants of the health care system and is related to the activities of decision-makers (at the national and local level) and health care providers responsible for shaping and efficient functioning of the health system. According to B. Bober (2016), the level of health safety is determined by the health care system (including public hospitals) and is closely related to the availability of health services.

The concept of patient safety is closely related to health safety. Patient safety, as a feature of health care systems, means the discipline of the health care sector, based on the use of scientific methods of

maintaining safety in order to create a trustworthy system of providing health services and reduce the incidence of adverse events and minimise their consequences, as well as to increase the chance of returning to normal after the occurrence of these events (Patient safety, 2017). A sense of safety may be subjective and result from personal experience, awareness of rights, knowledge of the principles of the functioning of the health care system and the availability of health services, as well as from the experience of other patients. In the individual dimension "patient safety means freedom, for a patient, from unnecessary harm or potential harm associated with health care" (The Council of the European Union, 2009).

Patient safety is also defined as a set of activities including "the avoidance, prevention and amelioration of adverse outcomes or injuries stemming from the process of health care" (Vincent, 2011). These activities apply to all participants in the health system, including policy makers, health service providers, medical staff and other stakeholders, and require cooperation within formal and informal networks. From the perspective of health service providers, safety is determined by the operating conditions (formal and organisational conditions, resources, infrastructure and competences) and responsibility for the consequences of adverse events.

It is recognised that safety is a dynamic property of the health care system; therefore improving patient safety means organisational continuous learning and knowledge transfer at the system level, resulting in a need to change the approach to setting organisational procedures and taking into account the specificity of processes, divisions, professions and levels (Wiig and Lindøe, 2009). Patient safety, as an indispensable determinant of the delivery of high-quality health care, concerns three basic elements of the system, such as: structure (resources, organisation of the health care system, safety culture, availability of knowledge, transfer of knowledge, trainings), process (activity of health care providers) and outcomes (adverse events and injuries, consequences of clinical activities by providers) (Jha et al, 2010).

Most developed countries have the following elements in their strategies for improving patient safety (Stroetmann et al, 2007):

1. a "just" or "fair" culture, conducive to reporting and questioning - incident reporting and analysis systems at local and national level;
2. an in-depth analysis process to identify and assess the causes of incidents and aggregated incident reviews;
3. a process that ensures the implementation of activities and demonstration of adequate improvement of patient safety and quality of care;
4. effective information exchange processes at various levels - national, organisational and clinical - for learning and improvement;
5. redefinition of compensation systems and their impact on culture and achievements in the field of patient safety.

R.M. Wachter indicates that improving security requires a multi-dimensional approach and identifies five main areas of relevant activities and initiatives such as: regulation, error reporting systems; information technology; the malpractice system and other vehicles for accountability and work force and training issues (Wachter, 2004).

The process of patient safety management aimed at permanently maintaining the designated security state has a multistage and complex nature. The organisation of safe processes for the provision of health services requires action both at the systemic level as well as at the institutional level. A comprehensive approach is essential in this process, including coherent actions related to the establishment of the following components: safety definition (the expected, target result of safety management), safety model (a description of the way in which organisation functions and accidents happen), safety management model (background assumptions adopted in the organisation to manage and improve safety, elements necessary for the management and improvement of patient safety) and safety management system (a set of systematic organisational processes necessary to manage the organisation to ensure and develop security, that aim to provide a structured management approach to

control the risk in operations and increase the organisation's ability to function safely) (Macchi et al, 2011).

It is indicated that four areas are important for effective implementation of patient safety practices, such as: safety culture, team work and leadership commitment, structural organisational features, external factors (financial and performance incentives, patient safety regulations), availability of implementation and management tools (training resources, internal organisational incentives) (Taylor et al, 2011). Patient safety management should be comprehensive and consistent with the overall management system. Safety management, treated as an integral part of good management in general, should be based on the model: Plan, Do, Check, Act, under which the following activities are undertaken (HSE, 2013):

- planning - defining and communicating acceptable performance and resources needed;
- doing - determining the risk profile, identifying and assessing of risks, controls/record identifying and process safety knowledge maintaining, organising activities and implementing the plan;
- checking - performance measurement - implementing and managing of control measures, investigating the causes of accidents, incidents or potentially accidental events;
- acting - performance reviewing, taking actions based on lessons learned, including inspection and audit reports.

Summing up, it should be emphasised that patient safety management is a complex, multifaceted process involving many different stakeholders of the health care system, which requires constant striving to ensure and maintain a state in which patients feel safe in the area of health. This process means a set of integrated activities consisting in planning (identifying threats and their conditions, setting safety and regulatory standards, procedures for reaching this state), organising (providing human, financial, material and information resources), stimulating to operate safely (creating and maintaining safety culture by training, promoting, motivating), controlling and improving (system for monitoring and processing of adverse events, measurement, analysis and evaluation of the achieved level of safety). These activities must be coherent and integrated at all health care system levels and take into account determinants of health policy, social needs, demographic changes and technological progress, as well as internal conditions and the specificity of the operation of entities providing health services.

Ehealth In the Health Care System - The Essence, Tools and Goals

The concept of eHealth is defined in many ways, indicating, in a different perspective, the scope of activities (services), tools or functions. In broad terms, according to the definition of the World Health Organization, eHealth is “the cost-effective and secure use of information communication technologies (ICT) in support of health and health related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research” (WHO, 2016a). The European Commission (2012) defines eHealth as “the use of ICT in health products, services and processes combined with organisational change in health care systems and new skills, in order to improve health of citizens, efficiency and productivity in health care delivery, and the economic and social value of health. EHealth covers the interaction between patients and health-service providers, institution-to-institution transmission of data, or peer-to-peer communication between patients and/or health professionals”.

In recent years, the concept of digital health has been promoted. WHO (2019) indicates that digital health or the use of digital technologies for health is rooted in eHealth and means a term that includes eHealth and mHealth as its subset. The European Commission (2019) use the concept digital health and care that means “tools and services that use information and communication technologies (ICTs) to improve prevention, diagnosis, treatment, monitoring and management of health and lifestyle”.
In addition, the concept of digital health interventions has been introduced. According WHO (2019) a digital health intervention is “a discrete functionality of digital technology that is applied to achieve health objectives”. Digital health interventions (DHI) may include activities such as: promoting

healthy behaviours, providing remote access to effective treatment methods, enabling patients to access information on their health status, improving results in people with chronic diseases, exchanging experiences with other patients, changing perceptions and cognitions around health, assessing and monitoring specified health states or health behaviours, titration of medication, improved communication between patients and health care professionals, explaining health priorities and making treatment decisions consistent with them (Murray et al, 2016). It is indicated that digital health interventions are conducted in four main areas such as (WHO, 2018b):

1. interventions for clients - potential or current users of health services, including health promoting activities and caregivers of clients,
2. interventions for health care providers - health care providers are members of the health workforce who deliver health services,
3. interventions for health system or resource managers - managers involved in the administration and supervision of public health care systems, including activities related to supply chain management, health financing, human resources management,
4. interventions for data services - cross-sectional functions, related to supporting a wide range of data management activities (collection, use and exchange of data).

Digital health interventions defined also as "the use of information and communication technology (ICT) as a tool to improve health systems and services" include mobile health (mHealth) and electronic health (eHealth) (Wilson et al, 2014). Mobile health (mHealth) is a dynamically developing field that can contribute to the transformation of health care and increase its quality and efficiency, and means medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices and including applications such as lifestyle and wellbeing apps that may connect to medical devices or sensors (e.g. bracelets or watches) as well as personal guidance systems, health information and medication reminders provided by SMS and wirelessly provided telemedicine (European Commission, 2004). MHealth is expected to play a significant role in changing health care towards a patient-centred and value-based delivery model, improving work-place productivity, increasing patient engagement and patient safety, better coordinating care, and facilitating payments (Deloitte, 2015).

The concept of telemedicine (telehealth) is also connected with eHealth. Telemedicine is defined as "the delivery of health care services, where distance is a critical factor, by all health care professionals using information and communication technologies for the exchange of valid information for diagnosis, treatment and prevention of disease and injuries, research and evaluation, and for the continuing education of health care providers, all in the interests of advancing the health of individuals and their communities" (WHO, 2010). It is emphasised that telehealth can contribute to improving (speeding up, reducing costs) equal patient access to high quality, cost-effective health services wherever they are, as well as increasing the uniformity of practice (higher quality of care) and providing universal health coverage, especially for vulnerable groups and ageing populations (WHO, 2016a).

It is also pointed out that the benefits of using eHealth (including mHealth and telehealth) services are multifaceted and relate to system performance levels. The main categories of benefits include (Reijonsaari, et al, 2005):

- quality of care: improved clinical data collection and analysis at organisational and national level, portability of patient information across health care network, improved patient-provider communication and more accurate and accessible patient records,
- cost: improved triage to reduce unnecessary office and emergency department visits, improved home care to reduce nursing home and hospital care, more robust disease management,
- efficiency: productivity of physicians increases, reduced paper flow and less telephone calls, faster processing of administrative transactions, automated scheduling and prescription refills.

However, there are a number of barriers that are not conducive to wider use of eHealth, in particular such as: lack of awareness and trust in eHealth solutions among patients, citizens and health professionals; lack of interoperability between eHealth solutions; limited evidence on a large scale regarding the cost-effectiveness of eHealth tools and services; lack of legal clarity for mobile applications for health and well-being and lack of transparency regarding the use of data collected by such applications; inadequate or fragmented legal frameworks, including the lack of reimbursement schemes for eHealth services; high start-up costs associated with the setting up of eHealth systems; regional differences in access to ICT services and limited access in deprived areas (European Commission, 2012).

The aspects mentioned above make the implementation of eHealth a difficult challenge at the system and executive level. EHealth means organisational (structural, procedural) and infrastructural changes, especially in the sphere of methods and communication tools that force the acquisition of new skills, thus generating the needs of interdisciplinary development.

An important challenge is the cross-sectoral cooperation and creation of well-functioning networks of relations between the participants of the health system (policy makers, organisations conducting health-related activities, medical staff and patients: potential and currently declaring needs in the area of health services and their families or friends) and sectors of services supporting eHealth (organisations responsible for information networks, etc.). According to G. Eysenbach (2001), eHealth is an area at the crossroads of medical informatics, public health and business, referring to health services and information provided or improved using the Internet and related technologies, and therefore in a broader sense it is not only technical development, but also state of mind, way of thinking, attitudes and commitment to networking, global thinking, to improve health care at the local, regional and global levels by means of information and communication technology.

In conclusion, it should be noted that eHealth can be considered a dynamic socio-cultural phenomenon meaning the development and implementation of digital technologies in the broader sphere of health and applies at various levels of the care system (macro, meso and micro) and in various dimensions of action relating to different stages of the service delivery process, supporting not only the treatment, but also prevention, health education and management activities (planning, organising, coordinating and monitoring health care).

The Use of Ehealth In the Management of Patient Safety - A Review of Scope and Functionality

Digital health interventions cover a wide range of services and tools that can be used at different stages of the patient safety management process. It is expected, that digital solutions should contribute to clinical decision support, more efficient use of health care resources, better targeted and integrated and safer health care, in particular regarding the exchange of information between health care professionals, reducing the number of avoidable errors and adverse events, and improving coordination and continuity of care and better adherence to treatment (European Union, 2017).

WHO (2016b) emphasises that key gaps in patient safety in any health care system include communication and teamwork, ordering and interpreting diagnostic tests, data management, transition between care levels, and completeness of patient records. EHealth can contribute to the reduction of these gaps by providing decision support for prescriptions and test orders, improving documentation and communication for transfer between providers, tracking and sharing the results of diagnostic tests and improving data monitoring and analysis (WHO, 2016b).

The core of digital health interventions is information transfer, which can ensure effective communication and interaction between participants in the health care system. In particular mHealth enables multidirectional communication, which can be implemented in the following types (WHO, 2016a):

- communication between individuals and health services - health call centres, health care telephone helplines, emergency toll-free telephone services;
- communication between health services and individuals - treatment adherence, reminder to attend appointments, community mobilisation, health promotion campaigns;
- consultation between health care professionals (mobile telehealth);
- intersectoral communication in emergencies - emergency management systems;
- health monitoring and surveillance - health surveys, surveillance, patient monitoring;
- access to information and education for health care professionals - access to information, resources, databases and tools, clinical decision support systems, electronic patient information, m-learning (access to online educational resources using mobile).

The benefits of implementing digital health interventions affect both the patients themselves and those providing health services, and may include effects such as: improvement of results, reduction of unwarranted variation, reduction of preventable harm, improvement of the appropriateness of health care, better patient centeredness, increased possibilities for monitoring and quality improvement (Shaw et al, 2017). The main functions of digital health interventions include (Shaw et al, 2017):

- electronic patient portals - providing patients with secure access to their health information and helping consumers to become active participants in decision-making about their health care;
- electronic patient reminders (mobile technologies) - delivering reminders to a large proportion of the patient population group; promoting successful outcomes by generating personalised communication between health care professionals and patients and impact on clinical workflow;
- information-sharing at discharge - critical to continuity of care and promotion of patient safety and promoting timeliness of preparation and transmission of patient information to primary care providers;
- computerised provider order entry including electronic prescribing - improving organisational efficiency and prescribing safety (in the field of compliance with medication guidelines);
- clinical decision-support systems - matching patient-specific characteristics to the database; creating personalised predictions for the assessment of disease status, diagnosis, appropriate treatment options and other clinical decisions; generating reminders and alerts for the patient when a deviation from the recommended care is detected and positive impact on patient safety, especially in terms of accessibility, clinical evaluation, data integration, compliance with guidelines, indicated care, organisational performance, patient outcomes, resource use and safety prescription.

Fundamental to the provision of safe, knowledge-based health care is appropriate collection analysis and feedback of health information, robust process and system design for clinical care and supports, risk management in all governance processes, and monitoring and activities based on real data connected with organisation performance and identified needs of the community (Stroetmann et al, 2007). In addition, it is pointed out that the key to effectively managing for health and safety are the following aspects: leadership and management (including relevant business processes); trained, qualified workforce; an environment in which people are trusted and involved (HSE, 2013).

WHO (2016c) indicates that digital interventions to involve patients in safer primary care fall into three broad categories such as: educating patients and health care providers for safer health care, obtaining retrospective or real-time feedback and engaging in improvement systems or services. Specific activities as part of strategies to increase patient engagement in safer primary care recommended by WHO (2016c) relate to:

- educating health care providers to involve patients, both at the organisational and individual level; including patient engagement and safety in educational curricula at undergraduate and postgraduate level and developing a learning culture, rather than a blaming culture;
- supporting patients to become actively involved - encouraging patients to report on safety incidents, near misses and safety concerns; actively promoting patient feedback systems; giving feedback to patients on follow-up actions taken about the issues they raised; considering legislation that supports patients and their families to engage in issues relevant for their safety

and providing patients with appropriate, accurate and up-to-date information about treatment and safety issues in a user-friendly language and format;

- broadening the ways in which patients are involved - exploring alternative ways of communicating with patients, such as telephone, e-mail and online video calls; putting in place systems to facilitate patient access to their health records; involving patient advocates, where appropriate, to support the engagement of patients at the direct care, organisational and policy level; supporting the work of patient-led voluntary associations and considering campaigns aimed at raising public awareness about the need for and benefits from the strengthened engagement of patients and their relatives in patient safety in primary care;
- recognising the importance of communities - adapting engagement strategies to the local social and cultural context and recognising that patients are part of social groups, families and communities and that these broader networks can be a positive force for change;
- providing an enabling and supportive environment - encourage and facilitate interaction among health care professionals, and engagement with patients and families; promoting open disclosure about safety incidents to patients; linking patient feedback systems to organisational systems for learning and improvement, similar to staff-initiated incident reports; providing information and support for self-care such as counselling, peer-support groups and coaching; designating and supporting patient safety champions or advocates, where appropriate, to help facilitate patient engagement and setting up mechanisms for patient engagement at the systems level.

In conclusion, it should be emphasised that the variety of digital solutions, including eHealth services and tools, creates a wide range of possibilities for supporting management processes in the areas of safety and quality of health care in particular. EHealth supports decision-making and controlling processes in the management sphere regarding the organisation and delivery of health services, as well as clinical decision, is a source and tool for data transfer, and enables measurement and monitoring of safety in the health care system, thus reducing errors and risk of occurrence adverse events. As a communication and education tool for patients and staff, eHealth supports the development of the idea of patient involvement and empowerment of patients in the health care system, which contributes to patient safety in a qualitative context related to accessibility, better communication, and information exchange processes.

Conclusions

The dynamic development of digital technologies creates opportunities for improving the health care system, in particular in ensuring patient safety. According to the World Health Organization (2016c), electronic tools will be crucial for improving safety, especially in the area of activities such as: the use of electronic health records for more accurate and complete patient records; timely and reliable sharing of health data; supporting the diagnosis, monitoring and management of diseases and conditions; effecting behaviour change and reduction of health risk, and empowering and engaging patients and families in their own care, support in organising communication between professionals in a way that reduces errors and improves coordination, reduction of unnecessary consultations and hospitalisations, improvement of access to knowledge about health conditions and management of them both for specialists and patients.

The implementation of digital solutions can be a source of threats, especially in terms of access to health data, the diversity of Electronic Medical Records, the lack of technical interoperability and access to digital health services (Commission to the European Parliament, 2018). The use of eHealth tools means the necessity of creating a convenient, coherent at the national and international level framework to ensure the safe functioning of health care systems. Key to the safety of patients is the shaping of data management systems, consistent knowledge management both in terms of personalised data and general health information. The necessity of efficient knowledge management concerns both the institutional and system level (in local and national dimensions) and also requires taking into account the international context. The condition for the effective and safe use of digital technologies in health services is cooperation in the international dimension. As the European Commission points out, the concerns related to electronic data exchange primarily regard the risk of breaching privacy, the cyber security threat and the quality and reliability of data, therefore the

following actions should be prioritised: the development of EU-wide standards for data quality, reliability and cybersecurity, EU-wide standardisation of electronic health records and better interoperability through open exchange formats (Commission to the European Parliament, 2018).

EHealth services and tools are widely used in various activities in the process of patient safety management, however, they require coherent, complex interaction at all levels of the health care system (macro, meso and micro) and intersectoral cooperation, in particular with organisations dealing in research and development of digital innovations, implementation of digital technologies and ensuring data security. Effective patient safety management is possible thanks to the involvement of all participants in the health care system. EHealth is a challenge for health care providers, managers and staff, and requires constant learning, readiness for change, and the responsible use of digital solutions. In addition, the potential of eHealth, digital health interventions can be used with the active participation of patients in developing health awareness, their involvement in communication and education processes.

To support the practical, operational dimension of the provision of health services, it is important to present examples of activities, eHealth projects and to promote good practices in the field of patient safety management. The article is valuable for identifying, systematising and highlighting the importance of digital solutions in improving the patient safety management process and is the starting point for more in-depth research.

Determinants of Horse Industry Network Management

Marta WINCEWICZ-BOSY

General Tadeusz Kosciuszko Military University of Land Forces, Wroclaw, Poland,

Abstract

The aim of the article is to indicate the main factors affecting the creation and management of networks in horse industry. The network approach is currently one of the main models for the implementation of economic and social activities. This approach is also visible in the area of the horse industry, whose author's model is the basis of the presented analyzes. The article focuses on the main determinants of the creation and management of network systems, such as: the specificity of the main good and the process of its creation, relations that create entities that are a participant of the system and the specificity of the entities themselves. The article was based on the analysis of literature and documents as well as participant observations, and as a result of empirical research conducted by the author since 2002.

Keywords: Horse industry, business networks, horses business relations, horse business management

Introduction

For ages horses accompanied humans in performing different duties. First, as an animal that was hunted - and therefore a source of meat and other post-slaughter products, then as a means of transport and tractive force. Over the course of history, the horse has been a companion to struggle and competition, as well as an element of recreation and the development of other forms of activity such as, for example: hippotherapy. Today, Horses are mainly business which reaches far beyond farming and trade. In many countries the horse industry is a field of economy which creates possibilities for development of different type entities. The most important and the most difficult task of contemporary equine business is to provide horses and clients with the desired characteristics (resulting from the desired use profile), at a specific time and place, at acceptable costs. In order to be able to offer a suitable horse to the client, at least a few years earlier, the breeder must make the right choice, and then the owner of the animal must properly manage his farming and work, while engaging properly selected entities and resources that create a specific network of relationships.

The aim of the article is to indicate the main factors affecting the creation and management of networks in the horse industry. The article was based on the analysis of literature and documents as well as participant observations, as a result of empirical research conducted by the author since 2002.

Network Approach

The dynamics of business activity makes it difficult to indicate the perfect form for running modern business. Internationalization, globalization, regionalization as well as the impact of competition and consumers are the reasons why the necessity of change and flexibility have become indispensable elements of the struggle of economic entities for survival and development. Changes on the market and technological progress strengthen the conviction that it is necessary to create specific systems that will achieve the intended goals. the business exchange to a large extent takes place in business relationships, which in different ways are connected to each other and form network-like structures (Laage-Hellman et al, 2018) (Håkansson et al, 2009). In the literature related to the analysis of agri-food markets, the authors point out that today's supply chains and networks are becoming the

dominant form of cooperation (Bijman et al, 2006). However, among the functioning of economic systems it is extremely difficult to set clear boundaries and indicate membership in networks or chains. This is all the more difficult since there has been a shift from a concrete and specific understanding of the network as a set of mutually intersecting threads combined into one understanding of a more abstract, or defining the network as a set of points in the communication structure (Blanc, 1995). The essence of the contemporary network approach is the overall relationship of the company with the environment, which form a network of connections (Ratajczak-Mrozek, 2009), based on the theory of graphs (Beineke and Wilson, 2005) and general system theory, created by von Bertalanffy (1950). This theory demonstrates the need to integrate the social and natural sciences and prefers a network approach based on the interaction of the components that make up the system (von Bertalanffy, 1950). Especially that such interconnected elements, functioning as a whole, are able to generate numerous synergistic effects.

The basics of the methodology of network thought were proposed by Gomez, Probst and Ulrich (Zimniewicz, 1999). Their concept is based on the following elements: parts and whole, network, openness, complexity, order, control and regulation, development. A special area of research is formed by business networks, which constitute a set of long-term formal and informal relationships that exist between two or more entities. The essence of the network approach is based on the idea of exchange and mutual trust, which are the basis of the system's flexibility and the increase of competitive advantage (Łapicka, 2009). The basic parameters of the efficiency of the supply network include: the ability to react quickly, optimize the use of resources and increase flexibility (Kearney, 1999). According to Krawczyk (2011), networks are a form of organization in which at least two legally autonomous and formally independent entities accept and accept the obligation to comply with specific, relatively stable relations that limit their freedom of market activities, but do not introduce hierarchical relationships. Christopher (2000), identifies the network as a network of related and interdependent organizations that work on the basis of mutual cooperation jointly control and streamline material flows and information from suppliers to end users. In 1990, Powell (1990) published the article "Neither market nor hierarchy: Network forms of organization", in which he presents the network as an element of the linear system of the market - hierarchy. He states that forms of activity identified primarily as a system of transactions, and attributed to either market or hierarchical relations, may also take another indirect form. Their diversity, apart from goals and strategy, are influenced by: context and social structure, relations (including interdependence), community of interests, reputation, management systems, power structure, interactions and other hard to measure factors. A ‘network organization’ is usually conceived as an organization that is quick and flexible in adapting to changes in its environment (Vega-Redondo, 2013). Networking is thought to facilitate the development of personal and professional opportunities (Baker, 2000) (Wolff et al, 2008) and contribute to organizational functioning by supporting greater organizational communication and access to resources (Forret et al, 2001) (Gibson et al, 2014).

In network forms, allocation sources are not located in individual entities, but in the relations they create. Networked enterprises are marked by heterogeneous inter-organizational processes and interdependencies (El-Sawy and Pereira, 2013) (Palo and Tähtinen, 2013), where value creation and capture is not a mere result of a dyadic relationship between provider and consumer, but value is created and captured by a collective effort of the involved network (Solaimani, 2018). Their main goal is to create opportunities for partners to better adapt to changing conditions and opportunities to share benefits and costs.

Horse Breeding

The basic factor determining a specific approach to the horse industry is the horse and his relationship with man. Because of the man's relationship to the horse created over the long history of both species, the horse obtained a position unmatched by any other animal. Its versatility and usefulness for a human being is not irrelevant. Although its role has changed over the centuries, it remains an important subject of interest. Changes in the ways horses are used significantly affect the farming processes, forcing its operators to adapt to market requirements, thus increasing flexibility.

While in the rearing processes changes can be made relatively in short periods of time, changes in the breeding area require a long time - counted in years.

Figure 1: Flows of horses between breeding and other types of use

By animal breeding, the most commonly understood is a set of zootechnical treatments aiming at the genetic improvement or preservation of the characteristics of hereditary animals (Szulc, 2005). It is the central area of horse business. Its quality and specialization are the main determinants of the possibilities of other areas. Farm animals come from farms, which through the rearing process, realized for the needs of particular types of activity, gain value and become the object of desire and satisfy the needs of customers. Consequently, the flow of goods (and services) from the farm to individual entities forming the area of use created due to various types of horse use (Fig.1). The main elements of this area are: sport, races, recreation, fate and industrial use, shows, security system, other types of use, which form the core of the horse industry. Flows carried out between individual areas often have the nature of feedback. Especially in relation to races, sports, recreation and shows in the use processes, the best individuals are selected, which are then returned to the breeding system. They form the basis of individual (species) progress aimed at strengthening the most desirable traits in the next generations.

Figure 2: The core of a horse business - subject groups

Based on the empirical studies, it can be concluded that the time of shaping individual breeding activity in the desired direction is 10-20 years, while the time of obtaining outstanding individuals can not be estimated. Although it is possible to identify certain trends on the market as to the

characteristics desired in horses, which will be the future object of use, this is not an easy thing. Offering products (horses) in accordance with the current fashion is possible only if you manage to hit the expectations of potential customers, long before they appear. The breeding process consists of a number of elements, which include, above all: feeding, nurturing, breeding, rearing youngsters, mortar to perform certain functions and work, selection of the future breeding material (because of bravery, productivity at work, type, construction, viability, fertility), group or individual selection of individuals for reproduction, formation of bloodlines, breeding (Pruski et al, 2006). Breeding activity is based on individual decisions of individual breeders. However, they are largely undertaken on the basis of signalers flowing from the area of use, as well as the area of entities conditioning the proper functioning of the horse business. These flows create a multidimensional network of multiplicative relations. A specific role is played here by properly created state policy and the system of regulation of national and international organizations (Fig. 2).

An important element is also the selection of appropriate entities that will cooperate in order to obtain a specific horse, consistent with the requirements of customers, providing various types of goods and services. These include: veterinarians, research centers, copulation centers, veterinary clinics and hospitals, veterinary laboratories, carriers, breeding material banks, stallions and other breeders, as well as suppliers and service providers typical of horse farms.

Breeding activity is a long-term process. It starts with individual and genetic selection depending on the future destination of the animal. This selection is based on the knowledge and many years of experience and intuition of the breeder. In the analysis of the time needed to create a horse with the desired traits, it is necessary to take into account the period of pregnancy and the time needed to obtain an age allowing for the entry into specific types of activities in the area of breeding and imprinting. From the point of view of economics, pregnancy is the basic manufacturing process - as a result of which an output good for further processing processes is obtained. Depending on the breed, it lasts from 270 to 370 days, most often it is 335 days.

During the rearing process, the horse gains the behavior and skills that allow effective cooperation with the human being. Between the second and fourth years of life, depending on the breed, individual individuals participate in bravery trials. Their aim is to determine the suitability for particular types of future use and further improvement of breeding. Around 6-7 years old, young horses start their professional career. Depending on the breed, horses cease to grow between 4-7 years of age, therefore it is assumed that the 7-year-old horse is already a fully developed individual (Beown and Powell-Smith, 1984). From that moment on, they become working horses - performing target tasks. The average lifespan of a horse is 25-30 years, depending on the physical and mental condition between 20 and 30 years pass to the so-called "retirement". This means a gradual withdrawal from use. Often, during this period, they change their place of residence to centers for "retired" horses, distant from urban centers, where they live their days spending time in pastures. These processes are further complicated by the fact that mistakes made in them cannot be reversed. You can make attempts to neutralize them, however, it is a costly and time-consuming element, and without a guarantee of success. Errors made affect the lower usability of horses for the targeted tasks and reduce the safety and comfort of cooperation with people, which is reflected in the reduction in their value.

Horse Farming

The main type of entity performing tasks in the use of horses in the horse industry is the horses farm. By farm for horses, in accordance with applicable EU regulations (Act on the system of identification, 2004)(Commission Regulation (EC) No 911, 2004), should be understood as: a farm or an agricultural enterprise, a training center, stable or room or other place where equidae are habitually kept, kept or bred. At the same time, the farm is the seat of the herd understood as any buildings, farms, pastures or open spaces in which a given herd or flock of different animals resides, and the animals are kept breeding and breeding. In order for an economic entity to be able to function efficiently and effectively, it is necessary to have adequate resources (land, capital and labor), proper location, and above all, there are needed customers whose needs can be satisfied.

The choice of appropriate human resources determines the quality of the processes implemented. Especially people who have contact with horses in their work should have special qualifications and predispositions. The physiological conditions of horses make feeding systems a particular area of concern. Horses are animals with a very sensitive digestive system and to keep them healthy, special attention should be paid to both the selection and the feeding process itself. Any sudden changes in this area affect the deterioration of health and can even lead to the death of an animal. Also, the extremely delicate psyche of these animals creates the need for great care of the staff, and its violations affect the digestive and immune system.

In today's world, in order to achieve an adequate level of meeting objectives, it is necessary to undertake cooperation with various entities. Their proper selection greatly influences the obtained results. Therefore, they must create a system that functions efficiently both in relation to the environment and properly organized internally. An important element is the selection of cooperating companies who can provide the right quality and quantity of goods and services to be delivered. To the group of suppliers of goods and services, which are necessary to ensure frequent and regular implementation, to ensure the proper functioning of the horse farm should be primarily: feed, linings, supplements, care and services: veterinary, blacksmith, accounting, administrative, waste disposal and related with manure removal. Among the goods and services, supplies of which should be organized and implemented on a regular basis, however with less frequency, include cleaning and disinfection agents, farm equipment, household items and tools, equestrian equipment, clothing, clothing for pharmaceuticals, care tools, components for maintenance of green areas, as well as services: transport, IT, organizational, financial-insurance, marketing, education, rehabilitation, consulting, storage. For supplies of low frequency, however, those without which the functioning of horse farms is impossible include the supply of machinery and equipment: agricultural, farm, training, and the supply of training equipment, elements of small architecture, substrates, means of transport and handling, as well as construction services and renovation, hotel and catering, medical, publishing, liquidation service of animals dead or killed out of necessity.

An equally important element as the quality and reliability of deliveries that are an important factor of trust is the ability to influence the product or service being the subject of the transaction. The specificity of usage diversity, adaptation to particular individuals, as well as the requirements of clients force a far-reaching individualization. Therefore, an important group of cooperators are craftsmen as well as micro and small enterprises, showing a high degree of flexibility and individual approach. For many owners and users of horses, the possibility of establishing personal relationships is also important. It is worth mentioning that in many cases the horse is treated not only as a pet (like a dog or a cat), but also as an important member of the family. There is often a far-reaching anthropomorphisation of horses. Therefore, also influencing its well-being by creating personal relationships with people around it is an important element of the horse's business relationship system.

Horse Industry as A Network of Entities

The term horse industry should be understood as any form of activity directly or indirectly related to horses. The basic areas of horse business are created by its core and core environment. The core elements of the horse business are: breeding and breeding, equestrian, horse racing, recreation, agritourism, hippotherapy, use in security systems, production and processing, and other specific types of use. On the other hand, the environment of the horse business is a system of activity of various types of entities conditioning the proper functioning of the horse industry (Fig.3) (Wncewicz-Bosy, 2012).

Figure 3: Horse Industry

The basic elements characterizing the compounds created within the equestrian industry include: caring for the safety of people in contact with horses, trust, primacy of quality, appropriate adaptation to the destination and the needs, knowledge and skills of customers. Therefore, the relationships established in this area are of a long-term nature, especially due to the acquired knowledge about the partner, thanks to which the cooperation offer can be better adapted. However, such cooperation does not mean being bound by forever and exclusivity. Each of the entities participating in this system is looking for solutions that are able to bring it closer to success on the market.

All entities participating in the system of the horse industry create a specific network of links based on cooperation and putting the well-being of horses above other values. They are also subject to the influence of the social system which, through its opinion-forming and law-making powers, influences both directly and indirectly their shape. This unique attitude of society to horses will make the horses always have a special place in them, regardless of the fate of individual economies. Nowadays it is also reflected in the possibilities of creating jobs, because "horses give work".

On the basis of the conducted research, it can be concluded that the horse industry integrates the activities of a very large number of entities. Apart from trust and concern for quality, emotions and personal relations that result from them are an important element. The separation of groups of entities due to their market functions allows to distinguish:

- regulators - including international organizations, state institutions, national organizations and the social system,
- breeding farms - operating in the field of breeding, including genetic and individual selection, and rearing, whose purpose is to provide horses which, as a result of further actions, will be of interest to consumers, will be brought to the market,
- specialized horse farms - being organizational units specializing in farming activities and work system with horses, which contribute to obtaining the desired characteristics by the clients,
- specialized entities forming a distribution system - a group of entities providing services, as a result of which clients obtain certain intangible assets (eg: knowledge, skills, artistic or sports experience) or goods (eg horses, post-mortem products),
- customers - the group of these entities includes primarily: owners, owners, spectators, riders, drivers and consumers of physical goods (eg: horse meat),
- suppliers of goods and services - constituting the largest group of entities conditioning the relevant efficiency and effectiveness of the industry system.

The horse industry is an economic area in which the importance of craft activity is very large. Saddlers, saddlers, tailors, shoemakers, purse-makers, blacksmiths and many other craftsmen, condition its efficient and effective functioning, and create opportunities to meet the needs of consumers at the appropriate level. In this area, the Make-to-order (MTO) and the provision of services (Service-to-Order) are also special. These systems, as indicated by Łebkowski and Klimek (2012), are related to the implementation of non-standard orders, for an individual recipient, and the order is implemented as part of a client consultation, the requirements of which are variable and unpredictable.

From the economy's standpoint, the shape of created network can be defined, among other things, based on expenses of particular entities. Due to a large variety in the area of the horse's usability purpose, the systems of expenses connected to them are different in every case. However, for research and identification purposes, we may attempt to apply aggregates, which will allow identification of their main flows within the horse industry. In building this model, a concept proposed by Hanley Centre (Report of Research, 2004) was used, where the foundation is identifying the supply chain of the horse business. The analysis of expenses flow in the entire horse industry makes it possible to build a model of a network of entities, including: consumers, expenses on final goods and services (final consumption) and suppliers of the first, second, third and fourth order. The direction of the expenses flow (financial flow) are opposite to the direction of goods and services flow. However, they are interrelated with a system of numerous interdependencies and feedback. The suppliers of the first order, located closest to the consumers, are the direct suppliers of goods and services, which are the objects of final consumption. Their offer is based on their operations, which require expenses on purchases and supply of goods and services provided by suppliers of the second order. The suppliers of the second order bear expenses on the suppliers of the third order, who provide goods and services essential for their functioning and creating offer for the entities making up the group of suppliers of the first order. The suppliers of the fourth order are mainly entities delivering raw material and entities connected to neutralization or disposal of waste. Efficiency and effectiveness of functioning of the particular entities influences the quality of the entire system, within which numerous correlation structures are created.

The human factor is of particular importance in the horse industry. Starting from the breeder himself by the staff as well as clients and cooperators, to the social system affecting both the hippie culture and the social perception of particular types of use. Appropriate knowledge, experience skills and constant improvement of competences are necessary in this area. In many cases, they decide not only about the quality and extent of the objectives, but also about the health and life of the participants in

the system. Often, there are also arrangements based on cooperation in one sphere and competing in another. The specificity of the horse industry means that in practice entities that compete on the market if they have the opportunity to cooperate in an area not covered by the competition system, are more willing to take it with competitors than with foreign entities. Knowledge about the partner, his strong weaknesses, is the basis for creating relationships, especially trust.

Conclusions

The horse industry is an economic subsystem whose participants form a network of both a structural, organizational and relational nature, for which the good of the horse is the overriding principle. The main factors affecting the creation and management of networks in the horse industry are:

1. a horse as an entity (object and subject) of activity, the specificity of which is associated with its intended use, the history of relationships with humans, the process of breeding, and anthropomorphisation;
2. breeding and rearing, which as processes of creating (producing) a good which is a horse with desirable traits, are long-lasting and require specific conditions of implementation and cooperation with specialized entities;
3. the specificity and diversity of suppliers of goods and services delivering specific goods, which are often highly individualized, and also created in cooperation with users;
4. diversity of types of use that increases the level of individualization and generates the development of the craft sphere;
5. the multiplicity of regulatory institutions and stakeholders related to particular types of use and supporting activities;
6. dependence on changes in consumers' needs, trends and fashions;
7. specific relations related to the system of values presented by system participants.

Research shows the importance of the horse industry as an economic subsystem creating conditions for the economic and social development of a large number of diverse entities; creating business and social networks covering the sphere of local, regional, international and global activity. Therefore, research should be continued both as part of the business management system and the national economy management system.

Abstract

Appropriate organization of the forwarding process is one of the basic elements of effective management of the operation of enterprises obtaining resources on the international market. The contemporary process approach and the resulting process management create opportunities for observing and analyzing processes and their key components. The use of mapping tools to get a picture of the processes being implemented can be an important tool for effective management of operations. For the processes of obtaining unique products such as steel ropes for mining shaft hoists, the conditions created by the forwarding process significantly affect the operating capabilities of the hoisting device. Therefore, from the point of view of process management, the basic element of management is its proper recognition. Therefore, the purpose of the article is to identify the organization of the steel rope shipping process for the needs of mining shaft hoists.

Keywords: Process management, steal ropes, freight forwarding process, steal ropes and wire industry.

Introduction

Process management is a natural and comprehensive management approach to business creation, creating the prerequisites for a highly efficient, agile, innovative and adaptable organization that far exceeds the reachable by traditional management approaches (Smith, 2003). Contemporary organizations are continually under competitive pressures and forced to improve their business models and business processes (Škrinjar, et al, 2007). Zairi defines a process as an approach for converting inputs into outputs (Weske, 2007). It is the way in which all the resources of an organization are used in a reliable, repeatable and consistent way to achieve its goals (Vugec et al, 2019). A business process is a coordinated chain of activities intended to produce a business result or a repeating cycle that reaches a business goal (Pourshahid, 2008). In other words, managing a business means managing its processes (McCormack and Johnson, 2001). As Harmon (2014) noted, all contemporary organizational structures, to a greater or lesser extent, emphasize the importance of business processes (Ranđelović et al, 2018). Thereby confirming that business process management is becoming an important part of organizations' operations (Lahajnar and Rožanec, 2016). Jeston and Nelis (2014) define BPM as achieving goals of an organization through management, improvement, and control of essential business processes. According to Weske (2007) business process management includes concepts, methods, and techniques to support the design, administration, configuration, enactment, and analysis of business processes.

The implementation of the process approach results in significant transformations within organizations. It should be assumed that the use of process maps, modeled in generally accepted standards such as BPMN, is just the beginning. Along with the increase of the process maturity of the organization (von Schel et al, 2015), further areas of its activity will be transformed (Stępniak, 2018).

However, before any improvement actions are taken, it is extremely important to properly recognize the process itself.

Identifying individual process elements is the starting point for further research, especially in the context of effectiveness and reliability analysis. And above all, it is the basis for proper process management as well as its development and improvement. Therefore, it has been assumed that effective and efficient process management is conditioned by its proper recognition. Therefore, the purpose of the article is to identify the organization of the steel rope shipping process for the needs of mining shaft hoists. This process is one of the most important elements of the steel rope industry system in the sphere dedicated to the use of ropes in mining. Its proper organization not only affects efficiency, but is an important element affecting the safety of exploitation of hoisting shafts.

Research Approach

In addition to the case study, as well as analysis of literature and documents as well as organizational and formal-legal conditions, research methods were used that included observations, and in particular participatory observations, which create the possibility of recognizing the process "from within". For imaging the observed process components, mapping methods have proved to be particularly useful, allowing to obtain a graphic image of the process. The article uses iGRAFX software to present process maps in BPMN standard. The final stage of the research procedure is the formulation of conclusions and recommendations

Freight Forwarding

The freight forwarding industry is an integral part of global commerce, since in transporting cargos, intermediaries play a vital role in the supply chain process (Pope and Thomchick, 1985). International freight forwarder is defined as an international trade specialist who can provide a variety of functions to facilitate the movement of cross-border shipments (Murphy et al, 1992). The freight forwarders offer transportation and information relations between hubs, plants, and suppliers (Richter and Stiller, 2018). A freight forwarding company generates its profit from the difference between the price that the customer is obliged to pay for the request execution and the costs of request fulfillment. These costs result either from the fulfillment by own transportation capacity, or from the external processing of orders in consequence of involving a subcontractor (Krajewska and Kopfer, 2006).

At a basic level, the forwarder advises clients on the best rates, routings, and modes of transporting goods to or from any area in the world (Custom Brokers, 2002). The forwarder must examine the carrier's total service offering. If intermodal services are needed, the carrier must be able to support the shipper's total requirements in a cost-effective manner. Today, freight forwarder plays an important role in the total supply chain process. Freight forwarders are able to offer the customer a multitude of services, which can save the shipper money in the long run. In the future, new technologies will enable the forwarder to make better decisions and to ensure efficient 'on time' delivery (Turner and Savitskie, 2008). Freight forwarders are concerned with forwarding and handling freight from importers or exporters who are their clients. They store cargo, secure its transport to its destination via air, sea or road, negotiate costs, prepare documentation, secure insurance, take care of port charges, and may even do customs clearance. I.e. freight forwarders handle the freight of their clients. For this reason, they are often also called cargo or freight agents (Bryant, 2015).

The classic forwarders are transformed 'into numerous and more complex activities as well as the function of logistics forwarding' unifying often all fields in the unique logistics service. They can be carriers, providers of special services such as "door to door", "just in time" or "outsourcing", can be included in transport and logistics supply chain, and have a significant part in determining of cargo flows (Jugović et al, 2016). Fourth-party logistics provider, abbreviated 4PL, lead logistics provider,

or 4th Party Logistics provider (Stanković et al, 2018), are consulting firms offering logistics consulting, transportation and supply chain management services.

There is also the need for new competencies from cross-functional areas (Thai and Yeo, 2012). Forwarding and logistic service specialists work in freight forwarding and logistics companies (TimCom, 2016). They are familiar with freight costs, port charges, fees, best modes and cost of transportation, documentation and so on (Bryant, 2015). In this connection modern forwarding service is to meet the following basic requirements (Kucheruk and Bozhok, 2016):

- services are to be based on a transport expedition contract concluded between the forwarder and shipper to implement a comprehensive service as to organizing shipments from the supplier to the consumer;
- services provided for hauling of goods in the scales of international traffic should comply with the rules of international treaties and agreements made between the countries participating in transportation;
- implementation of forwarding services, execution of transportation and other transport documents should be realized according to existing rules of cargo transportation on the appropriate mode of transport, and as for the carriage of direct combined routes
- subject to the rules of cargo transportation by all forms of transport which are included in delivery of goods (Bozhok, 2015)];
- providers should take into account the interests of consumers of freight services, progressive experience of freight supply and cargo traffic services and meet the requirements of an integrated approach, accuracy and timeliness of performance, safety and environmental performance, staff ethics, aesthetics conditions and in formativeness (Brady, 2001).

On the international market, freight forwarders provide significant support to sellers in fulfilling their obligations under the Vienna Convention on the International Sale of Goods (Final Act, 1980). Therefore, in the field of forwarding in international trade, typical activities include (Rymarczyk, 2017):

- Advice provided to clients in terms of transport conditions and costs, determining the best route, tariffs and transport regulations;
- Specific preparation of cargo displacement in the relationship requested by the client;
- Selection of carriers, transhippers and other subcontractors;
- Concluding transport contracts with the owners of transport;
- Formation of collective shipments and organization and protection of proper packaging for the transport and handling of goods;
- Concluding contracts for storage, appraisal and cargo control;
- Declaring goods for customs clearance and completing all formalities related to it;
- Preparation and completion of transport and commercial documents;
- Checking the condition of the parcel on delivery from means of transport and possible preparation of damage reports;
- Settlement of shipping costs related to shipments.

The service quality in forwarding is a significant determinant of demand (Šimková and Kone, 2013). In the competitive environment, it is an important tool for customer retention and also it has effects on the performance and economic results of the organization. When the company have a satisfied customer, it indicates competitive advantage and if company have a dissatisfied customer it creates a bad experience which results in affecting the attitude of the customers. There are various factors like reliability, transit time, over-supply, short supply and damaged, market considerations, carrier considerations, product characteristics which impacts spot and forward freight rates (Meixell and Norbis, 2008).

The Industry of Steel Ropes and Wires

The industry of steel ropes and wires dates back to 3000 BC, when plant fibers or slaughter products (tendons, skins) were used to create ropes. The history of the wire rope production beginning with its innovation by Oberbergrat Wilhelm August Julius Albert in 1834 (Feyrer, 2007), a royal engineer from the mining districts of Hanover (Haw, 2020). Due to the high axial strength and stiffness with flexibility in bending, steel wire ropes have been used extensively in many engineering application fields, such as elevators, mine hoisting, highway guardrail systems, energy absorber apparatuses, and so on (Xu et al, 2014). Wire Rope is made up of steel wires, generally braided in a helix (spiral) forming units known as strands. Generally speaking, the constituent steel wires are helically wrapped around core wires to form strands and likewise, several strands are helically wrapped around other strands or core materials to make a singular steel wire rope. The strands in the wire rope can vary in accordance with specific and desired properties (Steel Wire Rope, 2020).

Steel Wire Rope market maintains the average annual growth rate of 3.12% from USD 10024 million in 2013 to USD 10991 million in 2016 and hoping to reach USD 11888 million by 2021 (Steel Wire Rope, 2020). North America is witnessed to have the vast opportunities to lead the market shares due to increase in the mining sector revenue shares and also increasing innovative developments. Following North America, Asia Pacific is ranked second in leading the market shares. The rise in constructional buildings due to rapid increase in population is strengthening the demand of the market. Europe is anticipated to grow at a higher rate owing to increased adoption of these ropes in industrial sectors. With largest GDP in Europe, Germany is the largest consumption place, with a consumption market share nearly 25.5% in 2017. Following Germany, UK and France are the also important market with share of 13.3% and 13.5% (Global Steel Wire Rope, 2020). Products in the group of steel ropes and wires include: ropes and wire strands, construction wires, telecommunications cables, springs, stainless and colored wires (made of several types of metals). Product groups can be distinguished here: electricity permeable wires - animal control systems, cargo control system, plastic engineering, joining - binder metal alloys, liquid mineral transport system, heavy metals, sanitary and hydroponic installations, textile industry, equipment for extraction equipment (equipment, other products), natural and synthetic fiber ropes, products for packaging, securing and fixing. Ropes and wires are sold all over the world to a very wide group of customers on various markets, including: energy, oil and gas production and processing, mining (deep-well shaft, surface casting), railways and railways, civil engineering (elevators, road safety barriers), vertical transport (cranes, elevators), commercial and war shipping, shipbuilding, fishing, telecommunications, agriculture and horticulture, woodworking, and product security (including packaging).

Due to the progressing globalization and internationalization in the world economy system, at the turn of the 20th and 21st centuries there was a change in the rope production system. The regional producers that have dominated so far have been replaced by international concerns. It is a derivative of, among others, changes in the extraction system resulting from their economic analysis and depletion of mineral resources, as well as technological progress, which forced producers to develop a sphere of research and development activity, which entails significant investments (the need to incur more and more expenses). According to Global Steel Wire Rope Market 2019 Report key global manufactures in 2019 are: Wireco World Group, Tokyo Rope, Kiswire, Jiangsu Langshan, Guizhou Wire Rope, Fasten Group, Usha Martin, Bekaert, Xinri Hengli, Bridon, Juli Sling, Jiangsu Shenwang, Shinko, Xianyang Bamco, Dsr, Jiangsu Safety, Gustav Wolf, Ansteel Wire Rope, Youngheung, Pfeifer, Teufelberger, Hubei Fuxing, Redaelli, Haggie, Diepa, Brugg (Global Steel Wire Rope, 2020).

The specificity of the steel ropes and wires industry makes it necessary to establish numerous forms of cooperation, both with organizations related through the value chain and the logistics chain of individual entities, but also with companies that are links in the supply chain. This applies especially to connections with forwarding companies and scientific and research units. The latter create the possibility of gaining a competitive advantage due to wailing on new products and new applications of existing products. New production systems, methods and technologies are also extremely

important elements in this field. In order for products manufactured by this industry to be used, it is necessary to carry out numerous tests, trials and approvals related to strength and safety. It is also necessary to constantly check the technical condition of the products used during their operation.

Conditions for The Steel Rope Forwarding Process for Quick Mining Hoist

Mining shaft hoist is a set of equipment in the shaft, used to transport spoil, material and people in mining plants along vertical roads and inclination above 45°, in which the basic elements are: shaft, shaft tower, hoisting machine with a system of ropes moving the vessel hoists over guides and reloading equipment in the underground and on the surface of the mine. Mining shaft hoists is used for: people ride, spoil drawing, transport of materials and equipment, auxiliary transport. Issues related to ropes in mining shaft hoists are regulated by numerous national and international regulations and standards, among others: ISO 16124:2015, ISO 16839:2013, ISO 17893:2004, ISO 2232:1990, ISO 2408:2017, ISO 2532:1974, ISO 3108:2017, ISO 4101:1983, ISO 4345:1988, ISO 4346:1977, ISO 7800:2012, ISO 7989-1:2006, ISO 7989-2:2007, ISO 8793:1986, ISO 9649:2016, ISO/DIS 2232.

When deciding to buy a rope for a specific hoisting device, you should choose the right manufacturer. Each manufacturer has its own design and technological solutions created in cooperation with scientific and research institutions (entities). They are covered by a patent system. The construction of each rope is an individual element. Since the choice of rope design for a given device depends mainly on the design of the device and the conditions in which the rope works, the general principles of rope selection include:

- Determining the purpose of the rope.
- Indication of the quality of the wires used to make the rope.
- Determining the technology of implementation.
- Determining the operating rules.
- Identifying the most optimal rope parameters for a given device.
- The right choice of rope construction for its operating conditions.
- Compliance with occupational safety standards / conditions.
- Determination of external factors and the degree of their impact on rope operation.
- The right choice of rope construction for its exploitation conditions.
- Determining the determinants of the forwarding process.

This creates a product with individual features dedicated to the specific needs of the customer. This affects the organization of the forwarding process, as it requires appropriate organization of transport tailored to the product, and all the dates associated with it are a derivative of the production process and the agreed arrangements in the contract. Many elements accompanying the organization of the forwarding process result from the arrangements made at the stage of production control. Starting from the product parameters, through its transport and handling packaging, conditions of transport and handling, to the process of taking over the goods by the recipient.

Forwarding Process

It is customary in the steel rope and wire industry to organize the forwarding process on the manufacturer's side. The steel rope forwarding process for mining shaft hoists can be divided into four phases: pre-trade, contract conclusion, production and transport, settlement and closing of the process.

It should be noted that setting forwarding conditions begins at the stage of order construction. Due to the specificity of the product, it is necessary to properly compose the entire process, as a result of which the desired product will be delivered to the buyer.

Figure 1: Pre-trade phase [own elaboration]

In the pre-transaction phase (fig.1), customers recognize the possibility of obtaining the appropriate rope. They are in talks with producers, trying to obtain the best technical solution for themselves. Technical arrangements in the product sphere are accompanied by preliminary arrangements in relation to delivery conditions. Recognition of formal, legal and financial conditions for the production process and forwarding process has a special place.

Figure 2: Contract conclusion phase [own elaboration]

The second phase is the conclusion of the contract (fig.2). Transaction details will be agreed during negotiations. The contract clauses include, among others, issues regarding delivery terms and deadlines, related costs and the division of transport responsibilities and risk. Due to the product specificity and customs in the industry, INCOTERMS DDP (Delivered Duty Paid) is accepted as the delivery terms. This means a maximum of obligations on the part of the seller who is obliged to deliver the goods on the means of transport to the buyer's disposal at a specific destination, to bear the associated costs and risks. In addition, the seller is required to perform customs clearance on import. The seller bears almost all responsibility during the transport process. It covers the cost of transport and assumes the risk of delivering the goods to the agreed address. The seller also prepares goods for unloading, fulfills export and import obligations and settles all customs fees. The risk is transferred from the seller to the buyer when the goods are in the indicated place and are ready for unloading.

In this phase, the proper forwarding process is initiated after receiving the right information from the seller regarding: production data, units and production volume, product description, price and cost information, sales date, payment deadline, special customer requirements, packaging information and product security conditions in transport. Based on the information received, agreements are concluded and contracts concluded with subcontractors from the TSL market. In this phase, there is, inter alia, the choice of a carrier, booking of loading space for a specific route and on means of transport meeting the requirements related to a given load.

Figure 3: Production and transport phase [own elaboration]

The third phase is the implementation of the contract covering production and transport (fig.3). After determining the rope parameters obtained as a result of production, the transport packaging and the transport, storage and operational protection are adjusted. In addition to the rope production itself, it is necessary to order the manufacture of a drum for transporting the rope at this time, order appropriate preservatives and determine the method and entity that will secure it. Ordering appropriate handling equipment for loading, unloading, moving and securing the drum and rope and other substances during transport. For the determined dimensions of loading units, the means of transport, routes and conditions of transport (including the size of transported loads) are determined. For mining shaft hoists in the European area, for ropes up to 1000m, drums with a diameter of 3.5 m are most often used. The whole set - drum and rope - weighs about 16 tons. Drums with a diameter of 5 m are used for ropes over 1000 m to 1300. The whole set is about 20 tons.

Information related to the booking of means of transport is sent to the factory and is confirmed by subcontractors. Then all product instructions are collected and attached to the documents sent. The next step is to notify the customer about the delivery. In this phase, accounting documents (e.g. invoices) and all documents necessary for sending are also created. The factory sends all documents (including standards and shipping instructions) necessary for loading and transporting. It is necessary to obtain appropriate transport permits and preparation for shipment of finished products, after receiving confirmations and relevant documents from recipients and after they and the forwarder confirm their compliance with previous specifications.

Relocation of products to the customer begins preparation of products for shipment at the factory, notification of relevant entities about readiness to start transport processes and delivery of products to the point specified in the contract. For industry, steel ropes and wires forwarding process it is strictly dependent on the ordered product by the customer. It is therefore necessary to care for an appropriate level of customer service. Technical product standards impose the need to apply appropriate technical and administrative-economic solutions. An important element is the submission of customs declarations and controls, as well as the launch of fiscal instruments (financial and insurance)It is necessary to check the rope packaging for any transport damage. Record any such damage on the delivery note. When loading and unloading, take appropriate measures to avoid damage to the rope. In particular, take care not to damage the rope with the forks of the lift truck. This transportation operation should be performed in such a way as to completely avoid any possible of contact of between the wire rope and loading equipment (Steel Wire Rope, 2020). This phase ends with the delivery of the product to the final recipient.

Figure 4: Settlement and closing of the process phase [own elaboration]

The last phase is the settlement and closing of the transaction, which de facto means the completion of the forwarding process (fig.4). After delivery of the goods to the final recipient, the condition of the delivered product is checked and its compliance with the concluded contract is determined. After conducting appropriate checks and confirming that the transaction participants have fulfilled their obligations, payment for the delivered goods is made. The next stage is settlements with individual subcontractors, including making appropriate financial flows and closing financial and insurance instruments. Archiving documents ends this phase.

Conclusions and Recommendations

Proper organization of the forwarding process is an important element of effective process management. However, for this to be possible, it is necessary to properly identify the individual elements that make up this process. By using process mapping tools, you can get the right picture of the area under study.

Due to the nature of the product, this forwarding process begins at the stage of negotiating the order (order) of the product. Because products for the needs of mining shaft hoists are a unique element and their production is carried out under individual orders, it is necessary for each product to have an individual approach to the forwarding process. Also, due to the size of the loading units and their individual nature, an individual approach to the organization of the forwarding process is necessary for each order.

The steel rope forwarding process is a significant organizational challenge resulting from the product specificity as well as from the variety of entities involved. For its effectiveness, proper coordination of activities and creation of an appropriate information flow system is of great importance. For the quality of implemented flows and the results obtained, the knowledge and experience of the entities involved in this process are important, and expert knowledge - represented in particular by experts is a decisive factor in the effectiveness of conducted activities. Cooperation of specialists from various industries is a necessary factor influencing the success of concluded contracts. The ability to resolve disputes and act under stress are important features of freight forwarders. Just like space-time coordination.
Due to their specificity (the scope of the tasks being carried out and the need to coordinate many multidirectional flows), these processes are becoming more and more often the subject of 4PL's implementation, especially in relation to transactions on the international market.

The forwarding process involves a wide variety of entities that create a specific business network involving numerous research, control and regulatory institutions. Therefore, it seems right to conclude that research into the network of entities integrated through this process should be continued. At the same time, taking into account the importance of safety, quality and reliability for the operation of ropes in mine shafts, the view seems to be right about the need to continue research also towards the analysis of the reliability of management processes associated with reliability in the technical context and their interaction.

Avatar as The Modern Solution of Support the Customer Service in Public Services Management – Project Case Study

Piotr MASLOCH

War Studies University, Warsaw, Poland
p.masloch@akademia.mil.pl

Abstract

The paper present the basic issues and results of the realization the international project developing a method of providing public services and developing customer service standards tailored to the needs of people with special needs. The main goal of the project is to improve the functioning of local government units by developing and implementing an innovative model support for people with special needs. Regarding the very early stage of the project realization, in this paper only its first stage will be presented. It is based on the pilotage research made with the purpose to clarify the research questionnaire and prepare it for the final examination.

Keywords: avatar, customer service, public services management, case study, project

Introduction

Over the past several decades, we have seen a slowdown in demographic development in Poland. Forecasts indicate that in the next 10 years the number and share in the population of people aged 60+ will increase. This age will include many groups of people born in the baby boomers of the late 1950s and early 1960s. In turn, the age of late old age will include relatively few groups of people born during World War II. Therefore, Polish society is currently facing challenges arising from dynamic changes in the demographic structure of the population. One of the priorities of public policy implemented in Poland is the comprehensive development of social policy towards the elderly, the sick and the disabled in order to create and meet the special needs of this community in the future.

An increase in the number of people with special needs, an aging of population or social migrations are facts that are confirmed by numerous studies and statistical data. Older people, both as a social and demographic group, do not constitute a homogeneous community. The elderly population is distinguished from other social groups by four basic features:

1) feminization,
2) singularization,
3) decrease in income,
4) deterioration of health.

Age in itself is not a key factor affecting a person's old age. Senior has his own individual ideas about aging. The experience of aging raises an important aspect and justifies why we should refrain from generalizing when we talk about seniors. Personality, life history and experiences cause individual reactions of the aging organism and various diseases, and society's attitude and social relations are often integrated into the experience of aging. Aging is a process consisting of various elements. It includes objective facts such as: age of the person, functional skills or diagnosed diseases. In addition to these features, aging is a highly subjective experience in the perception of the disease and its syndromes or subjective feelings about functional and cognitive abilities.

There is a wide range of variables that affect aging and people experiencing aging. Successful aging is not only life without diseases, but also requires subjective satisfaction with life, participation in social life, good cognitive skills and mental resources.

The implementation of the project (details in acknowledgment), on the basis of which an avatar is to be created to support the service of older clients in offices, will facilitate access for people with special needs to services offered by offices, which will contribute to increasing satisfaction with the quality of life of the elderly and those weakened by diseases use of these public services.

The article presents the main motives for undertaking the subject of the project and preliminary data collected in the pilot study, which are to contribute to show the scale of the phenomenon of the problem examined in the project, as well as to recognizing the correctness of the motivation for changes planned in public units in the area of public services and customer service standards.

Literature Review

Every developing organization must invest in innovation, creative problem solving and the use of increasingly new technologies. Constant changes in the environment require flexible actions, developmental dynamics, the ability to take risks and meeting the needs of service recipients[1]. Such activities should also be undertaken in the area of customer service in public services management.

Public administration, as an integral part of the public sector, carries out important activities for the functioning of the state, and thus also the society. There is therefore a need to constantly improve the level and scope of services in this sector through effective customer service[2].

The role of public administration is to provide every citizen with a minimum amount of livelihood thanks to the basket of goods and services provided to him (public goods and services). Public administration bodies include: state authorities (including government administration, parliament) and self-government authorities at all levels (including local government, executive, supervisory and constitutive bodies)[3]. Public services provided by public administration are classified as follows[4]:

- basic private services (goods) are services (goods) consumed individually, delivered to the least-paid members of society;
- public exclusionary services, financed exclusively from public funds, are measurable through outcomes for society;
- publicly available public services, collectively consumed, for all or most of the society, totally or partially paid;
- basic public services, collectively consumed, widely available. The great diversity in the classification of public services in administration means that their significant significance in the economies of many countries is noticed.

[4] Bartels, K., & Turnbull, N. (2019). Relational public administration: a synthesis and heuristic classification of relational approaches. *Public Management Review*, 1-23.

The basic problem of modern administration is to ensure efficient and effective implementation of public services rendered[5]. The public services sector must adapt to new conditions; the role of a public administration employee in shaping the quality of services provided is increasing[6]. A high-quality public service is a determinant of effective management of an administrative facility. The most important entity in the relation donor - recipient of public service is a citizen, the applicant entitled to obtain the necessary high quality services[7]. Quality from the point of view of the recipient is what he needs, expects, requires, taking into account the duration of the service. A public administration employee must be aware that the client in the organization is currently in the spotlight. His opinions and assessments are a clear indication for the public authority for further functioning. The satisfaction of the stakeholder with the public service is related to the correct assessment issued to the employee, and hence also the assessment of the public organization. Thus, customer service in public services management is focused on meeting the following requirements[8]:

- customer orientation that ultimately assesses the quality of the service provided;
- continuous improvement, deepening knowledge, innovation in problem solving, using the opportunities provided by the organization's employees;
- employee development and commitment, is associated with an organizational culture based on trust and the transfer of full competence to employees; management based on processes and facts, consisting in the efficient use of used resources, obtaining the desired results, information management, which should be true, complete, reliable, professional;
- leadership and consistency of goals, leaders at all levels of the public organization are responsible for its development, promotion of values, its mission and vision;
- development of partnership, mutually beneficial relations between partners cause full integration both in generating knowledge, implementing plans and public goals, while applying generally accepted principles of conduct;
- public responsibility, ethical approach and conduct of employees, meeting the expectations of clients, employers, society;
- results orientation, where perfection depends on the ability to balance and satisfy the interests of groups, people in whose interest it is the functioning of a public organization.

The concept of customer service means many interrelated activities that determine customer satisfaction when purchasing a product (service), which is the last act of the process that usually begins with the order and ends with the delivery of the product to the customer[9].

Customer service is a set of activities to meet customer expectations, specific standards of services rendered or even as a customer-oriented corporate management philosophy. What's more, this process is an information system that consists of a specific concept of relationship management, service standards set, decisions made and methods of contact with the client[10].

Maintaining the right quality of customer service requires above all a continuous improvement of communication between the parties[11], which allows to present certain values, meet expectations and build trust.

Methodology of the Research

In connection with the implementation of the international scientific project "Innovative assistance model avatar for the carer of the elderly", a pilot survey was conducted at the beginning of 2020.

The survey questionnaire consisted of a main part comprising 23 questions and a metric with 4 questions. The main questions of the survey concerned two main areas. The first was related to the assessment of respondents in the operation and service of applicants at public administration offices. The second area concerned the expectations and requirements of clients regarding their service at public administration offices. The respondents' habits were also examined here, mainly in relation to computer skills and functioning on the Internet.

The pilot purpose was to verify the correctness (elimination of defects) of the assumed research procedure: selection of the examined people and the research tool used (survey). It was not used to verify hypotheses, but to provide information enabling the construction of a good research plan.

The study was qualitative (questionnaire test) and was carried out in the form of a meeting of people from a deliberately selected sample with the number N = 20. The pilot survey was carried out using the conventional method (verification, among others, whether the examined persons correctly understand all of the questions asked? Is the instruction attached to the survey clear for the examined persons? Are there any missing answers in the survey?), Supplemented with cognitive interview (suggestions for changes) / supplementing the scope and type of questions, analysis of the target group of respondents).

The research sample, due to the subject matter, was mostly elderly: 45% between 56 and 65 years old, 35% over 65 years old and the remaining 20% under 55 years old. 65% of the research sample were women and 35% men. 60% of respondents had higher education, 20% vocational, 15% secondary and 5% primary. 45% of the respondents are retired, 40% are working, 10% are pensioners and 5% are unemployed. The sample size ensured statistical significance of the results.

Research Results

Statistical analysis showed that all study participants have ever used public administration offices, but most of them (85%) used the services of a city, municipality or district office. The remaining part used the services of the poviat eldership. In most cases (50%), the respondents handle official matters several times a year (50%) or once every few years (25%). 10% of respondents could not accurately determine the frequency, while 5% of respondents admitted that they use several times a month, once a month or once a year. 10% of respondents had a problem determining the frequency of using public administration offices. In addition, 40% of respondents said they had been in charge of official affairs in the last six months to three years, 20% two months ago, 15% each month or last month, and 5% last week.

Then the respondents were asked about the type of matters they usually handle in public administration offices. It was a multiple choice question. 40% of respondents said that they handle matters related to waste management, location of landfills in the Department of Environmental Protection and replace the old ID card or produce an ID card in the Department of Civil Affairs. 20% of the respondents take care of matters related to social assistance - allowances and other benefits in the Municipal or Municipal Social Assistance Center; tax matters - tax payment, tax discontinuation etc. In the Tax Department and exchange of the registration certificate, production of the proof - vehicle registration / deregistration of the vehicle in the Communication Department. 15% of those surveyed deal with registration issues

[11] Riggs, J. A. (2019). Crisis Knowledge Management to Affect Customer Service. *Crisis*, *2*(2).

- permanent check-in, check-out, etc. In the Department of Civil Affairs; cases related to the issue of death and birth records, changes in civil status files in the Civil Registry Office and matters related to obtaining water and legal permits at the Department of Environmental Protection. 10% of the respondents arrange exchange of driving licenses, obtaining a driving license at the Department of Communication and obtaining maps for agricultural subsidies, obtaining information on spatial development plans, etc. at the Department of Geodesy and Cartography. 5% of respondents arrange obtaining building permits at the Faculty of Architecture and Construction. None of the surveyed group indicated dealing with job search or obtaining unemployment benefits at the Labor Office or registering a company at the Economic Development Department.

Participants of the study were also asked about the way in which they most often contact the authorities. It was possible to mark two answers. The respondents indicated that they most often contact personally (90%), by phone (25%) and by mail (5%). There was no indication regarding electronic contact and via the PUAP platform.

The respondents of the survey were also asked if they were satisfied with the manner of service in offices and here 100% of respondents said that they were rather satisfied. The respondents were also asked whether information on the location of individual cells / rooms of employees responsible for a given scope of tasks is legible. 95% of respondents said yes and 5% that rather not.

Another question concerned the service of applicants by office staff. The respondents positively responded to the statements that (1) information provided by the employees of the Office is understandable (100%); (2) information provided by the Office's employees is sufficient to settle the matter (95%); (3) employees of the Office always address clients culturally (95%); (4) the Office's employees are always happy to assist in completing documents (90%).

The next question was about determining what help or information the clients usually need when dealing with official matters. It was a multiple choice question. 70% of respondents indicated that they need information in which room they can do their business and information that prints are needed to settle the matter. 50% of respondents indicated that they need information on how to fill out forms to handle a given case. 40% of respondents indicated that they need information on the amount of fees in connection with settling a given case and how long the procedure will take. 25% of respondents indicated that they need information from where they can get printed matter to deal with a given case, and 15% indicated that they need information about where they can pay.

The respondents were also asked about how long they usually wait to settle the official matter (time spent in the office). 45% of respondents said they expected from 30 minutes to an hour; 40% that from 15 to 30 minutes; 10% for 1 to 3 hours and 5% for a maximum of 15 minutes.

When asked about the reason for the problems with reaching the right employee in the office (multiple choice question), 60% of respondents indicated incorrect oral information obtained from another employee of the Office; 50% of respondents indicated the employee's absence from work; 25% of respondents indicated incorrect data provided on the Office's website.

The survey also raised the issue of difficulties encountered when dealing with official matters (multiple choice). 40% of respondents said that they did not face any difficulties; 35% were asked to contact at another time; 25% were directed to the wrong person; 10% received incorrect information and 10% did not find an employee in the indicated room.

The respondents were asked (open question) what changes they would make regarding the office's operation. 30% of respondents answered this question. They suggested: (1) increasing the number of employees in the most sensitive departments such as the Communication Department; (2) more intuitive arrangement of the rooms of employees responsible for given cases; (3) better customer focus; (4) additional information on procedures and documentation; (5) increase in the number of employees; extended office hours; (6) shortening of certain cases and limiting the number of documents.

In the second part of the survey, regarding the improvement of official work, the respondents were to answer the question whether elderly people in the Office should be given special care. 90% of respondents said yes.

The respondents also answered the question of what problems in the offices most often face the elderly (multiple choice question). 75% of the respondents indicated the difficulty in reading on the information board in which room a given case was handled (illegible board, letters too small); 60% indicated the difficulty in completing the form; 55% indicated the difficulty in reading the form - letters are too small; 40% difficulty in understanding information obtained from officials (information spoken too quickly, too quietly) and the need to wait in queue to obtain information; 35% indicated the reluctance of officials to repeat the same information several times to an elderly person; 25% of the respondents indicated difficulty in moving around the Office due to mobility restrictions.

In relation to previous questions, the question was asked whether the respondents see the need to hire an employee whose main task would be to provide information to the Office's clients. 80% of respondents rated this idea positively and 20% negatively.

If the office hired such an employee, the respondents had to determine what information they should provide to applicants (multiple choice question). 85% of respondents thought that this would be information about which room a particular case can be dealt with and what documents are needed to settle a specific case; 55% of respondents indicated information on where to obtain documents to handle a specific case; 50% indicated a discussion of the procedure in place to deal with a particular matter; 45% of respondents indicated information on how to complete the documents necessary to settle a specific matter; 40% of respondents would like to know what additional actions should be taken to settle the matter; 25% of respondents believe that an employee should be able to call a given employee in a situation where a client of the Office cannot go to an employee due to various restrictions, and should also provide information about the Office's working time, especially on pre-Christmas days, long weekends, etc. ; 15% of respondents indicated that they should be able to read a given procedure and 10% that they should inform if the employee responsible for dealing with a given matter is present at work.

Respondents were also asked to specify the characteristics of the official who inspires their greatest confidence. Respondents indicated that it would be a woman (75%), wearing glasses (65%), short (45%), brunette (60%), elderly (60%), dressed in formal attire (85%) and with low tone vote (65%).

The third part of the survey was to determine the respondents' habits in the area of computer literacy. 65% of respondents use a computer on a daily basis, and use the Internet as much. These respondents declare average level (25%), high (20%) and average (15%) Internet skills. Only 5% rated their level of competence in this area as high.

In addition, people using the computer and the Internet use Skype or Messenger instant messengers to a small extent (35%); have their profile on social networking sites like Facebook (35%); use the websites of offices to search for necessary information (60%); use the application on a mobile phone (35%); and shop online (55%).

The last question concerned the possibility of introducing an application for clients to the office, which would contain all the forms together with information on how to complete them and where to submit them to settle a specific matter. 70% of respondents said that they would use such an application.

Summary and Discussion

The structure of the survey questionnaire requires a clear division of questions into three parts, as it was done, as this will help direct the respondents to the desired course of thinking, while suggesting to them how they should relate to individual questions: (1) The three-part division of the survey clearly separates questions about issues essential (1-part: the current state of affairs and how it is perceived by the respondents - this will allow to diagnose what brings applicants to the Offices and to what extent

assistance solutions should be sought for the implemented project, 2-part: what are the expectations of the applicants - answers to in this part, the questions in the right survey will create an image of the avatar's functionality, this is another part of the study used to diagnose the preferences of applicants in terms of the possibility of offering them assistance in the offices, 3-part: who thinks so - inform respondents that after knowing their habits and metric characteristics will allow targeting the developed solutions to specific social groups and adjusting them to the requirements of selected groups of clients as well as possible; (2) The division of questions in the survey results in a more favorable, subconscious perception of the fact that respondents complete the survey. The analyzed survey is quite long and complex, which translates into a possible reluctance to participate in such an extensive survey. The division into parts aims at creating the apparent satisfaction of the respondents from completing their individual stages. In a proper study, this will be important because the return of 100% completed surveys must be at a level ensuring sample representativeness.

Bearing in mind that the avatar originated from the functionalities specified in the actual study, carried out using the analyzed survey, is to support the elderly (60+) and those weakened by diseases, the study should cover exactly those people who will be able to use it. We are talking about people with some kind of social dysfunction and digital exclusion who are clumsy in dealing with official matters. The research sample should be focused on them, eliminating others who do not have such dysfunctions (which does not mean that if these people will be able to use the avatar they will not do it). Nevertheless, the elderly or those weakened by diseases or disabilities who are doing well in the age of digitization or have the support of other people (relatives, friends) should be excluded from the research sample, because their participation will not allow reliable results from the study.

Therefore, the first part of the survey questionnaire is the record, which allows to eliminate from the actual sample all persons who do not feel the need for support in dealing with official matters. Questions eliminating these questions include: (1) Age (analysis of pilot statistical data shows that the younger the better they are at dealing with official matters because they actively use the computer and the Internet and do not need to use additional supporting tools). (2) Computer and internet skills (analysis shows that people with competence in this area do not feel the need for support from the Office in dealing with matters). (3) The survey should be supplemented with a question about the independence of applicants in dealing with official matters. People with the support of relatives will not have problems with settling matters in the Offices. Therefore, respondents declaring active help from relatives in dealing with matters may ask if they would decide to become more independent if they had the opportunity to use the assistance of an avatar.

Other metric questions are: regarding gender, subject to a greater share of women due to demographic conditions, i.e. a higher percentage of women in the age group 60+; education - the proportion of persons with higher education should be proportionally reduced, who in the discussed age group use computers and the Internet more often, are more independent and, as a consequence, do not seek advanced help in dealing with official matters; status - referring to the avatar's orientation to help the elderly and debilitated diseases in most cases due to age, the answers can be accumulated on pensioners.

It can be also added to the record questions to diagnose the more sophisticated requirements that an avatar should meet (e.g. support for the visually impaired by using headphones and loud audio information, deaf people could use the option of displaying textual information).

Considering the above analysis and preliminary recommendations, in summary, after correcting the questionnaire, you can proceed to the actual study, and consider conducting this study using the Face-to-Face (F2F) direct questionnaire interview technique. It enables direct contact with the respondent. Thanks to this, the survey is completed on the basis of dialogue, and the respondent has the opportunity to ask questions, dispel doubts, which in the study of the elderly and those weakened by diseases may be of key importance.

Acknowledgement

The research results presented in the paper are financed by the European Union project "Innovative assistance model avatar for the carer of the elderly" POWR.04.03.00-IP.07-00-006/18, coordinated by War Studies University, realized in 2019-2022.

Employee Pension Plans as Retirement Saving Form

Bartosz Chorkowy

University of Opole, Opole, Poland
bchorkowy@uni.opole.pl

Abstract

The forecasts referring to the effectiveness of the system introduced by the law act in 1999 show that the retirement pensions paid in the future from the obligatory part of the system will be low and they will significantly decrease the life level of the pensioners. The forecasted low level of the effectiveness of the new pension system leads to a bigger interest in solutions which can partially reduce the poverty level of the future pensioners. This article is devoted to a new pension saving form, that is Employee Pension Plans (EPP). The goal of this paper is the attempt to answer the question whether the proposed form of saving can have a crucial influence on the pension amount of an average Polish citizen. The simulations of the potential pension benefits gained thanks to the suggested form of collecting capital will be analyzed in this article. Methodology: elaboration of the simulations and forecasts of the future pensions amount from the Employee Pension Plans by application of quantitative methods. Practical application: the presentation of forecasted effectiveness of EPP Social implications: improving the awareness of Polish society as far as Employee Pension Plans are concerned and their influence on the level of future retirement pension.

Keywords: pension system, savings, pillar 3

Introduction

The unfavorable demographic situation in Poland causes that we should look with bigger and bigger fear at Polish pension system efficiency. In recent years we can observe the decreasing number of births simultaneously with a growing average lifespan. These rates significantly influence the level of the retirement pension paid from the obligatory part of the retirement system, and in this way they determine its efficiency. Taking into account the demographic processes, at the same time we can state that the level of a retirement pension will decrease for the significant part of the Polish in the perspective of the coming several dozen of years. Currently the replacement rate, that is the rate of the last pre-retirement earnings to the first retirement pension, equals about 50%. In coming years, it is predicted that the rate will drop to about 20-30% (Chorkowy 2018).

Because of the lower and lower level of pensions from the base part of the pension system, saving in the auxiliary system part initiated by an employer or a future pensioner is the effective way of ensuring a higher life standard (Pieńkowska-Kamieniecka 2015).

Polish government made an effort to meet the above mentioned necessity by introducing a new form of saving for the retirement that is Employee Pension Plans (EPP) by the law act of October 5, 2018.

The aim of this paper is to present the potential effectiveness of the new common way of saving. Will the saving method significantly influence the level of the future retirement pension? Will it lead to a more decent life of an average Polish citizen in the old age?

The article discusses the demographic situation in Poland, as one of the main reasons of the inefficiency of the pension system and it presents simulations of various saving possibilities of EPP.

Demographic situation in Poland

The analysis of the demographic situation in Poland, presented in the context of its influence on the pension system efficiency, has been based on two indexes:

- the live birth rate.
- the average lifespan.

In 2017 in Poland the live birth rate was at the level of 402 thousand of children, what constitutes the growth in comparison to 2016 of about 20 thousand. Simultaneously, it has to be noticed that it has been the highest live births level since 2010. Unfortunately, this positive situation in 2017 is not continued in the following year. In the first half of 2018 193 thousand of live births were registered, what constitutes a fall of over 6000 comparing to the analogue period of the previous year. It will be reflected in the fall of birth rate of about 0.3 points to the level 10.1‰. At the same time, it has to be noticed that the level of the rate will be practically half the amount of the level in 1983 (the year of the last "baby boom" in Poland) when 723 thousand babies were born and the birth rate was at the level of 19,7‰) (http://stat.gov.pl)

The total fertility rate plays a crucial role in the presented study. The optimum value of the rate which ensures the replacement of generations equals 2.10 – 2.15. It means that for every 100 of women in age 15 – 49 years there are 210 – 215 born children. From the nineties of the 20th century in Poland the value of the rate is shaped much lower than 2 (in 2017 the total fertility rate in Poland equaled 1.45), what means that the number of births does not ensure the simple replacement of generations, and as a consequence it has a negative impact on the Polish pension system.

The second very important aspect of demographic changes in Poland, which has the influence on the situation of future pensioners, is the average lifespan for persons at the age equal to the age of retiring of the insured person. The average further lifespan is a statistic value, which defines the average period which passes from getting the right to retire to the death of the insured. It helps to set the probable period of the insured person at the retirement and to evenly divide the accrued means. The retirement pension granted in accordance with new rules equals the amount which is the result of the division of the basis of pension calculation by the average further lifespan of the future pensioner (Kochanowska 2017). An average further lifespan in Poland shows a growing tendency. The age category of 60 years1 noted the growing lifespan in years 1999-2018 of 36.2 months and reached the level of 262.2 months. The changes of the number and structure of population according to age are the result of changes in the demographic processes. At the half of 2018 the number of Polish population equals 38.4 million including 8 million of persons beyond the retirement age (men in the age of 65 or older, women in the age of 60 and older). It has to be noticed, that the share of the above mentioned age group in the general population in years 1990- 2017 increased by 8 percentage points, that is from 12.8% in 1990 to 20.8 % in 2017. Unfortunately, the growth of the older people number was accompanied by the drop of pre-productive number of people (0-17 years old). In 1990 the percentage of the above said group in Poland was at the level of about 29.6 %, whereas at the end of 2017 it equaled only 18%.

Summing up the above deliberation it has to be stated that Poland contends with a very serious problem of the unfavorable demographic situation. A low, not ensuring the replacement of generations, total fertility rate and a simultaneous growth of the percentage of people beyond the retirement age puts a big question mark to the future efficiency of Polish pension system. Therefore, the need of the individual additional saving in the period of professional activity for the future retirement pension appears.

[1] The analysis of the average lifespan was limited only to age 60 category. It results from the fact that in Employee Capital Plan it is the age when it is possible to start paying out means (despite the extraordinary situations mentioned in the law act).

Employee Pension Plans – the goal and the functioning rules

The law regulations referring to Employee Pension Plans were introduced by the Act on Employee Pension Plans of October 4, 2018 (Law gazette no. 2215 of 28.11.2018). According to the above stated Act the first employees can save money in EPP since the half of 2019 and everything is introduced in the following stages:

- from July 1, 2019 for subjects employing at least 250 persons,
- from January 1, 2020 for subjects employing at least 50 persons,
- from July 20, 2020 for subjects employing at least 20 persons,
- from January 1, 2021 for all other subjects and employees of public finances sector.
  The savings accrued within EPP are financed from three sources:
- participants' payments,
- employing subjects' payments,
- state subsidies.

The basic payment financed by the EPP participant equals 2% of the salary. In case when the employed salary is lower than 1.2 of the minimum salary multiplication factor, the participant is allowed to place an application to lower the contribution up to 0.5 %. Despite the basic contribution the employee can declare additional payment of max 2% of the salary.

The employing subject pays the basic contribution of 1.5 % of the salary. Besides, it has the possibility to declare additional contribution of 2.5 % of the salary.

The subsidiaries from the state budget are the third saving component of EPP. Each program participant once receives the so-called welcome payment equal 250 PLN.[2]. Additionally, in a calendar year on the account of participation in the EPP each participant will receive an annual bonus to EPP in the amount of 240 PLN[3].

The above amount will be financed from the Work Fund.

The process of investing in Employee Pension Plans is based on the funds of the defined date. The funds, also known as life cycle funds, are the instrument the aim of which is to facilitate long-term investing in order to accumulate and multiply the capital for the retirement. The characteristic feature of such financial instruments is defining their destination date. Simultaneously, the person managing the fund has the precise knowledge of the investment horizon duration and can adapt the portfolio risk of a given fund (Świder 2018). The investment strategy of EPP will take into account the necessity to limit the investment risk level according to the EPP participant age. In accordance with the article 40, point 1 of the Act the shares of the share part and of the indebted part in the value of the defined date fund assets will be following (The Act on Employee Capital Plans, art. 40 point. 1)

- starting from the first day of the fund creation till the day of starting 20 years to the defined date of the retirement date, the part of a share part must be in the scope of 60-80% of fund assets value, whereas the part of the indebted part must be from 20 to 40% of the fund assets value;

---

[2] The participant, who signs the agreement on running the EPP and for at least 3 full months is the EPP participant, and if for these months the basic payments financed by the participant are made, will be entitled to receive the „Welcome payment"

[3] The EPP participant will be entitled to receive the annual bonus if the amount of basic payments and additional payments financed by the employer and the participant in a given calendar year is equal at least to the amount of basic payments due from the amount constituting 6 times the minimum salary binding in a given year, or in case of persons whose salaries do not exceed the amount of 1.2 of minimum salary, at least 25% of the amount of basic payments due from the amount constituting 6 times the minimum salary binding in a given year.

- in the period of 20 to 10 years before the defined date, the part of the share part must be within 40-70% of fund assets value, whereas the part of the indebted part must be from 30 to 60% of the fund assets value;
- in the period of 10 to 5 years before the defined date, the part of the share part must be within 25-50% of fund assets value, whereas the part of the indebted part must be from 50 to 70% of the fund assets value;
- in the period of 5 years before the defined date, the part of the share part must be within 10-30% of fund assets value, whereas the part of the indebted part must be from 70 to 90% of the fund assets value;
- starting from the year when the fund reaches its defined date, the part of the share part must be max 15% of fund assets value, whereas the part of the indebted part must be not lower than 85% of the fund assets value.

For the management of defined date fund assets the investment funds company, the PTE Polish Retirement Company, the employee retirement company or the insurance company can take remuneration in the amount not higher than 0.5% of net assets value. Besides, the body managing the means can take remuneration for the achieved investment result. The level of this remuneration cannot be higher than 0.1% of net assets value and can be taken provided that the positive return margin is reached for a given year, and the achievements of the return margin in a given year are higher than the reference margin (The Act on Employee Capital Plans, art. 49 point. 1 and 2).

Participation in Employee Pension Plans is voluntary. The EPP participant can resign from making payments to EPP on the basis of a written declaration submitted to the employing subject. The resignation can be done once for the period of 4 years. If it is not prolonged by the employee, starting from April 1, the employing subject resumes payments for the EPP participant (The Act on Employee Capital Plans, art. 23 points: 1, 2 and 6).

The payments of the collected savings are possible from the age of 60 years of life, regardless retiring, or being professionally active. After reaching age 60 the participant is allowed to pay out 25% of the collected means, and the rest 75% divide into at least 120 monthly rates. The EPP participant has the possibility of paying out all means, in this case the tax has to be paid from the capital gains for the part exceeding 25% of all means. Besides, in accordance with article 100 point 1 of the Act the EPP participant after reaching age 60, can apply for the payment of the means saved in his EPP account in the form of so-called marriage benefit. In this case the following conditions have to be met: (The Act on Employee Capital Plans, art. 100 point. 2).

- the participant's spouse reached age 60,
- the participant's spouse has the agreement with the same financial institution,
- the spouses mutually declare that they want to benefit from marriage benefit payment.

The EPP participant has the possibility to pay out the means before reaching age 60 in the case of accidents defined by the Act:

- up to 25 % of the collected means in case of a serious illness of the EPP participant, a spouse or a child without the necessity of repayment
- up to 100% of the collected means in case of buying a house or a flat on loan. This possibility will be available for persons younger than 45 years. Besides the means paid out in this way have to be repaid within maximum period of 20 years.

The influence of Employees Capital Plans on the amount of future retirement pensions

Will the new method of saving for the retirement in the form of Employee Pension Plans have a significant influence on the amount of the retirement pension of the average Polish citizen? Will Employee Pension Plans be a "remedy" for the lowering replacement rate of the last salary by a pension? Or will it be the next (after Open Pension Fund) common way of saving money for the old age, but without a greater influence on the efficiency of the Polish pension system? These are only

some questions which arise in the discussions referring to EPP - a new form of saving for the old age. This elaboration makes an attempt to estimate the forecasted amount of retirement pension from Employee Pension Plans. The simulations were performed in four variants:

Variant 1 – joining EPP at age 26, the remuneration amount – an average remuneration in the national economy;

Variant 2 - joining EPP at age 45, the remuneration amount – an average remuneration in the national economy;

Variant 3 - joining EPP at age 26, the remuneration amount – 1.2 of minimum remuneration for work;

Variant 4 - joining EPP at age 45, the remuneration amount – 1.2 of minimum remuneration for work;

The following assumptions were made while elaborating the benefit payments simulations from EPP:

1. Yearly return rate from capital – 3% - monthly capitalization,
2. Increase of salaries – linear trend models were estimated:
    a. Model of an average salary in the national economy:
    $$y=1505,12 + 143,73 \times t;\ R^2=0,99 \quad (1)$$
    b. Model of minimum salary for work:
    $$y=380,67 + 81,89 \times t;\ R^2=0,97 \quad (2)$$
3. Payment for management 0,5% + 0,1% for positive return rate from capital higher than reference rate.

Detailed simulations in particular variants are shown in tables 1-4.

3.50%	261.34	284.92	308.49	332.07	355.65	379.23
4%	284.92	308.49	332.07	355.65	379.23	402.80

Source: Own elaboration

The analysis of the above simulations shows that the age of joining the program plays the key role in EPP. Reaching the average salary in the national economy and paying the minimum contribution amount (3.5% - 2% employee + 1.5% employer) at age 60 it will be possible to pay out at once (25 % of capital) over 40 thousand PLN and to get a monthly amount 1 thousand PLN for 10 years period. In case of paying the highest contribution the single amount to be paid will be over 89 thousand PLN, and a monthly amount to be paid per 120 months will equal about 2.20 PLN. For comparison a person earning an average salary in economy, who starts the participation in the system at age 45, provided paying the lowest contributions, will receive the single amount 12.3 thousand PLN and a monthly amount about 300,00 PLN for 10 years. In case of highest contributions (totally 8%) the EPP benefit will equal 26.9 thousand PLN and a monthly amount 670,00 PLN for 10 years.

It has to be emphasized that a monthly benefit, received by the person joining the EPP at age 26 will be equal 10.7 % of the last pre-retirement remuneration in case of minimum contribution, whereas in case of maximum contribution about 23.7%. For persons joining the system at age 45 the amounts will equal appropriately 4.6 % and 10%.

In case of remuneration at the level 1.2 of minimal salary the benefits from EPP will be significantly lower. Persons joining the system at age 26 and paying the lowest contributions at age 60 will receive a single amount about 25 thousand PLN and for 120 months about 600,00 PLN monthly benefit. In case of the highest contribution (8% of remuneration) they could get a single amount of almost 55 thousand PLN and about 1350,00 PLN a monthly benefit for 10 years. For a person joining the system at age 45 and paying the contribution of 3.5 % the single benefit will equal 7.6 thousand PLN, and a monthly benefit 190,00 PLN for 10 years. In case of maximum contribution these values will be appropriately 16 thousand PLN and 400,00 PLN.

The monthly benefits will equal 10.7 % of the last remuneration for persons earning 1.2 of minimum remuneration and joining the EPP system at age 26, with contribution at the level 3.5% and 23.2% of the last remuneration with contribution 8%. Whereas the monthly benefits for joining the EPP at age 45 the benefit will equal 4.8% of the last remuneration with minimum contribution, and 10% with maximum contribution.

Summary

The presented forecasts allow to state that Employee Pension Plans constitute a solution which can contribute to lowering the discrepancy between the level of the last pre-retirement remuneration and the retirement pension level. The above simulations show that the influence of EPP on the level of retirement pensions will not be significant and largely it will depend on the age of joining the system. Besides, with a great probability it has to be assumed that a greater part of systems participants will pay the minimal contributions. Similarly, the situation will develop in case of employers, for which the responsibility of co-financing the EPP contribution will constitute an additional financial charge. It will mean, as it is shown in the above simulations, a low level of benefits from EPP after participant reaches age 60.

These negative previsions show that in order to avoid poverty risk coming truth in the group of older people additional retirement means have to be collected during professional activity (Kowalczyk-Rólczyńska 2017). In case of additional pension insurance, a proper economic knowledge of financial markets and investment funds, and also the knowledge of retirement systems is an indispensable condition. Without the awareness of the principles of pension system functioning and the level of pensions ensured within a base system, it is hard to expect from particular individuals the initiative in the scope of necessity of additional pension insurance (Grzebieniak, Pieńkowska-Kamieniecka, Przybytniowski 2016).

Abstract

Critical thinking in the study of history is a necessity that must be mastered by history students so that they know the latest issues that can be drawn to historical events based on historical evidence. However, critical thinking in history learning is not as easy as imagined, because students still think that historical learning only accepts historical information without criticizing the source and still imagining it. The purpose of this study is to analyze the effectiveness of historical learning models to improve the student learning outcomes. Empirical data was obtained from 57 students who participated in a local history course which was divided into two classes, each A 29 regular classes and 28 regular B classes students collected through open and closed questionnaires, observation on tests and limited tests. Class A 29 using the MPBH model and class B using another model. A Collecting the data uses the techniques of tests and documentation. The effectiveness of MPBH was analyzed through t-test. The findings of this study, that MPBH is effective enough to achieve learning objectives and competencies in local history courses, so that MPBH is effectively used. Furthermore, MPBH effectiveness testing must be extended to a broader scale and different subject.

Keywords: Organizing, thinking history, Historical Thinking Learning Model, and Indonesia.

Introduction

History is not an inheritance but learning about human activities in achieving ideas in space and time. Studying the thought of history, and history is recognized as teaching the past, but life is not for the past, but rather acquires the meaning to be a dialogue with the present that is needed to design the future.

Learning history in the future emphasizes the analysis of sources and asks students to create and be critical of knowledge in learning history (Henderson, 2019). Historical thinking trains students to think critically, to understand, that learning history must be based on sources about a series of causal links that take place in continuity and change (Pratt, 2019). Efforts to support historical thinking by many history instructors by creating historical learning models.

Critical thinking is discussed in the curriculum in Indonesia, but the implementation of learning history is still far from expectations. The results of the study provide information: lack of interest in reading, *copy-paste* assignments from the internet, memorizing material, and teaching methods lectures (Retnosari P, Mustansyir, Nugroho H W, 2019).

Learning models to help students in the learning process and historical thinking has been widely implemented (Putri H, Zafri Z, Ofianto O, 2019). The results of the study with the theme of historical thinking have been conducted by other researcher (Aman, 2012) and (Ofianto O, Basry W, 2015). Safe Research found an evaluation model of historical learning, while Ofianto succeeded in developing *learning continue*s in history learning. Safe and Ofianto Research Results are more likely to find judgments in historical education, but do not criticize the contents of the historical material being taught. The identification of the problem above encourages research with a focus on how to develop the Historical Thinking Learning Model.

The critical history of learning through MPBH encourages students to understand the past, dismantle parts of historical stories, and find their meaning to practice developing students' thinking skills. MPBH is an alternative to linking contemporary social problems with selected historical problems, being critical of sources and building students' creativity to find solutions. Studying history with current problems illustrates that history can develop thoughts that emphasize scientific principles. The problem in the field is students consider history lessons to be memorized. Students assume that learning history is boring, so it needs a learning model that invites students to be active and think critically to improve the learning outcomes, one of which is MPBH. The purpose of this study is to analyze the effectiveness of historical learning models to improve the student learning outcomes

Literature Review

Historical a term to explain the negotiations of thought, which are reflected in human activities in achieving their life goals and moving continuously across the time dimension. Human activities in moving time bonds are arranged in chronological order and space. The historical subject material is taught as an academic activity to understand the soul of a change.

MPBH is based on a philosophy of constructivism education that begins with the cognitivism of the ideas of Piaget and Vygotsky. Cognitive describes that learning is an activity of assimilation and accommodation of controlled external activities. Constructivism prepares students to solve problems while building knowledge. In line with Piaget's view, Vigotsky argues that this form of social constructivism places great emphasis on cooperative or collaborative learning. The learning process occurs due to relationships with various elements. The view of constructivism about knowledge does not come suddenly but is built by the individual, when interpreting and interpreting his world (environment). Implicitly, the sentence implies that learning not only examines the subject but connects with social issues that occur to solve problems so that they can investigate the future.

Historical thinking is a concept of the way's historians think and apply it to the present world (Yuta Miki, Tomoko Kojiri, Kazuhisa Seta, 2015). Historical thinking is a type of thinking that studies history and applies it to the modern world. Think of history or historical thinking is Considered as the ability to reflect, synthesize, and construct understandings of history based on evidence (Cintia Salinas, M. E. Bellow, H.L. Liaw, 2011). The opinions of other states think historically. For this study we will focus on related but distinct elements; historical empathy and the construction of historical accounts (Thomas Fallace, A.D. Biscaal, Jenneifer Perry, 2007). Historical thinking requires linking two opposing views: first, the way of thinking so far is a legacy cannot be excluded, and secondly, if it does not try to ignore the relics, it must use presentism, which is the past seen in the present lens. This view implies that history is always actual (Wineburg, 2006). Thinking history requires participation in learning, which is linked to personal experience, observation, and n self-reflection. Practicing historical thinking requires learning models. Conceptually, the research model of learning is made of historical thinking. Historical Thinking Learning Model is a synthesis of the problem-based learning model (PBL) (H Nugraheny, S S Edie, Sutikno, 2019) with the model issues centered history` (Ferguson, 1996). Model Steps Issue Centered History:

Figure 1: Adaptive MPBH of Problem-based Learning The

The advantages of PBL are more focused on the problem being examined. PBL tends to explore contemporary problems by ignoring problems that are not related to the problem being examined. Students can build their knowledge. Encourage students to be able to think in a scientific setting. The shortcomings of PBL for use in learning history are too focused on the problem being made a topic so closing contact associates with similar problems in past events. Implementation of historical learning in solving problems can use problem-solving methods as a group or individually.

Achievement of student assessments at the stage is *Problem Statement* carried out with technical, interpretative, and emancipatory instruments. The instrument of technical questions to find out the competencies of students by using question words, where and when they occur. *Interpretative instruments* concern about why and how. Emancipatory instruments are aimed at issues about the effect of power on what happens and how people interpret and explain what happened and ask why something should happen.

The analysis phase uses instruments to analyze problems and relate them to history. *Verification* involves students to look for current information about land cases and historical sources. *Interpretation* provides examples of past comparison with contemporary or contemporary phenomena. *Generalization*. In finding solutions, students can find solutions in solving problems using technical instruments, interpretations, and emancipation.

Methodology

This research is a combination of research to build a product that is considered effective following standards (Ofianto O, Suhartono S, 2016). The subject's overall research was 57 students participating in local history courses in Faculty of Teacher Training, Lambung Mangkurat University consisting of two classes. The control class was named regular class A with a total of 29 students, while the experimental class was regular class B with 28 students. The subject of this research development resembles the model developed by (Dick W, Lou C, James O.C, 2008).

Table 1: Pre-test and Post-test Control Group Design (Quasi-Experimental)

Class	Pre-test	Treatment	Post-test
Experiment	O_1	X	O_2
Control	O_1	-	O_2

The test question used is an essay test with a validity test using an expert validity test with Cohen's Kappa coefficient of 0.590. Pretest and posttest were conducted to obtain research data. To find out the effectiveness of the model of historical thinking learning, the analyst conducted a t-test (Sugiyono, 2015).

The steps of developing historical thinking models, namely: (1) preliminary research, (2) planning of model development, (3) validation, evaluation, and revision of the model includes a) expert studies, b) one-on-one trials, c) testing try small groups, d) limited testing and e) Implementation of the model.

Results and Discussion

The study began by examining 10 thesis students of the History Study Program, Faculty of Teacher Training and Education, Lambung Mangkurat University. The component of the historical method for heuristics has a score of 2.80 which means that the heuristic ability of students is close enough. Critical scores reach 2.85, their ability to criticize is close to adequate. The interpretation of the score of 2.83 also informs that its interpretation ability is close to adequate. Likewise, the average value of historiography is 2.80, this score also informs, that the ability of historiography is close to enough.

This phenomenon illustrates, that students are still considered to need to develop learning models for historical methods courses so that historical education competencies are achieved. Problems about the history learning process, especially local history courses tend to memorize, central lecturers, while problem-solving skills are lacking, do not track sources, arithmetic in critical thinking, stutter in discussions, so as not to foster a collaborative atmosphere, this study develops learning models of historical thinking (Anis, 2019).

At the initial development level, the researcher models the previous situation with the idealized state based on the learning objectives. Continue to determine the characteristics of students and learning resources available. At level 2 so that the objectives are achieved, the existing sub-competencies are broken down into several themes in the hope of achieving sub-competencies. At the level 2 stage, the researcher developed 4 themes included in the learning model. The themes, among others, analyze the notion of history and historical science, historical sources and their depository institutions, oral sources, oral traditions and interview methods, as well as criticism and interpretation.

In level 3, the researcher draws up a learning plan for the historical thinking model concerning levels 1 and 2. The learning approach is used by using the historical thinking model. Allocation of time needed in the learning process for four meetings (1 month), with details of one face-to-face meeting and 3 meetings that are devoted to solving problems and connecting links with current phenomena through group discussion activities. The activity of solving problems and connecting with contemporary phenomena begins with throwing problems that must be solved by each group collaboratively. The first and second discussion activities will be concluded with plenary activities. So that students are always active and reactive in the learning process, at the beginning of the meeting a pre-test is held and at the end of the study ahead *Posttest is*. In the last level or the fourth stage, problems were arranged and built into the 5 questions pre-test and post-test essay questions but not included in the lesson plan.

Figure 2: Syntax of Historical Thinking Learning Model (MPBH)
Source: (Anis, 2019)

MPBH suggests a link between historical issues and contemporary social phenomena (Anis, 2019).The process of lecturing the historical method with the MPBH approach is harmonized with the learning plan that is prepared and agreed upon between lecturers, and students who take the history method lecture. After completing the lecture process evaluation is held to determine the success of the activity with *Pretest* and *Posttest*. During the discussion, activities take place an assessment of the process As is usual activity *pretest* written with essay questions, in essence, to find out the discourse of the subject that must be mastered by students, while at the end of the theme the implemented *posttest is* with the intent of knowing an increase in mastery of the subject matter in the theme that was discussed. The process of lecturing the historical method with the MPBH approach is supplemented by learning media,

as follows: 1) Written sources: documents, archives, and newspapers, 2) Historical evidence: stories, photos, pictures and videos, 3) Guides and method modules history, 4) Historical Thinking Worksheet.

The history method module is a summary of lecture material that will be taught to students of MPBH participants so that the learning process takes place more effectively. The historical thinking worksheet was adopted from that suggested by *The Benchmarks of Historical Thinking Project* (Peck, 2008). The proposed MPBH development product is a synthesis of the learning model *Problem-Based Learning* (PBL)with Historical Thinking. The product of the Development of Historical Thinking Model was reviewed by five experts to look for weaknesses and weaknesses to be revised.

The five experts sought an agreement with the use of Cohen Kappa and ICCS. Cohen Kappa is used to seek agreement between historians (Sgh) and historical education experts (Stn). The agreement between Sgh and Stn using Cohen Kappa (R Aloud, T Recount, 2017). With Cohen's Kappa coefficient of 0.590. This means that there is enough agreement Sgh as a historian and (Stn) as an expert on history education on the model of historical thinking. The significance value is 0.018. Because the significance value is smaller than the significance level used by 5% (0.018 <0.05), it means that the initial hypothesis was rejected and concluded that there was a significant agreement between expert 1 and expert 2 at the 5% significance level.

For 3 experts with different expertise, namely IPS, Technology, Education and Language Education experts, researchers used *Intra Coefficient Correlation (ICC)* (Landers, 2016).The ICC results among US Educational Technology experts, M language linguists, and IPS B Education experts had an ICC score of 0.741, with a significance of 0.000 <0.05. This means that there is an agreement between experts, at α 0.05. In general, this media is appropriate to be used.

Evaluation Results *in One to One*

the evaluation was *One to one* carried out to obtain information on the interests and comments of three students about the development of MPBH. Three students consisted of two female students and a student. One student with a *grade point average* moderate (GPA), another who is above medium and one student with a moderate IP. Each was given a guide to the MPBH model to be examined and studied.

Students need reading material related to the material being studied. Students feel the need to know and practice the historical significance of primary and secondary sources (verification). Students still doubt that current reality can be contacted with historical phenomena. They also admitted that MPBH could develop its thinking based on methods so that it was not fixated on formal history books and one-way historical views.

The highest value is 60, the average or *Mean* is 32.33. results *Posttest* shows the lowest value is 40 and the highest value is 87.50, the mean or mean is 70, 13. In addition to the *Pretest-Posttest* and *tests* in the small test lecture activities with the Historical Thinking Model, observations are also conducted, conducted by two young lecturers as observers.

Figure 3: MPBH Effectiveness Test Results

Results of the study by interviewing the one-two one evaluation and small group evaluation, students expressed and felt an interesting learning atmosphere and made them want to always think historically through MPB. On completing the history worksheets, students have difficulty in finding sources of archives containing historical information and historical phenomena. This is because they have never previously visited the regional and provincial archives.

The response of students in using MPBH based on the results of the questionnaire during 4 meetings of their interest in experiencing an increase. Descriptively proven, that the student responsible for the whole group was 68.54 with the lowest value being 50 and the highest was 79. The median value was 69. Asymp value. The Sig of the Chi-Square statistic (df = 2) is 0,000 <a. 005 thus rejects Ho and accepts Ha. These results provide information, there are differences in student responses from meeting 1 to meeting 3 there was an increase. These results indicate that students' interest in MPBH courses in local history courses is increasing. The development of students' knowledge of the posttest score from the first meeting was 60 maximum values, the second meeting the minimum value was 69.21 and the maximum value was 72.72, while the 3rd meeting the minimum value was 75.44 and the maximum value was 78.44. It means that from the first meeting to the third meeting had increased. The information also indicates that the competency of students in local history courses has increased.

After a limited test in the following year, the MPBH was implemented in the even semester of 30 November 2019. The subject chosen was related to how the Banjar people saw, interpreted, and then adapted to their environment so that it gave birth to the river culture which became the name of the city of Banjarmasin.

Class begins with a pretest, terminated. *The posttest* number of participants in the lecture was 45 students divided into 6 groups with group members consisting of 6 to 7 people. Lectures with subjects on rivers, small river *(handil*), and very small river (*saka*) are considered interesting and contextual by

student's college participants. This is indicated by the questions they raise, and the responses to the questions. The atmosphere in implementing *Posttest* and Posttest is very orderly.

This shows that the MPBH model can be carried out in the real test class with the result of increasing students' competence in learning historical methods, seen from the value *Mean Pretest* (54.02)> *Posttest* (75.24). The historical method module they already have. They have obtained information and historical facts about local history. The facts about the local history that they know are the raw materials for making proposals as a final bill from the participants of the history method courses following the problems, they like to know the difference between a certain value and the average value of the group of participants conducted a t-test. T-test results show that MPBH in the comparison class influences learning historical methods. This is demonstrated by an analysis of the pre-test and post-test results <0.05.

The implementation of MPBH for the Historical Method course has been tested in the Historical Education Study Program of the FKIP University of Lambung Mangkurat. MPBH in the history method course was tested on a limited test of three with each theme on local history, namely the issue of land that had been laid out during the reign of the Sultanate of Banjar (Sultan Adam's Law), river culture and fashion dynamics always actual and close to memory participants are considered enough. The drawback is the deepening of material outside the classroom must be done and remain controlled.

Other obstacles, students are still accustomed to being passive participants in lectures, not preparing themselves for college, and lack of reading, so it is rather difficult to express their ideas, critical and less able to connect current issues with historical issues. The atmosphere becomes liquid when the problem of the subject of localization and close to their memory and environment can be picked, so they feel close to the problem under discussion. Seeing this phenomenon, the MPBH which has been more refined seems to be able to use the effectiveness of this model better.

Research on the development of MPBH after it is carried out there are still limitations that include: Trial of the MPBH model for local history courses History is only applied to students of the Historical Education Study Program Faculty of Teacher Training and Education Lambung Mangkurat University in the sixth semester implemented at the end of November 2019 in the even semester 2015 in the same course with different students. Different characteristics of students as the subjects in this study are different. Through the results of small tests, limited tests and the implementation of the model, researchers assume, that MPBH can be used or applied to other students in the class. Do different study programs students, different faculties and different universities. It can be applied to new research is needed.

Before the implementation of small and large trials, the development of MPBH has not carried out simulations, but observers and students were only given a general explanation of this model. In addition to a small test and three limited tests, MPBH is also implemented in the Historical Method course in different classes so it needs to be developed and expanded with several related subjects. If the development of MPBH is used it is recommended for courses totaling 3 SKS. The effectiveness of the development of MPBH evaluation results is not compared to other approaches. Research that also uses PBL states that the PBL Model (in this case used at MPBH) can increase student activity and social skills (Dewi S, Sumarmi, Amirudin A, 2016).

The inquiry activities in MPBH are also called "inventions". Inquiry in MPBH requires students to find their own learning experiences and look for answers to the questions posed. An inquiry is a way of presenting lessons that allow students to find information with or without the help of the teacher. This involves students in the mental process of discovering the concepts taught themselves. Learning by using inquiry can improve students' knowledge and build their own learning experiences (Sumantri, Mulyana, Johar Permana, 2001).

Historical thinking is a continuous activity, in which there are activities in reading, writing, linking material to one another. Besides historical thinking in the form of analyzing the material obtained such as how to compare one historical event with another, why historical events occur, how their impact,

and how historical events can help for life today and be able to interpret events. By thinking historically students will always filter every information they get (Yulia Sofiani, Oka Agus Kurniawan Shavab, 2018). These skills require students to be able to hear, read historical narratives, and be able to explain why something happened.

Historical thinking 'has a central role in the theory and practice of historical education. At the very least, history educators must work with historical thinking models if they are to formulate potential developments in student progress through the school history curriculum, test these developments empirically, and form teaching experiences to maximize those developments (Seixas, 2017). Historical thinking skills are related to mastery of several document assignments and discuss the implications for future research (Merkt, Werner, and Wagner, 2017).

Conclusion

The MPBH model has proven to be effective in improving student learning outcomes and able to make students think more critically. The MPBH model is the right solution to use in overcoming monotonous and uninteresting historical learning. Through this model, students are required to think more creatively so that learning outcomes can improve. The next recommendation is to apply this learning model more in class and in more subjects.

Abstract

There is a recent trend in analytics which has burst into our world – it is a predictive analytics. The article is devoted to the tasks and results of the predictive analysis of the efficiency of the equipment of an industrial enterprise.

Keywords: predictive analytics in production, performance analysis of equipment, Overall Equipment Effectiveness, Key Performance Indicators, TEERo operator, TEERa automatic control.

Introduction

At the present time, we would like to talk about this today, there appeared a recent trend in analytics - predictive analytics. The central essence of predictive analytics is the task of determining the predictor or several predictors (parameters or entities that affect the predicted event). Based on the selected predictors, a predictive analytics model is formed with the help of which events in the future are predicted with a certain degree of probability. What are the questions that the predictive analytics answers in the production? In this article we would like to highlight the prediction of the technical condition of the equipment. Thus the following problems are solved [1-5]:

- stops in the operation of equipment are prevented by switching to equipment repair according to the state;
- the technical condition of the equipment is evaluated in real time;
- causes of equipment failures are identified;
- alerts about approaching failures are received.

Methods

OEE and Downtime Management

OEE (Overall Equipment Effectiveness) is an approach to monitoring and managing the life cycle of funds. It was proposed in the late sixties of the last century by the Japanese Nakajima (Seiichi Nakajima), but began to be used outside of Japan only in the late eighties.

The essence of the approach is to collectively analyze the metrics that characterize various aspects of the equipment operation, including downtime, speed reduction and quality loss [4].

Its structure already contains the analysis technique, which consists in a consistent immersion in the problem areas, whether it is a non-optimal organization of the equipment operation, its low productivity or the spoilage of the product [5, 6]. As a result of the analysis, the reason for the decrease in efficiency is revealed, on which it is necessary to focus attention.

OEE allows you to identify the losses and causes of inefficiencies. As a result, not only failures due to breakdowns are identified, but also losses due to inefficient equipment configuration, a decrease in the performance of its operation, or the expectation of receipt of materials. Ultimately, OEE allows you to see what the impact of the current performance of a particular piece of equipment on the performance of the whole production [7].

The availability of reliable results of measuring the productivity of funds allows you to make weighted decisions about capital investments, providing a faster return on investment [8]. Based on the OEE data, it is concluded whether it is possible to improve performance on existing equipment or whether its capabilities are actually exhausted and new equipment is needed to increase performance.

Calculation of OEE Indicators

To analyze the efficiency of the equipment, a KPI (Key Performance Indicators) system was developed. But before you start to consider them, you need to agree on terminology. As already mentioned, OEE is an approach to monitoring the operation of equipment [9-12]. At the same time, very often OEE refers to the coefficient itself, which characterizes the operation of the equipment. In order to avoid confusion, we will continue to talk about OEE when it comes to the approach, and the "OEE indicator" in the second case.

Essentially, the OEE is the ratio of fully productive operating time (ideal production time) to the planned operating time. Taking into account the loss of productivity and quality, this coefficient can be calculated by the formula 1.

$$\text{OEE} = \text{Accessibility} \times \text{Productivity} \times \text{Quality} \qquad (1)$$

Where: Accessibility = Working time / Planned time
Productivity = Produced products / (Perfect speed × Working time)
Quality = Quality products / Produced products.

It is easy to see that by substituting the multipliers in formula 1 and making the abbreviations, you can get the OEE equal to the ratio of the volume of produced quality products to the planned time multiplied by the ideal speed. Thus, it can also be defined as the ratio of the volume of produced quality products to the ideal volume that could be produced if the equipment worked during the planned time at the maximum (ideal) speed.

These calculations are given in order to clarify the meaning of this indicator.
Despite the fact that to calculate the OEE indicator you can do without information on working time and products, these quantities must be recorded.

They are needed, because besides the OEE indicator itself we are also interested in the whole triple of factors of formula 1: accessibility, productivity and quality. What for? For analysis.

The fact is that monitoring the OEE value is like a starting point.

Finding that the value of OEE is different from the target (for example, it fell compared to the previous period), you can see what affected this decline.

Analyzing the values of each of the three coefficients and comparing them, for example, with the values for the previous periods, we gradually localize the reason for the loss of efficiency. If the problem lies in the quality or speed of the equipment, this is a signal for the relevant services. If the problem lies in the area of availability, we can make a deeper analysis of the causes, which we will consider a little later, when we talk about managing equipment downtime.

Of course, the KPI set for performance evaluation is not limited to the four indicators described [13, 14]. They are the most common and in the future are detailed to the required level. Other important indicators will be considered below.

Experience of World Manufacturers

According to research, the best world producers reach the level of the production process with OEE values above 85%. The values of the main indicators, if this value is achieved, are given in Table 1. These data are relevant for continuous production. For discrete manufacturing, the same OEE is 80%.

Table 1: value of OEE indicators of the best world producers

Indicator	Meaning
Availability	90.0%
Productivity	95.0%
Quality of service	99.9%
OEE	85,4%

It should be noted that for many enterprises the value of the quality index exceeds that indicated in Table 1. However, according to the mentioned studies, the average value of the OEE indicator for producers does not exceed 60%. This fact points to the potential for optimizing production in terms of performance and availability.

What the value of OEE should be compared with

As already mentioned, the analysis of OEE indicators is the starting point for solving problems of loss of effectiveness. One of the most common approaches to monitoring is comparing the OEE indicator with a certain target value. If the difference becomes tangible, then it is necessary to look for the causes. There is a reasonable question, what it is necessary to compare with. The above indicators of world producers are good in terms of strategic goals, but for operational management it is better to use indicators that reflect the specifics of your production.

In this capacity, you can use the indicators obtained at your enterprise. For the current production status, the OEE value can be calculated, which will be compared in the future to assess the improvements made. Also, the values can be calculated for individual production lines, and then the best of them can become the target value for all other lines.

This will identify the problem areas of each of the lines and try to find and eliminate the cause.

In the same way, one can compare work at the present time with the same period in the past, which is important for industries with a strong seasonal component. In addition, it is possible to compare the performance of different shifts that work with the same equipment.

The challenges that must be addressed

One of the main objectives of OEE is to reduce the six most significant causes of loss of effectiveness (Six Big Losses) listed in Table 2.

Table 2: sixe big losses

Cause	Category	Comment
1	2	3
Loss	Loss due to downtime	There is some freedom in attributing to breakdowns, or to mini-stops

continuation of the table 2

1	2	3
Setting	Loss due to downtime	Includes changing and reconfiguration of tools
Mini-stop	Loss of speed	Usually includes stops for a time less than, for example, five minutes
Speed reduction	Loss of speed	Anything that does not allow the process to run at the highest possible speed
Spoilage at start-up	Loss of quality	Spoilage arising from warm-up, start-up and other early stages of production
Spoilage in production	Loss of quality	Spoilage arising from normal production work

Equipment Downtime Management

The meaning of downtime management (DTM - Downtime Management) is a deeper analysis of the reasons for stopping the operation of equipment. In fact, the task of managing downtime is to find the time intervals when the equipment did not work at all or worked at a reduced speed or quality, and classify these gaps according to the time model and the cause tree. After classification, time intervals are aggregated for each category. As a result, statistical indicators are obtained, which are used in the calculation of KPI.

Let us consider in more detail the time model and the tree of causes.

Figure shows an example of a time model.

Fif. Time model

It contains a set of time categories according to which down time and losses can be broken up into disjoint groups. It also contains the time categories that are used in calculating the KPI. The reduced time model is not fixed; it can be expanded with additional categories.

The causes tree is a detailed description of the categories of time and allows you to classify the reasons for downtime. For example, for an unplanned shutdown, you can specify that it can be caused by manual equipment stoppage, expectation of receipt of materials or breakdown. In turn, manual shutdown of equipment can be caused by reconfiguration, adjustment, etc. As a result of such consistent detailing, the cause tree is constructed.

In the future, downtime will be divided into groups according to the nodes of the tree and can be analyzed. More information about the cause tree will be given when describing the SIMATIC IT OEE / DTM configuration.

As we have seen, OEE and downtime management are close tasks and complement each other. Because of their similarity, they are often viewed in pairs, and the systems that solve these tasks are called OEE / DTM systems.

Results

Place of OEE / DTM systems in the Enterprise Information Environment

Based on the tasks to be performed, the OEE / DTM systems are MES-class systems. MES uses data obtained from various control systems existing in the enterprise (SCADA systems, controllers, etc.). Also, MES imports data from adjacent systems (LIMS, etc.) and upper (ERP) levels. As a result, a single information space for operational management is created, in which separate tasks are functioning. Each of them consumes the available data and provides new information, which in turn can be used by someone else. This is how the OEE / DTM system integrated into this space uses data from lower-level systems and calculates various KPIs that reflect the operation of the equipment. Moreover, the values of these KPIs enter the general information environment and may be of interest not only to OEE / DTM users, but also to other MES users. Also, these data can be exported to ERP and other systems, with the interface of interaction with them provided by means of MES, rather than OEE / DTM.

Of course, in order to obtain up-to-date data on the efficiency of the equipment, it is necessary to have advanced low-level monitoring systems that supply real-time information about the operation of the equipment. However, even with incomplete equipment, it is possible to obtain reliable data on efficiency, combining the data of available systems with the results of manual input.

The information environment allows you to simultaneously see performance indicators together with other performance indicators of production. On the operation of the equipment, reports can be generated, access to which is carried out within the same environment.

You can also send reports by e-mail. Thus, access to data is greatly facilitated and the culture of their use is changing. After the implementation of the system, you do not need to wait for the report to be prepared manually, just once you have configured the distribution system, receive a report, for example, in the morning of each day.

It is also possible to set up automatic distribution of reports when certain events occur, for example, when the efficiency falls below a specified level.

Note that when using the common information infrastructure, the resulting complexity of the system decreases, since the interaction of each component with each one is replaced by the interaction of all components with a single environment.

Automated control system for the machinery park of a machine-building enterprise

Automated control system of the machine tool fleet of the machine-building enterprise calculates and archives the following data:

- coefficient of planned time Cpt;

coefficient of available time Cat;

- coefficient of useful time Cut;
- coefficient of quality unplanned operations Cquo;
- the coefficient of poor quality unplanned operations of Cpquo;
- total equipment efficiency based on input of OEE operator data;
- absolute effective equipment performance based on data input of the TEERo operator;
- absolute effective equipment performance based on TEERa automatic control.

1. Cpt is the coefficient of the planned time.

$$Cpt = St / Ct \quad (2)$$

where: Ct is the calendar time;
St is the scheduled time.
Ct per day = 24 hours; Ct per week = 7 days; Ct per month = 28 ÷ 31 day; Ct = 3 months; Ct per year = 4 quarters;

$$St = Ct - \text{Unplanned time (Ut)}. \quad (3)$$

Unplanned times include the following machine status periods:

- holidays;
- weekends;
- changes;
- formal meetings;
- lunches;
- officially allotted time for inspection, maintenance and servicing of the machine;
- officially allocated time for testing new technology;
- officially allotted time for working out a new program;
- other official regulated activities;
- non-working time.

2. Cat is the coefficient of available time.

$$Cat = At / St \quad (4)$$

where: St is the scheduled time;
At is the available time.

$$At = St - \text{Loss of availability} \quad (5)$$

The loss of availability includes the following machine status periods:

- unplanned operator absenteeism (illness, shirking, etc.);
- equipment breakdown and repair;
- absence of a task to fulfill;
- lack of material;
- lack of tools;
- absence of a crane;
- lack of ancillary equipment.

3. Cut is coefficient of useful time.

$$Cut = Ut / At \quad (6)$$

where: At is available time;
Ut is useful time.

$$Ut = At - \text{Loss of non-core operations} \quad (7)$$

The loss of non-core operations includes the following machine status periods:

- tool layout at the beginning of the shift;
- cleaning tools and the working place at the end of the shift;
- obtaining and installing tools, devices;
- removal / returning of tools and devices;
- installation and removal of parts from the machine;
- changeover of the machine to a new part;
- control of the part on the machine by the technical process;
- personal needs.

4. Cquo is the coefficient of quality unplanned operations.

$$Cquo = STt / Ut \quad (8)$$

where: Ut is useful time;
STt is the standard time.

$$STt = Ut - \text{Qualitative unplanned operations} \quad (9)$$

The quality unplanned operations include the following machine status periods:

- replacement / sharpening of a worn tool;
- adjustment of equipment during the operation;
- equipment management (changing its operating modes).

5. Cpquo is the coefficient of poor-quality unplanned operations.

$$Cpquo = Nto / STt \quad (10)$$

where: STt is the standard time;
NTo is a net time based on the input of operator data.

$$NTo = STt - \text{own poor-quality unplanned operations} - \text{other poor-quality unplanned operations} \quad (11)$$

The following status-periods of the machine are related to own poor-quality unplanned operations:

- correcting the spoilage of this machine.

Other unfavorable unplanned operations include the following machine status periods:

- correcting the spoilage of another machine.

6. OEE is the overall efficiency of the equipment based on operator input.

$$OEE = Cat \times Cut \times Cquo \times Kno \quad (12)$$

where: Cat is coefficient of available time;
Cut is coefficient of useful time;

Cquo is the coefficient of quality unplanned operations;
Cpquo is the coefficient of poor-quality unplanned operations.

7. TEERo is the absolute effective performance of equipment based on operator input.

$$TEERo = Cpt \times Cat \times Cut \times Cquo \times Cpquo \quad (13)$$

where: Cpt is coefficient of planned time;
Cat is the coefficient of available time;
Cut is the coefficient of useful time; Cquo is the coefficient of quality unplanned operations;
Cpquo is the coefficient of poor-quality unplanned operations;
or

$$TEERo = NTo / Ct \quad (14)$$

where: Ct is calendar time;
NTo is the net time based on the input of the operator data.

8. TEERa is absolute effective productivity of the equipment on the basis of the automatic control.

$$TEERa = NTa / Ct \quad (15)$$

where: Ct is the calendar time;
NTa is a net time based on automatic control.

Conclusion

Predictive analytics based on the use of modern software products effectively solve problems and give excellent results, which in turn makes it possible:

- to reduce equipment downtime;
- to reduce equipment repair costs;
- to reduce the number of unplanned repairs;
- to monitor violations;
- to improve efficiency in the management of the machine building enterprise.

Aspects Related to Production Competitiveness in The Latvian Aquaculture Sector

Inese BIUKŠĀNE

Institute of Agricultural Resources and Economics, Rezekne Academy of Technologies, Riga, Latvia, inese.biuksane@inbox.lv

Abstract

In the world, the aquaculture sector is evaluated as highly productive, competitive and environmentally friendly sector with the potential to be developed as an alternative source of fish resources using the basis of inland water resources. The economic breakthrough in the EU and Latvia is related to development of aquaculture sector, where competitive production is one of conditions for economic recovery. The aim of the research is to evaluate and facilitate the production competitiveness of the Latvian aquaculture sector. On the basis of the available data and chosen indicators, the analysis includes and reflects the most important aspects of the Latvian aquaculture sector related to production competitiveness, with particular focus on production in micro and small enterprises. In addition, it provides an insight into the measures to be further implemented, in order to facilitate production competitiveness. The information reflected in the research can be useful in establishment, planning and implementation of the common policy of the aquaculture sector.

Keywords: Aquaculture, Enterprises, Financial Analysis, Latvia, Production Competitiveness.

Introduction

The Latvian aquaculture sector mostly deals with fish and crayfish breeding for commercial sales, where the breeding of aquaculture products takes place not only in open land ponds, but also in natural water flow basins and recirculation systems. In 2018, 766 ponds with the total area of 5.19 thousand ha, 1279 pools with total capacity of 15.74 thousand m3 and 37 recirculation systems with capacity of 5.73 thousand m^3 were used to breed fish and crayfish. The total amount of fish and crayfish sold in 2018 was 829.70 tons with the total market value 2.17 million EUR (Central Statistical Bureau, 2020). The greatest part of the aquaculture products (~85%) has been acquired from the open land ponds, whereas the rest products (~15%) – from the natural water flow basins and recirculation systems. In the local conditions, the open land ponds are mainly suitable for breeding carp-like fish; consequently, carps (60%) dominated in the composition of the products available in the market. The range of the products included also other fish – trout, sturgeon, tench, pike, crucian carp, zanders etc. 87 companies were engaged in farming fish and crayfish in 2018; they employed 340 people with the average net remuneration of 516 EUR (Central Statistical Bureau, 2020). Since 2005, the number of companies has increased 3 times, which largely can be explained by the entry of Latvia into the EU in 2004 and availability of support provided by the financial instruments to develop aquaculture.

Pollution of the environment, inimical spawning conditions and intensive fishing as well as a range of various other factors have negative influence on the condition of fish stock world-wide, resulting in increase in the significance of the aquaculture sector. There is a possibility to develop aquaculture as an alternative source of fish, where the basis of inland water fish resources offers broad opportunities of supplementing the fish stock much sought for on the market, simultaneously contributing also to the development of industrial and recreational fishing, processing and fishing tourism. The water resources in the territory of Latvia available for aquaculture are evaluated as qualitative and sufficient to ensure performance and development of the respective business (Agriculture Ministry, 2014). The economic breakthrough in the EU and Latvia is related to development of aquaculture sector (Agriculture Ministry, 2013), which at the global level is evaluated as a highly productive, competitive and environmentally friendly sector (Agriculture Ministry, 2014). One of the objectives

of the Common Fisheries Policy is to contribute to environmentally sustainable, resource efficient, innovative, competitive and knowledge-based aquaculture that can be facilitated by the development of the competitiveness and viability of micro, small and medium-sized enterprises (European Parliament and Council, 2014)**Error! Reference source not found.**. The development of the aquaculture sector depends on production competitiveness, which has become one of the key goals of development of countries, sectors and enterprises.

Research aim – to evaluate and contribute to the production competitiveness of the Latvian aquaculture sector. To reach the aim, the following work tasks were put forward: 1) to select the most important indicators to describe the aspects related to production competitiveness; 2) to evaluate production competitiveness of micro and small enterprises, at the same time providing proposals for improvement of production process.

The novelty of the research – account of the most important aspects in the Latvian aquaculture sector related to production competitiveness, with particular focus on production in micro and small enterprises. It offers a comprehensive insight into the competitiveness of aquaculture enterprises, which is reflected on the grounds of use of the fixed assets and labour involved in their production process. The research also provides an insight into the measures to be implemented further, in order to facilitate production competitiveness. The reflected information may be used in decision making in order to establish, implement and plan the common policy of the aquaculture sector.

There were used quantitative research methods in the research. The author mostly applied analysis and synthesis methods in development of conclusions and proposals. Microsoft Excel, Microsoft PowerPoint and IrfanView program were used in processing and analysis of the research results.

Materials and Methods

Production is a process of creating products intended for selling in the market. At the level of an enterprise, it includes decision making on the choice of products to be produced, technology to be applied in production, required production factors, market strategy, etc. Production factors in the classical economic production theory are the resources required for manufacturing products or provision of services: land, capital, labour and entrepreneurial abilities.

Capital plays a crucial role in ensuring production process, in the context of production resources it is understood as real capital – fixed assets and working capital, required for production. Productivity of fixed assets determines the level of technological development of an enterprise, which in turn influences the production competitiveness and development potential of the enterprise.

The composition of fixed assets in the aquaculture sector includes land and pond areas, fish and fish fry breeding shops and sheds, pools, recirculation systems, tractors, specialized computer hardware for fish breeding, oxygen cylinders, etc.

Production competitiveness in the Latvian aquaculture sector was evaluated by availability, capacity, utilization intensity and efficiency of fixed assets, as well as productivity of labour (Fig. 1).

Fig. 1: Indicators for Evaluation of Production Competitiveness (created by the author **according to Springate, 1978; Porter, 1990; Rurāne, 2001**)

The analysis of fixed assets availability will deal with evaluation of how many fixed assets are in the management of the enterprise. The analysis of fixed assets capacity will enable an assessment of the capital intensity in the enterprises (Rurāne, 2001). The analysis of fixed asset utilization intensity will allow reflecting the intensity of fixed assets involved in production process of enterprises, and will provide an opportunity to judge about the level of technical provision of the enterprises (Rurāne, 2001). The analysis of productivity of labour will allow evaluating the utilization efficiency of the labour attracted by the enterprises (Porter, 1990). In the framework of fixed asset efficiency analysis, the benefit obtained by the companies from the fixed assets involved in the production process will be reflected by assessing the return and profitability of fixed assets (Springate, 1978). To evaluate production competitiveness in general there were selected 6 indicators: Value of Fixed Assets per Company, Fixed Asset Capacity Ratio, Depreciation to Fixed Assets Ratio, Productivity of Labour, Fixed Assets Turnover Ratio and Fixed Assets Profitability Ratio. The evaluation embraced the period from 2005-2018. Considering confidentiality of data, the research does not comprise the information about the small enterprises in the period of 2006-2008 and 2011. The research also includes no evaluation of medium-sized enterprises, as the data about these enterprises are available for 2005 only, and the data for 2006-2008 and 2011 are confidential.

Results and Discussion

Production competitiveness of micro and small enterprises in the Latvian aquaculture sector was viewed according to availability, capacity, utilization intensity and efficiency of fixed assets, as well as productivity of labour, in general analysing 6 indicators (Fig. 2).

In 2005-2018, on average 0.21 million EUR of fixed assets per company were available for production needs of the aquaculture enterprises (Fig. 2a). In terms of capital, the small enterprises were the richest enterprises within this period; on average 1.47 million EUR of fixed assets per company were available for their production needs. In turn, 11 times less fixed assets were available to micro enterprises – on average 0.14 million EUR of fixed assets per company. Both the small and micro enterprises carried out restoration of fixed assets, which can largely be explained by the support of Financial Instrument for Fisheries Guidance, European Fisheries Fund and European Maritime and Fisheries Fund provided for purchase and restoration of production capital.

All in all the Latvian aquaculture sector can be evaluated as fixed asset intensive sector (Fixed Asset Capacity Ratio – 4.26), where production requires significant capital investments (Fig. 2b). Both the micro and small enterprises were fixed asset intensive – no considerable differences were observed between these groups of enterprises. Since 2005, the capacity of fixed assets in the aquaculture sector has increased per 49% suggesting that more and more fixed assets are involved in production process.

The wear intensity of fixed assets involved in production process of the Latvian aquaculture sector cannot be evaluated as high (Depreciation to Fixed Assets Ratio – 0.002), suggesting that there are regular investments into the restoration of fixed assets (Fig. 2c). Higher wear intensity of fixed assets

was observed in micro enterprises, in turn, it was lower in the small enterprises. Since 2005, the wear intensity of fixed assets in the Latvian aquaculture sector has risen, suggesting that the fixed assets available for production needs of the aquaculture enterprises are used more intensively, and they physically wear out and technically grow obsolete faster.

c) Depreciation to Fixed Assets Ratio (coefficient)

d) Productivity of Labour (thousand EUR)

e) Fixed Assets Turnover Ratio (%)

f) Fixed Assets Profitability Ratio (%)

Fig. 2. Indicators describing the production competitiveness of Latvian aquaculture sector from 2005 until 2018 (EUR, coefficient, %) (calculated and created by the author according to Central Statistical Bureau, 2020)

The productivity of labour in the Latvian aquaculture sector can be evaluated as low (on average 13.72 thousand EUR per employee in 2005-2018), which can be explained by lack of knowledge and experience in the field of aquaculture (Fig. 2d). In this period, the highest productivity of labour was observed in small enterprises exceeding the average indicator in the sector by 8%. Since 2005, the productivity of labour in the Latvian aquaculture sector has improved 4 times, reaching 23.04 thousand EUR per employee in 2018. The micro enterprises experienced the most rapid increase of this indicator.

Fixed assets turnover ratio in the Latvian aquaculture sector was influenced by the resources involved in the production process – the more profitable the fixed assets and knowledgeable the labour were

involved in the production process the greater return was achieved (Fig. 2e). In 2005 - 2018, the fixed assets turnover ratio the Latvian aquaculture sector constituted 26.87%, which has reduced by 33% since 2005. In the aquaculture sector, the greatest return from the fixed assets involved in the production process was achieved by the small enterprises (Fixed Assets Turnover Ratio – 36%), and smaller return – by micro enterprises (Fixed Assets Turnover Ratio – 27%).

Between 2005 and 2018, the fixed assets available to the Latvian aquaculture sector have been insufficiently profitable, whereof the negative profitability of fixed assets suggests (except for 2009 - 2013 and 2015) (Fig. 2f). In this period, the small enterprises operating in the aquaculture sector were more financially profitable. Although the profitability of fixed assets in the Latvian aquaculture sector has improved by 89% since 2005, it still cannot be evaluated as sufficient (the Fixed Assets Profitability Ratio was -0.88% in 2018).

To improve the management of fixed assets and the efficiency of their use, as well as to enhance the efficiency of the labour, aquaculture companies must use not only productive (innovative) fixed assets and knowledge-based labour in the production process, but must also have the capacity of fixed assets and number of employees which is fully utilized for production purposes (neither too little nor too much). It is also important to provide for timely and proportionate investments in renewal of fixed assets through regular fixed asset restoration and disposal of obsolete and unused fixed assets. To improve labour productivity it is recommended to promote the increase in knowledge and qualification of the high-level employees, simultaneously introducing various measures to induce workers, improving the working conditions and working environment as well as work organization.

Conclusions

The economic breakthrough in the EU and Latvia is related to development of aquaculture sector, where the competitiveness has become one of the key objectives for development of countries, sectors and enterprises. The production competitiveness in the Latvian aquaculture sector was evaluated from several aspects, with particular focus on production in micro and small enterprises. The indicators applied in the process of evaluation enabled to understand the most important aspects related to production competitiveness and the measures to be implemented further in order to contribute to the development of the Latvian aquaculture sector.

The Latvian aquaculture sector can be described as fixed asset intensive sector, where the production of products requires considerable capital investments. The wear intensity of fixed assets involved in production process was not high, showing that there are consistent investments made to ensure the technical level, which was largely facilitated by the availability of support from the EU funds and financial instruments. The production resources involved in production process are not used rationally and efficiently enough. Although the Latvian aquaculture sector has a good level of technical supply, the production capacities are not fully used. Productivity of labour in this sector is still low, which can be explained by the lack of knowledge and experience in the aquaculture field. The resources involved in production process did not provide sufficient return and profitability. Currently, the production of the Latvian aquaculture sector is not competitive enough, besides, in all the groups of enterprises. The production competitiveness in the Latvian aquaculture sector can be facilitated by using productive fixed assets and knowledge-based labour in the production process, as well as ensuring optimal and rational involvement thereof in the production process, simultaneously envisaging proportionate investments in provision of the technical level.

Abstract

1.3 billion people have vision impairment, 70 per cent of which, live in developing countries, such as Egypt, which has a population of over 98 million. Banks' websites and ATMs are not accessible, and staff has negligible expertise to deal with visually impaired customers. Accordingly, this research investigates the challenges that face people with visual disability, and the reasons behind preventing them from opening bank accounts independently, and thus jeopardizing their privacy. The study also identifies the main variables that affect e-banking accessibility together with the mediating and moderating factors. Then, the research develops an accessible prototype e-banking system. A survey strategy is used, where questionnaires are used for surveying people with visual disability. Data collected is statistically analysed using structured equation modelling. Focus groups are also used to obtain group feelings and perceptions. Semi-structured interviews are conducted to get a deeper understanding pf the perspective of decision makers in banks and governmental representatives. Data collected is interpretively analysed in order to know more about the governmental rules, laws and projects that are established for people with visual disability. It also utilises the experiment method on evaluating the developed and proposed e-banking system in order to gain reliable results. Based on the statistical and interpretive analysis together with the reviewed literature, derived conclusion and recommendations are made to decision makers at banks and governmental representatives.

Keywords – E-banking, accessibility, visual disability, financial inclusion, digital divide, assistive technologies.

Introduction

People with visual disabilities find many difficulties to perform the most common daily tasks. In such scenarios, technology, far from providing always a solution, sometimes raises the existing barriers. Several reasons and challenges exist, where the main issues refer to a lack of standards with respect to accessible information and communication technology (ICT) interfaces and the wide diversity of requirements brought by the wide variety of special needs of potential users. One important challenge faced by visually impaired people is how to preserve their privacy and security in their daily lives. Sighted people are able to monitor their surroundings to protect themselves from privacy threats. For example, when using a mobile device in public, sighted people can hide sight lines between the screen and nosy bystanders. When sharing a photo online, they can not view to make sure that it does not include private content before sharing it (Tilse et al., 2007; Venkatesh and Sykes, 2013).

Approximately 1.3 billion people live with some form of vision impairment. The concentration of people living with either moderate or severe vision impairment is higher in developing countries than in developed countries. Internet users in Egypt were reported by the Egyptian ministry of Communication and Information Technology to be over 37 million users (Hussien, and Abd El-Aziz, 2019; Hussien, and Abd El Aziz, 2017; Raja, 2015; Abood et al., 2015). E-banking is rapidly growing, where bank customers are adopting electronic transaction systems in developing countries in general and in Egypt in particular (Llanto, 2015; Poushter, 2016). People with visual disability cannot open a

bank account or have an online banking because of the Egyptian banking regulations (Abd El Aziz, et al., 2018; Wentz, et al. 2017; Abd El Aziz, 2012); as they mainly depend on family, friends or third parties to manage their bank account. Although Automatic Teller Machines (ATMs) has a great potential, people with visual disability in Egypt face many challenges in using ATMs, checking balance, handling bank cards, and making online purchases.

Research problem

Being able to manage one's money is an essential component of independence and an essential day-to-day task. For people with visual disability, managing finances is very relevant to maintaining independent living (Tilse et al., 2007). Although the different banking services are used nowadays for several types of payments, it is considered as an inaccessible solution for people with visual disability. Without accessible banking solutions, many people will be excluded from vital services. Privacy might also be adversely affected. For example, users might have to depend on third parties, such as a spouse, children, and friends—or, in some instances, complete strangers—to deal with banking services such as buying any product using a credit card or an inaccessible ATM; which could expose them to greater security risks.

Despite the existence of technology in Egypt, where almost all banks have launched their websites, and provided e-services via ATMs, payment cards, and even phone banking. Yet, many banks' websites and ATMs are not accessible, and staff has negligible training or expertise to deal with customers with visual disability. ATMs are also not equipped with the required technology to be used by people with visual disability. Most Egyptian banks reject dealing with people with visual disability, making them financially excluded, and jeopardizing their privacy. A number of researchers have tackled this digital divide, but Egyptian people with visual disability have received insignificant attention regarding this matter.

Research Aim

In order to reach all potential customers, banks should offer banking services to people with visual disability that accommodate their accessibility needs. Banking services may be accessible to the broad range of users, by being inclusively designed, where users' human attributes, skills, competencies, and functional capacities are considered when designing any banking services. Yet, challenges that face people with visual disability in e-banking, remain unexplored (Okonji and Ogwezzy 2018).

Accordingly, the aim of this research is to investigate the spectrum of challenges that face people with visual disability when dealing with Egyptian banks, and the reasons behind preventing people with visual disability from opening bank accounts independently. The study also seeks to identify the main variables that affect e-banking accessibility together with the mediating and moderating factors. Finally, the research seeks to develop an accessible prototype e-banking system.

Research Questions

The overall aim of this study can be achieved by answering the research questions below:

1. What are the key challenges facing people with visual disability in the banking industry?
2. What are the main dimensions that affect e-banking accessibility with respect to people with visual disability?
3. What are the mediating and moderating factors affecting e-banking accessibility?

Literature review

The World Health Organization (WHO) has classified disability into three key definitions that are often used interchangeably but have different meanings: Impairment, Disability and Handicap. 'Impairment' refers to an abnormality in the anatomy, anatomical, physiological, or psychological function. On the other hand, 'Disability' refers to any limitation of an individual's ability to perform an activity in a normal manner. Finally, 'Handicap' refers to a shortcoming for a person due to an impairment or a disability that hinders him/her from fulfilling of a normal role on an equal level with a peer group due to physical and social barriers **(Lang, 2007).**

Visual Disability

Disabilities are divided into Mobility Impairment, Cognitive, Hearing, Speech, and Visual Impairment. Visual impairment refers to an impairment in vision that, even with correction, affects the educational performance. It ranges from low vision impairment to total blindness (Zitkus, et al., 2016). The International Classification of Diseases classifies four levels of visual functions which are: normal vision, moderate visual impairment, severe visual impairment, and blindness. People with moderate and severe visual impairment are classified as low vision people. The last classification is blindness, which is the focus of this research together with the perception of people with visual disability towards banking accessibility.

The WHO (2018) estimates that with regards to distance vision, 188.5 million people have mild vision impairment, 217 million have moderate to severe vision impairment, and 36 million people are blind, with around 90% living in low-income settings (WHO, 2018). They can be divided into: inability to see images clearly and distinctly, loss of visual field, inability to detect small changes in brightness, color blindness, and sensitivity to light (Ahmed, et al., 2017).

Due to the negligible attention paid to people with visual disability, there is no accurate or updated statistics of the number of people with visual disability in Egypt. According to the Egyptian State Information Service (2017), the number of people with disabilities in Egypt is around about 10.7 per cent of the total population (SIS, 2017). In Egypt there is lack of awareness about the visually disabled people and how to deal with them. Many parents of visually disabled people might deal with a low vision person as a blind person due to lack of awareness. Not to mention the lack of computer-based courses in schools which facilitate the educational process for people with visual disability (Marshall, et al. 2009).

Electronic banking accessibility

Internet accessibility standards are mainly provided by the World Wide Web Consortium (2008) - an international organization that provides a range of recommendations to ensures websites' accessibility to users with disabilities (Wentz et al., 2015). The World Wide Web Consortium (W3C) guidelines address the needs of people with disabilities and usability with assistive technologies (Raja et al., 2015; Caldwell et al. 2008). For people with visual disability, accessibility is improved by including options of adjustable fonts, keyboard navigation options, images' description, structured text suitable to screen readers; and captions for images, in order to maintain a consistent design.

In many western and industrialized countries, there are ethical and commercial justifications for creation of business websites accessible to users with disabilities. In such countries, a range of drivers are promoting the inclusion of persons with disabilities to accessible financial services.

Automatic Teller Machine Accessibility

In Australia, Canada, Turkey, the USA, and the UK many banks have deployed talking ATMs (Ulldemolins et al., 2012). The talking ATMs provide audible instructions enabling visually impaired persons to independently use the machine (RNIB, 2012). All audible information is delivered privately through a standard headphone jack on the face of the machine or a separately attached telephone handset. Information is delivered to the customer either through pre-recorded sound files or via text-to-speech program. In the USA, a final ruling on ATM accessibility standards was notified by the American Department of Justice under the Americans with Disability Act. The standards specified by the ruling included the provision of voice guidance systems, braille signs on ATM keys, and input controls for people with visual disability users. All ATM owners are complying with these guidelines when constructing or altering ATMs. Similarly, the Australian Bankers' Association and the Indian Banks' Association adopted ATM accessibility standards extensively covering issues of technology and physical accessibility especially for customers with disabilities (Gupta, 2014). Conversely, in many developing countries, business organizations have yet to comply with the W3C guidelines and many people with disabilities continue to grapple with internet access (Chigona et al., 2009; Venkatesh and Sykes, 2013).

The Belgium BNP Pariba's case

The BNP Pariba bank developed "An Accessible Bank for All" program for customers with a disability to carry out their banking transactions in a user-friendly way possible. Some accessibility features are included in the software running on their ATM's. They are mainly useful for people with visual disability. The voice assisted withdrawal has been available for all users of the BNP Pariba's ATM's since 2010. This feature is activated when plugging in a standard 3, 5-inch earphone into the jacket of the ATM after which the screen is switched off and the dialog is started up through the ear phones.

The interaction with the machine goes through the numeric keypad, with tactile indications on the buttons: 5dot on 5, circle on "OK", cross on "Cancel" and vertical bar on "Modify". BNP Paribas Fortis was the first bank in Belgium to offer this feature, in the meantime a second bank, Belhus, has an equivalent service.

Problems that face people with visual disability in banking

People with visual disability are marginalized with regards to accessing e-banking (Gallagher et al., 2012). Tackling this is important; as they are restricted from making electronic payments, their participation in society is limited. Moreover, they have to pay extra costs due to the additional administrative charges posed by the central bank for physical cash deposits and cash withdrawals. These benefits could not be gained by people with visual disability; as they do not have same access to technology-enhanced platforms for financial transactions (Warren, 2007; Wentz et al., 2018).

Mobile Payment

Mobile phones have transformed telephony profoundly. They are equipped with functionalities which exceed telephony needs, and which inspire the development of value-added mobile services, the use of mobile phones as access devices, and mobile commerce in general. The number of mobile phones in use far exceeds any other technical devices that could be used to market, sell, produce, or deliver products and services to consumers. These developments open beneficial opportunities to merchants and service providers.

Purchased products and services have to be paid for. Initially, fixed-line telephony billing systems were modified to charge mobile telephony. Later, mobile telephony billing systems were introduced, and used also to charge various mobile services when such services emerged. Yet, payments based on billing systems have several limitations. These include comparatively high payment transaction fees, merchant and service provider complaints about unfair revenue sharing, and the necessity to provision services to billing systems (Peirce and O'Mahony, 1999, Tewari and O'Mahony, 2003). In some areas, such as the European Union, credited payment services to third parties require a (limited) credit institution license. The lack of suitable payment instruments has for a long time been regarded as a factor that hampers the development of mobile commerce.

Mobile payments are payments for goods, services, and bills with a mobile device (such as a mobile phone, smart-phone, or personal digital assistant (PDA)) by taking advantage of wireless and other communication technologies. Mobile devices can be used in a variety of payment scenarios, such as payment for digital content (e.g., ring tones, logos, news, music, or games), tickets, parking fees and transport fares, or to access electronic payment services to pay bills and invoices (Dahlberg, et al, 2008). Payments for physical goods are also possible, both at vending and ticketing machines, and at manned point-of-sale (POS) terminals.

A mobile payment is carried out with a mobile payment instrument such a mobile credit card or a mobile wallet. In addition to pure mobile payment instruments, most electronic and many physical payment instruments have been mobilized. Furthermore, mobile payments, as all other payments, fall broadly into two categories: payments for daily purchases, and payments of bills (credited payments). For purchases, mobile payments complement or compete with cash, checks, credit cards, and debit cards. For bills, mobile payments typically provide access to account-based payment instruments such as money transfers, Internet banking payments, direct debit assignments, or electronic invoice acceptance (MUNOZ-LEIVA et al., 2017).

In the early 2000s, mobile payment services became a hot topic and remained so even after the burst of the Internet hype. Hundreds of mobile payment services, including access to electronic payments

and Internet banking, were introduced all over the world. Strikingly many of these efforts failed. For example, most, if not all, of the dozens of mobile payment services available in EU countries and listed in the ePSO database in 2002 (Carat, 2002) have been discontinued. To facilitate the development of better mobile payment services, it is important to understand the lessons of this history by learning what previous studies have discovered about mobile payments and about the mobile payment services markets, as well as what issues have remained unanswered.

Assistive Technologies for Financial Inclusion

The Technology Related Assistance to Individuals with Disabilities Act of 1988 described an assistive technology device as "any item, piece of equipment, or product system, whether acquired commercially off the shelf, modified, or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities." The purpose of assistive technologies is to support people with disabilities to carry out daily activities including using computers, mobiles and the web that they would otherwise find impossible or difficult to do. Examples of these technologies for people with visual disability are: screen readers, refreshable braille displays, optical character recognition software, speech recognition software and talking browsers. Assistive technology is used to assist people with visual disability to access computers, internet, and information technology (Suwannee, 2013).

When designing an electronic banking channel, designers should ensure that the e-banking channel can be accessed by everyone whatever his disability. In the banking sector, the people with visual disability customers can use computer screen readers to access the internet banking websites. Also, they can use mobile screen readers to access mobile banking applications. ICT-enabled banking can be made accessible and inclusive of users with varying needs and preferences. Some effective practices from the report are shared below (G3ict 2015):

- ATMs can be equipped with voice output, touch screen navigation, Braille and tactile lettering, audio and visual feedback and cues, and graphic icons for navigation can benefit persons with varying disabilities, as well as individuals with low literacy and language limitations.
- Accessible internet banking through websites and web portals allow persons with disabilities and others to operate their finances when a physical visit to a Bank branch is difficult.
- Financial institutions can offer multiple ways to contact customer service including email, IVR systems, SMS, telephone relay, and video conferencing.

Screen Readers

A screen reader is a piece of software which interrogates the contents of the screen on a computer and turns the contents into a non-visual form. This can be presented in synthetic speech using speakers, or braille using braille displays devices, or both. It allows blind users to hear what sighted users see on their computer monitors (Edwards and Launikonis, 2008). With respect to using the internet, screen readers parse the HTML of each page visited and read aloud what is presented on the page (Mankoff et al, 2005). Screen readers do much more than read web pages; they can be used with any software running on the computer. Therefore, they must be keyboard-compatible with that software.

Optical characters recognition software (OCR)

This software converts any scanned paper using desktop scanner which is scanned as a picture into electronic document. Therefore, people with visual disability can read and edit it either through the OCR software itself or convert it into any accessible document format such as Microsoft word document file (.doc/docx file). Moreover, this converted file can be printed in Braille form (BHATIA, 2014).

This software allows people with visual disability to access books or any printed documents without a need for sited person to read it to them. Unfortunately, most OCR software does not support recognition of the Arabic papers, except one software produced by Sakha Company, which support the Arabic language but unfortunately its recognition accuracy is very low and it is discontinued. Examples of OCR software are Kurzweil 1000 by Kurzweil Educational Systems Company and Read iris software by I.R.I.S. Company (Bhatia, 2014).

Research Methodology

The research methodology refers to all the techniques that are used to conduct the research, collect the required data for the research, and answer the research questions. This section will discuss the way to achieve the research aim through using the research strategy. The research approach will also be discussed together with the research methods used to collect data.

This research is mainly conducted to identify the challenges that face Egyptian people with visual disability in the banking sector, and the main dimensions that affect e-banking accessibility together with the mediating and moderating factors with regards to people with visual disability. The research also seeks to develop an accessible prototype e-banking system.

A survey strategy is a systematic strategy for gathering, analyzing data from the target population about their opinion on something. In this research this strategy will be used, where a simple random sample will be selected to represent the research population, which are people with visual disability in Egypt. This strategy is considered suitable because it enables fast data collection and finding significance answers easily (Punch, 2003; Creswell, 2012).

The research uses the mixed methods approach, where both quantitative and qualitative methods are used; in order to benefit from the strengths of both approaches (Johnson, et al. 2007; Sekaran & BOUGIE, 2016; Onwuegbuzie and Leech, 2004). This is clear because a qualitative research helps in gaining deeper and detailed understanding of the problem. On the other hand, a quantitative research allows generalisation of conclusions and flexibility in the treatment of data. Suitable methods for addressing the research questions include: structured questionnaire, semi- structured interviews, focus groups and experimentation.

Structured questionnaires are considered suitable for surveying a relatively large number of people who are visually impaired, and collecting data which can be statistically analyzed (Creswell, 2002) using structured equation modelling. Focus groups are also useful to obtain detailed information about the group feelings, perceptions and opinions. On the other hand, semi-structured interviews are appropriate for the research; as they allow a deeper knowledge about the perspective of decision makers in Egyptian banks and governmental representatives. Data collected can be interpretively analyzed in order to know more about the governmental rules, laws and projects that established for people with visual disability will be conducted (Sekaran and Bougie, 2016; Jackson and Bazeley, 2019).

Although, literature reveals that testing users via experiments on evaluating web accessibility is very expensive and time consuming; experiments are considered the most successful method to detect accessibility problems (Mankoff, 2005; Jay et al, 2008; Brajnik et al, 2010). Accordingly, the underlying research utilizes the experiment method on evaluating the developed and proposed e-banking system in order to gain reliable results. Finally, based on the statistical and interpretive analysis together with the reviewed literature, derived conclusion and recommendations are made regarding e-banking accessibility.

The research variables

Efficiency

Regarding E-Banking, users believe that using this service will result in changing the nature of banking, navigation patterns, number of site visits, and number of transactions executed (Dwivedi, et al. 2017; Bhatiasevi, 2016; Martins, et al., 2014; Zhou et al., 2010). Furthermore, based on UTAUT, both Bhatiasevi (2016) and Zhou et al. (2010) concluded that Efficiency significantly influences the continuous use of E-Banking.

Ease of Use

Users feel connected to technologies that are convenient and simple to use (Alalwan, et al., 2017; Ozturk, et al., 2016; Shareef, et al., 2017). The easy accessibility of a technology tends to motivate users, making them highly inclined to adopt the technology (Dwivedi, et al., 2017; Oliveira et al., 2014; PIKKARAINEN et al., 2004). Thus, when updating a given technological service automatically, users should not experience difficulty or complexity in using the technology; otherwise, their usage will plummet significantly (Yu, 2012, Liebana-Cabanillas, et al., 2017; Yiu, et al., 2007).

Facilitating conditions (FC)

FC is "the degree to which an individual believes that an organisational and technical infrastructure exists to support the use of the system" (Venkatesh et al., 2003). A number of studies have indicated the positive influence of FC on the level of usage among users (e.g. (Dwivedi, et al., 2017A; Dwivedi, et al., 2017B; Rana, et al., 2016; Shaikh and Karjaluoto, 2015; Yu, 2012; Zhou et al., 2010). The capacity to log in to personal accounts, the ability to transfer money from one account to another, and a high level of compatibility support the use of M-Banking (Shaikh and Karjaluoto, 2015).

Price value (PV)

PV is defined as "the consumers' cognitive trade-off between the perceived benefits of the applications and the monetary cost for using them" (Venkatesh et al., 2012). During the course of using a technological service, users tend to compare the prices they paid for the technology and the discounts they might get from the continuous use of the technology (Alalwan, Dwivedi, et al., 2014; Al-Sukkar, 2005; Baabdullah, 2018; Laukkanen and Lauronen, 2005). Thus, they will tend to increase their level of usage when they are rewarded by discounts (Laukkanen and Lauronen, 2005). However, in the context of Internet banking and M-Banking, consumers will radically become reluctant to continue using a technology when the providers of the service increase its prices (Njenga and Ndlovu, 2012). In such circumstances, the users of the technology tend to switch their usage to a competing service (SCHIERHOLZ and Laukkanen, 2007; Raleting and Nel, 2011).

As indicated by Alalwan et al. (2017), when the PV level is higher, customers become more enthusiastic about continuing to use a technology. It should be ensured that the benefits derived from the technology use are greater than the monetary costs paid by the customers for continuing to use the technology (Lee, et al., 2012). Accordingly, users who are unable to pay the required money for continuing the use of upgraded technology (such as M-Banking) fail to show interest in continued use.

Reliability

Customers feel highly motivated to adopt and use systems that can provide the maximum reliability (Peters, et al., 2016; Upadhyay and Jahanyan, 2016). In the case of E-Banking, the benefits that the customers will get by using the facility will help them to grow interested in it, and thus the propensity to use the technology will increase due to the sensitivity of using online financial services (Zhou, 2011). This sensitivity demands the highest degrees of reliability in the provided technology.

Security/Privacy

Security and privacy in the context of e-banking defined as "a potential loss due to fraud or a hacker compromising the security of an online bank user" (Lee, 2009; Liao, et al., 2011). Financial transactions using IT devices are a great threat to customers as criminal acts can be done quickly without any physical interaction (Cheung and Lee, 2006). As a result, most of the customers are reluctant to adopt e-banking services due to its security and privacy concerns (Lee, 2009; Lee and Turban, 2001; Yousafzai et al., 2009; Poon, 2007). Today, a number of banking services are offered through the Internet and smart devices, thus customers are highly concerned about security issues more seriously. Privacy/security issues have proven barriers hence, customers keep on eye what kind of data is collected, for what purpose, how long these data is stored, and for what purpose their data is processed (Yoon and Steege, 2013).

Drawing on the various studies in literature, the issue of security and privacy were found to be the most important determinant factor which obstruct customer adoption of Internet banking (Koskosas, 2011; Yoon and Steege, 2013). Moreover, information privacy and security issues were identified as serious limiting factors on the adoption and use of e-banking applications (Khalfan and Alshawaf, 2004). Accordingly, the security and privacy widely considered as the most important factor which hinders the acceptance of Internet banking among banking customers.

E-banking Accessibility

According to Barnes and Vidgen (2002) accessibility is concerned with how to access and interact with a system, whether it is easy to navigate, the design is appropriate, and how a user focuses the design principles to improve the website accessibility. The purpose of aesthetic design is to create an

accessible e-banking system (Ahmad and Al-Zu'bi, 2011; Alam and Yasin, 2010; Shergill and Chen, 2005). Under website accessibility/usability Yoon and Steege (2013) includes perceived usefulness (PU) and perceived ease of use (PEU) as factors that positively influence customer's perception towards e-banking. In literature, accessibility has been found and perceived to be the significant factor in determining customer interaction in e-banking (Casalo et al., 2008; Hasbullah et al., 2016; Shergill and Chen, 2005; Yoon and Steege, 2013).

Moderators: Demographics and Technology Literacy

There is quite a number of factors used as a moderator to study user acceptance of the technology. For instance; Sun and Zhang (2006) classified moderators into three groups such as organizational, technological and individual factors in which age and gender lay in the third group and suggested, research on moderating factors add great value. Prior studies have suggested that gender plays an important role in explaining behavioral intention in information system research (Sun and Zhang, 2006; Tarhini, et al., 2014; Venkatesh et al., 2003). For customer acceptance or rejection choice in the Internet and mobile banking gender and age significantly influenced the decision in Finland (Laukkanen, 2016). Moreover, the study of Yousafzai and Yani-de-Soriano (2012) revealed technology readiness, age and gender moderate the attitude intention among Internet banking users in the UK. In this study we used technology Literacy, age and gender as moderators in customer's usage determinant factors.

Research Framework and Hypotheses

This section presents the research framework as well as the research hypotheses developed from the model. Figure 1 depicts the e-banking accessibility framework adopted in the Egyptian context. The framework consists of nine variables. Efficiency, Ease of Use, Facilitating Conditions, Price, and Reliability are five constructs that are considered as the main dimensions affecting e-banking accessibility in Egypt, and they are mediated by Security, and moderated by Technology Literacy and User’s Demographics. Thus, the research hypotheses could be developed as follows:

H1: There is a significant impact of the Research Variables on E-banking Accessibility

H2: There is a significant impact of the Research Variables on Security

H3: There is a significant impact of Security on E-banking Accessibility

H4: Security mediates the relationship between Research variables and E-banking Accessibility

H5: Technology Literacy moderates the relationship between Research variables and E-banking Accessibility

H5: User’s Demographics moderates the relationship between Research variables and E-banking Accessibility

Figure 1 Research Framework

Conclusion

People with visual disability have been facing many challenges in a variety of industries. The banking sector in particular has been posing many challenges to those with visual impairment. This research investigates the challenges thry face people and the reasons behind preventing them from opening bank accounts independently, which invades their privacy. The study also identifies the main constructs that affect e-banking accessibility together with the mediating and moderating factors. Then, the research develops an accessible prototype e-banking system.

Appendix

- Do you have a bank account?
- Do you have e-banking account?
- Do you use e-banking services?
- How long have you been using e-banking?
- How frequently do you use e-banking?
- When do you most frequently use e-banking?
- The website is clearly structured and traceable
- The website does not contain too many pop-ups and banner advertisements
- The website is graphically appealing and attractive
- The website menu design is easy to understand
- The website is easy to use, login, and navigate
- The website functions properly
- I think that learning to use Internet banking would be easy for me
- I think that interaction with Internet banking would be clear and understandable
- I think that using Internet banking does not require a lot of mental effort
- I think that doing what I want via Internet banking would be easy
- It is easy for me to become skillful at using Internet banking service
- I find Internet banking easy to use
- Learning to use Internet banking is easy for me
- My interaction with Internet banking is clear and understandable
- It is easy for me to remember how to perform task with Internet banking

- It is easy to get Internet banking to do what I want it to do
- Overall, I think that using Internet banking would be easy
- I trust that transaction conducted through Internet banking is secure and private
- I trust payments made through Internet banking channel will be processed securely
- I believe my personal information on Internet banking will be kept confidential
- I have the resources necessary to use Internet banking.
- I have the knowledge necessary to use Internet banking.
- Internet banking is not compatible with other systems I use.
- My living environment supports me to use internet banking.
- My working environment supports me to use Internet banking.
- Using Internet banking is compatible with my life.
- Help is available when I get problem in using Internet banking.
- The website is always available
- The website performance is satisfactory
- The website information is accurate
- The website information content is well organized and easy to understand
- The website presents its security certificate and policy explicitly.
- The website keeps my credit card information secure.
- The website does not share personal information with other sites.
- The website gives me confidence when doing e-banking transactions.
- It protects information about my Web-shopping behavior.
- It does not share my personal information with other sites.
- This site protects information about my credit card
- The website makes it easy to find what I need.
- The website offers banking products at a low cost.
- The website provides a variety of packages and offers that suits my needs.
- The website makes it easy to find what I need.
- It makes it easy to get anywhere on the site.
- It enables me to complete a transaction quickly.
- Information at this site is well organized.
- It loads its pages fast.
- The website is simple to use.
- The website enables me to get on to it quickly.
- The website is well organized.
- Internet banking services are reasonably priced.
- Internet banking is good value for the money.
- At the current price, Internet banking provides good value.
- I think Internet banking services are expensive to use.
- I think Internet banking enabled handsets are expensive.
- I think the subscription fee to use Internet banking is expensive for me.
- I believe my Internet banking transaction information will not be lost during an online session.
- I believe my Internet banking transaction information will only reach the target bank account.
- I feel comfortable using devices to conduct Internet banking operations.
- I am comfortable in conducting Internet banking operations.

The Efficiency of Financing The Health System. Romania in The European Context

Abstract

Access to healthcare is important for everyone and the existing economic national status influences this aspect. A high standard in this area is essential and large variations in the quality of the sector are increasingly visible within many countries. As medical care becomes more complex, expenditures continue to grow leading to the knowledge's necessity about the health sector's impact and importance in the state's economy. The analysis of the public health system's efficiency financing consisted of evaluating the different aspects of population health and the degree of this sector's financing, during different periods of time, aspects that are influenced by the degree of performance of the hospital units, which depends on the technology used or human resources available. Romania is analyzed in the European context, due the need of comparison in order to form an overview of the financing health services efficiency. The financing of the health sector influences the health status of the population, which is why we will analyze the degree of efficiency of the financing of health services in Romania, in the context of the EU. The actuality of the theme and the global interest for the problem of financing the health sector, are the premises of a complex analysis, and the main objective of the present paper is to quantify the degree of efficiency of the financing of the health sector in Romania, in a European context, using Data Envelopment Analysis (DEA) and Euro Health Consumer Index (EHCI).

Key words: Economy, Financing, Health, Efficiency

JEL Classification: A10, H51, I15

Introduction

Health is seen as a robust predictor of economic growth because the economic development of any nation is closely linked to the health status of its population. For this reason, financing in the field of healthcare have an important role in ensuring efficient services within this system, an aspect reflected in the people's health status. The population's health status is largely determined by the economy of the country; therefore rich countries tend to have significantly better health outcomes than poor or developing ones. In the current period, this observation is critical, given that globalization has been implicated in generating economic convergence within and between some countries. To understand the existing changes in the health status of the population it is necessary to understand the reason for their origin, respectively the recent changes in the global economy. In the last decades, the problems existing in the health status of the population at a global level have generated an increasing interest in approaching this segment, to discover the factors that contribute to the deterioration of health. The literature published on this topic has produced important informative research on a set of problems and determinants in this regard, but the reality shows that the current state of health cannot be a prosperous one in the conditions of a precarious economy.

Financing healthcare is a major concern for all countries, including developed countries, given that population health requires a solid financial base, and spending on these services is constantly increasing. This fears strict current affairs in the present economic context, as more and more states are facing difficulties in financial support of this sector. The economic status determines, in most cases, the degree of financing of the health services, an aspect that is reflected in the efficiency degree of the health institutions and, thus, in the health status of the population. To determine the degree of efficiency of the health services there are several calculation methods and different indicators, to identify the segment in which a state has a low level of it. The use of efficiency indicators within hospital units can lead to a wide range of activities for it to grow. However, the national decision-makers need to focus on the areas and on the factors that need improvement, such as no hospital beds or programs for the prevention of certain conditions, given that each hospital unit and country has different needs, which requires the identification of priorities according to the needs of the population.

Research Methodology

The research methodology used to achieve the objectives includes qualitative and quantitative research; qualitative research offered the possibility of a deep understanding of the subject of the research and, in this way, the chance of a complex explanation of it, through methods such as the analysis and synthesis of the specialized literature, which ensures the formation of a faithful image on the studied phenomena. The qualitative dimension used supported the analysis of the state of the knowledge, as well as the argumentation of the importance of the financing and the efficiency of the financing of the health sector. We selected the specialized literature according to content, with emphasis on the efficiency of financing the health sector. Thus, in the end, a number of 62 cases were analyzed. After identifying and analyzing the conceptual framework based on the specialized literature and the existing studies in this regard, we determined the efficiency of the financing of the health sector by carrying out a quantitative analysis. The quantitative part of the research methodology is based on the grouping method, the comparison method, the indicator method, the data analysis methods using statistical techniques such as graphs and tables, the efficiency analysis method-Data Envelopment Analysis (DEA) and Euro Health Consumer Index (EHCI), in order to capture and analyze Romania's position within the European Union, from this point of view. The data needed for the quantitative analysis are available on official websites, respectively www.healthpowerhouse.com, www.ec.europa.eu.

Literature Review

Field (1993) defines an efficiently funded health system as a result of all the state's economic resources invested in health care, institutions and research, with positive results on life expectancy, premature mortality rate, decreased incidence of illness and prevention of related problems of health. (Field, M., 1993, p. 10). Roemer (1991) defines efficient health systems as "the combination of resources, organization, financing, and management that culminated in the delivery of health services to the population." (Roemer, M., 1991, p. 31). Lassey et al. (1997) define the effective financing of a health care system as "the association of the financing mechanisms with the medical care provided in specialized institutions, the support of the state of health, information systems, organizational structures, human resources and management structures that support the provision of health services to all categories of patients." (Lassey, M., et al., 1997, p. 3). The specialized literature presents other studies on this topic, such as Pavelescu (2013), Murgea (2016), Mihalache et al., (2018), Mihalache et al., (2019).

The literature in the field presents other research on this topic, namely Arrow (1963), Anderson and Poullier (1999), Getzen (2000), Berger and Messer (2002), Alfonso and Aubyn (2005), Bokhari et al. (2007), Kulkarni (2016). Analyzing the efficiency of health systems in terms of public spending for health, an important contribution was made by Rivera (2010), who identified a positive correlation between public spending for the health sector and self-assessment of health, arguing that investments in health prevention are less expensive and more important than the costs of treating the diseases and have an important role in the self-assessed health condition. (Rivera, B., 2010, pp. 1313 - 1319).

The analysis of the measurement of the efficiency of the health system is influenced, according to Naylor et al. (2002) of two problems, respectively: (1) the health of the population of a country is not only affected by the expenses for the health services, but also by a multitude of other factors such as the social, economic and natural environment; therefore, external influences to the health system must be taken into account to correctly estimate the efficiency of the financing of the health system; among these external factors, (2) education has been widely recognized as an important factor, after funding, which influences the health status. (Naylor, D., et al., 2002, pp. 13-34). Thus, to measure the degree of efficiency of the financing of the sanitary sector, different methods can be used; Data Envelopment Analysis (DEA) is a non-parametric model that allows the measurement of efficiency and which uses mathematical programming in rendering the efficiency boundary. Charnes et al. (1978) define DEA as "a mathematical programming model of data observation that provides a new way to obtain empirical estimates of extreme relationships, such as production functions and/or surfaces of efficient production possibilities, which represent the stone of fundamental of the modern economy." (Charnes, A., et al., 1978, pp. 429 - 444). According to a research conducted by Hollingsworth and Peacock (2008), in 2003, there were 188 studies using the DEA model to evaluate the effectiveness of healthcare, the first study to be published in 1983. (Hollingsworth, B. & Peacock, S., 2008, p. 83). Among the authors who have used the DEA method to measure the efficiency of financing the health sector, we can mention Giuffrida and Gravelle (2001), Hollingsworth and Wildman (2003), Retzlaff-Roberts et al. (2004), Lauer et al. (2004), Afonso and Aubyn (2005), Ferrier et al., (2006), Hollingsworth, (2008), Nițoi (2009), Caballer-Tarazona et al. (2010), Nedelea et al., (2010), Roman and Suciu (2012), Popescu et al. (2014).

In order to measure the efficiency of the financing of health services and the efficiency of the health system in general, the Euro Health Consumer Index (EHCI), present in the report published by the Health Consumer Powerhouse, can be used, which is an index which compares the efficiency of the systems. of health. The aim of the study was to select a limited number of indicators in a certain number of evaluation domains that, in combination, can present the degree of efficiency of the health systems in the analyzed states. The criteria according to which the indicators were selected, according to Björnberg (2017), are relevance, scientific validity, and feasibility. Since 2004, the Health Consumer Powerhouse (HCP) publishes a wide range of comparative analyses on the efficiency of healthcare in different countries, with the help of the Euro Health Consumer Index (EHCI); the most representative publication in this regard is the annual Euro Health Consumer Index (EHCI) report. In January 2008, the Border Center for Public Health Policy and HCP released the first report, "Euro-Canada Consumer Health Index"; new editions were published in 2009 and 2010. (Eisen, B. & Björnberg, A., 2010, pp. 1 - 48); in this type of report, we mention: Euro Health Consumer Index, launched in July 2008; a new edition was published in 2016, and another edition, in 2017. (Björnberg, A. & Uhlir, M., 2008, pp. 1-61). Euro Health Consumer Index Diabetes launched in September 2008; a new edition was published in 2014. (Garrofé, C., et al., 2014, pp. 1 - 71). Among the publications that used the Euro Health Consumer Index (EHCI), in order to analyze the efficiency of the financing of the health sector, we mention Clarke et al. (2003), McCabe et al. (2005), Baggott and Forster (2008), Gonçalves (2011).

The Importance of The Efficiency of The Financing of The Health Sector

An efficient health system is directly proportional to the development of health policies and funding, aspects that lead to the quality of the medical services offered, an idea supported by Green and Matthias (1997): "first, health services must focus on components such as policy development, financing, provision of services, and regulation of the type and quality of services, conditions for the (health) system to become effective." (Green, A. & Matthias, A., 1997, p. 13). Blank and Burau (2007) argue, in the second edition of the book "Comparative Health Policy", that the efficiency of a health system comes from the financing and management of resources. Matcha (2003) defines an effective health system as "any combination of those components identified by a company, which facilitates the efficient provision of medical services to its members." (Matcha, D., 2003, p. 4).

Among the authors who have studied the importance of financing health services, from 1970 to 1990, are Kleiman (1974), Newhouse (1977, 1978), Culyer and Jonsson (1986), Donaldson and Dunlop (1986), Parkin et al. (1987), Culyer (1989), Milne and Molana (1991), Getzen and Poullier (1991), Gerdtham and Jonsson (1991), Hitiris and Posnett (1992), who demonstrated the existence of a positive correlation between the efficiency of public spending and health and population health, in most OECD countries; thus, increased financing of this sector supports the general state of better health of the population. More recent research has also focused on evaluating the link between public spending on health, population health and GDP growth, respectively Murthy and Ukpolo (1994), who analyzed the influence of health spending. per capita, in the USA, in the years 1960 - 1987, on the health status of the population; the results of the study show that an increased volume of health expenditure per capita leads to a better overall health (Murthy, V. & Ukpolo, V., 1994, pp. 797-802); Hansen and King (1996), considering that there is a strong correlation between GDP and health care expenditures, shows that within the 20 OECD countries analyzed, the higher the GDP, the higher the expenditures for health services; it can be considered that the state allocates a larger volume of financial resources to this sector and, on the other hand, the population may allow a closer investigation of the health status. (Hansen, P. & King, A., 1996, pp. 127 - 137). Gruen and Howarth (2005) consider that the financial resources allocated to the health sector are essential for safe health services, because "the resources are needed for a qualitative production process, and the costs measure the value of the services offered." (Gruen, R. & Howarth, A., 2005, p. 34). Starting from Roemer's theory (1977), according to which each country has a certain type of health care system that is the result of its history, economic development, and ideologies, it can be stated that the efficiency of the financing of this sector is closely linked, besides other aspects, of the economic state. Also, Audretsch et al., (2015), Goldberg (2016) argue the importance of financing the health sector within the Bismarck economic model; Paolucci (2011), Del Vecchio et al., (2014) talk about this in the Beveridge model; Shishkin et al (2014), Arentz et al (2012), Knickman and Kovner (2015) support the importance of financial resources in economic models of financing the health system such as the private health insurance model and the Semashko model.

The efficiency of financing the health sector based on the DEA model (Data Envelopment Analysis)

In order to carry out this study, a sample of 28 countries was selected, the member countries of the U.E. The model focuses on an area of national interest, respectively health. The data subjected to quantitative research were taken from sites such as Eurostat, OECD - Organization for Economic Cooperation and Development, all data being accessed at the end of 2019. The role of this model is to identify for the decision-making units taken into account, the scores of efficiency to form the boundary of efficiency. The applied model is oriented in the calculation of the efficiency score on the input variables, respectively and on the basis of the variable scale returns (VRS), thus being able to observe those changes of values of the inputs that could take place, the results of the variables of output type not changing it. The use and description of the DEA model was achieved using the notations and approach used by Crețan (2015).

In order to carry out the study, we chose a number of 3 health efficiency indicators, respectively (1) infant mortality; (2) life expectancy; (3) the number of hospital beds, indicators that we correlated with the budgetary expenditures in the health sector (% of GDP). The period subject to the analysis is focused on the years 2016 and 2017. The study used, as the first working instrument, a statistical analysis that has the role of allowing each indicator to be highlighted using four parameters: maximum, minimum, standard deviation and value average. The second working tool in the research is represented by the non-parametric Data Envelopment Analysis (DEA). The variables used, as input (resource type variable) and output (result type variables) in the two analyzes, are shown in the following table:

Table 1: The variables used

Input	Output
Budgetary expenditure in the health sector (% of GDP), (noted I1)	Infant mortality rate (1000 babies), (noted O1)
Number of hospital beds, (noted I2)	Life expectancy, (notat O2)

Table 2: Glossary of data used in the DEA model

Indicators	Unit	Data source
Budgetary expenditure in the health sector	% of GDP	Eurostat
Number of hospital beds	Number of hospital beds	Eurostat
Infant mortality rate	% 1000 born	Eurostat
Life expectancy	Years	Eurostat

Correlating the usefulness of the indicators chosen for research purposes with the availability of data from official sources, we presented the results in the following table:

Table 3: Descriptive analysis of the health sector (2016)

Indicators	Minimum	Maximum	Standard deviation	Average
I1	1,90	8,50	1,80	6,28
I2	12,81	674.830,00	163.667,94	119.902,94
O1	73,70	81,90	2,78	78,45
O2	2,40	10,10	1,97	4,34

Source: author

Table 4: Descriptive analysis of the health sector (2017)

Indicators	Minimum	Maximum	Standard deviation	Average
I1	1,80	8,20	1,81	6,12
I2	2.990,00	670.443,00	163.267,51	122.446,79
O1	74,40	82,50	2,62	79,15
O2	1,60	9,00	1,73	3,95

Source: author

From the analyzed data, it is observed that the year 2016 stands by its values above those of 2017. In this case, Romania is well above the average in terms of infant mortality rate, I hold the maximum at this indicator in both years; thus, in 2016, Romania registered an average of 6.9 ‰ of infant mortality and 7.1 ‰ in 2017. Also, in 2016, our country registered a no. of 134,572 hospital beds, compared to 408,245 hospital beds in France, 664,364 in Germany or 252,029 in Poland. As regards life expectancy, in 2017 it is 75.3 years, compared with 82.7 years in France or 82.5 years in Spain. These aspects are a consequence of the poor financing of the health sector, given that Romania allocates to this sector an amount lower than the average of the studied countries; in 2016, our country allocates 5% of GDP to the health sector, while Germany allocates 11.3%, Sweden and France 11%, the Netherlands 10.5%; In 2017, Romania's financing for the health sector remains below the EU average, allocating 5.2% of GDP, respectively $ 442.37 per capita expenditure for health, compared to Luxembourg, which, although allocating a percentage of this sector 6.2% of GDP, this equates to $ 6,236.00 per capita health expenditure, or Sweden which allocates 10.9%, respectively $ 5,600.10 per capita.

Analysis of the health sector's efficiency. The efficiency model of the health field is composed of two input variables: budgetary expenditures in the health sector (% of GDP) and the number of hospital beds, and as output variables are used: infant mortality rate and life expectancy. It can be seen (Table 16) that there are the same number and the same effective countries in both years, namely: Belgium, Czech Republic, Germany, Ireland, France, the Netherlands, Slovakia, and Finland. Given the average value in both years found in the range [0.64- 0.66], the most inefficient countries that depart considerably from the efficiency frontier are Romania, Bulgaria. The minimum efficiency score belongs to Romania in both 2016 and 2017, 0.31 respectively 0.29.

Table 5: DEA results on efficiency score

Countries	2016	2017
Belgium	1,00	1,00
Bulgaria	0,37	0,34
Czech Republic	0,40	0,39
Denmark	1,00	1,00
Germany	1,00	1,00
Estonia	0,36	0,34
Ireland	0,85	0,82
Greece	0,42	0,44
Spain	0,71	0,59
France	1,00	1,00
Croatia	0,78	0,68
Italy	0,85	0,82
Cyprus	0,35	0,38
Latvia	0,85	0,64
Lithuania	0,44	0,39
Luxembourg	1,00	1,00
Hungary	0,41	0,39
Malta	0,44	0,44
Netherlands	1,00	1,00
Austria	1,00	1,00
Poland	0,42	0,42
Portugal	0,35	0,44
Romania	0,31	0,29
Slovenia	0,44	0,42
Slovakia	0,41	0,39
Finland	1,00	1,00
Sweden	0,78	0,78
United Kingdom	0,78	0,78
Maximum	1,00	1,00
Minimum	0,31	0,29
Average	0,66	0,64
Standard deviation	0,28	0,28
Efficient country	8	8

Source: author

The analysis of this sector shows the same efficient countries in both 2016 and 2017, namely Belgium, Denmark, Germany, France, Luxembourg, the Netherlands, Austria, and Finland, which also allocates the highest percentage of GDP to health. In 2016, Belgium allocated health 10.4% of GDP, Denmark 10.4%, Germany 11.3%, Austria 10.4%, France 11.0%; the least efficient country is Romania, which allocated to health a percentage of GDP of 5% in 2016, and in 2017 a percentage of

5.2%. The analysis shows a low efficiency for 2016 in countries such as Bulgaria, Estonia, Cyprus, Portugal and for 2017 in Bulgaria, Estonia, Cyprus; it is difficult to increase the efficiency of the financing of this sector, which is why the situation, from year to year, remains approximately constant in most states that are inefficient from this point of view.

Thus, the developed countries, which allocate a higher percentage of the GDP to the healthcare sector, maintain their high efficiency of these services. However, it is necessary to consider the fact that countries such as Spain, Sweden, the United Kingdom, Ireland, maybe effective on a particular segment of health services, such as life expectancy in Spain, Sweden, infant mortality in the United Kingdom, Ireland, however, may be less effective in terms of the number of hospital beds (Ireland 12,169 hospital beds in 2016, Sweden 23,885 hospital beds in 2016) or the frequency of certain types of conditions. It is difficult for a state to be effective in all segments of health services, but increased funding can influence these aspects.

The efficiency of financing the health sector based on the EHCI index (Euro Health Consumer Index)

The EHCI (Euro Health Consumer Index) is the most complex way of calculating the efficiency of the health sectors, including the efficiency of their financing. EHCI 2017 consists of 6 components, respectively: (1) patients' rights and information, maximum score 125; (2) waiting time, maximum score 225; (3) system results, maximum score 300; (4) coverage with basic services, maximum score 125; (5) prevention, maximum score 125; (6) pharmaceutical products, maximum score 100. To calculate the degree of financing efficiency, the average of one component or the average of the 6 sub-components can be correlated with the percentage of GDP allocated to the health sector or with expenditure per capita for health.

In terms of patient rights and information, the maximum score, respectively 125, was reached by the Netherlands (Figure 1), meaning that it enjoys the highest degree of efficiency in this segment; In this regard, Romania is among the last places, with 71 points, followed by Bulgaria, with 67 points, and Greece, with only 58 points. Slovakia has the highest efficiency in terms of waiting time, respectively 225 points; Romania has a low degree of efficiency in this regard, registering 113 points, as well as Spain and Sweden. The highest degree of efficiency regarding the results of the health system is occupied by Finland, with 289 points out of 300; Romania is in the last place, with 122 points.

The maximum score, respectively 125, for coverage with basic health services of the population, is found in the Netherlands and Sweden; within this category, Romania shares the last place with Greece, with only 52 points. In terms of prevention, the United Kingdom and Ireland are equally efficient, respectively 113 out of 125; Romania is in the last place with 48 points. The most effective grade for pharmaceutical products is found in the Netherlands and Denmark, with 89 out of 100 points; Romania is last, with 33 points, before Bulgaria with 39 points; the degree of efficiency calculated based on the EHCI index, correlated with the percentage allocated from the GDP for the EU member countries, in 2017.

Figure 1: Values of the efficiency of the health services, the year 2017

Figure 2: The degree of efficiency calculated based on the EHCI index, correlated with the percentage allocated from GDP for the EU member states, in 2017

Source: author, based on data available at EHCI (2018), https://healthpowerhouse.com/media/EHCI-2018/EHCI-2018-report.pdf

It may be noticeable that the degree of efficiency of health systems in the member states of the U.E. largely depends on the degree of financing (Figure 2). Belgium allocates 10.2% of GDP to the healthcare sector and has an efficiency rating of 8.32%, Germany allocates 11.3% of GDP to health care and has an efficiency rating of 8.64%. Romania has the lowest level of efficiency of 4.39%, as well as the lowest percentage of GDP allocated to this sector, 5.2%. The highest level of efficiency is found in the Netherlands, respectively 9.24%, a country that allocates 10.1% of GDP to health; although France allocates a higher percentage of GDP to the health sector (11.5%), it represents 4,026.15 USD per capita of health, compared to the Netherlands, which allocates a lower percentage of GDP (10.1%), but this means $4,746.01 per capita spent on health. This applies to the state of Luxembourg, which, although allocating 6.1% of GDP to the health sector, this means $6,236.00 per capita spending on health.

Results & Discussion

The efficiency of the financing of the health sector is a problem, as well as addressed, so difficult to solve. It is known that well managed financial resources can lead to an increased degree of efficiency of the health sector, but at present, most states are facing difficulties in ensuring a solid basis of health services. The costs of this system are rising at a rapid pace, which is a problem even for developed countries.

Within the analysis of the efficiency degree using the Data Envelopment Analysis (DEA) method, having as variable budgetary expenditures in the health sector (% of GDP), number of beds in hospitals, infant mortality rate, and life expectancy, Romania is the last place, with the lowest degree of efficiency, both in 2016 and in 2017. This means a low percentage of GDP allocated to health care (5% in 2016 and 5.2% in 2017), an increased infant mortality rate (6.9% in 2016 and 7.1% in 2017), low number of beds in hospitals according to population needs and low life expectancy compared to the rest of EU member states Within the analysis of the efficiency degree using the Euro Health Consumer Index (EHCI) method, a method that can provide a degree of efficiency in the general model of health services, taking into account a comprehensive number of indicators, Romania is still on the last place, with a total score of 549 points. This score represents a total of the scores obtained on the 6 categories considered by this index, respectively the patients' rights and information (maximum score: 125, score obtained by Romania: 71), waiting time (maximum score: 225, Romania: 113), system results (maximum score: 300, Romania: 122), coverage with basic services

(maximum score: 125, Romania: 52), prevention (maximum score: 124, Romania: 48), pharmaceuticals (maximum score: 100, Romania: 33).

It is difficult for a state that allocates one of the lowest percentages of GDP to the healthcare sector, such as Romania, to be able to have an increased degree of efficiency of these services. It is obvious, from the analysis carried out, that the financial resources influence the degree of efficiency of the health sector. not always influenced by the degree of efficiency of the health sector, which, in turn, is not always influenced by the financial resources; thus, the health status of the population may also depend on hereditary factors or factors such as living environment, working environment, vices, food, etc. Also, the efficiency of the health sector can be influenced by the behavior of the medical professionals or the lack of interest of the decision-makers. În acest sens, România se confruntă cu o lipsă acută de personal medical, în special după aderarea la Uniunea Europeană, atunci când cadrele medicale au migrat într-un număr foarte mare.

Conclusions

For the concretization of the right to health care in equity, quality and accessibility, the choice of the financing system, as well as the reimbursement and payment mechanisms bring important determinants, such as (1) the collection of financial resources, (2) the transparency and efficiency management of the available resources, (3) establishing the health of the population as a priority, (4) developing prevention programs for certain diseases, etc. Thus, financial mechanisms are required to promote cost-effective healthcare. It is necessary that the financing of the health system be effective through the capacity of managing the existing funds, so as to ensure the coverage of the requests of patients, the increase of the safety and quality of the care process, the acquisition of progressive technologies, the diminution of the existing disparities in accessing these services.

For greater efficiency, the financing modalities existing in health services should be adapted according to the country in which they operate. Each health system has its own advantages and disadvantages, as well as changes according to the needs of the population. In this sense, in order to determine the degree of efficiency of health services, there are several calculation methods and different indicators, in order to identify the segment in which a state has a low level of it. The use of efficiency indicators within hospital units can lead to a wide range of activities for it to grow. However, it is important that the national decision makers focus on the areas and on the factors that need improvement, such as no. of beds in hospitals or programs for the prevention of certain diseases, considering that each hospital unit and each country have different needs, which requires the identification of priorities according to the needs of the population; for example, there are states such as Spain, Sweden, the United Kingdom, Ireland, which may be effective on a particular segment of health services such as life expectancy in Spain, Sweden, infant mortality in the United Kingdom, Ireland, but may be more less effective in terms of the number of hospital beds or the frequency of certain diseases.

According to the efficiency's analysis of the health sector's financing, Romania ranks the last places, meaning that the low percentage of the GDP allocated to this system influences the infant mortality rate, the existing number of beds in hospitals, the life expectancy, the patients' rights and the information, the coverage of the population with services, basic healthcare, waiting time, prevention, range of pharmaceuticals, as well as health system outcomes. These aspects are influenced by the available financial resources, but also by other factors, which represent a limitation of the present study. Also, the limits of this study are also given by the fact that there are certain ways of calculating the efficiency of the financing of the health sector, in which certain indicators are used; In this respect, it depends on the correctness of each hospital unit to report the indicators correctly.

marcin.paska@pwr.edu.pl

Abstract

The paper concerns the topic of technology acceptance among manufacturing organizations. Those organizations seem to be especially relying on technology and it is a factor, which differentiate them from others. The approaches to technology acceptance analysis are presented. Based on that, it is assumed that technology acceptance influences the organizational performance of manufacturing organizations. Empirical study based on 264 organization is performed in order to verify this assumption and identify whether this relation is stronger for manufacturing organizations.

Keywords: Management, Technology Acceptance, Manufacturing Organizations.

Introduction

In a nowadays competitive world, innovative use of technology has become a key survival factor in manufacturing industry. New technologies have enabled industries to increase their performances, efficiency and due to its advantages are able to create better and transparent relationships with customers. Contemporary organizations are obliged to create new technologies to satisfy customer needs and serve customers better.

The success of a new technology depends, among other, on how well it is accepted by its intended users (Davis, 1989; DeLone & McLean, 2003). Many technologies face the problem of low adoption rate, despite the benefits. An understanding of what makes people accept or reject a new technology can help speed up the adoption rate (Sitorus et al., 2016).

A company oriented on its development should perceive its success in the need to transform its production capacity, switch from manual operations to increasingly organized and automated ones. The success of implementation of new technologies depends on many different, often unexplored, factors that ultimately determine the degree of acceptance by intended users (employees of the manufacturing company) (Davis, 1989).

Within Industry 4.0, many connected systems are entering production to optimize the processes. Fully connected smart production becomes a system that exposes company employees to direct contact. The result of this direct contact of an employee with a new technology (information system) is attitudes and behaviors that accept or reject the technology. Rejection by the user is not an isolated problem, as it often happens that the introduced system does not achieve the success it was intended, irrespective of how technically valuable the future product is.

The continuous development of the technologies that surround economy at the same time poses a threat to established business models, but when they are properly used, it brings the opportunity for

dynamic development in new directions. This is the basis for diversifying operations, optimizing production, reducing resources used and responding more flexibly to the needs of customers (Paska, 2019). International companies are trying to shape the evolution of technological applications to their own advantage. Therefore, the effect of advanced and dynamic technologies, whose acceptance by poorer users depends on many factors - including such as technology availability, safety and quality – seems to become critical at many levels.

The experience of many manufacturing organizations is proof that many technologies face problems during and after their implementation (adoption) in organization life, despite the overt benefits of its future use. As it was pointed out by the Austrian economist Joseph Schumpeter, innovation in the form of production technology appears to be a significant change in the function of production, consisting in a different than previously combined production factors occurring in a discontinuous way (Nahotko, 2019)

Therefore, it is important to understand whether the acceptance or rejection of technology really influences the performance of the manufacturing organization as a whole.

The aim of this paper is to analyze the existing approaches to the measurement and understanding of technology acceptance and to present the results of the pilot study, verifying that the level of technology acceptance positively influences the organizational performance, and confirm that proper use of technology is important for ensuring the efficient performance of manufacturing companies.

Technology Acceptance Models

The literature review in the field of research related to the acceptance and adoption of new technology by intended users of manufacturing companies is connected to the analysis of various technology acceptance models (). The field of research related to technology acceptance had a great literature coverage at the turn of the XX century. The most important contributions seems to consist of: Theory of Reasoned Action (Ajzen & Fishbein, 1980) Theory of Planned Behavior (Ajzen, 2012), Technology Acceptance Model (Davis, 1989), Personal Characteristic of Innovating (Hölzle et al., 2011)Task-Technology Fit (Goodhue & Thompson, 1995), Unified Theory of Acceptance and Use of Technology (Venkatesh et al., 2003), and others that will be subtly described in table 1.

The described theoretical models take the form of a tool and attempt to explain the use of different technologies in different countries. As a result of the empirical research performed to verify them, some were confirmed while others gave conflicting results. Moreover, these theories have been developed over the years and resulted from the extension of each other (Venkatesh et al., 2016).

It is worth emphasizing at this point that all the theories regarding the acceptance of technology collected and presented here are designed to measure the degree of acceptance and satisfaction of individuals in relation to any technology or information system, but from different points of view, depending on the design and determinants that present their structure.

Table 1: The overview of the technology acceptance models

Source	Name of Model		Constructs
M. Fishbein, I.Ajzen	TRA	Theory of Reasoned Action	Attitude, subjective norms, perceptions
I.Ajzen	TPB	Theory of Planned Behaviour	Attitude, subjective norms, perceived behavioural control
S.Taylor, P.Todd	DTPB	The Decomposed Theory of Planned Behaviour	Relative advantage, complexity, compatibility, normative influence,

			efficacy, facilitating conditions, Attitude, subjective norms, perceived behavioural control
F.Davis	TAM	Technology Acceptance Model	Perceived usefulness,perceived ease of use, attitude
E.M.Rogers	DOI	Diffusion of Innovation Theory	Innovation features, innovators characteristics
A.Bandura	SCT	Social Cognitive Theory	Personal factors, environmental influences
H.Triandis	MPCU	Model of PC Utilization	Affect, individual beliefs, social factors, habit, facilitating conditions, complexity, long-term consequences
F.Davis, Bagozzi	MM	Motivational Model	Intrinsic motivation, perceived benefits, external pressure
V.Venkatesh	UTAUT	The Unified Theory of Acceptance and Use of Technology	Performance expectancy, effort expectancy, social influence, facilitating conditions
V.Venkatesh	UTAUT2	The Unified Theory of Acceptance and Use of Technology 2	Performance expectancy, effort expectancy, social influence, facilitating conditions, habit, hedonic motivation, price value

Theory of Reasoned Action (TRA)

During review of the literature related with current subject in an attempt to understand the factors influencing the decision and maintaining the acceptance of new technologies by intended users, one that cannot be ignored is important theory proposed by M. Fischbein and I. Ajzen. This theory is Theory Of Reasoned Action. These two scientists dealt with socioligical and psychological research, which aimed to study the users' behavior in the use of IT(Kuo et al., 2015).

Fig 1. Theory of reasoned action

Source: Ajzen & Fishbein (1980)

This theory became one of the most basic theories of human behavior. Is the result of a research program that began in the late 1950s on the Persuasion Models of Psychology. TRA is considered to

be one of the earliest technology acceptance theories. In that period was the beginning of studying the individuals' behavior through the impact of attitude.

They explained their theoretical model, whose task is to translate human behaviors, with the help of the main cognitive elements, which also include unfavorable or favorite of person's feeling for a behavior, social norms and social influence, intentions and individual decision to do or do not do a behavior. Their aim was to develop a theory that could predict, explain, and influence human behavior (Ajzen & Fishbein, 1980).

Theory of Planned Behavior (TPB)

In the following years of scientific research, Ajzen expanded TRA, thus introducing Theory of Planned Behavior. This model in relation to TRA was expanded with a new construct, which was Perceived Behavioral Control (PBC) as a new variable is added to extend TRA model. Basically, PBC is determined by the availability of resources, opportunities and skills, as well as the perceived significance of those resources, opportunities and skills to achieve outcomes (White et al., 2015). Such an extensive form of the model allows it to be successfully applied in understanding individual acceptance and usage of technologies.

Fig 2. Theory of planned behavior

Source: White et al. (2015)

Technology Acceptance Model (TAM)

The theoretical roots of TAM can be found in the expectancy-value model and the theory of reasoned action. Technology Acceptance Model (TAM) was introduced by Davis (1989).TAM explaining the user behavior towards technology or system having been implemented by institutions (Turan et al., 2015).This has been pointed out and maintained in Davis's assertion that there are two fundamental factors that are responsible and determine user acceptance. These two key factors are perceived ease of use and perceived of usefulness (Fathema et al., 1989). Perceived of usefulness (PU) is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance", and perceived ease of use (PEOU) defined as "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989).TAM posits that the attitude of

an individual to using a particular system is the most important factor that will influence their adoption and utilization of such a system.(Usoro et al., 2010).

Fig 3. Technology Acceptance Model (TAM)

Source: Davis (1989)

Technology Acceptance Model (TAM) aim at understanding better why users accept or reject a given technology, and how user acceptance can be improved through technology design (Ammenwerth, 2019). User acceptance is often a pivotal factor in the success or failure of a new information system (Davis, 1993). The goal of the Technology Acceptance Model is to understand better why users accept or reject a given technology, and how user acceptance can be improved through technology design. TAM was developed by Fred D. Davis in the late 1980s (Davis, 2016).

During last last thirty-five years have been a lot of models developed that are widely used based on TAM however, TAM seems to be the most common theory among the plurality of studies of various information systems to study user behavior in terms of technology acceptance.

The basic premise of the Technology Acceptance Model is that the more accepting users are of new systems, the more they are willing to make changes in their practices and use their time and effort to actually start using the system.

Motivational Model (MM)

As Davis and Bagozzi emphasized using the Motivational Model, the use of the system depends on two types of motivation: intrinsic and extrinsic (Davis et al., 1992). The extrinsic motivation is defined as the perception that users will want to perform an activity because it is perceived to be instrumental in achieving valued outcomes that are distinct from the activity itself, such as improved job performance. The intrinsic motivation is defined as the perception that users will want to perform an activity for no apparent reinforcement other than the process of performing the activity.

Technology Acceptance and Organizational Performance

Organizational performance is considered as one of the most important measures of benefits, which organization is gaining from various factors (Bieńkowska, 2015). The modern functioning of the manufacturing organizations has no doubt that without automated production processes their measurable economic results would not be possible. That automation based on the real use of technology that has achieved agreement in the acceptance of the technology process paves the way for economic success. The role of technology is gaining momentum and importance with each month of industrial life. The chemical, pharmaceutical, aviation, and automotive industries are only one part

of the progressing innovation markets, in which the number of products offered increases, without the implemented technology this effect would not have been achieved. The importance of the acceptance of a given technology is undoubtedly the clearest in the sense of the development, efficiency, and performance of the organization. The technological infrastructure challenges not only in the dimension of dynamics development and maintaining the growth of broadly understood productions, but also gains importance in the field of human resources. Therefore, it becomes more important and becomes a challenge for society through cooperation with technology. That is why the role of the technology acceptance process has great importance for scientists and people associated with practical management in various businesses of industries. Therefore, presented content can be considered that acceptance of technology should be equated to success only when technologies are implemented and already in actual used.

As it was pointed by Cascio and Montealegre (2016), the rapid advances and the increased reliance on technology brings the very important and significant question, how it is changing work, which is highly salient for scholars of organizational psychology and organizational behavior. The role of technology acceptance in shaping organizational performance is discussed in the literature, however it is usually connected to the information technologies – specific type of technologies used in organizations. Researches conducted by Aral and Weil (2007) provides evidence of a general relationship between IT and organizational performance, as well enhance knowledge of the specific factors driving these general results. Their conclusion demonstrate that different IT assets are associated with different types of performance benefits for firms that are generally consistent with their strategic goals. Despite the fact that scholars are still struggling in order to create and to specify the underlying mechanisms linking IT to the financial performance of organizations, particular case studies indicate that effective and efficient use of IT is a key factor in differentiating successful firms from their less successful counterparts. It has become a widely held belief that technology is fundamental to a firm's survival and growth. (Bharadwaj, 2000). Results in this field of researches are consistent with the notion that IT contributes to a firm's future performance potential (Bharadwaj et al., 1999), highlighting the importance of IT-enabled organizational change (Bresnahan et al., 2002). Scientists and practitioners are interested in the relationship that exists between investments in technology and the effect of organizational performance. The conducted study posits that the driver of IT impact is not the investment in the technology, but it is related to acceptance of technology and actual usage of the technology, which may be a key variable in explaining the impact of technology on organizational performance (Devaraj & Kohli, 2003).

The role of IT is also valid for manufacturing organizations, especially in the context of other technologies use. The current picture of technology appears as a network of interconnected equipment, tools, and production machinery. Integrated with each other through a network of sensors and detectors, they take the form of cyber-physical systems that are gaining popularity. The dimension of the digital era is responsible for integrating robotization with existing human activities, which as a result has changed significantly and allows to exceed the current event horizon on production lines. (Wang et al., 2015). The use of appropriate technologies by users supports the growing level of computerization, which more and more corresponds to the future user potential. This increase aims to meet production requirements. Production systems have the features of intelligence, which is characterized by flexibility, efficient use of resources (optimization), ergonomics in the broadly understood application and the ability to integrate the client and business partner in the process of creating added value (Waibel et al., 2017).

Moreover, the use of any technology is a result of its acceptance, and in effect, focuses on acquiring new knowledge, new components, and new kind of systems that will become responsible for creating more competitive products in manufacturing companies and in the provision of services. Those are designed to broadly optimize related processes (Torkkeli & Tuominen, 2002).

The use of technology is associated with innovation. The technology allows for efficient operations of manufacturing processes. Research conducted in the field of innovative technologies is associated with an increase in the efficiency of the organization. The conducted study estimates the impact of product innovation on initial market share, and the results show that the product's advantage relative

to competing products has the strongest market share impact (Robinson, 1990). Undoubtedly, manufacturing companies that use properly selected technology for their needs, which is generally accepted by its users, has a high degree of technological competence. A higher level of technological competence for each organization has a chance to be more innovative than companies with a low level of competence. Using new technologies increases not only technical competence but generally has an influence on production flexibility. As a result of the efficiency and performance of the organization grow. Greater efficiency means greater opportunities, and thanks to these competencies the company can become a pioneer in the market thanks to the development of new innovative products that can be produced at lower costs in a shorter time. These are advances that the use of technology for manufacturing plants gives (Malerba & Marengo, 1995).

The fourth industrial revolution within production technologies, in particular cases, as an effect of the positive acceptance technology process, presents itself as new performance opportunities. The previous conventional production lines consisted of one line, which was adapted to usually one type of product. Usually there was an open-loop conveyor belt with input and output ends and the machines run along the line. In most cases, there's no communication between the machines in the production line.

As practitioners from the world of business indicate, which is also supported by scientists, the nearest future of manufacturing companies aims to implement the concept of smart factories under a roof whose key role will be played by technology, robots and industrial machines.In a factory near the future, in a smart factory, the role of man will be greatly changed (Brettel et al., 2014). The operator of new technologies, in the thresholds of an intelligent factory, works directly with the technology, which consists of machines, and these are a system of interaction of software, mechanics, pneumatics, electronics and hydraulics. The new role of man in the era of new production technology is limited to the role of monitoring the working status of production lines. The operator's activity from the manual routines performed in practice begins to encounter a different scope of other duties. The key qualities on which the desirable features of modern manufacturing process technologies are based are: speed, proper detail, readability, specificity, repeatability, reliability, efficiency, effectiveness as well as the form and structure of communication that allows for more efficient adaptation and integration of man with the machine (Paska, 2019), which furthermore contributes to the organizational performance. Based on those considerations, the following hypothesis can be formulated:

H1: The technology acceptance has a positive influence on organizational performance of manufacturing companies.

Research Methodology and Results

The survey was conducted in order to verify the proposed hypothesis. The main survey was preceded by the pilot survey conducted in the fourth quarter of 2019 among the group of 25 managers (acting as competent judges). According to obtained results, some ambiguous questions were rewritten and it was established that proposed questions are understood by respondents as it was intended by researchers (which is a prerequisite for establishing a questionnaire as a valid measurement method (Czakon, 2019)). The main research was conducted in December 2019, among 263 organizations located in Poland, which was the only condition limiting the sample (organizations were surveyed regardless of size, industry or type of business etc.), using CAWI method. For the purpose of this study, the sample was limited to the manufacturing companies (128 responses). Sample characteristics are presented in Table 2.

Table 2: Research sample overview

Organization size	local organization
Micro (below 10 people)	12
Small (11-50 people)	37
Medium (51-250 people)	42
Large (above 250 people)	37
Total	128

Variables Overview

The hypothesis verification was based on three key variables: technology acceptance, organizational performance and source of revenue (see table 3).

Technology acceptance was measured based on a single item variable (as this study is treated as the pilot one) on the 5-points' Liktert scale.

Organizational performance was measured based on Balances Scorecard concept (Kaplan & Norton, 1996), being the framework that allows to draw together multiple measures aimed at financial performance, internal business processes, customer perspectives, and innovation and learning. Within these 4 perspectives, ensuring consistency between the strategic objectives and the projects implemented by the organization, 8 measures of the organizational performance were indicated. They were rated on the 5-points' Likert scale (from well below expectations to well above expectations with the middle point: as expected).

Source of revenue was measured as a single item variable, based on the information whether the main source of revenue of the company is connected to manufacturing, trade or services.

Table 3: Variables overview

No.	Variable	No. of items	M	SD
1	Technology acceptance	1	3,56	0,97
2	Organizational performance	10	3,40	0,74

Research Results and Discussion

In order to verify the proposed hypothesis, the correlation and regression analysis was performed. The correlation analysis using r-Pearson coefficient was performed and revealed that there is strong and statistically significant relation between technology acceptance and organizational performance of manufacturing companies ($r = 0{,}473$, $p < 0{,}001$, $N = 126$). Since the correlation analysis does not allow to conclude on the cause-effect relation between the variables, as the second step, the regression analysis was performed. The statistically significant model was obtained ($F(1,124) = 35{,}807$, $p < 0{,}001$). The fit of the model was sufficient considering that only technology acceptance was tested in order to confirm the cause-effect nature of the verified relation ($R2 = 0{,}224$, which means that technology acceptance variance describes 22,4% of the organizational performance variance, which is a very high value for single variable regression). Therefore, the obtained results allow to accept the hypothesis H1 stating that: The technology acceptance has a positive influence on organizational performance of manufacturing companies.

In order to further confirm that the issue of technology acceptance is especially important for manufacturing companies, the regression analysis with moderator was performed. The main source of revenue of the company was set as a moderator (manufacturing company or trade / service company).

Table 4: Regression analysis with moderator – results

Model description	R^2	Delta R^2	Moderator coeff.	Standard error	t Stat	P Value
Technology acceptance, Source of revenue, Moderator *dependent v.: organizational performance*	0,171	0,014	0,095	0,044	2,131	0,034**

The obtained results are presented in table 4. The statistically significant (F(3,257)=17,695, p < 0,001) and fitted (R2 = 0,171) model was obtained. The results show that the source of revenue is a statistically significant moderator of the analyzed relation. Hence, the influence of technology acceptance of organizational performance is stronger among manufacturing companies then among trade or service ones.

Therefore, the obtained results allow to confirm that technology acceptance is a significant factor influencing performance of the organization. Moreover, what was assumed based on the literature review, manufacturing organizations are among those, which are more susceptible for such influence. It can be concluded that manufacturing organizations should pay extra attention on shaping the acceptance of technology used by their employees in order to gain benefits from such use and boost their performance.

Conclusions

The performed theoretical and empirical analysis allowed to fulfill the assumed aim of the paper. The existing approaches to the analysis of technology acceptance were described and discussed. Then, the empirical pilot study was performed verifying that the level of technology acceptance positively influences the organizational performance. The performed empirical study also confirmed that technology acceptance influence on organizational performance is stronger among manufacturing companies, thus it can be assumed that it is a factor especially needed to ensuring the efficient performance of manufacturing companies.

It is worth noting that performed research has the character of the pilot one. The sample of manufacturing companies was not sufficiently large but it was enough to form first conclusions and verify, whether the assumed relation is truly stronger in manufacturing companies than in trade or service ones. Therefore, the established conclusions allow to declare the acceptance of technology in manufacturing companies as a valid field of research. The analysis of the existing models of technology acceptance also revealed that there is a need to indicate factors influencing technology acceptance in such companies, which are specifically dependent of their manufacturing technologies and because of that, especially exposed to the consequences of acceptance and rejection of them by employees.

Abstract

The data mining, which is also known as knowledge discovery in databases, is successfully used to extract valid, previously unknown, understandable, useful, and actionable information from large structured and unstructured databases. The data mining has got importance for supporting the crucial business decisions, disease diagnostics, or predictions what may happen in future. In this paper, we present the application of *Apriori* algorithm of data mining to mine associate rules among the marks scored by students in prerequisite and successor mathematics courses in an engineering degree program. The analysis of rules reveals that students who scored better marks in the prerequisite courses will 100% confident, maintain their performance same in the successor courses. The mined rules also revealed that association rule mining could be used effectively for predicting the grades and also adapting the teaching methodologies to teach mathematics course.

Keywords: Educational Data Mining, Association Rules, Confidence, Support.

Introduction

The most important targets of any educational system are to furnish students with the knowledge and skills required to switch into successful professions within a specified period. How effectively global educational systems meet this goal is a major determinant of both economic and social progress.

In Baker, R.S. (2014) mentioned that in recent years, increasing attention to Artificial Intelligence (AI) inspired the development of data mining and analytics in the pedagogical domain. Data mining is the method to obtain additional characteristics and models from a large data set. Data mining uses the methods of machine learning, statistics, and database systems. It is mentioned by Fayyad, U. et al (1996) that data mining is a field of knowledge discovery in databases (KDD), which is the area of detecting the individual and hypothetically advantageous information from large amounts of data set. The data mining concentrating in the educational area is called as Educational Data Mining (EDM). EDM refers to the techniques, tools, and research designs utilized to obtain information from educational records, typically online logs, and examination results, and then analyses this information to formulate conclusions. In Berland, M. et al (2014) mentioned that the EDM is theory-oriented and focuses on the connection to pedagogical theory. In Papamitsiou, Z. and Economides, A. A., (2014) mentioned that presently, little empirical evidence exists to support a theoretical framework able to gain wide acceptance in the scientific community. Given that in the real world there is a great diversity of different learning contexts, they determine the analytical approaches utilized by EDM. Therefore, how EDM can be beneficial in real educational practices, as demonstrated in the research, could be crucial.

The website International Educational Data Mining Society (2011) mentioned that Educational Data Mining is an emerging field, concerned with rising procedures for discovering the exclusive and

progressively large-scale data attained from educational surroundings, and uses those methods to better understand students and the settings in which they learn. Koedinger K. et al (2008) states that EDM permits users to extract knowledge from student data. This experience can be used in different ways such as to substantiate and assess an educational system, enhance the quality of T& L processes, and lay the groundwork for a more effective learning process.

EDM can present universities with a clear picture of specific hindrances to student learning. For example, students can fail in advanced subjects because they did not learn the basic information from the prerequisite subjects. Using data mining (DM) techniques to analyze student information can help identify possible reasons for student failures. Data mining delivers many procedures for data analysis. The enormous quantity of information presently in student databases surpasses the human capability to evaluate and obtain the most useful information without help from computerized analysis procedures. Knowledge discovery (KD) is the process of nontrivial extraction of implicit, unknown, and potentially useful information from a large database. Data mining has been used in KDD to discover patterns with respect to a user's needs. The pattern definition is an expression in language that describes a subset of data. An example of a KDD pattern definition was use by Agrawal, R. (1993).

The section 2 presents association rule mining, in section 3 we present the data and methods, and discussion of results is presented in section 5. We conclude our work in section 6.

Association Rule Mining

The association rule mining was introduced by Agrawal, R. (1993) in 1993 in an international conference on Management of Data and since then it has received a notable attention of the researcher in every domain of life. The association rule mining is one of the mostly used machine learning algorithm for hidden patterns discovery in large database. Association rule mining, in brief, employs the use of machine learning models to analyze data for hidden patterns or co-occurrences in a database. It identifies frequently occurring *if-then* associations that are called association rules An association rule is composed of two parts; an antecedent (if) and a consequent (then) and are written as "*antecedent → consequent*". The antecedent is an itemset in the database and the consequent is an itemset in the database that occurs in combination with the antecedent.

We need to reproduce here to the terms from Lustgarten J. L. et al (2008) used to understand the association rule mining.

Itemset – a set of one or more items i.e. {Butter, Bread, Milk} in a transaction database.

K-itemset – an itemset which contains K items. For example, {Butter, Bread, Milk} is a 3-itemset.
Support (denoted by 's') – is frequency or occurrence of an itemset X. It is one of the measure of interestingness that tells about the usefulness and certainty of a rule. A 5% support means total 5% of transactions in database follow the rule.

Frequent itemset –an itemset X is frequent if support of X is no less than a minimum support threshold.
Confidence (denoted by 'c') – conditional probability that a transaction having X also contains Y.
Strong rule – an association rule having support greater than or equal to the user-specified minimum support threshold and confidence greater than or equal to a user-specified minimum confidence threshold.

An association rule *butter → bread* is presented in Figure 1.

Figure 1: Butter → Bread association rule

This direct applicability to business problems together with their inherent understandability (even for non-data mining experts) made association rules a popular mining method. Moreover, it became clear that association rules are not restricted to dependency analysis in the context of retail applications, but are successfully applicable to a wide range of business problems.

To predict grades in a course on the basis of performance in the prerequisite course(s), we used the *Apriori* algorithm described in Markus H. (2005), which is a quite favorite algorithm for frequent itemset mining and identification of association rules over transactional databases. It proceeds by identifying the frequent individual items in the database and extending them to larger and larger itemsets as long as those itemsets appear sufficiently often in the given database. The frequent itemsets determined by *Apriori* algorithm can be used to determine association rules which highlight general trends in the dataset. We present here an example having few transactions in the database as shown in Table 1.

Table 1: Example transactions database

Transaction ID	**Items bought**
T100	{A, B, D, K}
T200	{A, B, C, D, E}
T300	{A, B, C, E}
T400	{A, B, D}

Let minim support is 60% and minimum confidence is 80%.

Step 1: Scan the database for 1-itemsets candidates and frequent 1-itemsets.

1-itemsets candidates (C-1)

Itemset	Support (%)
{A}	100
{B}	100
~~{C}~~	~~50~~
{D}	75
~~{E}~~	~~50~~
~~{K}~~	~~25~~

Frequent 1-itemsets (L-1)

Itemset	Support (%)
{A}	100
{B}	100
{D}	75

Step 2: Scan the database for 2-itemsets candidates and frequent 2-itemsets.

2-itemsets candidates (C-2)

Itemset	Support (%)
{A, B}	100
{A, D}	75
{B, D}	75

Frequent 2-itemsets (L-2)

Itemset	Support (%)
{A, B}	100
{A, D}	75
{B, D}	75

Step 3: Scan the database for 3-itemsets candidates and frequent 3-itemsets.

3-itemsets candidates (C-3)

Itemset	Support (%)
{A, B, D}	75

Frequent 3-itemsets (L-3)

Itemset	Support (%)
{A, B, D}	75

Step 4: Extract all strong association rules from the database.

Frequent Itemsets	Support (%)
{A}	100
{B}	100
{D}	75
{A, B}	100
{A, D}	75
{B, D}	75
{A, B, D}	75

Candidate Rules	Confidence (%)
A → B	100
B → A	100
~~A → D~~	~~75~~
D → A	100
~~B → D~~	~~75~~
D → B	100
~~A, B → D~~	~~75~~
A, D → B	100
B, D → A	100
~~A → B, D~~	~~75~~
~~B → A, D~~	~~75~~
D → A, B	100

The strong association rules that satisfy the minimum support (60%) and confidence (80%) thresholds are given in Table 2.

Table 2: Strong association rules

Candidate rule	Support (%)	Confidence (%)
A → B	100	100
B → A	100	100
D → A	75	100
D → B	75	100
A, D → B	75	100
B, D → A	75	100
D → A, B	75	100

Data and Methods

1.1 Data Collection

The data consists of the total marks (0 – 100) scored by the forty-four students who passed the second course in Calculus (SC) and Differential Equations (DE) course of an engineering degree program taught by the same instructor in two consecutive semester of fifteen weeks. The course Preliminary Calculus is a prerequisite of the Differential Equations course. The sample marks data is presented in Table 3.

Table 3: Sample dataset

S. No.	Marks scored by students	
	2nd Course in Calculus	Differential Equations
1	63.7	76.3
2	68.5	70.5
3	76.2	81.3
4	62.8	81.5
5	63.0	62.8
6	66.3	76.5
7	76.8	91.3
8	81.9	76.5
9	76.1	70.3
10	54.2	63.0

Data Cleaning

There are a number of data cleaning techniques in the literature such as fill missing values, binning, regression, and clustering – some are mentioned in Kiron, D. et al (2012). We did not use any algorithm or technique to handle the missing values in the marks dataset. The data of the students who passed Calculus course in preceding semester but did not pass the DE course in the successor semester was not included in this study. The students who did not registered course taught by the same instructors in the two consecutive semesters was also not included in finding the association rules.

In educational systems, assessment is a predictable component as it has a wide impact on learning. The student's performance in a course is also based on teaching methodology, faculty behavior towards the student, and faculty tone and communication style in the classroom. These factors influence participation of the student in a class. If different faculty will teach the course, the student's association in class will be affected and hence it results in the performance of the students' grades in the class. The value of the data in this study is that one faculty taught the prerequisite as well as the successor courses to the same students. This ruled out the earlier mentioned side effects of two courses taught by two different faculty.

Data Discretization

The *Apriori* algorithm works on nominal attributes that requires o discretize any numerical data in the datasets. Discretization is a typically preprocessing step for machine learning algorithms that transformed continuous-valued feature to discrete one as mentioned in Lustgarten J. L. et al (2008). Cios K. J. et al (2007) states that the goal of discretization is to reduce the number of possible values a continuous attribute takes by partitioning them into a number of intervals. The marks scored by students in two courses in this study are numerical and we have converted that to a nominal data consisting of ten categories use MS Excel. The categories and their corresponding range is given in Table 4.

Table 4: Numerical to nominal – range and category

Sr. No.	Marks Range	Category
1	90 < Marks <= 100	C-10
2	80 < Marks <= 90	C-9
3	70 < Marks <= 80	C-8
4	60 < Marks <= 70	C-7
5	50 < Marks <= 60	C-6
6	40 < Marks <= 50	C-5
7	30 < Marks <= 40	C-4
8	20 < Marks <= 31	C-3
9	10 < Marks <= 20	C-2
10	0 < Marks <= 10	C-1

The scored marks of the students in two courses transformed into categorical data, a sample, is given in Table 5. Now, scored marks have been made to be eligible for applying mining association rule since association rule mining support nominal data only in Weka.

Table 5: Scored marks transformed to Nominal Data

Marks Numerical Data		**Marks as Nominal Data**	
2nd Course in Calculus	**Differential Equations**	**2nd Course in Calculus**	**Differential Equations**
63.7	76.3	C-7	C-8
68.5	70.5	C-7	C-8
76.2	81.3	C-8	C-9
62.8	81.5	C-7	C-9
63.0	62.8	C-7	C-7
66.3	76.5	C-7	C-8
76.8	91.3	C-8	C-10
81.9	76.5	C-9	C-8
76.1	70.3	C-8	C-8
54.2	63.0	C-6	C-7

Results and Discussion

Apriori algorithm was applied on the dataset using a publically available free data mining tool developed at Waikato University and available at Weka (2019). The Weka tool allows users to apply most of the data mining algorithms on a given dataset. The summary of categories of performance of students in two courses produced by Weka is presented in Figure 2 (a) and Figure 2 (b).

Figure 2 (a): Summary of 2nd Course in Calculus data

Figure 2 (b): Summary of Differential Equations data

The Weka generated set of association rules with the minimum confidence of 70% and minimum support of 20% are given below.

Number of cycles performed to mine the association rules = 18
Generated sets of large itemsets are given below.
Size of set of large 1-itemsets = 9
Size of set of large 2-itemsets = 4

The strong rules of interest selected from the association rules mined with different combination of supports and confidences are presented in Table 6.

Table 6: Strong association rules mined

Rule No.	Antecedent – 2nd Course in Calculus	Consequent – Differential Equations	Confidence (%)
1	C-10	C-10	100
2	C-6	C-7	100
3	C-9	C-9	80

The analysis of rules reveals that students who scored marks in the range of 80 < marks <= 90 and 90 < marks <= 100 in the prerequisite course will, 100% confident, maintain their performance same in the successor course i.e. Differential Equation.

There is only one strong rule that reveals that we are 80% confident that students who scored marks in the range of 50 < marks <= 60 in the prerequisite course i.e. 2nd Course in Calculus can improve their performance in the successor course. i.e. Differential Equation.

The analysis of the data disclosed that there are only two students (2/44*100 = 4.5%) whose performance was lowered in the successor course as compared to the performance in prerequisite course, but it was not mined as strong rule.

Conclusion

Apriori algorithm proved to be successful in finding the hidden association among prerequisite and successor courses in mathematics to predict grades. The association rules generated in this study were later verified by the expert instructors involved in teaching the related course. The study can further be extended for finding association rules among the related courses in given baccalaureate program in any discipline.

Mistakes Made by Executives and HR Managers in Personnel Selection Interviews and Options for Avoiding Them

Ing. Martin MOSER, MA MSc

University of Sopron, Alexandre Lamfalussy Faculty of Sopron, Hungary,
martin.arnold.moser@phd.uni-sopron.hu

Abstract

Executives and HR managers face many challenges today, such as demographic change, shortage of skilled workers, development of the diversity of the staff, pressure to expect service quality, increase in mental stress, etc. Personnel selection is one of the most critical issues for a company because it is an investment in human capital, which can be a decisive competitive advantage for an organization. For many companies and industries, it is becoming increasingly difficult to find suitable staff, since applicants tend to be interested in large corporations or attractive brands. Furthermore, tasks in our society are becoming increasingly complex and demanding, which means that the requirement profiles are becoming more and more specific. This makes the search and selection of suitable employees more important. Few companies can afford to make wrong decisions in the personnel selection process despite their good economic success. This scientific paper describes and discusses, based on the methodology of a qualitative research via problem-centered interviews as well as a literature review, on the one hand, the mistakes that executives and/or HR managers can make during the personnel selection interviews, on the other hand, what the consequences are and what options exist to avoid these mistakes.

Keywords: Competitive Advantages, Human Resource Management, Organizational Management

Introduction

Personnel selection is one of the most critical issues for a company, because it is an investment in human capital, which can be a decisive competitive advantage. For many companies and industries, it is becoming increasingly difficult to find suitable staff, since applicants tend to be interested in large corporations or attractive brands. Furthermore, tasks in our society are becoming increasingly complex and demanding, which means that the requirement profiles are becoming more and more specific (Krings, 2017, p. 1). The current demographic development also confirms that in many industries it is very difficult to get skilled workers. This makes the search and selection of suitable employees more important. Few companies can afford to make wrong decisions in the personnel selection process despite economically good success (Lorenz & Rohrschneider, 2015, p. 1). Due to the increasing size and complexity of many companies, personnel policy measures are no longer used only for personnel administration, but also take on an important coordination function. In order to coordinate the actions of the individual employees in a company accordingly and to ensure a consistent company policy, binding criteria for personnel selection, group-oriented forms of personnel deployment and personnel management based on target values are used (Holtbrügge, 2015, p. 4).

The aim of this scientific article is, on the one hand, to describe the mistakes that executives and/or HR managers can make during the personnel selection interviews, on the other hand, what the consequences are and what options exist to avoid these mistakes. The chosen methodology is the qualitative approach of the problem-centered interviews as well as a literature review, including the current knowledge on the respective subject. Through the openness and flexibility of this method, the discovery of unknown facts is made possible, higher information content is generated and the viewpoint of the interviewees is centered. The data collection will be conducted by guided and problem-centered interviews. The basis for the preparation of the interview guide and the related questions are the information and current knowledge base from the literature on this subject. The interview guide consists of an introduction and a main part. The introduction serves to briefly outline the meaningfulness and

usefulness of the survey. In the main section, questions are asked about possible mistakes made by executives and HR managers in personnel selection interviews and options for avoiding them. When conducting the interviews, it has been tried to ask open questions where possible and appropriate in order to gain as much information as possible from the interviewee and not lead him or her in a specific direction (Mayring, 2016, pp. 67-68). The problem-centered interview selects a linguistic approach to determine his or her position on the basis of subjective meanings. It's tried to establish a situation of trust between the individual parties. Although the interview partners are directed by the guideline through certain questions, they react openly and without any specific answer possibilities. This approach has the advantages of being able to check the general understanding of the interviewees, as well as the disclosure of subjective opinions and the discussion of concrete terms of the interview situation (Mayring 2016, pp. 68-69). The areas of application for the problem-centered interview are mainly within theory-based research, since it integrates the aspects of the primary problem analysis into the interview. It is particularly suitable if in principle a lot is already known about the research field. The standardization through the interview guide facilitates the comparability of the conducted interviews and thus also the subsequent evaluation (Mayring, 2016, pp. 70-71).

The evaluation method is based on the summary approach of the qualitative content analysis according to Mayring. The entire material is screened without any specific preliminary considerations and the respective recordings of the interviews are transcribed. In a further step all utterances, which do not change the content, are removed, since the main interest is aimed only at the content-based information (Mayring, 2016, pp. 115-116). A comprehensive content analysis is used for the data evaluation. The aim is to reduce the material to its essential contents and to create a manageable basic form. Written statements will be structured in order to subsequently draw conclusions for the research. For this purpose, the obtained information will be divided into categories. The category system should not be very detailed. Afterwards the results will be discussed and put into context with the relevant literature. The category system can be reworked and adapted after carrying out the pre-study (Mayring, 2016, pp. 115-116).

Personnel Selection

In the age of a shortage of skilled workers, recruitment and personnel selection are the pillars of an active personnel strategy that aims to increase the inflow of human capital. The job market does not allow waiting and experiments, but requires systematic actions to increase the base rate and hit rate. Personnel selection is a key success factor in the value chain in order to minimize wrong decisions in personnel deployment. Mismanagement is associated with considerable follow-up costs in connection with fluctuation, new advertisements, personnel development, low motivation for work and performance deficits (Treier, 2019, p. 122). Personnel selection refers to the assignment of applicants to positions in an organization through recruitment and the use of selection techniques, which are based on a requirement analysis and serve to find the most suitable applicant for the respective position (Kauffeld, 2014, p. 100). The basis of personnel selection and personnel development is the identification and promotion of job-specific suitability of the employees (Holtbrügge, 2015, p. 10). The so-called suitability diagnosis is an essential part of the selection of personnel, with the help of which it can be checked whether and to what extent an applicant is suitable for a specific job. It is more likely to be suitable for a specific position, the better it is able to cope with the respective requirements due to its requirements. Accordingly, the correspondence between the desired professional position and the requirements of the applicant is analyzed (Schuler & Höft, 2007).

The design of the personnel selection process plays an essential role for the efficient procurement of employees. The prerequisite for this is an exact recording and creation of the requirement profile or job description. In general, different ways of procurement, different evaluation principles of the application documents as well as several selection procedures are available. From these, the respective company can design the best recruitment process for its purposes (Lindner & Lohmann, 2012, pp. 5-6).

Personnel marketing has become more professional in recent years in terms of channel breadth (e.g. use of social media) and the use of IT, but with the risk of falling prey to the maximization principle in order to counteract the impending scarce need for personnel. At this point, an increase in candidates is

often no added value if this is accompanied by a decrease in the fit and the administration costs skyrocket. The progress in the selection of personnel is sobering, because personnel managers use comparatively few psychological tests and continue to rely on their intuition based on non-standardized interviews and application documents in decision-making processes (Treier, 2019, p. 123).

At the initiative of the professional association of German psychologists, for example, DIN 33430 ("Requirements for procedures and their use in job-related suitability assessments") was adopted in 2002, which describes requirements for personnel selection. The background to this decision was the low forecast validity of many personnel selection procedures. The standard specifies that only those processes are used that can be demonstrated to be related to the requirements. Furthermore, all aspects of the implementation and evaluation of the procedures as well as the interpretation of the results should be defined and documented in advance. The process of personnel suitability assessment must be documented in such a way that the result can be understood. The aim is to increase the quality of the selection of applicants and to provide verifiable proof of their legality (Hornke & Winterfeld, 2004; Kersting & Püttner, 2006). DIN 33430 unlocks the standards that are already common in Great Britain and the Netherlands. However, it is not mandatory, but only serves as a recommendation (Lorenz & Rohrschneider, 2015, p. 4). A targeted selection of personnel starts with an open and honest self-assessment of the company, the environment and the task. Success can only be achieved by fitting the person and position (Lorenz & Rohrschneider, 2015, p. 5).

The process of personnel selection is divided into different stages. Figure 1 shows the ideal typical process of recruiting new employees. For reasons of clarity and taking into account the question to be dealt with in this scientific article, only the phase of the selection process should be described in more detail.

Fig. 1: Process overview of personnel selection

To check the quality of the personnel selection process, an evaluation using a cost and benefit analysis should be carried out. This serves the specific determination of the financial income of a personnel selection process (Kauffeld, 2014, p. 100). After reviewing the documents or pre-selecting potential candidates by telephone, there is direct interaction between applicants and those responsible for the company. The company usually specifies the process with which it wants to check the suitability of the candidate. Interviews are usually conducted so that the company can get an idea of the applicant. If necessary, these can be supplemented with tests and self-assessment by applicants through questionnaires (Lindner & Lohmann, 2012, p. 64).

Various procedures can be used to make the personnel selection decision. These include the assessment center or the structured assessment of the application documents. The leading decision-making instrument is usually the personal interview (Welk, 2015, p. 64). Personnel selection interviews are also referred to as job interviews. Depending on the company and the position to be filled, the respective

framework conditions for a personnel selection interview can vary. As a rule, representatives of management, personnel management and the immediate supervisor (e.g. department head) take part in these discussions. Personnel selection interviews are used to fill new positions and/or management positions in the company (Welk, 2015, p. 63). The aim of personnel selection interviews is that on the one hand the respective company can get a general picture of the applicant, on the other hand it can check the written documents and find out the expectations of the applicant. In addition, the potential performance of the applicant should be estimated. In turn, the applicant can get a more precise picture of the company and the relevant area of work in a personnel selection interview and assess development opportunities. Successful personnel selection interviews require detailed preparation from both sides (Lindner & Lohmann, 2012, pp. 64-65). The next chapter deals with the common mistakes in personnel selection interviews and their causes more in detail.

Recruitment goes hand in hand with personnel selection to increase the hit rate. That is why more and more companies are not only investing in recruiting, but also in selection procedures that allow a candidate's future work performance to be validly assessed. The call for future work performance is determined by the job's requirement profile. Because only when it is known what requirements a particular workplace places on an employee will you be able to identify and select a suitable employee (Treier, 2019, p. 130).

In aviation for example, professional selection of personnel has been practiced successfully for more than fifty years. From joining the company, i.e. the beginning of pilot training, to being promoted to captain after ten to fifteen years, 97% of the candidates are still on board at Lufthansa. This is no coincidence, because large airlines use procedures that meet the special requirements of this professional group when choosing their future pilots. By systematically ensuring a high degree of accuracy between future personnel on the one hand and job requirements and corporate culture on the other, the airlines have been able to minimize problems and risks for decades. People have different talents, which are very different for them. Such dispositions lead to people developing an affinity for certain activities. Everyone knows from his own experience that he prefers to take care of things and topics with a high affinity – this is where you are most likely to become a professional. Companies must therefore find out where the individual talents of their applicants lie in order to select a suitable candidate and use them according to their strengths. Personnel selection procedures and potential analyzes serve to identify these personally strong investments, but also any weaknesses (Hinsch & Olthoff, 2019, p. 91).

Mistakes in Personnel Selection Interviews

The consideration of mistakes and their causes in the course of personnel selection interviews is essential, since the selection of personnel or personnel search requires costs that vary with the type of position to be filled and the number of applications. Basically, all investments are sensible, through which a new competent employee can be won. Costs are not justifiable that arise from failure to achieve goals and new search activities over and over until the respective position is successfully filled (Lorenz & Rohrschneider, 2015, pp. 2-3). To find out whether someone fits into a company, a department or a team, it is necessary to find out what drives the applicant. Therefore, a company needs employees with knowledge of human nature and the ability to empathize an interview (List, 2013, pp. 26-27).

Research shows that judgments about other people are made in the first seconds of getting to know each other. So after this short time there is already a relatively firm opinion about another person. This poses certain dangers in the personnel selection interview, since the entire further perception is channeled. After a subjective opinion has been formed in the first seconds of an encounter, it is further confirmed unconsciously. If the first impression was positive, the subjective filters result in all positive subsequent impressions being perceived particularly clearly and evaluated as confirmation of the first impression. Negative follow-up impressions are accordingly assessed as low or not perceived correctly (Lorenz & Rohrschneider, 2015, pp. 109-110). Figure 2 shows the causes of observation and assessment mistakes in the course of personnel selection interviews that can be made by managers and/or personnel.

Causes of observation and assessment mistakes

Intra-personal influences	Interpersonal influences	Situational influences	Assessment procedures
Selective perception	Sympathy and antipathy	Influences in the situation	Inadequate exercise
Prejudices	Primacy effect	Influences outside the situation	Not exactly defined criteria
Status error	Recency effect		
Personal value structure	Halo effect		
Assessment type	Order effect		
egoism			

Fig. 2: Causes of observation and assessment mistakes

Intra-Personal Influences

Selective perception is the selection of information by the interviewer according to his personal situation. The applicant's objective assessment suffers as a result, as does prejudice or status errors, in which academic titles convey their suitability. A shift in the personal structure of values can, for example, set the bar for the applicant's performance unattainably high (Lindner & Lohmann, 2012, p. 65).

Interpersonal Influences

The effects of sympathy and antipathy must be analyzed just as critically as so-called primacy or recency effects. This means the comparatively high attribution of weights of first and last impressions, which may influence the other effects. The sequence effect is the phenomenon in which applicants are judged better or worse, depending on the quality of the representation of previous or subsequent applicants (Lindner & Lohmann, 2012, p. 65). The effect of sympathy and antipathy means that applicants who appear likeable are rated better than those who convey a rather unappealing picture. This can quickly lead to the competencies of an applicant who immediately makes a sympathetic impression being completely overestimated or that of an applicant who seems rather unappealing to be devalued. This is one of the main sources of error in recruitment interviews. Furthermore, it must be taken into account that the feeling of sympathy is ultimately subjective (Lorenz & Rohrschneider, 2015, p. 112).

Situational Influences

Situational influences include, for example, the room temperature or a possible unpunctuality of the applicant, which may have a lasting impact on the course of the conversation (Lindner & Lohmann, 2012, p. 66). Other situational influences that make it difficult to make general statements about the personnel selection interview are e.g. the level of awareness between the two interviewees, the situation on the job market, the age or the age difference of the interview partners, the differences in level of education and social origin, as well as gender (Neuberger, 2015, p. 24).

Assessment Procedures

Due to inadequate training or familiarity of the interviewer with the conversation situation, the procedure as such can lead to distortions. In addition, the assessment criteria cannot be clear or at least inconsistent between the interviewers (Lindner & Lohmann, 2012, p. 66).

Other Sources of Mistakes

If the interview is conducted using closed questions, this reduces the information about the applicant and the presentation of complex content suffers. Too fast staffing can lead to incorrect staffing if it is not adequately checked whether the right employee has been found for the right job at the right time, which is also associated with additional avoidable costs (Welk, 2015, p. 64).

In many industrial companies, personnel selection primarily takes place via resumes and personal interviews. The assessment is based on past performance. In the foreground are also professional job requirements. Process and interpersonal skills of applicants are rarely systematically determined. Therefore, their evaluation is all too often done from the gut. It is therefore not surprising that, according to a study by Intersearch Executive Consultants, inadequate management skills, inadequate leadership skills, inadequate social skills and inadequate adaptability are the most common reasons for unplanned new appointments. For this reason, larger companies in particular rely on assessment centers when hiring new employees, with the help of which they systematically pay attention to the non-technical skills and abilities of their applicants (Hinsch & Olthoff, 2019, pp. 91-92).

Consequences and Options to Avoid Mistakes

Mistakes in personnel selection interviews can mean that the qualifications required for certain tasks are not available with enough employees or that managers are only selected based on their professional qualifications and not on the basis of their leadership skills. A possible consequence would be that skills shortages of individual employees have to be compensated by other team members over a longer period of time. Hiring an unsuitable applicant may result in the applicant leaving the company after a relatively short time. The employer cannot continue the employment relationship during or after the probationary period, or the employee ends the employment relationship himself due to excessive or insufficient demands. High fluctuation rates or early fluctuation can mean considerable costs for companies if the employee concerned has to be released and compensated and new transaction costs for advertising, search and selection of new candidates. As a rule, these costs increase with the economic importance of the position in the company (Weuster, 2004, pp. 5-6).

The most common mistakes of judgment arise from making intuitive judgments. The evaluation therefore takes place at the same time as the observation, which, however, has not yet been completed at this point in time. It is therefore advisable to divide the assessment process into three phases (observing, describing, evaluating). In the first phase, only what can be observed and described is included in the assessment (concrete behavior and no generalizations). In this phase, your own judgment is deliberately put at the back. In the second phase, what is observed is put into words and recorded in a neutral manner. This also includes the continuous documentation of the conversation. You should therefore take as many notes as possible throughout the interview. The evaluation takes place in the third phase. Here, the notes from the selection interview are systematically evaluated in advance. The quality of a decision increases when it takes place in a dialogical process. In this context, it makes sense to conduct several interviews with changing interview partners with the applicant. The evaluation is then carried out in a large group. The combination of different perspectives can significantly improve the quality of the decision-making process and reduce the fluctuation in this part of the company (Krings, 2017, p. 66).

The creation of an in-house guide for personnel selection interviews enables the different applicants to be compared objectively. The following content structures the process (Welk, 2015, pp. 64-65).

1.) Greeting: e.g. brief description of the course of the conversation and an introductory round
2.) Description of previous professional development
3.) Information about the current position and competencies/tasks
4.) Information about the future position and area of responsibility
5.) Questions about the company
6.) Questions from the applicant
7.) Questions from the company

8.) Clarification of the general conditions
9.) Conclusion of the conversation
10.) Farewell

An essential point for avoiding mistakes in personnel selection interviews is appropriate preparation by the interviewer. In some cases, the selection of personnel requires special content and time-based process management in order to best meet the needs of the applicant and the interests of the company. The first step is to clarify who should take part in the conversation (or conversations) on the part of the company. It is important to ensure that all decision-makers involved also take part in all discussions (typical combination: line manager and HR specialist). The positions of the company interview participants make it clear to an applicant how he perceives the importance of his person or the respective position. For this reason, the next superior manager should also take part in the personnel selection interview or at least briefly meet the applicant. Furthermore, a conversation with the current job holder and future colleagues, as well as a job visit can be taken into account and scheduled. The preparation of a personnel selection interview includes the development of a question guide as well as the preparation of information materials with which the job and the respective company are to be explained in more detail to the applicants. The documents can also be made available to applicants as a printout or information brochure (Weuster, 2004, pp. 179-180).

The best way to reduce perception distortions and assessment errors is to prepare personnel selection interviews in writing. The interview guide already mentioned secures your own conversation behavior and ensures that all necessary information is requested. It also ensures that all applicants are faced with the same questions (Lorenz & Rohrschneider, 2015, p. 113). By selecting the questions in the personnel selection interview, it can be determined and controlled how much information is obtained and how well it is suitable to arrive at an assessment of the applicant. The decisive success criterion is the "how" of a question. Closed questions that can be answered with “yes” or “no” should be avoided as much as possible due to their low information value. Unanswered questions generate a higher information content and usually begin with a "W" (what, who, when, where, why, etc.). This form of question requires a comprehensive and complete answer and the taking of your own position. The necessary information about an applicant and his or her suitability for the position to be filled can only be learned through suitable questions. Before carrying out the personnel selection interview, the interviewer should consider which types of questions are used and which should be avoided for reasons of fairness. It must be checked whether, for example, provocative questions from the respective applicant are appropriate for the position in question. If the position requires a discussion of difficult conversation situations and conversation partners in everyday work, it can be useful to include such a short phase in the interview. At the beginning of the recruitment interview, you should work with open questions to gain as much information as possible. In the following course of the conversation, the type of questions can then vary or be changed as soon as comprehensive information about a certain aspect has already been obtained. In order to achieve effective results, some rules should be considered in the interviewer's conversational behavior. This includes, for example, giving the conversation partner time to think, listening carefully and asking questions in the event of ambiguities or identified contradictions (Lorenz & Rohrschneider, 2015, pp. 114-116). For the planning, implementation and evaluation of personnel selection interviews, essential legal bases must also be observed. The storage and use of data may only take place after prior notification of the applicant and his given consent. The use must be purposeful. The purpose must have been made known to the person and consent must be given (Krause, 2017, pp. 92-93).

Conclusions & summary

Personnel selection is one of the most critical issues for a company and represents a decisive competitive advantage (Krings, 2017, p. 1). The current demographic development confirms that it is very difficult to find skilled workers in many industries, which makes the search and selection of suitable employees more important. Very few companies can afford to make wrong decisions in the personnel selection process (Lorenz & Rohrschneider, 2015, p. 1).

Aptitude diagnostics form an essential part of personnel selection, with the help of which it can be checked whether and to what extent an applicant is suitable for a specific job (Schuler & Höft, 2007). Targeted personnel selection starts with an open and honest self-assessment of the company, the environment and the task (Lorenz & Rohrschneider, 2015, p. 5). The leading decision-making instrument for personnel selection decisions is usually personal interview (Welk, 2015, p. 64).

The consideration of mistakes and their causes in the course of personnel selection interviews is essential, since the selection of personnel or the search for personnel requires costs that vary with the type of position to be filled and the number of applications (Lorenz & Rohrschneider, 2015, pp. 2- 3). The most common errors of judgment arise from making intuitive judgments. It is therefore advisable to divide the assessment process into three phases (observing, describing, evaluating) (Krings, 2017, p. 66). The creation of guidelines for personnel selection interviews enables the different applicants to be compared objectively (Welk, 2015, pp. 64-65). An essential point for avoiding mistakes in personnel selection interviews is appropriate preparation by the interviewer. In some cases, the selection of personnel requires special content and time-based process management in order to best meet the needs of the applicant and the interests of the company (Weuster, 2004, pp. 179-180). By selecting the questions in the personnel selection interview, it can be determined and controlled how much information is obtained and how well it is suitable to arrive at an assessment of the applicant (Lorenz & Rohrschneider, 2015, pp. 114-116). For the planning, implementation and evaluation of personnel selection interviews, essential legal principles must also be observed (Krause, 2017, pp. 92-93).

Resumen

A lo largo de la historia del siglo XX, Venezuela fue considerada una nación de puertas abiertas al mundo, los factores de atracción estaban anclados a un nivel de vida estable y al desarrollo de sus fuerzas productivas. Entrado al siglo XXI, la situación se revierte, el país presenta un patrón migratorio completamente distinto, más de cuatro millones de personas han emigrado, según cifras de la ACNUR (2019). En este sentido, el objetivo de esta investigación es caracterizar el proceso migratorio venezolano, haciendo énfasis en su dinámica más reciente, abordando el problema desde una óptica descriptiva y documental. Los resultados develan que se ha venido configurando el mayor movimiento migratorio en la historia reciente del continente americano, y cuyo efecto ha provocado un desequilibrio en la región. Entre las causas más relevantes de este éxodo destacan factores de carácter económico y social, como la caída vertiginosa del Producto Interno Bruto (PIB), el proceso hiperinflacionario que ha erosionado el poder adquisitivo de la moneda nacional, la inseguridad jurídica y personal, entre otras razones. Lo anterior, ha derivado una crisis humanitaria de grandes dimensiones que exige una respuesta inmediata a la población.

Palabras clave: Inmigración, emigración, crisis, Venezuela.

Introducción

La migración es un proceso demográfico complejo relacionado con múltiples aspectos económicos, sociales y políticos que inciden en la vida cotidiana de las personas, por un mundo, políticas y gobiernos cada día más cambiantes. El fenómeno se compone de la salida de un individuo (emigración) de una comunidad, estado o país (lugar de origen) por un tiempo determinado y la llegada de este al nuevo territorio (inmigración) o lugar de destino. La historia de la humanidad ha permitido recopilar diversos hechos migratorios, pues desde que la especie humana existe, hay indicios de migración. Las personas han tenido que desplazarse de un lugar a otro en búsqueda de alimentos, abrigo, vestimenta o producto de grandes catástrofes naturales o sociales.

A medida que la sociedad fue avanzando, con el desarrollo de los medios de comunicación y transporte (automóviles, ferrocarriles, aviones, barcos, entre otros), este proceso demográfico tuvo mayor auge, haciendo posible la migración masiva de personas, en una escala global nunca antes vista. Se trata de migraciones de tipo socioeconómico, estimuladas por un proceso de desigualdad creciente entre los países desarrollados y subdesarrollados, y acentuados, en especial en este último caso, por deficiente gestión de los gobiernos.

De esta manera, la migración ha contribuido en mejorar las condiciones de vida de las personas tanto en los países de origen como en los de destino. No obstante, no todos los movimientos migratorios se producen en circunstancias favorables. En los últimos años, de acuerdo a la Organización Internacional para las Migraciones (OIM, 2018), se ha registrado un aumento de las migraciones y los

desplazamientos provocados por conflictos, persecuciones, situaciones de degradación y cambio ambiental, y por una acusada falta de oportunidades y seguridad humana.

De acuerdo a la Organización Internacional del Trabajo (OIT, 2015) existen alrededor de 232 millones de migrantes en el mundo, sin embargo, los datos que ofrece la OIM (2018) aseguran que la cifra alcanza los 244 millones de personas, de los cuales el 65% son trabajadores. Cifra que devela la cantidad significativa de personas que dejaron de pertenecer a la fuerza de trabajo de sus naciones para hacer vida productiva en otras tierras, por lo que son individuos en edad activa (que incluye a jóvenes) y muchos de ellos, de condición calificada. Situación que preocupa a dicha institución y a otros organismos internacionales que han tratado el tema para delinear políticas de migración de alcance mundial.

Para el caso de Venezuela, que ha sido caracterizada como una nación de puertas abiertas a los flujos poblacionales interesados en las actividades económicas, en la actualidad se presenta un patrón migratorio completamente distinto, pues se han registrado emigraciones masivas, en especial de población joven y calificada de acuerdo a De la Vega y Vargas (2017), devenidas por problemas con la alimentación, realización personal, inseguridad, escasez de medicamentos, bajos salarios, corrupción, entre otros inconvenientes, que demandan la atención inmediata del gobierno, que no ha querido otorgar el reconocimiento tácito de la diáspora que se está presentando. Bajo estas consideraciones, este trabajo compone una caracterización del proceso migratorio venezolano, haciendo énfasis en su dinámica más reciente, abordando el problema desde una metódica descriptiva - documental.

América Latina Ante El Desafío De La Migración

La migración en América Latina, dada su vinculación al viejo mundo, desde los períodos de la colonia, la independencia y hasta mediados del siglo XIX y parte del XX, ha sido activa, la región recibió inmigrantes de ultramar cuya presencia aún es notoria en varios países. Aruj (2008) expone que 55 millones de europeos aproximadamente se movilizaron a tierras americanas y actuó como válvula de escape, posibilitando la organización o reorganización de los estados europeos. La región fue también escenario del arribo de personas procedentes de otras subregiones del viejo continente según las Naciones Unidas (2006), como de poblaciones africanas salidas del sistema de esclavitud vigente hasta el siglo XIX, de asiáticos, principalmente chinos y japoneses y, en menor escala, de inmigrantes de otras regiones, tales como el Medio Oriente; dejando huellas profundas en la cultura y sociedad latinoamericana.

Posteriormente, la recuperación económica y social del continente europeo, el mantenimiento de vínculos con las antiguas metrópolis y el establecimiento de estrechas relaciones políticas, comerciales y económicas con los Estados Unidos, se conjugaron con las grandes transformaciones mundiales de la economía y provocaron que América Latina y el Caribe se convirtieran en fuente de emigración (Naciones Unidas, 2006). También se tienen los desplazamientos poblacionales generados por la crisis económica de 1930, y los conflictos políticos, económicos y sociales de algunos países latinoamericanos, que desencadenaron una migración entre países fronterizos de América y hacia territorio europeo u otras partes del mundo desde la década de 1960 (España, Italia, Francia, Portugal, Países Bajos, Reino Unido, Japón, Australia, Israel y Canadá)

De igual manera, se tienen las migraciones producidas en las últimas dos décadas del siglo XX hasta la actualidad, que según algunas estimaciones ha movilizado en todo el mundo a más de 150 millones de personas que actualmente no residen en su país de origen. Estadísticas conservadoras del Centro Latinoamericano y Caribeño de Demografía (CELADE) - División de Población de la Comisión Económica para América Latina y el Caribe (CEPAL) permiten sostener que el número de migrantes latinoamericanos y caribeños ha aumentado sensiblemente, pasando de más de 21 millones de personas a inicios del año 2000 a casi 25 millones de personas hacia finales del mismo año (Naciones Unidas 2006). Si se compara esta cifra con los 232 millones de migrantes que reporta la Organización Internacional del Trabajo (OIT, 2015), se obtiene una proporción superior al 10% de los migrantes internacionales del mundo.

Cabe destacar, que América Latina experimenta desde hace décadas, pérdidas de población altamente calificada, cuyo retorno se hace imposible consolidarse (Martínez y Orrego, 2016), a pesar de que varios países han propuesto medidas para establecer vínculos con sus comunidades de emigrados y apoyar redes científicas asociadas a las diásporas (De la Vega y Vargas 2017). Motivo de particular preocupación es la situación de las economías más pequeñas, que suelen verse afectadas por la emigración de sus profesionales hacia países desarrollados en búsqueda de salarios altos, mejores condiciones laborales y posibilidades de desarrollarse profesionalmente de acuerdo a Rosales, Nigenda, Galárraga y Ruiz (2010).

Muñoz (2016) al cotejar información sobre emigrados latinoamericanos (cerca del 4% de la población regional, según una estimación mínima), observa que el número más cuantioso de emigrantes corresponde a México, seguido del conjunto de los países de la Comunidad del Caribe y Colombia, que exceden holgadamente el millón de personas en cada caso. Otros nueve países de América Latina superan el medio millón y sólo uno cuenta con menos de 100.000 personas. Estas cifras acusan una considerable presencia de latinoamericanos y caribeños fuera de sus países de nacimiento.

Inicios De La Migración En Venezuela

Venezuela ha sido caracterizada en su historia migratoria como un país de puertas abiertas a los flujos poblacionales, interesados en las actividades económicas nacionales (Álvarez de Flores, 2007). En la población actual está presente una variedad étnica producto de la constante mezcla de nacionalidades, que lleva en la sangre y en los apellidos la marca indeleble de los antepasados inmigrantes (Taylhardat, 2003).

El cacao y el café durante el período colonial (siglo XIX) marcan el inicio de la presencia de migrantes en el país, compuesta principalmente por comerciantes españoles, canarios y alemanes (Muñoz, 2016). Las exportaciones de estos productos de creciente demanda en el mercado mundial, representaban el pilar de la economía venezolana, alcanzando el 92% para el año 1920 según Álvarez de Flores (2007). En el siglo XX, Venezuela continuó siendo un lugar de destino atractivo para los migrantes europeos, por su estabilidad económica y política. Situación que se extendió durante los años de la Segunda Guerra Mundial y la posguerra.

De acuerdo a Massey, Arango, Hugo, Kouaouci, Pellegrino y Taylor (1998), la década del cincuenta y los primeros años de la década del sesenta, Venezuela se convirtió en un importante punto de atracción para unos 335.000 inmigrantes, de los cuales el 70% era de Europa del Sur (Italia, España y Portugal) y el 30% restante de países de la región sudamericana y de otras nacionalidades. Parte de esto se debe a que, durante la dictadura de Marcos Pérez Jiménez, se minimizaron los requisitos para el ingreso al país. Álvarez de Flores (2007) señala que luego del derrocamiento de Pérez Jiménez, la Junta de Gobierno decide no otorgar nuevos permisos a los inmigrantes que querían radicarse, salvo cónyuges, hijos o padres ya residenciados, lo que explicaría el saldo negativo de inmigración que se registra en 1963.

El Petróleo Como Factor De Atracción En La Migración

Con el llamado “boom petrolero”, que contempló un alza progresiva de los precios del petróleo a partir de los años 70, se acentuó la prosperidad económica de Venezuela, trayendo consigo un aumento de la inmigración de personas provenientes de países fronterizos, disminuyendo los arribos masivos de europeos. En este momento de la historia, se instalaron particularmente colombianos, atraídos por las grandes oportunidades generadas por el petróleo y ante la posibilidad de adquirir mayores ingresos, en comparación con su país de origen (Álvarez de Flores, 2007; Muñoz, 2016).

Durante la misma época de bonanza que experimentaba la nación, que requería mano de obra en los diferentes sectores de la economía, aunada a la crisis política y el asentamiento de dictaduras militares en Chile, Argentina, Uruguay y Bolivia, estimularon la migración de recursos humanos calificados hacia Venezuela (Pellegrino,1989). Tal panorama se mantuvo constante hasta los años 1982-1983, cuando se produjo una baja de los precios del petróleo en el mercado internacional,

acompañado de la reducción de los volúmenes de exportación, que pone de manifiesto un cuadro de real crisis en Venezuela que se venía presenciando desde el año 1979 (Álvarez de Flores, 2007). Estas dificultades obligan al ejecutivo nacional (Luis Herrera Campins) a tomar decisiones importantes en materia económica.

Posteriormente, el endeudamiento externo, tanto público como privado, así como las crecientes sumas destinadas al servicio de la deuda, comprometieron seriamente la capacidad de inversión y gasto del Estado venezolano (Torrealba, 1987). Para 1989, el presidente Carlos Andrés Pérez, inició la aplicación de un programa de ajuste para la estabilización de la moneda y de la economía nacional, denominado "El Paquete", que luego provocó el rechazo de los sectores menos favorecidos, generándose sucesos de violencia los días 27 y 28 de febrero, conocido como "El Caracazo".

Por todo ello, Freitez (2011) afirma que durante los años ochenta y noventa Venezuela da un giro en sus pautas migratorias, pues la crisis tuvo efectos desalentadores sobre los movimientos migratorios provenientes del exterior, que además contribuyó a procesos de retorno de los extranjeros que habitaban en el país y a la emigración de venezolanos, quienes reaccionaron frente a ese contexto de recesión económica, descomposición social y deterioro institucional. En el mismo orden de ideas, Baraldi y Gainza (2013) exponen que durante este tiempo eran habituales los retenes, las redadas y las deportaciones de los migrantes sin documentos; incluso los migrantes irregulares, sin importar su nacionalidad, eran deportados a la frontera colombiana.

El Nuevo Milenio Y Los Nacientes Problemas Migratorios

Al iniciar el nuevo milenio, los factores de atracción de inmigrantes intrarregionales empezaron a disminuir y de acuerdo con cifras del censo del año 2011, los extranjeros alcanzaron el 4,2% (1.156.578) del total de la población en Venezuela, estimada en poco más de 27.227.000 personas (INE, 2014). Siendo la principal colectividad de extranjeros la formada por los provenientes de Colombia, Perú, Ecuador, Brasil y Cuba. Escenario diferente al de la década de los ochenta, donde representaban un 7,4% de la población total (Muñoz, 2016).

Instalado y direccionando las riendas del país, Hugo Rafael Chávez Frías, se pudo elevar los niveles de bienestar de la población más vulnerable gracias a los altos precios del petróleo, particularmente entre 2003 y 2009 (Freitez, 2011). Sin embargo, no se tienen evidencias de la recuperación del país como atractivo para los migrantes internacionales. Por el contrario, se registra un incremento apreciable de nacidos en Venezuela residentes en el exterior, que pasó de 378 a 521 mil personas, durante 2005-2010 según Freitez (2011) con apoyo de estadísticas de la División de Población de Naciones Unidas y del Banco Mundial.

A partir del año 2013, con la llegada al poder de Nicolás Maduro Moros como presidente de la República, se ha acentuado en el país, una situación caracterizada por la polarización política, donde además se evidencian altos niveles de inseguridad, la caída de los precios del petróleo, altos niveles de inflación, caída de las reservas internacionales, mayor control de precios, devaluación del bolívar, cierre técnico de numerosas empresas, escasez de productos básicos, entre otros inconvenientes provenientes de su proyecto político-económico (Gutiérrez, Romero, Díaz y Sulbarán, 2017), que mantienen hoy en día a Venezuela con las expectativas más bajas de crecimiento en la región (Romero, Hernández, Gutiérrez y Portillo, 2017).

La situación del país actualmente se debate en una profunda crisis económica y social que se devela a través de sus principales indicadores económicos, que describen su comportamiento según cifras del Banco Central de Venezuela (BCV) y organismos internacionales como el Fondo Monetario Internacional (FMI), pues la tasa de inflación anualizada al cierre del año 2015 se ubicó en un 180,9%; el Producto Interno Bruto (PIB) experimentó un 5,7% de decrecimiento; y el índice de escasez alcanzó más del 20% (cifra correspondiente al año 2013, última fecha de publicación de este indicador). Cabe destacar, que el BCV y otras instituciones del Estado no han publicado cifras oficiales de la situación socioeconómica del país

Por lo que el informe "Perspectivas Económicas Globales" del FMI estimó la inflación de Venezuela para el año 2017 en 1.133,0% y para el cierre del año 2018 la ubica en 2529,6%; esto debido al financiamiento monetario de profundos déficits fiscales y la pérdida de confianza en la moneda nacional. Asimismo, este informe aseveró que la crisis económica del país se profundizó con la contracción del PIB real en 12% para 2017 y predijo una caída del 6% para el 2018. Este último indicador se acercó al 5% que previó la CEPAL para el cierre del mismo año (FMI, 2017).

A mediados del año 2019, el BCV publicó algunas cifras de la situación económica del país luego de varios años de silencio. Los principales datos revelan que la economía venezolana se contrajo en 26,8% en el primer trimestre de 2019 en comparación con el mismo período del 2018; demostrando una recesión económica (contracción del PIB) que se mantiene desde el primer trimestre de 2013. Además, la entidad indicó que la inflación acumulada para el primer trimestre de 2019 fue de 4.679,5% y que la producción petrolera continuaba en caída. Estos nuevos datos oficiales revelan el descalabro de la economía nacional que se suma a la crisis política e institucional.

Cabe señalar, que este panorama económico alarmante ha incidido en la precaria situación social de la población, reseñada por el estudio realizado por la Universidad Católica Andrés Bello (UCAB), Universidad Central de Venezuela (UCV) y Universidad Simón Bolívar (USB), denominado ENCOVI (Encuesta sobre Condiciones de Vida); el cual muestra la pobreza multidimensional de la población, que consiste en un promedio ponderado de privaciones que tienen los hogares o algunos de sus integrantes en cuanto a vivienda, servicios, estándar de vida, educación, trabajo y protección social.

De esta manera, el porcentaje de hogares pobres fue de un 41% para el año 2015, mientras que para el 2016 este indicador subió a 46%. Para el 2017 el estudio registró 48% hogares en pobreza y para el 2018 este indicador alcanzó la dramática cifra de 51% (Encovi, 2018). La justificación de este escenario en materia de pobreza se corresponde al acelerado incremento de los precios que lleva a la pérdida de capacidad de compra; según el mismo estudio el 89% de los hogares venezolanos no tienen suficientes ingresos para comprar alimentos.

Tal situación económica y social, aunada al descontento político, han provocado una serie de emigraciones nunca antes vista (Muñoz, 2016; Castillo y Reguant, 2017). En cuestión de pocas décadas, Venezuela pasó de ser un país receptor a emisor de migrantes, debido a las condiciones políticas, económicas y sociales presentes en el país (Padilla, Torres y Michelena, 2015), desencadenando un escenario cargado de expectativas de crecimiento personal, económico y hasta profesional en la población.

Censos de otros países e informes de organizaciones internacionales muestran según Freitez (2011) que la diáspora hasta 2010 era de 521.620 personas y que los principales lugares de destino en ese momento eran Estados Unidos, España, Colombia, Portugal, República Dominicana, Ecuador, Canadá, Chile, Italia, Reino Unido, Aruba, Alemania, México y Francia. En referencia a esto, De la Vega (2014), señala que para 2013 más de 1.200.000 venezolanos (4,3% de la población total) habían dejado el país. Muñoz (2016) agrega que la diáspora venezolana se ha dirigido en los últimos años a Estados Unidos, España, Colombia y Ecuador, de forma notable.

Es preciso señalar siguiendo a Azócar (2018), que la crisis económica y política del país, ha llevado a visualizar en el extranjero una ruta segura para conseguir recursos económicos en monedas con mayor fortaleza adquisitiva. Este autor con apoyo de estadísticas de organizaciones no gubernamentales en Venezuela, muestra que, en el año 2016, más de 378.500 venezolanos entraron a Colombia legalmente para estabilizar su situación migratoria. Para el 2017, se tiene un registro de 153.000 venezolanos que se quedaron más tiempo del que les permite la tarjeta de turista (90 días), por lo cual están viviendo bajo la figura de estatus ilegal. Asimismo, Azócar (2018) afirma que durante el año 2017 y parte del 2018, 750.000 venezolanos cruzaban la frontera a diario bajo condición emigratoria, pero del 20% al 30% de este grupo poblacional, utilizaron la ruta por Colombia para seguir su camino hacia Ecuador, Perú y Chile.

Por su parte, el Servicio de Análisis de Entorno PERFIL 21, Consultores 21 (2017) expone que en promedio 1,97 personas han emigrado por núcleo familiar, por lo que la diáspora se elevó a 4.091.717 personas para el año 2017. Esta cifra también es manejada por ENCOVI (2017), quien habla de una emigración que asciende a 3 o 4 millones de venezolanos en el extranjero para la misma fecha, que representaría del 10 al 12% de la población total. El estudio además asegura que el 80% de la emigración desde Venezuela ha salido básicamente durante los años 2016 y 2017, teniendo como lugar de destino países como Colombia, Perú, Chile, Estados Unidos, Panamá, Ecuador, Argentina, entre otros.

Estadísticas de la Oficina del Alto Comisionado de las Naciones Unidas para los Refugiados, ACNUR, demuestran que para el año 2019 la diáspora ha superado los 4 millones de emigrantes, pues en el año 2018 salieron un número importante de personas. Estas cifras alarmantes resaltan la necesidad urgente de apoyar a las comunidades de acogida en los países receptores. Cabe resaltar, que los países latinoamericanos han recibido a la mayoría de los venezolanos migrantes; Colombia acoge alrededor de 1,3 millones, seguido de Perú con 768.000, Chile 288.000, Ecuador 263.000, Argentina 130.000, Brasil 168.000, países como México, Panamá, Estados Unidos y Costa Rica también albergan un gran número de migrantes (ACNUR, 2019).

Por su parte, El Fondo de las Naciones Unidas para la Infancia, UNICEF muestra una preocupación por los informes sobre casos de xenofobia, discriminación y violencia contra niños y familias venezolanas en las comunidades de acogida. Los asociados humanitarios de este organismo proyectan que hasta 4,9 millones de personas se encuentran en el extranjero por factores como la violencia, inseguridad y amenazas, así como la falta de alimentos, medicinas y servicios esenciales (Naciones Unidas, 2019). Representando el éxodo más grande en la historia reciente de la región.

No obstante, a pesar de las diferencias presentadas en cuanto a los totales de la emigración, por no tener acceso a fuentes estadísticas oficiales que permitan realizar alguna aproximación precisa (Freitez, 2015), lo verdaderamente preocupante es que la mayoría de estos venezolanos en el extranjero es considerado como capital humano calificado y en edad productiva (Padilla *et al.,* 2015; Vargas, 2016; Mazuera, Albornoz, Morffe, Ramírez y Carreño, 2019), lo que representa una pérdida dramática de capital intelectual y social. Es importante aclarar, que el capital humano involucra conocimientos, experiencias, habilidades y destrezas, por lo que la pérdida de este es significativa para la sociedad y su desarrollo; aún más si se trata de personal joven y calificado; esta última connotación es definida por el Sistema Económico Latinoamericano y del Caribe, SELA (2009) como aquella persona que ha logrado una educación correspondiente al tercer nivel (universitaria) y que nació en un país distinto al de residencia.

Ante esta situación que cada día se agudiza, la ACNUR (2018), alienta a los Estados del mundo a garantizar que los venezolanos tengan acceso a los territorios y a los procedimientos de determinación de la condición de refugiado, ya que se ha producido un aumento de 2.000% en el número de venezolanos que han solicitado el reconocimiento de condición de refugiado en todo el mundo desde 2014, principalmente en países de América Latina y aunque más de 94.000 nacionales lograron acceder a los procedimientos de determinación de la condición de refugiado en 2017, otros con necesidad de protección optan por diversas alternativas de residencia legal, que otorgan el derecho al trabajo, acceso a la salud y la educación.

Sin embargo, ACNUR ratifica que cientos de miles de venezolanos permanecen sin documentación o permiso para residir legalmente en países de acogida, situación que los expone a la explotación, la trata de personas, la violencia, el abuso sexual, la discriminación y la xenofobia. Este organismo pide a los países tener mayor sensibilización en atención a un complejo contexto político y socioeconómico que vive Venezuela en estos momentos de su historia.

Consideraciones Finales

La migración venezolana sufre una transición, pues pasa de ser un país receptor durante buena parte del siglo XX, a uno emisor, desde comienzo del siglo XXI, destacando dentro de este último proceso, la pérdida de su capital humano, población económicamente activa, con alto nivel de calificación y

experiencia, con formación a nivel de pre y posgrado, empresarios e incluso, migración de retorno de aquellos que eligieron a esta nación para desarrollar su proyecto de vida y que hoy se devuelven a sus países de origen.

Hasta el año 2019 se registra una migración masiva de venezolanos, que tiene detrás la desesperación y altos niveles de estrés por lo que sucede en el país, seguido de la violencia e inseguridad, poco poder adquisitivo, inflación, desempleo, escasez de alimentos y medicamentos básicos, sumándose a ello la crisis política e institucional; que denotan la falta de condiciones mínimas de vida, que violan los derechos humanos y se considera un crimen de lesa humanidad, que cataloga a la migración como forzada.

El panorama expuesto, muestra los rasgos de una crisis humanitaria de gran relevancia, pues Venezuela está hipotecando su desarrollo con este fenómeno social que exige acciones urgentes para aliviar el sufrimiento de quienes huyen del país y el impacto de este fenómeno en los países receptores. Cabe resaltar, que a corto plazo no se evidencia cambios que se materialicen en la aplicación de políticas públicas, programas o instrumentos de carácter público orientados a revertir la intención de emigración de la población venezolana.

Analysis of Psychophysical Predispositions of Persons Performing Tasks of Security Control Operators

Piotr UCHRONSKI

WSB University, Department of Transport and Information Technology, POLAND
E-mail: uchronski.p@gmail.com, puchronski@wsb.edu.pl)

Abstract

An airport is a specific place that requires employees performing tasks related to air operations to possess specific skills and specialist knowledge. However, the knowledge and practice learned are not the only factors conditioning the correct performance of official duties, and thus the safety of flight operations. This relationship is particularly noticeable during the security check of persons and luggage carried out by the airport manager. These tasks are performed by security control operators, who also have an entry on the list of qualified security guards. This work shows that in addition to the professional qualifications necessary to perform the abovementioned profession, the psychophysical predisposition of such a person is also very important. The paper presents the results of research carried out using a specialized tool which is the Polipsychograph. The research was attended by people who perform the tasks of a security control operator on a daily basis. These are people with many years of experience in performing security checks and having all the required training and certificates entitling them to this work. Notwithstanding the foregoing, the study also involved totally outsiders, working in a completely different nature and not taking part in the process of controlling people and luggage. These two professional groups were then subjected to a comparative analysis to identify the characteristics of people working in airport security.

Keywords: airport, security control, psychophysical predispositions

Introduction

Screening of people and baggage at the airport is one of the necessary requirements for using public transport by air. This obligation is a kind of ailment for a passenger who, when choosing an air transport, is sometimes forced to submit to very restrictive requirements specified in national and EU regulations regarding civil aviation security. This inspection is carried out using specialized equipment, whose effectiveness often determines the quality of the inspection. Advanced technical devices not only support human work, but also significantly affect airport capacity. It should be noted that the main purpose of the security check is to prevent prohibited items and prohibited substances from being carried on board aircraft. The catalog of these things was quite precisely defined in the EU 1998/2015. These include:

- pistols, firearms and other devices that fire projectiles - devices that are capable or appear capable of being used to cause serious injury by firing a projectile,
- stunning devices - devices designed specifically for stunning or immobilizing,
- objects with a sharp point or sharp edge - objects with a sharp point or sharp edge that can be used to cause serious injury,
- working tools - tools suitable for use to cause serious injury or threat to aircraft safety,
- blunt tools - items that can be used to cause serious injury when used to hit,

- explosive materials and devices, and incendiary substances and devices - explosive materials and devices and incendiary substances and devices that are capable of or appear capable of being used to cause serious injury or threat to aircraft security.

The catalog of these items, however, is not listed in the Regulation in an enumerative manner, allowing the safety control operator (SCO) to assess whether a given object or substance may pose a threat to an air operation being carried out at a given time. Thus, the safety and security of passengers using this form of transport depends on the training and skills of SCO.

Security control is performed by security control operators - people with specific training dedicated to carrying out tasks consisting in screening luggage and controlling people entering the airport's protected areas. These skills are confirmed by the state certificate issued by the Civil Aviation Authority.

Therefore, the Security Control Operator, in addition to formal powers, also has specialist theoretical knowledge allowing it to analyze situations that may occur at the security checkpoint and to make a decision based on applicable legal regulations and the so-called Heuristics. Heuristics play an increasingly important role in the way people work. It involves the use of practical rules of conduct based on experience and the use of simplified methods of assessing the situation, allowing to save time and resources used to solve unstructured problems.

Formal and legal powers to perform security checks are not the only factors conditioning obtaining the required effectiveness of tasks performed by the security check operator. In addition to theoretical knowledge, the attitude of the employee to his duties, his experience and level of training are also very important. The topic of effectiveness of security controls in the context of employee selection was presented in detail in [Skorupski, Uchroński, 2016].

Nevertheless, an important argument deciding about the selection of candidates for the security control operator are their psychophysical predispositions. this topic, which is very sensitive from a social point of view, is bypassed in the literature, inclining mainly towards the assessment of the work of active security control operators who are already performing their duties. This article is an attempt to examine the psychophysical predispositions of both active SCOs and potential candidates for SCO who have no experience in civil aviation security. This approach may allow for so-called pre-selection of candidates for pkb, selecting from among them only those who have the best prognosis in the scope of possessed abilities of analyzing the x-ray image and considering potential problems.

During security checks on persons and luggage, SCO is exposed to a number of external stimuli related to passenger service. Access control, preparation of the passenger for control, conversations are just a few of the many factors that significantly affect the way and effectiveness of security checks performed.

Especially in the studied area, the functioning of the Nideffer model can be observed, which divided human attention into four types: narrow, wide, internal and external. This model illustrates how a person functions when performing his duties. The predisposition areas listed above, in turn, significantly affect the psychophysical predisposition of employees performing tasks in the field of security control and the effectiveness of this control.

In order to examine the dependence of psychophysical predispositions of employees performing SCO tasks on the effectiveness of their control, tests were carried out with the participation of SCO actively working at security checkpoints. A specialized device was used for testing, which was designed to test people in the field of correct operation in an environment exposed to strong stress and time pressure. This device is a Polipsychograph.

Current state of research

Review of the literature dedicated to the control of safety of people at airports indicates the existence of several important research trends:

1. Analysis of criteria for evaluation of screening systems. The following are usually considered in this regard: the throughput of a security screening checkpoint, passenger comfort and efficiency in detection of prohibited items. This paper addresses the last issue.

2. Analysis of factors affecting the effectiveness of a security screening checkpoint. They are most often considered in qualitative terms. Our paper adds quantitative analysis to this research.

3. The use of various research methods to analyse the issue.

4. Taking into account the uncertainty of information in the analysis of a security screening system. It makes it necessary to select a proper research methodology. In this paper we use a fuzzy inference system since the authors consider it to be adequate to the nature of the problem.

Criteria for Evaluating A Security Screening System

Analyses of throughput at a security screening checkpoint often appear in the literature. The article written by Hainen et al. (2013) presents an analysis of factors that influence the time period spent by a passenger at a security screening checkpoint. Kirschenbaum (2013) proposed a different approach to this problem; i.e. he analysed a passenger's individual characteristics that have an influence on throughput at a security screening checkpoint. Attempts are also made to produce alternative solutions that would combine all kinds of passenger and baggage screening (Yildiz et al., 2008). A review of such new methods can be found in (Leone & Liu, 2011). One of the more interesting methods is the one whereby a risk level is dynamically assigned to a passenger (Nikolaev et al., 2012; Nie et al., 2012). Wieneke and Koch (2009) proposed a method which involves automatic tracking and the classification of passengers passing through an airport by using many chemical sensors. This method allows one to locate threats and quickly notify security screeners. Statistical studies on the time that passengers have to wait at a security screening checkpoint are presented in Barros & Tomber (2007).

The comfort and satisfaction of a passenger who is subjected to security screening at a security screening checkpoint was studied by Alards-Tomalin et al. (2014). Their research showed that the type of activities that security screeners undertake has a great impact on the subjective perception of security in aviation. It is mandatory for all passengers to be screened by the WTMDs that are analysed in that paper. Gkritza et al. (2006) have analysed the impact of the type and intensity of the taken control actions on the subjective satisfaction of the passenger. It also depends on the level of awareness of hazards present in aviation as well as on cultural or religious background (Rusiłowicz, 2011). Also, the need to draw on the experience of other disciplines, e.g. medicine (Wetter, 2013), is emphasised.

Factors Affecting the Effectiveness of a Security Screening System

As Yoo & Choi's (2006) studies show, the human factor is of greatest importance as far as the effectiveness of screening at a security screening checkpoint is concerned. However, technical equipment, i.e. its efficiency and proper operation, are also very important. These aspects were tested in our paper in terms of their influence on the effectiveness in detecting prohibited items. They are important because they constitute an expensive element of an airport security system, and additionally, they are not always used effectively (Stewart & Mueller, 2014; Gerstenfeld & Berger, 2011). This is because it is easy to justify the costs of developing infrastructure related to security, but it is much more difficult to quantitatively determine the actual effect of such investments

(Stewart, 2010). Increasingly important role in security screening (also with the use of WTMD) is played by computer systems. So it is becoming increasingly important to raise questions regarding their resistance to external, unlawful interference with their structure. This matter has been discussed in the work by Wolf et al. (2014), which indicates the need to intensify the works to better protect against cyber-attacks. In general the problem of trusting the applied support equipment is analysed in greater detail in (Kirschenbaum et al., 2012).

Research Methodology

As for methodology, the process of passenger screening at an airport was analysed by using different methods; for example, Concho & Ramirez-Marquez (2012) proposed that a multi-objective evolutionary approach should be used. The effectiveness of screening as well as its cost and throughput at a security screening checkpoint were the criteria that they took into account. In (Akgun et al., 2010) an interesting model was presented in which the vulnerability of critical infrastructure, which also includes airports, to terrorist attacks was examined. The proposed approach was called FIVAM (Fuzzy Integrated Vulnerability Assessment Model). It is based on the theory of fuzzy sets and is focused on searching for gaps hidden in the system, resulting from its internal functional relationships. In turn, in (Liou et al., 2011) it was proposed to use the rough sets based on dominance to examine the service systems at airports. The basis of the developed model is formed by a set of decision rules in the form of "if ... then ...” statements. Similar rules but in the form of fuzzy conditional sentences are used in this article. Oliva, Panzieri & Setola (2011) carried out studies in the area of analysing the security of critical infrastructures by using fuzzy set methods.

Research tool – Polipsychograph

The tests were carried out using a system designed to design and carry out psychological tasks testing human mental, cognitive and motor skills in connection with the assessment of his professional capabilities or diagnosis of possible deficits of various origins. This system is used to measure psychological and psychophysiological variables of the examined unit. Tested abilities are recognized in the context of accompanying reactions and physiological processes manifested by skin-galvanic reaction, depth and frequency of breathing, pulse frequency - which allows additional interpretation of the obtained data. In both cases, apart from a ready set of test and rehabilitation tasks, it is possible to design your own test or rehabilitation tasks (due to their content, form, display rhythm, etc.). Thanks to this, it is possible to individualize the diagnostic or rehabilitation process. Therefore, the device can also be used to test research hypotheses in scientific research in the field of psychophysiology.

The system consists of three basic elements. They are:

- Computer (portable or desktop).
- Control program.
- Psychophysiological State Meter..

In the system, the computer performs the functions of programming and controlling both the diagnostic and therapeutic process. Its software enables flexible selection of test tools depending on the sphere studied and is open. This means that they can be gradually extended with new applications or existing ones can be modified. Picture 1 presents the device visualization.

Fig. 1: Illustrative image of the Polipsychograph. Source: own.

5 SCOs were tested - experienced people who have been working directly for pkb for at least several years, carrying out tasks related to the security control of persons and luggage. This work requires them to have certain skills that enable them to fulfill their basic duty, which is to ensure the safety of air operations. One of these skills that is required of SCO is, therefore, the divisibility of attention that NIdeffer illustrated in the manner specified in Table No. 1.

Table 1: Divide the attention according to Nideffer. Source: Nideffer, 1994.

		The direction of concentration	
		external	internal
Area of concentration	wide	**wide external** Used in the quick assessment of the situation, e.g. where the threat is located.	**Wide inner** Used in the analysis of current work and its planning. e.g. analyzing why an object was not detected**.**
	Narrow	**Narrow inner** Focus only on one or two external matters**.**	**external narrow** Used when visualizing future activities and controlling emotions, e.g. controlling stress levels

When analyzing an overexposed image, in many situations there is a change in concentration (switching attention) from one to the other. According to Nideffer, concentration control means control over both its direction and scope. When SCO has problems, e.g. of a personal nature, it means that he is using the wrong way to concentrate in a given situation.

Effective concentration means using the right kind in a given situation. SCOs lose focus when they pay attention to the wrong object during an inspection. The relationship between the scope of attention and the degree of concentration is shown in the chart below (Unesthal, 1988).

Fig. 1: The relationship between the scope of attention and the degree of concentration is shown in the chart below

Research

Tests with the participation of SCO, were to determine the level of concentration required for the implementation of tasks by SCO on the one hand and indicate the necessary psychophysical predisposition of employees, and on the other to determine the relationship between the results of tests carried out and the level of achievable effectiveness of baggage security check. The effectiveness of security controls of individual people participating in the tests will in turn be verified on the basis of the HMC (Heimann Management Console), where the results of all SCOs are verified. Based on this tool verifying the quality of SCO work based on the virtual projection of images of prohibited items (TIP – treat images projection) displayed in real time on the screen of the monitor supporting the RTG device [Uchroński 2019], the people responsible for the quality of the airport security control carried out, gain knowledge in the field of skills, and thus the effectiveness of operators during their work.

Tests were carried out in the following areas verifying behavioral impact on respondents:

- addition test (three tests with varying degrees of difficulty),
- numbers test (consisting of searching on a matrix of numbers indicated by the system),
- complex coordination test (consisting in selecting the correct result of adding two displayed digits as soon as possible),
- simple coordination test (consisting of verification of motor coordination by pressing the key assigned to the number displayed on the monitor screen),
- line test (based on determining the number of lines displayed on the monitor), literal memorisation test (based on memorizing a string and restoring them from memory).

These tests, with the exception of the line test, required SCO to work on time, which simulated the real working conditions of SCO operating under continuous time pressure and the associated stress. The line test, in turn, provided information about SCO in the field of perception skills in space. This is an extremely valuable ability, because the main task of SCO is to analyze the image of x-rayed luggage. The efficiency of SCO's work also depends on this skill.

The topic of SCO predisposition testing (or SCO candidates) is often overlooked in the recruitment or training of security personnel. Attention is paid here mainly to the physical characteristics (fitness) of the candidate and possible skills to distinguish colors as a necessary element conditioning the possibility of analyzing x-rayed luggage. Both in practice and in literature there is a lack of a method for pre-selecting candidates for SCO, which would forecast the achievement of the required effectiveness of baggage screening. This action would allow for a precise selection of the staff responsible for airport security in the field in question, on the other hand, for delegating employees duties in accordance with their capabilities resulting from their psychophysical limitations.

This proposal proposes a method for assessing both SCO and SCO candidates.

Table 2 summarizes the results of tests carried out with the participation of security control operators.

Table 2: List of test results carried out with the participation of security control operators. Source: own study

	SCO 1	**SCO 2**	**SCO 3**	**SCO 4**	**SCO 5**
Test 1	30,36	13,53	17,15	13,92	12,30
Test 2	12,04	16,34	14,78	15,33	8,99
Test 3	19,96	20,13	22,93	18,05	15,65
Test 4	54,41	36,59	57,30	35,43	59,25
Test 5	59,86	59,95	59,96	59,93	59,96
Test 6	36,93	47,85	45,49	43,76	37,21
Test 7	59,80	59,91	59,93	59,89	59,95
Test 8	101,60	159,30	177,09	203,31	124,43
average	46,87	51,70	56,83	56,20	47,22

As we can see, the biggest differences in the time necessary to perform a given test are visible during test 4 and test 8. Test 4 (number test) required spatial perception skills from employees. They were supposed to find on the matrix of numbers the number indicated by the test program.

Analyzing the results presented in Table 2, 2 people coped with this task best, achieving a time almost twice as fast as the other SCOs (SCO 2 and SCO 4). On this basis, it can be concluded that these people (SCO 2 and SCO 4) stand out from the others by their spatial analysis ability, thus they will work more efficiently in pkb by analyzing the content of x-rayed luggage. Other people (SCO 1, SCO 3, SCO 5) also performed the test correctly but they already needed about 40% more time to perform this test.

The graphic representation of the results of these tests is shown in Fig. 2

Fig. 2: Graphic representation of test results. Source: own study..

Equally significant differences can be observed by analyzing the results of test No. 8. Here, the operators had to demonstrate the ability to remember a literal. Their task was to memorize a sequence of numbers and then, from memory, to map their order as displayed on the device's monitor. During this test, SCO 1 and SCO 4 deserved distinction, who completed this task in the shortest possible time. This test, in turn, showed the impact on the security control process of the ability to remember the image presented on the pp monitor. This is an extremely valuable and useful skill in the case of manual control of luggage, when the SCO physically searches luggage, which as a result of its analysis have a reasonable suspicion that it contains an object or prohibited substance. On the other hand, memory trained in this way allows you to quickly remember the numerous procedures and order of tasks performed by SCO. This, in turn, minimizes the risk of making wrong decisions and committing an error resulting in a decrease in the effectiveness of air operations control.

Correct answer to test tasks

However, in order to be able to reliably assess the quality of tests carried out by SCO, in the context of their actual predispositions, it is necessary to relate the results of the time needed to complete the tests to their correctness. These relationships are presented in Tab. No. 3. Incorrect answers can be seen when performing tasks in the case of 4 tests, while in test No. 1 only one employee marked the wrong answer, which can be statistically treated as a margin of error. A similar situation occurs in the case of test No. 3. Both of the above mentioned tests concerned the summation of numbers displayed on the PP monitor. In the second case, employee No. 3 was mistaken twice, which may suggest a negative impact of stress on the correctness of the answers given, and thus on the number of errors that the employee may make while performing official duties at security checkpoints.

Tab. 3: Correctness of tests performed. Source: own study.

	SCO 1	SCO 2	SCO 3	SCO 4	SCO 5
Test No. 1 [max 5]	4	5	5	5	5
Test No. 3 [max 10]	10	10	8	10	10
Test No. 6 [max 9]	7	7	9	9	8
Test No. 8 [max 14]	4	11	10	11	11

Particularly noteworthy are the results of test No. 6 (line test) and Test No. 8 (literal memorization test). As we can see in Tab No. 3, these tests gave the most difficulties to the test participants. Only two respondents (SCO 3 and 4) provided correct answers to all tasks specified in test No. 6. However, he completed the test the fastest (SCO 1 and 5), with 9 out of 9 possible points, they achieved 7 and 8 points, which, given the nature and duration of the tests, is satisfactory.

Test No. 8 required SCO to demonstrate the ability to retrieve from memory the sequence of numbers indicated by the system. This test was to show the impact of short-term memory functioning on the process of detecting prohibited articles. As can be seen in Table 3, 4 SCO's (SCO 2,3,4,5) approached the maximum number of points possible to obtain. SCO No. 1 achieved the lowest number of points, which can be interpreted as uncertainty in operation in practice as a result of improperly fixed material. Graphic representation of the results of the tests is shown in Figure 3.

Fig. 3: Graphic representation of the results of the tests carried out.

It should be noted that SCO took part in the test with at least several years of experience and has extensive substantive and practical knowledge.

Effectiveness of detection of prohibited articles

The results of their work are verifiable in a dedicated HMC system that provides supervisors with a daily knowledge of the level of detection efficiency. On this basis, we can assess the existence of dependence of tests carried out using the Polipsychograph and the predispositions of the examined

people on the effectiveness of detecting prohibited items hidden in the luggage of passengers. Table 4 presents the results of this assessment provided by the HMC system.

Tab. 4: Results of the assessment provided by the HMC system. Source: own study.

Screener	Pd	Pfa
SCO 1	0,87	0,03
SCO 2	0,90	0,01
SCO 3	0,79	0,02
SCO 4	0,81	0,06
SCO 5	0,91	0,01

Analyzing the data, it can be seen that among the subjects deserved distinction two SCO (SCO 2, SCO 5) who achieve the highest detection rate (PD) with the lowest error rate indicator (PFA). These relationships are presented in Figure 4.

Fig. 4: Dependence of the detection of prohibited articles on the indicator of the amount of misinterpretation of the image. Source: own study.

Analyzing the results of tests carried out using the Polipsychograph and comparing them with the real results of the effectiveness of SCO in detecting prohibited articles, we can conclude that the psychophysical predisposition of persons performing tasks related to security control is one of the key elements determining the opportunity to work in this profession.

The research showed precisely that the respondents are characterized by very similar psychophysical abilities. It is justified because all these people, as working on the basis of legal regulations regarding the protection of persons and property, and having the so-called entry on the list of qualified security guards (in accordance with the Act on the protection of persons and property), undergo a series of psychological and physical examinations, based on which they receive the right to have at work all types of direct coercion measures.

Security guards undergo detailed medical examinations that include the following:

1. general examination of the state of health, including assessment of the hearing organ and balance, the circulatory system, the musculoskeletal system and the nervous system;

2. specialized tests:

- ophthalmic, in the field of eye assessment, in accordance with the regulations issued on the basis of art. 15 paragraph 7 of the Act of 21 May 1999 on weapons and ammunition (Journal of Laws of 2012, item 576 and of 2013, item 829),

- psychiatric, in the field of mental disorders referred to in the Act of 19 August 1994 on the protection of mental health (Journal of Laws of 2011 No. 231, item 1375), as well as disease states and disorders of psychological functioning specified in provisions issued based on art. 15 paragraph 9 of the Act of May 21, 1999 on Weapons and Ammunition;

3. other specialist examinations and auxiliary examinations, if a physician authorized to conduct a medical examination, hereinafter referred to as an "authorized physician", finds that they are necessary for the correct assessment of the health condition of the person applying for an entry or who has an entry on the list of qualified physical protection workers .

In addition, each employee undergoes at least every 3 years detailed psychological examinations including:

1. Rating:

- intellectual skills,

- personality, including functioning in difficult situations,

- level of social and emotional maturity;

2. other psychological tests, if a psychologist authorized to conduct a psychological examination, hereinafter referred to as an "authorized psychologist", finds that they are necessary for a proper assessment of the psychological functioning of the person applying for an entry or who has an entry on the list of qualified physical protection workers.

(source: Regulation of the Minister of Health of 19 December 2013 on medical and psychological examinations of persons applying for an entry or having an entry on the list of qualified physical protection workers).

Comparison of SCO and Civilian Employee Test Results

Our research has also shown that, in addition to common predispositions to perform a specific profession, directional and specialist training and practice are very important. These trainings allow you to train the senses that are most used at work. To confirm this thesis, five people unrelated to civil aviation security were tested on the Polipsychograph, and their tasks mainly include ground handling of aircraft. The results of these tests are shown in Table 5.

Tab. 5: Test results of persons who do not carry out security control tasks. Source: own study.

	effective time 1	effective time 2	effective time 3	effective time 4	effective time 5
Test 1	20,21	17,23	18,44	18,06	17,79
Test 2	15,90	17,52	15,15	11,35	18,13
Test 3	30,29	19,38	21,67	26,65	42,06
Test 4	92,33	48,91	44,74	54,87	60,99
Test 5	59,84	60,02	59,97	59,96	60,00
Test 6	44,80	49,40	57,74	45,06	83,04
Test 7	59,86	59,93	59,98	59,88	59,92
Test 8	212,69	232,03	253,68	152,18	256,19

Based on the data from Tab. 5, we can conclude that there is a large discrepancy in the time-movement coordination of people who perform SCO tasks and those whose work does not consist in analyzing an x-ray image using an X-ray device. In particular, these relationships can be observed during activities that require the involvement of at least several areas of perception.

The biggest differences can be observed in the examined area by comparing the results of tests No. 4,6,8 where correct movement coordination with simultaneous time pressure and the need for mental analysis of the given area were important. In addition, test No. 8 showed how important for SCO's work is spatial perception, allowing for proper image analysis. Fig. 5 graphically illustrates the abovementioned depending on:

Source: own study.

Fig. 5: Results of tests of persons not carrying out tasks related to security control.

The research also confirmed that, in addition to the natural skills possessed by SCO and those acquired during training with the use of specialized equipment, non-substantive elements

significantly affecting the way and quality of SCO's work are very important. These elements, described in detail in [Skorupski, Uchroński], are also the attitude of the employee to the tasks he performs. This attitude, associated with employee motivation, determines the existence of so-called human factor, which is still the main reason for the occurrence of broadly understood inconveniences and errors that are an indicator of the quality of work performed and assessment of the operation of the airport security system.

Source: Own study.

Fig. 6: Comparison of time to complete tests carried out by SCO and other employees.

Fig. 6 shows the results of comparing the effective time of tests performed by both SCO and other employees. As we can see, SCO's testing time is on average about 36% shorter than the same tests performed by random people. It should also be noted that all persons participating in the test had not previously faced the same or even similar psychophysical predisposition test, and their selection was completely random.

Therefore, during the tests, not only the time of completing the test tasks was compared, but also the level of errors made by both SCO and other people not related to this profession. The test results are presented in Fig. 7.

Fig. 7: Comparison of the number of errors made during tests by SCO and other employees. Source: own study.

As we can observe, only in one case the test results are more favorable for an employee not related to security control. In other cases, the unit number of errors made by SCO is definitely smaller or the same as the number of errors made by other employees. The average difference between one professional group and the other in this respect is slightly more than 3% in favor of SCO. This chart, in addition to the presentation of the SCO skills themselves in solving imposed tasks, also shows the impact of external factors on the quality of work done and their resistance to stress caused by time pressure and awareness of the assessment they are subjected to. This issue is extremely important from the point of view of civil aviation security, has been described in detail in [Uchroński, 2019].

Not without significance for the results of the tests carried out is the fact that security control operators additionally undergo detailed medical examinations that allow them to determine their psychophysical predisposition to perform the tasks specified in the Act on the protection of persons and property. It is a kind of pre-selection of candidates for security officers, i.e. people who use the broadly understood means of direct coercion in carrying out their tasks.

Summary

Resistance to stress and the ability to think analytically and to properly assess a given situation are therefore necessary for making the right decisions that often determine the health or life of protected people. Such processes occur during security checks on persons and luggage. The scope of the work touches a completely new area for the authors in the field of psychology. This is the psychology of work, which plays an increasingly important role in the work of people performing tasks for specific professional groups. SCO's work is undoubtedly one of those vulnerable professions where proper selection of staff and understanding by superiors of the mental, social or sociological processes occurring among subordinate employees can determine airport security, and thus air operations. Nevertheless, it is worth considering the obvious conclusions of the research. The main starting point for the conducted research was the inability to prepare people for the tests. The test results have clearly shown that with virtually the same number of errors made by both professional groups, SCOs are able to work by more than a third faster and more efficiently compared to other professional groups for which there is no requirement to carry out detailed verification of their predispositions. Of course, this is not a rule, because among such people there are certainly people who meet the profile compatible with the appropriate security guard, but from the point of view of airport security and its capacity, it is necessary that only such employees entrust the duties of a security control operator.

Abstract

The global logistics infrastructure and the transport services market are developing in the context of international integration processes. The impact of these processes on freight traffic is associated with nations' desire to better integrate in production by building cross-border production networks and manifests in the creation of integrated transport and logistics systems. The global logistics management system aims to respond in real time to market changes, make decisions about business and inventory risks, reduce distributors' costs, soften the supply chain and make the market reaction more flexible. Numerous economic ties between countries stimulate mutual interest in creating an effective integrated production and logistics infrastructure with standardized elements. The processes of international economic integration have become one of the most important factors in the transformation of the global logistics system. Thus, in the context of globalization, the production and logistics infrastructure and logistics services market directly affect the level of economic development of countries, defining conditions of entrepreneurship development. The modern, hypercompetitive market of logistics services is entered by new players, suggesting that existing companies undergo transformation and develop innovative business models, which at the current stage is impossible without the use of advanced digital technologies.

Keywords: Logistics, Globalization, Regional Macrologistic Systems, Digital Technologies.

Introduction

The relevance of studying the development of production and logistics systems in the context of globalization is determined by the fact that the globalization of international economic relations presents new requirements for production and logistics infrastructure efficiency. The global logistics infrastructure and the transport services market are developing in the context of international integration processes. The impact of these processes on freight traffic is associated with nations' desire to better integrate in production by building cross-border production networks and manifests in the

creation of integrated transport and logistics systems (Polyanin et al., 2018; Pirogova et al., 2019; Plotnikov et al., 2019; Pollitt, 1999; Vertakova et al., 2019).

The global logistics management system aims to respond in real time to market changes, make decisions about business and inventory risks, reduce distributors' costs, soften the supply chain and make the market reaction more flexible. Numerous economic ties between countries stimulate mutual interest in creating an effective integrated production and logistics infrastructure with standardized elements. The processes of international economic integration have become one of the most important factors in the transformation of the global logistics system (Volkova et al., 2019).

The object of this study is the process of logistic globalization. The subject of the study is a set of factors for the development of production and logistics systems in the context of globalization. The purpose of this article is to analyze the features of the development of production and logistics systems in the context of globalization. Research objectives are formulated as studying the concept of a global logistics system, its role and importance; studying the features of the formation of regional macro-logistic systems; considering the use of digital technology in global logistics systems.

The concept of a global logistics system, its role and importance

Studies into the impact of globalization on today's market of logistics services reveal that in order to provide an advantage on the market today, a vendor must take into account the following factors while providing delivery services: timely service; environmentally friendly service; special terms; emerging technologies; corporate social responsibility; costs; quality of services; flexible schedules (Volkova and Plotnikov, 2016). Modern research identifies five key factors in the globalization of logistics operations: economic growth, reliance on the supply chain, regionalization of the market, technological progress, and deregulation of the economy. These factors are the driving forces that encourage firms to enter the global logistics services market (Volkova et. al., 2019).

Simultaneously, the desire for a company to expand its international operations is its desire to grow and survive in a competitive environment (Plotnikov et al., 2018). All these factors possess the properties of a driving force, and at the same time, there are the following motives for the behavior of companies: seeking economic growth and increased profits; good return on assets, optimization of financial costs; need to develop new markets to support growth; regionalization that brings about the reduction of trade duties, eased trade restrictions, common standards for transport documentation and common freight systems; striving for greater customer satisfaction; increasing the efficiency of companies by deregulating the sphere of finance and transport.

In the development of logistics, the modern stage is described as the stage of logistic globalization (Gedik and Turğut, 2017; Hayaloğlu , 2015; Majercak, 2020; Shumin and Hua, 2017). Studies show that the transition to the globalized economy means a new era in the development of capitalism which causes the expansion of commodity movement and creates demand for logistics services. The concept of "globalization" has two aspects. On the one hand, globalization is an objective process, the content of which is the growing interconnection and interdependence of national economies based on global markets for goods, services, labor and capital. On the other hand, globalization is an invisible force-majeure that imperatively nudges entities entering the global economic space to comply with established general technological, economic, legal, socio-political relations, norms and requirements.

The globalization of the development of logistics systems is also directly affected by the internationalization of economic activity (Vertakova and Plotnikov, 2019). Globalization is an entirely new level of internationalization of world economic relations, marked by tight competition and at the same time close collaboration. Global logistics can be defined as a phenomenon related to the strategy and tactics of building sustainable macro-systems linking business entities around the world on the basis of divided labor, partnership and cooperation in the form of treaties, agreements, masterplans maintained at the international level.

In the context of globalization, logistics is also an important means of reducing the costs of all types of resources, both in the production sphere and in the sphere of goods circulation. It thus becomes a means of making greater profits and ensuring that businesses remain competitive. Thus, the economic essence

of global logistics is to implement the goals and strategies of the entities of the logistics services market in which their interests manifest. The technological essence of global logistics is to reduce the operational costs of working time, shorten the production cycle as well as cut delivery times and, of course, material costs. The scientific and technical essence of global logistics lies in the fact that it is implemented based on information management technologies in the areas of production and goods circulation by optimizing information flows, as well as providing timely, complete and reliable information to customers (Desyatirikova et al., 2017; Dubovik et al., 2018; Polyanin et al., 2017). The socio-political essential feature of global logistics is manifested in the improvement of services, the elimination of customs, tariffs, taxes and other barriers to the movement of goods, services, capital and labor.

Having considered the essential features of logistics activity in the macroeconomic sphere, we can conclude that the essential basis of global logistics determines the globalization of relations between international participants whose economic activity is the subject of logistics management. The essence of global logistics as a special type of activity, in our opinion, is to ensure the optimal use of all resources of national economies and transnational companies interacting in a single global market space and increase their efficiency through the creation and use of international macro-logistic systems and centers, transport and telecommunication infrastructure, favorable international legal, customs and tax regulation of logistics flows.

Thus, the geographical expansion of the scope of logistics activities is associated with several external factors. The determining ones among them are growth in global volumes of commodity distribution; expansion of IT technologies and communications; regionalization; deregulation of the sphere of international relations; concentration of efforts and interaction of political actors at the global level. The most important internal factor in the globalization of logistics consists in the essence of the object of its activity, which is service. Logistic service can, on the one hand, provide profit to the supplier, on the other hand, it can reduce customers' costs for all types of business processes integrated into the supply chain.

Globalization creates new customer expectations and requirements for the logistics of all components of the reproduction process from sources of raw materials to end consumers, explained by increased volatility of crucial factors that affect the efficiency of their operations and services. The globalization of the world economy creates competition in commodity markets. Customers producing goods compete for the buyer and offer various benefits. For example, previously the buyer could change the loading order with a 10-day notice, but now almost half of the sellers let customers change loading orders a day before shipment or even later. Thus, operating conditions for providers are becoming more complicated.

In connection with the development of new forms of online trade, logistics companies feel the need to integrate their processes and systems both vertically and horizontally, improve coordination, and increase the level of mutual trust. Customers' expectations become an important factor impacting the global market of logistics services, forcing providers to increase the level of logistics services from 3PL (integrated logistics outsourcing) to 4PL (integrated logistics outsourcing) and 5PL ('virtual' logistics). Thus, the system of business relations in logistics contains contradictions that give rise to changes in all of its areas, turning logistics into a globalized structure.

We can distinguish the following main trends affecting the development of logistics systems in the context of globalization:

1. Forming demand. Demand for any product is significantly increased due to increased mobility, unhindered movement of goods and services and access to better logistics infrastructure. The expanded trade and logistics infrastructure mean that customers and users can be served anytime, anywhere, thus helping increase the company's sales.
2. Reducing the cost of doing business. Enhanced logistics infrastructure helps keep business value low, as transporting products from one place to another becomes virtually uninterrupted due to improvements in port, rail network, road and civil aviation infrastructure. All this is

undeniably important, because delays over long distances not only increase the trading cycle, but also worsen the quality of some goods and lead to lower prices in the markets.

3. Connecting customers around the world. Many countries, whose industry has many potentially effective areas, such as electronics, mechanical engineering, microchip design, automotive components, etc., can only contribute to world markets if they improve their trade logistics infrastructure and network systems. Otherwise, the business opportunities of these countries may get trampled by competitors from other countries with a more developed logistics infrastructure.
4. Fast economic growth. In the development of any country, economic growth plays a vital role, and today this is largely due to the expansion of trade and logistics infrastructure, which creates demand in the economic system for various products. Improving the logistics infrastructure not only contributes to the growth of the state economy, but also helps state enterprises achieve sustainable high performance in international markets by expanding the process of trade supplies.
5. Timely provision of critical supplies. An efficient logistics system in international trading operations helps companies deliver products to their international customers on time. Due to the complex functionality of the logistics system and the long distance between two countries, the problem of security, care and shipping times often causes nightmares for suppliers, especially in the case of perishable and expensive products and goods with expiration dates. Examples include newspapers, flowers, and seafood.
6. Bridging the gap between supply and demand. This phenomenon is one of the main problems that any company faces in international markets at all levels - from finding raw materials to work in progress and distributing it among consumers. Thus, better transportation of goods and timely delivery of products help fill the gap between the demand and supply of a product. Improved communication using road, rail, runways and the sea helps companies efficiently allocate their resources.

Thus, the concept of 'global logistics system' can be defined as follows: this is a new stage in the development of logistics activities that meets the imperative challenges of globalization to increase the efficiency of the reproduction process (production, distribution, exchange and consumption) through the creation and development of global interstate transport and logistics, distribution and other macro-logistic systems.

Features of the formation of regional macro-logical systems

The macro-system of logistics in the broad sense is a socio-economic system, the subjects of which are united by the common interests of optimizing economic flows in order to minimize costs and expenses. At present, building management of economic systems based on a macro-logistics approach is gaining popularity, since any system has a certain degree of entropy in the areas of management, technological process, service, information and finance, all of which is significantly decreased thanks to an integrated management system. Macro-logistics system is a structural and compositional integrity, united by common strategic goals and objectives, functioning in the market of transport and logistics services for the supply (development, overhaul) and promotion (repair and maintenance) of the finished product (road) to users based on the logistics concept. At the same time, the road transport sector is expanding to the boundaries of economic research, forming into a complex logistics system with a multilayer flow process.

The theoretical basis for constructing such a macro-logistic system is provided by the reproductive approach to production resources. Moreover, the logistic approach to the activation of reproduction processes allows for the intensive development of system links. Characteristic features of such an organization are self-development stemming from the cyclical nature of the reproduction process and adaptability to changes. Emphasis in the development of this system is made on qualitative parameters. Thus, the boundaries of the regional macro-logistic system depend on the state and degree of development of the transport and logistics services market and are determined by the cycle of

reproduction of roads and the economic cycle of their operation. It should be noted that the division into cycles is rather arbitrary and is designed to separate the production and technological processes of the road sector from the scope of circulation of its products.

During operation, the state of the road is constantly changing both technically (the state of the roadway, roadsides, artificial structures, etc.) and in the economic sense (dynamics of traffic volumes, freight and passenger traffic, composition of traffic flow, etc.). As a result, periodic fluctuations and changes in transport and operational indicators occur within the regional organizational and economic cycle of road operation. Of importance are the changes that occur during the operation of roads while providing road support for the transportation process, aimed at creating the necessary conditions to satisfy the need of all sectors of the national economy in road transportation of goods and passengers with minimal time and resources. Having extrapolated the traditional stages of capital movement in the sphere of circulation to a logistic facility that is a highway, we can state the presence of traditional functional forms and stages of circulating assets turnover:

- monetary – flow processes of acquiring material, technical and labor resources – as part of the scope of circulation;
- production – flow processes of construction and installation works on the road – reproduction;
- commodity (sale of finished products) – flow processes of road operation – another part of the scope of circulation.

At the end of the generalized flow process, the money received from the operation of roads is returned to the budget in the form of tax revenues, acquiring its original cash form. At the same time, the most specific and important flow process of the sphere of circulation is the implementation of transportation process on roads, ensuring the involvement of not only finished products of the road sector, but also products of other industries in the national economy. The model of a regional macro-logistic system is represented as a set of functionally interconnected blocks out of which logistic flow processes are synthesized. This representation allows for providing improved organization of stream processes of reproduction and circulation at all levels (micro-, meso-, macro-) in the road sector.

Logistics has many directions (e.g. procurement, production, marketing, etc.), and considering each of them significantly changes the content of the functions implemented during the construction, reconstruction, overhaul, repair and maintenance of roads. The logistics object also changes depending on the key positions of consideration, operating interests within the scope of marketing, management, financing, and technological processes. At the regional macro-level, the main thing is to correctly formulate the goals of logistics optimization, assessing the needs for their implementation, without being limited to solving problems of material and technical support and transportation of goods.

The results of the regional macro-logistic system are evaluated from the standpoint of integrity as final industry results. Hence, the concept of the result for logistic systems of different levels and scales will be transformed depending on the complexity of their internal structure. The goals of the macro-logistic system are assessed based on whether planned strategic goals of regional programs for the development of the transport complex have been achieved and whether major operational processes (reconstruction, major repairs of roads) have been optimized. Setting strategic goals is associated with decisions with long-lasting consequences; cancelling or correcting these decisions would entail additional costs and losses in the national economy.

Most current configurations of regional transport and logistics systems no longer meet modern requirements. In the traditional scheme of regional transport and logistics systems, there is mainly a direct interaction of each demand point with the source of goods flow serving it (Fig. 1).

Figure 1: Scheme of the raster structure of regional transport and logistics systems

Given that the logistics network consists of many links interrelated by both main and associated flows, separate supporting network nodes can be built in order to project an intermediate structure between supply and demand. As a result, the demand of nodes at different levels of regional transport and logistics systems is supplied by the source through auxiliary structures. Moreover, at the axial level of the regional transport and logistics systems, a scale effect is realized, as measured by the discount coefficient of the total transport costs within the system.

In contrast to the already widespread scheme of a star-shaped regional transport and logistics system, which has one or two central support nodes or 'hubs', the optimal configuration looks as follows (Fig. 2). In this scheme, one can distinguish 'hubs' – central support nodes and 'spokes' – regional points of departure/destination. Support nodes with connecting arcs represent the regional transport and logistics system and are defined as the axial level; the rest of the system refers to the level of the spokes. With respect to any departure/destination route, an element of the axial level (a hub or an axial arc) is present, in contrast to the raster structure, where any pair of system nodes is connected directly.

Figure 2: Scheme of the satellite-like regional transport and logistics system

Organizational actions in system objects, united by shared target results, give rise to flows and the need to optimize the processes occurring in them, which is a function of logistics. In variant study of ways to achieve the strategic goals of the macro-level, economic indicators are formed that determine the need for various types of resources. This is the origin of the logistics flow. The ongoing rationale for investing in construction forms the primary information and financial flows, which are still abstract but begin their directed movement towards the consumer. Progressing through the levels of the regional macro-logistic system, information becomes detailed, gets used as input by various software products, processed and output as valuable data for users. Financial flows from the results of preliminary calculations of efficiency are expressed as cash settlements between subjects of industrial relations. The material flow is formed much later, only when implementing specific project decisions necessary to achieve the goals of the macro level.

In the macro-environment, abstract flows without a material basis (informational, financial flows) are primary, which makes it possible to make economically sound organizational and production decisions in the future. Subsequently, these flows must be structured into two components, one of which is transformed into a material flow, acquiring material form, while the second one continues its movement, carrying out its substantial support during the construction, reconstruction, and overhaul of highways.

After putting the finished object into operation, the material flow ceases to exist in the original form of original material resources, becoming the material basis of the structural parts of the road, thereby continuing its functioning in the form of a finished product at the time when it is brought it to users (the stage of road operation). Let us limit this period to the time when it becomes necessary to increase the throughput and carrying capacity of the road. It should be noted that at the same time, relatively small manifestations form within the material flow which function during maintenance and repair of roads, and it is impractical to consider them at the macro level.

Here, the role of financial and information flows increases again. Road tolls and other payments and deductions established by law form the road fund, creating the basis for implementing strategic goals of the macro level. Information flows, functioning both in the environment of the road economy and in its external environment, synthesize certain information products (road measuring stations, GPSS, etc.) that help optimize the movement of transport and logistics flows on roads and reduce costs for other sectors of the economy.

Thus, two kinds of flows exist in the regional macro-logistic system (abstract and material), which is its distinctive feature and should be considered when organizing logistics systems at other levels. Optimization of the development of industries in the national economy is inextricably linked with a focused and comprehensive presentation of flow processes in the road sector, which is possible only under the condition of organizational, technological, economic and informational unity. The increased importance of aggregate results should be taken into account when solving large-scale tasks at the macro level. With the functioning of the macro-logistic system, it is possible to improve many interconnections that are based on mutual dependence and necessary interaction of various organizational structures in the performance of the logistics process.

The Use of Digital Technology in Global Logistics Systems

Innovation and adaptation of advanced technologies are key elements in the process of developing global logistics systems. Modern technologies used in the management of physical flows in the supply chain can be divided into two groups depending on the estimated time of their adoption (Table 1). Technologies that will be used in global logistics systems in the next five years belong to the first group, and those that will be used in the more distant future form the second group.

Table 1: Technology Trends in Global Logistics

	Relevant within <5 years	Relevant in > 5 years
Technological trends are presented according to their importance for the logistics services industry from the most important (potentially destructive) to gradual improvements.	Robotics and automation. Internet of things. Cloud logistics. Big data analysis. Augmented Reality. Inexpensive sensor solutions.	Self-driving vehicles. Electric cars. Artificial Intelligence. 3D printing. Unmanned aerial vehicles. Blockchain. Next-generation wireless connectivity. Bionic boost. Computer vision.

Technologies listed in the Table 1, are used in logistics and supply chain management for servicing material flows in the physical world (i.e. as part of the supply system, production, intelligent warehouses, spare parts management, distribution to end consumers, autonomous logistics and transport) and to improve processes in the virtual world (i.e. integrated planning, analytics or ensuring the visibility of the goods throughout the supply chain).

Digital transformation, especially in the field of transport and logistics, helps the company remain competitive in a market that is constantly growing with the development of technology. Obviously, the widespread adoption of digital technologies in the field of transport and logistics is occurring as reliable new platforms solve problems associated with insufficient use of assets, increase supply chain efficiency, improve supply and demand balance, and improve overall connectivity and visibility. Thanks to improved operational connectivity and visibility between previously isolated systems, parties can easily connect to each other throughout the supply chain. With rapid advances in technologies such as artificial intelligence, biometrics, automation and GPS, a well-coordinated orderly work is expected in the global logistics industry. Below are some technological trends that can revolutionize the logistics industry:

1. Electric cars. Electric vehicles are energy efficient, economical and have lower maintenance costs compared to internal combustion engines. There are three main ways in which electric cars can enter the logistics industry: traditional manufacturers will either produce them themselves, or invest in batteries for them, or they will invest in startups that produce such electric cars.

2. Increasing digitization. New digital technologies in logistics help customers track their deliveries in real time and help optimize logistics operations. Moving from the age-old method of tracking orders on paper to a digital platform will leave less room for errors. For example, delivery based on mobile apps has made booking more convenient, reducing human intervention. In the future, robotic process automation may be used to implement full automation in logistics. The current workforce entering the market is technically savvy, which contributes to the growth of digitization in logistics. In addition, digitally accumulated data helps accelerate the implementation of actions related to customer needs, optimal routes, fuel consumption and turnaround time.

3. Blockchain technology and the Internet of Things (Plotnikov and Kuznetsova, 2018). Customers today are interested in ensuring that the supply chain process is transparent because they want to track the load in real time. Blockchain technology and the Internet of things are

capable of providing end-to-end cargo visibility. This will increase accountability and transparency in the supply chain process. Blockchain will help improve security, reduce fraud, facilitate seamless transactions, increase accuracy and ensure accurate data recording. The Internet of Things will create a connected environment that will have end-to-end visibility, optimal warehouse management and efficient fleet management using digitally connected devices. These devices can help you track routes, maintain schedules, monitor vehicle usage and reduce vehicle downtime. IoT systems using visual and acoustic fuel-powered sensors and GPS will help intelligent vehicles. The Internet of Things can also be used to predict the delivery time of each batch and for preventative maintenance to help avoid breakdowns.

4. Computer vision for classifying technology. Computer vision is an advanced algorithm by which a computer can see the real world based on the data that was entered it. This allows the computer to make decisions just like people would. In logistics, if the cargo is damaged during transit, the customer must accept it if it is within acceptable limits. However, if it is not within acceptable limits, the goods must go through a predefined process. This is due to the large number of decision-making gaps, since approval is required at several levels. Computer vision can be used to more effectively classify cargo damage. Labeled data can be entered into the computer, based on which it can tell whether the damage is within acceptable limits or not. This eliminates the need for consumers to obtain multiple permissions from different parties and speeds up the delivery process.

The use of advanced digital technologies in global logistics activities will be efficient if the following factors are considered: strategic vision of the entire global logistics network according to the system strategy, which is important for raising awareness of market changes; establishing open and direct links between the components of the global logistics network, as well as integrated planning and forecasting; focusing production at specific points serving a geographically expanded market; intensively using digital communication technologies in logistics, which minimizes reliance of companies on geographical location as a key factor in forming their business network; involving the human factor, which is important for teamwork and senior management throughout the process of changing global logistics associated with the decentralization of operations; reverse logistics, where digital technologies can significantly improve the management methods of reverse logistics companies, because information processes that occur after the product is consumed become more accurate and allow for controlling these physical flows; knowledge sharing and dissemination.

Conclusion

Thus, in the context of globalization, the production and logistics infrastructure and logistics services market directly affect the level of economic development of countries, defining conditions of entrepreneurship development. It is advisable to study how traditional logistics becomes globalized, bearing in mind that globalization of the sphere of logistics services is the result of the imperative impact of the objective irresistible force of globalization of the world economy. For sustainable development of territories, their transport and logistics should be seamlessly integrated and unified, and for this it is necessary to manage the development and functioning of the transport and logistics infrastructure as a macro-regional logistics system covering adjacent regions of the country.

The modern, hypercompetitive market of logistics services is entered by new players, suggesting that existing companies undergo transformation and develop innovative business models, which at the current stage is impossible without the use of advanced digital technologies. Today, logistics service providers are not limited to the implementation of one business model and simultaneously use different models, i.e. the real world of global logistics flows is thus complemented (and not replaced) with a virtual world in which advanced technologies provide customers with higher value logistics services.

Abstract

One of the key trends of the 21st century is the digitization of the economy. This trend is fundamentally changing many areas of the economy and society. It is transforming the Public Procurement System (PPS). The aim of the study is to explore the possibilities of increasing the effectiveness of PPS by digital methods. The subject of study is the digitization of Russia's PPS. The objectives are as follows: to consider the features of electronic document management in the field of public procurement; to study the essence and features of a unified information system in the field of public procurement; to analyze current trends in the development of digital technologies used in the implementation of public procurement. Research methods include the study of relevant legislation and literature, institutional and system analysis, comparison, and other. The analysis showed that the improvement of PPS and digitization are put forward as key priorities of the state economic policy. This is true both for Russia and for other countries of the world. Digitization of PPS necessitates the creation of a new institutional form of the public procurement market, the formation of a "smart" procurement economy. The study is based on Russian experience and identifies the main directions of PPS modernization by way of its digitization. The results of the study may be in demand in other countries, as well as internationally.

Keywords: Public Procurement System, Digital Technologies, State Economic Policy, Russian Economy.

Introduction

Digitization is a global modern trend (Andriole, 2005; Parker et al., 2016; Schwab, 2016; Volkova et al., 2019; Wellisz, 2016; and others). The creation of new innovative digital technologies and their diffusion radically change the economy and society (Dubovik et al., 2018; Edler and Fagerberg, 2017; Gawer and Cusumano, 2014; Negroponte, 1999; Plotnikov and Vertakova, 2015; Polyanin et al., 2017; Teece, 2018; and others). The main advantages of digitization are saving time and financial resources, as well as an increase in the level of coordination and quality of processes. In this regard, in many countries of the world state programs for the digitization of the economy and public administration are adopted. Moreover, the implementation of these programs in different countries of the world has institutional features. There is also the specificity of digitization of individual areas and processes.

In this article, the subject of study is the digitization of the Public Procurement System (PPS) of Russia. The aim of the study is to explore the possibilities of increasing the effectiveness of PPS with digital means and methods. The importance of studying this issue is determined by two circumstances, as described below.

- Firstly, a significant part of the national income is redistributed through PPS. According to official data, the share of public procurement is about 25% of Russia's GDP. Given the purchases of state-owned companies and corporations, this value is estimated to reach 40% of Russia's GDP. Some of these funds are spent inefficiently. The introduction of digital methods will improve the efficiency of procurement and the national economy (Plotnikov et al., 2018).
- Secondly, digital technologies are scalable. PPS problems exist in many countries. Effective methods of digitization of this system, developed on the example of Russia, can be used in other countries. They can also be used in commercial procurement systems and in international practice.

Materials & Methods

The study is based on the materials of the Russian economy. This allows us to give its results a specific character. As a theoretical and methodological basis of the research, the authors' developments were used, both from Russia (Desyatirikova et al., 2017; Fedotova et al., 2019; Ivanov et al., 2019; Polyanin et al., 2018; Vertakova et al., 2019; and other) and from other countries (Falco and Kleinhans, 2018; Shrivastava et al., 2016; Tambe and Hitt, 2014; Todoruţ and Tselentis, 2018; Zuehlke, 2010; and other). The presented results are a substantially supplemented and revised version of the materials published earlier in Russian in the book "Digital transformation of the economy and cluster development" (Volkova, Nikitin, Plotnikov, 2019).

The study considered the institutional specifics of Russia. It is governed by the provisions of Russia's Federal Law No. 44-FZ "On the Contract System in the Sphere of Procurement of Goods, Work, and Services to Ensure State and Municipal Needs" (further referred to as Law No. 44-FZ). Procedures for the application of this Law were considered taking into account the digitization of the Russian economic policy (Strategy for the Development of the Information Society in the Russian Federation for 2017-2030, Federal Project "Normative Regulation of the Digital Environment", National Program "Digital Economy of the Russian Federation", Decree of the President of the Russian Federation No. 204 "On National Goals and Strategic Objectives of the Development of the Russian Federation for the Period up to 2024", draft Federal Law "On Experimental Legal Regimes in the Field of Digital Innovations in the Russian Federation", Federal Law No. 63-FZ "On Electronic Signature" and others).

For research methods of institutional, system, comparative, historical, economic and technological, managerial, economic, legal, retrospective analysis are used.

Results & Discussion

The introduction of digital technologies in the PPS can solve several problems existing in this area. Advanced information technologies for data analysis and market modelling can play a decisive role in the process of improving the scope of public procurement as an integral part of the national economy.

Electronic Document Management

Electronic document management is a set of processes for working with documentation carried out in electronic form. The concept of electronic public procurement is to translate into the format of electronic standards the procedures established by law. Electronic document management in the Russia's PPS is regulated by Law No. 44-FZ. As is stated in it, "it is allowed to exchange electronic documents stipulated by the legislation of the Russian Federation and other regulatory legal acts on the contract system in procurement between participants in the contract system in the field of procurement, including the submission of applications for participation in determining the supplier."

In procurement, applications for participation in determining the supplier, final proposals and documents sent in the form of electronic documents must be signed with an enhanced electronic signature and submitted using the Unified Information System (UIS). In Law No. 44-FZ, the term "enhanced qualified electronic signature" is used; the abbreviation "enhanced electronic signature" is also given there. These concepts are defined in Federal Law No. 63-FZ "On Electronic Signature." Both types of electronic signatures are created by cryptographic transformation of the document, confirming authorship and the absence of changes after signing.

As stipulated by Law No. 44-FZ, the UIS, when interacting with other information systems, ensures the use of an enhanced unqualified electronic signature for signing electronic documents provided for

by this Law. Strengthened electronic signature keys, as well as certificates of electronic signature verification keys intended for use for the purposes of the Law, are created and issued by certification centers that have received due accreditation. In cases stipulated by international treaties of the Russian Federation, the indicated keys of enhanced electronic signature and certificates of keys to verify electronic signatures must be created and issued by certification centers created in accordance with the law of a foreign state.

In accordance with Russia's Law on electronic signature, information in electronic form, signed by a qualified electronic signature, is recognized as an electronic document, equivalent to a paper document signed with a handwritten signature, and can be used in any legal relationship. However, information in electronic form, signed with a simple electronic signature or an unqualified electronic signature, is equivalent to a paper document signed with a handwritten signature, only in cases established by federal laws, normative legal acts adopted in accordance with them or an agreement between participants in electronic interaction.

If federal law or other authority requires that a document must be stamped, an electronic document signed with a strengthened electronic signature and recognized as an equivalent paper document signed with a handwritten signature, is recognized as an equivalent document on paper signed by handwritten signature and stamped. In terms of establishing requirements for certificates of electronic signature verification keys and enhanced electronic signature keys, approval is also required from the Federal Security Service of the Russian Federation.

Unified Information System

The UIS is a specialized website where all the information and necessary documents related to public procurement are collected. In accordance with Law No. 44-FZ, the UIS provides for the formation, processing, storage and provision of data (including automated) to participants in the contract system; monitoring compliance with the law in procurement planning and implementation; filing applications for the determination of the supplier in the form of electronic documents. Moreover, all information contained in the UIS is publicly available and is provided free of charge and is also posted on the UIS official website.

Problems in the official site of public procurement continue to manifest today, even though the UIS was conceived and financed from the federal budget to resolve these exact problems. Among them, the following:

1. Lack of integration of budget and procurement processes, which can be overcome at the technological level through the interaction of information systems for managing budget planning of authorities with the official website. Because budget and procurement processes at the technological level are fragmented, it is difficult to assess the effectiveness of procurement procedures in terms of the degree to which planned procurements are implemented and goals are achieved.
2. Lack of integration of the procurement process with the implementation of State Programs. The technical requirements for the creation of the UIS and the development of the Procurement Management subsystem do not provide for interaction with information systems for managing state programs.
3. The search capabilities of the UIS are severely limited. For the UIS, the problem of an inconvenient procurement information search service continues to be significant, as the smart search service on the official website has not been implemented.
4. Lack of analytical capabilities in the UIS. The system creates significant difficulties for those who are searching for concluded contracts. It is not possible either to search for a contract by its number. It is not possible to collect aggregated statistics on the examination of the results of the contract.

The functionality of the UIS as of 2018 was monitored, and the results that some of the functions available in the public part were inoperable. Areas in which the lack of analytical data is most detrimental are as follows: general data on purchases of the customer and its subordinate organizations; analytical data needed to calculate the initial (maximum) prices of state (municipal) contracts;

analytical data necessary to select a method for determining the supplier; analytical data on the results of the execution of state (municipal) contracts. The issue of the loss of statistical tools for monitoring procurement information is closely related to issues related to the functioning of the UIS. After the abolition of key statistical forms, only fragmentary restoration of procurement information is possible.

Information Technology Used in the PPS

Public procurement is one of the factors in the growth of the national economy, playing an important role in the development of small businesses and their participation in the economic evolution of the country, and influencing the economic development of its regions. However, structural shifts occurring in the world economy as well as growing prominence of the innovation and informational factors dictate the emergence of future governments, which, in turn, determines fundamental changes in the state regulation system, the infrastructure of information systems, including in the field of public procurement for state and municipal needs.

The introduction of e-commerce in public procurement not only eliminates corruption risks, but also helps to increase the availability of procurement for a wide range of small and medium-sized businesses. Digitization of the economy presupposes the launch of a large-scale economic development program for a new technological generation (Volkova et. al., 2019). It should be noted that advanced IT-technologies for data analysis and market modeling can play a decisive role in improving the scope of public procurement as an integral part of the economy of our country.

The implementation of the digital agenda involves using information and communication technologies, new business processes and digital models, along with creating digital assets. The directions of development of the digital economy within the framework of national policy include digital transformation of economic sectors and cross-industry transformation, digital transformation of goods and services markets.

The process of digitization of the procurement system has been completed. Until the end of 2017, the only electronic procedure in the contract system was the electronic auction. The rest of the procedures: tenders (and their varieties), quotation requests, requests for proposals and purchases from a single supplier remained paper-based, and as of 2018, their share as part of the procurement of goods, works, services of certain types of legal entities (state corporations, corporate customers in which the government is a stakeholder, resource supplying organizations) was significant.

Transferral of purchases into electronic format is a worldwide trend that is characteristic not only of the Russian state procurement system. For example, the European Union Procurement Directives are part of the Europe 2020 strategy and provide for the full digitization of procurement by the end of 2019. In connection with that the legislation of the member states is subject to unification, and public procurement is expected to become formalized and fully digitized.

The PPS is an important part of the information and telecommunication infrastructure of the public sector economy, a significant component of e-government, and therefore dependent on information technology and development factors of software and hardware, the theory of intelligent systems. An intelligent system is a software system, a set of interacting with each other elementary structures and processes, capable of solving tasks that were traditionally performed by a person, but integrated into a whole by performing the function of intelligent processing and belonging to a specific subject area.

Extensively using simplified procedures to provide services is a measure that allows achieving elimination of bureaucratic restrictions and increasing the efficiency of meeting public needs. This measure is ensured by the comprehensive digitization of the contract system in public procurement. Of importance are creating customer-oriented management systems, selecting the most promising ideas and best development practices, establishing a feedback system, and reviewing and analyzing feedback.

Main Measures for Developing PPS

The following measures are advisable as conducive to the digitization of the contract system:

1. To create based on the UIS, a system of statistical indicators of state and municipal procurement accessible to all interested parties. Users should be able to create databases at their discretion using filters (i. e. selecting conditions.

2. To create an analytical subsystem of the UIS or make it openly accessible. To use the capabilities of UIS to implement support for a single technological cycle of procurement activities.
3. To ensure the integration of budgetary and procurement processes, which can be achieved through the interaction of information systems for managing budgetary planning with the procurement system. To ensure the integration of the procurement process with the implementation of state procurement programs embedded in government programs.
4. To expand the search capabilities of the UIS based on the technologies of intelligent information retrieval. To exclude the possibility of placing distorted information passed from the procurement management subsystem to the UIS.
5. To ensure the continuity of procurement supporting documents not only by the technical means of the official website (subsequently the UIS), but also by the legal regulation of the procedure and form for the preparation of such documents. To update, according to the goals and principles of the PPS, the normative legal acts regulating the functioning of the official site, as well as the requirements for its technological and linguistic means.

Today, attention is increasingly paid not only to the transparency of the supplier selection, but also to the efficiency of the procurement process itself. To date, a significant level of transparency of procurement procedures has been achieved in comparison with the now-obsoleted law on placing orders, but the efficiency and ease of implementation of the procedures remain substandard. Due to duplicate processes, customers must carry out most actions twice: first on paper, and then entering the same information into the unified information system and on various electronic platforms, usually in an unstructured form.

Thus, the procurement process, on the one hand, has become transparent and digitized; on the other hand, this result has been achieved by increasing the bureaucratic burden carried by state and municipal employees. One of the most important tasks today is to simplify procedures for customers and suppliers, structure information in information systems, and, therefore, increase the efficiency of the entire contract system.

Conclusion

The topic of digitizing the procurement process is very relevant. It is through the digitization of procurement that many existing problems are addressed in the contract system not only in Russia (the example of which was considered), but also in other countries. The procurement system is constantly evolving and modernizing; however, the improvement of the system inevitably leads to its complexity, which causes unintentional errors. Digitization is designed to prevent these violations. It is necessary to solve pressing problems and develop initiatives conducive to the effective implementation of digital technologies in procurement at the federal, regional and municipal levels.

Federal Law 44-FZ contains the basic principles of organizing public procurement, including the principle of openness and transparency, providing free and gratuitous access to information about the contract system in the field of procurement. Along with this, there is a principle of procurement efficiency. Achieving these principles in modern conditions requires the digitization of the Public Procurement System. The main results and directions of digitization are considered by the authors in the article. For further successful development in this area, modernization of state regulation of the digital transformation of the economy is required.

Acknowledgments

The study was supported by a grant from the President of the Russian Federation on state support of leading scientific schools of the Russian Federation No. NSh-2702.2020.6 “Conceptual foundations of a new paradigm of economic development in the era of technological and social transformation”.

Abstract

The authors offer a methodology for developing a model of dependence of key company performance indicators – sales profit and unit costs on different factors, which operate in competitive environment, as exemplified by a modern Russian company, and for determining the nature of correlations and the degree of factor influence with the use of Data Mining methods. The methodology is based on studying correlations between key factor features by means of pair correlation linear coefficient analysis based on statistical evaluation of input information on the Russian company performance indicators. The use of methods of Data Mining correlation and regression analysis, which take into consideration the factors of external and internal environment of the company, allows deriving a universal established model for calculation of sales profit and unit costs for the purpose of using it for development of scenarios for accepting planned decisions in the company.

Keywords: methods of Data Mining; correlation analysis; regression analysis; planned solutions; environmental factors; regression coefficient; factor features.

Introduction

We have previously examined the role of cost information in managing a business. However, only cost information is not enough (Kaverina, Terenteva and Ivanova, 2019). Problems concerning optimization of selection of scenarios for accepting planned decisions can be solved in different ways (Xu et al., 2005). We offer our solution based on Data Mining technology. A concept of templates (patterns) underlies the modern Data Mining (discovery-driven data mining) technology, which reflect fragments of manifold relations in bulk data. The templates are patterns of data samples, which may be compactly expressed in an intelligible form. The templates are searched for through the use of dedicated methods (Russel and Klassen, 2020, p. 25). Data Mining methods allow to determine the existence, force of correlation between features under study by calculating indicators of correlation between the pair correlation linear coefficient, the partial correlation coefficients, the total multiple correlation coefficient, the determination and allow to determine, how the effective feature changes at the average with the change of factor features.

Methodology for optimization of selection of scenarios for accepting planned decisions

To solve the problem concerning optimization of selection of scenarios for accepting planned decisions in Russian companies, a methodology is offered for developing a model of dependence of key company performance indicators – sales profit and unit costs on different factors, which operate in competitive environment. Analytical study of the mechanism of dependence between the features is expressed as follows: y=f (x(1), x(2)…..x(n))

The purpose of the study is to reveal the nature of correlation and the degree of influence of arguments *x(1), x(2),…….x(n)* (factor features) on function *y* (effective feature).

Problem solving through the use of the Data Mining method includes the following stages:
1. Economical problem definition and the purpose of solving thereof. 2. Statistical evaluation (processing) of input information. 3. Deriving an equation of correlation between effective and factor features. 4. Interpretation of the equation derived.

Based on this method a model of dependence of the estimated values of sales profit and unit costs on different factors is built. Based on input data of the Russian company for 3 years from 2017 to 2019, through the use of Data Mining methods it is necessary to give an economical appraisal of the existing relation between changes in sales profit and unit costs values and environmental factors, and to determine through the use of derived analytic expressions (correlation equations) the estimated values of sales profit and unit costs for the company. Further, to make statistical evaluation of input information through the use of the Data Mining statistical package. The most basic requirement with regard to the factor features – they should be the key ones for the company operations (tables 1, 2). First of all it should be noted that the groupings under study are homogenous. Unit costs and profit for all periods are calculated with the use of the common methodology (Zakharenkova and Igotti, 2018, p. 48).

Table 1: model 1 – input values

Periods	Unit costs, (C), USD	Factor features			
		g	h	v	t
2017	0.86	0.53	-0.32	0.24	0.47
Q 1	0.87	0.06	-0.03	0.09	0.13

Q 4	684.0	9.253	-1.745	0	0.827	0.093	0.037	1.454

Where: S(p) – sales profit (effective feature), thous. USD; x – changes in wholesale prices for the products sold, thous. USD; z – changes in prices and rates for materials (changes in contract delivery terms for the target period), thous. USD; c – organizational violations (production process violation; breach of contract by suppliers, etc.), thous. USD; l – changes in the output, thous. USD; m – changes in the product composition (changes in the output assortment; relative changes in the quantity of each product description in the total output), thous. USD; q - changes in the average level of operational costs per unit, thous. USD; n – changes in the cost structure, thous. USD; x, z, c, l, m, q, n – factor features.

Correlations between the factor features have been studied based on the analysis of the pair correlation linear coefficients introduced in tables 3 and 4. The pair correlation linear coefficients are verified for significance by t-criterion, which has Student's distribution with k=n-2 degrees of freedom at the prescribed significance level of a=0.05 or 0.1. The calculated value of t-criterion is compared with the tabular one. If t-calculated is more than t-tabular, the pair correlation linear coefficient is significant (Sokolov and Sagitov, 2016, p. 187).

Table 3: model 1 - pair correlation linear coefficient matrix

Variables	g	c	h	v	t
g	1				
c	-0.174	1			
h	-0.098	0.394	1		
v	-0.173	-0.108	-0.322	1	
t	0.417	-0.363	-0.045	-0.093	1

The multiple correlation coefficient significance is verified through Fisher and Snedecor statistics of F-criterion with the selected level of a significance (0.05 or 0.1), the number of degrees of freedom for bigger variance m-1 and the number of degrees of freedom for smaller variance m-n, that is F(tabular)=(a, m-1, m-n). The calculated value of F-criterion is compared with the tabular one. If it is more, multiple correlation and determination coefficients are significant (Russel and Klassen, 2020, p. 233).

Based on the statistical evaluation of the input information, it has been found that it presents a roughly homogeneous, normally distributed grouping. Following the correlation analysis, the problem defined above reduced to finding multiple dependence C=f(g, h, v, t) and dependence S(p)=f(x, z, c, l, m, q, n).

Following the comparative analysis, the following linear dependences have been selected as per the models under study:

$$C=a_{(0)}+a_{(1)}g+a_{(2)}h+a_{(3)}v+a_{(4)}t \quad (1)$$
$$S(p)=a_{(0)}+a_{(1)}x+a_{(2)}z=a_{(3)}c+a_{(4)}l+a_{(5)}m+a_{(6)}q+a_{(7)}n \quad (2)$$

With linear dependences (1) and (2), regression coefficients a(1), a(2), …. a(n) demonstrate a medium degree of impact of each factor on the effective feature with fixed positions of other factors. The intercept term of the regression equation $a_{(0)}$ has no economic value, therefore, it is not interpreted economically. It only points to the origin of those intervals of ordinates, which have already been given particular value (Sokolov and Sagitov, 2016, p. 245).

Table 4: model 2 - pair correlation linear coefficient matrix

Variables	x	z	c	l	m	q	n	S(p)
x	1							
z	-0.103	1						
c	0.354	0.314	1					
l	-0.150	-0.118	0.103	1				
m	0.453	0.040	0.194	0.240	1			
q	0.360	0.437	0.172	0.236	0.208	1		
n	0.136	0.064	0.211	0.414	0.459	0.445	1	
S(p)	0.445	-0.418	-0.034	-0.052	0.198	-0.222	0.070	1

Tables 5 and 6 contain regression coefficient values for the data bases under study. According to the above-mentioned information, linear equations as per the models will take shape as follows:

$$C=0.868+0.012g+0.099h-0.02v-0.096t \quad (3)$$
$$S(p)=252.2+56.391x-20.027z-76.180c-6.329l+0.273m-142.601q+6.934n \quad (4)$$

Sign "+" at factors means that the growth of their values results in the growth of the unit costs *(C)* or the sales profit *(S(p))* values. Sign "-" demonstrates reduction of the resulting values.

Table 5: model 1 - regression coefficient

Intercept term $a_{(0)}$	$a_{(1)}$	$a_{(2)}$	$a_{(3)}$	$a_{(4)}$
0.868	0.012	0.099	-0.002	-0.096

Table 6: model 2 - regression coefficient

Intercept term $a_{(0)}$	$a_{(1)}$	$a_{(2)}$	$a_{(3)}$	$a_{(4)}$	$a_{(5)}$	$a_{(6)}$	$a_{(7)}$
252.2	56.391	-20.027	-76.180	-6.329	0.273	-142.601	6.934

Thereafter, based on the selected model, a project of cost value per 1 USD of the output and the sales profit value are determined (table 7).

The calculations made show that the deviation result as per model (3) is within the range from -0.06 USD to +0.05 USD. The deviation value is insignificant. The target value of the unit costs for 2019 coincides with the calculated one (0.56 USD), which confirms reliability of the developed model. This indicator is influenced most significantly by the assortment shift and changes in the prime cost of particular types of products. The influence of changes in wholesale prices, grade and quality is less noticeable. The deviation value as per model (4) is within the range from -9.7 thous. USD to +7.7 thous. USD. The target value of the sales profit for 2019 calculated as per the model (2,301.6 thous. USD.) is 2.4 thous. USD less than the calculated one (2,304.0 thous. USD). Subject to a significant period of study (3 years), the deviation value is insignificant, therefore, such model is reliable and can be used for calculation of the target sales profit value.

Table 7: calculation results as per the models

Periods	Unit costs, (C), USD		Deviation (+,-)	Sales profit (S(p)), thous. USD		Deviation (+,-)
	as per calculation	as per the model		as per calculation	as per the model	
2017	0.86	0.80	-0.06	2,427.1	2,432.0	+4.9
Q 1	0.87	0.85	-0.02	533.9	534.6	+0.7
Q 2	0.85	0.85	-	509.7	508.2	-1.5
Q 3	0.84	0.84	-	631.1	633.4	+2.3
Q 4	0.87	0.86	-0.01	752.4	755.8	+3.4
2018	0.93	0.92	-0.01	1,418.0	1,420.7	+2.7
Q 1	0.94	0.92	-0.02	418.0	416.2	-1.8
Q 2	0.90	0.91	+0.01	118.0	118.7	+0.7
Q 3	0.90	0.95	+0.05	258.0	259.8	+1.8
Q 4	0.92	0.93	+0.01	624.0	626.0	+2.0
2019	0.56	0.56	-	2,304.0	2,301.6	-2.4
Q 1	0.69	0.69	-	571.0	578.7	+7.7
Q 2	0.55	0.56	+0.01	552.0	555.1	+3.1
Q 3	0.51	0.54	+0.03	497.0	493.5	-3.5
Q 4	0.53	0.58	+0.05	684.0	674.3	-9.7

Conclusion

Therefore, based on the undertaken studies, we may confirm that the above-mentioned factors as per models (3) and (4) determine to a significant extent the level of unit costs and the value of profit on sales of the company products. Accordingly, the presented models, developed with the use of Data Mining methods, are reliable and can be recommended for development of scenarios of the company performance targets in the future.

Abstract

Today, in some countries more, in others - less effective in the process of development of the digital ecological environment, digital transformation, representing the introduction and use of modern digital technology in the field of material and non-material production in order to increase productivity and competitiveness. The main objective of the development of the digital economy in Russia - the creation and development of the digital environment - infrastructure, which in the future should bring material production to the next level and provide a solution to the problems of the international competitiveness of domestic production and the national security of Russia. And on top of the main objective -increasing quality of life. Between the formation of the country's digital economy and increase the welfare of the population there is a direct relationship: no welfare is difficult to achieve the formation of a real digital economy, and without increasing prosperity becomes virtual. The aim of this work is to reveal the urgency and complexity of the problem of risk management is a digital transformation. The processes of digitalization and automation provide great opportunities for development. At the same time they are accompanied by certain risks.The article deals with issues related to the development of new risk assessment methods and their impact on business processes in the formation and development of the digital economy. article applied scientific methods of research: empirical methods, historical and theoretical (literature analysis), systems analysis, computational and constructive, vertical and horizontal analysis, and use of economic and statistical methods and other approaches.

Keywords: Digital Transformation, Digital Ecological Environment, The Contribution to GDP Growth, Prospects of Development Barriers, Risk Management, Fragmentograms

Introduction

The proliferation of digital technologies for a long period determines the trajectory of development of economy and society and have often led to fundamental changes in people's lives. Formation of the digital economy - a priority for most countries - economic leaders, including the US, UK, Germany, Japan, etc. As a rule, they are characterized by a long period of implementation of the "Agenda for Digital Development" and priority succession -. From building a base of information and communication infrastructure to form a coordinated policy in this area, and programs to support the widespread introduction of digital technologies.

The idea of "new public management (management)" and the "New Economic Policy" is well known in Russia. Our task does not include a full review of the theoretical literature, we only note that it is quite extensive and diverse study problems (work Servryukovoy LV, AV Obolon. OV Sivintsevoy VL Tambovtseva, and other).

In this study we restrict ourselves to the key provisions of which have a significant impact on the strategy and approaches to digitization. Since the beginning of the new century, issues of digitization of the economy being actively discussed in scientific and popular publications, she devoted to seminars and conferences. In the last years the band released a series of studies on the introduction of digital technologies in various fields, and have been published numerous books, monographs and textbooks. The problem of the digitalization of the economy developed in the works of Russian and foreign scientists and economists, as the Berbers AB, (AB 2017 Berbers). Hulin VG Chernov GV (Hulin VG Chernov GV 2018). New Age is not brought to the subject of new ideas at the same time focusing on academics addressing urgent and concrete problems. Structural and logical models to ensure the economic and fiscal security that can be implemented using digital technology are reflected in the works Tkacheva TY Afanasyeva LV, et al. (Afanasyeva, LV, Tkachev TY 2015). However, in terms of unpredictability of the processes occurring in the Russian economy become of particular interest as macroeconomic research, presented in the works of LS Belousova and other Russian economists (Tsiklauri VY 2017). taking place in the Russian economy become of particular interest as macroeconomic research, presented in the works of LS Belousova and other Russian economists (Tsiklauri VY 2017). taking place in the Russian economy become of particular interest as macroeconomic research, presented in the works of LS Belousova and other Russian economists (Tsiklauri VY 2017).

Results and Discussion

By the digital economy includes activities in which, unlike traditional forms of management, production efficiency, the use of technology, equipment performance, storage, sale, delivery of goods and services is significantly increased due to the handling of large volumes of data and use the results of their analysis Currently, there are dozens of definitions of the digital economy. Synthesizing important to them, we distinguish two approaches to the interpretation of the study categories.

First, narrower, in which the digital economy - an economy based on the production of digital goods and services. This includes areas of activity in which the process of production of goods or services is carried out on a digital basis (the traditional products and services that have been converted into electronic digital form).

Second, advanced approach - is an economic unit in which goods and services are produced with the predominant use of digital technologies, and the data in digital form is a key factor of production and services. Quantitative criterion here can serve the following: more than half of the added value in the company (industry) and in the whole national economy is created using digital technology: big data; unmanned artificial intelligence technology; Distributed system registry; quantum technologies; new production technologies; Internet industry; robotics and sensing; virtual and augmented reality, wireless communications [2].

More specifically, the digital economy will be defined as the economic activity with the production of information goods (IT) and services, information and communication technologies (ICT) (digital economy - the first level), as well as activities related to the production of goods and services, predominantly or completely produced based on digital technology, carrying out economic entities, the business model which is based on digital products or services (the second and third levels) (Fig. 1).

Fig.1 : levels and components of the digital economy

At the present stage of the world economy is entering a new phase of digital development, which is characterized by including the active transformation of institutions and governance mechanisms. Today, Russia is one of the leaders of the digital economy - its share is about 3.9% of GDP, which is 2-3 times lower than that of the leading countries.

The European Commission has published the level of development of the digital economy in which Russia lags behind in the development of the Euro Union and the United States. The share of digital technologies in the GDP of Russia holds 4.1% (Figure 4), while the US GDP - 10.9%, China - 10%, the EU - 8.2%.

Fig.2 : The share of digital technologies in the country's GDP in 2017.

However, even now visible and a number of positive trends, so that the volume of the digital economy has grown steadily in recent years. In the period 2011-2015, the digital economy, had 24% of the total growth of Russia's GDP. [7] Our country has a great potential and prospects of further development: according to the expert group Digital McKinsey, digitalization of the Russian economy

can increase the country's GDP in 2025 to 4,1-8,9 trillion rubles, amounting to 19-34% of the total increase in GDP.

The digital economy will have an increasing and decisive impact on economic growth [3-5]. You can use the approach of Huawei for evidence linking digitalization and economic well-being, which experts offer to evaluate the effect of different digital aggregated indices on key macroeconomic indicators [6]. Comparing the ICT development index and per capita GDP (. Figure 3) confirms the hypothesis: in developed countries with a high level of ICT implementation impact of digital technology on the scale of the economy and economic growth is significantly higher.

Fig.3: Comparison of the ICT development index and per capita GDP

The experience of leading countries shows that it is due to:

- increasing the efficiency research and product development (development process accelerates innovation with rapid prototyping, automated analysis, etc...);
- optimization of manufacturing and logistics operations;
- more efficient use of resources ("smart" IT systems help to optimize the consumption of raw materials, spare parts and reduce losses) [8].

Another factor influencing the growth of GDP by digitalization, is to increase the impact of the production and nonproduction assets. For example, the introduction of Internet of Things (IoT) enables companies to achieve greater output of finished products, reduce downtime of equipment and vehicles, to optimize capacity utilization, reduce repair costs.

Another factor: the digitalization of industries leads to changes in the demand for factors of production and goods and services produced. Change model of value-added, reduced the influence of intermediaries. The importance of individual approach to demand generation through the creation of

unique digital services and flexible digital companies interact with customers. Demand outstripping growth rates of companies and individuals in the digital services that accompany the use and operation of [9-11]

One of the main conditions for the implementation of large-scale government investment in the deployment of digital technology is to assess the contribution of the relevant events in the economic growth in terms of cost-effectiveness.

Regardless of the scenario of economic development require guarantees sufficient return on such investments to support the feasibility of their implementation.

The introduction of digital technology - one of the key drivers of economic growth. The cost structure of sectors of the Russian economy products and services of the ICT sector is already a significant share. In some industries (machine-building, chemical industry), the intensity of the costs of ICT products conform to the US level, and in science, education, public health, the financial sector and the transport sector even exceeds it. However, in such a large proportion of Russia's GDP in sectors such as trade and timber industry complex, and in some service sectors are observed significantly lower values of intensity of ICT costs. In engineering, in recent years the level of ICT expenditures (relative to the release) is about 8%, which is comparable to the costs of the transport sector. In general, the intensity of the products the cost of ICT in Russia lags behind the US level (2.46% vs. 3.08%). To a large extent the backlog of individual segments of the Russian economy on the level of digitalization is related to low levels of investment in the digital infrastructure (software, electronic component base and others.), Which in Russia (1.46% of GDP) is far behind the US level (2.80 % GDP). In terms of sanctions more expensive imported technology is slowly replaced with domestic, constraining the pace of upgrading the digital infrastructure. that in Russia (1.46% of GDP) is far behind the US level (2.80% of GDP). In terms of sanctions more expensive imported technology is slowly replaced with domestic, constraining the pace of upgrading the digital infrastructure. that in Russia (1.46% of GDP) is far behind the US level (2.80% of GDP). In terms of sanctions more expensive imported technology is slowly replaced with domestic, constraining the pace of upgrading the digital infrastructure.

Digitalization of industry leads to a change in demand for the factors of production. Under the influence of digital technologies and the associated new business models transform not only individual sector, but the whole structure of the economy and the cross-industry interactions. Calculations ISSEK the HSE show that in the baseline scenario with moderately favorable macroeconomic and institutional conditions (primarily faster growth of investment activity in all sectors of the Russian economy and maximize the effect of scientific and technological development), digitalization can significantly improve factor productivity as the industries and the service sector

The core of the development of the digital economy is the information industry. To ensure the digitization of other sectors, it needs to grow faster than the growth of the economy as a whole, and in 2030 may reach 4.6% of GDP (in 2017, it is estimated that - 3.6%).

Fig. 4 presents estimates of digitalization contribution to value added growth of individual sectors of the economy. To a large extent the growth will be associated with an increase in production efficiency. Process automation and robotics, accompanied by a radical renewal of fixed assets, will result in a reduction of the share of labor factor contribution to economic growth, while the growth of capital contribution in almost all sectors of the economy. The development of digital infrastructure in the first place can affect the increase in the rate of growth of the financial sector, the transport and construction sectors. Estimates show that the digitization of a positive impact on the efficiency of the manufacturing industries (the most - the chemical industry and mechanical engineering).

Fig.4: The average annual value of the additional contribution of the growth factors in the value-added sectors of the economy as a result of digitalization in the period 2019-2030 gg.

, Subject to the necessary levels of investment digitalization will be a key factor in economic growth. By 2030, GDP growth will be more than half related to digitization and provided not only by the development of information industry, but also by increasing the efficiency and competitiveness of other sectors of the economy. So, in general, for the period from 2017 to 2030 the contribution of the information industry in the GDP growth of almost 4% and the digitalization of the sectors of the economy - about 30%.

By 2030, GDP growth will be more than half related to digitization and provided not only by the development of information industry, but also by increasing the efficiency and competitiveness of other sectors of the economy. So, in general, for the period from 2017 to 2030 the contribution of the information industry in the GDP growth of almost 4% and the digitalization of the sectors of the economy - about 30%.

Presidential Decree of May 7, 2018 № 204 "On the national objectives and strategic goals of the development of the Russian Federation for the period till 2024" set the tasks to be carried out to the government in the implementation of the national program "The digital economy of the Russian Federation."

Of the main tasks of the Russian program of the digital economy in the emerging global digital space should be highlighted:

- providing technological leadership;
- formation of a qualitatively new structure of economic assets;
- digitization of material production, services in general, the entire socio-economic, political and social life of society;
- forming digital principles economic resources;
- the formation of the domestic business community and civil public trust in the CE and the digital environment through attractiveness of institutional and regulatory frameworks and the work of state bodies, in particular structures such as multi-functional centers;
improving the welfare of the population;
- security and sovereignty of the national space CE;
- ensure the effective participation of the country in all the processes of formation of a global ecosystem of CE and global digital space, in particular, it provides for the establishment of at least 50

smart cities based on information and communication technologies (ICT) and the system of "electronic official," which should reduce the level of bureaucracy and allow go to state bodies to digital media instead of paper. The processes of digitalization and automation provide great opportunities for development. At the same time they are accompanied by certain risks. Since MK Chernyak and MM Czerniakow, in his work "Innovation risks of the digital economy" have developed a classification of risks inherent in the digital economy (Fig. 5) (MK Tcherniakov 2018).

Fig.5: Classification of risks inherent in the digital economy

Risks are associated primarily with the advent of a large amount of new information and communication technologies (ICT), which are characterized by new types of vulnerabilities (vulnerability). In 99% of cases leads to the vulnerability threats.

In early 2017, a report by Global Risks Report on the global risks that pose the greatest threat to mankind for the next ten years. This fact clearly demonstrates the importance of developing new techniques, risk assessment and prevention methods at all stages of development of socio-economic systems. In addition, approaches are being developed to minimize risks should be based not only on traditional methods of preventing accidental events, but also to apply the latest advances in the study of flow processes, the theory of fuzzy sets, IT-technologies, etc.

Some of them dwell in more detail, let's start with the traditional. To select a risk management method, you first need to carry out identification, assess the likelihood and consequences of each type of risk. Only this will work out a system of measures that prevent, prevent or reduce possible damage. Usually isolated and used in practice several groups of risk management methods (exposure to risk):

1) risk aversion;
2) Dissipation (distribution);
3) hold (with subsequent risk reduction);
4) transfer risks;
5) compensation.
As an example shown organizational management risks (Table 1)

Table 1: Organizational and management risks

Kinds organizational and managerial their risk	evaluation probably STI risk	evaluation level loss	Methods of risk reduction				
			Evasion the risk	dissipation (distribution)	retention (followed by decrease risk)	Transfer of Risk	Compensation
Availability and warranty perform planagrafika performance works	low	Central	Monthly development budget plan enterprise.	Creating a matrix organizational structure	project management IPMA standards and PMBok planning schedule in the environment: ▪ Spider expert, ▪ Primavera project, ▪ microsoft project	duplication, kvorumirovanie, verification and validation phases of the project	High-precision design and business process implementation in SADT - technology (ARIS, UML, IDEF4 technologies)
Interest all participants performing planagrafika	low	Central	Duty and sense of purpose all participants perform business process scenario in strict accordance with passport workplace and process technology	Duty all participants to improve the business process scenario in strict compliance with the passport workplace and process technology	High motivation for the results achieved in the work and discipline	The motivation of the participants the project is aimed at receiving end result, not short-term profits. tough budget financial planning.	Organization of competitions and Brigade responsibility the company
Opportunity duplication organizational disruptions	low	low	The use of dual-channel enterprise management systems	A complete and comprehensive scheduling of business processes	duplication, reservation, aggregation and controlling of current administrative actions	duplication, kvorumirovanie, verification and validation stages of the	Statistical collect all information and database collection

				through the dispatch center		project team economic security	data in the analytical center

Relationship with local authorities authorities	low	low	Local authorities are granted tax and customs preferences	Funding and sponsorship of local-level events	Additional financial support local budget Local events and festivals	establishment friendly relations with republican authorities authorities	Establishing pre-govornyh the Legal iCal agreements on cooperation and mutual responsibility

It is necessary to take into account the rapid development of the digital economy. With the use of innovative technologies, new communication channels, telecommunications began to change the concept of modern business: from the technological support of business processes for the provision of information services. It is because of this there is a continuous transformation of technologies and management practices. Opening perspectives create a wide field for the growth of new risks that can not be quantified, characterized by a lack of reliable information on the links between the causes of the risks and adverse consequences. The presence of hypothetical risks that hardly calculated and analyzed, as scientific knowledge in the field available. Proceeding from the above it can be stated Prof. AN Bryntsev in their work in order to minimize risks in the digital economy offers use fragmentograms method. Recall that under the fragmentograms be understood matrix relationships problematic conditions and situations (or risks), a decision which substantially modifies the original settings, because it reveals not only the level has an impact on a particular element of the system, but also helps to establish links between actors involved in the process under consideration, namely, the relationship between their behavior and its consequences. This ultimately helps to evaluate the interaction of the elements of the matrix. Accordingly, for each type of activity to build their fragmentograms, tailored. Solution to the problem of passage of fragments is reduced to search the priority issues, eliminating that significantly improves the predictability of developments in this area, as well as removed or significantly weaken other risks. This may be a root cause analysis, which are located at the bottom of the tree of the current reality, etc. (17)

Where G- material flow, information flow I-, F- cash flow,- Ki - moiety in the stream

Thus, the main objective is to move the barriers to cascade from the second level barriers (Figure 6), i.e. reduction of uncertainty in the formation of business processes. This in turn leads to higher probability of occurrence of a scheduled event, thereby enhancing the stability of the system.

Conclusion

To summarize, it should be noted that Russia will need a lot of time to build in the key sectors of the digital economy and competitive enterprises. The first step in this direction - a large-scale application of IT technologies, taking into account the risks involved and the search for methods to minimize them.

The publication was made within the framework of the state task of the South state UNIVERSITY for 2020 (0851-2020-0034)

Mechanisms Contributing to The Development of Eco-Innovations: The Case of Moderate Innovators

Magdalena MARCZEWSKA

University of Warsaw, Faculty of Management, Warsaw, Poland
mmarczewska@wz.uw.edu.pl ORCID: 0000-0003-4301-2741

Abstract

The aim of the study is to obtain new knowledge about mechanisms contributing to the development of product eco-innovations by companies-suppliers of environmentally sound technologies in countries classified as moderate innovators. The research uses qualitative methods and it is based on multiple case-study analysis. The research results reveal that eco-innovations are developed thanks to feedback loops between companies' knowledge, technical expertise and market information (obtained from customers and competitors). The importance of these elements of the mechanism contributing to the development of eco-innovations differ, however, between types of enterprises in the countries studied (i.e. companies-suppliers of finished products and the companies supplying the products components). Component product providers place greater emphasis on tracking their competitors' moves and analysing their products, while final product suppliers focus more on customer needs and their actions to great extent depend on the exclusive expertise and experience of their executives.

Keywords: Eco-Innovation, Environmentally Sound Technologies, Product Innovation

Introduction

The activities of companies in the 21st century focus, among others, on two trends in which opportunities for development are perceived. Firstly, it is the pursuit of new knowledge and innovation (Liczmańska-Kopcewicz, Wisniewska, 2019). Secondly, it is a tendency for sustainable business development (Azzone, Noci, 1996; Bansal, Roth, 2000; Bilan, Mishchuk, Pylypchuk, 2017). For these and other reasons, companies have begun to consider both aspects - innovation and ecology (Cleff, Rennings, 1999).

The present study attempts to build on the research findings related to drivers of eco-innovations. Although important contributions to the knowledge on eco-innovations drivers have been made, there is still a research gap concerning mechanisms contributing to the development of eco-innovative products, especially in companies from countries classified as moderate innovators (European Commission, 2015, p. 10). Most of the previous literature focuses on identifying and listing eco-innovation drivers using quantitative research methods and examples of innovation leaders. Only a few present actual processes that led eco-innovations development in the companies. This paper seeks to fill this gap in the study by focusing on innovative companies-suppliers of environmentally sound technologies. It aims to discover and describe mechanisms contributing to the development of product eco-innovations using the example of companies-suppliers of environmentally sound technologies from countries classified as moderate innovators by focusing on selected case studies and addressing the following research questions:

1. What are the mechanisms contributing to the development of product eco-innovations?
2. How the mechanisms contributing to the development of product eco-innovations differ among the companies-suppliers of environmental technologies, depending on the type of technology?

This paper contributes to existing body of knowledge in several ways: it presents sector specific mechanisms contributing to the development of product eco-innovations; apart from listing the drivers of eco-innovation it describes in detail the processes that led to their development; it

concludes with the identification of model according to which product eco-innovations are developed.

The article proceeds as follows. First, the theoretical framework concerning eco-innovation and their drivers is presented. The next part of the paper is focused on research method, sample selection justification and research limitations. It is followed by the main section of the paper that presents empirical evidence of the mechanisms contributing to the development of product eco-innovations. The article ends with conclusions presenting main research findings.

Theoretical Framework: Eco-Innovations and Their Drivers

Previous studies on eco-innovations in the environmental technology sector concern, among others, the definition of the phenomenon (James, 1997; Rennings, 2000; Kemp, Pearson, 2007; Kanerva, Arundel, Kemp, 2009), its characteristics (Horbach, 2013; Díaz-García, González-Moreno, Sáez-Martínez, 2015; Díaz Lopez, Montalvo, 2015), categorizing according to the type of environmental impact (Horbach, Rammer, Rennings, 2012), diversity (Carrillo-Hermosilla, Del Río, Könnölä, 2010), drivers and determinants (Horbach, 2008; Demirel, Kesidou, 2012; Cai, Zhou, 2014; Marinescu, Ciocoiu, Cicea, 2015; Ryszko, 2017), development (Pujari, Wright, Peattie, 2003; Morand, 2008; Rashid et al., 2015), diffusion (Kemp, Volpi, 2008; Bossle, de Barcellos, Vieira, 2015) and the connection with enterprises performance (Pereira, Vence, 2012; Cheng, Yang, Sheu, 2014; Przychodzen, Przychodzen, 2015; Majerník et al., 2019).

Most of the research focused on the development and diffusion of eco-innovation is based on quantitative analysis covering all types of eco-innovative solutions (e.g. product, process, organisational, marketing) in different industries of a given country or region (Del Val Segarra-Oña, Peiró-Signes, 2013; Cuerva, Triguero-Cano, Córcoles, 2013; Frondel, Horbach, Rennings, 2008; Demirel, Kesidou, 2012; Becker, Englmann, 2005; Theyel, 2000). Much less research has focused on a particular type of innovation in the specific industry (Türpitz, 2003; Kivimaa, 2007). Comparative analyzes of countries, regions or industries are also encountered relatively rarely (Triguero, Moreno-Mondéjar, Davia, 2013).

Past research related to the topic of this article concerns mainly determinants of eco-innovation development. Two main perspectives can be applied while categorizing drivers of eco-innovations. On the one hand, environmental economics literature usually emphasizes the main role of regulation in eco-innovation development (Brunnermeier, Cohen, 2003; Rennings, 2000; Oltra, 2008; Triguero, Moreno-Mondéjar, Davia, 2013; Li, 2014). On the other, innovation literature focuses on the importance of other, non-regulatory, determinants of eco-innovations, mainly supply-side factors (for example firm specific factors, such as organizational capabilities, R&D activities, firm size) (Hart, 1995; Demirel, Kesidou, 2012; Ryszko, 2016) and demand-side factors (like societal requirements, consumer's attitude, CSR, competition) (Díaz-García, González-Moreno, Sáez-Martínez, 2015; Rehfeld, Rennings, Ziegler, 2007; Kammerer, 2009). In practice, eco-innovation is usually driven by a mixture of all factors mentioned above (Horbach, 2008; Belin, Horbach, Oltra, 2009; Cuerva, Triguero-Cano, Córcoles, 2013; Oltra, 2008; Cleff, Rennings, 1999; Rennings, 2000; Del Val Segarra-Oña, Peiró-Signes, 2013; Zuzek, 2015; Horbach, Rammer, Rennings, 2012) and it is difficult to assess, which of these factors are the most important in the development of eco-innovations. Empirical research provides various points of view on this topic. However, the trend is to conduct relevant analysis with regards to geographical region and the type of eco-innovation in order to perform relevant assessment of the importance of eco-innovation drivers (Oltra, 2008). Such approach is used in this study in order to research mechanisms contributing to the development of eco-innovations.

Research Method

The article is based on a multiple case-study approach. The detailed research procedure has been developed based on the approach proposed by Robert Yin (2014) and consisted of the following research steps: planning, design, preparation, data collection, data analysis and reporting. In the

process of data analysis, the following three techniques have been used: explanation building, chronological sequences and cross-case synthesis (Yin, 2014, pp. 147-168). The specific cases were selected using purposeful selection along with the principles of theoretical sampling and taking into account their suitability in terms of data availability, which will allow to answer research questions (Glaser, Strauss, 2006, pp. 45-78; Flick, 2011, pp. 63-64). One of the main criteria while selecting the research sample was companies' success in the development and market implementation of product eco-innovations. The time boundaries of the multiple case study have been set by the life cycle of each company.

In order to facilitate the elaboration of a detailed research plan and to identify the most valuable information from the viewpoint of the study, a brief pilot case study was conducted in May 2014 in a company from northern Italy. The company was excluded from the research sample. The results allowed to define appropriate data sources, develop preliminary interview scripts and prepare a plan of effective cooperation with companies.

Two countries have been selected for the purpose of this research - Poland and Italy. In 2015, when the research sample was selected, these countries were ranked in the Innovation Union Scoreboard, respectively, at the 2nd position, with the overall score 42 and at the 18th position, with a score of 95. Italy seems to be an appropriate point of reference for Poland for several reasons. Firstly, it is a country situated in the same group as Poland in terms of innovativeness - according to the Innovation Union Scoreboard is a group of so-called moderate innovators (European Commission, 2015, p. 10). Secondly, it is a country that according to the general rate of eco-innovation can be classified as a representative of the EU average, as it is located right next to the average value for all Member States of the European Union (Eco-Innovation Observatory, 2014b). Thirdly, on the basis of the general indicators from Eco-Innovation Scoreboard it can be concluded that Poland and Italy have similar eco-innovation activity structures, since all discussed indicators are relative to each other in the same proportion in both countries (i.e. in Italy these indicators are about twice as high as in Poland) (Table 1). This should facilitate comparative analysis.

The condition of the proportionality structure of eco-innovation indicators is also met by Sweden (all three indicators are about three times higher than in Poland). Nevertheless, it is a country with the most developed innovation system (belongs to the group of innovation leaders), representing one of the highest eco-innovation need awareness across the European Union (European Commission, 2015, p. 10; Eco-Innovation Observatory, 2014b). A detailed analysis of all the Member States, and the gap between indicators of eco-innovativeness in these countries and Poland is presented in Table 1.

An additional argument to the comparative analysis of Poland and Italy is the existence of a similar structure of both economies. Both countries are dominated by micro-enterprises and small enterprises (ISTAT, 2014; GUS, 2014).

Preliminary selection of Italian companies has been made using reports and rankings of the most eco-innovative companies developed for the largest trade fair in the environmental technology sector in Italy – *Ecomondo* in Rimini 2014 (67 companies met relevance criteria). The Polish companies have been selected from a sample of 63 winners of five editions of GreenEvo - Green Technology Accelerator initiative run by the Ministry of the Environment in 2010-2014 which was aimed at selecting the best Polish environmental technologies and supporting their international transfer.

The collection of data took place in the period of December 2013 - June 2015. A variety of data collection methods have been used to capture information from various sources and built a large database of information in accordance with data triangulation principles (Table 2).

Case study research method has several limitations. However, this analysis has planned for reducing these potential problems. To reduce internal validity problem explanation building and time-series analysis have been applied in the phase of data analysis (Yin, 2014, pp. 47-48). External validity has been ensured by applying analytic generalization (Yin, 2014, p. 48). In order to mitigate reliability problem, a research protocol and database were developed. To increase the construct validity, the research planning and data collection stages benefited from multiple sources of evidence, chain of evidence and key informants' opinions on the case study plan and the draft research report (Yin, 2014, pp. 46-47).

Case Evidence: Mechanisms Contributing to The Development of Eco-Innovations

Analysed companies are innovators and pioneers among environmental technology providers and can be classified as "first to the market" according to Ansoff and Stewart (Ansoff, Stewart, 1967). These companies are actively engaged in research and development, increase their employment over the years (which is at a similar level in all analysed companies), invest in both infrastructure and staff development, and constantly seek new markets. Table 3 presents basic information on the companies selected for the multiple case study analysis. In the selected sample there are two companies manufacturing environmental protection machinery, which can be used directly by users and treated as part of larger production lines (Recyclers, Biomassers). The other two companies are engaged in developing wide-ranging products that are mostly purchased by companies or persons as part of other

installations or products (Geosynthetics, Polyurethanes). Such sample selection allows to make comparisons in following two dimensions:

- between companies from different countries (Poland-Italy);
- within companies representing similar type of technology in two different countries (machines [Poland] - machines [Italy], components [Poland] - components [Italy]).

Table 3: Multiple case study analysis – sample characteristics

Case name*	Eco-innovation	Form of business organisation	Year of establishment	Number of employees (in 2013)	Turnover (in 2013)
Geosynthetics (Italy)	Geotextiles	Joint stock company	1945**	45	16 092 552 EUR
Polyurethanes (Poland)	Chemical substances used to improve energy efficiency in the building industry	Limited partnership	1995	45	10 166 068 EUR

Biomassers (Poland)	Equipment for processing biomass for energy applications	General partnership	1991	21	862 610 EUR

** Case names are not company names. The data for research has been anonymized.*
***The company was established in 1704. In 1942 because of World War II the business was closed for three years. The company resumed its business in 1945.*
Source: Own elaboration.

Mechanisms contributing to the development of product eco-innovations by companies-suppliers of environmentally sound technologies vary depending on the technology type, the age of organization, and the country of origin. In general, companies producing innovative component solutions look more closely at the market situation, than companies offering the final product. The difference can be seen particularly looking at their relations with competitors and customers. Companies developing innovative components focus on a detailed analysis of the actions taken by competitors and research products they offer. Moreover, more experienced enterprises that operate longer on the market look at competitors' product offers not only in terms of technology (analysis of technical data sheets, examining the quality of the raw materials used in the production process, specifying the suppliers of raw materials, examining samples of products) but also their financial results (cost analysis and balance sheets analysis). The fundamental difference between these types of companies in Poland and Italy is the lower maturity of the former. The Polish company was established in the 1990s, when the political system along with the economic situation in the country changed and private enterprises flourished. The Italian company can be seen as a mature business with very long traditions, roots dating back to 1704 and a continued activity since 1945. Analysis of managerial decisions taken in both companies, their turnover and employment structure allow to conclude that the processes of dealing with competitors are very similar, and the differences described above result from shorter market experience of Polish company.

Component manufacturers in both countries also have a similar approach to their customers. They constantly build their customer relationship advantage. Both companies are willing to pursue personalized orders. For the Italian company it is a priority to meet the individual needs of each client. The Polish company is more willing to adapt production to entire customer groups, preferably strategic customers.

The importance of competition is marginal for companies that aim to produce and sell final products. These companies rely primarily on the knowledge and experience of their executives and their own research and development activities to develop new solutions. They use knowledge from the supply side of the market mainly to verify a company's position. However, the demand side of the market plays an important role for these companies. Both product lines, Polish and Italian, were created and developed in the initial period inspired by customer needs and were willing to offer various product improvements for individual clients. Later, the Italian company abandoned the offering of personalized products. Nevertheless, it never stopped its constant contact with customers, and continued with extensive customer service at all stages of the transaction and comprehensive after-sales support. In the case of Polish company knowledge of customers preferences and expectations directly affects the decisions of the shareholders on trying products developments and improvements. Information from customers often directly translates into machine production, and relationships with them are maintained for a long time. Figure 1 presents main activities of companies-suppliers of environmentally sound technologies aiming to produce and sell products-components or final products.

Figure 1: Main activities of companies-suppliers of environmentally sound technologies aiming to produce and sell products-components or final products

Source: Own elaboration.

The development of eco-innovative products was possible thanks to various companies' resources including in particular unique characteristics of the organization and organizational knowledge, which is a combination of general knowledge, skills, abilities and motivation along with values and economic efficiency of its exploration, development and utilization (Dosi, Faillo, Marengo, 2008, pp. 1165-1166). Based on the research results, it can be confirmed that key competences and dynamic business capabilities are important for creating eco-innovative products, especially by market pioneers. However, it is not possible to clearly identify and enumerate these characteristics in each case because they constitute tacit knowledge. Often even company owners were not able to describe them in detail, but the observation of the company allows to confirm their existence and importance. The research in each case have revealed, however, the existence of numerous sources of organizational knowledge that underlie key competences and dynamic capabilities. Companies engaged in the production of innovative machines focus on the accumulation and multiplication of knowledge in the company, mainly through research and development, cooperation of their employees (mainly those with professional skills, less often with technical), recruiting qualified staff (after college) and collecting information from customers. Companies - component suppliers in the knowledge acquisition process are more based on cooperation with outside actors (i.e. universities, research institutes) and their environment. They perform consultation with specialists or fellow

professors, participate in conferences, seminars, exhibitions and fairs, and study of various thematic expertise. All companies emphasized the importance of two key groups of scientific knowledge - technical knowledge and business knowledge in the process of product innovations development. Technical knowledge included important for each company area of science, while business knowledge was understood as a general knowledge about the market and entities operating on it, price, finance, effective decision-making, communication, management, customer service, problem solving, interdisciplinary knowledge. Figure 2 presents a detailed list of knowledge sources underlining key competences and dynamic capabilities of the companies from the sample.

Figure 2: Sources of knowledge essential for the development of product innovations by companies-suppliers of environmentally sound technologies

Source: Own elaboration based on multiple case study analysis.

Companies-suppliers of environmentally sound technologies develop product eco-innovations according to a similar mechanism that can be explained using the interactive model of the innovation process described in the literature by Rothwell and Zegveld (1985, p. 50). The specifics of this process were slightly different in the analysed cases, but it is clear that eco-innovative products were the result of various companies' actions, acquired information and feedback loops between the technological capabilities of the company and the signals coming from its environment. This mechanism applies to both: radical and incremental innovations developed in companies over the years. Most often, the companies started with radical innovations and continued with creating products that were the evolutionary development of previously developed solutions. The exception to

this rule is the case of a company offering briquetting machines whose breakthrough product on a global scale was developed at a later stage of activity. Nevertheless, the majority of product eco-innovations created by companies-suppliers of environmentally sound technologies is incremental innovation.

Conclusions

The paper examined mechanisms contributing to the development of product eco-innovations by companies-suppliers of environmentally sound technologies. The multiple case study analysis reveals that it can described be using an interactive model defined in the literature by Rothwell and Zegveld (1985). It consists of a series of feedback loops between the technological possibilities of the company and the signals coming from the environment. Different stages of product eco-innovation development process differ, however, between types of enterprises in the countries studied (i.e. companies-suppliers of finished products and the companies supplying the products components). Component product providers place greater emphasis on tracking their competitors' moves and analysing their products, while final product suppliers focus more on customer needs and their actions to great extent depend on the exclusive expertise and experience of their executives. Nevertheless, in all analysed companies representing countries classified as moderate innovators feedback loops between knowledge, technical expertise and market information (obtained from customers and competitors) are key process in the development of eco-innovations.

Analysis of Relationships Between Museums and Stakeholders - A Quantitative Approach

Cosmin ILIE

PhD student, 3nd year at Dunarea de Jos University of Galati, Romania Faculty of Economics and Business Administration, Galati, Romania,
cosmin_ilie2005@yahoo.com

Abstract

Simple recognition of the stakeholders' importance is a competitive advantage for a museum. Based on studies and researches issued in the last years, applying the principles of stakeholders' theory will maximize the benefits offered by them.This paper aims to study the museums' relationships with their stakeholders and the implications of their involvement in museum management. The results of a questionnaire filled in by 100 respondents from three major segments (management team, specialized staff and administrative staff) from targeted museums were evaluated by statistical methods: testing the answers' coherence and consistency by the cronbach's alpha coefficient and the analysis of four hyphoteses by chi-square, pearson's r and spearman correlation coefficients, using spss software.

Keywords: Stakeholders, Museums, Management, Statistical Methods, Correlation Coefficients

Introduction

One of the main development factors of a country is the investment in culture, largely due to the satisfaction offered to citizens who participate in such activities. When we refer to the subcategory proposed to our analysis, the museums, the international practice shows us that the majority is governed by public, central or local authorities. The public financing of museums is frequently criticized, due to the discrepancy between the economical performance, the value of the assets and the value perceived by citizens (Milone & Pizzi, 2019).

If traditionally the value of a museum is given by the assets it houses, from the economic point of view the success of a museum is measured in the profit margin. But even the value of the assets is perceived differently according to the context factors which influence their activities.

Today, museums are perceived as management institutions, but Milone & Pizzi (2019) show that their impact in society cannot be quantified only economically, because a huge part of their economical performances are tied to intangible elements (the impact in the community, reputation, localization, as well as partnerships with other entities). The real reduction in the contribution of public subsidies to museums in recent years has led to the need to invest the available resources more efficiently and to diversify the sources of funding.

According to Moreno-Mendoza & Santana-Talavera (2019) an efficient method to counteract the effects of income reduction, especially public subsidies, is a serious analysis of the museum's relations with its stakeholders, but also the perception of the museum's personnel regarding the involvement of the external stakeholders in the institution's activity.

Theoretical background

The role of museums is evolving rapidly in contemporary society. In the context of changing the visitors' needs, both social and recreational, and taking into account the technological advance, Arinze (1999) argues that museums must constantly re-evaluate their programs and improve their offer in order to be effective, relevant and to correspond to the community's demands. That is why more and more

efforts are being made to reflect the objectives and mission of the institution in the values of the community of which it is part. According to Bitsos, Tomas, Magaha & Samuelson (2019) these changes makes the specialized personnel to take a multidisciplinary approach and constantly engage in consultations with the community. Thus, the museums capacity to adapt their mission to the changing needs of the community represents, as Green (2006) admits, the key by which they ensure for a long time their performance and existence, as trustworthy cultural institutions and with prospects for the future.

According to the researchers in management, a second important element in this equation is the need to increase the attention on stakeholders, especially the external ones and their commitment to the institution in the most diverse contexts. If the activity of the internal stakeholders is easily recognizable in the planning and decision-making processes, regarding the external stakeholders, Lehtinen, Aaltonen & Rajala (2019) think that it might be crucial for the organization's performance and for surviving on a long term. All recent research on the involvement of external stakeholders advocates the benefits of their involvement.

Stakeholder theory generally deals with how partnerships with various categories of stakeholders should be managed and how to co-opt them in the decision-making process (Parmar, Freeman, Harrison, Wicks, Purnell & De Colle, 2010). The one who gave the stakeholder theory and conceptualized is, without a doubt, Freeman (1984), but an adaptation of the theory for museums was suggested by Legget (2006): individuals or organizations that have an interest or influence in the museum's ability to achieve its goals.

From Freeman to this day, a whole specialized literature has been developed on stakeholders, and on the benefits of partnerships with them, but the weak point of this literature is precisely that the debate is focused on identifying stakeholders and specific characteristics, rather than testing the implementation of the stakeholder theory, the quantification of results in the management performance of the institution and of the effective impact on the organization, such as access to resources or competitive advantages.

Even if there is a lack of strategic thinking regarding the competitive advantage offered by stakeholders, Kotler & Kotler (1998) have been showing for two decades that museums have become more and more aware of the importance of stakeholder groups (public, private or non-profit) with an active interest in museum practices and policies.

The study proposed by this research was part of a larger project (ILIE, 2019) based on museum research, on the stakeholders theory, researches and studies issued in the last decades in the field of museum organizations. A questionnaire with 20 items with Liquert scale answers and 4 segmentation items was filled by internal stakeholders of a museum (staff). The target audience was represented by museum employees from Romania: management, specialized and administrative personnel and the main purpose was to identify the perception of respondents about museum relations with stakeholders (internal and external). The main research instrument was a questionnaire, that was sent to the majority of the museums and public collections from Romania and it was filled in by 100 persons of the major 3 segments: management, specialized and administrative. The questionnaire was sent to the participants through e-mail enclosed with a letter of intent and a privacy statement.

The Distribution Of Results And Preliminary Conclusions

Regarding the distribution of the respondents, they are employed in local museums (33%), regional (36%) and national (31%) which give a good balance, a favourable representation within the study with almost equal segmentation of interest groups.

CHART 1

National museums are generally governed by the Ministry of Culture, regional ones by the county councils and local ones by town halls or entities and private persons (usually owners).

Regarding the type of financing (CHART 2) the public funding is the majority (53%), mixed (31%) and private (15%) – usually being private collections of local importance.

CHART 2

The results confirm the division of the museums participating in the study by the degree of importance. 15% belonging to the private area are most likely of local importance, belong and managed by founders – private persons and legal persons, monasteries, churches, various associations.

The respondents' structure is very close to a museum's internal structure: management (35%), specialized (51%) and administrative (14%) personnel. The share of specialized personnel (curators, conservators, researches, restorers) is gratifying, because this is the first segment to be actively involved in designing the museum's programmes and services.

CHART 3

Regarding the accumulated service of the position we can see that the museum organization is generally a stable environment with an emphasis on personal development and with possibilities of advancement according to the professional accumulated service: over 3 years (76%), between 1-3 years (20%) and under 1 year (4%).

To exploit both, statistical methods and for a profound analysis of the study' results, four working hypotheses have been established:

HYPOTHESIS I: the function in the museum influences the opinion about the benefits brought by involving the external stakeholders in improving the activity;

HYPOTHESIS II: the accumulated service in the museum influences the perception about the benefits brought by involving the external stakeholders in improving the activity;

HYPOTHESIS III: the museum's importance influences the perception about the benefits brought by involving the external stakeholders in improving the activity;

HYPOTHESIS IV: the museum's type of financing influences the opinion about the benefits brought by involving the external stakeholders in improving the activity.

Instrumentation/ Methods of Statistical Analysis

The results were evaluated by statistical methods: testing the answers' coherence and consistency by the Cronbach's Alpha coefficient and the analysis of four hyphoteses by the Alpfa Chi-square, Pearson's R and Spearman correlation coefficients. The most appropriate technical way to perform these analyzes is the SPSS software

Cronbach's Alpha Analysis

Cronbach's Alpha Analysis is the best way to measure the internal consistency of a questionnaire when we have several items that use a Likert scale (the model: Strongly disagree to Strongly agree).

Cronbach's Alpha was run on a sample of 100 people who provided answers to the items in the questionnaire. The result shows a coefficient of **0.883**, indicating a high internal consistency of responses for the chosen scale.

Table 1: Reliability Statistics

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
.883	.883	20

In the table that shows the total statistic of the items used in the questionnaire the last column represents Cronbach's Alpha value if one of the items was to be erased. Removing any item, except for 3 of them would give a lower score. That is why the items should not be erased, but rather better studied (the whole table can be studied from the appendix).

Table 2: Statistics – the 3 items that needs to be better studied

	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Squared Multiple Correlation	Cronbach's Alpha if Item Deleted
The financing of the museum corresponds only to current needs, with insufficient funds for development	**72.09**	**123.816**	**.057**	**.294**	**.891**
A bigger share of own revenues (taxes, sales, sponsorship, branding) is the key to the sustainable development of museums	**71.86**	**121.464**	**.176**	**.227**	**.887**
Involving people outside the institution in museum management is beneficial for improving the work	**72.57**	**121.629**	**.137**	**.263**	**.889**

The **Chi-square** test is used to determine if there is a significant difference between the expected frequency and the observed frequency in the study at one or more categories. The use of the Chi-square test implies devising two hypotheses: the negative hypothesis that shows that there is no significant difference between the expected and observed frequency, while the alternative hypothesis states that they are different. The significance level, when we are sure that the difference is not due to a chance, is set to 0.05.

The **Pearson's R** coefficient is a useful descriptor of the linear association of two variables and provides access to two key properties: magnitude and direction. When the result is close to 0 there are no correlations, but when it gets closer to -1 or +1 it shows a strong correlation, negative or positive between the variables.

The **Spearman** correlation coefficient indicates the direction of the association between the independent variable and the dependent variable. If the dependent variable has the tendency to increase when the independent variable increases then the Spearman correlation coefficient is positive, otherwise the coefficient is positive. A coefficient close to **0** indicates that there is no tendency for the dependent variable to increase or decrease when the independent variable increases.

Data analysis. Results and Debates

We used the SPSS software to analize the collected data. For each one of the four hypothesis we have created a contingency table which reflects the distribution of responses on each correlation based on the chosen hypothesis.

The distribution of responses corresponding to the first hypothesis implies the creation of a double entry contingency table which allows the observed frequencies classification (Table 3).

Table 3: contingency table associated with the first hypothesis

		Involving people outside the institution in museum management is beneficial for improving the work					Total
		Total disagreement	Disagreement	No agreement, no disagreement	Agreement	Total agreement	
The job you have in the museum organization	management	5	2	13	9	6	35
	Specialized personnel	2	9	13	19	8	51
	Administrative personnel	1	1	7	5	0	14
Total		8	12	33	33	14	100

In the first table we can see that less than half (47%) of respondents agree with the benefits brought by the involvement of external stakeholders in the museum's activities. The most reluctant are: the management and administrative personnel, while the specialized personnel is the most receptive (over 50% agree).

Testing the first hypothesis with SPSS is shown in Tables 4 and 5.

Table 4: Testing the first hypothesis with chi-square test

	Value	Df	Asymp. Sig. (2-sided)
Pearson Chi-Square	11.049[a]	8	**.199**
Likelihood Ratio	12.993	8	.112
Linear-by-Linear Association	.000	1	.992
N of Valid Cases	100		

a. 9 cells (60.0%) have expected count less than 5. The minimum expected count is 1.12.

In this case, the value of asymptotic significance (0.199) is higher than the significance level (0.05) and the Pearson Chi-Square value (11.049) is less than the chi-square value found in the Chi-Square distribution table by degrees of freedom (15.51) in the context of 8 degrees of freedom. The null hypothesis is accepted and we can say that there is no association between the independent (the function in the museum) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

Table 5: the first hypothesis tested with Pearson`s R si Spearman methods

		Value	Asymp. Std. Error[a]	Approx. T[b]	Approx. Sig.
Interval by Interval	Pearson's R	-.001	.096	-.009	.993[c]
Ordinal by Ordinal	Spearman Correlation	-.009	.097	-.092	.927[c]
N of Valid Cases		100			

Table 6: contingency table associated with the second hypothesis

		Involving people outside the institution in museum management is beneficial for improving the work					Total
		Total disagreement	Disagreement	No agreement, no disagreement	Agreement	Total agreement	
Accumulated service of the position	Less the 1 year	3	1	0	0	0	4
	Between 1-3 years	2	2	9	7	0	20
	Over 3 years	3	9	24	26	14	76
Total		8	12	33	33	14	100

The results of testing the first hypotheses are also validated by the Pearson's R and Spearman correlation coefficients because their values (-0.001 and -0,009) are negative, but close to 0 which shows a lack of correlation between the independent (the function in the museum) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

The distribution of responses corresponding to the second hypothesis involves creating a new dual-entry contingency table, which allows the classification of the observed frequencies (Table 6).

We can see that less than half of respondents (47%) believe in the benefits brought by the involvement of foreign stakeholders: those with accumulated service of under a year 4/4 disagree, between 1 and 3 years are open to the involvement of those outside the organization (16/20) and those over 3 years, a little over 50% believe in such partnership (40/76).

Testing the second hypothesis with SPSS is shown in Tables 7 and 8.

Table 7: Testing the second hypothesis with **chi-square test**

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	32.775[a]	8	.000
Likelihood Ratio	24.434	8	.002
Linear-by-Linear Association	14.240	1	.000
N of Valid Cases	100		

In this case, the value of the asymptotic significance (0.000) is inferior to the significance level (0.05) and the Pearson Chi-Square value (32.775) is higher than the chi-square value found in the Chi-Square distribution table by degrees of freedom (15.51) in the context of 8 degrees of freedom. The hypothesis is accepted and thus we can say that there is an association between the independent (the accumulated service in the museum) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

Table 8: the second hypothesis tested with **Pearson`s R si Spearman methods**

		Value	Asymp. Std. Error[a]	Approx. T[b]	Approx. Sig.
Interval by Interval	Pearson's R	.379	.096	4.058	.000[c]
Ordinal by Ordinal	Spearman Correlation	.295	.091	3.062	.003[c]
N of Valid Cases		100			

The results of testing the second hypothesis are also validated by the Pearson's R and Spearman correlation coefficients because their values (+0.379 and +0,295) are positive which shows a strong correlation between the independent (the accumulated service in the museum) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

The distribution of responses corresponding to the third hypothesis involves creating a new double entry contingency table, which allows the classification of the observed frequencies (Table 9).

Table 9: contingency table associated with the third hypothesis

		Involving people outside the institution in museum management is beneficial for improving the work					Total
		Total disagreement	Disagreement	No agreement, no disagreement	Agreement	Total agreement	
Museum category	local	3	2	13	14	1	33
	regional	3	7	9	13	4	36
	national	2	3	11	6	9	31
Total		8	12	33	33	14	100

In this case, we see similar shares on all segments. No category exceeds 50% of positive responses. We draw the conclusion of a feeling of reluctance.

Table 10: Testing the third hypothesis with **chi-square test**

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	14.881[a]	8	.061
Likelihood Ratio	15.282	8	.054
Linear-by-Linear Association	1.183	1	.277
N of Valid Cases	100		

The value of asymptotic significance (0.061) is higher than the significance level (0.05) and the Pearson Chi-Square value (14.881) is inferior to the chi-square value found in the Chi-Square distribution table by degrees of freedom (15.51) in the context of 8 degrees of freedom. The assumed hypothesis is null and thus, we can say that there is no association between the independent (the museum's importance)

and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

Table 11: the third hypothesis tested with **Pearson`s R si Spearman methods**

		Value	Asymp. Std. Error[a]	Approx. T[b]	Approx. Sig.
Interval by Interval	Pearson's R	.109	.096	1.089	.279[c]
Ordinal by Ordinal	Spearman Correlation	.101	.099	1.003	.318[c]
N of Valid Cases		100			

The results of testing the third hypothesis are also validated by the Pearson's R and Spearman correlation coefficients because their values (+0.109 and +0.101) are positive, but close to 0, which shows a lack of correlation between the independent (the museum's importance) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

The distribution of responses corresponding to the fourth hypothesis involves creating a new double entry contingency table, which allows the classification of the observed frequencies (Table 12).

Table 12: contingency table associated with the fourth hypothesis

		Involving people outside the institution in museum management is beneficial for improving the work					**Total**
		Total disagreement	**Disagreement**	**No agreement, no disagreement**	**Agreement**	**Total agreement**	
Tip of museum financings	**Public**	5	7	15	22	5	54
	Private	2	2	6	2	3	15
	Mixt	1	3	12	9	6	31
Total		8	12	33	33	14	100

If public and mixed-funded museums have a share of at least 50% of positive responses to the perception of the benefits of external stakeholders regarding the private segment, only 30% perceive positively, 37% are indifferent, 33% disagree. In order to understand these results we have to be aware that most of the private museums are of local importance. The partnerships with private entities are influenced especially by the museum's location and visibility. Thus, small museums or from rural areas incur difficulties in generating partnerships with persons or entities outside the museum. It is a big time consuming activity and it is impracticable for small museums which also have little personnel.

Table 13: Testing the fourth hypothesis with chi-square test

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	7.476[a]	8	.486
Likelihood Ratio	8.104	8	.423
Linear-by-Linear Association	.751	1	.386
N of Valid Cases	100		

In this case the values of asymptotic significance (0.486) is higher than the significance level (0.05) and the Pearson Chi-Square value (7.476) is inferior to the chi-square value in the Chi-Square distribution table by degrees of freedom (15.51) in the context of 8 degrees of freedom. The assumed hypothesis is null and thus, we can say that there is no association between the independent (the

museum's type of financing) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

Table14: the fourth hypothesis tested with **Pearson`s R si Spearman methods**

		Value	Asymp. Std. Error[a]	Approx. T[b]	Approx. Sig.
Interval by Interval	Pearson's R	.087	.094	.865	.389[c]
Ordinal by Ordinal	Spearman Correlation	.057	.098	.564	.574[c]
N of Valid Cases		100			

The results of testing the fourth hypothesis are also validated by the Pearson's R and Spearman correlation coefficients because their values (+0.087 and +0.057) are positive, but close to 0, which shows a lack of correlation between the independent (the museum's type of financing) and the dependent (the benefits brought by involving the external stakeholders in improving the activity) variable.

Conclusions

Most of the stakeholders are aware of their potential role in obtaining competitive advantages for the museum, in bringing more value for the community. They are also a good resource for identifying new sources of information, experience, finance. Community stakeholders (various community centers, commercial organizations, NGOs, associations) can play an important role in experience exchange regarding the partnerships with stakeholders and through the input of innovative ideas.

Even if there is a lack of strategic thinking regarding the competitive advantage offered by stakeholders, we can tell for sure that in the last two decades that museums have become more and more aware of the importance of stakeholder groups (public, private or non-profit) and the benefits of their involvement.

The results of the study led by Ilie (2019) and the testing of the four working hypotheses proposed by the present work represents a mirror of the perception of the main actors in museums, regarding the involvement of external stakeholders in the management and activity of the institution. We could see that 47% of the respondents considered the involvement of the stakeholders as a beneficial one, 33% are indifferent and 20% disagree. From the point of view of specialization the most receptive are the specialized personnel, and from the point of view of seniority only those with work experience over 3 years exceed 50% of positive answers. We also learned that if the category of the museum does not change the general perception about the benefits brought by the involvement of external stakeholders, the answers of the 3 types (local, regional and national) are positive in a proportion of almost 50%, the type of financing is a factor that shows us greater diversity. The staff from museums financed exclusively from public or mixed funds is aware of the benefits brought by the involvement of stakeholders in proportion of over 50%, while those in the private sector, look reluctantly-33% agree, 33% indifferent and 21% manifesting disagreement.

The limitation of our study is the short number of respondents and short period of analysis. Future research could fill this gap by extending the period of analysis and the number of respondents. Further more, te adoption of qualitative methods in order to understand the perception of the museum factors about the relationship with stakeholders (internal and external) will represent a useful tool to understand it.

The State Management of Agriculture in The Transition to Innovative Reproduction

Victor N. Potekhin

Candidate of economic sciences, The Urals State Agrarian University,
Ekaterinburg, Russia, e-mail: vnp1@ya.ru

Abstract

The article proposes the author's conceptual model of state management of agricultural development in the context of the transition to innovative reproduction. This model involves the use of the basic socio-economic law of development, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the budget structure of social working time and free time at all levels of management.

Keywords: Agriculture, Public Administration, Conceptual Model Of Public Administration Of Agricultural Development

Introduction

The public administration is a system of interaction between the state apparatus and all participants in social production in the process of performing objective socio-economic functions aimed at ensuring a stable state and developing productive forces, consumer forces, production and superstructural relations.

The conceptual model of state management of agricultural development

In the context of the transition to an innovative method of production, the goals and content of the activities of the state apparatus undergo significant changes. The sphere of agriculture, to which the activity of the state should be directed, is no exception. In this regard, public administration in the agricultural sector is designed to provide a qualitatively new level of solving problems: food security; providing the country's population with affordable organically pure domestic food products; providing appropriate raw materials for industry; cardinal improvement of the ecology of arable and other lands, water basins and forests.

We propose the author's conceptual model of state management of agricultural development [1; 3; 4; 5; 6] in terms of innovative reproduction, consisting of 9 blocks interconnected vertically and horizontally.

Table 1: The conceptual model of state management of agricultural development in the transition to innovative reproduction

1. The innovative scientific base, an adequate theory, a system-holistic methodology, a truly humane innovative ideology and a socio-economic policy for the development of agriculture, the resettlement system, infrastructure, comfortable living conditions and livelihoods, taking into account the universal and	2. A system of objective goals, principles, criteria, stages, tasks, objective indicators of assessing vital functions at the economic level, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the budget structure of social working time and free time , calculated in	3. The system of innovative reproduction of personnel of all categories - fundamental education, a rational worldview based on an interdisciplinary methodology, general and professional training, creativity, social, spiritual, moral, scientific, technological, environmental culture, aimed at increasing the share of useful

socio-economic laws of development humanity and society in nature, calculated in kW/h and other units of the dimension of physical quantities.	kW/h, taking into account the action of the basic socio-economic and other universal and socio-economic laws of nature and society.	cost-results and reducing the share useless, harmful, loss of cost-results in the budget structure of social working and free time.
4. The legal, information, and managerial support for the processes of innovative reproduction, taking into account the universal and socio-economic laws of human-society development in nature, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the budget structure of a social worker time and free time by level of management.	5. The widespread introduction of breakthrough technologies of a new generation based on the use of new physical, socio-economic and other principles in materials, energy systems, production, management, information, legal and other technologies, aimed at increasing the share of useful cost-results and reducing the share of useless ones, harmful, loss of cost-results in the budget structure of social working and free time.	6. The widespread use of new physical and other principles in the organization of labor and everyday life of every person during working and free time, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results, calculated in kW/h.
7. The innovative system for the development of strategic, tactical, operational development of agriculture, aimed at constantly increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the budget structure of social working time and free time of each person and society (in kW/h), based on universal monitoring of the new generation, using new physical, etc. principles, artificial and socio-economic intelligence by levels of management.	8. The innovative system of preliminary and complete accounting, control, analysis, amendments to the personal and aggregate strategic, tactical and operational activities of the employed and free population, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the structure of their budget social working time and free time by level of management, measured in kW/h.	9. The innovative system of constant comparison of personal and aggregate strategic, tactical, operational actions with real results obtained in kW/h and other units of the physical quantity dimension, reflecting qualimetrically actual fulfillment and non-fulfillment of the time-bound activities and whose fault at each level of management.

This matrix makes it possible to obtain a three-dimensional, non-linear, three-dimensional socio-economic model that objectively reflects any actually dynamic process of social reproduction in real time and serves as the basis for an adequate imitation of socio-economic processes.

The main socio-economic law of development passes through the entire conceptual model, aimed at increasing the share of useful cost-results and reducing the share of useless, harmful, loss of cost-results in the budget structure of social working and free time at all levels of management, measured in kW/h.

In the future, this model can and should be presented in the form of a state standard-regulation for the development of rational (objective) forecasts, programs, plans.

Abstract

Environmental pollution and the depletion of natural resources have led governments to attach increasing importance to eco-innovation. We had to change the way we think about resource use. That is why the concept of a modern circular economy model was created, which enables economic growth while optimizing resource consumption. The article presents the definition of the concept of eco-innovation and circular economy. It also presents the management of European Union projects aimed at implementing a circular economy and eco-innovative solutions worldwide.

Keywords: Eco-Innovation, Circular Economy, Management

Introduction

The need to take measures to protect the environment and the risk of shortages of raw materials have made it necessary to pursue the objectives of sustainable economic development. To achieve this, eco-innovative measures are necessary. The introduction of a circular economy is helping to achieve this. It is designed to change the existing linear model based on the production - consumption - throw away to a loop model where waste, if any, becomes a raw material. The aim of this paper is to present the evaluation of the imperatives of eco-innovation in a global context.

The conceptualization of eco-innovation

In recent years, eco-innovation has becomes increasingly important. This is because the environment is increasingly polluted and opportunities are being sought for sustainable economic development that will contribute to growth without causing damage to the ecosystem. Taking into account the conclusions of analytical work and strategic documents of the OECD, EIO, EC can be defined as an innovation that improves the efficiency of the use of natural resources in the economy, reduces the negative impact of human activity on the environment or strengthens the economy's resistance to environmental pressures (Szpor, Śniegocki 2012, p. 3).

Eco-innovations are aimed at developing new products and processes that significantly reduce negative environmental impacts. They have to be considered from three perspectives:

- individual organisations and enterprises in the production and service sectors,
- spatial layouts (communes, cities, provinces, regions of different sizes, up to a global scale),
- consumers (individual and institutional) (Białoń (ed.) 2010, p. 25).

The definitions of eco-innovation treat the prefix “eco” as a characteristic describing an environmental advantage. Therefore, eco-innovations are considered to be innovations consisting of new processes, techniques, practices, systems and products that avoid or reduce the burden on the

environment (Ziółkowski 2008, p.3). It follows that eco-innovations are those innovations that consciously seek to reduce the environmental burden (Woźniak, Ziółkowski, 2006, p. 21, 37). They are therefore a combination of innovation (innovation, creativity, change) with environmental sensitivity and environmental awareness of the organisation. "Eco" added before the term innovation does not distort its character. The preparation and implementation of eco-innovations of different nature (product, process, technological) is still aimed at building a competitive advantage and is of an effective nature. It is important that eco-innovation is designed to help build a competitive advantage for businesses. The expected effect of the implementation of eco-innovation is an increase in environmental effectiveness, which means directly, e.g. reduction of energy intensity of production and indirectly an increase in the economic competitiveness of the enterprise (Woźniak, Ziółkowski, 2006, p. 21, 37).

Circular Economy

Price volatility, dwindling resources of raw materials and the risk of scarcity have led the world of business and politics to change their thinking about resource and energy use (Ellen McArthur Foundation 2015, p. 2). Despite the growing degradation of the environment, global economies operate on the basis of a traditional, linear model of activity. It is characterised by a strategy based on a diagram from the raw materials from which the products are made to the consumption and disposal of waste. This model does not take into account the environmental burdens generated by production and consumption processes and the natural limits of economic growth associated with the depletion of non-renewable resources, such as mineral resources or fossil fuels (Pichlak, Kruczek 2017, p. 22). This led to attention being paid to the modern model of the circular economy (CE). The essence of a circular economy is a maneuverable (non-linear) flow of materials with the simultaneous use of natural resources at the lowest possible environmental cost. The introduction of a circular economy leads to the achievement of social and economic benefits and ultimately to the construction of a system in which the economy, the environment and society are coordinated in terms of achieving sustainable development objectives (Xuan et al., 2011, Seroka-Stolka, Ociepa-Kubicka 2019). Return material flow means closing material flow loops by taking various measures, e.g. repair, reuse, recovery or recycling of materials or products, so that they can be used as inputs in subsequent production processes (Romero, Molina 2012). Closing the material flow loop is due to the design of value-added products as long as possible, thus eliminating excessive waste generation and emissions (Hobson, Lynch 2016, pp. 15-25).

There are many definitions of a circular economy. According to a report by the Ellen McArthur Foundation, "the circular economy is an industrial system that is intentionally renewable and self-healing" (Ellen McArthur Foundation 2013, p. 7). In economic terms, it is a "spiral-loop economy that minimises the flow of materials, energy and environmental degradation, without limiting economic growth or technical and social progress" (Lieder, Rashid 2016, p. 37).

A circular economy is characterised by significant transformations in the production and consumption chains, as well as the redesign of industrial systems. The basis of circular economy is to optimise the use of resources according to the 3R principle (reduce, recycle, reuse) (Xuan et al., 2011; Lieder, Rashid 2016). CE is based on a modern product concept, more efficient production and value recovery using materials. This allows a circular economy to be embedded in the sub-discipline of industrial ecology (Anderson 2007, pp. 133-140). The concept of a circular economy is currently becoming the direction of the main stream of structural changes thanks to environmental protection initiatives developed and more and more often implemented in many economies (among others in the European Union countries, the USA, China and Japan) (Hobson, Lynch 2016).

Managing the diffusion of the concept of a circular economy depends on the political, cultural and social system. In China, CE relies on the integration of closed material flow loops and industrial symbiosis into its development strategy (Hobson, Lynch 2016). Part of the CE management concept, implemented in Korea and Japan, aims to increase consumer responsibility in the use of materials and

products (Winians et al., 2017, s. 825-833). In the European Union, however, circular economy management is based on efficient waste management (Lieder, Rashid 2016).

Circular economy in European Union projects

The management of the implementation of a circular economy in the European Union countries is based on strategic projects whose task is to financially support the implementation of eco-innovative projects. One of these is Europe 2020, the EU's strategy for smart, sustainable and inclusive growth.

A very important programme is GEKON - Generator of Ecological Concepts, which is a joint initiative of the National Centre for Research and Development (NCBR) and the National Fund for Environmental Protection and Water Management (NFEP&WM). The programme co-finances scientific research, development and implementation work in the area of innovative pro-ecological technologies (http://program-gecon.pl).

European Commission's main programme "Roadmap to a Resource Efficient Europe", assumes the priority of implementing the circular economy concept to improve security of supply through better product design, sustainable management of natural resources, increased reuse, recycling and substitution of raw materials and saving resources (European Commission 2011, p. 2).

Eco-innovations are also supported by the GreenEvo project - Green Technology Accelerator. This is a project of the Ministry of the Environment, which was prepared with a view to international transfer of proven domestic environmental technologies to foreign markets (http://greenevo.gov.pl).

The largest funding for research and innovation activities for the period 2014-2020 comes from "Horizon 2020", The EU Framework Programme for Research and Innovation. The programme brings together three existing European funding initiatives for scientific development: The Seventh Framework Programme for Research and Technological Development (FP7), the European Institute of Innovation and Technology (EIT) and innovation support instruments available under the Competitiveness and Innovation Framework Programme (CIP). Eco-innovation activities will be supported under the sectoral programme "Industrial Leadership" sub-action: "Access to finance" and "Innovation in SMEs" (Janik 2014, p. 453).

The HORYZONT 2020 programme offers a new financing instrument - the Fast Track to Innovation (FTI). It is dedicated to innovations that have high potential to be implemented on the market and have a chance for success (Janik 2014, p. 453).

The European Commission allocated EUR 46.62 billion out of over 77 billion of the Horizon 2020 budget. Of the total amount spent, Poland gained almost EUR 475 million (1.12% of the budget for EU countries) and is a leader among the countries of Central and Eastern Europe, but it is still a modest result compared to the European leaders - Germany, Great Britain, France, Spain and Italy. The analysis concerns 702 competitions evaluated by the EC in the scope of signed grant agreements for the implementation of projects before 5 June 2019 (https://www.kpk.gov.pl/przeanalizuj-horyzont-2020-nowe-interaktywne-narzedzie-do-statystyk-na-stronie-kpk-pb-ue).

Important sources of funding for eco-innovation are the structural funds spent within the framework of the Intelligent Development Operational Programme (OP-IR), the Infrastructure and Environment Operational Programme (OP-I&E) and 16 Regional Operational Programmes (ROP). The Intelligent Development Operational Programme assumes support for scientific research and development works leading to innovations in environmental technologies, low carbon technologies and enabling rational management of resources. The Operational Programme Infrastructure and Environment (OP IE) also provides for financial support for eco-innovation. Eco-innovative activities will also be supported by 16 Regional Operational Programmes. These programmes will constitute a significant source of funding for the activities of SMEs, with a strong emphasis on innovative projects, including research and development (Janik 2014, p.454).

The LIFE Programme will finance eco-innovation through a sub-programme for the environment (policy area Environment and Resource Efficiency - Innovative solutions for better implementation of environmental policy and integration of environmental objectives into other sectors) and a sub-programme for climate change (policy area Climate Change Mitigation and Adaptation - Enhancing Adaptability to Climate Change) (Regulation (EU) No 1293/2013 of the European Parliament and of the Council of 11 December 2013 on the establishment of a Programme for the Environment and Climate Action (LIFE) and repealing Regulation (EC) No 614/2007 (OJ EU, L 347/185 of 20.12.2013).

In 2015. The European Commission has published "Closing the loop - An EU Action Plan for the Circular Economy", which aims to move towards a sustainable, low-carbon, resource-efficient and competitive European Union economy. The main actions presented in the plan are:

- introducing environmental standards for secondary raw materials in order to facilitate their identification and increase their market potential,
- supporting circular economic activities relating to recycling, product durability, biodegradability and reducing the presence of substances hazardous to plastics,
- take action to reduce food waste, including reducing losses in the production and supply chain, improving expiry date labelling and developing tools to achieve sustainability, i.e. halving food waste by 2030,
- improving production processes, including the inclusion of guidance on best practice in waste and resource efficiency in industrial sectors in reference documents,
- measures for the re-use of water, including a legislative proposal on minimum requirements for the re-use of waste water,
- establishing minimum requirements for Extended Producer Responsibility (European Commission 2015).

These projects aim to meet the main challenges of reducing demand for primary raw materials and energy. They also aim to remove barriers to the development of new markets, improve resource efficiency, especially in the secondary use of materials, and promote new business models to reduce energy consumption and greenhouse gas emissions (Lieder, Rashid 2016).

In 2018, EU Member States adopted legislation to make the Community a world leader in waste management and recycling. Recycling of municipal waste is to be carried out:

- 55% by 2025.
- 60% by 2030.
- 65% by 2035.

In addition, stricter rules for the calculation of the recycling rate will contribute to better monitoring of the real progress of the circular economy. On the other hand, based on the existing obligation to collect glass, paper and cardboard, metals and plastics separately, the new provisions on separate collection will contribute to better use and quality of secondary raw materials: hazardous household waste will have to be collected separately by 2022, bio-waste by 2023 and by 2025 - textile materials. In a circular economy, landfilling should not take place because it can cause water, air and soil pollution. By 2035 the amount of municipal waste to be landfilled is to be reduced to a maximum of 10% of the total amount of municipal waste generated (European Commission 2018).

In the last 20 years, EU Member States have improved their waste management performance. In 1995, an average of 64% of municipal waste was landfilled in the EU, in 2000 this figure fell to 55% and the average recycling rate was 25%. In 2016, only 24% of waste was already landfilled in the EU as a whole and the recycling rate increased to 46%. However, there are still problems and differences between EU countries. In 2016, ten EU Member States landfilled more than 50% of waste and six incinerated a minimum of 40% (Table 1).

Table 1: Municipal waste: Situation in individual European Union countries

Country	Generated municipal waste (kg per capita). Data from 2005.	Generated municipal waste (kg per capita). Data from 2016.	Share of recycling and composting. Data from 2016.	Share of landfilled waste. Data from 2016.

Eco-innovation in a Global Context

An important impetus to the development of a circular economy is the challenge for the members of the United Nations to achieve the Sustainable Development Goals (SDGs) under the UN Agenda 2030. 5 of the 17 objectives concern development based on the reuse of raw materials, which is characteristic of the circular economy (https://sustainabledevelopment.un.org/sdg7).

UN members are required to implement the Sustainability Targets, based on national priorities and implementation strategies and the results achieved by the adopted indicators for each target.

Eco-innovation has the potential to lead to significant economic opportunities. But investors need a clear and credible price signal and long-term targets now to make the appropriate investment decisions for a greener future. Even with such a price, the costs of some innovations may be very high initially, and government will have to share the risk of new technologies with the private sector in some circumstances. A number of other measures are already being employed by countries to support environment-related research and development (R&D) (https://www.oecd.org/env/consumption-innovation/42957785.pdf).

The concepts of eco-innovation are increasingly adopted by industry and policy makers as a way to facilitate more radical and system-wide improvement in production processes and products and in corporate environmental performance. Eco-innovation can be understood in terms of its target, mechanism and impact. The primary focus of sustainable manufacturing and eco-innovation tends to be on technological advances for the modification and re-design of products or processes, as in conventional innovation. However, some advanced industry players have adopted complementary organisational or institutional changes such as new business models or alternative modes of provision, for example, offering product-service solutions rather than sale of physical products (https://www.oecd.org/innovation/inno/43423689.pdf).

OECD Project on Sustainable Manufacturing and Eco-innovation Advisory Expert Group recommended:

Sustainable manufacturing indicators:

- Develop a toolbox or manual to help manufacturing companies use existing indicator sets to improve their environmental performance by providing guidance and general recommendations on the use, terminology, standard processes and methodologies of indicators.
- Standardise methodologies for material flow analysis at the micro level (i.e. at the corporate or product level), as this is considered as one of the most effective tools for improving energy and resource efficiency.

  Global eco-innovation platform:
- Collect interesting examples of different levels of eco-innovation from around the world and conduct an in-depth study on processes that help achieve eco-innovation in order to draw lessons for practitioners and policy makers.
- Collect good examples of policies that promote eco-innovation and conduct an in-depth study on how they function. This can be followed by the identification of result-oriented, dynamic new-generation innovation policies that encourage industry to lead ecoinnovation efforts (https://www.oecd.org/innovation/inno/43423689.pdf).

A major problem of eco-innovation is the problem of world agriculture. The world's population has always faced food shortages. This has resulted in industrialisation, i.e. intensification, concentration and specialisation of agricultural production. However, the foundations for the success of such agriculture were laid by the use of non-renewable natural resources, which are becoming increasingly scarce. The environmental impact is loss of fertile soils, water and air pollution and loss of biodiversity. It has also resulted in social inequalities and reduced the quality of food products. Despite overproduction, the industrial model of agriculture has not solved the problem of world hunger. That's why there are now attempts to replace it. The main challenge for the coming decades is therefore to increase food supply while reducing pressure on the environment. These challenges can be presented as balancing demand and sales, ensuring the sustainability of the desired food supply, eradicating hunger, enhancing the climate and preserving biodiversity and ecosystem services while feeding the world. A fundamental transformation of agriculture is needed - moving away from the status quo towards sustainable production through environmentally sound farming practices. The transformation of agriculture is part of the so-called great transformation from the industrial era to a fundamentally new era of sustainability in all dimensions of civilization development (Buttel,

Magdoff, Foster 2000, p. 833-834). There is also a need to fundamentally change the system of agriculture based on the inputs of synthetics into an agriculture based on the properties of nature - the circulation of energy and nutrients, reintegrating agricultural and animal production. Farmers are not only supposed to maximize yields, but also to take care of the complex system of food circulation between plants, soil and soil microorganisms (Roberts 2008, p. 249). The rationale for sustainable agriculture is as follows:

- industrial agriculture is losing its spell,
- growing awareness of the limitations of the global ecosystem (biosphere),
- the growing importance of non-food goods (multifunctionality),
- to question the progress formula to date,
- food quality - health, quality of life,
- the need to increase productivity (Zegar 2012, p. 11).

The new economy must therefore take account of externalities, define the social and ethical framework necessary for sustainability and lead to economic decisions that respect fundamental natural rights.

Organic farming is also a very important issue in the problems of eco-innovation in agriculture (Council Regulation (EC) No 834/2007 of 28 June 2007 on organic production and labelling of organic products and repealing Regulation (EEC) No 2092/91) . The area of organic farming is growing all over the world and Poland is also among the countries with the highest growth of organic agricultural land. This trend will continue to grow in the future. Although organic farming is developing dynamically on all continents, the demand for organic food is mainly concentrated on Europe and North America. This means that organic products are transported over long distances, mainly by road and air, which significantly increases the carbon footprint of organic food production. The market for organic products is developing mainly in highly developed countries, as the prices of organic products are clearly higher than those of conventional production. In the long term, organic farming will remain a source of food supply for a larger but still limited proportion of consumers, as most of them will still be primarily price driven in their choice.

Environmental issues are a very important issue for global economies. Immediate eco-innovation measures are needed to halt climate change. Ambitious plans are therefore needed to help fulfil this task. Biomass is important in achieving climate protection and circular economy objectives. Biomass incineration is the best way to use organic agricultural and industrial waste. Biomass can be an excellent source of energy. It can be used in electricity production and for heating and transport as a biofuel.

Biomass is the oldest and most widely used renewable energy source today. It is all organic matter existing on Earth, all substances of plant or animal origin that are biodegradable. These are residues from agricultural production, forestry residues, industrial and municipal waste (Commission Regulation (EU) No 651/2014 of 17 June 2014 declaring certain categories of aid compatible with the internal market in application of Articles 107 and 108 of the Treaty). It is the third most valuable natural energy source. The advantages of biomass include products made during combustion that are safer for the environment than those made from fossil fuels, because e.g. the content of harmful elements is lower. Biomass sources are distributed fairly homogeneously, reducing the need for transport. Biomass has a theoretically more favourable carbon dioxide balance than fossil fuels by absorbing part of it in the process of photosynthesis. In practice, however, the carbon balance is much less favourable than the research results due to emissions from biomass production and transport.

Biofuels, on the other hand, are fuels created from biomass processing (Directive 2009/28/EC of the European Parliament and of the Council of 23 April 2009 on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC) . They are renewable energy sources as opposed to fossil fuels. The advantage of biofuels is that the energy bound inside the biomass can be stored infinitely long without any risks. Another advantage is the reduced dependence on oil. The disadvantage is that the production and

combustion of biofuel, according to research, has a worse energy and environmental balance than the combustion of fossil fuels. This is related to the environmental degradation associated with the growing acreage of crops and high consumption of fertilizers. It is also disadvantageous to increase the cultivated area by grubbing up tropical forests. Both biofuels and biomass have their great advantages, but they must be well managed.

Currently, the economy is based on fossil fuels such as gas, oil and coal. With biomass, we can create a bioeconomy that is independent of fossil resources. The bioeconomy is a pro-ecological economy that uses biomass as well as solar and wind energy. Biomass can be used in many industries, such as paper and construction. It is also the basis for food. It can replace oil in the plastics, chemical and pharmaceutical industries. It is also used to produce heat. The use of biomass can complement other renewable energy sources, such as wind power plants, which are dependent on weather conditions. Biomass burning, on the other hand, can support countries such as Poland, where energy production is mainly fossil fuel-based, which will help transform the economy into a more eco-innovative one (http://biomasa.org.pl).

Unlike fossil fuels, biomass is a renewable energy source. The plants grow continuously, so access to them is very easy. However, it is important to remember to use biomass in a sustainable way, because although it is renewable, the amount of biomass is not unlimited.

The eco-innovation solution in a circular economy is to use municipal waste that can be used as secondary raw materials in production. The role of economic clusters, in which waste from one company is used by another in production, should also be strengthened. Emphasis should also be placed on the extended responsibility of companies, which would have to collect and manage the same waste as it produces itself, thus increasing the availability of raw materials for producers.

A form of implementation of a circular economy may also be the possibility of replacing ownership by other forms of using the products. In this case, the entrepreneur will make the products available to other entities and provide services within their scope. Rental, digitisation and sharing can also contribute to reducing waste. Repairing and improving products can also be a better way to manage waste, which will contribute to extending their life. Eco-innovative measures applied in the circular economy are a key element in building an economy that is designed to achieve sustainable development objectives.

Summary

Eco-innovative actions are necessary to achieve sustainable economic development objectives. To achieve this, a circular economy is needed that eliminates the concept of end-of-life, since the materials used to manufacture the product at the end of its life can be reused. Its advantages include independence of economic growth from limited resources, the possibility of regenerating the ecosystem, optimization of resource use, reduction of pollution emissions and development of new technologies and innovation. Therefore, there is a need to manage eco-innovation in such a way that a strategy for the development of a circular economy is introduced on the widest possible scale. This paper present strategic directions which can be used to implement eco-innovation solutions in global economy.

Abstract

Relevance. In the context of survival of the majority of companies on the market today, the accounting and analytical aspects of the formation and effectiveness of the equity of organizations are crucial in the process of making financial, economic and organizational management decisions. Research objective: forming the accounting and analytical system of the organization's own capital. Research methods: As a research toolkit, universal methods of cognition were used, such as dynamic, comparative, logical, functional, inductive and deductive, as well as specific research methods - analysis and synthesis, modeling, concretization and abstracting, grouping and others.Achieved results and significance of the research: the accounting and analytical system of equity of an economic entity and its subsystem are characterized; on the basis of the research, the concept of the accounting and analytical system of equity was developed, its elements are shown, their brief description is given.

Keywords: Own Capital, Accounting and Analytical System, Equity, Accounting, Analysis, Audit.

Introduction

Today, Russian enterprises operate in crisis conditions, exacerbated by the ongoing sanctions policies of foreign partners. Established economic relationships strongly require enterprises to use highly efficient management technologies that contribute to maintaining financial stability and solvency of economic entities, thereby ensuring their economic security. And management decisions of both tactical and strategic nature should undoubtedly be based on reliable operational information in the necessary analytical sections, formed by the accounting and analytical system of an economic entity.

The first developments of the accounting and analytical system in the economic scientific community appeared in the 90s of the last century, and since then research in this area has continued. Nevertheless, despite the many developments in this area, the issues of creating an optimal

accounting and analytical system of economic entities under conditions of uncertainty have not lost their relevance and are only becoming more severe.

Today in economic literature the accounting and analytical system of enterprises as a whole has been studied quite widely, however, the development in the field of its formation in individual areas of accounting and analytical work is clearly not enough.

The basis of this study is the formation of the accounting and analytical system of the organization's own capital, which is the potential, without which the functioning of any economic entity is impossible.

Literature Review

The research showed that in economic literature there is no single concept of accounting and analytical system as such. The views of the authors vary. So, if Thagapso M.B. (Thagapso, 2015), for example, understands this as the coverage of data processed by the accounting and analytical system, then another researcher Ivanov E.A. (Ivanov, 2014) under the accounting and analytical system sees the functions, techniques and methods of processing information of the accounting and analytical system. Gudzinsky A. D. described that as an integrated system of methods for accounting and analytical support of management through the implementation of specific internally systemic and system-wide functions "(Kchatyan, 2017).

The authors' point of view also differs as to whether the accounting and analytical system is an independent information structure, or it can be considered as a part (element) of the general accounting system of the enterprise.

The accounting and analytical system is understood as a complex of interconnected functional subsystems (elements) that provide continuous collection, systematization, processing and subsequent evaluation of information generated by accounting for analyzing the performance of an economic entity and audit, confirming the accuracy of the information provided by its accounting system for making appropriate managerial decisions (Alimov, 2009).

Opinions of authors-economists specializing in accounting and analytical and financial sciences - also sometimes differ significantly with regard to the formulation of the concept of organization's capital.

In the works of foreign researchers, capital (equity) is identified as net assets, which was the basis for the interpretation of capital in the Conceptual Framework of IFRS. Thus, J. Betge defines capital as the difference between the assets and liabilities of organization (Betge, 2000).

In the works of Scherr J.F. (Scherr, 1993) the concept of enterprise capital is formulated as the net asset value of an economic entity, i.e., the difference between the value of its assets and liabilities. Anthony R. and Rhys J. give a similar definition of the organization's capital, identifying it with the concept of net assets (Anthony, 1993).

To a greater or lesser extent, modern domestic and foreign researchers also adhere to the understanding of the essence of enterprise capital as the residual value of assets minus (covering) total liabilities.

Official definitions of equity reveal the conceptual framework of financial reporting (IFRS Conceptual Framework, 2018): "Equity is the residual share in the assets of an organization after deducting all of its liabilities", this is nothing more than the difference between total assets and total liabilities. From this, it follows, that the value of equity has a value equal to the value of net assets.

Thus, determination of equity is possible only by calculation based on a comparison of all economic resources (total assets), reduced by the amount of debt owed by the owners of the organization for

contributions to the authorized capital, and total liabilities, reduced by the amount of income for future periods.

Based on understanding of the international concept of equity, it should be noted that the provisions of Russian regulatory documents provide for a similar vision, and the procedure for calculating equity in accordance with the Order of the Ministry of Finance of the Russian Federation requires its calculation as the difference between the assets taken into account in net assets and liabilities, taken into account net assets (Order of the Ministry of Finance of the Russian Federation dated August 28, 2014 No. 84n "On approval of the procedure of net asset value". When calculating the net assets of the organization according to the balance sheet, we can conclude that their value is equal to the sum of the outcome of section III "Capital and reserves" and the indicator "deferred income" (section IV of the balance sheet "Short-term liabilities", line 1530).

It is worth noting that, based on the requirements of fundamental approaches to the disclosure of financial statements in the balance sheet, the items of assets and liabilities should, first of all, be separated on a temporary basis (less than 12 months and more than 12 months since the reporting date). It follows that a certain part of the amount of "deferred income", which will be reflected in the composition of the income of the related reporting periods more than 12 months after the reporting date, should be shown as of the reporting date in the section "Long-term liabilities". Whereas the sum of deferred income, which will be recognized as income next to the reporting date of the reporting period, should be reflected in the "Short-term liabilities" section on line 1530. This will allow to get more realistic reflection of the financial condition of the organization in the balance sheet at the reporting date, but this circumstance will not affect the calculation of net assets.

The traditional disclosure of the elements of capital and liabilities in the balance sheet gives a general idea of the expense of which financial resources the organization makes the necessary investments in assets.

Materials and Method

In the course of the research, normative acts and regulations on accounting and reporting, as well as the works of domestic and foreign scientists on a given topic, were critically comprehended. As research tools, universal methods of cognition were used, such as dynamic, comparative, logical, functional, inductive and deductive, as well as specific research methods - analysis and synthesis, modeling, concretization and abstraction, grouping and others.

Results

Accounting and analytical and evaluative issues of the formation and efficiency of use of equity are crucial in the process of making financial, economic and organizational managerial decisions (Plaskova, 2019).

Equity is the most important essential part of economic entity functioning, due to the fact that it is the main source of property formation of the latter, that is, this is the potential without which the functioning of the enterprise is impossible, as well as its further development. The financial well-being of an economic entity, its solvency and financial condition, therefore, economic security, depend on the state of its own capital, therefore, the study of the accounting and analytical system of the company's own capital is of indisputable importance today.

We present the accounting and analytical system of the economic entity's own capital as one of the components of its management system that combines accounting and analytical operations related to the formation and use of its own capital. Based on reliable credentials, the system provides ample opportunities in terms of timely and comprehensive analysis of the efficiency of use (including factor analysis) of the organization's equity.

It is advisable to start the organization of the accounting and analytical system of own capital with the development of its basic concept (Fig. 1).

The main component in the accounting and analytical system of equity formation is precisely the accounting subsystem, the basis of which is the primary information accumulated by all types of accounting carried out at the enterprise - financial, managerial, tax. The primary information carriers are unified or independently developed primary documents at the enterprise.

The accounting subsystem provides the collection, accumulation, classification and generalization of the necessary information for analysis and audit of the formation and effectiveness of the use of equity of an economic entity.

Exactly based on primary documents, synthetic and analytical accounting of the equity of an economic entity is carried out. In the future, all the data of synthetic and analytical accounting are summarized in its registers, that forms a consolidated accounting of equity, which, in turn, is the information basis for the formation of enterprise reporting, which, on the one hand, acts outgoing in the accounting subsystem, and on the other hand, incoming information in the analytical subsystem of the enterprise (Vandina, 2015).

Fig. 1: The concept of accounting and analytical system of equity of the enterprise
(Compiled by the authors)

All elements of the accounting and analytical system for the formation and use of equity (Fig. 2) have different goals, objectives, objects, methods and are intended for different users of information.

The main component in the accounting and analytical system of equity formation is precisely the accounting subsystem, the basis of which is the primary information accumulated by all types of accounting carried out at the enterprise - financial, managerial, tax. The primary information carriers are unified or independently developed primary documents at the enterprise.

The accounting subsystem provides the collection, accumulation, classification and generalization of the necessary information for analysis and audit of the formation and effectiveness of the use of equity of an economic entity (Fedotova et al., 2018).

Exactly based on primary documents, synthetic and analytical accounting of the equity of an economic entity is carried out. In the future, all the data of synthetic and analytical accounting are summarized in its registers, that forms a consolidated accounting of equity, which, in turn, is the information basis for the formation of enterprise reporting, which, on the one hand, acts outgoing in the accounting subsystem, and on the other hand, incoming information in the analytical subsystem of the enterprise (Vandina, 2015).

Fig. 2: Elements of the accounting and analytical system for forming the equity of economic entities*

(Compiled by the authors)

The analytical subsystem of the accounting and analytical system of equity is designed to determine the level of efficiency of its use, due to the fact that equity is the basis of any economic entity A sufficient amount of the company's own capital provides it with financial stability, a certain margin of financial strength necessary to ensure its economic security, as investors are more willing to invest their funds in those enterprises where the share of equity is quite high. Therefore, the economic entity is obliged to conduct an analysis of the efficiency of using its own capital, following which managerial decisions are made to maintain the amount of equity at a sufficient level and, if necessary, take measures to increase it (Butkova, 2018).

The audit of equity in the accounting and analytical system performs a control function, since during the audit, the legitimacy of the formation and change in the value of equity, as well as the accuracy of the reporting of all operations related to the formation and use of the equity of the enterprise, is checked (Bexultanov et al., 2018).

Moreover, at present, enterprises need to pay close attention to the organization and constant implementation of internal control over the formation and use of their own capital due to the fact that a quality audit allows not only to avoid errors in the formation of equity, to eliminate its inefficient use, but also to level out the differences of the economic entity with its shareholders.

Conclusion

Optimally built accounting and analytical system of equity opens up real opportunities in terms of optimizing and increasing the efficiency of using the equity of an economic entity. Today, it is the main and most reliable information source of the management system, which enables to minimize the risk of uncertainty when making management decisions. At the same time, the unity, interconnection and interdependence of all the components of subsystems of the accounting and analytical system allows not only to make the necessary tactical decisions timely, but also to develop strategies for the development of the organization for the future.

Extending Sustainable Business Model Archetypes with a Stakeholder Value Creation Perspective

Tugba Orten TUGRUL

Izmir University of Economics, Izmir, Turkey
tugba.tugrul@ieu.edu.tr

Abstract

This conceptual paper aims to extend sustainable business model archetypes developed by Bocken et al (2014) by incorporating a stakeholder value creation perspective suggested by Freudenreich et al (2019) and holistic sustainability orientation recommend by Elkington (1998). Among eight archetypes, only two sustainable business models, adopting a stewardship and developing scale up solutions, embrace a triple bottom line approach and aim at creating value with and for a wide range of stakeholders. In addition, meeting the needs of shareholders is a common characteristic of all almost all archetypes, excluding repurposing for society/environment. Sustainable business models focusing on material-energy efficiency, renewable energy sources and sustainable production-consumption engage with value delivery network actors to create value. In line with triple bottom line approach, only four of the archetypes integrate economic, environmental, and social benefits for sustainable development.

Keywords: Sustainable business models, triple bottom line approach, stakeholder theory, value creation

Introduction

Corporations around the world are trying to meet a new demand; integrating sustainability principles to their key strategies, decisions, and operations to achieve sustainable development. According to the WCED (1987: 43), sustainable development is the "development that meets the needs of the present without compromising the ability of future generations to meet their own needs". In other words, organizations are being called upon to take responsibility for their operations' impacts on the natural environment and society, and thus, apply sustainability principles to the ways in which they conduct their businesses. Triple bottom line approach emphasizes the integration and reconciliation of environmental, social and economic concerns into business decisions Elkington (1998). It is also argued that stakeholder orientation is a precondition for sustainability (Zink, 2005). Firms should not only create value for a wide range of stakeholders but also support stakeholders to actively participate in the value creation process of the sustainability-oriented business models (Freudenreich et al., 2019). Therefore, this conceptual paper aims to extend sustainable business model archetypes developed by Bocken et al (2014) by incorporating a stakeholder value creation perspective suggested by Freudenreich et al (2019) and holistic sustainability orientation recommend by Elkington (1998).

Corporate Sustainability from a Stakeholder Perspective

Bowen, known as the Father of corporate social responsibility (CSR), provided the initial definition as "the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of action which are desirable in terms of the objectives and values of our society" (1953: 6). CSR definitions proliferated during the 1970s and began to include a stakeholder approach (Carroll, 1999). As one of the most notable contributors of the period, Johnson (1971: 50) stated that "a socially responsible firm is one whose managerial staff balances a multiplicity of interests. Instead of striving only for larger profits for its stockholders, a responsible enterprise also considers

employees, suppliers, dealers, local communities, and the nation". In the 1990s, the CSR concept transitioned significantly to stakeholder theory as an alternative theme (Carroll, 1999). Although corporate social responsibility (CSR) and CS both aim to balance economic goals with social and environmental responsibilities, and have similar conceptualizations, they differ depending on the nature of the relationships among sustainability dimensions (Montiel, 2008). CS concept embraces a triple bottom line approach and argues that the economic, social, and environmental dimensions are interconnected, complementary (Bansal, 2005; Branco and Rodrigues, 2006; Dyllick and Hockerts, 2002; Elkington, 1998), whereas CSR treats social responsibility and economic performance as independent factors (Montiel, 2008). CS describes a nested system that recognizes that the economy is part of society, which in turn is part of the larger ecological system. Triple bottom line conceptualization of CS argues that to achieve sustainable development, environmental integrity, economic prosperity, and social equity principles must be integrated (Elkington, 1998). As a result, organizations must apply all these principles to their products, policies, and practices to achieve sustainable development at corporate level (Bansal, 2005). Regarding CS, there is no commonly agreed definition (Rego, Cunha, and Polónia, 2017; Montiel and Delgado-Ceballos, 2014) and measurement in the literature (Montiel and Delgado-Ceballos, 2014). From a business level perspective, each organization should choose its own specific ambition and approach regarding corporate sustainability (CS) depending on organizational aims and strategies and operating situations (Van Marrewijk, 2003).

Stakeholder theory is one of the main theories used in the literature to explain CS strategies and behaviors (Montiel and Delgado-Ceballos, 2014). Stakeholder theory embraces a managerial perspective and articulates two important issues; understanding the shared sense of the value the firm creates and the responsibilities of the firm has to stakeholders (Freeman, 1994). The word stakeholder first appeared in the management literature in an international memorandum at the Stanford Research Institute (Freeman, 1984). Freeman (1984) initiated a broader discussion in his book Strategic Management as a Stakeholder Approach. Freeman (1984: 5) defines a stakeholder as "any group or individual who can affect or is affected by the achievement of the firm's objectives". Market stakeholders, also called primary, engage in economic transactions with the firm, including shareholders, creditors, employees, suppliers, wholesalers, distributors, and customers (Zu, 2009). On the contrary, non-market stakeholders do not engage in direct economic exchange with the firm, including communities, public, governments, media, activist groups, business support groups (Zu, 2009). Firms should meet the needs of all stakeholders without compromising their ability to meet the needs of future stakeholders (Dyllick and Hockerts, 2002). However, different stakeholder groups often have distinct set of expectations, needs, interests and objectives that often conflict with each other (Neville and Menguc 2006; Polonsky, 1995; Sen et al., 2006). For example, occupational health and safety or employment equity and distinction are important issues of concern to employee stakeholder group, whereas product safety and truth in advertising are of concern for all corporations in managing their relations with customers. Incorporating corporate sustainability requires firms to develop a broader range of stakeholder relationships and meet these conflicting demands (Amini and Bienstock 2014; Clarkson, 1995; Dyllick and Hockerts, 2002; Mitchell et al., 2010). However, given the limited organizational resources, it is clear that not all stakeholder issues can be addressed (Maignan and Ferrell, 2005). Companies need to first identify the relevant stakeholder groups, then determine the stake and importance of each group, and then discuss how well their expectations/needs are met and finally modify corporate policies and priorities accordingly (Freeman, 1984). For instance, economically sustainable companies target shareholders and creditors, ecologically sustainable companies focus on the environment, and socially sustainable companies add value to the communities within which they operate. It is also argued that sustainability problems can be solved only together with stakeholders (Freudenreich et al., 2019).

Sustainable Business Models from a Stakeholder Perspective

Sustainable business models (SBMs) do not only incorporate a triple bottom line approach but also consider a wider set of stakeholders (Bocken, at al. 2014). By SBMs, firms can create competitive advantage, capture economic value for itself, and deliver social and environmental benefits (Boons and Lüdeke-Freund, 2013; Lüdeke-Freund, 2010). Bocken et al (2014) propose three SBM types (technological, social, and organizational) based on the innovation-focused categorization of Boons and Lüdeke-Freund (2013) (see Table X). Technological innovation oriented SBMs focus on maximizing material productivity and energy efficiency (MMPEE) (e.g., lean manufacturing and de-materialisation), creating value from waste (CVW) (e.g., industrial symbiosis and cradle-2-cradle), and substituting non-renewable resources and current production systems with renewables and natural processes (SRNP) (e.g., solar and wind-power based energy production). Socially SBMs emphasize delivering functionality rather than ownership of products (DFO) (e.g., rental, lease and shared products-car sharing, maintenance contracts and extended warranties and pay-per-use services), engaging with all stakeholders to develop and sustain long-term health and well-being of their value networks (ASR) (e.g., upstream and downstream stewardship) and encouraging sufficiency by promoting sustainable consumption (ES) (e.g., second-hand markets and frugal business models) . SBMs with an organizational innovation focus are more about delivering of social (RSE) (e.g., social enterprises) and environmental benefits rather than economic profit and providing sustainable solutions at a large scale (DSCS) (e.g., franchising, and collaborative business models). Freudenreich et al (2019) argue that the concept and analysis of value creation through sustainable business models need to be expanded regarding different types of value created with and for different stakeholders. It is also claimed that sustainable business model archetypes developed by Bocken et al (2014) lacks stakeholders' contributions to value creation processes. This conveys the need for extending the current model. Table 1 presents an extended framework by integrating value creation process with and for stakeholders and main sustainability benefits provided. Among eight archetypes, only two sustainable business models, ASR and DSS, aim at creating value with and for a wide range of stakeholders by providing benefits related to all dimensions of sustainability. In addition, meeting the needs of shareholders is a common characteristic of all archetypes, excluding RSE model. Regarding value co-creation approach, beside ASR and DSS archetypes, RSE model creates value with a wide range of stakeholders. In addition, MMPEE, SRNP and ES sustainable business models engage with value delivery network actors to create value. In line with CS triple bottom line approach, only four archetypes, DFO, ASR, ES and DSUS, integrate economic, environmental, and social benefits for sustainable development.

Table 1: The Extended Sustainable Business Model Archetypes

SBM Archetype	DSS	RSE	ES	ASR
Definition	Deliver sustainable business model solutions at a large scale to maximise benefits for society and the environment.	Prioritize delivery of social and environmental benefits rather than economic profit through close integration between the firm and local communities and other stakeholder groups.	Offer solutions that actively seek to reduce consumption and production.	Engage proactively with all stakeholders to ensure their long-term health and well-being.
Sustainability Benefit Examples	***Economic***: generate revenue from a variable (e.g., franchising or licensing) or fixed fee (e.g., mergers and acquisitions) paid for scaling up a solution. ***Environmental***: contribute environmental sustainability on a global level . ***Social:*** support local, small and innovative business to go to scale through, such as, franchising, licensing and collaborative models, and change consumption patterns.	***Environmental***: regenerate flora and fauna, offer societal benefits at a low environmental cost. ***Social:*** deliver nutrition, health and education to low-income markets, while being embedded in community and employment rich.	***Economic:*** increase profitability (premium pricing), customer loyalty, and market share from provision of better products (longer lasting, durable). ***Environmental***: reduce resource consumption and environmental impact through using less product (longer lasting, durable goods) and reusing products across generations (second-hand goods). ***Social:*** provide higher quality, longer lasting, durable, less energy consuming products, support a more sustainable lifestyle, provide products and services to low-income markets by eliminating superfluous or over complex functionality and features.	***Economic***: generate revenue and brand value from premium pricing of certificated products. ***Environmental***: protect environmental resource and bio-diversity and minimize chemical fertilizers and water consumption. ***Social:*** offer energy efficient and environmentally friendly products and ensure long-term health and well-being of stakeholders.
Value created with stakeholders	All	All	Suppliers Retailers Customers	All
Value created for stakeholders	All	Employee Communities General public	Shareholders Customers General public	All

SBM Archetype	DFO	SRNP	CVW	MMPEE
Definition	Provide services that satisfy users' needs without having to own physical products.	Reduce environmental impacts and increase business resilience by addressing resource constraints ' limits to growth' associated with non-renewable resources and current production systems	Eliminate waste by turning waste streams into useful and valuable input to other production and making better use of under-utilized capacity.	Do more with fewer resources, generating less waste, emissions, and pollution.
Sustainability Benefit Examples	Economic: generate revenue from the ownership of assets and service for upgrading and repairing. Environmental: reduce resource consumption through enhanced product longevity and durability and reuse of materials. Social: educate consumers to shift away from ownership and enable access to previously not affordable products by paying for the use of the service not for ownership of the products.	Economic: generate revenue through new nature-inspired innovations in products and services. Environmental: reduce use of non-renewable resources, emissions associated with burning fossil fuels, and synthetic waste to landfill.	Economic: reduce costs through reusing material and turning waste into value. Environmental: reduce footprint, waste and virgin materials use.	Economic: reduce costs, generate price reductions and profits through maximized material productivity and resource efficiency. Environmental: reduce resource consumption, waste and supply chain emissions through product and production process redesign.
Value created with stakeholders		Suppliers Retailers Wholesalers Distributors		Suppliers Retailers Wholesalers Distributors
Value created for stakeholders	Shareholders Customers	Shareholders	Shareholders	Shareholders

Source: Adapted from Bocken, at al. 2014

Conclusion

This conceptual paper demonstrate that only limited number of sustainable business model types incorporate a triple bottom line approach and consider a wide range of stakeholder interests, namely ASR and DSS. However, business strategies, policies and practices need to create economic, social and environmental value with and for a wide range of stakeholders to achieve sustainability. Drawing on the sustainable business model framework of Bocken et al (2004), future studies can reveal how companies integrate different stakeholder issues in value creation and delivery process in developing sustainable solutions. In addition, management of stakeholder relationship is a promising research venue (Freudenreich et al., 2019).

Abstract

Motivation: Many methodological problems are associated with measuring and assessment of the company's financial standing. Various methods have been developed to assess the current and future financial standing of enterprises. Their usefulness requires development and verification based on the example of a specific enterprise. The evaluation of one of these methods is the subject of this article.
Aim: The major research objective of the study is to propose a synthetic method of assessing the condition of a company and verify its correctness based on data referring to a deliberately selected listed company. **Results:** This article shows that a synthetic measure constructed on the basis of selected financial indicators allows for a comprehensive assessment of the company's financial condition in dynamic terms. The constructed synthetic measure can also be used for a comparative analysis of the financial condition of companies over a given period of time.

Keywords: Financial Condition, Complex Phenomenon, Synthetic Measure, Zero Unitarization Method (ZUM)

JEL: C32, C51, C53

Introduction

The assessment of the company's financial condition is a crucial instrument of company management. It should be used by the company's management to make short and long-term decisions in the field of corporate finance, including the control of the course of economic processes relative to the assumptions adopted (Bień, 2008, p. 81). Financial analysis makes it possible to assess the company's financial standing, its liquidity, threat of bankruptcy and the perception of the company's condition and potential by investors and contractors. The basic instruments of financial analysis are liquidity, debt, operational efficiency and profitability ratios. The above groups of indicators, allowing the assessment of the picture of the effects of a company's activities recorded in its financial statements (*i.e.*, balance sheet, profit and loss account, cash flow statement) can be used to construct various methods and models for assessing the company's financial condition (Altman, 1968; Altman *et al.*, 1977; Hadasik, 1998; Sharma, 2001; Nam & Jinn, 2000; Kitkowski 2013; Yang & Dimitrov, 2017; Chatterjee, 2018; Haider, Ou & Pettit, 2019). These models and methods are generally based on both microeconomic data derived from the entity's financial statements and macroeconomic data describing processes in the economy (Acosta-González, Fernández-Rodríguez & Ganga, 2019; Fernández-Gámez *et al.*, 2019).

The financial situation of an enterprise is essentially a complex phenomenon, *i.e.*, a multidimensional construct described by many different characteristics. Complex phenomena are the subject of multidimensional comparative analysis (MCA) research, also referred to statistical comparative analysis (SCA) or multidimensional statistical analysis (MSA).

As Kukuła (2000, p. 7) reports, complex phenomena are those phenomena that described by at least two characteristics that can have different titers and different orders of magnitude. Multidimensional methods are used to analyse this type of phenomena, which are commonly used by researchers in many fields, such as, for instance, economic sciences, tourism, medicine, demography (Kukuła, 2000, p. 22-32).

The company's financial condition seen as a multidimensional construct is a typical example of a complex phenomenon. This means that in order to properly and reliably assess it, many aspects of the entity's functioning must be taken into account. The subject literature emphasizes that there are many methods for assessing the economic and financial situation of a company. These methods include, among others, discriminant analysis, logit or probit analysis, artificial neural networks, survival analysis (Łapińska *et al.*, 2018; Zdunek-Rosa & Huterska, 2018; Hasanaj & Kuqi, 2019). In this context, a properly constructed synthetic measure can also be a useful tool for analysing and assessing a company's financial condition.

This article presents a method of assessing the financial condition of a company using a synthetic measure. This measure is based on a multidimensional assessment that uses key financial indicators that reflect areas of analysis such as profitability, debt, liquidity, and efficiency.

The major objective of the work is to propose a synthetic method of assessing the condition of the company and verify its correctness on based on data characterising a deliberately selected listed company.

Materials and methods

Index analysis and one of the methods of multivariate comparative analysis (MCA) were applied in this article to assess the financial condition of a selected company and a synthetic measure was constructed.

In order to illustrate the essence of the synthetic measure constructed by the authors, the financial indicators describing the financial situation of one of the largest Polish companies operating in the chemical industry - CIECH S.A. were used. This company was selected for analysis deliberately, since in recent years it has been marked by significant fluctuations in its financial situation, which was reflected also in stock market listings and assessments of brokerage house analysts. The company's financial data covering the period from the second quarter of 2008 to the third quarter of 2019 (a total of 46 quarterly data) was used. The data comes from the website www.biznesradar.pl.

The construction of the synthetic measure of the financial condition assessment basically consists of three stages (Marcinkowska, 2007, p. 586):

1. selection of assessment criteria and partial measures,
2. bringing partial measures to comparable quantities,
3. synthetic measure design.

The synthetic meter construction procedure is determined by many factors. It depends on the nature of diagnostic variables (*i.e.*, variables selected for evaluation of the phenomenon under study - in the case under study – the ratios), the scale of their measurement, standardization procedure, weight system and formula for aggregating these variables (Panek, 2009). If diagnostic variables are expressed in different units of measure and/or have different numerical ranges, then they should be transformed to obtain variables without titles and unified as to the range of values they can take. The subject literature (Panek, 2009; Walesiak, 2014) points to numerous methods of normalizing diagnostic variables.

One of these methods is the zeroed unitarisation method, which allows normalization of diagnostic variables based on trait range testing. This method meets all the postulates for standardization procedures for diagnostic variables (Kukuła, 2000, p. 81). Variable values obtained as a result of its application are contained in the range [0;1].

Depending on the nature of the diagnostic variable, standardization is done using the following formulas:

a) for stimulants, *i.e.*, diagnostic variables whose increase in value causes an increase in the assessment of a complex phenomenon:

$$z_{ij} = \frac{x_{ij} - \min_i x_{ij}}{\max_i x_{ij} - \min_i x_{ij}}, \quad [1]$$

b) for destimulants, *i.e.*, diagnostic variables whose increase in value causes a decrease in the assessment of a complex phenomenon:

$$z_{ij} = \frac{\max_i x_{ij} - x_{ij}}{\max_i x_{ij} - \min_i x_{ij}}, \quad [2]$$

c) for nominatives, *i.e.*, diagnostic variables that have a specific value, which is most favourable, from the point of view of assessing a complex phenomenon, called the nominal value:

$$z_{ij} = \begin{cases} \frac{x_{ij} - \min_i x_{ij}}{c_{0j} - \min_i x_{ij}} & dla\ x_{ij} < c_{0j} \\ 1 & dla\ x_{ij} = c_{0j} \\ \frac{\max_i x_{ij} - x_{ij}}{\max_i x_{ij} - c_{0j}} & dla\ x_{ij} > c_{0j} \end{cases} \quad [3]$$

The following relationships occur for nominative features:

$$z_{ij} = 1 \Leftrightarrow x_{ij} = c_{0j} \quad [4]$$

and

$$z_{ij} = 0 \Leftrightarrow x_{ij} = \min_i x_{ij} \ \text{ lub } \ x_{ij} = \max_i x_{ij}\ , \quad [5]$$

where:
z_{ij} – the normalized diagnostic variable *i* for the object *j* taking the value from the range [0;1],
x_{ij} – value of the characteristic *i* in the *j*-th object,
$min_i\ x_{ij}$ – the lowest value of the characteristic *i* from among the objects contained in the set [1, 2,…, *j*],
$max_i\ x_{ij}$ – the highest value of the characteristic *i* from among the objects contained in the set [1, 2,…, *j*],
c_{0j} – nominal value of the characteristic in the *j*-th object.

The next stage is the construction of a synthetic measure based on the following formula:

$$Q_i = \frac{1}{k}\sum_{j=1}^{k} z_{ij}\ , \quad [6]$$

This formula assumes the same meaning of all diagnostic characteristics describing the complex phenomenon studied (weights are the same for all diagnostic characteristics).
The procedure presented above was used to construct a synthetic measure for assessing the company's financial condition.

The results of Research

Fifteen financial indicators, which characterize four basic areas of the company's activity, i.e., liquidity, debt, profitability and efficiency of operations, were adopted to examine the economic situation of the company selected deliberately. These indicators make up a set of potential diagnostic variables. Table 1 shows the list of diagnostic variables along with the determination of their nature, i.e., the impact of the assessment of the company's financial standing.

Table 1: Potential diagnostic variables

Category of indicators	Indicator	Nature of diagnostic variable
Profitability	ROE	stimulant
	ROA	stimulant
	Operating profit margin	stimulant
	Net profit margin	stimulant
Debts	General debt	destimulant
	Equity debt	destimulant
	Long-term debt	destimulant
	Sustainability of the financing structure	stimulant
Liquidity	2nd degree of coverage	stimulant
	Cash liquidity	neutral variable (0.2 *)
	Fast liquidity	neutral variable (1.0*)
	Current liquidity	neutral variable (1.2-2.0*)
Efficiency of operations	Cycle of receivables	destimulant
	Cycle of payables	stimulant
	Inventory cycle	destimulant

**means the nominal value (or range of nominal values) of a diagnostic variable, i.e., the value (range of values) of a variable for which the level of the complex phenomenon is the highest.*
Source: own study.

Potential diagnostic variables were analysed for the degree of differentiation and correlation between individual variables. In order to assess the degree of variation in the variables, the coefficient of variation and the relative amplitude of fluctuations were calculated (Kukuła, 2000, p. 49). All of the financial indicators proposed were used to construct the synthetic measure. After determining the nature of individual diagnostic variables (see Table 1), their values were normalized by the zero unitarization method (ZUM), which also allows the unification of the nature of the variables, i.e., allows the conversion of the destimulant and neutral variable into stimulants (Kukuła, 2000, p. 92). In the last stage of the construction of the synthetic variable, aggregation of normalized variables for individual quarters of the analysed period was made.

Figure 1 presents the change in the financial condition of the audited company in dynamic terms, which is described by a synthetic measure. The synthetic measure values are normalized in the range [0; 1]. The closer the value of this variable to unity, the better the company's financial condition.

Figure 1: Values of the synthetic measure of the financial condition for the CIECH SA company in the period from the second quarter of 2008 to the third quarter of 2019
Source: own study.

In the period examined, the synthetic measure took values in the range [0.241; 0.809]. The CIECH SA company had the worst financial situation in the second quarter of 2009, and the best – in the second quarter of 2017. Therefore, the results obtained show significant fluctuations when it comes to assessing the financial standing of the company under study. The assessment of the financial condition of the examined company in the analysed period using the proposed synthetic measure shows a high degree of convergence with the assessments made by brokerage houses and the company's market valuations, reflected in stock market listings.

Conclusions

The study presents the use of one of the methods of multivariate comparative analysis, i.e., the construction of a synthetic measure to assess the financial condition of an enterprise. This method – based on the ratio analysis – allows a comprehensive assessment of various aspects of the business entity's operations, i.e., financial liquidity, debt, profitability and efficiency of operations. In this article, the synthetic measure was constructed to assess the financial condition and was verified based on the data of a deliberately selected listed company. In this way, the company was assessed following a dynamic approach, which allows observing the development of the complex phenomenon (here its financial condition) over time. The synthetic measure can also be used for a comparative analysis of the financial condition of many enterprises over a given period of time (CIECH).

Abstract

Relevance. Today, innovation plays an important role not only as a catalyst for the global progress of mankind, but also as an additional opportunity for commercial organizations to strengthen their position in markets of any level. This is a complex, long and resource-intensive process, which involves taking into account the maximum number of both external and internal conditions that, one way or another, can affect its results. For the implementation of commercially effective innovative projects in the field of production and organizational processes at the stage of development of an innovative project, the analysis of the internal environment of the organization plays a decisive role. **Research objective:** choosing the most appropriate method for analyzing the internal environment, which is necessary for the transition from the stage of basic research to applied development in the implementation of innovative projects. **Methods:** The main research tool used in the work is a system analysis, which enables building a system of economic analysis of innovation based on the work of Russian and foreign scientists. **Results achieved:** proposed by various authors critical analysis of the possibilities of using the methods was carried out. **Practical significance and applicability of the results**: the methodology for analyzing the internal environment of the organization is adapted for innovative activities and recommended for use at the stage of transition to applied research.

Keywords: Internal Environment Analysis, Investment Project, Innovation, Research And Development.

Introduction

Innovative activities are always associated with a high degree of risk and uncertainty (Mukhtarova et al., 2017; Ziyadin et al., 2019; Korableva et al., 2017; 2018; Bisultanova Korableva et al., 2018). Before conducting applied research and development, it is necessary to set a whole vector for the development of innovations. At the stage of fundamental research and development, research areas and the possibility of introducing one or another innovation are determined. For this purpose, it is

necessary to analyze the conditions in which innovations will be implemented. First of all, this contributes to the analysis of external environment in order to find opportunities to increase the effectiveness of the organization through the adoption of a particular innovative decision, identify the associated risks and threats, as well as an analysis of internal business conditions to identify opportunities for implementing an innovative project within the organization. Analysis of the results of basic research is a key element of the analysis of internal business conditions.

Materials and Methods

To select the most suitable methodology for analyzing the internal environment necessary for the transition from the stage of basic research to applied research, the scientific works of Russian and foreign economists were studied. As a part of the study, the analysis of possibilities of using the methods proposed by the authors was made; conclusions on the adaptation of the proposed methods to innovative activities were generalized and systematized.

Results

Internal environment analysis is necessary to identify the key places in the organizational and production processes, which merit special attention. For this purpose, you should use methods of comprehensive analysis of the organizational and technical level of the organization, which is based on "three groups of analytical indicators: the level of equipment and technology; organizational level of production; indicators of management analysis" (Lysenko 2010).

As an internal analysis applicable to all types of innovations, the organization's potential and resource availability should be examined to assess the feasibility and possibility of implementing innovations of a particular type. In this regard, the analysis of the organizational-technical, techno-economic levels and other production conditions enables determining the organization's capabilities for introducing innovations of a certain type.

The analysis of the organizational-technical level plays a crucial role for the implementation of process and organizational innovations aimed at modernizing internal production and organizational processes.

It is important to pay attention to the fact that for innovative activities the analysis of the organizational and technical level in dynamics almost does not matter, since the dynamic and normative analysis of indicators explores the current deviation from basic and normative indicators, while innovative activities deal with exclusively new or modernized technological and organizational processes. For this reason, the results of non-fulfillment of the plan or deviations from last year's indicators have a weak connection with innovative activitiy and relates to management activities. As part of the choice of the direction of applied research, the study of dynamic performance indicators of production processes allows us to identify stagnant processes, where the size of the reserve for improving efficiency is not determined.

Nevertheless, the classical indicators of the organizational and technical level analysis at the stage of determining the direction of applied research are either not used, or are used with a reservation and modification.

A.D. Sheremet identified 3 main groups of indicators that reflect the technical level of production (Sheremet, 2017):

- Indicators of the level of tools used (capital-labor ratio, technical equipment, energy-labor ratio, mechanization and automation of production processes, etc.);

- Quality indicators (degree of perfection) of the applied equipment and technology (progressiveness of technological processes, equipment of workplaces with technically advanced

tools and devices, the proportion of detail operations processed by group methods, quality, reliability, and durability of products) (Muzychenko, 2008);

- Implementation and development of new progressive machinery and technology (the number of measures to be implemented taking into account the economic efficiency of implemented organizational and technical processes).

These indicators of the technical level of production are related to technical equipment and are considered, for the most part, by narrow specialists. And the insufficient size of any of these groups, reflecting the technical level of production, indicates the need for modernization of production processes.

To make a decision on the implementation of process innovations, it is necessary to study current scientific-technical and technological levels of production, linked to the economic efficiency assessment.

In our opinion, to assess the scientific-technical level of production, we should use the groups of indicators presented in the work of S.I. Kuznetsov "Improving the analysis of the organizational-technical level of production at enterprises of various forms of ownership", among which the following indicators are highlighted:

- Indicators of availability and condition of the main equipment;
- Indicators of mechanization and automation of labor;
- Indicators of technical capacity of labor (Kuznetsov, 2009).

We support the point of view of N. Bazhenov that “the need for modernization of production is reflected in indicators of mechanization and automation, as well as technical capacity of labor. Moreover, “the higher the proportion of progressive and automatic equipment, the higher the level of quality of products (services)” (Bazhenov, 2011).

Thus, the following coefficients should be used to assess the organizational and technical level of the organization.

The coefficient of work mechanization in the classic sense shows the share of products produced in a mechanized way, in the total volume of production represented by formula (1):

$$C_{WM} = \frac{Goods\ produced\ in\ a\ mechanized\ way}{Total\ volume\ of\ goods\ produced} \quad (1)$$

Where

C_{WM} – the coefficient of work mechanization.

It is important to note that in complex production processes in which manual or mechanized labor is used at different stages of the production cycle, the volume of produced goods must be adjusted by multiplying by the share of mechanized production processes in one production cycle.

The coefficient of labor mechanization characterizes the share of working time spent on mechanized work in the total amount of working time spent on production and is determined by the formula (2) (Kuznetsov, 2009):

$$C_{LM} = \frac{Working\ time\ to\ produce\ products\ in\ a\ mechanized\ way}{Working\ time\ to\ produce\ the\ entire\ volume\ of\ products} \quad (2)$$

Where C_{LM} – the coefficient of labor mechanization.

The coefficient of mechanization on labor intensity, reflecting the ratio of the coefficient of mechanization of labor to the coefficient of mechanization of work (Kuznetsov, 2009), is calculated by the formula (3):

$$C_{Mli} = \frac{C_{LM}}{C_{WM}} \tag{3}$$

Where C_{Mli} – the coefficient of mechanization on labor intensity.

In our opinion, the coefficient of labor mechanization for making a decision on the use of innovations in the production process should consider the costs of using mechanized and other labor. Thus, to determine the economic feasibility of the production process at a certain level of mechanization of work, it is necessary to use the coefficient of costs of mechanized work, determined on the basis of formula (4):

$$C_{MWC} = \frac{Costs\ of\ mechanized\ production}{Total\ production\ costs} \tag{4}$$

Where C_{MWC} – the coefficient of the cost of mechanized works

The level of work mechanization in the future can significantly affect the economic efficiency of the organization, therefore, it is necessary to determine the degree of change in the current level of mechanization of work. In this case, we need to calculate the level of costs for the production of one unit in a mechanized way. To do this, use the coefficient of work mechanization specified in the formula (1). By dividing the costs of producing the entire volume of production, in one way or another, by the entire volume of output, we can determine the costs of producing a unit of production. Thus, due to the ratio of the expenditure rate for mechanized work and the cost ratio, the economic efficiency of production is determined in a mechanized way (5).

$$E_{MW} = \frac{\frac{Costs\ of\ mechanized\ production}{Goods\ produced\ in\ a\ mechanized\ way}}{\frac{Total\ production\ costs}{Total\ volume\ of\ goods\ produced}} = \frac{C_{MWC}}{C_{WM}} \tag{5}$$

Where E_{MW} – economic efficiency of mechanized work.

The lower the indicator of the economic efficiency of mechanized work, the more effectively mechanized labor is used. If the indicator of economic efficiency of mechanized work is more than 1, the mechanization of production processes is inefficient and requires modernization and implementation of innovations. A coefficient of economic efficiency tending to zero indicates insufficient mechanization of production processes. Thus, with a decrease in the indicator under study, the coefficient of work mechanization should tend to 1. Low coefficients of mechanization of work and the economic efficiency of mechanized work indicate a low technical level of production processes and the need for their modernization.

This technique can be used to evaluate the effectiveness of any part of the processes of independence from the main activity of the organization.

With regard to technical equipment, the classic indicator of capital-labor ratio, determined by the ratio of the fixed assets value to the number of production workers, is calculated by the following formula (6):

$$CLR = \frac{Fixed\ assets\ value}{Number\ of\ production\ workers} \tag{6}$$

Where CLR – capital-labor ratio

This indicator also characterizes the technical equipment of the organization and the automation of production processes. However, this does not always indicate the efficiency of using fixed assets, since fixed assets having a higher level of automation also have a higher cost, despite the fact that the number of staff of such fixed assets is significantly reduced, and the qualification requirements are growing. For this reason, to determine the need for the introduction of modernization from an economic point of view, it is recommended to use the capital-labor ratio on wages.

$$CLR_W = \frac{Production\ fixed\ assets\ value}{\text{ФОТ}_{\text{пп}}} \quad (7)$$

Where CLR_W – capital-labor ratio on wages;

WF_{PP} – wage fund for production personnel.

In this case, the main condition for the modernization of technical conditions is that the growth rate of the fixed assets value and the wage fund for production personnel should be greater than 1, while the growth rate of the production fixed assets value should be higher than the growth rate of the wage fund for production personnel.

$$GR_{production\ fixed\ assets\ value} > GR_{WFpp} > 1 \quad (8)$$

When deciding on the implementation of technological innovations, the technological level of production is also extremely important, since on average, 25-40% of the cost of products depends on the level of production.

According to D.V. Lysenko, to analyze the technology of production processes the following indicators are used (Lysenko 2010):

- The share of technological advanced processes;
- Flow rate;
- The coefficient of technological equipment of production
- The share of products manufactured by advanced technological methods, and the share of work performed by advanced technology;
- The share of machine time in the technological complexity;
- Indicators of technological discipline;
- Unification and standardization ratios.

The level of automation of production processes is also important in assessing the technological level, since "the use of modern technologies allows us to increase the consumer properties of products (the quality of services provided), and also reduces current production costs".

To identify the potential opportunities for innovations in the technology of the production process, it is necessary to identify the level of automation. For this, necessary to analyze each stage of the production process, regardless of whether the production process is performed sequentially or in parallel. This analysis is carried out similarly to the scientific-technical level of production, only when determining the coefficient of mechanized work, the share of mechanized production stages in the whole production cycle is estimated:

$$C_{WM_{PC}} = \frac{\text{Products produced in a mechanized way}}{\text{Total volume of goods produced}} \quad (9)$$

Where $C_{\mathrm{WM_{PC}}}$ – coefficient of work mechanization of production cycle.

When choosing the direction of studying the organizational system and developing organizational innovations, the commercial effectiveness of the current organizational system should be investigated.

One of the indicators characterizing the complexity of production processes in the organization's activity is the indicator of the skills of performers, which shows the degree of proximity of the average level of all employees to the highest level. More qualified personnel are capable of the most active implementation of innovations, therefore, the qualification coefficient of production personnel, determined by formula (10), can reflect the organization's readiness for technological innovation:

$$R_{PQ} = \frac{\sum_{i=1}^{i'}(ip_i)}{i'N} \quad (10)$$

Where K_{PQ} – performers qualification rate;

p_i – the number of workers of the i-th category;

i' – the highest category of this production sector;

N – the total number of workers in the manufacturing sector (Korshunov, 2006).

Moreover, a higher qualification of workers leads to a higher level of wages. And, despite the fact that decisions to change the organizational and managerial structure and issues of labor organization are more managerial in nature, such changes should have a positive economic effect. Therefore, to determine the economic efficiency of the organizational system, the basis should be laid on the indicator of salary return. Salary return indicator is determined by the formula (11):

$$SR = \frac{\text{Sales revenue}}{\text{WF}}, \quad (11)$$

Where SR – the indicator of salary return.

Separately, to determine the effectiveness of management, the coefficient of management efficiency is used, determined by the formula (12):

$$\mathrm{C}_{ME} = \frac{\text{Sales revenue}}{\text{Management costs}}, \quad (12)$$

Where C_{ME} – the coefficient of management efficiency [43].

Also, to assess the organizational level, a manageability coefficient is applied, which reflects the actual degree of workload of the 1st manager in comparison with the normative level. This coefficient is calculated by the formula (13):

$$C_M = 1/m \sum_{i=1}^{n} \frac{r_{a_i}}{r_{n_i}} \quad (13)$$

Where C_M – the manageability coefficient;

m – the number levels of control;

r_{a_i} and r_{n_i} – actual and normative numbers of employees per 1 i-th head (Lysenko, 2010)

In our opinion, the calculation of the above coefficients helps to make decisions about the need to modernize the organization of labor. To do this, there are four stages:

1. Assessment of the coefficient of manageability:

- C_M = 1: the number of managers corresponds to the normative value: organizational work is organized rationally;

- C_M < 1: the number of management personnel is insufficient in the current organizational system;
- C_M > 1: management resources are used irrationally.

However, if the controllability coefficient deviates from 1, it is important to evaluate the management efficiency, since when maintaining or increasing the management efficiency, it is necessary to revise the regulatory management system itself.

2. Analysis of the dynamics of the coefficient of management efficiency:
- C_{ME} decreases: managerial model is ineffective;
- C_{ME} grows: management costs are used effectively.
3. Analysis of the dynamics of the coefficient of qualification of performers:

- R_{PQ} decreases: the level of preparedness of performers decreases, which can lead to a deterioration in the quality of products and the impossibility of timely targeted measures to establish production;

- R_{PQ} grows: the level of competence of production personnel is growing, which leads to an increase in the innovative potential of the organization.

4. Assessment of the dynamics of the salary return indicator:

– SR decreases: the organizational system is inneficient and requires the adoption of certain measures;
– SR grows: staff efficiency is growing.

Based on the above assessments, it is possible to draw certain conclusions and make a decision about the need of implementing organizational innovations. Typical decision-making options for organizational innovations are presented in table 1.

Table 1: Options for decisions on the implementation of organizational innovation in the analysis of the organizational level

Coefficient of manageability	Management efficiency coefficient	Performer qualification coefficient	Salary return	Conclusions on the modernization of the organizational structure
<1, =1, >1	↑	↑	↑	The organizational system works efficiently: the staff is ready for research and the implementation of technological innovations; adjustment of the regulatory indicator of controllability is required.
<1, =1, >1	↓	↓	↓	The organizational system is ineffective in all components and have to be changed.
<1, =1	↓	↑	↑	In the current management structure,

				management costs should be reduced.
>1	↓	↑	↑	The management team is hypertrophied and needs to be restructured; the production staff works efficiently.
<1, =1, >1	↑	↓	↑	The organizational structure is built efficiently, however, the lack of qualified personnel leads to the inability to implement technological innovations and for this purpose measures for improving the qualifications of employees should be taken.
<1, =1, >1	↑	↑	↓	The organization of the management system is effective, but the work of the staff is oversaturated with qualified, highly paid personnel: if the current economic effect is negative in the long term, this situation can provide a positive effect with the competent use of labor resources due to long-term technological development
>1	↓	↓	↑	The administrative apparatus is used irrationally and requires restructuring. Despite the positive short-term effect of the use of labor resources, in the long term, an excess of executive staff and a lack of qualified personnel will lead to a decrease in the production and innovation activities of the organization
<1, =1	↓	↓	↑	An exceptional case when the lack of manageability does not lead to a decrease in the efficiency of labor resources. However, such a scenario is possible only in the short run. In the long run, this situation will lead to a decrease in the organization's production and innovation activity.
>1	↓	↑	↓	Unreasonably high level of manageability and increase in the qualification of production personnel reduce the efficiency of the workforce: management must be restructured, and the work of production staff must be rationalized
=1	↓	↑	↓	High management costs with the normal use of managerial resources leads to a decrease in the effectiveness of the entire organizational system, including an excess of qualified personnel at this

				stage.
<1	↓	↑	↓	The lack of manageability, leading to a decrease in the effectiveness of the entire organizational system, within which managerial resources should be increased with a systematic decrease in the level of skills of performers
<1, =1, >1	↑	↓	↓	With well-managed management costs, the use of production personnel is extremely inefficient: a decrease in the qualifications of personnel while reducing salary return indicates the need for a complete change in the structure of the organization of production and the construction of a management system in accordance with its requirements.

Conclusion

Internal environment analysis of the organization plays a decisive role at the stage of developing an innovative project in the field of production and organizational processes and enables determining the organization's capabilities for introducing innovations of one type or another. For innovative economic analysis, classical methods of economic analysis should be applied, but they should be adjusted considering the features of innovative activities.

Abstract

Modern tasks of increasing the competitiveness of the national economy, ensuring the country's economic security, and moving the economy to a new level of technological development actualize the issues of improving the labor protection system and its development in the framework of modern world trends. Work-related traumatism and occupational diseases result in loss of working time, personnel problems, and significantly reduce labor productivity. In the article, the authors use statistical data, analytical and law enforcement materials of the Federal service for Labor and Employment to consider the types of job-related accidents, to analyze the causes and conditions of traumatism and mortality. The authors conclude that it is necessary to focus on the problems of developing the system of preventing work-relayed traumatism and occupational diseases, forming the interest of the parties of social and labor relations in meeting the requirements of regulatory documents on labor protection, carrying out activities aimed at improving working conditions, protecting the life and health of employees. The transition from the remuneration model of occupational safety and health management and payments for harmful working conditions to a modern system of occupational risk management will make it possible to implement preventive approaches to preserving the employees' health in the workplace, to reduce financial losses of businesses associated with unfavorable working conditions, to increase labor productivity and production efficiency in general.

Keywords: Occupational Safety, Employee, Employer, Occupational Traumatism, Occupational Diseases

Introduction

The labor protection system creates the foundation for developing and implementing the set of measures to create conditions for maximum security of employees' life and health. At the present stage, its improvement is particularly relevant due to increasing globalization and innovative modernization of production in all countries of the world, which is accompanied not only by new

technological opportunities, but by an increase in threats and risks to the life of people in various fields of work as well.

Work-related traumatism and occupational diseases result in loss of working time, personnel problems, and significantly reduce labor productivity. These are negative socio-economic, financial and material consequences not only for a particular organization, but for the country as a whole as well. For the global economy, losses from accidents and occupational diseases are estimated at 4% of GDP, for European countries and the United States - 3% of GDP. 2.78 million people die every year as a result of occupational accidents or workrelated illnesses (Work for a brighter future – Global Commission on the Future of Work International labor Office – Geneva: ILO, 2019). Prevention of occupational traumatism, prevention of occupational diseases, improvement of the labor protection system and its legal basis are the most important social and economic tasks not only in Russia, but internationally as well. Implementation of employees' right for labor protection is impossible without a well-functioning system of state control (supervision), as well as trade union control over labor protection.

The issues of developing and further improving labor protection are the subject of ILO annual reports dedicated to the World labor protection day, which indicates the importance and relevance of the problem and the need to take into account the latest trends in the development of international standards on labor protection. Ensuring safe working conditions and expanding social protection are identified as the main priorities and areas of cooperation between the ILO and various countries. «All workers, regardless of their contractual arrangement or employment status, must equally enjoy adequate labor protection to ensure humane working conditions for everyone...It is time for safety and health at work to be recognized as a fundamental principle and right at work." Global Commission on the Future of Work International Labour Office notes in its annual report (Work for a brighter future, 2019, p. 38-39).

The relevance of the topic is proved by the fact that the Russian Federation actively ratifies the ILO conventions on occupational safety and health issues: the ILO Convention № 187 "On Principles that Promote Safety and Health at Work", ILO Convention № 174 "On Preventing Major Industrial Accidents", ILO Convention № 176 "On Safety and Health at Work in Mines", ILO Convention № 167 "On Safety and Health at Work in Construction", etc.

In December 2017, the Russian Federation Ministry of Labor and Social Protection and the International Social Security Association (ISSA) signed the Memorandum of Understanding and Cooperation to promote the concept of "zero accident" (Vision Zero). The concept is a qualitatively new approach to the organization of prevention, combining three areas - safety, occupational health and well-being of employees at all levels of production.

Currently, a new holistic concept of ensuring healthy and safe working conditions is being developed, and attention is being paid to the experience of a number of countries in adopting and implementing comprehensive laws on safety, environmental protection, labor protection, hygiene and the production environment.

The national security strategy of the Russian Federation, approved by Presidential Decree № 683 dated 31.12.2015, aims at increasing the competitiveness of the national economy, at ensuring the country's economic security, and at moving the economy to a new level of technological development. All these tasks are closely related to improving the labor protection system. The General agreement between the All-Russian associations of trade unions, the All-Russian employers' associations and the Government of the Russian Federation for 2018 - 2020 focuses on ensuring the safety of employees' life and health in the course of their labour activity as one of the national priorities in order to preserve the human capital, which should be supported, including by improving the legislative and other regulatory framework, taking into account foreign and international legal regulation of labor protection.

Methodological Framework

The object of the study is social relations that develop in the field of labor protection, while implementing the measures aimed at improving the safety of employees' labour activity, preserving their life and health.
The research is based on an interdisciplinary approach. The methodological basis of the research is made by general scientific and specific scientific methods of cognition. The methodological instrumentarium is chosen taking into account the specific goals of the work.

The dialectical-materialistic method of cognition enables to study the system of labor protection in its development, in interdependency of all its individual manifestations and in interaction with related phenomena, to justify the advantages and disadvantages of various approaches to solving the issues of its improvement.

The paper uses the following methods of formal logic: description, comparison, classification, analysis and synthesis, etc. The research techniques include analyzing the causes and conditions for traumatism, employees' mortality, types of accidents, and their classification. The work also used specific scientific methods of cognition: comparative-legal, formal-legal, statistical, structural-functional method for substantiating the main directions of improving the legal and organizational basis of the labor protection system in modern production.

Discussions

Great attention has always been paid to Issues of labor protection. PhD theses, monographs, and scientific articles by Russian and foreign authors are devoted to considering various aspects of labor protection: A. Mikhailov (2013), E. Kryazhev (1997), A. Neverova (2014), S. Saidakhmedov (2009), O. Kuznetsova (2015), A. Petrov (2015, 2016), A. Khabibullina (2015), R. Meshechkina, N. Zholobov (2016), M. Buyanova (2016), Martina Gogolova (2015), Sergey S. Kudryavtsev, Pavel V. Yemelin, Natalya K. Yemelina (2018), Maureen F. Dollard, Daniel Y. Neser (2013), Veikko Rouhiainen (2018), Ioannis Anyfantis, Georgios Boustras, Alexandros Karageorgiou (2018). The problems of developing the labor protection management system taking into account modern international trends in this area are revealed in the works of G. Z.Feinburg (2016), E. A. Kuznetsova (2017), S. N. Kudryashova (2015). The authors share the position of individual scientists, debate with some of them and draw their own conclusions based on other scientists' opinion.

The work "The Development of Higher Education in Occupational Health and Safety in Estonia and Selected EU Countries" by authors Karin Reinhold, Virve Siirak, Piia Tint (2014) presents the experience of educational institutions in foreign countries on the organization of training in the field of occupational safety and its inclusion as a mandatory discipline in the curricula of all specialties (both technical and socio-economic); this experience is interesting for further studying.

Results

The concept of "zero accident" was developed by the International Social Security Association and launched in Singapore on the 4th of September 2017 at the XXI World Congress on occupational safety and health. For the first time in Russia, an ample debatable about the "Zero Accident" program developed in the framework of the panel discussion "Zero Accident Concept", to what extent international experience is applicable in Russia" at the All-Russian labor protection week, which was held from April, 10 to April, 14, 2017. Speaking at the 10th European regional meeting of the International labour organization (ILO) in Istanbul (Republic of Turkey) in October 2017, the Russian Minister of labour and social protection Maxim Topilin noted that Russia shared the principles of the concept of "zero" traumatism promoted by the International social security organization. In this regard, in 2018 the state program "Employment promotion" was supplemented with a new subprogram - "Safe labor". The purpose of the subprogram is to create conditions to form the culture of safe work and to increase the effectiveness of measures aimed at preserving the life and health of employees in the course of their work.

The subprogram is implemented in the following areas: developing and implementing the precautionary model of labor protection management; modernizing tools for state labor protection management; stimulating employers to improve working conditions in the workplace.
In 2019, the Ministry of labor and social protection of the Russian Federation developed the methodology for organizing internal control (self-control) of compliance with labor legislation, the methodology for remote training on labor protection, and methodological documents for employers in order to identify hazards, to assess occupational risks and to reduce their level based on the best world practices for the most traumatic types of economic activities. In addition, the concept of conducting a public awareness campaign aimed at promoting occupational safety and health of employees was developed.

Official statistics from the Federal service for labor and employment make it possible to draw the conclusion about the trend of reducing the level of general traumatism (About the results of 2019 in labor protection: Russian Ministry of Labour).

During 11 months of 2019, there were 4,078 accidents with severe consequences, which is 9% lower than in the same period of 2018 (4,479 cases). Figure 1 reflects the overall positive trend in traumatism decrease over the 5 years from 2015 to 2019.

Fig. 1: Dynamics of accidents with severe consequences for 2015-2019.

In 2019 a decrease in the number of deaths in the workplace is noted as well: during 11 months of 2019, the number of workers died is 12% less than in the same period of 2018 (1,018 and 1,158 people, respectively). However, the number of deaths traditionally remains the highest in construction, manufacturing, transport, agriculture and extraction of mineral resources.

Fig. 2: The number of fatalities in the workplace

When it comes to agriculture, official statistics on the number of casualties in the workplace allow us to compare agriculture with traditionally traumatic activities such as construction, transport and communications, as well as manufacturing.

The largest number of injuries and accidents, including fatal ones, falls on the livestock industry, crop production, maintenance and repair of equipment. At the same time, high-risk professions include those of an animal breeder, a tractor driver, a shepherd, a driver, a utility worker, a fitter, a milkmaid (Galyanov I. V., Koshechkin Yu. V., Studennikova N. S., Barabanova S. V., 2016).

The analysis of the typology of industrial accidents with severe consequences that occurred in the 1st half of 2019 in organizations of the Russian Federation shows that almost every fourth accident (25%) occurred as a result of a victim falling from a height or as a result of the impact of moving, flying, rotating objects, parts, machines and mechanisms (27%); 15% – falling on an even surface of the same level, 11% – as a result of falling, breakdown, collapsing of objects, materials; 8% – as a result of traffic accidents (Operational data for 2019. Federal Service for Labor and Employment).

Fig. 3: Types of workplace accidents with severe consequences that occurred in the 1st half of 2019

Among the main causes of accidents at workplace are: design deficiencies and insufficient reliability of machines, mechanisms, equipment, operation of faulty machines, mechanisms, equipment, violation of the technological process, violation of safety requirements when operating vehicles, road traffic offense, non-use of personal protective equipment by the employee, finding the victim in the state of intoxication by alcohol, drugs and other toxic substances. At this, a significant number of injuries are caused by unsatisfactory organization of work performance.

It should be noted that the reporting forms of the state labor inspectorate take into account only the types and causes of accidents with severe consequences, fatalities, and group accidents, a significant number of accidents remains unexplored. It seems appropriate to improve the system for analyzing and generalizing the information about accidents at workplace, their causes in the context of economic sectors and occupation of affected workers.

The documents of inspections performed by the Federal service for Labor and Employment form the idea of the most typical violations and shortcomings in the field of labor protection in agricultural production organizations. Thus, in accordance with article 217 of the Russian Federation Labor Code to ensure compliance with labour protection requirements, ensuring control over their implementation every employer, engaged in production activities where the number of employees exceeds 50 persons, shall organize a labour protection service or open the post of a specialist on labour protection, having the necessary training or experience in this area. However, some employers do not comply with this provision.

A large block of violations is traditionally associated with non-compliance with the requirements for training and employees' knowledge assessment. Agricultural organizations do not observe the established deadlines for training and testing of knowledge of labor protection requirements, not all managers and specialists, including mid-level executives who are directly responsible for the safety of workers, pass training and testing for labor protection. It is noted (Aleshin S., 2013) that the persons responsible for the state and organization of work on labor protection are not familiar with their specific official duties (functions) on labor protection. In some organizations, there are no commissions to check the knowledge of labor protection requirements; instructions, training on labor protection, on-the-job training, and checking labor protection knowledge are not carried out in accordance with the established procedure, as a result of which employees are suspended from work at the request of the labor Inspectorate (Report of the State Labor Inspectorate in the Chuvash Republic, 2017). One of the problems is the formalism when carrying out instruction on labor protection. Organizations do not develop instructions on labor protection for all types of work or professions, or they are not reviewed in a timely manner due to the emergence of new legal acts on labor protection. In some organizations, there are no programs for conducting introductory training and training on labor protection in the workplace. Logbooks of occupational safety instructions are filled in untimely.

According to item 19 of the Rules on labor protection in agriculture, approved by the order of the Ministry of labor and social protection of the Russian Federation dated 25.02.2016 № 76n, works that are associated with increased danger and are performed in places of constant action of harmful, dangerous production factors must be performed through work-permits to executing works of increased danger. The work permit must be issued by officials authorized by the employer, in accordance with the recommended model, which is provided for in the Appendix to the Rules. The list of employees' professions and types of work that are subject to heightened labor protection requirements is approved by the local regulatory act of the employer. At the same time, some organizations do not approve the lists of high-risk jobs, and work-permits for performing such works are not always issued in a timely and correct manner.

"Rules on labor protection while operating electrical installations" are enacted by the Order of the Ministry of Labor and Social Protection of the Russian Federation dated 24. 07. 2013 № 328n. Reports and analytical materials of inspections performed by the state labor Inspectorate indicate that organizations commit gross violations of labor protection rules and regulations when operating electrical installations. For example, testing of ground loops and insulation of electrical wiring is not

always carried out in a timely manner; electric welding transformers are often operated without protective barriers of current-carrying parts and protective earthing, metal structures of buildings, pipelines of the heating system and grounding buses are used as a reverse welding cable. In production capacities, in workshops, power electric equipment cabinets and other electrical switchgear are not under lock and key, on the doors there are no warning labels (signs) about the danger of electric shock and dispatching names (Aleshin S., 2013).

The procedure for authorizing the personnel to service the electrical equipment, including electric welding transformers and accumulator plants is violated. So, cases of operating the equipment for cold metal working (lathe machines, drilling, sharpening, etc. machines), the woodworking equipment without serviceable protective protections of cutting zones are revealed. It is noted that most drilling machines do not have a spindle returning mechanism, devices for secure fixing the processed products. Sharpening machines often do not have hand arm rests, and abrasive wheels do not pass the test for mechanical strength.

In a number of organizations, equipment for gas-flame metals treatment (welding and cutting) is operated with defective or unverified by state checkup pressure gauges of reducing gears, with faulty and not securely fixed gas flexible pipes; technical inspections and tests of portable acetylene generators, torches, burners, and gas pressure regulators are not carried out. Safety requirements are not met at workplaces on engine driven currents and other storage devices for example, dump pits are not always equipped with safety grates, storage hoppers are not covered with solid or grille flooring, and open pits of bucket carriers and inclined conveyors do not have protection covers. As a result of such violations, employees suffer serious injuries, including fatal ones.

One of the problems is providing employees with high-quality and certified special clothing, special shoes and other personal protective equipment. Article 212 of the Russian Federation Labour Code using equipment for personal and collective protection of employees that passed compulsory certification or declaration of conformity as prescribed by the law, purchasing and outgiving special-purpose clothing, footwear and other means of individual protection, washing and decontaminants are related to the employer's responsibilities. Typical violations are: no calculation of the need in such equipment, unsatisfactory record of their outgiving and returns by employees, violation of the terms for testing and checking their proper functioning; failure to replace or repair special-purpose clothing and other personal protective equipment collapsed before the end of the term for their using for reasons beyond the control of employees.

Given these considerations, it is possible to draw the following conclusions and to formulate separate directions for improving labor protection.

1. A human-oriented agenda requires an equally urgent – and additional - attention to the broad role of technology in promoting decent work (p. 43).
In the past few years, there has been a growing demand from manufacturing organizations for so-called "smart technologies"in Russia. New programs and technological developments are used in different industries, however their implementation is not sufficient and they are expensive. Developments in digital technologies in the field of labor protection cover several areas: documentation design, complex coordination of various operations, automation of management processes, and others. Thus, the "Production Control" program, which is an integrated system for ensuring work safety, is in demand. The program is aimed at prevention and control of processes related to the requirements of labor protection, industrial safety and environmental protection. It is used to identify risks, to keep records of all incidents, and to build global analytics in terms of security measures effectiveness. Such a development as "a smart helmet" monitors the employee's health indicators, the temperature in the work area, the content of harmful impurities in the air or the concentration of explosive gases. If a worker is in danger, a high degree of emergency or deviation from the norm is detected, the module instantly communicates with a single cloud platform and transmits information. "Digital" training is used to train workers in various safety skills.

Technologies can free workers from hard work, exhausting routines and dangers, and reduce work stress and potential traumatism. However, technologically driven production processes can make labor unnecessary, eventually removing workers and inhibiting their development. The Global Commission on the future of work aptly notes in its annual report that "automation can reduce worker control and autonomy, as well as the richness of work content, resulting in a potential deskilling and decline in worker satisfaction" (Work for a brighter future, 2019, p. 43). The approach to artificial intelligence should be based on the principle of " human-in-command", which ensures that the final decisions that affect the organization of work are made not by algorithms, but by people.

2. One of the most important ways to prevent occupational traumatism is to improve the efficiency of the occupational safety management system.

In order to maintain the existing positive trends in the field of labor protection, the Russian Ministry of Labor has been implementing a program-targeted method of labor protection management since 2015, which develops a risk-oriented approach to the social insurance system for occupational accidents and occupational diseases and control and supervision activities in the field of labor protection.

The "Safe work" subprogram is aimed at developing and implementing a preventive model of labor protection management with simultaneous formation of Incident and Injury Free culture.

To ensure a unified approach, the "Model state program of a Russian Federation subject for improving working conditions and labour safety" has been developed and recommended for use. Currently, programs to improve working conditions and labour safety have been enacted in all subjects of the Russian Federation. The program activities include improving the regional regulatory framework for labor protection, improving the competence of employees and employers in the field of labor protection, and developing mechanisms for employers ' material interest in improving labor conditions and safety. Businesses in developed and many developing countries treat expenditures on labor protection as an investment, while in Russia they are perceived as costs that will never pay off and will not return. Taking into account how much the organization loses when there is a high level of employees' traumatism (compensation for material damage, re-organization of production, investigation of accidents, additional payments to victims, hiring and training a new employee), it is much easier and more strategically correct to conduct preventive measures in the field of labor protection.

In addition, since 2014, the transition from the system of workplaces certification to the system of special assessment of working conditions has been made. In contrast to the certification, which described the actual values of working conditions, the new procedure represents a comprehensive scope of work to assess working conditions in the workplace, which addresses issues of labor protection, social security of employees and planning the organization's expenses aimed at improving the created conditions.

3. A significant number of accidents are related not only to the technical conditions of work, but to unsafe behavior of people in the workplace as well. In this regard, it is necessary to pay attention to forming high production practices among employees, unconditional compliance with labor safety requirements and an intolerant attitude to any deviations from labor protection requirements.

4. Analysis of international and Russian legal acts in the field of labor protection makes it possible to conclude that Russian legislation generally complies with international norms and standards in the field of labor protection. Further development of the Russian legislation on labor protection is connected with transition to the system of accident and occupational diseases prevention in the workplace.

It seems appropriate to improve the concept of labour protection, embodied in article 209 of the Russian Federation Labor Code, by adding and defining it as "system of *safety provision*, preserving the life and health of employees in the course of work activities, which includes legal, socio-economic, organizational-technical, sanitary-hygienic, medical-preventive, *psycho-physiological*, rehabilitation and other activities".

Russia is interested in the experience of organizing labor protection in the Federal Republic of Germany. There are several parts in the German labor protection system: technical labor protection, social labor protection, medical labor protection, etc. (Buyanova, 2016). This approach contributes to a more orderly and clears organization of the labor protection system. The US experience in strengthening the legal responsibility of employers for violations of labor protection requirements can be used to improve Russian legislation (Khabibullina, 2015).

It is necessary to draw attention to the need for the Russian Federation to ratify International labour organization conventions № 129 "On labour inspection in agriculture", № 184 "On safety and occupational hygiene in agriculture", and № 161 "On occupational hygiene services".

Conclusion and Recommendations

Thus, modern tasks of labor protection system development require not only responding to violations, accidents at work, but focusing on the problems of developing the system for preventing occupational injuries and occupational diseases as well, on forming the interest in the parties of social and labor relations in meeting the requirements of normative documents on labor protection, carrying out measures aimed at improving working conditions, protecting the life and health of employees. The transition from a remuneration model of occupational safety and health management and payments for harmful working conditions to a modern system of occupational risk management will make it possible to implement preventive approaches to preserving the employees' health in the workplace, to reduce financial losses of businesses associated with unfavorable working conditions.

New Directions of Financial Statement Fraud Detection Methods

Joanna WYROBEK

Department of Corporate Finance, Cracow University of Economics, Cracow, Poland,
wyrobekj@uek.krakow.pl

Abstract

The purpose of the paper was to present new developments in the area of financial statement fraud detection techniques. The paper analyzes new tools and data sources and shows research gaps that are not yet covered with the research. The novelty factor in the article is the presentation of these gaps.

Keywords: financial fraud detection, data mining, NLP

JEL classification: G30, G39, C38

Introduction

The stability of the financial system depends on multiple factors. One of them is the fairness of the stock market game and the resulting investors' confidence in investing in this market. Enron and Worldcom scandals showed the weaknesses of the external financial statements audit and the need to strengthen the supervision systems concerning corporate fraud. As a result, almost all countries all over the world introduced new regulations on how public corporations are to comply with the law. New regulations imposed on companies also required new supervision tools and controls performed by the commissions responsible for the stock market oversight. This paper attempts to observe recent developments in artificial intelligence applied to the prediction of corporate fraud.

State of the art

One of the first and well-known fraud-detection models was developed by M. Beneish (1999) and it predicts earnings manipulation of publicly traded companies based on several financial ratios calculated from the balance sheet and income statement data. Many analysts and information agencies use this model until today, however, many researchers developed his idea into more sophisticated systems with much better prediction accuracy. Table 1 shows the most relevant publications which followed the Beneish paper.

Table 1: Previous research results

Data	Accuracy	Recall	Algorithm	Source
Financial ratios	71.7	68.4	ANN	Green, Choi (1997)
Financial ratios	54.5	20	Logistic regression	Calderon, Green (1994)

**We chose the most popular version of the Beneish model with the proportion of costs for errors 40:1 and unweighted probit, ** Another version of the Beneish model estimated with a Weighted Exogenous Sampling Maximum Likelihood with the proportion of costs for errors 40:1.*

The results of the research provide the relatively good performance of the models. Still, in most cases, there was room for improvement, especially that in some of the older papers, the performance measures were based on cross-validation or substitution of the known data to the model instead of the separate validation sample. It is difficult to determine which model estimation method proved to be the most efficient because this depended on the size of the data sample and how extreme were the analyzed samples. For instance, Beneish research concentrated on the most significant financial scandals of the XX century, whereas Dechow's model was trained on an extensive sample, which included all US public companies which manipulated their financial statements. A variety of performance results for the same method also suggest that the selection of the method depends on the specific data sample (size, period, the scope of data). In the table, one can see that researchers successfully implemented various data mining and AI methods. Still, a dominating model was logistic regression because it produces a linear, easy to use and interpret formula for fraud prediction. Nevertheless, one of the most efficient classifiers was artificial neural networks, which proved their usefulness on the validation sample.

Extending the Financial Statement Data Model

The analysis of the literature from recent years shows that new publications explore new ideas concerning:

* extending the data sources used for the training of the model (not only financial statement data),

* implement new models of data classification and new methods of data extraction.

The first development is new sources of data used in fraud recognition. Table 2 shows that newer publications use nonfinancial statements and nonfinancial information conveyed in financial reports as well as the data from outside of the company, which is coming from analyst calls, discussion forums, investor portals, and psychological tools measuring the market sentiment and the CEO's personality.

Table 2: Corporate Fraud Detection developments

Development	Example of research
Numerical financial data	Cecchini et al. (2010a)
Linguistic analysis of financial texts	Cecchini et al. (2010b)
Financial ratios	Beneish (1999), Dechow et al (2011)
Non-financial variables from financial statements	Yuan et al. (2016)
Linguistic analysis of analyst calls	Larcker and Zakolyukina (2012)
Linguistic analysis of management report	Purda and Skillicorn (2015)
Traits extracted from oral speech (from analyst calls)	Hobson et al. (2012)
Linguistic analysis extracted from social media (investor forums)	Dong et al. (2018)
Risk factors taken from questionnaire research	Lenard et al. (2006)
Linguistic analysis of employees emails	Holton (2009)
Context-based features	Abbasi et al. (2012)
The employment history of the CEOs	Ericson et al. (2006)
CEO personality analysis	Johnson et al. (2011)

source: own compilation based on Dong et al. (2018), Amani F. and Fadlala A. (2017) and Table 1.

As can be seen from Table 1 and Table 2, the development of fraud detection models went in the direction of non-linear models and various sources of data that go far beyond financial statements. Information provided by multiple data sources is non-linear and context-dependent and quite possibly, the multi-dimensional functions describing the probability of fraud can have multiple extrema. Nonfinancial information which proved to be useful in fraud detection included:

- CEO's turnover (Dechow et al. (1996)),
- Big 4 Auditor (Fanning and Cogger (1998)),
- Audit fee higher than the average in the industry (Hribar, Kravet, Wilson (2011)),
- The remuneration package for directors (Armostrong, Jagonizer, Larcker (2010)),
- Market returns (Dechow et al. (2011)),
- The CEO duality (Feng et al. (2011)),
- Time of CEO employment (Erickson et al. (2006)),
- Religion (Koerber, Neck (2006)),
- Analysts call information (Hobson et al. (2012)),
- Age of a company (Erickson et al. (2006)),
- M&A activity (Erickson et al. (2006)),
- Percentage of outside directors (Armstrong et al. (2010)),
- Number of institutional investors (Armstrong et al. (2010)),
- Various economic predictors which in a quantitive or descriptive way characterize a company (Hribar et al. (2011)),
- Number of board meetings (Erickson et al. (2006)),
- Percentage of a "core" CEO salary in the total CEO remuneration (Feng et al. (2011)),
- Whether the company is below or above the analyst's expectations (Perols and Lougee (2011)),
- Number of business sectors in which a company operates (Hribar et al. (2011)),
- Auditor's opinion was in any way different from the standard version (Hribar et al. (2011)),
- Initial Public Offering (Hribar et al. (2011)),
- High risk of the court case (Hribar et al. (2011), Perols (2011)),

- Linguistic analysis features based on the contents of analyst calls (Larcker et al. (2012)),
- Linguistic analysis features based on the contents of management reports (Purda and Silikorn (2015)),
- Traits extracted from oral speech (Hobson et al. (2012)),
- Traits extracted from social media (Dong et al. (2018)),
- Corporate Governance implementation (Mahesarani, Chariri (2016)).

The second development in financial statement fraud detection is the implementation of the automatic personality perception tools and generally extensive use of natural language recognition tools (for opinions, emotions, sentiment). Automatic personality perception is an essential topic in psycho-linguistics and focuses on determining a person's personality from the text and oral interviews. The most famous personality measures system used in automatic feature detection is the Big Five system, which follows the binary values for extraversion, neuroticism, agreeableness, conscientiousness and openness. On top of personality recognition researchers extract emotions from oral interviews and video files, parse any written documents or internet websites in search for opinions, emotions and sentiment. Table 3 shows the most popular existing tools.

Table 3: Popular tools used for feature extraction from different types of data

Type of contents	Name	Commercial or free	Selected functionalities
NLP, Sentiment analysis	LIWC (API: Receptiviti)	commercial	Extracts certain words or phrases from texts which are meaningful for psychological features; it contains dictionaries of such words for many languages. This software sets standards for NLP and sentiment analysis.
NLP, Sentiment analysis	RIOT Lite/RIOT Scan	free, open-source	Extracts certain words or phrases from texts which are meaningful for psychological features, but it does not come with a dictionary
NLP, Sentiment analysis	TAPA	free	Extracts certain words or phrases from texts which are meaningful for psychological features, allows adding weights to words. Allows for using their own dictionaries and character norms.
NLP, Sentiment analysis	FreeLing	free	Divides text into tokens, performs morphological analysis of texts, parts of speech tagging, rule-based dependency parsing
NLP, Sentiment analysis	SenticNet	free, open-source	Extract certain words and phrases from the given text and categorizes emotions conveyed in them in terms of four affective dimensions (Pleasantness, Attention, Sensitivity, and Aptitude) and polarity is floating number between -1 and +1 (where -1 is extreme negativity and +1 is extreme positivity)
NLP, Sentiment analysis	Python: NLTK	free, open-source	It offers easy interfaces to more than 50 linguistic resources, allows for word classification, tokenization, finding a stem of a word, parts of speech tagging, parsing of texts, semantic reasoning, wrappers for industrial-strength NLP libraries.

Type of contents	Name	Commercial or free	Selected functionalities
NLP, Sentiment analysis	Java: Stanford CoreNLP	free	Offers parts of speech tagging, named entity recognizer (labels sequences of words in the text which are the names of things), text parsing, sentiment analysis, pattern learning, open information extraction tools
NLP, Sentiment analysis	Cython: SpaCy	free, open-source	Allows division of the text into tokens, recognition of named entities (labels sequences of words in a text which are the names of things), dependency parsing (creation of the grammatical sentence structure and relationships between "head" words and words which modify these heads), sentiment analysis
NLP, Sentiment analysis	Gensim	free, open-source	Topic modeling (classifies texts into topic clusters), indexes texts, finds similarities, prediction of the next word based on previous words, transforming words into vectors
NLP, topic modeling	Meaning Extraction Helper	free	Creates datasets for semantic analysis, processes customized content-coding schemes, word frequency analysis, topic modeling
NLP	IBM Watson	commercial	Detects emotional tones
NLP	Vader-Tots	free	Tokenizes text, sentiment analysis
NLP	Contextualizer	free	Extracts words that surround selected keywords or phrases, the user specifies words meaning positive or negative emotions and the software extracts them.
NLP for conversational data	ConverSplitter Plus	free	Splits apart transcribed files by each speaker, detects speaker tags and removes timestamps and other useless marks.
NLP, Sentiment analysis	Bitext	commercial	Sentiment analysis of texts
NLP, Sentiment analysis	MoodPatrol	commercial	Recognizes emotions and sentiment in texts
NLP, Sentiment analysis	Synesketch	free, open-source	Textural emotion recognition and maps emotions into images
NLP, Sentiment analysis	Tone API	commercial	Analyzes the emotional tone of a text.
NLP, Sentiment analysis	Repustate API	commercial	Emotions detection, social media sentiment analysis
audio, video, text for emotions and sentiment	Mixed Emotions	free, open-source	Estimating arousal, valence, big5 personality traits, emotion detection, and sentiment detection of texts.

Type of contents	Name	Commercial or free	Selected functionalities
speech analysis	PRAAT	free, open-source	Emotional state identification (feature extraction)
speech and video recognition and processing	OpenSMILE	free, open-source	Emotional state identification (feature extraction)
speech recognition and processing	OpenEAR (C++ code)	free, open-source	Emotional state identification (feature extraction)
speech recognition and processing	MIR Toolbox	free, open-source	Emotional state identification (feature extraction)
speech recognition and processing	Psysound	free, open-source	Emotional state identification (feature extraction)
speech recognition and processing	Marsyas (Music Analysis, Retrieval, and Synthesis for Audio Signals)	free, open-source	Emotional state identification (feature extraction)
speech recognition and processing	Vokaturi	free version and commercial version	Emotion recognition from speech
human body audio recognition	GoodVibrations	commercial	Emotion recognition from speech, heartbeat rate, lungs, other organs
facial expressions and speech	Affectiva	commercial	Facial and physical expressions recognition for emotions and intensity (heart rate), speech analysis
facial expressions	FlowingSoftware	free	Facial and physical expressions recognition for emotions and intensity
facial expressions	Cyflogic	free academic use	Facial and physical expressions recognition for emotions and intensity
facial expressions	CERT (The Computer Expression Recognition Toolbox (CERT))	free academic use	Facial and physical expressions recognition for emotions and intensity
facial expressions	Face++	commercial	Facial and physical expressions recognition for emotions and intensity, it can read postures
facial expressions	EmoVu	free	Facial and physical expressions recognition for emotions and intensity
facial expressions	Face (Microsoft Azure)	commercial	Facial and physical expressions recognition for emotions and intensity
facial expressions	Emotient	commercial	Facial and physical expressions recognition for emotions and intensity
facial expressions	Kairos	commercial	Facial and physical expressions recognition for emotions

Type of contents	Name	Commercial or free	Selected functionalities
facial expressions	Project Oxford	commercial but one can request it for free	Facial recognition of eight core emotional states – anger, contempt, fear, disgust, happiness, neutral, sadness or surprise
facial expressions	Face Reader (Noldus)	commercial	Facial and physical expressions recognition for emotions and intensity, eye tracking, physiology data
facial expressions	SightCorp	commercial	Facial and physical expressions recognition for emotions
facial expressions	SkyBiometry	commercial	Facial and physical expressions recognition for emotions
facial expressions	Imotions	commercial	Facial expressions, eye tracking, electrodermal activity, EEG, EMG, ECG
biometric detection	CrowdEmotion	commercial (startup)	Biometric detection, recognition of emotions
facial expressions	FacioMetrics	commercial	Facial and physical expressions recognition for emotions
facial expressions and semantic text analysis	AlchemyAPI	commercial	Facial and physical expressions recognition for emotions, analysis of texts for emotions and sentiment
facial expressions and text recognition	Vision API	commercial	Detects emotions from facial expressions and texts
facial expressions, pose and joint detection	Nviso	commercial	Facial and physical expressions recognition for emotions
wrist movements	PredPsych	free, open-source (R toolbox)	Wrist velocity, wrist height, grip aperture, physical expression of emotions

As can be seen in Table 3, there exist nowadays multiple libraries and programs which are capable of detecting emotions (lying) and personality types. One of the popular tools is the Linguistic Inquiry and Word Count (LIWC) software. LIWC was created based on text extraction and the vectors with word counts. Creators of the LIWC used this data for machine learning where the output vectors were the results of paper personality tests run on research objects. Another popular tool is the Sentic net, which is a knowledge base that contains over 100.000 natural language semantics, sentics and polarities which allow determination of 4 affective emotions: pleasantness, attention, sensitivity, and aptitude.

OpenSMILE is the acronym of open-source software for automatic extraction of features from audio signals and for classification of speech and music signals. OpenSMILE is capable of recognition of emotions, age, gender, personality. A similar tool is Praat but it has fewer functionalities than OpenSMILE.

FACS, Face++, Noldus, EmoVu, Affectiviti and CERT, are capable of recognizing facial expressions and can recognize different prototypical facial expressions. Face++ can also read body movements and postures.

Synesketch, NLTK, CoreNLP, Cython and SpaCy are used for natural language processing of text. They allow: tokenization, parts-of-speech tagging, dependency parsing, lemmatization, sentence boundary detection, named entity recognition, entity linking, similarity analysis, text classification,

rule-based matching, training and serialization. Gensim is a similar tool but with a narrower scope of functionalities and concentrates on topic modeling and document similarity analysis.

Freeling is a primary language processing suite for such purposes as tokenizing, morphological analyzers, lemmatizing, PoS tagging, chunking, etc. is a need for most NL applications such as Machine Translation, Summarization, Dialogue systems, etc.

Receptiviti API is used to analyze texts, tweets, emails, chats, surveys and voice data to provide insights into various aspects of people's personal lives, such as personality, emotion, tone and relationships.

Repustate API is used for sentiment analysis in the text. This API is based on linguistic theory and review cues based on POS tagging, lemmatization, prior polarity and negations.

Researchers also analyze linguistic styles (Newman et al. (Newman et al. 2003)) of how the directors communicate and the amount of information revealed to the media (Buller, Burgoon(Buller and Burgoon 1996)). Since social media use a specific language, researchers create dedicated dictionaries which should measure emotions in posts on social media (Loughran, McDonald (Loughran and Mcdonald 2011)). Social media and media informational contents include not only emotions and opinions, but also more direct information used in fraud prediction such as:

- The number of breaking news (Pak and Zhou (2014)),
- The number of messages on investor forums (Dong et al. (2018)),
- The number of comments to messages on investor forums (Dong et al. (2018)),
- Social connections of the CEOs modeled with graph databases (Kiedrowicz et al. (2018)).

As can be seen from table 4, new research that uses described new techniques of information extraction and new data sources seem to improve the efficiency of fraud detection.

Table 4: Fraud detection accuracy when financial data is supported by nonfinancial and social media information

Data type	Accuracy	Recall	Method	Source
Analysts calls	89.21	n.a.	logistic regression	Larcker and Zakolyukina (2012)
Management reports	82.95	93.57	logistic regression	Purda and Skillicom (2015)
Management reports	67.3	65.3	C4.5 (decision tree)	Humpherys et al. (2011)

Data type	Accuracy	Recall	Method	Source
Financial social media	52.38	49.18	LR	Dong et al. (2016)

Conclusions and Recommendations

Figure 1 shows a summary of the financial fraud development methods. Detection techniques initially used financial and numerical data, mostly financial ratios and the most popular models, such as probit and logit functions. The first step of their evolution was increasing interest in nonfinancial variables from financial statements, basic data mining techniques and interest in the CEO's narcism. In the next step, researchers learned how to deal with unstructured data, extracted traits from speech and documents and used more sophisticated artificial intelligence techniques. Recently, one can see in the literature increasing interest in social media contents and extensive use of natural language processing. As to the future, if one looks at recent trends, there seems to be a gap in the research for a better understanding and measurement of the CEO personality traits, video recognition and other developments of affective computing.

Figure 1: Development of corporate fraud detection models and algorithms

Recent developments in presented software tools suggest that in the future one may expect a better usage of video materials which can be tracked for physical signals of lying (facial expressions, physical symptoms of lying – heartbeat, breathing, blood pressure, wrist movements, perspiration, body posture) and better penetration of the internet resources for sentiment analysis. We also expect an improvement in the number of personality traits and emotions which can be detected so researchers can identify not only narcissuses but also psychopaths, excessive ambitions, tendency to manipulate other people, the criminal mind, arrogance, sycophants, lawbreakers, ease of rationalization (popular attributes of conscious fraudsters). It also seems that the recent developments in financial and non-financial reporting and the increasing trend for standardization of these reports will enable the researchers to use this new data in the prediction process.

Marta DARON
Czestochowa University of Technology, Częstochowa, Poland, marta.daron@wz.pcz.pl

Abstract

The motivation for undertaking the research was to prove an influence of various tools of logistic management on the enterprise development. Authors of the paper specified tools of logistic management as IT systems more and more often used by different enterprises. To indicate the impact of IT systems (in particular ERP, CRM and SCM systems) on enterprise development there were compared 10 economic branches on the grounds of the use of these systems. The aim of the research was to determine, in what trade the IT systems are applied to the highest extend and how does it impact the enterprise development. Additionally, there was analysed and compared the use of IT systems by enterprises functioning in particular industries of the Polish and German economy. In the research there were conducted analysis based on the methods of multidimensional benchmarking. The measure of development based on the application of systems fostering logistic management by enterprises of different industries was calculated and the concentration analysis by the means of HH index was conducted. The results of the research were presented in form of Tables.

Keywords: Development, IT Systems, Logistic Management

Introduction

The successive activity of enterprises depends on the effective management. The management is more and more connected with logistics, that makes it possible to organize flows of goods, people or information in every area in our life. There are many solution the leaders of a company may use to improve an enterprise prosperity, but the choice of appropriate tools is not an easy way. However, the use of IT systems supporting logistic management seems to be rational nowadays because of still growing amount of information the enterprises should gather and process. The IT systems can definitely foster the enterprise management, but the aim of the paper is to check, how the use of IT systems, especially ERP (Enterprise Recourse Planning), CRM (Customer Relationship Management), SCM (Supply Chain Management) systems affect the enterprise development.

The authors considered this area of research very actual and interesting. The comparison of industries in reference to the use of systems supporting logistic management enables to consider some special needs or demands of particular enterprises in order to improve their activity. The comparison of a whole industry, but in different economic conditions (in Poland and i Germany) makes the problem more complex and interesting, that can bring a new light on the analysed area. Namely, the use of IT solutions supporting logistic management affects the enterprise development at different levels in different economic conditions. According to the research data, the impact of ERP, CRM and SCM systems applied in various organizations is doubtless high, and leads to more skilful and effective management, thereby to more successive prosperity of enterprises, irrespective of some economic determinants. In the research there were used the methods of the multidimensional comparison analysis which enables to calculate the measure of enterprise development and a distance of an industry from the estimated pattern.

In the paper the authors tried to indicate how the application of systems supporting logistic management influence enterprises' development functioning in different sections of Polish and

German economy. To achieve this aim of research some methods of numerical taxonomy were used, and in particular the methods of linear ordering of objects. The analysis was conducted on the basis of statistical data available for years 2009 and 2017 from Central Statistical Office (GUS for Poland) and Statistical Office (Statistisches Bundesamt for Germany). The aim of the study was to determine the similarities and differences in terms of the grade of application of IT systems, as ERP, CRM and SCM in the enterprises of various trades in Poland and Germany.

Research Questions

In order to conduct the research the following research questions were stated:

- Does the application of IT systems effect the enterprise development?
- To what extent different industries apply IT systems supporting logistic management?
- Which of the analysed industries are characterized by the highest measure of development in reference to application of ERP, CRM and SCM systems?

To answer in detail the questions above, and some further questions, that may result from the research, the study might to be extended in time. There is a basis for further discussions in this area.

Literature Review

Modern enterprises need to use information gathering and processing technologies to be able to operate in global supply chains. Information technologies (IT), enabling the flow of information, play an important role in the business and financial results of the enterprise. IT makes the supply chain more reliable, load-resistant and at the same time efficient (Tseng et al. 2011). Enterprises have many solutions to choose from. Firstly, they can implement those that enable conducting a customer-oriented strategy - CRM (Jelonek 2006, 2015, Pozza et al. 2018, Sulaiman et al. 2014). CRM as an IT system enables the implementation of CRM strategies. Customer records, grouping of contacts with clients, project management and other possibilities of this system enable an individual approach to the client.

Secondly, enterprises can choose the solutions that enable global exchange of information between partners in the supply chain - ERP (Mesjasz-Lech 2015, Hendricks et al. 2007, Kot et al. 2015). ERP systems support both specialized production functions as well as quality management, repairs, service and creation of management reports. Characteristic for ERP is the generation of comprehensive financial analyzes for the needs of management. ERP systems combine various processes in an enterprise and its supply chain through one logical database. However, despite the fact that most of the major ERP systems contain a CRM module, in practice the use of separate CRM systems is observed in many organizations (Haddara and Constantini 2017).

Thirdly, enterprises can use SCM systems, often called complementary to ERP (Lo et al. 2008), because the ERP system integrates information within one application, and individual applications of the SCM system use it as a source of current data. There are two types of SCM systems: internal regarding supply, production and distribution, and external enabling integration of the enterprise with its suppliers and customers. Thanks to the SCM system, enterprises can more flexibly and effectively influence their suppliers and clients, including them in executive or planning processes (Su and Yang 2010).

The research presented in the article is based on the use of the above-mentioned systems in Polish and German enterprises of various trades.

Research Design and Methodology

A deep cognition of both simple and complex economic phenomena influencing an enterprises' prosperity in different trades is possible only by means of a thorough multidimensional analysis, by which some statistical methods are used. The units' research according to the complex phenomena

(those, which are described by many variables) does not bring the possibility of direct confirmation, which of these test units shows the highest level of the complex phenomenon. It is, therefore necessary the use of some methods from the field of statistical multidimensional analysis, specifying – some methods of benchmarking, that allow to explain such issues as following:

- an evaluation of differences among researched units in terms of complex phenomenon,
- an ordination of researched units in terms of level of complex phenomenon.

In the statistical analysis there are significant these definitions:

- an object (the statistical unit being researched),
- variable (the specification describing population of objects and having for every single object some defined value),
- measurement of variables (the assignment of numbers for every object in such a way, that these numbers reflect relations among objects).

By the use of methods of multidimensional statistical analysis there is necessary to know how the variables can be divided according to the specific features they can poses. There are distinguished stimulants (variables having higher values, which are desired from the perspective of general character of researched phenomenon), destimulants (variables having higher values, which are not desired from the perspective of general character of researched phenomenon) and nominants (variables having deviations from normal level, which are not desired from the perspective of general character of researched phenomenon).

Linear ordering methods constituting the basis of multidimensional benchmarking are widely used especially by the evaluation of objects variety according to the achieved level of economic development. The application of these methods enables, i.a.:

- hierarchy of objects in multidimensional fields of features. The hierarchy because of its special character cannot be measured directly,
- extraction of objects which characters are similar in terms of analysed features,
- designation of development pattern for researched objects'
- indication of the most informative features and evaluation of impact of essential variables on the level of economic growth.

The aim of grouping methods is, in turn, to separate out of sets similar in terms of some elements. It is done not only to designate the function value of particular criterion, but also to find such a displacement among groups, which may influence value improvement of criterion function. Multidimensional benchmarking enables to study a complex phenomenon specified by few variables, which constitutes development potential of enterprises functioning in different economic sections. The development potential is defined by means of economic indicators. It has been researched the variable vector, as following:

$$X = [X_1 \dots X_m],$$

by which *m* means number of variables. By the application of multidimensional benchmarking methods there should be extracted variables defined by the same units of measurement with similar orders of magnitude, and that is why it is recommended to normalize the variables in order to standardize both - measurement units of variables and orders of magnitude of variables. An often used way to normalize variables is the standardisation conducted according to the scheme:

$$z_{ij} - \frac{x_{ij} - \bar{x}_j}{S_j}, (i - 1, 2, \dots, n; j - 1, 2, \dots, m)$$

wherein particular symbols mean:

n – the number of objects

z_{ij} – standardized variable value X*j* for i-th object,

$\bar{x}_j$ - arithmetic average of a variable X*j*,

S_j – standard deviation of a variable X*j*.

The term that enables the comparison of objects relative to each other, from the view of complex phenomenon, is the similarity defined as the fact, that objects are the more similar, the more similar are the variable values defining particular complex phenomenon. The similarity perceived in this way is measured in the multidimensional benchmarking by means of the distance between objects, that assigns one value to the two objects. It is therefore necessary to denominate the Euclidean distances of particular objects in relation to the reference object according to the scheme:

$$d_{i0} = \sqrt{\sum_{j=1}^{m}(z_{ij} - z_{0j})^2} \qquad \text{(i=1, …, n)}$$

wherein,

$$z_{0j} = \begin{cases} \max_i z_{ij} & \textit{for stimulants} \\ \min_i z_{ij} & \textit{for destimulants} \end{cases}$$

It was established, that the influence level of all variables on the analysed phenomenon is the same. There was estimated the measure of development for each object according to the scheme:

$$m_i = 1 - \frac{d_{i0}}{d_o} \qquad \text{(i=1, …, n),}$$

wherein d0 means distance between pattern and anti-pattern of development defined by the scheme:

$$d_0 = \sqrt{\sum_{j=1}^{m}(z_{ij} - z_{_0j})^2} \qquad (i = 1, \ldots, n)$$

wherein:

$$z_{_0j} = \begin{cases} \min_i z_{ij} & \textit{for stimulants} \\ \max_i z_{ij} & \textit{for destimulants} \end{cases}$$

For the measure of development defined in this way, which values are in the range [0,1], it is accepted, that the higher its value , the higher the level of researched phenomenon.

For studies in this paper there was estimated the synthetic measurement aimed to analyse the concentration of logistic management potential influencing the development of enterprises functioning in different economic branches. Economic studies should be based on numerical recognition of concentration strength understood as a grade of irregular distribution of values of variables features for particular units of researched statistical population. In aim to research the concentration strength there was applied the Herfindahl-Hirschman Index (HHI), which values are in range (1/n; 1), and the higher its value, the stronger concentration. The Herfindahl-Hirschman Index was estimated according to the scheme:

$$H = \sum_{i=1}^{n} z_i^2$$

wherein z_i means the value share of the researched feature of i-th object in the total sum of values of the studied phenomenon for all analysed *n* units.

Results

The unit of the economy is a section. Economic sections differ, i.a. in the grade of the use of various IT systems supporting logistic management in particular enterprises. It is, therefore necessary to evaluate the intensity of application of IT systems in various industries. As a tool of this evaluation there were used the methods of multidimensional data analysis. In the aim to evaluate the potential of IT systems as factors influencing enterprise development in various economic sections in a context of logistic management, there was used the method of linear ordering from the field of multidimensional benchmarking. It was established, that the IT systems potential may be determined by the synthetic variable, which comprises the use of various software types – ERP, CRM and SCM. In the research there were analysed ten key economic sections, as following: Industrial processing (C Section), Production and supply of electricity, gas and steam, water supply. Sewage and waste management (D and E Section), Construction (F Section), Trade and Repair (G Section), Transport and Storage (H Section), Accommodation and Catering (I Section), Information and Communication (J Section), Real Estate Market Service (L Section), Science and Technology (M Section), Administration and Support Activities (N Section). Furthermore, the economic sections listed above were compared in two European Union countries – Poland and Germany, and for the researched the data from Polish and German statistical office for the years 2017 and 2009 were analysed. It was assumed, that the grade of the IT systems constitutes the basis of logistic management development of enterprises in particular industry. The determination of synthetic variable has enabled to create a ranking of industries in terms of the intensity of the IT systems application. In the research the following variables were distinguished:

X_1 – the share of enterprises of particular industry using ERP systems in order to transfer information between different departments of an enterprise (eg. accounting, marketing, production),
X_2 – the share of enterprises of particular industry using CRM systems in order to manage customer information that enable to collect and store customer information, and to provide access to these information for various enterprise departments,
X_3 – the share of enterprises of particular industry using CRM systems in order to manage customer information that enable to analyse customer information for marketing aims (e.g. pricing, promotion management, choice of distribution channels)
X_4 – the share of enterprises of particular industry using SCM systems in the area of electronic exchange of information on supply chain management with suppliers or recipients.

The all variables are characterized as stimulants. These variables create the potential of enterprises of particular industry. The results of the linear ordering were depicted together for all four variables groups – the application of three different IT systems: ERP, CRM, SCM in Poland for the year 2009 (Table 1.), and for the year 2017 (Table 2.), in Germany for the year 2009 (Table 3.), and for the year 20017 (Table 4.). All the Tables 1. – 4. present the ranking of industries (from above there are placed the industries having the highest measure of development value). This way of results depiction enables to compare, how high was the level of ERP, CRM and SCM systems application by enterprises in particular industries.

Table 1: The results of linear ordering – the distance of objects from the development pattern and the measure of development for IT systems (ERP, CRM, SCM) potential in Poland in the year 2009

Industry/Economic Section	The distance of objects from the pattern	Measure of development
Information and Communication - J	0.620938	0.986024
Trade and Repair - G	2.693774	0.939370
Production and supply of electricity, gas and steam, water supply. Sewage and waste management – D; E	3.786250	0.914781
Science and Technology - M	4.187435	0.905751
Industrial processing - C	4.302620	0.903159
Transport and Storage - H	4.609612	0.896249
Administration and Support Activities - N	5.143177	0.884240
Real Estate Market Service - L	6.031202	0.864252
Accommodation and Catering - I	6.225903	0.859870
Construction - F	6.368566	0.856659

Source: own compilation

The enterprises of the Information and Communication Industry, that use IT systems (ERP, CRM, SCM) present the best conditions for the enterprise development potential in the context of applied IT systems supporting logistic management. In the other industries the development conditions are also good, what is confirmed by the high value of the measure of development index. In the case of Poland, in both analysed years 2009 and 2017 (Tables 1. and 2.), the best economic section, in terms of the application of IT systems supporting the logistic management in enterprises, was the Information and Communication Industry (J Section), what, in reference to its activity specification based on the application of various IT solutions, seems to be obvious.

Table 2: The results of linear ordering – the distance of objects from the development pattern and the measure of development for IT systems (ERP, CRM, SCM) potential in Poland in the year 2017

Industry/Economic Section	The distance of objects from the pattern	Measure of development
Information and Communication - J	0	1
Trade and Repair - G	3.540649494	0.930355964
Industrial processing - C	4.310378517	0.915215511
Administration and Support Activities - N	4.474036010	0.911996393
Production and supply of electricity, gas and steam, water supply. Sewage and waste management – D; E	4.557612487	0.910352457
Science and Technology - M	4.987700823	0.901892685
Transport and Storage - H	5.600680813	0.889835462
Real Estate Market Service - L	6.002094444	0.881939717
Accommodation and Catering - I	6.287688223	0.876322131
Construction - F	6.631460859	0.869560175

Source: own compilation

It is worth noticing, that in the year 2017 the Information and Communication Industry achieved the result of 1, what indicates, that this economic section may constitute a pattern to follow for enterprises of other industries, taking into consideration the enterprises development as a result of the given IT systems use. Invariably for two analysed years – 2009 and 2017 on the second place in the ranking is the G Section – Trade and Repair Industry. By the other economic sections it is to observe,

that there are slight fluctuations in terms of ranking places occupied by them. In both analysed years – 2009 and 2017 the last three places are taken by Real Estate Market Service – L, Accommodation and Catering – I, Construction – F. It should be stated, that despite of the ranking of the best (in reference to the measure of development perceived from the perspective of IT systems application supporting logistic management in enterprises) industries, all researched economic sections are characterized by the very high value of the measure of development, and their Euclidean distances relative to the pattern is very small. Taking into consideration the results of the research it should be added, that there are definitely some areas in the enterprises of industries placed lower in the ranking, that need to be improved.

A bit different looks the situation in the case of Germany in the researched years 2009 and 2017 (Tables 3. and 4.). There are to observe greater fluctuations by the placing of industries ranking of the best developing economic sections in reference to the use of IT systems supporting logistic management in enterprises.

Table 3: The results of linear ordering – the distance of objects from the development pattern and the measure of development for IT systems (ERP, CRM, SCM) potential in Germany in the year 2009

Industry/Economic Section	The distance of objects from the pattern	Measure of development
Production and supply of electricity, gas and steam, water supply. Sewage and waste management – D; E	2.302680	0.946580
Trade and Repair - G	2.721688	0.936859
Information and Communication - J	2.948839	0.931589
Industrial processing - C	4.043305	0.906199
Real Estate Market Service - L	4.911742	0.886052
Administration and Support Activities - N	5.239075	0.878458
Science and Technology - M	5.462872	0.873266
Transport and Storage - H	5.852989	0.864216
Construction - F	5.862623	0.863992
Accommodation and Catering - I	6.218069	0.855746

Source: own compilation

While in the analysed year 2009 (Table 3.) the economic sections D and E (Production and supply of electricity, gas and steam, water supply. Sewage and waste management) indicated the best result in relation to the measure of development calculated in the research, they felt on the 4th place in the industry ranking in the year 2017. In the year 2009 only third place of the Information and Communication Industry (J Section) which activity is based on the use of different ICT solutions, can be also considered unusual. The last three places were taken by the economic sections, as following: Transport and Storage – H, Construction – F, Accommodation and Catering – I. Similar to Poland all analysed industries in German economy indicated the high value of the measure of development, but despite of that there are still some issues by the application of IT systems supporting logistic management in German enterprises to improve.

The linear ordering methods used in the research enabled not only to indicate the best industries, but also to determine their similarity to the pattern the enterprises should follow to succeed. The analysis, in reference to the application ERP, CRM i SCM systems supporting logistic management in enterprises, allows to compare to what extent the application of these systems may influence both - the enterprises development of the given industry, and the decision-making concerning some future activities fostering enterprise development.

Table 4: The results of linear ordering – the distance of objects from the development pattern and the measure of development for IT systems (ERP, CRM, SCM) potential in Germany in the year 2017

Industry/Economic Section	The distance of objects from the pattern	Measure of development
Trade and Repair - G	1.393940	0.965825
Information and Communication - J	1.481566	0.963677
Industrial processing - C	2..692511	0.933989
Production and supply of electricity, gas and steam, water supply. Sewage and waste management – D; E	2.972921	0.927114
Real Estate Market Service - L	4.376903	0.892693
Science and Technology - M	4.722806	0.884213
Administration and Support Activities - N	5.015551	0.877036
Transport and Storage - H	5.142960	0.873912
Construction - F	5.569970	0.863443
Accommodation and Catering - I	6.107582	0.850263

Source: own compilation

The potential of logistic management tools based on the application of ERP, CRM i SCM systems constitutes an internal element of enterprises structure leading to their development. Considering separately the variables creating the potential of logistic management, there are concentration indices (HHI) presented in Tables 5. and 6. worth noticing.

Table 5: Herfindahl-Hirschman Indices for the use of IT systems potential in Poland in the years 2009 and 2017

Variable	HHI in 2017	HHI in 2009
The application of ERP systems	0.231	0.307
The application of CRM systems in order to manage customer information that enable to collect and store customer information, and to provide access to these information for various enterprise departments	0.213	0.256
The application of CRM systems in order to manage customer information that enable to analyse customer information for marketing aims (e.g. pricing, promotion management, choice of distribution channels)	0.245	0.296
The application of SCM systems in the area of electronic exchange of information on supply chain management with suppliers or recipients	0.256	0.329

Source: own compilation

In the concentration analysis there was researched the grade of the use of ERP, CRM, SCM systems in enterprises of particular industries in Poland and Germany. The high concentration is to observe by all analysed features in both analysed years 2009 and 2017. The highest values of the HH Indexes in this variable group appeared in the number of enterprises using SCM systems. The presented research data showed also, that in the year 2017 in comparison to the year 2009 the concentration inequality in reference to the grade of the application of all analysed IT systems has decreased. It means, that the enterprises functioning in various industries are becoming more and more eager to use many tools supporting logistic management, which are IT systems.

Table 6: Herfindahl-Hirschman Indices for the use of IT systems potential in Germany in the years 2009 and 2017

Variable	HHI In 2017	HHI in 2009
The application of ERP systems	0.119	0.139
The application of CRM systems in order to manage customer information that enable to collect and store customer information, and to provide access to these information for various enterprise departments	0.107	0.107
The application of CRM systems in order to manage customer information that enable to analyse customer information for marketing aims (e.g. pricing, promotion management, choice of distribution channels)	0.120	0.114
The application of SCM systems in the area of electronic exchange of information on supply chain management with suppliers or recipients	0.116	0.194

Source: own compilation

In the case of German enterprises in comparison to Polish enterprises it is to observe a lower level of concentration for all features and both years 2009 and 2017 analysed in the research. The highest values of the HH Index in this variables group appeared in the number of enterprises using CRM systems enabling to analyse customer information for marketing aims (e.g. pricing, promotion management, choice of distribution channels). The concentration analysis indicates not significant irregularity among researched variables in different economic sections in Germany. It means, that enterprises of various industries in German economy use many tools supporting logistic management, which are IT systems, to much higher extent in comparison to Polish enterprises.

Discussion

The research paper confirmed, that logistic management has a huge impact on the enterprise development. In the study the logistic management is defined as the grade of the application of IT systems supporting management. In the research the attention was paid to the IT system as: ERP systems, enabling the planning of all issues connected with all – production, distribution, or marketing; CRM systems providing some special power for an enterprise by collecting, storing and processing customer information; and finally SCM systems organizing flows of various types inside and outside an enterprise. The measure of development calculated by the means of the variables described as the use of particular system indicated, that all analysed industries present high values, and the distance from the estimated pattern is small. It may be stated, that the use of ERP, CRM, SCM systems influence the enterprise development.

The comparison of research results from two economies – Poland and Germany – allowed to draw several conclusions. Namely, the Polish and German industries are applying IT systems supporting logistic management to a similar extent. Despite of some economic differences between these two analysed countries, especially when we look few years in the past – the year 2009 – the measure of development presents similar values. It means, that the application of ERP, CRM and SCM systems not only support the enterprise activity, but also influences enterprise development.

There are many fields in enterprises, where the IT systems listed above may be applicated. Their highest impact is definitely seen by the organization of production (extremely precious are here the ERP systems that control the remain recourses of an enterprise and determine the future resources) and distribution of products (the SCM IT systems enable to plan almost all logistic processes; the supply chains can hardly be managed without these systems). In other areas of a business organization very helpful are definitely the CRM systems leading to better connection with end consumers. The CRM systems applicated in order not only to gather, store and process some

customer information, but also to analyze these information in reference to better sales records. The CRM systems play also an important role in different departments of an enterprises, as i.e. Accounting or a Customer service. The results of the research presented in the paper show the consciousness of enterprises by the use of IT systems supporting logistic management. During following years the application of all analyzed systems has increased in all enterprises regardless the industry, type, model or different economic conditions of activity. The prosperity of enterprises is seen by the prism of overwhelming digitalization of data that are nowadays the highest value of an enterprise.

Study limitations

The study reflects one of many possible analyzes of enterprises development by the means of use of logistic management tools. Another approach that may be used in further research is the use of other tools supporting management of an enterprise and leading to its development. The problem is in lacking of macro data for whole industries. For the multidimensional benchmarking data must be compatible according to time and variables feature. The particular enterprises using some effective instruments of logistic management cannot create a pattern for other organizations. Another step in the development of the problem may be the comparison of industries of totally different economies, with different business conditions e.g. in terms of the location or financing. It is worth checking, what are the measure of development values (development understood as the use of logistic management tools) in the industries or particular enterprises functioning on the hard business areas.

Conclusion

The issue discussed in the paper, namely enterprise development due to logistic management is very complex. In addition the problem in reference to different economies – to Poland and Germany- is more complicated in terms of the lack of examples in science literature according to the use of logistic management tools in different business conditions. The range of logistic management tools is very wide, so the choice of some appropriate instruments supporting enterprise functioning is not easy. The use of IT solutions fostering logistic management of enterprises is more and more often chosen, because of the standing access to the information exchange we have nowadays by means of desktop or mobile devices. Despite of this fact, the digitalized data are much easier to process, and the systems as ERP, CRM, SCM definitely facilitate the organization activity. The methods of multidimensional comparison analysis used in the research were aimed to answer i.e. how the use of IT systems supporting logistic management affects the enterprise development. The measure of development of enterprises using ERP, CRM, SCM systems indicated very high values, which confirms that there is strong impact to observe by all of the industries analysed. Moreover the Euclidean distances from the estimated pattern to follow by all enterprises in order to succeed is very small. It is wart noticing, that the values of HH Index meaning concentration of the use of particular IT system analysed, are also high. The high value of the measure of development and the HH Index are compatible, which indicates, that the higher grade of ERP, CRM, SCM systems application, the higher is the measure of development value. The attention should be also paid to the fact, that the use of the given IT systems in Polish and German industries are similar. From all the data presented in the research it is concluded, that the enterprise development highly depend on the application of IT systems fostering logistic management.

Mobile Devices in Organization Need or Whim – Case Study from University of Information Technology and Management in Rzeszow

Malgorzata RATAJ

University of Information Technology and Management, Rzeszow, Poland
mrataj@wsiz.rzeszow.pl

Abstract

Organizations are very different now compared to the last three or five years. New mobile technologies are changing business models, strategies and trends in organizations. Mobile technologies resulted in many challenges not only for organization and employees but also for end customers. The main goal of this article is examining the technological maturity of the end customers - in this case students of the University of Information Technology and Management in Rzeszow (UITM), Poland. To answer the research questions three steps were taken. At the beginning a literature review was carried out. Then the global statistics on mobile solutions (devices and applications) were analysed to discover technology trends. At the end the text-based survey was conducted among 640 persons representing 25 countries. The research results allow to draw a conclusion that the rapid development of mobile devices and mobile applications is forcing organizations to create new strategies - to implement new technologies. The research also led to discover that end customers of the UITM are technologically and mentally ready for using mobile technologies.The results presented in this article are a part of two-years research project: The adoption of a mobile solution in the context of university education. The project was financed by statutory grant from University of Information Technology and Management in Rzeszow, Poland.

Keywords: Mobile Devices, Mobile Technologies, Mobile Applications.

Introduction

The society of the 21st century is the society of mobile devices. In times of mobile technology domination, the quality of corporate applications often determines the choice of a specific offer: bank, store, office or training. New technologies have changed, change and will change strategy of nowadays organizations.

First part of the article presents literature review with current knowledge on the subject of interest.

Introducing mobile devices in business organizations require considering the technological trends, therefore second part of the article familiarized author with statistical data with current trends in area of mobile devices, mobile Internet and mobile applications. The following rankings have been considered: Statista, RFBenchmark, Teachthought, eMarketer or the Polish Internet Research Report.

Fast-growing organizations know the value of employee training. It is obvious that mobile training saves employees time and employers time and money. Mobile learning is not only used in the formal university education but also in education in the workplace. The last part of this paper discusses the problem of acceptance of mobile devices in the context of the University of Information Technology and Management, private university in Poland. The empirical analysis of questionnaire led to answer the questions: Are end customers mentally and technically prepared for mobile learning? The prepared Questionnaire can be used at universities and educational institutions of all profiles. The analysis of the research answers will allow university authorities and managers in organizations to discover if end customers are ready to implement mobile learning.

Literature Review

The general overview of the field of interest will help us not only to summarize and evaluate the research area goal but also familiarize us with present-day solutions of mobile learning used at universities worldwide.

Mobile devices are part of our daily life, this resulted in many new technologies for organizations such as: Bring You Own Device (BYOD) - Bring Your Own Device according Kearney is (2012) "the strategy that allows employees, business partners and other users to use a personally selected and purchased client device to execute enterprise applications and access data", or Mobile Device Management (MDM) solution which helps organizations to deploy, monitor and manage all the mobile devices in their organization. Deyan calculated that 78.48% of organizations in the US had BYOD activities in 2018.

One of the successful tools in many business segments today are Augmented Reality (AR) and Virtual Reality (VR). Slusarczyk et al (2019) mentioned: "Virtual reality offers human recourse (HR) employees a new way to provide an interesting experience for candidates and employees through basic HR processes—hiring, adapting, training, organizing work. Interactivity, which is at the heart of AR/VR, allows not only assessing the competences and skills of a candidate or company employee, but also identifying his strengths and weaknesses".

It seems that organisations need to work on a mobile technology to meet the need and demand of their business partners current employees and also to encourage potential employees.

Of course, implementing mobile devices in an organization has many challenges. One of the challenges will be examined in this article – end customer technological maturity. Customers' and employees' response to mobile technologies depends on how open they are to new technological solutions. What approach do they have to mobile applications? Are they ready to improve their qualifications using mobile applications?

Research conducted in the team of Jorge De-la-Calleja (2020) from the Polytechnic Puebla, Mexico show that Mobile Learning System have 82.4% acceptance by users. Several surveys of student's attitudes towards m-learning have been conducted but further studies are needed to better understand the reality of developing countries.

Mobile learning is not only used in the formal education but also is used in informal education in the workplace or in museum institutions. Language teachers have especially been interested in using these devices as a means of providing learning opportunities.

The researchers from Taiwan in article "Review of trends from mobile learning studies: A meta-analysis" (2012) indicate that 86% of the analyzed studies show positive results for mobile learning. The study in this article confirms this trend - 65.3% students at the University of Information Technology and Management in Rzeszow reported wanting lecturers to integrate mobile applications into courses.

In article of Crompton, Burke (2018) we can read: "higher education faculty are encouraged to consider the opportunity to expand their learning possibilities beyond the classroom with mobile learning".

The Technological Trends

Does the dynamically growing market of mobile devices have a chance to change the way of doing business? How mobile devices market look like today?

To answer this question, we will consider mobile technology trends in three training/educational areas:

The global mobile education market is growing dynamically, and according to forecasts, this trend should continue. In 2020, it will reach $ 37,800,000, according to a study by statista.com, (18.10.2019).

Fig. 1: The global mobile education market in 2011-2020 (in millions of dollars)

Which applications are the most popular among owners of mobile devices?

It is not surprising that the most popular are games that make up almost 25% of all downloads. But, remarkably, educational materials are already in third place among the most downloaded applications in the Apple App Store (Figure 2, www.statista.com (18.08.2018)). This information indicates that mobile device users not only want, but use mobile education.

Fig. 2: Selected popular applications in the Apple App Store in May 2018 (number of downloads in percent)

What Polish statistics show? Are we technically prepared for mobile learning? To answer this question, we have to analyse access to three tools necessary for m-learning, these include: mobile devices, mobile Internet and mobile applications.

How popular are **mobile devices** in Poland? According to the eMarketer report in 2015, 7,400,000 people used the tablet. According to forecasts, by 2020 this number is to increase to almost 10,000,000, i.e. more than a quarter of our society will have tablets (emarketer.com, 05/10/2019).

Mobile Internet is required to use mobile applications. In the ranking of mobile Internet speed and quality of mobile operators in Poland, according to RFBenchmark, two networks were at the forefront: T-Mobile and Orange. Based on 26,127 measurements among mobile Internet users, it can be seen that the best average data upload speed is 11.94 Mb/s (TMobile). On the other hand, Orange services with 30 Mb/s rank first in terms of data download speed. These parameters are sufficient for working with mobile applications. They will allow for video conferencing or downloading large files.

How popular are educational websites? According to PBI reports: On average, almost 19,000,000 Internet users visit education-related websites once a month, of which 13,900,000 use a computer, and 11,600,000 million mobile devices. In August 2017, educational services were in sixth place in terms of the most-visited thematic categories with over 16,000,000 users (Educational websites, Polish Internet Research Report, pbi.org.pl).

Fig. 3: Number of applications available in the Apple App Store in 2008-2017 (www.statista.com)

The Apple App Store was launched in July 2008, and already in April 2009 recorded 1,000,000 application downloads. According to analyses by the Statista.com team, it is estimated that in 2022, iPad users worldwide will download approximately 2,600,000 applications from the Apple App Store.

According to the Educational App Store, there are currently 500,000 **educational applications** on the market. An undoubted drawback is the lack of Polish language versions of educational applications.

The Figures 1-3 leave no doubt that the market related to mobile devices and mobile applications is developing dynamically and Poland is not lagging behind in this field.

Every academic teacher faces a difficult decision: "Do I want to enrich classes with materials using mobile devices?". The analysis is the basis for conducting a survey that sheds light on: How do students at Polish universities use mobile devices? Are they open to mobile learning?

Interesting data have been collected by Eurostat (2019), concerning Internet and Information and Communication Technologies (ICT) use among students from Poland and the European Union (EU). The level of digital skills is high: 89% of Polish students have basic or above basic overall digital skills, whereas 87% overall in the EU. Only 38% of Polish students use Internet resources for any educational activity (59% in EU). Also, learning from online courses is not popular (7% of users). The reason may be low student awareness of good quality online courses in one's native language. The second reason could also be the lack of e-learning infrastructure at some universities.

Acceptance of mobile devices in the context of UITM

Research Methodology

The research population consists of students from UITM - 5,157 students from 25 countries. Almost 12.5% (640) of the overall student population participated in the research. Is the research sample representative? To verify it we checked two attributes: gender and level of education. Figures 4 and 5 provide graphical representations of the answers.

Fig 4: Gender of UITM student population versus research sample

As shown, 50.3% of UITM students are female, while 49.5% of our research sample were female, a difference of only 0.8%. The male population differs by just 0.1%. Thus, our sample is almost identical to the population of interest. During recruitment were entered into the database 0.6% missing data, but we assume it does not influence the research results.

Fig. 5: Level of education of UITM students versus research sample

While 77.9% of UITM students' study at the bachelor's level, 80.8% of our participants did so, to give a nonsignificant difference of 0.1%.

As shown, our sample has characteristics of the whole population in the specified attributes of gender and level of study. Our sample is representative, and we can generalize our study results to the whole population of UITM students.

All students participated voluntarily in the survey and all data were collected anonymously. Research participants represent 11 fields of study provided by University, with 69.9% of all participants and the majority of the overall University student body studying in the five fields of Management, Computer Graphics, Information Technology, Aviation Management, and International Management.

The 29 questions of survey grouped into three sections. The first section comprised personal information on age, field of study, year of study, gender, sex, and country of origin. The second section asked about the specifications of mobile devices owned by students and how they use mobile tools.

The final section asked about attitudes towards current and, more importantly, future use of mobile devices in education.

The survey was designed by experts – educators form UITM. The data were collected from students in a class and the instructor was one of the researchers.

The Statistical Package for the Social Sciences – IBM SPSS Statistics 25 (SPSS) - was used to compute all data. All survey variables were provided in a nominal scale; thus, before applying computer analysis, we coded all data, and text-based answers were transformed to numbers. The questionnaire analysis was based on the descriptive statistics.

Results

A total of 640 students, including 322 (50.3%) female and 318 (49.7%) male students, participated in the study.

At the beginning of our study we checked if students owned **mobile devices**. The survey indicates that 99.7% of participants own a mobile device, including 100% women who participated in the study. We suspect that non-admission of ownership of mobile devices was a student joke. Nevertheless, we found these answers statistically significant.

The largest percentage of respondents in the study were students from Poland studying in the home country, so it is not surprising they have an unlimited or 10 GB Internet package. The foreign students' situation is slightly worse. For example, almost 35% of students from Kazakhstan do not have access to **mobile Internet**. Also, students from Ukraine have an unlimited Internet package less frequently than their Polish colleagues. This does not mean that students do not use the Internet and mobile applications; they often use the university's Wi-Fi network.

In the open question, students were asked about the most frequently used **educational mobile applications** related to their field of study, to which 45% of the students responded that there were educational applications related to their field of study but unfortunately did not provide any particular names. Students mainly use an application to manage their learning process - muczelnia (20%). In addition, because of the university's high level of internationalization, the apps for learning foreign languages were among the most frequently mentioned (9,6%). A mobile application for the Khan Academy website containing teaching materials for a wide range of school subjects were used by 11,5% of students. The findings showed that students use mobile devices to support learning despite m-learning not being formally included in the curriculum.

In total, 65.3% of students reported wanting lecturers to integrate mobile applications into courses. 58.1% believe that mobile education will help them gain better scores. 53.8% declared that they learn faster thanks to mobile devices. 23.6% claim that educational applications will help them be more focused and involved during study. These data demonstrate that students' attitudes towards m-learning are positive. Interestingly, however, 73.4% of students do not want to completely abolish direct (face-to-face) relationship with colleagues.

The results of our study demonstrate the technological maturity of end consumers of mobile education – in this case, students at the private University in Europe. They also indicated that mobile learning is a promising pedagogical technology to be implemented in modern organization.

Conclusion

Successful deploying of mobile technologies is not a matter of accident, but depends on users' acceptance of the technology.

This article presents the dynamic development of mobile devices and their application. It seems, after the analysis development of the educational application market in the light of polish reality, that a reasonable option is supporting traditional methods of teaching by mobile technologies.

The survey questionnaire checking students' attitudes towards mobile learning was design is in line with good practices taken from researches from: Ankara University, Turkey, Liverpool John Moores University, England, Queensland University of Technology, Australia or University of Winchester, England. The survey questionnaire will be published - in December 2020 – on completion of research project: The adoption of a mobile solution in the context of university education on the web page of UITM. The survey questionnaire can be used in practice by other educational institutions that are wondering if their end customers are ready for mobile learning. The research led us to discover that the mobile learning system holds wide acceptance, satisfaction, and applicability from UITM students' perspectives. Applying mobile learning tools in the curriculum will help students gain new competences and skills to adapt to the expectations of future

Author leave for future studies analysis of teachers' technological maturity and approach to teaching with mobile devices, asking primarily into whether teachers are familiar with new mobile devices and applications. The question arises: How to encourage students and educators to gain new skills and competences? The challenges are also necessity to create educational applications tailored to the needs of particular field of study or translating already existing into polish language.

65.3% students of University of Information Technology and Management in Rzeszow reported wanting lecturers to integrate mobile applications into courses what encourages author to analyze the results obtained in particular subjects by students who use mobile education applications and to compare such scores with students who have traditional lessons. This study is not without limitations. The Statistical Package for the Social Sciences – IBM SPSS Statistics 25 (SPSS) - was used to compute all data. It is true that the functionality of this package has not been fully used. Only basic statistics were made, which allowed author to visualize some characteristics and trends - what was the author's intention. However, the software used during the research provides a solid background for extending analyzes and interesting data visualization, which will be use in the next article.

Abstract

Despite the importance of combating money laundering and terrorist financing, there is still no single methodology for determining the extent amount of money laundering, based on the statistical information provided by the public financial monitoring authorities, since a large part of these financial flows is still outside the official statistics. The aim of the study is to develop methodological bases for determining the amount of money laundering through the real sector of economy, state and local budgets, and the segment of financial intermediaries. While determining the amount of money laundering, authors also have taken into account the level of shadow economy and indicators of quality and efficiency of state regulation of the national economy. The amount of money laundering in the country was determined using the Minkowski metric. The information base for the paper was data from the State Audit Service of Ukraine and the State Financial Monitoring Service of Ukraine. The paper presents the results of an empirical analysis concerning measurement of money laundering in Ukraine, which showed that the lowest level of money laundering was recorded in 2007; during 2008-2009 there was a slightly increase in the amount of money laundering as a result of the activation of destructive processes both in the global financial system and in the national economy; 2010-2013 can be considered a period of post-crisis stabilization and, accordingly, a slight fluctuation in the amount of money laundering, while the intensification of the military-political conflict in Ukraine again intensified the increasing of money laundering with the highest level in 2014. Thus, the correspondence of the trend of volatility of the calculated amount of money laundering to the real political and economic processes in Ukraine confirms the adequacy of the developed approach to its estimation. The methodological approach made it possible to comprehensively evaluate both implicit and explicit flows of money laundering and create an effective information base for evaluating the effectiveness of anti-money laundering instruments in the context of ensuring economic security in the country. Further scientific research requires the forecast the amount of money laundering in Ukraine. The results of the research can be useful for governments in order to adequately respond to destabilizing factors in the national economy.

Keywords: Money Laundering, Minkowski Metric, Economic Security, Financial Monitoring.

Introduction

The financial and economic security of the state is ensured by introducing an effective early diagnosis system, enhancing supervision of systemically important banks, improving macro-prudential banking regulation through the introduction of a countercyclical capital buffer, and strengthening measures in anti-money laundering and terrorism financing (S. Kozmenko and Vasyl'yeva (2008), Sofjan (2018), Stankevičienė et al (2014), Vasylyeva et al (2014), Lewandowski (2016). Money laundering is not only a criminal act, but also an ever-present threat to the stable development of the financial market and the corporate sector as a whole (Pilipenko et al (2019)). Leonov et al (2014) justify that institutional investors as subjects of initial financial monitoring in the area of preventing and counteracting the money legalization (laundering) or terrorist financing, should be advisable to improve the system of regulation and supervision of these institutions for the protection the consumers' rights of financial services. However, the scale of money laundering in the country are determined not only by the transparency of economic relations in the country, but also the level of social security and the political stability in the country (Bilan et al (2019), Bilan (2019), Kozmenko and Kuzmenko (2013), Lyeonov and Liuta (2016), Stukalo et al (2018). According to the United Nations Office on Drugs and Crime, the global money laundering amounted at 2.7% of world GDP in 2009, while by the beginning of 2019 this figure has almost doubled to about 5% of world GDP (2.0 trillion USD, which is, for example, equivalent to the annual GDP of countries such as Italy, Brazil, or Canada). This rapid growth in money laundering clearly confirms the dynamically increasing threat to economic security in both national and global contexts (Zarutska (2018)). That is why finding new tools to prevent money laundering is a key task of national and international oversight bodies. The need to develop anti-money laundering regulatory measures urges the development of methods for determining the amount of money laundered, which would take into account both actual data and implicit components of this process.

Literature Review

Vasilyeva et al (2013) and Gospodarchuk and Suchkova (2019) recon that the money laundering is one of the drivers of appearance of internal and external imbalances in the financial sector. Similar opinion is shared by other scholars (Vasilyeva et al (2016)), who substantiate the following negative factors affecting the banking system development: significant number of bank liabilities generated in foreign currency, imbalance between the terms of investment and borrowing, high level of credit risk, insufficient capitalization of banks and using financial services for money laundering. Buriak et al (2015) empirically identify how expansion of money laundering processes increase fragility of systemically important banks and financial system as a whole. According to Aryani and Hussainey (2017), Deaconu et al (2016), Evana et al (2019), the riskiness of the bank's activities and the financial institution's tendency to use its services for legalization of funds correlates with the quality of the financial reporting.

Assessing the volume of criminal income legalization requires a thorough study of the causes of its occurrence and the mechanisms of its formation. Thus, the analysis of such a source of the legalization of criminal income as narcotics trade and the evaluation of the further mechanisms of the legalization of funds received from this type of activity were carried out in the works of Alasmari (2012, 2013). Particular attention should be paid to money supply and inflation which is also related to impacting factors such as money laundering. The two factors money supply and inflation are a particular characteristic of Ukraine and systematically lead to destructive consequences in the economy. The study of this problem was carried out in the works of Sasongko and Huruta (2018). An equally important factor in expanding the process of criminal income legalization in Ukraine is the dollarization of the economy. This phenomenon was investigated in the works of Kaminskyi and Versal (2018).

The main forms and tools of illegal financial transactions are tax evasion or avoidance and withdrawal financial resources abroad (Bilan et al (2018), Bilan et al (2019), Budzyńska (2016), Dobrovič et al (2018),

Grytsenko et al (2010), Pilipenko et al (2019). According to Muljavka and Reznik (2013) one of the key actions to anti-money laundering should be the expansion of the tax police authority and its institutional restructuring into a large-scale law enforcement body that would combat economic and corruption crime. Other scientists (Masri et al (2019)) have justified that international tax practices are a form of international tax avoidance in order to lower tax liabilities and to conceal the source of illegally obtained funds.

Considerable attention to the development of methodological approaches to determining the risk of money laundering is reflected in the work of such scholars as Dmytrov et al (2011, 2014, 2017), Boyko and Roienko (2014), Kostyuchenko et al (2018), Levchenko et al (2019), Berzin et al (2018). An innovative solution for analyzing predisposition to commit illegal activities in the financial services markets involves taking into account public trust in financial institutions, which is determined based on a combination of regulatory rules and the behavior of economic agents (their feelings, emotions and other subjective characteristics) (Bilan et al (2019), Brychko et al (2019)).

Today's drivers of global economic development are innovative technologies that not only dramatically change the architecture of the financial system, but also create completely new approaches to managing and executing business processes based on Big Data, robotics, artificial intelligence, the Internet thing and more (Karaoulanis (2018)). The Internet and digital devices are a driver of economic growth (Afonasova et al (2019), Nathan et al (2019)). At the same time Industry 4.0 has created an environment conducive to illegal criminal proceeds (Bilan et al (2019)).The paper of Gasparėnienė et al (2017) was aimed to define the concept of a digital shadow economy and identify its determinants and channels. Knezevic (2018) conducted a research on an impact of blockchain technology platform on the financial sector through cryptocurrency, and an impact on activity of money laundering.

The use of cryptocurrency and other digital currencies as innovative financial instruments is another topical trend of money laundering through IT technologies. In particular, Mabunda (2018) justifies that the emergence and rapid spread of cryptocurrency in the world leads to the improvement of money laundering schemes through the Internet, since the peculiarities of circulation of virtual money allow for uncontrolled transactions within different countries. Stokes (2012) conducted a money laundering risk analysis of two virtual currencies: Linden Dollar, a global currency in the Second Life interactive online environment, and Bitcoin, an experimental virtual currency that allows transferring value using peer-to-peer technology. The study found that these virtual currencies are in demand among criminals in the field of money laundering, but they are not suitable for large-scale laundering. Šimonová, Čentéš, & Beleš, 2019 continued a study on the peculiarities of using innovative forms of money for money laundering. They focus on the existing problems in the field of regulation of the electronic money market and the mechanism for countering the illegal circulation of these assets for money laundering.

The rapid development of information technology has led to the emergence of cyber-attacks, which is one of the threats in the functioning of the anti-money laundering system. The study of this issue is reflected in the works of such scientists as (Filipkowski (2008), Horne (2014), Mirea et al (2011), Piller and Zaccariotto (2009), Şcheau and Pop Zaharie (2017), Sekgwathe and Talib, 2012)). In turn Stiawan et al (2017) review various cyber-attack techniques and penetration test methodologies to assist security service personnel in relevant security assessments on their network systems. Simultaneously (Federici, 2007) notes that the use of various data mining methods in modern conditions can be useful for understanding the links between people and suspicious operations in order to track money laundering and terrorist financing activities.

Many scientists studied the use of electronic payment systems and online banking for money launderings, namely Merenkova (2008), More et al (2015), Trautman (2013), Tropina (2014).

However, the latest technologies are used both for money laundering and for counteracting this process. Thus, Plaksiy et al (2018) study the possibilities and benefits of applying Big Data for financial investigation data analysis. The visualization of ML/CFT typologies with the use of graphs is being

considered as a result of the study. Leonov et al (2019) engage in the active use of the latest information processing methods, succeeding in the prototyping of information system for monitoring banking transactions.

In scientific works of Kordík and Kurilovská (2017) special attention is devoted to the study of mechanisms of counteraction to money laundering. However Klochko et al (2016) justify the need to bring in criminal liability for offenses in banking activities, which allows to protect the interests of consumers of financial services and increase the level of confidence in the national financial system. Subeh and Boiko (2017) have proposed innovative methodological approach to estimate the effectiveness of regulatory authorities using a queueing system. Kadhim et al (2019) confirmed the necessity for banks' stress testing as one of the primary steps to counteract money laundering.

The most commonly used approach for determining the amount of money laundering is The Walker Gravity Model (Walker (1995)). Walker's model for money laundering assumes that the share of proceeds from unlawful activity generated in one country and sent to another country depends on both the mass and 'attractiveness' of the second country, and the distance between the two countries. It was revised and re-estimated for the Netherlands by Walker and Unger (2009, 2013) by using the distance between the countries in the attractiveness factor, instead of its square.

Given the need for a comprehensive assessment of the volume of criminal income legalization, it is advisable to analyze the existing econometric approaches to the evaluation of economic phenomena and processes. Thus, the approach to the integrated assessment of social security is reflected in the work of Zavora and Chepurny (2014). The work of Formánek (2019) deals with a complex spatio-temporal regression model. The team of researchers, namely Rungsrisawat et al (2019) use the ARDL technique to explore the nexus between crime, socio-economic strains, and economic growth. In turn, in the works of Bivainis and Skačkauskienė (2009), an approach is proposed to solve the problem of assessing the evolution of indicators over time. In addition, data mining and artificial intelligence can serve as a methodological tool for determining the amount of money laundering (Dahooei et al (2018), Kuziak (2016), Slapikaite and Tamosiuniene (2017), Vasilyeva et al (2019), Njegovanovic (2018).

Methodology and Results

A methodology has been developed for determining the amount of money laundered based on the use of mathematical modeling in economics. It involves determining the actual losses from money laundering schemes, as well as calculating an adjusting factor to take into account both explicit and implicit money laundering flows.

First, actual losses from money laundering schemes are assessed. In different countries, this amount can be specified based on the data from the relevant anti-money laundering agencies and government statistics agencies. In Ukraine, this indicator is based on the data from the State Audit Service of Ukraine and the State Financial Monitoring Service of Ukraine. Thus, the operating results of the State Audit Service allow determining two indicators: the amount of money laundered through the state budget and local budgets. In its turn, the data from the State Financial Monitoring Service are used to assess the amount of money laundered through the real sector of the economy and financial intermediaries. The mathematical formalization of this stage is based on the additive convolution of these three indicators.

For the practical implementation of first stage of methodology, we will use Table 1 to formalize the dynamics of the amount of money laundered through the state budget, the amount of money laundered through local budgets and the amount of money laundered through the real sector of the economy and financial intermediaries for 2007-2018.

Table 1: Data for assessing the real volume of money laundered

Year	Amount of money laundered through the real sector of the economy and financial intermediaries	Amount of money laundered through the state budget	Amount of money laundered through local budgets
2007	9,745,614	488,524.77	554,184.40
2008	12,349,333	1,219,706.32	515,381.68
2009	11,365,557	1,308,422.72	992,598.71
2010	14,945,389	7,323,744.68	1,001,618.04
2011	22,702,164	1,109,218.08	1,228,780.89
2012	29,203,021	1,099,530.16	524,724.02
2013	4,482,439	737,850.92	936,838.66
2014	3,961,062	1,546,713.31	567,682.87
2015	1,113,910	819,552.20	730,796.59
2016	11,336,889	709,139.87	511,510.85
2017	928,802,849	608,922.82	510,658.76
2018	124,346,271	623,651.51	470,314.24

Based on the data in Table 1, it is possible to conclude that no consistent patterns were observed regarding the mechanisms for applying money laundering schemes during 2007-2018. Thus, 2017 and 2018 were the most critical years for the real and financial sectors of the economy in terms of the amount of money laundered, when the value of the indicator under study exceeded the average annual indicator by almost 44 times. In turn, when studying public finances, we note that the largest amount of financial resources was laundered through the state budget in 2010 and 2014. The period from 2009 to 2011 demonstrated the peak of money laundering through local budgets. This indicates that criminals use various money laundering schemes and try to increase the amount of money laundered every year.

Second, it is necessary to calculate the adjustment index, which will increase the actual amount of money laundered based on the amounts of laundered money that were not potentially revealed by state regulatory authorities. The following seven indicators are proposed to be selected as components of this index.

The level of the shadow economy. Accounting for this indicator is due to the need to formalize sources of income, which in the future will require laundering. The shadow economy creates monetary resources that are used by criminals either to commit other illegal actions or develop various money laundering schemes.

The corruption control index is currently the most significant disincentive indicator in terms of money laundering for Ukraine. This indicator can be used as an argument that the government is joining private interests and, accordingly, receives illegal income in the form of profit by business entities and in the form of bribes. Thus, taking this indicator into account is mandatory when forming the index for adjusting the amount of money laundered towards its decrease.

Government performance index. The rationale behind this index is that the high quality of public services and the independence of public services from political pressure extremely impedes the money laundering processes. Thus, the competent and highly effective performance by the ministries and departments of Ukraine of the functions assigned to them makes it impossible for the criminals to generate illegal income and use a significant number of schemes (for example, with state property, securities, etc.). Leonov et al (2014) substantiate a systemically important role in determining the effective and fair rate of government bonds' yield to prevent the legalization of illicit income and the withdrawal of funds abroad.

The above index is supplemented by the regulatory quality index. Its use is conditioned by the need to take into account the level of implementation by the ministries and departments of Ukraine of the state policy and adopted provisions. Considering the fact that anti-money laundering activities are based on fulfilling the requirements of international organizations implemented in the laws of Ukraine (FATF, MONEYVAL, etc.), the effectiveness of law enforcement in Ukraine directly affects the level of money laundering.

Political stability and absence of violence/terrorism. This indicator is used due to the need to take into account political instability. This indicator is especially significant for Ukraine since the power shift takes place every five years, and therefore, first, government officials are involved or directly carry out the money laundering because they hold power for a short period, and second, it is much easier for criminals to hide illegal incomes in conditions of constant changes and instability.

The rule of law index directly reflects the probability of crime and the general level of public confidence in the judiciary. Thus, this indicator reflects a certain component of the general indicator of the propensity (desire) of economic entities to accumulate illegal income followed by its subsequent laundering.

The results of the publicity and accountability index are interesting in terms of the openness of companies and freedom of the media. Thus, the first characteristic of this index describes the likelihood of attracting a company to the shadow sector of the economy, and the second opportunity for the media to honestly covering and carrying out objective journalistic investigations related to the activities of public officials, etc.

Thus, it is fair to point out that the corruption control index, the government performance index, the regulatory quality index, the political stability and absence of violence/terrorism index, the rule of law index and the publicity and accountability index are indicators that more or less describe certain manifestations of corruption. For Ukraine, corruption and the shadow economy are the main sources that stimulate money laundering. Corruption allows criminals to escape punishment and unimpededly implement all money laundering schemes.

As for the mathematical formalization of calculating the index for adjusting the total amount of money laundered, we note that it must be presented as an exponent of the Minkowski parametric metric of naturally normalized indicators.

This stage is complex, and there is a need for its step-by-step description:

The first step involves the formation of an information base for the index adjusting the actual amount of money laundered, represented by the dynamics of seven time series: the level of the shadow economy, corruption control, government performance, political stability and absence of violence/terrorism, regulation quality, the rule of law, transparency and accountability (Table 2).

Table Error! No text of specified style in document.**: Data on the index for adjusting the real amount of money laundered**

Year	Corruption control	Government performance	Political stability and absence of violence/terrorism	Regulation quality	Rule of law	Transparency and accountability	Shadow economy
2007	-0.80	-0.67	0.17	-0.43	-0.73	0.06	28.00
2008	-0.84	-0.72	0.04	-0.53	-0.68	0.09	34.00
2009	-1.04	-0.83	-0.30	-0.57	-0.76	0.06	39.00
2010	-1.03	-0.78	0.01	-0.52	-0.81	-0.08	38.00
2011	-1.05	-0.82	-0.07	-0.60	-0.82	-0.13	34.00

2012	-1.08	-0.58	-0.09	-0.60	-0.78	-0.28	34.00
2013	-1.13	-0.65	-0.78	-0.62	-0.80	-0.32	36.00
2014	-0.99	-0.41	-2.02	-0.63	-0.79	-0.14	43.00
2015	-0.98	-0.52	-1.96	-0.59	-0.81	-0.09	40.00
2016	-0.81	-0.57	-1.86	-0.43	-0.77	0.00	35.00
2017	-0.78	-0.46	-1.87	-0.32	-0.71	0.01	32.00
2018	-0.87	-0.42	-1.83	-0.22	-0.72	-0.01	30.00

Based on the data given in Table 2, it is fair to note the following patterns:

– during 2007-2018, all the indices studied were negative; exceptions were the political stability and absence of violence/terrorism index in 2007-2008 and the publicity and accountability index in 2007-2009 and 2016-2017;

– during the years 2007-2018, with the exception of the publicity and accountability index, the average of all indices was less than -0.5 units;

– the most negative values of the indices studied were traced with respect to the corruption control index (mean -0.95, lowest in 2013 equaled -1.13) and political stability and absence of violence/terrorism index (mean -0.88, lowest in 2014 was -2.02).

This indicates the existence of a favorable environment in Ukraine for the money laundering and, accordingly, the need to adjust the actual amount of money laundered to obtain relatively real data.

Continuing the practical implementation of the methodology for determining the amount of money laundered in the context of the formation of the adjustment index, we proceed to the second step. Thus, it is necessary to normalize the indicators of the information base of the adjustment index using the natural method for incentives and the Savage normalization for disincentives (Levchenko et al (2019)).

For incentives (corruption control indices, government performance, political stability and absence of violence/terrorism, regulation quality, rule of law, publicity, and accountability), we apply natural normalization:

$$n_{it} = \frac{f_{it} - \min\limits_{t} f_{it}}{\max\limits_{t} f_{it} - \min\limits_{t} f_{it}} \tag{1}$$

where f_{it} – the actual value of the i-th indicator-component of the adjustment index for the t-th year;

n_{it} – the naturally normalized value of the i-th indicator-component of the adjustment index for the t-th year;

$\min\limits_{t} f_{it}$ – the minimum possible value of the i-th indicator-component of the adjustment index over the studied time range;

$\max\limits_{t} f_{it}$ – the maximum possible value of the i-th indicator-component of the adjustment index over the studied time range.

For the disincentive (level of the shadow economy), we apply the Savage normalization formula:

$$n_{it} = \frac{\max\limits_{t} f_{ti} - f_{ti}}{\max\limits_{t} f_{ti} - \min\limits_{t} f_{ti}} \tag{2}$$

The calculations made based on formulas (1) and (2) are summarized in Table 3.

Table 1: Normalized values of indicators of the index for adjusting the amount of money laundered

Year	Corruption control	Government performance	Political stability and absence of violence/terrorism	Regulation quality	Rule of law	Transparency and accountability	Shadow economy
2007	0.96	0.40	1.00	0.48	0.67	0.93	1.00
2008	0.84	0.28	0.94	0.23	1.00	1.00	0.60
2009	0.27	0.00	0.78	0.14	0.44	0.92	0.27
2010	0.30	0.12	0.93	0.28	0.08	0.57	0.33
2011	0.23	0.02	0.89	0.06	0.00	0.45	0.60
2012	0.16	0.60	0.88	0.08	0.26	0.09	0.60
2013	0.00	0.45	0.57	0.01	0.10	0.00	0.47
2014	0.40	1.00	0.00	0.00	0.20	0.43	0.00
2015	0.44	0.74	0.03	0.08	0.04	0.56	0.20
2016	0.91	0.62	0.07	0.49	0.38	0.78	0.53
2017	1.00	0.89	0.07	0.75	0.78	0.81	0.73
2018	0.74	1.00	0.09	1.00	0.73	0.74	0.87

The third step is aimed at determining the weighting coefficients of priority of indicators for assessing the index for adjusting the amount of money laundered. Since an assumption is made that the considered indicators are of equal priority, the corresponding onew_i (the weight coefficient of the i-th indicator-component of the adjustment index) takes the value of 1/7. At the same time, it is fair to say that the goal of developing this methodology is the formation of universal principles, i.e. the use of such economic and mathematical tools that will allow adapting to changes in the internal and external environment. Therefore, given the changing economic and political situation in Ukraine, or the application of the proposed methodology to another country, this step may be transformed and the weighting coefficients of the i-th indicator-component of the adjustment index may take different values. Weighting is usually based on an expert method.

The fourth step involves intermediate calculations, namely the calculation of the Minkowski parametric metric in the context of indicators of the information base of the index for adjusting the actual amount of money laundered.

At the final fifth stage, the adjustment index is directly calculated – the exponent of the Minkowski parametric metric in terms of indicators of the information base of the index for adjusting the actual amount of money laundered (formula 3).

$$I_{kt} = exp(M_{mt}) = exp\left(1 - \sqrt{w_i \cdot \sum_{i=1}^{7}(1 - n_t)^2}\right) exp\left(1 - \sqrt{w_i \cdot \sum_{i=1}^{7}\left(1 - \frac{f_{it} - \min_t f_{it}}{\max_t f_{it} - \min_t f_{it}}\right.}\right. \quad (3)$$

where I_{kt} – index of adjustment of the actual amount of money laundered.

The results of calculations according to formula (3) are presented in Table 4 (column 2).

Table 4: Dynamics of Minkowski metric and index for adjusting the actual amount of money laundered

Year	Minkowski metric	Index for adjusting the actual amount of money laundered
2007	0.67	1.960275006
2008	0.57	1.766179903
2009	0.33	1.385018664
2010	0.32	1.372054102
2011	0.25	1.289611991
2012	0.32	1.372237918
2013	0.19	1.213107852
2014	0.21	1.237898848
2015	0.25	1.284987375
2016	0.48	1.610586896
2017	0.60	1.830284811
2018	0.61	1.844962014

At the third stage of development of the methodology for determining the amount of money laundering, the estimated amount of money laundering is determined by applying a multiplicative model of adjusting the actual amount to the corresponding adjustment index:

$$ML_t = (RL_t + SL_t + LL_t) \cdot I_{kt} \quad (4)$$

where ML_t – estimated (real) amount of money laundering for the t-th year;

RL_t – the amount of money laundered through the real sector of the economy and financial intermediaries;

SL_t – the amount of money laundering through the state budget;

LL_t – the amount of money laundering through the regional budgets.

I_{kt} – the index of adjustment of the actual amount of money laundering for the k-th year.

The results of the calculation of the amount of money laundering are presented in the figure 1. At the same time, in order to understand the real scale of the money laundering in Ukraine, the share of the calculated (actual) amount of money laundering in GDP has been determined.

Fig. 1: Dynamics of money laundering in Ukraine during 2007-2018 years

The results of the empirical investigation showed that the lowest level of money laundering was recorded in 2007. During 2008-2009 there was a slightly increase in the amount of money laundering as a result of the activation of destructive processes both in the global financial system and in the national economy. 2010-2013 can be considered a period of post-crisis stabilization and, accordingly, a slight fluctuation for money laundering, while the intensification of the military-political conflict in Ukraine again intensified the increasing of money laundering with the highest level in 2014. The anomalous value of money laundering in Ukraine in 2018 is due to the disclosure of a large-scale scheme for laundering illicit funds in the amount of 1.5 billion USA dollars.

Conclusions

Combating the money laundering and terrorism financing is a major challenge for national and international supervisory and regulatory authorities to ensure sustainable economic development and security. It is advisable to use foreign experience of countries that also have a bank-centered model of financial market to combat the legalization of criminal income. According to Kozmenko et al (2011) point out that Ukraine repeats the path of financial development of Germany.

Summing up the above calculations, it is fair to say that the amount of money laundering during 2007-2018 was cyclical, with periods of decline in 2012, 2015, and 2016, as well as 2019. Anomalous value of the amount of money laundering in 2018, the average growth rate of this indicator for the period under review will be 20%. This indicates an intensive increase in the volume of criminal proceeds legalization, even after significant periods of its decline. Thus, the correspondence of the trend of volatility of the calculated amount of money laundering to the real political and economic processes in Ukraine confirms the adequacy of the developed approach to its estimation. The methodological approach made it possible to comprehensively evaluate both implicit and explicit flows of money laundering and create an effective information base for evaluating the effectiveness of anti-money laundering instruments in the context of ensuring economic security in the country. The development of methodological support for measuring an amount of money laundering, in fact, serves as an informational basis for sound management for agencies engaged in state regulation, control and supervision – in identifying the risk of money laundering and developing measures to minimize or neutralize it through information systems; during the formation of the macroprudential policy of the state, in developing strategic plans for the development of the country.

Abstract

Liberalization and rationalization are the *main factors* that favor the modification of migration processes and the growth of relevant migration indicators. Factors that determine the global migration movement can also be attributed to the expansion and acquisition of a mass of technologies that aim at reducing the sense of distance, which allow you to quickly and quickly change locations of stay, without changing the conditions and principles of work, contact audiences, etc. It is in this context that *the focus* of research on migration processes in general, and those areas where small changes in which, can potentially have a significant impact on the economic situation and further development, including innovation, becomes relevant. *The hypothesis* of investigation is the migration of highly skilled personnel exerts a set of influences on the economic and innovative development of the recipient country and the donor country. Applied analytical *methods*, comparative analysis, classification, allow to achieve the aim. The authors grouped the main indicators of the migration processes impact on the countries of departure (donor countries) and those leaving (recipient countries) in terms of economic and innovation component. The analysis presents *the results* in qualitative and quantitative terms. The IT market is analyzed, indicators of its development are given, and major trends are identified, including in comparison with the world ones. The peculiarities of migration processes of specialists in this field are described. As *implications*, it is proposed to include the migration of highly skilled workforce in the assessment indicators Country Innovation Index.

Keywords: Migration, Innovative Development, Economic Development, IT, Highly Qualified Personnel.

Introduction

long with the powerful development of information technology and innovative processes, humanity is increasingly focused on the constant search for ways to improve their lives. The processes of globalization and internationalization cause a change in the vector of international activity and cooperation, where they open a wider space for the movement of labor between regions, countries and continents. Thus, labor mobility makes the analysis relevant of a wide range of economic, socio-demographic, political and technological changes in the recent period.

With the processes of deepening of innovative development and economic transformation, more and more formation of life of society in general, and of each individual in particular, becomes evident, which becomes tangible in work processes, private life, public and spiritual sphere, etc (Ginevičius et al., 2018).

Along with the powerful development of information technology and innovative processes, humanity is increasingly focused on the constant search for ways to improve their lives. Thus, liberalization and

rationalization are the main factors that favor the modification of migration processes and the growth of relevant migration indicators. Factors that determine the global migration movement can also be attributed to the expansion and acquisition of a mass of technologies that aim at reducing the sense of distance, which allow you to quickly and quickly change locations of stay, without changing the conditions and principles of work, contact audiences, etc (Čajka et al., 2018).

The aim of the article is to investigate the main factors and directions of influence that carry out the migration processes of highly skilled specialists on the countries economic and innovative development (the example of the IT industry). According to the aim of this article it was suggested to explore the latest research in the field, which is presented by the Literature Review.

In order to study global processes, the structure of the migrant's distribution is presented in accordance with the total population in percentage terms by continents. The factors that influence the increasing trend of increasing the number of highly skilled labor migrants from Ukraine are analyzed. The authors analyzed ranking of Ukraine, that characterize it`s state of socio-economic development, which causes an increase in the migration activity of highly qualified personnel in particular. It is determined that Global Innovation Index, Ease of doing business index, Sustainable Society Index (Human, Economic, Environmental Wellbeing), The Global Peace Index, Index of Economic Freedom, Index of Happiness are the main indicators that shape the above factors. Thus, in the course of the study these indicators were analyzed, and the Ukraine place was determined according to them in the overall rating. It was Compared the Global Innovation Index of Ukraine with other countries that are recipient countries for Ukrainian IT professionals, and it was analyzed the structure of the Summary Innovation Index, which is formed annually for European countries.

The prospect of further research may be quantitative determination of the migration processes influence on the state of countries economic and innovative development, forecasting and economic-mathematical modeling of changes in the country's economic development in changing or maintaining migration trends, factor analysis of the impact of highly qualified personnel migration on economic development.

Literature Review

It is in this context that the focus of research on migration processes in general, and in particular those areas where small changes in which, can potentially have a significant impact on the economic situation and further development, including innovation, becomes relevant (Filipishyna et al., 2018).

Particularly noteworthy is the type of migration that is encouraging from the point of view of the host countries, since they are making some efforts to promote, simplify procedures and encourage migration (Piekutowska et al., 2018). This type of migration includes the migration of highly skilled labor. These cadres shape the potential of countries for further economic and innovation development, as they often have higher education, special skills and professional skills in their field (Churilova et al., 2019). The sphere, which is closely connected with the innovative development and gives the basis for the economic development of the country, declares it on the territory of the world space is the sphere of Information technologies. The highly qualified personnel employed in this field is one of the driving forces for the future development (Belas et al., 2018). At the same time, the innovation growth is related form the level of creative development which proved by the authors in the paper (Bilan et al., 2019e).

With this in mind, it is relevant to study migration issues among highly qualified IT industry professionals in the case of Ukraine and the corresponding impact on the country's economy, in detailing the aspects of the relationship of this particular type of migration with economic indicators and innovation potential.

The main indicators which influence macroeconomic stability, the marketing factors of the country's competitive advantages are allocated in the papers (Lyulov et al., 2018; Ivanová et al., 2018; Bilan et al., 2019c; 2019f); the role and influence of economic freedom on macroeconomic stability were

analyzed by the scientists in the paper (Yevdokimov et al., 2018). The authors in the paper (Vasilyeva et al., 2019; Djalilov et al., 2015) proved that dynamics of bifurcation transformations in the transition economy influenced on the temp of the innovation development.

The analysis of the impact of innovative enterprises activity on ensuring the indicators of state development is analyzed in the work of Zakharkina et al. (2018), Kondratiuk-Nierodzińska (2016).

Prediction of the most obvious indicators of loss of intellectual capacity of the country on the basis of analysis of socio-economic impact of intellectual potential of young people on economic and human development is made in the papers (Pryima et al., 2018; Mishchuk et al., 2019; Koceva, 2019; Lyeonov et al., 2016; GrenÄÃkovÃ et al., 2019; Petrushenko et al., 2014; Shvindina, 2019).

The importance of values of young employees, researches on labor migration are laid down in the papers of Titko et al., (2020), Romanska (2017), Zholkver (2019), Garden (2019).

Besides, the range of the scientists (Bilan et al., 2019d) analysed the level of trust among business and government as an indicator which influenced on the economic and innovation development of the country.

The role of highly qualified personnel in forming relationships with stakeholders as part of economic and social development is examined in the papers (Syhyda, 2013; Bilan et al., 2018; 2019b; Abaas et al., 2018). The migration of highly skilled personnel exerts a set of influences on the economic and innovative development of the recipient country and the donor country.

Methods

It was applied analytical methods that were showed by graphical method of trend analysis and descriptive approach. Also, it was used comparative analysis, structural analysis of classification features, allow to achieve the aim of research migration impact on different areas of country management.

The database of the article was formed by studies of leading world scientists, official and statistical information of national and international organizations, such as Ministry of Finance of Ukraine, the World Bank, Department of Economic and Social Affairs of United Nations, the World Intellectual Property Organization (WIPO, a specialized agency of the United Nations) and Cornell University, INSEAD.

Also the methodical approach in this study is based on an analysis of results interviewing directly IT specialists and IT companies that was taken by the all-Ukrainian forum www.dou.ua (DOU: The community of programmers, 2019).

Results

With the advent of the 21st century, the international environment has been radically changing in which states act as key players in the modern paradigm of the common market, according to which the international economy is not a direct interaction of the national government with other national governments, but an economic (not political) interaction between the regional economic communities (Barnz V. and Lebedur L., 2003).

Thus, a new approach to international internationalization becomes a relevant issue for consideration by politicians, scientists and practitioners. Globalization processes necessitate the study and modification of approaches to the role and place of civil society institutions in the field of regulation of labor processes and employment of the population, infrastructure development of national and regional labor markets (Yevdokimov et al., 2018; Lyulyov et al., 2017). Hence, employment processes cause a steady increase in global migration rates and reallocation of the labor force in both global and national and regional labor markets (Garden et al., 2019). The main factors that currently

affect rethinking of approaches to migration processes are the scientific and technological progress, world market, the constant change of market specialization, changes in the structure of social and labor potential, as well as geopolitical and geocultural processes (Bilan Yu et al., 2019b).

There are many kinds and forms of migrations. In studying the conditions that encourage people to leave their country. In addition, the establishment of classification has a great influence theoretical school, according to the principles which the scientist makes their hypothesis.

Migration processes in its essence are subject to classification on a large number of factors.

The generally recognized classification of migration is the distribution by qualitative feature, namely, migration originates from the country under consideration or into it, immigration and emigration accordingly are distinguished. In most cases, migration is divided into internal and external on the grounds of crossing the state border. In addition, there is a breakdown by kinds and type of migration by such features as: distance, duration, nature of the organization, purpose, reasons, scale, etc. Steven Castles, director of the Oxford University Refugee Study Center, among the total number of migrants distinguish such group as highly skilled business migrants (Stephen Castles, 2008). These are high-level managers, administrators, specialists, technicians and those who move within the internal labor markets of multinational corporations and organizations, or those who are seeking employment through international labor markets. This group of migrants is in demand in most countries, which leads to offers for special programs of the type "Highly skilled and business migrants" (Kasianova, 2016).

Thus, comparing highly skilled labor in migration processes with other types, it should be emphasized that this group has certain special characteristics, namely:

– these migrants are in most cases highly educated and focused on lifelong learning;
– in most cases, migrants aim to leave the donor country forever without plans to return;
– migrants are in demand both in the donor and recipient countries;
– this type of migrant fully comply with migration laws and are responsible citizens;
– they often migrate with their families;
– this type of migration is due to particular reasons where people seek not only higher wages but also in a common vision of a better standard of living and security.

It is impossible to consider individual types of migration and their impact on the economy and innovation without understanding the overall structure of migration processes. Thus, according World Migration Report 2020 of International Organization for Migration the number of international migrants globally in 2019: 272 million (3.5% of the world's population) and 74 per cent of all international migrants were of working age (20–64 years) (Khadria et al., 2020).

Considering the number of migrants in recent years according to the division into parts of the world (Fig. 1) provided by the United Nations Department of Economic and Social Affairs, we can say that on average, every 10th European is a migrant, and Ukraine is not an exception (United Nations, 2020).

Fig. 1: International migrants as a percentage of total population by major area of destination
Source: United Nations, 2020

Ukraine is the largest European country in terms of area, so any changes in the absolute values of migration indicators in Ukraine are immediately reflected in the analysis of all European countries (Pimonenko et al., 2018). Despite the fact that an indicator of the number of migrating Ukrainians tends to decline (Fig. 2), according to the Department of Economic and Social Affairs Population of United Nations Ukraine is among the world's Top 20 countries, whose population migrates. For example, in 2019, the number of such citizens of Ukraine was 5.9 million. It is interesting to note that along with Ukraine in this list are such countries as the United Kingdom, Germany, the USA, Poland, Italy, for which Ukraine is a donor of labor migrants (United Nations, 2020).

So, in 2019 Ukraine ranked 8th in absolute terms of migrant donor countries (Fig. 2). But if you analyze this graph in more detail, it should be said that most of the countries that precede Ukraine are much larger in area and population (India, Mexico, China, Russia, Pakistan), Bangladesh, smaller in area but overall population is still more than the population of Ukraine (more than three times), only Syria is smaller than Ukraine in terms of area and population.

Fig. 2: Twenty countries or areas of origin with the largest diaspora populations (millions)
Source: United Nations, 2020.

But it is obvious that such a rapid jump in the number of emigrants is due to the difficult geopolitical situation and aggravation of the military conflict. Therefore, it can be argued that among the countries whose population size and area are approximately equal in indices, Ukraine occupies a leading position as a migrant donor country. The current situation actualizes the issue of migration research in Ukraine: cause and effect, alternative opportunities and threats, which carries outflow of population from the territory of Ukraine (Vdovtsova, 2019; Bilan et al., 2011; Nur-Al-Ahad et al., 2019). The current situation actualizes the issue of migration research in Ukraine: causes and effects, alternative opportunities and threats, which outflow of population from the territory of Ukraine is fraught with (Naghshpour et al., 2019).

To study the impact of migration on the country's economic growth, let us research the IT industry, which is one of its driving forces.

IT industry today is very attractive for young people, the reason is primarily high income, because most contracts are funded by the investments outside the state. Also, the industry is characterized by a constant change and improvement of technology, knowledge, skills of its employees, and their compliance with international standards and requirements (Nemanja et al., 2019). On the one hand, this progressiveness is a positive factor for Ukraine in general, as it contributes to the development of innovation in the country, as well as reaching level of developed countries in the field of intellectual labor potential. Experienced IT industry personnel play the part in attracting foreign investments, creating companies and opening branches with internationally raised capital in Ukraine.

The ranking of the 10 largest IT enterprises in Ukraine by number of employees is shown in Table 1.

Table 1: top 10 largest IT companies in Ukraine (as of July 2019)

Place in rating	The company name	Cities where the company's offices are located	Specialists in Ukraine, number of people	Increase in six months (January 2019 - July 2019)	Technicians, number of people
1	EPAM	Kyiv, Kharkiv, Lviv, Dnipro, Vinnytsia	7500	+900	6700
2	SoftServe	Kyiv, Kharkiv, Lviv, Dnipro, Exactly, Chernivtsi, Ivano-Frankivsk	7082	+749	5780
3	GlobalLogic	Kiev, Kharkiv, Lviv, Mykolaiv	4363	+214	4071
4	Luxoft	Kiev, Dnipro, Odessa	3670	-250	3598
5	Cycle	Kiev, Kharkiv, Lviv, Dnipro, Odessa, Vinnytsia	2867	+4	2506
6	NIX	Kharkiv	2004	+301	1794
7	Infopulse	Kyiv, Kharkiv, Lviv, Odessa, Vinnytsia, Zhytomyr, Chernihiv	1900	+49	1681
8	Intellias	Kyiv, Kharkiv, Lviv, Odessa, Ivano-Frankivsk	1521	+301	1233
9	DataArt	Kiev, Kharkiv, Lviv, Dnipro, Odessa, Kherson	1474	+173	1278
10	ZONE3000	Kharkiv, Lviv, Dnipro	1450	+150	392

Market size of the IT industry is an important economic indicator. It shows how much information technology is developed in the country compared to other countries. Thus, proof of the development of the IT market is a positive trend in absolute and relative terms of the total number of technicians engaged in major IT –companies of Ukraine (Fig. 3).

Fig. 3: Market growth and number of IT specialists in Ukraine (2015-2020)
Source: N-iX, 2019

Despite the significant growth of the IT industry in Ukraine, the level of migration among representatives of the IT professions continues to increase. Thus, according to Julia Ruda, 2018 nearly every other representative of the profession thinks about leaving abroad. Destination countries include Poland, Germany, and the United States. The proportion of people considering returning is extremely low and is less than 5%.

Experienced and highly qualified personnel who have knowledge, experience and skills at the level of specialists of developed countries can leave the country and migrate to other countries where the standard of living is higher (Fig. 4).

Fig. 4: Plans for relocation of specialists outside Ukraine in the largest 50 IT companies in Ukraine

Source: developed on DOU: The community of programmers, 2018

Ukraine's current internal IT market is growing much faster than in other countries. In 2016, overall growth was 22% (while developed markets in the world are growing no more than 5% per year) 3, in 2017 - 27% 4. Today, the IT industry accounts for over 3% of Ukraine's GDP (US $ 5 billion), along with the agrarian sector (US $ 17 billion) and metallurgy (US $ 14.3 billion) (Karpenko, 2018).

In the ranking of the level of spending on the IT sector and depending of economic development on this level, the state ranks one of the last places among the countries with the IT sector ($ 32.2 GDP per capita, according to 2015 data). The development of the domestic IT market shows one-sided trends (Rollnik-Sadowska et al., 2018). The low level of IT consumption in Ukraine is at the same time the consequence and the cause of the low level of well-being of citizens (it is the raw material and not the technological basis of the economy that causes the lagging behind developed countries) (Garden et al., 2019; Zakharkina et al., 2018). Domestic IT market is US $ 1.1 billion - against US $ 3 billion in India and US $ 7.1 billion in the UK. And it is not about the production of hardware or the creation of packaged software, but only one segment - outsourcing.

In the IT services export market, Ukraine is now 5 times more modest than Poland ($ 3.2 billion versus $ 16.3 billion). If you look at the overall IT market of Ukraine, it grows across all three segments: the hardware market; packaged software market; services market (Ivanová et al., 2018).

The all-Ukrainian forum www.dou.ua (DOU: The community of programmers, 2018) constantly conducts research into the market of IT-specialists, most often by interviewing directly specialists in this field and companies representing the industry. Yes, a survey was conducted among IT professionals who moved abroad and were willing to share their experiences of moving and living in another country. The study surveyed IT professionals who migrated to countries such as Poland, Germany, the United States, the Netherlands, the United Kingdom, and Canada, and analyzed the situation separately. To include other countries in the analysis, they were combined into regions: Western Europe (including Scandinavia and the British Isles), Central Europe (including the former Yugoslavia), the Baltic States and the former USSR. There were also responses from Asia, Australia, New Zealand, South America and Africa, but too few to analyze even at the regional level, so these responses are only included in the sample as a whole.

Thus, according to the results of the study, the following results were obtained regarding the country to which the interviewed IT specialists migrated (Fig. 5).

Fig. 5: Distribution structure of regions of the countries to which the Ukrainian IT specialists migrate

Source: developed on DOU: The community of programmers, 2018.

It is safe to say that most of the migrants from Ukraine who are employed in this field are highly qualified IT specialists , that is, at the time of departure they already have experience working directly on the industry profile, which is shown in Figure 6.

Fig. 6: Results of the interviewing IT professionals who migrated regarding professional orientation at the time of departure and at the time of the survey

Source: developed on DOU: The community of programmers, 2018

The age of the departed is an almost perfect histogram with a peak of 31.5 years now and 29 years at the time of departure (Fig. 7).

	more than 40	36-40	31-35	26-30	21-25	up to 21
Now	5%	14%	36%	34%	10%	1%
At the time of departure	2%	8%	24%	41%	23%	2%

Fig. 7: Distribution of age structure of migrant IT professionals according to the survey
Source: developed on DOU: The community of programmers, 2018.

Another factor that must be considered analyzing migration trends of highly qualified specialists from Ukraine IT industry is that they do not go alone, but with their families (more than 40%), which respectively increased the total number of migrants (Dmytrów et al., 2019). This fact also indicates that these professionals do not transfer money into the home country, do not pay taxes, which means they in no way take part in the formation of GDP as a result of their departure. Also, family migration reduces the likelihood of their return to the country from which they migrated in the future (Limosani et al., 2017).

The main feature that distinguishes representatives of the IT sector from other migrant workers is financial capacity (Titko et al., 2020). Among the first reasons for the departure of specialists are not income, but the quality of living environment (education, health care) (Domina et al., 2018), the prospects for company development, as well as access to another culture, the opportunity to learn about other countries (Fig. 9).

Fig. 8: Reasons for IT professionals to move

Source: developed on DOU: The community of programmers, 2018.

The living environment consists of many indicators that complement each other and form a holistic picture of living standards. The most significant of these indicators are the Global Innovation Index, Ease of doing business index, Sustainable Society Index (Human, Economic, Environmental Wellbeing), The Global Peace Index, Economic Freedom Index, Happiness Index (Fig. 9).

Fig. 9: Ukraine in the international indices in 2016-2019 (Ivanová E et al., 2019)

Thus, according to (Global Innovation Index, 2019) the Global Innovation Index, Ukraine ranked 47th in 2019, while in 2018, 2017 and 2016, the figure was 43, 50, 56, which indicates an overall positive trend. However, the countries visited by Ukrainian specialists have a much higher position in the Global Innovation Index ranking:

1) 2019: Poland – 39, United States of America – 3, Germany – 9;
2) 2018: Poland – 39, United States of America – 6, Germany – 9;
3) 2017: Poland – 38, United States of America – 4, Germany – 9;
4) 2016: Poland – 39, United States of America – 3, Germany – 10.

The ease of doing business rankings based on the average of each economy's ease of doing business scores for the 10 topics included in the aggregate ranking. For the economies for which the data cover two cities, scores are a population-weighted average for the two cities. A positive change indicates an improvement in the score between 2016/17 and 2017/18 (and therefore an improvement in the overall business environment as measured by Doing Business), while a negative change indicates a deterioration and a 0.00 indicates no change in the score (Koceva, 2019). In 2018, Ukraine ranked 71st (ranking = 68.25, change +0.94), in 2019 – 64 (ranking = 70,2, change +1,95). At the same time Poland ranked 40th (ranking = 76.9, change - 0.5), Germany - 22 (ranking = 79.3, change +0.4), USA – 6 (ranking = 83.6, change +0.4).

By the Economic Freedom Index, based on the calculation of 12 factors that characterize the rule of law (property rights, judicial efficiency and government integrity); the level of government intervention (tax burden, government spending and fiscal health); the effectiveness of regulation (business freedom, freedom of work and monetary freedom); openness of the market (freedom of trade, freedom of investment and financial freedom) Ukraine ranked 147th in 2019 and 150th in 2018, respectively, among 186 countries for which this indicator is calculated (with only 180 fully rated). This indicates that it is difficult for professionals to achieve company success through government policy, the imperfection of the judiciary, the legal system, etc.

The corresponding tendency is characteristic of Ukraine according to the majority of the analyzed indicators, which confirms the fact of dissatisfaction with the quality of life by highly qualified specialists of the IT sector.

In the general context of migration processes, it can be said that increasing labor mobility contributes to the economic development of the world, because it enables more efficient allocation of labor and economic resources (Koceva, 2019). But in fact, the economic effects of international migration may differ from theoretical expectations, due to a number of factors for both donor and host countries (Mikhaylova et al., 2019).

The migration of highly skilled professionals is one of the key factors in the redistribution of goods. Information and people are key resources for value creation. Studies conducted on the impact of migration on the performance of the economy (Koceva, 2019; Titko et al., 2020, Balkytė et al., 2011; Mishchuk et al., 2019; Kondratiuk-Nierodzińska, 2016; Lyulyov O. et al., 2018) allow us to understand the relationship between migration processes and economic development. However, a number of issues need further investigation (Bombiak, 2019). Namely, the impact of large-scale migration on the economic growth of the donor country and the recipient country. In order to understand this issue, it is advisable to identify the positive and negative aspects of the migration processes of highly qualified personnel for donor and recipient countries. The study will be carried out on the example of information technology.

From the perspective of the donor country. The outflow of highly skilled IT professionals in the country has one of the consequences a slowdown in the development or recession of science-based and high-tech areas, which in its turn has global implications that go beyond the individual sectors of the country's economy (Palienko et al., 2018). Consider the mechanism of this process. Migration of top IT professionals abroad (and there is no doubt that a significant proportion of those leaving the IT industry in donor country belong to this category, given the prospect of competing in highly competitive markets), leads to reduced competition in the domestic market. On the one hand, it contributes to the reduction of unemployment in the industry and promotes the recruitment of new specialists, which is a positive indicator (Kačerová, 2016). However, on the other hand, it reduces the level of competition among the best professionals in the industry. That is, there is a phenomenon where the attractiveness of the industry is increasing for newcomers, but there is a shortage of personnel among high-level professionals. The consequence is a reduction in the potential of the industry as a whole. In its turn, the decline in the industry's potential is reflected in the performance of the companies that form the industry and their market positioning. This can be traced at the structural changes (Serebryakova et al., 2018). The share of outsourced IT companies (to a large extent, supporting the activities of powerful international IT companies) and niche companies is

growing. In addition, a significant portion of the industry's output is export-oriented, which also has two aspects: a positive one – foreign currency flows into the country's economy - and a negative one - an industry product aimed at developing high value-added industries overseas rather than domestically (Karabasevic D., 2018). The activity of freelancers is also characterized by these aspects. This affects the state of science-based and high-tech sectors of the country's economy, which are gradually losing competitiveness (Ministry of Finance of Ukraine, 2020). As a result, at the macroeconomic level, import of science-based and high-tech products increases and their export decreases. The next link in the chain reaction is the relocation of investment resources to less science-based industries, and as a result to the production of lower value-added products. The minimization of high-tech cost component in the business model guides business structures (enterprises) along the trajectory of movement from process to primary industries (Tommaso, 2018, 2019). The global consequences of migration of highly skilled workers is a decrease in the share of high value-added industries and an increase in exports of raw materials, as a result, the country's economy functions as a raw-material and forms a typical economic model of a "third world country" (Djoemadi Faizal Rochmad, Setiawan M., Noermijati N., Irawanto D. W., 2019; Papp et al., 2019).

However, flow of foreign currency earnings from emigrants (to relatives and family) into the country is considered as a positive effect of large-scale migration, despite their considerable volume, these funds are directed mainly to consumption and do not solve the problems caused by labor migration.

Consider the importance of migration processes among the economically active population for the donor country. In terms of economic development, one of the benefits of labor migration is the infusion of currency (Afanasiev et al., 2019).

For example, according to various estimates, such revenues in Ukraine are from $ 1 to $ 5 billion every year. According to the Ministry of Finance of Ukraine, 2020, in 2016 private money transfers amounted to $ 7.5 billion or 7.9% of GDP, of which 20% came through informal channels, in 2017 $ 9.3 billion came to Ukraine (6% of GDP), in 2018 it was up to $ 11.1 billion. In 2019 – 8.7 billion dollars (6% of GDP), of which almost 50% arrived through informal channels. In 2016, most transfers were made from Poland, Russia, the USA (Fig. 10), but in 2019 the situation was changing towards an increase in receipts from the Czech Republic, Italy and a decrease in foreign currency inflows from the USA and Russia.

Accordingly, these receipts help to improve the competitiveness of the country's economy, but only in the context of individual industry markets (Golovchanskaya et al., 2018). Particularly it can be applied to the production of goods and the provision of services, the need for which migrant workers themselves declare in the implementation of migratory capital funds (Šanda et al., 2018). In Ukraine, these are mainly basic necessities, health care services, education, transport and more. In recent years, the real estate market (secondary and primary) has become quite significant in this regard, where migrant workers not only implement the acquired capital but also invest into extensive development of other related industries (Chocholatá et al., 2018). Matthias Benz and Robert Kirchner (Zholkver, 2019) state that their families' money is spent, in particular, on consumption (31.7%), construction or purchase of housing (19.4%), health treatment (8.7%), health treatment of children (6.9 %). Thus, according to the expert, Ukrainian labor migrants, although working abroad, still contribute to the growth of domestic consumption, which benefits the domestic economy , but do not significantly increase the investment aimed at the production of goods with high added value, and consequently, do not solve the problems caused by labor migration.

Fig. 10: Amounts of receipts into Ukraine from other countries in 2015-2017
Source: developed on RBC-Ukraine, 2018

From the position of the recipient country. The benefit of the recipient country is to obtain cheaper and highly skilled workers, who increase the overall technological level and competition in the industry, contributing to the intensification of its development processes and increasing its competitiveness on the international market (Dimian et al., 2018). Even if there is no discrimination in the wages of local specialists and immigrants, which sometimes takes place, national economy savings origin from no need to invest in the education of visiting professionals, since these costs are already borne by their country of origin.

Mass immigration of highly skilled workers may cause temporary increase in unemployment in the relevant industries for local professionals, but further development of the industry counteracts this effect, making it temporary (Hovhannisyan et al., 2018).

Thus, decrease in the unemployment rate is observed in Poland (7.1% in June 2017 compared to 8.3% in December 2016), which indicates that the country has passed the main stage of instability associated with mass immigration (in the case of Poland both highly skilled and low skilled). Migration is one of the key reasons that has led to Poland's economic success in recent years. The country's economy is booming. As a result, the GDP of the Republic of Poland shows a steady upward trend (2.8% in 2016 and 3.9% in II quarter of 2017 compared to previous periods) (Romanska, 2017).

The consequences of migration of this category of specialists for the recipient country's economy are contrary to those of the donor country and are: increasing the share of production and exports of high value-added goods, increasing the level of competitiveness of the economy, and the growth of GDP and other macroeconomic indicators (Formánek, 2019). Thus, as a result of the migration of highly skilled personnel, the gap in the level of economic and social development between the recipient country and the donor country is widening (Podra et al., 2020).

If we consider the impact of migration processes not globally, but separately on different groups of countries, on different industries and spheres of a particular country, it turns out that there are both positive and negative consequences (Table 2).

Table 2: the impact of labor migration of highly skilled staff on donor countries and on recipient countries (SWOT analysis)

Sphere	Advantages	Disadvantages	Opportunities for the future	Threats to the future
Impact of migration on the donor country				
Economics and Finance	Receipt of hard currency (freely convertible currency) into the country. Reducing the pressure of excess work force in the local labor market and, accordingly, social tensions in the country	Decrease in receipts to national GDP, decrease in tax revenue, due to non-payment of taxes by those who have previously worked and are now migrated	Accelerating of technology exchange, increasing of business opportunities, and export facilities for producers, as migrants abroad generate demand for national goods in the host country	Activation of inflationary processes through transfers of funds. Growth in labor remittances of migrant workers can lead to a decrease in output for export
Human capital	Free training of new professional skills of the workforce for the exporting country, familiarity with advanced work organization, etc.	A "brain leak", of qualified, initiative personnel	Reducing unemployment. Improving the quality of human capital in the future (for those who want to migrate)	Load on the social system of the country. Shortage of workers in certain specialties in the labor market
The educational industry	Acquiring new knowledge and skills of migrants returning to their homeland	Human capital outflow. Deterioration of the quality of human capital	Increasing motivation for education or skills for those who wish to migrate in the future	Shortage of entrants due to the departure of children together with their parents - highly qualified specialists
Social Aspect (Family Relationships)	Improving the well-being of poor working-class families	Deepening social inequalities through increased funding for families receiving money transfers from abroad	Changing roles in migrant families. Reducing the burden on local authorities and social institutions that take care of citizens' lives	The weakening of family ties through distance, and the inability to constantly communicate effectively. Destruction of families
Innovative development	Investing to innovative industries by creating joint ventures with foreign founders	Staff insufficiency / absence to generate innovation.	Using the gained experience for develop innovative activities	The loss of knowledge-intensive and high-tech industries competitiveness
Other areas	Increased productivity among remaining citizens	The number of economically active population is decreasing	Development of services for potential migrants	The elderly population is growing, and the number of young people is decreasing
Impact of migration on the host country				
Economics and Finance	Reduction of production costs. Foreign workers, by creating additional demand for goods and services, stimulate production growth and additional employment	Rising unemployment through additional competition in the labor market	Increasing the competitiveness of domestic products and the competitive position of the whole country	Overload of production facilities. Increasing competition of specialists in the domestic market; rising unemployment
Human capital	The intellectual capital receipt	The reorientation of specialists to less skilled work (temporary phenomenon)	Increasing the country's intellectual potential, including due to rising competition in the labor market	The own cadres substitution to foreign ones, population migration abroad
The educational industry	Reducing the cost for training specialists	There is no direct negative float	Increase in the practical training level by growth the industries capacity, increasing the number of practice bases	No direct threat was detected
Social Aspect (Family Relationships)	Increasing cultural diversity	Increasing the burden on local authorities, social institutions and migration service	Openness of the country. Following the globalization trends as a factor of the improving the image in the international labor market	The well-being deterioration of professionals families who have lost competitive labor to migrants in the labor market

Sphere	Advantages	Disadvantages	Opportunities for the future	Threats to the future
Innovative development	Involvement of highly qualified professionals in the process of innovation through increased competition in the labor market	There is no direct negative float	Improving personnel potential as a catalyst of the country innovative development	Information leakage. Loss in competition of international markets due to the experienced professionals return to their country
Other areas	Import of skilled work force saves on the cost of education and vocational training Improving demographic situation in the country, slowing down the overall pace of population aging	Social tensions in society. discrimination against migrant workers	Establishment of intercultural relations; internationalization of the population. Increasing demand for the social needs of migrants - the development of other social institutions, religions	Conflicts on racial, national, regional grounds, rise in crime and other negative phenomena

Source: Own research

As we see, the migration of highly skilled IT workforce can cause significant changes in the assessment of many functioning countries (Sriviboon, C., 2020). Taking into consideration this conclusion, it is advisable to analyze and group the areas potentially affected by the international migration processes of IT professionals (Table 3).

Table 3: alternative consequences for the donor country of migrants in the IT industry (high skilled workforce)

Feature of migration processes among IT specialists	Benefits for the donor country	Disadvantages for the donor country	Opportunities for the donor country	Threats to the donor country
Migration of IT specialists by section	Increase of opportunities of career growth for the specialists of lower qualification. Increase in foreign currency earnings	Reducing the development of high value-added industries. Reducing the real consumption of supporting industries for the IT industry	Increasing demand for educational services for IT professionals	Decrease of real investments, decrease of development of other industries
Migration with family	Increasing vacancies in the domestic labor market not only in the IT sector but also in others where family members were employed	Lack of currency receipts	Establishing close community relations with national diasporas in other countries	Changing the social structure of the country, reducing the number of able-bodied population and children, adolescents
The relocate is temporary	Training of domestic specialists; increasing and disseminating international experience	Reduction of revenues from temporary taxation at the time of temporary migration	Increasing the country's innovation potential; increasing opportunities for international cooperation	Disparities in the requirements for the qualification of IT specialists in the future. Dissatisfaction with specialists returning to the country. Temporary relocation may be followed by migration without return.

Source: Own research

Therefore, migration processes are one of the important factors that are taken into consideration when examining the economic situation and development of countries (Prokop et al., 2019). But at the same time, the migration of highly skilled IT professionals can have an impact on the formation and development of country innovation (Afonasova et al., 2019). To date, this indicator is not included in a number of issues that are taken into account when analyzing the innovative development of European countries by the European Commission. According to the European Innovation Scoreboard 2019 (European Innovation Scoreboard, 2020), in the 2018 summary Ukraine innovation index is 0.311. Summary innovation index is formed on the basics and analysis of indicators Human resources, Attractive research systems, Innovation-friendly environment, Finance and Support, Firm investments, Innovators, Linkages, Intellectual assets, Employment impacts, Sales impacts. Each of

these indicators is formed accordingly based on the analysis of specific data. Thus, accordingly the indicator Human resources is formed on the basis of New doctorate graduates, population with tertiary education, lifelong learning. But these figures only take into account the actual increase, but do not consider the amount of population with tertiary education and lifelong learning population leaving the country with almost no intention of returning. Thus, when considering the migration of highly qualified staff, having higher education degree and lifelong learning aspirations, this indicator can dramatically change the value of Human resources and Summary innovation index. For the donor country, this may have an impact towards reducing the summary innovation index. At the same time, for the host country, considering the migration processes of highly qualified personnel, in particular the IT industry, can dramatically increase the summary innovation index.

Conclusions

In order to study global processes, the structure of the migrant's distribution in accordance with the total population in percentage terms by continents is presented. According to data from the Department of Economic and Social Affairs Population of United Nations Ukraine is ranked 8th among the countries with the largest number of migrants in the world.

In general, it has been found that the IT market of Ukraine is showing unilateral trends, and that despite the strong development of the industry in Ukraine, it is several times more modest than in some developed countries such as the UK, USA, Poland, and even developing countries (India). In view of this is formed a stable judgment that the migration rates of Ukrainian IT professionals continue to increase.

In most cases, the regions where Ukrainian IT professionals migrate are Western and Central Europe, North America and a small number in the Baltic States. An analysis of the age structure showed that these are mostly young people (21-35 years old). The main factors behind which highly skilled IT workers migrate are not income but quality of living (education, healthcare), company development prospects, as well as access to another culture, opportunity to learn about other countries.

Based on an analysis of several world rankings by indices characterizing quality of life, economic, political, social, etc. (Global Innovation Index, Ease of doing business index, Sustainable Society Index, The Global Peace Index, Index of Economic Freedom, Index of Happiness) it is determined that Ukraine does not occupy key positions in the rankings, which clearly demonstrates its competitiveness in comparison with the leading countries in terms of social, economic development, standard of living and quality of life.

Comparing the Global Innovation Index of Ukraine with other countries that are recipient countries for Ukrainian IT professionals, and analyzing the structure of the Summary Innovation Index, which is formed annually for European countries, it is proposed to include the migration of highly skilled workforce in the evaluation indicators, as taking into account the turnover of specialists and can reflect significant changes in assessing a country's innovation and economic development.

The study grouped the main indicators of the impact of migration processes on donor and recipient countries in terms of economic and innovation component. It is determined that, despite the number of benefits (including financial benefits), for the donor country, labor migration of highly skilled workers reduces the share of high value-added industries and growth of raw material exports, as a result, the country's economy functions as a raw material and forms a typical economic model of the country "of the third world". The effects of the migration of this specialists category on the economy of the recipient country are opposite and consist in increasing the share of production and export of goods with high added value, increasing the level of the economy competitiveness and the GDP growth and other macroeconomic indicators.

Thus, it is determined that as a result of the migration of highly qualified personnel, the gap in the level of economic and social development between the recipient country and the donor country is widening.

According to the aim of the article main factors of migration of highly qualified specialists influencing the economic and innovative development of countries were identified. So, the study found that the hypothesis was correct and the migration of highly skilled personnel influences the economic and innovative development of both the recipient country and the donor country.

The findings allow allocating the directions for further research as follows: quantitative determination of the migration processes influence on the state of countries economic and innovative development, forecasting and economic-mathematical modeling of changes in the country's economic development in changing or maintaining migration trends, factor analysis of the impact of highly qualified personnel migration on economic development.

The Problem of The Growing Similarity of The Level of Disposable Income in The Countries of The Visegrad Group

Michał Bernard Pietrzak

Nicolaus Copernicus University in Toruń, Poland
e-mail: pietrzak@umk.pl

Abstract

The article deals with the issue of the growing similarity of the level of disposable income in the Czech Republic, Poland, Slovakia and Hungary in the years 1996-2017. The studied countries have been associated within the Visegrad Group. At the beginning of the 1990s, these countries underwent a series of economic reforms necessary to transform from central planned to market economies. This made it possible to record systematic socio-economic development since the mid-1990s, which also translated into an increase in the level of disposable income of households. This process continues to this day. In the period under review two key events should be noted: the accession of the Visegrad Group countries to the European Union and the occurrence of the global financial crisis. The events had a significant impact on the growth of disposable income per capita in the period 2004-2008 and a slowdown in the years 2009-2012. The main objective of the study is to analyze changes in disposable income per capita in the Visegrad Group countries in the period 1996-2017 and to identify the convergence process of the level of disposable income. The implementation of the goal allowed to state that the level of disposable income in the examined countries was becoming more similar, which is undoubtedly the result of their mutual economic cooperation, globalization processes taking place and the countries belonging to the EU structures.

Keywords: Disposable Income, Convergence, Households, Visegrad Group.

Introduction

At the beginning of the 90s, the countries of Central and Eastern Europe began their political transformation. In 1991, the Czech Republic, Hungary, Poland and Slovakia formed the Visegrad Group, whose goal was to strengthen political and economic cooperation. As a result of the transformation, these countries have undergone a series of economic reforms that allowed the transition from a centrally planned to a market economy. The institutional and economic reforms led to systematic socio-economic development (Kurowska-Pysz et al. 2018; Łapińska 2013, 2016; Simionescu et al., 2018), which in turn had an impact on the increase in disposable income of households (Jankiewicz, 2018a, Saman, 2018). In 2004, the countries of the Visegrad Group joined the structures of the EU. Membership in the EU has undoubtedly resulted in the further development of selected countries in the institutional, economic and social dimensions (see Formanek, 2019; Simionescu et al. 2017, 2018; Bednář & Halásková, 2018; Balcerzak & Pietrzak, 2016; 2017). The similarity of many economic and social processes in the case of the Visegrad Group countries and countries belonging to the EU is indicated in the literature (see Kuc, 2015; 2017a; 2017b; Hadaś-Dyduch, 2016; 2017; 2018; Hadaś-Dyduch et al., 2019, Stanišić et al. 2018; Meyer & Meyer, 2019; Kuc-Czarnecka et al., 2020)

The subject of the article concerns the issue of changes in the disposable income per capita in the Visegrad Group countries and their growing similarities over the years. The literature on the subject most often considers the problem of economic convergence related to GDP (Wójcik, 2017; Kravčáková & Kotulič, 2015). Verifying the hypothesis of economic convergence for a group of countries means identifying long-term trends in the development of their level of GDP per capita and other economic categories, including the level of disposable income. In addition, consideration of the

problem of economic convergence makes it possible to answer the important question whether in the long run countries with lower levels of economic development are able to catch up with richer ones. The issues of absolute and conditional β-convergence, σ-convergence, club convergence and stochastic convergence were raised in the works of Baumol (1986), Barro & Sala-i-Martin (1995), Mankiw et al. (1992); Sala-I-Martin (1996a, 1996b), Kuc (2015, 2017a, 2017b).

In the literature the differences in the level of GDP per capita and productivity between EU countries are highlighted, where disproportions between new members and countries that joined the community before 2004 are pointed out (see Cheba, 2015; Cheba & Szopik-Depczyńska, 2017; Szopik-Depczyńska et al. , 2017; 2018a; 2018b). It is emphasized that the countries of Central and Eastern Europe are characterized by a significantly lower level of GDP per capita, and thus also a lower level of many macroeconomic and social indicators (Jermolajeva et al., 2017). However, since the Visegrad countries have joined the EU, they could have been described as a group of countries forming a convergence club, where the process of economic convergence takes place both within the club and throughout the EU. The systematic increase in the level of GDP per capita translates into an increase in the level of disposable income in households and a change in the structure of their expenditure (Gavurova et al. 2018; Głodowska, 2017; Jankiewicz, 2018a; 2018c; 2019). These changes are associated with the quick modernisation of these economies, in particular with institutional changes (see Balcerzak & Pietrzak, 2016; Balcerzak, 2020), an increase in the level of innovation, which triggers TFP growth (Jakimowicz & Rzeczkowski, 2019a; Jakimowicz & Rzeczkowski, 2019b; 2019b; Kijek & Matras-Bolibok, 2019; Roszko-Wójtowicz et al., 2019; Zygmunt, 2019), an increase in economic relations related to the belonging of these countries to international structures, or the increase in financial integration and their engagement in foreign trade (see Stverkova et al. 2018; Skare & Porada-Rochoń, 2019a, 2019b). An important factor is also the improvement of the labor market of the surveyed countries (see Georgescu & Herman, 2019; Bieszk-Stolorz & Dmytrów, 2019; Dmytrów & Bieszk-Stolorz, 2019; Tatarczak & Boichuk, 2018), which is a factor supporting the enrichment of households.

The aim of the article is to analyze changes in the level of disposable income per capita in the Visegrad Group countries in 1996-2017. The choice of such a long time of analysis made it possible to consider the variability of disposable income in three periods. The first ones concerns the years 1996-2004, where the Czech Republic, Hungary, Poland and Slovakia, after successful reforms related to the transformation and stabilization of the economy, carried out further system changes aimed at adapting economies to the possibilities of functioning within the EU. The second period concerns the years 2005-2008, in which the countries noted dynamic development related to functioning in the EU structures. The last period concerns the years 2009-2017, which includes the occurrence of the global financial crisis and the slower progress of the economies to economic equilibrium.

The level of disposable income indicates the wealth of the household and is the main factor shaping the structure of consumer spending (see Jankiewicz, 2018a, Shaw et al., 2017). In the article, the author puts forward a research hypothesis saying that there was a process of convergence of disposable income per capita in the countries under investigation. The verification of the hypothesis is an important contribution in the discussion on the issue of the similarity of the structure of household consumption, which changes along with the globalization process (see Hadaś-Dyduch, 2017, 2018; Swinnen, 2017) and as a result of duplication of international consumption patterns (see Salvati et al., 2018).

Methodology

The study concerns the analysis of changes in the level of disposable income per capita in the Visegrad Group countries, while the focus will be on the ongoing process of growing income similarity. Therefore, an attempt will be made to establish absolute β-convergence for disposable income. The concept of absolute β-convergence are presented in the works of Baumol (1986), Barro & Sala-i-Martin (1991, 1992, 1995), Sala-i-Martin (1996a, 1996b). Confirmation of the occurrence of

absolute β-convergence proves that in the long run all the studied countries will strive for the same level of disposable income per capita. Within a certain time, this income will be achieved on a common path of sustainable growth.

If the convergence process occurs, there should be a negative correlation between the disposable income growth rate per capita and its initial level. The absolute β-convergence hypothesis is tested by estimating the following model

$$Y^* = \beta_0 + \beta_1 \ln Y_0 + \varepsilon \quad , \qquad (1)$$

$$Y^* = \frac{1}{T} \ln\left(\frac{Y_1}{Y_0}\right), \qquad (2)$$

where Y_0, Y_1 are the values of the disposable income per capita in the initial and final periods, β_0, β_1 are structural parameters of the model, T is the number of periods studied, ε is a random component.

Obtaining a statistically significant parameter β_1 with a negative assessment confirms the hypothesis about absolute β-convergence for the examined group of countries. Otherwise, the hypothesis should be rejected. The value of the assessment of the parameter β_1 informs about how much of the distance between the average initial income for all countries and the value of income at steady state has been covered during the T years. The higher the absolute value of β_1, the faster the countries converge to equilibrium.

For panel data a dynamic panel model is used to verify absolute β-convergence (Baltagi, 1995):

$$\ln\left(\frac{Y_{it}}{Y_{it-1}}\right) = \beta_0 + \beta_1 \ln Y_{it-1} + \eta_i + \nu_i + \varepsilon_{it}, \quad (3)$$

$$\ln Y_{it} = \beta_0 + (1 + \beta_1) \ln Y_{it-1} + \eta_i + \nu_i + \varepsilon_{it}, \qquad (4)$$

$$\ln Y_{it} = \beta_0 + \gamma \ln Y_{it-1} + \eta_i + \nu_i + \varepsilon_{it}, \qquad (5)$$

$$\gamma = (1 + \beta_1), \qquad (6)$$

where: Y_{it} gives the values of the disposable income process per capita, $\beta_0, \beta_1, \gamma_1$ are parameters of the model, t is time variable, i is index for the country, η_i gives individual effects of a panel model; ν_i are time effects, $\varepsilon_{it}$are disturbances.

The UMM system estimator is most often used to estimate the parameters of a dynamic panel model (Blundell & Bond 1998). The two-step estimation process is a development of the UMM estimator for equations in the first differences (Arellano & Bond, 1991). In the case of using the panel model, obtaining a statistically significant parameter γ with an assessment less than one confirms the hypothesis of absolute β-convergence. The average annual convergence rate is given by the formula

$$b = -\ln(\gamma) \qquad (7)$$

and the time it takes to move halfway between the average level of initial income and equilibrium income by formula (see Barro & Sala-i-Martin, 1995)

$$c = \frac{-\ln(2)}{\ln(\gamma)}. \qquad (8)$$

Analysis of changes in the level of disposable income

The empirical study focused on the level of disposable income per capita in the Visegrad Group in the years 1996-2017. The data were obtained from the Eurostat database. Table 1 presents the level of disposable income per capita in the years 1996, 2004, 2009 and 2017 and its percentage changes in the periods 1996-2004, 2004-2009, 2009-2017. Initial analysis of the data in Table 1 indicates a systematic increase in disposable income, both before joining the EU in 2004 and after accession. In 1996, the highest level of disposable income per capita was obtained in the Czech Republic (2,871.23 Euro). In Hungary and Poland the initial disposable income per capita was at a similar level (2,286.16 and 2,344.45 Euro, respectively), and in Slovakia at the lowest level (1,986.85 Euro).

Table 1. Disposable income in the Visegrad countries
(Source: own work based on Eurostat data)

Countries of EU	Dispisable income p.c.				Percentage change			
	1996	2004	2009	2017	1996-2004	2004-2009	2009-2017	1996-2017
Czech Republic	2871,23	5056,72	7941,08	9380,72	76,12%	57,04%	18,13%	226,71%
Hungary	2286,16	4962,47	5480,92	7127,9	117,07%	10,45%	30,05%	211,78%
Poland	2354,45	3607,46	5240,6	7326,82	53,22%	45,27%	39,81%	211,19%
Slovakia	1986,85	3868,67	7527,5	9328,57	94,71%	94,58%	23,93%	369,52%
all countries (average)	7982,55	11446,5	13519,4	15575,3	43,39%	18,11%	15,21%	95,12%
"old" countries (average)	11339,3	15531,5	17423	19544,9	36,97%	12,18%	12,18%	72,36%

In the years 1996–2004, as a result of system reforms carried out in the early 90s and actions aimed at institutional preparation of economies for accession to the EU, the level of disposable income has grown very dynamically. In the case of Hungary, it more than doubled (117.07%). Slovakia, the Czech Republic and Poland also recorded high disposable income growth rates at 94.71%, 76.12% and 53.22% respectively (see Table 1). As a result of such a strong upward trend, disposable income per capita for Poland and Slovakia in 2004 amounted to 3607.46 and 3868.67 Euro, respectively. In the case of the Czech Republic and Hungary, disposable income of households was at a higher level compared to Poland and Slovakia in 2004, respectively 5,056.72 and 4,962.47 Euro.

The year 2004 was crucial for the countries of the Visegrad Group due to their accession to the structures of the EU. The membership resulted in a significant increase in the level of their disposable income, which in 2009 amounted to 7941.08, 5,480.92, 5,460.60 and 7,527.50 Euro respectively for the Czech Republic, Hungary, Poland and Slovakia. Slovakia recorded the highest increase in disposable income per capita at 94.58%. The increase in disposable income for Czech Republic and Poland was at a comparable level of 57.04% and 45.27%, respectively. It is important to emphasize the very low increase in disposable income in Hungary in 2004-2009 at the level of 10.45%. Hungary was undergoing an economic crisis during this period and. As a result of reforms, the Hungarian economy entered the recovery phase only after 2012.

It should be emphasized that, despite the global financial crisis in 2008-2009, the level of disposable income of households for the Visegrad Group countries again significantly increased in the years 2009-2017. As a result, in 2017 the Czech Republic and Slovakia had the highest level of disposable income, 938.72 and 9328.57 Euro, respectively. In the case of Hungary and Poland, disposable

income was at a lower level in 2017 and amounted to 7,127.90 and 7,326.82 Euro, respectively. It should be emphasized that in the period 2009-2017 the growth rate was lower than in the years preceding 2009. The growth rate of disposable income per capita amounted to 18.13%, 30.05%, 39,81% and 23.93%, respectively for the Czech Republic, Hungary, Poland and Slovakia. One of the main arguments justifying this situation is the fact that the studied countries were at the time under the influence of the global financial crisis, which significantly affected the global economic slowdown.

Summing up the analysis, it should be emphasized that in the period 1996-2017 there was a systematic increase in the level of disposable income in the examined countries, respectively for the Czech Republic, Hungary, Poland and Slovakia 226.71%, 211.78%, 211.19% and 369.52 (Table 1). The analysis confirms the diversity in the level of development of the economies of the Visegrad Group countries. The Czech Republic and Slovakia achieved a similar level of disposable income in 2009 and 2017, in spite of the fact that the countries were characterized by significant differences in the level of socio-economic development in favor of the Czech Republic. The economic development of Hungary and Poland went completely different, which also achieved a similar level of disposable income in 2012.

It should be emphasized, however, that despite differences, there is still a high similarity of the economies of the Visegrad Group countries and in social, economic and institutional conditions for their development. In addition, the presented analysis clearly indicates that the largest increase in disposable income for the countries studied was recorded in the period 1996-2004, after which, in the subsequent periods 2004-2009 and 2009-2017, the speed of growth decreased. This means that for the Visegrad Group countries a convergence of disposable income may occur, which was expressed in the research hypothesis set out in the article.

In the first stage, the Pearson's linear correlation value between the logarithmic rate of increase in disposable income in the period (t-1, t) and the value of disposable income in the year (t-1) was determined. The significant correlation value obtained at the level of -0.36 indicates the potential convergence of disposable income in the countries. In order to verify the research hypothesis, the parameters of the dynamic panel model were estimated, where the model specification was expressed using equation 5.

Table 2. The result of the estimation of the dynamic panel model (Source: own estimation)

Parameters	Parameters Estimated	p-value
γ	0,94	≈0,00
α_1	0,49	≈0,00
Statistical test	The value of the statistical test	p-value
AR(1)	-4,05	≈0,00
AR(2)	-1,38	0,16

The obtained estimation results are presented in Table 2. Parameter γ turned out to be statistically significant. The obtained assessment of the parameter γ lower than one allows the verification of the research hypothesis presented in the article about the convergence process of disposable income per capita. The average annual convergence rate for a group of selected countries is 5.24%, and the time it takes to move halfway between the average level of initial income and steady state level of income is 13.22 years. The statistical properties of a random component of the model were also examined. In the case of autocorrelation properties of increments of random component, a negative, statistically significant first order autocorrelation and statistically insignificant second order autocorrelation were obtained. This demonstrates the choice of the UMM was statistically justified (see Baltagi, 1995).

Conclusions

The article deals with the issues related to the development of the level of disposable income per capita in the years 1996-2017 in the Visegrad Group countries. The aim of the study was to identify the trends of disposable income and to determine the process of its convergence. For each of the countries, a dynamic increase in disposable income per capita was established. Permanent growth over the years was mainly due to the reforms carried out in the political system, the accession of countries to the EU, which lead to the systematic increase in the level of socio-economic development (see Simionescu et al., 2017; 2018). It can be stated that selected countries are becoming more and more economically similar to the so-called old EU, including the main determinants of welfare such as investment outlays (see Rogalska et al., 2017; Wigren & Wilhelmsson, 2007, Tvaronavičius and Tvaronavičiene, 2008), level of innovation (see Mejlgaard et al., 2018), or the development of the digital economy (see Balcerzak, Pietrzak, 2017; Azzouz et al., 2018). Therefore, with the increase in the level of socio-economic development of the Visegrad Group countries, including institutional and structural changes in these economies, a further upward trend in the level of disposable income per capita should be expected.

Realization of the goal of the article allowed to verify the research hypothesis on the convergence of disposable income per capita for the examined group of countries. This means that long-term trends in the level of disposable income have been established, according to which selected countries will strive for the same level of disposable income. The target income level should be achieved on a common path of sustainable growth. It should be emphasized that the established average annual convergence rate and the time needed to reach halfway to a steady state level of income may change over time. The identification of the disposable income process for the Visegrad Group countries indicates that even in crisis situations and in the event of structural changes in economies, they should aim at a similar steady state.

Electronic Banking Services for Micro and Small Enterprises in Poland

Mariusz SROKA

Faculty of Management, Czestochowa University of Technology, Czestochowa, Poland,
mariusz.sroka@pcz.pl

Abstract

The theoretical part of the article presents general knowledge about electronic banking services and the importance of ICT networks for the development of this field of economy. Premises causing the dissemination and development of the offer of electronic banking services for micro and small enterprises were also presented. The practical part of this study presents the results of research conducted among owners and managers of micro and small enterprises in the Silesia region covering such aspects as: the degree of using electronic banking services, the most common forms of using electronic banking services, the most important electronic banking services from the point of view of micro and small enterprises, determinants of the use of electronic banking services and threats resulting from the use of electronic banking services. Conclusions and proposals for further research complete the study.

Keywords: Electronic Banking Services, Micro Enterprises, Small Enterprises, Poland.

Introduction

Using banking services in a classic way is out of the question. ICT networks allow convenient, simple, fast and above all cheap use of banking services by enterprises and individual clients. Computer and telecommunications networks enable the execution of a transfer order or checking the account balance from anywhere. This solution allows enterprises freedom of account operations, while banks have the ability to control their operations and ongoing contact with clients (Badawi et all, 2017); (Grzywacz, 2016).

The popularization of electronic banking services determines the access of enterprises to particular telecommunications services. These services can be implemented through such media as: traditional telephony, mobile telephony, fax-modem services, ISDN, leased lines, packet data transmission, WAN, MAN and LAN. The development of ICT techniques and technologies can now be regarded as an accelerator of all business processes. Observing the dynamic development of the banking services market and integrated IT systems dedicated to business organizations, there is a convergence of banking areas with the areas of corporate finance (Liao and Tow Cheung, 2016).

The modern banking system is one of the more active areas of occurrence of various financial innovations. Innovation in financial service, both for companies and individual recipients, can be considered search and selection of various methods and forms of payment that meet the needs of customers. As a result of increased competition among banks, the quality of their services is improving. It is primarily the banks that are currently deciding on the basic choice of distribution channels for their products and services, but customers should not be depreciated in this respect (Kocisova et all, 2018).

In recent years, significant progress has been made in Poland in the field of IT applications in banking. It is well known that banks have a large number of settlement operations. The fast and error-free service of these operations can be performed only with the use of appropriate IT systems. A number of banking activities are significantly accelerated due to instant access to information stored in databases (Kaczmarek, 2016).

An important problem in the field of banking financial services is the concern about the security of funds accumulated on the account. In Poland, there is still a lack of confidence in the electronic transmission of data. This is primarily due to the lack of sufficient public awareness in this regard. This is particularly evident in the areas of electronic payments. There is a perception that there is still a lack of sufficiently secure electronic transaction channels.

The noticeable process of decreasing the number of operations carried out in banks by micro and small enterprises in the classical way for electronic operations is very dynamic. For this purpose, less time-consuming, more efficient and safer information technologies are used. This applies to the entire range of electronic services offered by banks to individual and business clients. The market for these services is expanding to include the following forms of activity:

- preparation of technical and information infrastructure,
- information services provided electronically,
- commercial and banking operations carried out using electronic devices (Gąsiorowski and Podsiedlik, 2015); (Omariba et all, 2012); (Sławek, 2017); (Sravanthi, 2016).

The methods of conducting banking operations have a significant impact on the development of micro and small enterprises. Therefore, it is important to improve this area through the use of modern technologies and IT techniques. However, the use of IT infrastructure in micro and small enterprises is associated with organizational changes that should be carried out in them and with incurring some financial expenses. However, as a result of such transformation, the efficiency of financial management is increased and the level of company profits increases. This is one of the most important conditions that determines the functioning of micro and small enterprises on the market (Laith Talal Khrais, 2013).

Banks strive to modernize the banking systems existing in their branches. This possibility is largely guaranteed by legal regulations and market realities. Banks provide their clients with the option of carrying out banking operations electronically. This process is conditioned by:

- an increase in the number of documents in the banking sector,
- high costs of traditional banking services,
- introducing new banking services,
- competition between banks,
- changes in legislation affecting the dissemination of an electronic document in business transactions,
- increased threat of criminal activity.

Considering the above premises, it should be assumed that electronic banking services are an indispensable tool in micro and small enterprises. Therefore, it becomes important to organize the individual stages in the processes of selection, design and implementation of electronic banking services in these enterprises (Ranisavljevic and Jovic, 2016); (Liébana-Cabanillas et all, 2013); (Nso, 2018); (Khan, 2017).

Research Methodology

The survey using the questionnaire was conducted from January 7 to January 21, 2020. The respondents were the owners and managers of micro and small enterprises in the Silesia region. The selection of the research group was intentional. 146 business entities took part in the study. After checking the correctness, completeness and logic of the answers given, 128 questionnaires were classified for further analysis. The condition of participation in the research was consent to anonymous completion of the questionnaire. The survey contained 1 single-choice question and 4 multiple-choice questions.

The test results are summarized in the tables. The tables are based on the relationship (1), illustrating the frequency of answering y-type responses (y = a, b, ...) within the question x (x = 1, 2, 3, ..., 7, 8).

$$k_{x,y} = \frac{\sum e_{x,y}}{\sum E_x} \cdot 100 \ [\%] \ , \qquad (1)$$

wherein:

$\sum e_{x,y}$ - the number of y-type answers (y = a, b, ...) given under question x,

$\sum E_x$ - total number of answers given under question x

The aim of the research was:

- determining the degree of use of electronic banking services by micro and small enterprises;
- obtaining knowledge about the most common forms of using electronic banking services in micro and small enterprises;
- isolating key (most relevant) electronic banking services for micro and small enterprises;
- diagnosing the determinants of using electronic banking services in micro and small enterprises;
- learning the opinions of respondents about the risks arising from the use of electronic banking services.

Presentation and Discussion of Research Results

The first survey question concerned the use of electronic banking services in micro and small enterprises and the business profile of the enterprise. In the surveyed group of business entities, 100% of respondents use such services in various degrees and forms. Regarding the profile of the company's activities - 55% respondents indicate a commercial activity, 35% for service activities and 10% on production. The research results for this survey question are shown in Figure 1. This part of the research is not surprising and its results were predictable. Nowadays, it is difficult to imagine the functioning of any enterprise without access to an ICT network. It should only be noted that in family businesses, transferring competences related to IT activities to the younger generation is a common phenomenon. This is due to the fact that people born in the nineties and later are much better educated in the field of computer science. This information was obtained during a direct survey interview on a sample of 24% of the surveyed population.

Fig. 1: Degree of use of electronic banking service and business profile

Source: Own research

The second survey question concerned the form of using electronic banking services by micro and small enterprises. The research results for this survey question are shown in Figure 2. As can be seen, the vast majority of respondents (96%) indicate the use of banking services via websites and payment cards (51%). Telephony comes next (28%). The questionnaire did not specify whether it is landline or GSM, but we can assume that this applies to services provided through smartphones. ATMs were indicated by 15% of respondents, which indicates a trend aimed at limiting cash transactions. A very small percentage of respondents (5%) pointed to stationary bank branches, which means that it is not possible to completely eliminate bank branches, as there are activities and procedures that require a personal visit to the bank.

The third survey question concerned the identification of key (most significant) banking services for micro and small enterprises. The research results for this survey question are presented in Table 1. The most important services for micro and small enterprises surveyed indicated the current PLN account (100%), domestic transfers (95%) as well as information about accounts (90%) and credit cards (70%). A small percentage of respondents indicated such services as: foreign currency loan, foreign currency deposit and foreign currency account. This state of affairs is most likely due to the fact that the majority of respondents conduct their activities only with contractors from Poland, providing services and goods to the local market. Another reason for such indications may be the attractive offer of banks in the field of conversion into universally acceptable currencies of the world, which does not require the freezing of funds on company accounts.

Fig. 2: The form of using electronic banking services

Source: Own research

Table 1: Key banking services for micro and small enterprises

Answers	Indications [%]
Current PLN account	100
Domestic transfers	95
Account informations	90
Credit cards	70
PLN loans	35
Foreign transfers	21
Investment account	12
Currency account	8
Currency deposit	5
Foreign currency plan	4

Source: Own research

Another survey question referred to the determinants of the use of electronic banking services by micro and small enterprises. The research results for this survey question are presented in Table 2. The respondents indicated as the most important determinants: Reduction of time-consuming, direct contacts with the bank branch (92%), more effective management of funds on the account (85%) and reduction of the number of paper documents (75%). Less important for the respondents from the point of view of the activities of micro and small enterprises were: improved security of cash

disposition, faster access to financial information and access to new banking products (14%). It should be presumed that such indications result from the real needs of micro and small enterprises operating on the local market and the proper adjustment of banks' offer to the needs of entrepreneurs.

The last survey question concerned the threats to development of electronic banking services. The research results for this survey question are presented in Figure 3. The majority of respondents (98%) point to the threat arising from broadly understood electronic crime. In this aspect, the research results should be treated optimistically, taking into account the awareness of entrepreneurs about the possibility of cyber attacks and attempts to phishing login data in electronic banking systems. Relatively many indications (56%) were at the expense of telecommunications services. It should be assumed that this is due to the belief in the high costs of these services outside the country (especially in countries outside the European Union) and the presumption of entrepreneurs with a significant financial burden for telecommunications services. This aspect requires a separate approach and research, which in the author's opinion should constitute a more comprehensive study. A small percentage of respondents pointed to the costs of system implementation and maintenance (32% and 15%, respectively), which is also confirmed by taking into account previous responses regarding the use of dedicated systems.

Table 2: Determinants of the use of electronic banking services in micro and small enterprises

Answers	Indications [%]
Limiting time-consuming, direct contacts with the bank branch	92
More efficient account management	85
Reducing the number of paper documents	78
Acceleration of payment transactions and cash flow	21
Access to new banking products	14
Faster access to financial information	12
Improving the safety of cash management	10

Conclusions

Electronic banking services set new directions in the development of commercial techniques and processes, and these are very important aspects from the point of view of the activities of micro

and small enterprises. Through IT networks it is possible to carry out most of the financial operations related to the means of payment stored on the account. This is confirmed by studies in which 100% of micro and small enterprises indicate that they use such services. Equally important are the possibilities of obtaining information on the state of cash and operations carried out now and in the past. This is possible by checking the course of all transactions carried out after referring to the account history. Thus, it becomes possible to automatically load defined accounts, create all types of reports, select information and print selected documents. Data sorting is done according to selected and given criteria, for example transfer amount, posting date, etc. Thanks to this, possible mistakes that could arise during the preparation of orders are kept to a minimum. This is indicated by research. The surveyed group of micro and small enterprises indicated that the key services are: account information (90%), domestic transfers (95%) and the current zloty account (100%). Planning and managing finances is also easier. As a result, by obtaining full and timely information, you can control the cash flow of your bank account to a much greater extent. Account management can also be carried out from outside the country via ICT networks. However, this is not the most important issue for micro and small enterprises. Only 8% of respondents indicate a currency account as significant from the point of view of their business activity. 21% of respondents declare their willingness to use foreign transfers. Most likely it depends on a group of contractors in which foreign entities constitute a much smaller percentage than domestic economic entities.

In the organizational and economic aspect, the conducted research and analysis provide grounds for stating that the importance and relevance of the issues raised is undeniable. Electronic banking services allow for a high level of information flow, which gives flexible and quick access to accounts. This is reflected in the research carried out. In the surveyed group of enterprises, as determinants of the use of electronic banking services, 92% point to the reduction of time-consuming and direct contacts with the bank branch and 85% to more efficient management of funds accumulated on bank accounts. The respondents' indication of faster access to information at the level of 12% is most likely due to the fact that electronic access to the account should assume that the service is satisfactory.

The use of electronic banking services carries real threats, such as: computer piracy, hacking into IT systems and the possibility of unauthorized interception of information. Therefore, institutions providing telecommunications services and enterprises using extensive computer systems for their operations are forced to incur costs on security systems. Nevertheless, these costs may turn out to be disproportionately low in relation to the losses resulting from the above mentioned activities. Existing advanced technologies and techniques are not perfect, because no information can be sufficiently protected and is vulnerable to being taken over by unauthorized persons. The optimal solution is the simultaneous use of the latest security systems as well as proper management and organization. This is confirmed by studies in which 98% of respondents indicate electronic crime as a threat to the development of electronic banking services and 56% the cost of telecommunications services, taking into account, among others, the costs of security incurred to protect transferred data in ICT networks.

Users of electronic banking services must be sure that the incoming data is correct in formal and logical terms. It is also important to encode transmitted and stored data. There is a special need in the electronic payment systems for standardizing procedures, because only then it is possible to make payments both nationwide and international. Telecommunications infrastructure adequate to the needs of enterprises has an impact on the functioning of these systems.

The preliminary (exploratory) research and analysis carried out do not close the topic. It seems reasonable to repeat the survey in which the Likert scale will be used. This would make it possible to determine the model of the examined set of enterprises taking into account the predilection relating to the area of electronic banking services. This, in turn, would allow the identification of key selection factors, development, restrictions and risks associated with the use of electronic banking services.

Abstract

Global markets, general computerization and digitalization, as well as technological development often force to redefine competencies of current employees. At present, employees are functioning in a very dynamic, diverse and multicultural environment. The changing expectations of employers and market requirements result in the need to continuously develop and enhance competencies. Therefore, it is important for employees to develop competencies, which are desirable on the job market, to be able to work in the numerous professions of the future. This publication presents categories and types of competences, as well as trends in the development and changes of competencies of employees. Possibilities of improving competencies have been indicated. Challenges faced by the higher education system as well as relevant expectations towards graduates of higher schools have been defined. An assessment of the demand amongst entrepreneurs for selected competencies of employees (creativity, entrepreneurship, teamwork, communicativeness) has been carried out in the light of the conducted research in selected European Union countries.

Keywords: Competencies, Job Market, Creativity, Entrepreneurship, Teamwork, Communicativeness

Introduction

The job market is undergoing an intensive transformation. The future of work and professional competencies of the future are often discussed during global debates and on economic forums. Heads of corporations, political leaders, intellectuals and journalists continue to discuss the challenges to be faced by the job market in the nearest future. One of the most significant transformations is the changing character of work. New technologies allow to work at any place and any time. The conditions of work are also changing.

Thus, the transforming environment forces new competencies amongst employees. Today, young people often have different competencies than their older colleagues and are driven by different values. The younger generation of future employees comprises people who function in the digital world and combine the virtual worlds with the real one. They regularly use social media, which, to a large extent, serve to replace reading the press, communicate with others or expand knowledge. They are open to changes, they easily adapt to new situations, and they value independence, which is often related with mobile work. On the other hand, employers note openness to change, the will to improve and develop, as well as creativity and critical-thinking abilities. According to forecasts, innovativeness, inventiveness and creativity are the competencies, which will be most desirable and sought by employers in the foreseeable future.

Employment in the knowledge economy is characterized by increasing demand for more highly skilled workers (Ishak, Eze, Ling 2010, Triki, Zouaoui 2011). Shaping the future character of work will depend on the development of digitalization and robotization. It is estimated that as much as 40% of jobs in Poland, and over one half in the world, are threatened by automation (Gumtree 2017

Report). It is also emphasized that the development of new media as well as the growing number of data open a new era, which allows modeling the social systems on a huge scale, where we will have to learn to think and act in an entrepreneurial manner (Future Work Skills 2020). It is estimated that even 30% of skills, which are valued by today's employer, will change in the coming years.

Thanks to the development of new technologies more people will find jobs in new professions. This, in turn, results in the need to continuously gain knowledge and change the approach to learning. Modern technologies make work easier and simplify processes, however they will not replace the human. Therefore, it is important to constantly develop competencies of future employees, which are desired by employers. The purpose of this publication is presenting the expectations and the assessment of entrepreneurs of the selected desirable competencies of graduates of higher schools - the future employees.

Concept and categories of Competencies

According to various researchers, businesses involved in the global area need to have certain competencies, capabilities and skills that are important. These competencies can be the fundamental building blocks of competitive advantage. Sanchez, Heene, and Thomas define competence as the ability to create, gain access to and co-ordinate tangible and non-tangible assets (Kuppusamy 2008). Source literature provides numerous definitions of "competencies".

Usually competencies are divided into professional competencies and personal competencies, referred to as behavioural (Armstrong 2004).

Professional competencies are defined in reference to the given job position. They are directly related with execution of tasks, for example technical abilities, knowledge of the industry. They are defined as "hard" competencies. Hard competencies are developed along with obtaining professional experience. They may also be improved through formal methods, such as university courses or training. Personal competencies refer to behaviours and are related with personal characteristics of managers, which are contributed to the fulfilled professional roles. Personal competencies are defined as „soft" competencies. Soft competencies of managers, as opposed to hard competencies, are not easy to improve. This usually requires a change of behaviour. In business processes, hard competencies of the management still play an important role. They facilitate, amongst others, development of products, implementation of new solutions, or building authority. From the perspective of the last few decades, requirements concerning hard competencies may be deemed as constant. Whereas the significance of soft competencies is growing. These competencies contribute to effective execution of the company's strategy where not only the abilities of single persons are used but also the synergy of the entire team (Jędrzejczyk 2013).

Both hard and soft competencies may be developed and improved. In particular, soft competencies may dominate in many workplaces. Recruiters and professional advisors admit that hard competencies often decide about getting the job, but soft competencies may cause losing it. According to some, hard competencies may soon be replace by machines. This particularly refers to routine repeatable tasks, based on algorithms.

According to Rostkowski, competencies mean all attributes of employees (knowledge, skills, experience, abilities, ambitions, values, style of operation), the possession, development and use of which contributes to executing the strategy of the employer (Rostkowski 2004).

In turn, F. Delamare Le Deist and J. Winterton (Delamare Le Deist, Winterton 2005, see Oleksyn 2006,) divide competencies into four categories:

- cognitive – ability to learn, understand and remember. Related to openness, curiosity and cognitive passion;
- functional – abilities allowing effective performance of the given profession or working at the given position;

- social – refer to relations with other people (ability to cooperate, initiate and maintain contacts, execution of common goals, ability to solve conflicts);
- metacompetencies – ability to learn and reflect, combined with ability to cope in conditions of risk and uncertainty.

The proposed typology of competencies was defined as a holistic competence model.

At present, there is a visible trend of a wider understanding of the term "competencies". Its semantic scope is successively becoming close to the semantic scope of the term "human capital. Pursuant to this understanding, competencies of employees comprise the following elements (Oleksyn 2011):

- abilities and aptitudes, important in the given job, as well as internal motivations;
- education and knowledge;
- experience and practical skills;
- attitudes and behaviours expected by the employer;
- formal authorizations to act on behalf of the organization – managing certain affairs, decision-making, signing contracts and incurring liabilities, external representation;
- psychophysical attributes important in the given job (creativity, entrepreneurship, courage, strength, physical fitness, good health).

To date, no model set of competencies has been distinguished in spite of numerous experimental research conducted in this area by many science & research centres (Jędrzejczyk 2013, Case Di Leonardi, Hagler, Marshall, Stobinski, Welsh 2020). Most important competencies, which are frequently distinguished on lists of competencies prepared by various researchers in this field – both in individual and organizational terms include (Jędrzejczyk 2013, see Oleksyn 2006):

- knowledge;
- experience and skills;
- creativity and innovativeness;
- independence;
- accountability;
- entrepreneurship;
- business orientation;
- professionalism;
- decision-making ability;
- efficiency and effectiveness;
- communicativeness;
- ability to cooperate;
- ethical behaviour;
- intelligence;
- personal culture and work culture;
- assertiveness.

Therefore, the conducted analysis of the concept of "competencies" indicates the following trends (Jędrzejczyk 2013):

1. The concept of competencies is most often defined as a combination of the employee's knowledge, experience and skills, along with possessed intellectual skills and adopted attitudes, which are aimed at effective execution of the enterprise's strategic goals.
2. A growing number of authors indicate that defining competencies as knowledge, skills and abilities is not sufficient, because competencies are then treated too narrowly. Apart from these components, other elements are also important, including: values pursued by employees (honesty, loyalty), styles of operation (e.g. perfectionism), ambition (e.g. self-motivation, self-development), personal characteristics (e.g. empathy).

3. Competencies are deemed to include any and all aptitudes, which allow executing professional tasks on an appropriate level.

Improvement of management competencies in enterprises

In today's conditions, professional management of competencies became a necessity in basically every enterprise. Competencies of individual employees may more and more often decide about the enterprise's success or failure.

The success of a company depends on the development of its staff, take the great importance the proper education, which is the basis for the subsequent improvement of skills (Ślusarczyk, Herbuś 2014).

Therefore, a necessary condition for the effective functioning of the current enterprise is continuous improvement and adaptation to current market changes (Żukowskis, Pypłacz, Sasak 2015).

The fast technological progress, reducing the human role in the process of manufacturing goods, advanced IT technologies and the dynamics of development force a change in the approach to work, as well as the need to redefine roles in organizations. Skills, qualifications and competencies of older employees are no longer sufficient. In the era of evolution of professions, there will always be need for improvement and obtaining new competencies so as not to reduce own attractiveness on the job market.

Both in management theory and in practice more and more attention is paid to human resources, in particular to soft competencies of employees. This is related with issues such as: staff development, training, and education. These activities are connected with the development of the human potential in organizations, complementing knowledge, as well as improvement of skills and qualifications useful in professional work. This development will also contribute to broaden cognitive horizons of employees, improve innovativeness and entrepreneurship.

Improvement of management competencies means a process of developing existing, or obtaining new qualifications, skills, attitudes, knowledge and experiences, expected by superiors. The effects of this process should be expressed through the level of executed business tasks (McCauley, Velsor 2004).

Competencies may be obtained and improved using various methods. Most often, three principal sources of improving competencies are indicated (Jędrzejczyk 2013):

- experiences obtained during work;
- information and guidelines received from other members of the organization;
- formal methods of improvement (training, workshops, and management courses).

However, learning in educational institutions is important because employees obtain knowledge, later applied during work, in various schools and at various educational levels. This is the basis of further development in organizations, where they will later work. In regard to some employees, companies support their further education during employment. Most often this refers to university and post-graduate studies, as well as complementing vocational education (Oleksyn 2011).

Intercultural competences and intercultural dialogue request an international co-operation in education (Suciu, Pompili Pagliari, Neagu Trocmaer, Donolo 2013). Today, learning should not stop upon collecting a diploma. College studies expand horizons, inspire, and equip with knowledge required at the start of employment. However, it is difficult to define even one industry sector where possessed knowledge does not have to be updated or where one does not need to keep up with the trends. Learning does not end with the completion of the last year of studies. It can be said that this is only the beginning. In order to perform best work in a changing environment, we should set for continuous learning. It is worth to consider courses and training that raises qualifications.

Soft competencies, developed already at the early education stage, may help graduates to be distinguished amongst other candidates in the future and get the dream job. One of the multicultural activities in terms of improvement of competencies already in college may include student exchange programs such as Erasmus, which support the development of competencies of Europeans; or engagement in various social undertakings which require cooperation with others. New skills must be obtained in an ongoing manner. Knowledge may be gained from commercial companies during training or so-called learning crowd (Internet communities and mobile learning courses).

En employee must have competencies, which are valuable for the enterprise, so that it is interested in engaging the employee and paying him for competencies used in accordance with the company's interests. In case of particularly valuable competences, it will be in the company's interest to undertake numerous legal activities (e.g. a non-competition agreement), as well as non-legal (e.g. increasing the tangible satisfaction from work) to keep the employees with valuable competencies. (Juchnowicz 2014).

Currently, all professions to appear in the coming future cannot be foreseen, so it is worth to be creative.

Challenges and expectations towards graduates of higher schools

Modern universities are functioning not only as centers of research and teaching, but also as institutions, whose mission is to prepare the future cadre of the economy, through professional and comprehensive process of teaching students (Kurowska-Pysz 2014). Universities are forcing a huge challenge associated with intense adjustment of educational program to labor market requirements. It means that educational program should lay emphasis on the development of specified competencies of future employees (Smoląg, Kot, Oane-Marinescu 2015).

The challenges faced by higher education require the academic staff to notice and accept the expectations of the job market for graduates of higher schools. The most important task of today's higher schools is to prepare students to (Report O1 2016):

- accept responsibility for own development;
- make decisions concerning professional career;
- shape creative thinking and activity;
- improve interpersonal skills;
- develop the spirit of entrepreneurship.

All this leads to a change of the roles and requirements addressed to academic teachers, who often become advisors in the development of their students, and moderators of the process of obtaining competencies. This situation causes changes in the learning process, introducing new and more effective methods. Therefore, practical teaching methods are increasingly important especially in the context of developing competencies.

More and more often employers are looking for employees with strictly defined competencies. They indicate low practical skills and insufficient adjustment of young employees to work, in particular in terms of possessed competencies. Therefore, it is important to take action already at the stage of education at school or university. This may include activities aiming at equipping graduates of universities with higher level of transversal competencies, since improvement of the quality and adequacy of learning programs in the area of practical and transversal competencies constitutes an important element in many documents of the European Union. Employers and job market institutions should be included in the process of preparing and executing learning programs and taking account of practical experience in the plans of class programs, which should be prepared in account of foreseeing or shaping the future career paths (Guide for implementation 2018).

It is important to raise the level of employability of graduates, amongst others through development of skills related with entrepreneurship. Apart from ensuring education and skills related with the

future profession, schools must improve "general" and "key" skills of students, which are not necessarily related with defined professions, but allow graduates to find a job and move around the job market (e.g. communicativeness, entrepreneurship, ability to learn, as well as ability to work in a team etc.) (Guide for implementation 2018).

Activities should be carried out to support equipping young people with transversal skills by way of improving active cooperation between higher education institutions and partners from outside of the school in order to adjust to current and future needs of the job market (Guide for implementation 2018).

The task of higher schools and academic teachers is constant adjustment of their teaching methods to fulfil the requirements of the modern world, and teaching new competencies, desirable on the job market.

Assessment of the demand for selected transversal competencies in the light of conducted research

Employers indicate that students and graduates are not prepared to function on the job market because their knowledge and skills are not in line with the demand on the market (Reimers, Kanter 2014; OECD 2017). This maladjustment results, on the one hand, with an increasing unemployment rate and, on the other hand, inability to find properly qualified employees (Leceta, Renda, Könnölä, Simonelli 2017).

The conducted research was initiated by an attempt to explain identified signals from entrepreneurs concerning the combination of the needs reported by the job market and methods of educating future young employees in higher schools. The research concerned the entrepreneurs' view on transversal competencies of graduates of higher schools in four countries of the European Union, and it was one of the elements of a project carried out by one of the authors of this publication.

The main goal of the research was an analysis of the demand for selected transversal competencies amongst entrepreneurs in the selected European Union countries. In particular, this covered the assessment of the demand for competencies such as: entrepreneurship, creativity, communicativeness, teamwork. Therefore, the subject of the studies covered four competencies, selected during consultations with experts, deemed as particularly desirable in graduates of higher schools, who enter the job market (Report 02 2016).

The research population comprised enterprises with any legal form, in any industry branch, and of any size, operating in the following European countries: Poland, Slovakia, Slovenia and Finland. In total, 135 enterprises participated in the study.

Research was conducted in the form of an indirect poll, as a survey. A survey questionnaire was applied, prepared in a Google form. The survey included 24 closed questions and 1 open question, along with a data sheet. A five-step grading scale was used to assess the demand for transversal competencies. The following scale was adopted (Report 02 2016):

1 – competence not needed
2 – competence needed very rarely (incidentally)
3 – competence needed but rarely used
4 – competence needed and frequently used
5 – competence very much needed and systematically used

The division of enterprises participating in the research is presented in figure 1.

Fig. 1 : Percentage share of enterprises participating in the research

Source: own elaboration

The following definitions of individual competencies were adopted for the purpose of the research (Report 02 2016):

Entrepreneurship: a set of knowledge, skills and attitudes allowing to adapt to change, identify new opportunities of development and their critical evaluation, foresee and create new innovative solutions, take rational risk as well as implement and realize ideas.

Creativity: a set of knowledge, skills and attitudes connected with the practical application of creative thinking in order to come up with original and useful solutions to problems and to develop new concepts or new links with already existing ideas and concepts.

Communicativeness: a set of knowledge, skills and attitudes relating to a reliable transfer of information and establishment and maintenance of appropriate interpersonal relations which are the foundation of effective professional activity, clear and comprehensible expression and interpretation of ideas, thoughts, feelings, facts and opinions in speaking and writing, understanding non-verbal messages, listening to and respecting other people's opinions, being able to negotiate, make public appearances and self-presentations.

Teamwork: a set of knowledge, skills and attitudes allowing to work in a way that is based on activity and commitment to tasks carried out by a group as well as on aspiration to achieve a mutual aim, provide work-improving solutions, adopt joint responsibility for task completion, effectively exchange knowledge and experience, receive feedback, work together on solving problems and support each other in task execution.
Conducting expert research led to distinguishing attributes which form relevant competencies. Specification of these attributes is presented in table 1.

Table 1: Analysed transversal competencies and their characteristics

Transversal competence	Attributes forming the defined competencies
Entrepreneurship	– ability to initiate and accept changes, – ability to perceive and critically evaluate entrepreneurial opportunities, – ability to plan creative solutions, – ability to create and implement new, creative solutions, – ability to take rational risk,

	– ability to translate ideas into specific activities.
Creativity	– ability to use creative thinking techniques, – ability to create original and useful solutions to problems, – ability to create new concepts or new connections between existing ideas or concepts.
Teamwork	– ability to be actively involved in tasks, – ability to build friendly atmosphere and positive relationships, – ability to solve conflicts in a group, – ability to motivate others to act, – ability to encourage others to reach a common goal, – ability to respect norms and rules of a group as well as their tasks and ideas, – ability to effectively transfer information.
Communicativeness	– ability to transfer information in an effective and reliable way, – ability to establish and sustain good interpersonal relationships, – ability to express concepts, thoughts, opinions in speaking and writing in a clear and comprehensible way, – ability to interpret non-verbal messages, – ability to listen and respect opinions of others, – ability to negotiate, – ability to express and defend one's own opinion, – Ability to speak in public and give self-presentations.

Source: own elaboration based on (Report 02 2016)

In the opinion of surveyed entrepreneurs, the key transversal competence is "entrepreneurship" – this competence received the largest number of indications as strongly demanded and used often or systematically. The lowest level of indications was reported in regard to "communicativeness". Creativity and teamwork had similar results (figure 2). Average results for individual abilities - defined within the scope of the 4 transversal competencies – are as follows: entrepreneurship: 4.32, creativity: 4.19, teamwork: 4.2, communicativeness: 4.03 (Report 02 2016).

Fig. 2: Aggregate results of research concerning individual transversal competencies (average grades for individual abilities – within the scope of indicated transversal competencies)

Source: own elaboration based on (Report 02 2016)

Within the scope of the assessment of entrepreneurship, assessed as highly demanded and systematically used (grade 5) was the "ability to bear the consequences of own decisions" (57.8%) as well as the ability to create and implement new creative solutions (54.1%). Assessment of the competence "Entrepreneurship" – presented by the average value of results of particular competences is as follows: rate 5: 49.3% of answers, rate 4: 35.8% of answers, rate 3: 12.4% of answers, rate 2: 2.2% of answers, rate 1: 0.3% of answers. In the view of nearly half of the respondents competence "entrepreneurship" was rated as very important. In addition, there was a high proportion of assessments "4" - allows to define this competence as desired by employers and expected among graduates entering the labour market. In the "creativity" area, a quite varied level of grading particular abilities may be observed. According to respondents, the most needed competence was the "ability to create usable problem solutions" (59.3% of indications). In the view of nearly half of the respondents competence "creativity" has been assessed as very important. This competence also received high ratings percentage "4". The level of demand for this competence should therefore be assessed as high (rate 5: 45% of answers, rate 4: 33.6% of answers). In "teamwork", almost all abilities were assessed as equally needed. The "ability to share knowledge and experience" received most results (48.1%) as a highly needed and systematically used competence (grade 5). The ability to motivate others to take action and the ability to initiate and maintain proper interpersonal relations each received 46.7%. Nearly 80% of respondents rated the high demand for the competence of "team work", giving it a rating of "5" or "4". This allows defining this competence as desired by employers and expected among graduates entering the labour market. In the communicativeness area, grades of individual abilities were quite varied. Respondents indicated that the ability of effective and reliable delivery of information was the most needed competence (55.6% of indications). The ability to read body language and the ability of public speaking and auto-presentation received lowest grades. Among the analyzed competence – area "communication" received the lowest score in the assessment of entrepreneurs' demand. It does not change the fact that in the opinion of the employers 'communication' to is the most needed and important competence among employees (Report 02 2016, Szwajkowska, Przybyłek 2017).

Fig. 3: Aggregate results for individual competencies – obtained in individual countries participating in the research

Source: own elaboration based on (Report 02 2016)

Comparing obtained results of research in individual countries in should be noted that in Finland the most appreciated competence is teamwork (4.39) and entrepreneurship (4.29) - fig.3. Entrepreneurs from Finland - subsequently - pointed to the competence of the "communication" (score of 3.98), the last place went competence "creativity" with a score of 3.85. In Poland the highest score of the demand received competence "entrepreneurship" with a score of 4.42. The next position got competence "creativity" (score of 4.37). Polish entrepreneurs - subsequently - pointed to the

competence of “teamwork” (score of 4.2), the last place went competence “communication” with a score of 4.15. In Slovakia the highest score of the demand received competence “creativity” with a score of 4.24. The next position got competence “entrepreneurship” (score of 4.22). Businesses from Slovakia - subsequently - pointed to the competence of “teamwork” (score of 4.03), the last place went competence “communication” with a score of 3.86. In Slovenia the highest score of the request received competence “entrepreneurship” with a score of 4.28. The next position got competences “teamwork” (score of 4.21). Businessmen from Slovenia - subsequently - pointed to the competence of “creativity” (score of 4.11), the last place went competence “communication” with a score of 4.06 (Szwajkowska, Przybyłek 2017).

Contemporary enterprises operate faster, are more flexible and geographically dispersed. Dynamic work, multitasking and daily challenges require creative and critical thinking. Entrepreneurship and initiative are also of significant importance. Therefore, entrepreneurship is often linked with creativity. It is connected with effective thinking and action, readiness to make decision independently, including business decisions, and ability to act in a rational manner and achieve a measurable result in the form of profit. An entrepreneurial person does not act passively and in a routine manner, but organizes the work in a creative and innovative manner. Creativity in turn, as a resource, which is unique, valuable and difficult to imitate, may distinguish the enterprise on the market. Such activities are driven by teams, which may be the key element of the enterprise’s strategy. Constituting flexible forms of work organization, they are characterized by substantial knowledge, innovative manner of thinking, and seeking unconventional solutions.

A modern employee operates in a very dynamic and diverse environment, which often combines not only numerous personalities but also cultures, especially in international structures. Therefore, the ability to cooperate and communicate effectively is so important. A company, which functions well, should be built on cooperation and transparent internal communication rules.

One of the challenges of international cooperation of enterprises is working in multicultural teams, often virtual teams working asynchronously. Cultural diversity contributes to the growth of creativity and innovativeness of team members, improvement in communication, work satisfaction, and creates an atmosphere favorable to achieving above-average team results since it enables access to persons, who represent various environments and contact networks, models of thinking and perception, and knowledge. Therefore, team diversity, understood as a combination of varied abilities and experiences, helps to work out better and more innovative solutions due to combining different skills, competencies and points of view.

Hence, research results confirm that the combination of these four tested competencies seems to be the appropriate set of attributes of a potential employee in demand on the job market.

Conclusion

Competencies of employees constitute the most valuable capital at the disposal of the enterprise. Today, personal processes aim not only at attracting, assessing and planning the development of employees, but mainly at adjusting their competencies to the company’s needs and using them in accordance with these needs. The competence-based approach to human resources management is essential nowadays, and this results from both internal needs (clients, activities of competition) and external needs (motivating employees effectively, including motivating to develop).

Competence management systems introduce an innovative manner of perceiving the human being (with their skills, knowledge, personality) as a factor, thanks to which the company may achieve an actual competitive edge.

In the changing world, the requirements of the job market are also changing, and completely different attributes and skills become desirable. Professional experience and education are no longer enough to be a fully-fledged participant of the job market. These must be accompanied by soft competencies, the role of which is growing along with the progress of globalization of processes. Companies engage

employees with well development soft skills, because they are more effective at work, in particular in interactions with people. Therefore, employers expect that the person entering the job market will have basic soft competencies along proper education. Many entrepreneurs sees personal and interpersonal competencies as the basic criterion, while academic and intellectual preparation comes second. In the future, the role of soft competencies will increase, and they should supplement knowledge obtained in colleges, to allow them to adjust to working in a multicultural, dynamically changing professional environment diversified in terms of age and country.

The job market is globalizing at an increasing pace, work is executed in multinational multicultural teams. Therefore, more and more enterprises bet on employees with communicativeness, creativity, entrepreneurship or ability to work in a team. Soon, some professions will disappear from the market, and others will be transformed or changed. There will be many new professions. Hence, we should be aware of the need to continuously raise and update our competencies, as well as of the fact that in the future employees will combine many professions. Future employees should know how to prepare for these changes and what competencies will turn out to be mostly demanded by employers in the nearest future. Higher schools should prepare students to changes occurring faster than ever before, and to obtain competencies in professions which will be created in the future so as to meet future social challenges.

A challenge for the future is therefore to find a way to shape the competencies of the future in a flexible educational system. This may be achieved through a change in the future teaching system, where schools would constitute institutions serving to train and develop competencies demanded on the job market.

How Does Stakeholder Pressure Affect Strategic Environmental Types. The Evidence from Polish Companies

Oksana SEROKA-STOLKA

oksana.seroka-stolka@wz.pcz.pl,

Abstract

The paper includes an empirical analysis of the relationship between environmental strategic types and the stakeholder pressure. The stakeholder theory posits that the stakeholder pressure is one of the most powerful determinants affecting the implementation of environmental issues into corporate strategies and provide enterprises with the motivation to adopt advanced corporate environmental strategies. The study was conducted among Polish companies operating in three industries. The results of the study confirm a positive impact of the stakeholder pressure on the advancing environmental strategic types. Moreover, the results show a stronger pressure of stakeholders on the proactive environmental strategic type, than on the reactive strategic environmental type. Surprisingly, the regulatory pressure has positive and significantly the strongest effect on the proactive environmental strategic type. However, the internal stakeholder pressure has a stronger effect on the proactive environmental strategic type than the external stakeholder pressure.

Keywords: Environmental Strategies, Stakeholder Pressure, Strategic Management.

Introduction

Nowadays, the environmental issues are of growing interest for enterprises. For this reason, companies should take into consideration various persons and interest groups – stakeholders who are interested in the environmental protection and who exert certain manners of influence. The literature emphasizes that stakeholders interested in pro-ecological activities exert a pressure on companies to take environmental actions and adopt more environmentally friendly strategies (Garcés-Ayerbe et al., 2012). In particular, that pressure emerges against enterprises that are a nuisance to the environment. Therefore, enterprises design their environmental strategies in an attempt to respond to environmental demands of those groups of stakeholders whose needs are perceived as the most essential (Henriques and Sadorsky 1999; Buysse and Verbeke 2003; Sharma and Henriques 2005).

The aim of the paper is to assess the impact of the external and internal stakeholder pressure on the continuum of strategic environmental types - from reactive to proactive strategic environmental types. Additionally, the study examines the relationship between the total power of the stakeholder pressure on strategic environmental types.

Corporate Environmental Strategic Types

The literature presents two main leading approaches to the classification of environmental strategies: the non-progressive and progressive approach. The non-progressive approach classifies companies' strategic environmental responses using tools such as a matrix formed by axes that measures the degree of application of different variables. This approach contemplates a strategic analysis of companies' environmental behavior based on different orthogonal dimensions, not always related to the degree of the environmental effort (Garcés-Ayerbe, et al., 2016). The progressive approach (continual) to strategic response patterns presents environmental strategies that ranges from reactive to proactive (Sarkis et al. 2010, Abreu et. al. 2013) or from laggard to eco-innovative strategies (Garcés-Ayerbe, et al., 2016). The progressive approach provides a continuum of strategic possibilities and capabilities of companies to change their strategic responses to stakeholders: first to regulatory then to non-governmental stakeholders (Garcés-Ayerbe et al., 2016). The progressive approach of the strategic classification is dominant among scholars (Hunt and Auster, 1990; Henriques and Sadorsky 1999;

Buysse and Verbeke, 2003; Murillo-Luna et al. 2008, 2011). The criteria identifying the strategic environmental types are mostly based on the degree of commitment to the natural environment (Henriques and Sadorsky (1999), advancing environmental practices Buysse and Verbeke (2003), and strategic possibilities (Murillo-Luna et al. 2008). The classifications of strategic environmental types are presented in Table 1. Although, the presented classifications of stakeholders do not fully present what the literature explores, it can be concluded that there are some slight differences between the presented progressive classifications of companies' responses to environmental issues. Nevertheless, the dominant at first strategic attitude of securing the compliance with the law is gradually extended with voluntary „beyond regulation" activities for the environmental protection, as a sign of legal regulation anticipation and meeting regulatory requirements. The progressive strategic approach to environmental issues is typical for the strategy evolution perspective, in line with the adaptation cycle, and the reaction to the problems of adaptation cycle are different types of enterprises environmental strategies. Furthermore, companies can choose the areas of involvement in the different decision areas that is why, a company's environmental strategy may differ depending on width and depth dimensions of a company' activity.

Table 1: Environmental strategic types classifications

Authors	Environmental strategic types classifications
progressive environmental strategic types classifications	
Hunt, Auster (1990)	Beginner – fire fighter – concerned citizen – pragmatist – proactivist
Winsemius, Guntram (1992)	Reactive – receptive – constructive – proactive
Roome (1992)	Non-compliance – compliance – compliance plus – commercial and environmental excellence – leading edge
Henriques and Sadorsky (1999)	Reactive – defensive – accommodative – proactive
Buysse, Verbeke (2003)	Reactive strategy – pollution prevention – environmental leadership
Murillo-Luna et al. (2008)	Passive – attention to legislation – attention to stakeholders – total environmental quality
Peiro-Signes et al. (2012)	Low-environmental proactivity – medium environmental – high-environmental proactivity
Albertini (2014)	Newly concerned – compliance – opportunistic – proactive
non-progressive environmental strategic types classifications	
Steger (1993)	Offensive – innovative – indifferent – defensive
Vastag et al. (1996)	Reactive – proactive – strategic – crisis preventive
Klassen and Angell (1998)	Reactive posture – opportunistic posture – proactive posture – compliance posture
Winn and Angell (2000)	Deliberate reactive – unrealized – emergent active – deliberate proactive
Carmona-Moreno et al. (2004)	Experienced – hopeful – indifferent – incipient
Lee and Rhee (2007)	Reactive – focused – opportunistic – proactive
de Abreu (2011)	Defender – reactor – sleeper – innovator

Stakeholder Pressure and Stakeholder Groups

According to Freeman definition, "a stakeholder is any group or person (actor) who is influenced or may influence the achievement of the organization's goals" (Freeman 1984, Freeman, Moutchnik, 2013). Freeman and Liedtka (1991) consider an organization as the system of primary stakeholder groups

which survival and success depend on the capacity to create value for these stakeholders by satisfying their demands and expectations.

The literature proposes various taxonomies to classify the stakeholders that can exert pressure on organizations to adopt environmentally friendly behaviors (such as greening strategies). Stakeholders can be classified according to their location in relation to the enterprise - *internal and external stakeholders.* External stakeholders include competitors, suppliers, customers, consumers, media, environmental organizations, local communities, and internal ones include management, shareholders/owners and employees (Freeman, 2010). External stakeholders, unlike internal stakeholders, do not have control of critical organizational resources (Sharma and Henriques, 2005), but "they have the capacity to regulate or mobilize the organization's environmental practices" (Freeman, 1984). A number of external stakeholder groups exist, including customers (clients), government regulators, shareholders, and society in general represented by non-governmental organizations.

Clarkson (1995) distinguishes between *primary stakeholders*, without whose participation and support the organization cannot survive (e.g. customers, suppliers, regulators), and *secondary stakeholders*, which affect and are affected by the organization but are not engaged in transactions with it and are not essential for its survival (e.g. media, non-governmental organizations) (Clarkson, 1995).
Following the stakeholder theory, Henriques and Sadorsky (1999) differentiate four groups that demand enterprises to protect the natural environment: *regulatory stakeholders* (governments, trade associations, informal networks, competitors), *organizational stakeholders* (suppliers, clients, employees, shareholders), *community stakeholders* (community groups, environmental organizations, other potential lobbies), and the media. This classification of stakeholders includes the changing of the strategic response to the stakeholders: first to regulatory then to non-governmental stakeholders. Buysse and Verbeke (2003) proposed an alternative classification: *regulatory stakeholders* (national and regional governments, local public agencies), *external primary stakeholders* (domestic and international customers, domestic, and international suppliers), *internal primary stakeholders* (employees, shareholders, financial institutions), and *secondary stakeholders* (domestic and international rivals, international agreements, non-governmental organizations). Darnall et al. (2010) introduce the classification as follows: *primary stakeholders* - external (value chain participants i.e. commercial buyers, household consumers, suppliers), *primary stakeholders*- internal (management and non-management employees), and *secondary stakeholders* as societal stakeholders (environmental and community organizations, labor units, industry associations), and *environmental regulators* (governments).

A special type of stakeholders distinguished by Fineman and Clark (1996) are stakeholders demonstrating the mission to protect the planet, which include national and local pressure groups. It is worth explaining that there are some differences between the traditional concepts of real stakeholder and pressure groups and regulators, as indicated by Fassin (Fassin 2009).

Opposite to these stakeholder classifications, Sharma and Henriques (2005) argue for a classification in context of how stakeholders affect organizations' strategies. on the basis of the resource interdependences between the organization and its stakeholders. Scholars argue that enterprises do not react differently to different groups of stakeholders, but when they perceive pressure on environmental matters from one of them, they begin to perceive pressure from the others. Thus, the proactiveness of the environmental strategy does not depend on the origin of the pressure but on its intensity (e.g., Murillo Luna et al. 2008; Rueda-Manzanares et al. 2008; Sarkis et al. 2010; Gonzalez-Benito et al. 2010; Sprengel and Busch 2011; Garces-Ayerbe et al. 2012).

Enterprises trying to satisfy different expectations and goals of various interest groups and persons should consider the influence (pressure strength) of stakeholders in developing their environmental strategies. Enterprise relations with stakeholders may occur in three forms:

- strength (stakeholder power),
- legitimization (stakeholder legitimization),
- persistance (stakeholder demands urgency) (Mitchell et al., 1997).

The stakeholder power is based on the enterprise dependence on shareholders. The basis of the legitimization are the assumptions of the legal norms system, but also of the system of values and beliefs regarding environmental problems. The urgency relates to the time in which stakeholder claims require a response. Following the theoretical base of the stakeholder theory, Mitchell et al. (1997) indicate that green stakeholders have often been classified by importance, determination by power, legitimacy and urgency (i.e., Harvey and Schaefer, 2001; Fernandez-Gago and Nieto-Antolın, 2004; or Eesley and Lenox, 2006). Furthermore, Abreu et. al. (2009) distinguish three categories of environmental pressure: the pressure from environmental legislation, from environmental impacts and from the stakeholder environmental demands (Abreu et. al. 2009).

Conceptual Framework

As the result of stakeholder pressure from various interest groups, enterprises adopt more advanced environmental strategies. Academics claim that the stakeholder pressure has a positive influence on the adoption of proactive environmental strategies (Henriques and Sadorsky 1999; Buysse and Verbeke 2003; Garcés- Ayerbe et al. 2012). The scholars argue that "the greater the perceived pressure from a stakeholder group, the greater the strategic environmental proactivity response to environmental issues" (Garcés-Ayerbe, et al., 2012). Authors point out the importance of the pressure of stakeholders to change the strategic environmental response types from passive to proactive (Murillo-Luna et al. 2008). The approach to the stakeholder pressure presented by Murillo-Luna et al. (2008) is more consistent with the main purpose of this paper because it is mainly interested in the total effect of the power of stakeholders pressure on adopting of environmental strategic types. However, there is no consensus about the influence of the external and internal stakeholder pressure on strategic environmental types. What is more, the previous research studies were conducted in developed countries (e.g. USA, Canada), but it is still a gap how each stakeholder pressure influence the companies from the East European Union countries.

Based on arguments from the past research, the following hypotheses are proposed:

H1: The total effect of stakeholder pressure is stronger on the proactive environmental strategic type in comparison to environmental strategies with lower level of adaptation
H2: The effect of external stakeholder pressure is stronger on the proactive environmental strategic type in comparison to environmental strategies with lower level of adaptation
H3: The effect of internal stakeholder pressure is stronger on the proactive environmental strategic type in comparison to environmental strategies with lower level of adaptation
The research framework is presented in Figure 1.

Fig. 1: Conceptual framework

Methodology

The research was conducted among companies operating in three industries: food (40%), fuel and energy (36%), and chemical (24%). These industries were chosen from a few reasons. The industry, still remains, the main anthropogenic source of environmental pollution. The included industries in population sample have the most significant impact on the natural environment. Moreover, within the same sectors or industries, it can be observed the effect of isomorphic pressure (Murillo-Luna et al., 2011). The identification of various industries allows us to differentiate the impact of the stakeholder pressure. A questionnaire survey was e-mailed to 800 firms. The questionnaire contained an instruction how it should be completed. We received 192 questionnaires, but in 12 of them answers were missed. The final sample consisted of 180 companies, and the survey response rate was 24%. The questionnaire survey was fulfilled by management staff responsible for the environmental management, or production management. The general size characteristics of the firms in the sample include both small-enterprises – from 10 to 49 employees – (13%), medium-sized enterprises – from 50 to 249 employees – (35%), as well as large firms with more than 250 employees (52%).

To identify strategic environmental types, the proposition of Murillo-Luna et al. (2008) was used in the research study. This validated tool presents four types of environmental response patterns: passive response (organizations which pay little attention or make little effort to environmental issues), attention to legislation response (organizations which adopt environmental practices which are only compliance with the environmental law), attention to stakeholders response (organizations, which dedicate the necessary time and resources to environmental protection in order to comply with legislation, and attend to the environmental pressures from other stakeholders), total environmental quality response (organizations with total effort to environmental issues in all dimensions of company's activity) (Murillo-Luna's et al. 2008). The environmental strategy in the above approach is a set of environmental activities, that are incrementally undertaken as various resources emerge and gain strategic features. Each pattern of the environmental strategy is a special configuration of environmental goals and allocations of internal resources adopted to the requirements of the environment.

However, the above instrument has been modified by adding new names of the environmental strategic types as follows: passive, reactive, attention to stakeholders and proactive environmental types. Additionally, using Henriques and Sadorsky's (1999) description of environmental strategic types, two items were added. The first item, expressing the level of the environmental support of top management to environmental issues, the second one, the frequency of corporate environmental reporting. The enriched instrument identifies environmental strategic types on the continuum: from the least advanced, to the most advanced environmental strategic types. The most advanced environmental strategic type - proactive - involves stakeholder management and top management support for environmental issues, investment in environmental research development, the adoption of preventing and correcting pollution measures, environmental staff training and the allocation of environmental responsibilities, and corporate reporting to environmental issues.

The four descriptions of environmental strategic types (passive, reactive, attention to stakeholder and proactive) were included in the questionnaire. Respondents were asked to choose the most appropriate description of the environmental strategy if at least four of the attributes of each description were suitable for their companies.

To measure the power of the influence of ten stakeholder groups, the 5 point Likert scale was used (1- " lack of pressure" to 5 -"very high pressure") (Boone, 2012). Stakeholders were divided into external and internal groups by the criterion of stakeholders' location in the company as follows: external stakeholder groups (regulators, competitors, suppliers, clients, NGOs, media, consumers) and internal (top management, shareholders, employees) stakeholders. (Freeman, 2010).

In order to evaluate the statistical significance of the differentiation of the stakeholder pressure in enterprise groups identified by the criterion of environmental strategy types, a one-way analysis of variance (One Way-ANOVA) was used. Kendall's tau correlations were used to assess the correlations

between stakeholder groups and environmental strategy types (variables were coded in the increasing order of their advancement).

Due to the fact that the measurement of the dependent variable in the variance analysis is made in the interval scale, variables describing the pressure of individual stakeholder groups (external and internal stakeholders – interval dependent variables) were aggregated.

Testing the assumptions of the dependent variable distribution normality and the assumptions of the variance homogeneity revealed that the requirements of the variance homogeneity in groups (Levene's test for two variables: for "total stakeholder pressure" was 4.87, $p<0.05$, for "internal stakeholder pressure" was 14.90, $p<0.05$). In the case there are different variances in groups, it is possible to use Welch's t-test to evaluate the equality of means.

Results

The results of the self-classification by enterprises, indicate that 37% of Polish companies chose a reactive environmental strategy, 35 % of companies chose a strategy of "attention to the stakeholders" and 28% of companies recognized a proactive environmental strategy. No company was identified that declared the passive environmental strategy. As the result, the sample consisted of three groups of companies with different environmental strategies. Table 2 shows the results of the analysis of variance relating to the impact of stakeholder pressure on environmental strategic types.

The results of the variance analysis and the obtained level of test probability (at the significance level $\alpha = 0.05$) indicate the lack of the justification for rejecting hypotheses referring to the equality of means in the distinguished subgroups. The hypothesis on a significant differentiation of the effect of the total stakeholder pressure (F Welch-38.46 $p<0.05$), the external stakeholder pressure (F Welch-23.41 $p<0.05$) and the internal stakeholder pressure (F Welch-43.00 $p<0.05$) on environmental strategy types in examined enterprises can be adopted.

In the next step, post-hoc tests were made in order to evaluate which environmental strategy types differ in terms of the effect of the stakeholder pressure. The obtained post-hoc test results reveal significant differences between the effect of the stakeholder pressure on enterprise environmental strategies, except for two strategy types: proactive and attention to stakeholders environmental strategies.

The stakeholder pressure increases as the environmental strategy type advances. The strength of both external and internal stakeholder pressure as well as of the total pressure, exerted on enterprises that adopted the proactive type of the environmental strategy is at the highest level in comparison to enterprises with the reactive and attention to stakeholders environmental strategies (Table 2). The hypothesis H1 was confirmed. However, the effect of the external and internal stakeholder pressure as well as the total pressure on environmental strategy types does not statistically significantly differ between the proactive and attention to stakeholders environmental strategy types. Despite this, the results suggest that environmental strategies of enterprises with a lower adaptation level are less responsive to the pressure exerted by stakeholders (Tables 3-5). Hypotheses H2 and H3 were confirmed.

In the next step, the correlation analysis was conducted, which suggested that strong and statistically significant pressure was exerted by regulators (0.78; $p<0.001$) on the proactive type of the environmental strategy. In addition, moderate correlations were obtained for the effect of the pressure exerted by management (0.48; $p<0.001$) and shareholders / owners (0.40; $p<0.001$) on the proactive type of the environmental strategy. The obtained results indicate that the more advanced environmental strategy type, the stronger the pressure exerted by stakeholders (Table 6).

Discussion and Conclusions

This research explores the relationship between the external and internal stakeholder pressure and the total impact of the stakeholder pressure on environmental strategic types. There is a positive relation between the pressure exerted by (external and internal) stakeholders on the proactive environmental strategic type. The stakeholder pressure increases in line with changes in strategic response of the enterprise from reactive to proactive and the pressure strength is not homogeneous.

Obtained results are consistent with academics who claim that the stakeholder pressure has a positive influence on the adoption of proactive environmental strategies (Henriques and Sadorsky 1999). What is more, scholars argue that the stakeholder pressure not only positively but also linearly influences environmental strategies on their continuum (Fineman, Clarke, 1996; Murillo-Luna et al. 2008). As expected, our results are supported by Buysse and Verbeke (2003) that more proactive environmental strategies are associated with a deeper coverage of stakeholders.

Our results confirm that the pressure of regulators is the most important external pressure what is consistent with former studies (Freeman, 1984; Backer, 2007; Zhu and Sarkis, 2007; Sarkis et al., 2010).

Surprisingly, results revealed that pressure exerted by regulators has the strongest effect on the proactive environmental strategic type, which is not consistent with the previous studies. Buysse and Verbeke (2003) argue that the environmental leadership (proactive environmental strategy) is not related to a growing importance of environmental regulations, thereby suggesting a role for voluntary cooperation between enterprises and the government. These results also differ from what was found by Murillo-Luna et al. (2008) and Garce´s- Ayerbe et al. (2012) that organizations with reactive environmental strategies are under more pressure from regulators than organizations with proactive environmental strategies (Murillo-Luna et al. 2008; Garce´s- Ayerbe et al. 2012). These differences can be explained by the specificities of the Polish regulatory context, related to bureaucracy, high level of social legitimacy, and issue legitimation among industries. From this reason, it can be expected that restrict regulations may more threaten proactive environmental companies than it is expected. Regulatory pressure can also hurt a company's public image which is also crucial for companies with proactive strategic types.

Our results indicate that, among internal stakeholders, top managers play a vital role in perceiving the stakeholder demand for environmental protection what is fully consistent with other studies (Henriques and Sadorsky, 1999; Sharma, 2000; Sharma and Henriques, 2005). The degree of proactivity is greater when managers perceive more stakeholder pressure in high polluting companies (Garce´s- Ayerbe et al. 2012). Managerial interpretations are crucial, since they ultimately determine the importance of stakeholders and are the most powerful determinant among internal shareholders to adopt the most advanced environmental strategies (Sarkis et al., 2010). Henriques and Sadorsky (1999) state that managerial perceptions of the importance of the stakeholder pressures were associated with a more proactive strategic type (Henriques and Sadorsky, 1999).

Regulatory bodies and government (Freeman, 1984) are the most obvious external stakeholders when it comes to environmental issues and are typically associated with coercive pressures (Zhu and Sarkis, 2007). Some of these pressures may come in the form of voluntary initiatives for matters such as pollution prevention. Companies may also adopt proactive environmental strategies as one means to preempt regulatory threats. Implementation of proactive environmental strategies may also build informal relationships and accrue political capital (Darnall et al., 2010).

To conclude, the pressure of stakeholders is a source of the adaptation of activities related to the environmental protection demands and forces changes in the strategic responses of enterprises. External and internal stakeholders may significantly affect the proactive approach to strategic management of enterprises. However, companies' strategies may also differ because of specific context related to demands from stakeholders. From this reason, our results require further investigation especially according to the relation between PES and regulatory pressure. It may exist other mediation or moderation variables which influence the obtained results.

Appendix

Survey items for strategic environmental types

Passive environmental strategic type

- Environmental objectives are currently not pursued in our company.
- Our company has difficulties with financing environmental protection and hardly dedicates time to deal with problems of the natural environment.
- Our company does not currently use technical or organizational instruments to protect the environment.
- Our company does not plan to implement environmental certificates i.e. ISO 14001, EMAS within the next 3 years.
- Our company does not have any person who is responsible for solving environmental problems.
- Top management does not support and is not involved in environmental issues in our company.
- Our company does not report environmental issues.

Reactive environmental strategic type

- Environmental objectives of our company are limited to compliance with legislation on environmental matters.
- Our company devotes time and financial resources necessary on environmental protection not only to comply with legislation on the environment.
- Environmental instruments used in our company do not bring any positive changes in the production and work methods and/or the modification of the organizational structure.
- Environmental instruments (measures) adopted by our company are not certified according to ISO 14001 or EMAS standards.
- Environmental problems are solved by external professionals and/or by a person from our company who is not directly responsible for environmental issues in our company.
- Our the top management selectively supports and engages in environmental activities only in the required range.
- The company prepares reports irregularly, if necessary.

Attention to stakeholder strategic type

- Environmental objectives of our company are not just limited to compliance with legislation on the environment, but also to attend to the environmental requirements of customers, suppliers and other stakeholders.
- Our company devotes time and financial resources to environmental protection to comply with legislation and in order to response to the environmental pressures from stakeholders.
- Environmental instruments (measures) implemented by our company have required improvement of the production, and work methods and/or the organizational structure.
- Some of the environmental instruments (measures) adopted by our company are certified or are in the process of obtaining a certificate (e.g. ISO 14001, EMAS or other).
- The company regularly solves environmental problems with the participation of external professionals specialized in environmental matters or has a qualified person(s) from our company who is responsible for environmental issues and take care of environmental issues.
- Out top management partially supports and engages in environmental activities to meet the requirements of stakeholders.
- Our company regularly reports to external stakeholders on environmental issues, but we report irregularly to internal stakeholders on environmental issues.

Proactive environmental strategic type

- Environmental objectives of our company are among the priority to meet the environmental requirements of all interested stakeholders.
- Our company allocates a significant part of the budget for environmental protection that goes beyond complying with legislation, and in order to respond to pressures from different stakeholders.
- Environmental instruments (measures) used in our company bring improvement in the production process, organizational structure and working methods.
- The implemented environmental instruments in the company are supported by certificates obtained by the company (ISO 14001 or EMAS, or others).
- Responsibility for environmental issues is delegated to one or several people (team) dealing with environmental issues in the company.
- Our top management fully supports environmental initiatives and is involved in any new environmental activities.
- The company regularly/cyclically reports to external and internal stakeholders.

TEI Modelling of the Interpretation of Islamic Holy Book: Tafsīr al-Ṭabarī Case

Abstract

The corpus of *Tafsīr al-Ṭabarī* is considered as one of the high regard Islamic corpora. The importance of this corpus is revealed in the deep interpretation (*Tafsīr*) of the Holy Quran. This corpus is characterized by an important and rich knowledge that is often used by different researchers and Islamic individual communities. Indeed, the normalization of *Tafsīr al-Ṭabarī* corpus can improve information retrieval and text analysis to achieve advanced results. In this context, we aim to develop and experiment a standardized Arabic version of *Tafsīr al-Ṭabarī* with XML based standard: Text Encoding Initiative (TEI). To achieve this, we start with proposing an encoding model based on TEI and adapted for the *Tafsīr* text structure. Then, we elaborate and experiment an automatic encoding module to generate the standardized version of *Tafsīr al-Ṭabarī* based on our model. The obtained results are encouraging despite some problems related to some exceptional cases.

Keywords: Quran interpretation, Arabic *Tafsīr* corpus, TEI normalization.

Introduction

Religious manuscripts have been processed as important corpora in human literature. These corpora have been so far the subject of many academic researches and projects especially in Artificial Intelligence and Natural Language Processing. It is the case of many Islamic corpora. In fact, one of the advantages of applying NLP tasks on the Islamic text is the implementation of intelligent systems, which can allow information retrieval and text analyzing. In addition, it can assist all societies to build knowledge about the text of the Holy Quran and the *hadith* (or Prophetic tradition). The normalization of the Arabic Islamic corpora can support NLP applications to achieve advanced results. Since on the one hand, the standardization of the text will support the compatibility and the interchangeability between NLP applications; on the other hand, this conception can improve the automatic processing of the Arabic Islamic corpora. It considers mainly the corpora that contain a rich and complex text format, and a deep analysis of knowledge of important subjects such as *Tafsīr* (interpretation) of the Holy Quran like the famous corpus of *Tafsīr al-Ṭabarī.*

Although, according to our knowledge, no study has solely focused on the corpus of *Tafsīr al-Ṭabarī* from the standardization perspectives. The standardization (normalization) of this category of manuscript could lead to a new presentation of the text based upon a descriptive and detailed structural and semantic annotation. However, the representation of such corpora poses a serious structuring and text unification problems. This is mainly related to the amount of the knowledge and the details that exists in this manuscript which rise the complexity of the identification of the multiple types and categories of the text and the annotation of each part properly.

Our main objective is the normalization of the Arabic *Tafsīr al-Ṭabarī* corpus, which requires the selection of a standard for encoding all parts of the text. To reach that, we based on Text Encoding Initiative (TEI) guidelines (http://www.tei-c.org/). Indeed, the TEI guidelines present conventions of usable coding in several domains and can be applied to any sort of text (Burnard et al., 2016). To realize the standardization of *Tafsīr al-Ṭabarī*, we start with a study on the NLP processing of the Arabic Islamic manuscripts in general and the *Tafsīr* corpus in specific. Then, we elaborate on a TEI

customized model that maintains the *Tafsīr al-Ṭabarī* structure. Moreover, to realize the normalization process of *Tafsīr al-Ṭabarī*, we implement an automatic encoding module to generate a standardized version of the corpus.

In the present paper, Section 2 introduces a state of art on the processing of Islamic religious corpora and an overview on the *Tafsīr al-Ṭabarī* corpus. Second 3 presents the proposed *Tafsīr al-Ṭabarī* TEI modelling that contains, first, an overview on the TEI elements selection then, second, the proposed TEI model. Section 4 introduces our module to generate the *Tafsīr al-Ṭabarī* standardized version. This section is followed by an evaluation step. In the end, we close our paper with a conclusion and some perspectives.

State of the Art

Since the early stages of the NLP field, the processing of religious corpora was the topic of multiple studies and projects. This was also the case of Islamic corpora which concentrated mostly on the processing of the text of the Holy Quran, the *hadith* and the *Tafsīr* in Arabic language.

In this section, we present, in the first part, some of the realized works that focused on the processing of Arabic Islamic manuscripts. In the second part, we focus on a study of the Arabic *Tafsīr al-Ṭabarī* corpus regarding the characteristics and the structure of the text.

The processing of the Arabic Religious Islamic manuscript

The religious texts are a type of scripts related to religious education and traditions. They characterized with a spiritual aspiration and provides religious commandments (Elster, 2003). Through many fields of researches interpreted religious text, there are several studies focused on Islamic manuscripts in the Arabic language such as (Seddik et al., 2015; Azmi et al., 2014). Many of these projects adopted NLP fields such as ontology modelling, text annotation, linguistic analyzing, and information retrieval to experiment with several intelligent processing. Though, the majority of NLP processing on Islamic scripts and corpuses has largely focused on the ontology modelling, especially for the Holy Quran script. In this context, we present as follow some of these works.

The authors in (Seddik et al., 2015) focused on compiling a large Arabic corpus of the Holy Quran, annotated with anaphoric relation and anaphoric information, providing multi-dimensional feature vector rich with most of the basic anaphoric information needed in statistical anaphora resolution systems. The authors proposed a large and valuable language resource for researchers who are investigating in anaphora resolution systems like investigating and analyzing the Quran script. The established resource offered the accessibility to a combination of the basic features of two of the large and rich corpuses; Quranic Arabic Corpus (QAC) and QurAna corpus.

In (Basir et al., 2018), the researchers focused on the fact that determining the fields of a keyword searched in the Quran can convert to be a guide to improve the knowledge in a certain domain. The authors adopted this idea and proposed that the keyword searched in the Quranic ontology can be applied for extracting the relevant fields. The researchers developed the domain ontology in TopBraid Composer with the medical and economic topics mentioned in the Quran. The process continued with running the queries to depict the appropriate role of ontology. Then, it proposed certain recommendation for the proposed Quranic ontology to attaining semantic search from all domains and the result by searching from *ayah* (Quranic verse) to domain, or domain to *ayah*.

According to (Saad et al., 2009), The authors proposed an approach to create an ontology from Islamic knowledge including the holy Quran. The presented approach allows the automatic generation of ontology instances concentrating on the concepts of the Quran and based on the traditional Information Extraction Systems, and Natural Language Processing and Text Mining techniques. In order to obtain the ontology instances, the researchers proposed the relative grammar and the extraction rule.

The authors in (Menacer et al., 2014) presented a systematic approach allowing the structuring and the organizing of the prominent *Tafsīr* books of the Holy Quran into a digital portfolio or ePortfolio. The proposed digital ePortfolio can offer the possibility of building and exchange digital and interactive content in the topic of the *Tafsīr*, the Quran, and the relative Islamic issues. This study has as an objective to propose a methodical approach for establishing, structuring and developing an ePortfolio for *Tafsīr* books. The project started with the ePortfolio development of Al Asfahani *Tafsīr* book.

The researchers in (Aman et al., 2017) presented a review of different ontology-oriented approaches for building specific ontologies for Islamic knowledge domain. The researchers mainly focused on a review of ontology development approaches for Islamic knowledge domain. The objective was to realize a comparative study between the approaches of manual ontology creation and the semi-automatic ontology learning approaches in the Islamic knowledge domain. Then, this study focused on identifying the main problems and challenging tasks in ontology development and shortcomings of existing approaches in the Islamic knowledge domain.

The ontology modelling provides more relevant and semantic resources which present an important factor in the Information Retrieval field. The realized studies have produced several ontologies for Islamic knowledge based on different NLP methods and technologies. However, ontology development has faced a lot of problems as time and resource consuming. Besides, several ontologies still partial regarding the richness and value of the knowledge figured in such Islamic scripts.

In the following section, we present an overview on one of the major necessary Islamic corpuses for the interpretation (*Tafsīr*) of the Holy Quran through the well-known corpus of *Tafsīr al-Ṭabarī*.

Overview on Tafsīr al-Ṭabarī

The corpus of *Tafsīr al-Ṭabarī* is one from the most important and high regard to Sunni Islamic corpora. This corpus is being written between 838 AD and 923 AD by the Persian scholar *Muhammad ibn Jarir al-Ṭabarī*. He is a scholar, historian and exegete of the Quran who composed all his works in Arabic language (Abu Zaho, 1984). His most influential and well-known works are his Quranic interpretation known as *Tafsīr al-Ṭabarī* and his historical chronicle *Tarikh al-Rusul wa al-Muluk* (History of the Prophets and Kings), often referred to *Tarikh al-Ṭabarī* (Abu Zaho, 1984).

Tafsīr al-Ṭabarī corpus is the earliest major running interpretation of the Quran to have survived in its original form. Like his history, Al-Ṭabarī is notable for its comprehensiveness and citation of multiple, often conflicting sources. Al-Ṭabarī has relied on narratives of the Islamic prophet Muhammad, including narrations and comments of *sahabah* and *tabi'in*. *Hadiths* are selected based on their authenticity (Brown, 2009; Abu Zaho, 1984). The following example of Fig. 1 illustrates the statement of the *hadith* number 6505 cited in the *Tafsīr* of *Surat al-Baqarah*, from the *ayah* 286.

القول في تأويل قوله تعالى: لَهَا مَا كَسَبَتْ وَعَلَيْهَا مَا اكْتَسَبَتْ.
قال أبو جعفر: يعني بقوله جل ثناؤه: " لها " للنفس التي أخبر أنه لا يكلفها إلا وسعها. يقول: لكل نفس ما اجترحت وعملت من خير " وعليها "، يعني: وعلى كل نفس " ما اكتسبت "، ما عملت من شر، كما:
6505 - حدثنا بشر قال، حدثنا يزيد قال، حدثنا سعيد، عن قتادة قوله: " لا يكلف الله نفسا إلا وسعها لها ما كسبت "، أي: من خير " وعليها ما اكتسبت "، أي: من شر - أو قال: من سوء.

To say in the interpretation of God says: "laha ma kasabat waealayha ma aktasabat.": It has what earned and it has what gained.
Abu Jaafar said: he means by saying most of his praise: "her" for the same, which he told that it does not cost only its power. Says: For every soul what I was hurt and worked of the good "and it", means: and on all the same "what I gained", what worked from evil, as:
6505 –Bachar reported that, Yazeed said that, Saide told them, about Qatada saying: "God does not cost a soul only what it has earned," ie: the good "and what has gained", that is: from evil - or said: bad.

Fig. 1: Extraction from *Tafsīr* of *Surat al-Baqarah*, *ayah* 286, *hadith* number 6505.

Al-Ṭabarī focused on the preface of the *Tafsīr* to give general facts about the Quran, including its superiority to any other text, what *Tafsīr* and *Tawil* are, the seven *qira'at* (readings), companions who commented on the Quran and the naming of the *Surah*. Al-Ṭabarī adopted the methodology of establishing the corpus, starting with the explanation of the meaning of the *ayat* (Quranic verses) based on other *ayat* and *hadiths*, and by the words of the *sahaba* and *Tabi'ins* and then he continues by citing the view that prominent for him (Brown, 2009; Abu Zaho, 1984).

Modelling of Tafsīr al-Ṭabarī with TEI

An XML version of the corpus of *Tafsīr al-Ṭabarī* can make the processing of the information more flexible and easier for the different application. Besides, the XML representation of the fundamental features and hierarchical schema of the corpus can help us to avoid the redundancy and time-consuming processing. Therefore, we choose to develop a TEI representation of *Tafsīr al-Ṭabarī*. In fact, this standard support XML annotation and provides the main XML structure that respect the granularity of the structure of the document divisions. Besides, it recommends various modules and allows the encoding of multiple data categories without losing the specification and the typologies of the components such as the named entities, the quotations and other types of text that can be found in the *Tafsīr al-Ṭabarī* (Sperberg-McQueen, et al., 2019; Burnard et al., 1996).

This section starts with an overview on the range of the elements that can be employed in the encoding process. Then, as a second subsection, we introduce our proposed TEI model.

Selected TEI elements

From the TEI classes and modules, we can select many elements that can be adapted to the text specification and provide a conceptual and semantic representation of the text of *Tafsīr al-Ṭabarī* in an appropriate way. We present first a summary of the TEI elements allowing the encoding of the text structure. Table 1 illustrates this category of elements.

Table 1 : TEI elements for the text structure

Element	Description
<text>	This element contains any kind of distinct text, whether unitary or composite.
<body>	The element <body> means the text body. This element contains the whole body of a single unitary text without the front or the back section.
	The element means the text division which contains a subdivision of the front, the body, or the back of the text.
<head>	The element <head> represents the heading and contains any type of heading, like the title of a section, or the heading of a list, etc.
<p>	The element <p> marks the paragraphs of the text.

To support the text structure, the TEI guidelines recommend a set of flexible elements that contains the sections and the passages of the text (Sperberg-McQueen, et al., 2019). It starts with <text> elements that can have any type of text and includes the <body> element. This element contains purely a single text unit. Then, the <body> element encloses all the divisions and the subdivisions of the text inside elements. The <head> element is essentially used as a type of heading for the division elements. Then, the <p> element indicates mainly a part of the text as a paragraph.

The TEI guidelines propose a module of quotation encoding. We selected from this module a set of elements that can harmonize with the specification of the text of *Tafsīr al-Ṭabarī*. Table 2 illustrates this group of elements.

Table 2: TEI elements for quotation encoding.

Element	Description
<q>	The element <q> refers to "quoted". This element contains a distinguished part of text which is surrounded using quotation marks or a similar method. It is not limited to direct speech or thought, technical terms or jargon, authorial distance, quotations from outside the corpus, and passages.
<quote>	The element <quote> means the quotation. It contains a passage attributed by the author to refer to an external text.
<said>	The element <said> refers to the speech or the thought. This element indicates passages thought or spoken, explicitly or implicitly indicated in the source , directly or indirectly reported and by real persons or imaginary characters.

The quotation can be indicated in a printed source by changes in typography, by special punctuation marks (single or double or angled quotes, dashes, etc.) and by layout (indented paragraphs, etc.), or it may not be explicitly represented at all. The <q>, <quote> and <said> elements can represent the quotation and maintains it specificity (Sperberg-McQueen, et al., 2019).

Regarding the corpus of *Tafsīr al-Ṭabarī*, the text contains a different kind of named entities (for example the information related with the persons, places and dates). Indeed, The TEI guidelines suggest a module of named entities encoding, which allows us to encode these sequences of text. Table 3 illustrate these elements.

Table 3: TEI elements for named entity encoding.

Element	Description
<persName>	The element <persName> refers to a personal name. It contains a part of the name like the proper noun or the proper noun phrase referring to a person.
<name>	The element <name> is for Name or proper noun. This element contains a proper noun or noun phrase.
<placeName>	The element <placeName> contains an absolute or relative place name.
<date>	The element <date> refers to a date entity in any format.

The module of named entities encoding in TEI guidelines offers many elements that may be used for the encoding of these entities (Sperberg-McQueen, et al., 2019). From the list of these elements, the <persName> element presents a part or all the phrase that indicate a proper name of a person. The <placeName> element allows the encoding of any information that defines a place name. Also, the <date> element which can contain information about a date.

The last selection of elements that we focused on is related to the representation of the poetic verses and the distinctive segments of text that have a contextual specificity comparing with the rest of the text. Table 4 highlights some of these components in TEI encoding.

Table 4: TEI elements for poetry and segments encoding.

Element	Description
<l>	The element <l> refers to a verse line. It contains a single or incomplete line of verse.
<lg>	The element <lg> means line group. This element contains one or more verse lines functioning as a formal unit, like a stanza, verse paragraph, etc.
<seg>	The element <seg> defines an arbitrary segment. The <seg> element may be used to mark any segments of the text of interest for processing.
<s>	The element <s> signifies s-unit. It contains a sentence like division of a text. The <s> element may be used to mark orthographic sentences, or any other segmentation in the text. For a segmentation which is partial or recursive, the element <seg> should be used instead.

The TEI guidelines offer various elements to encode a special part of the text like the poetry (Sperberg-McQueen, et al., 2019). The element <l> can hold one line of verse. The element <lg> represent a group of <l> elements as a group poetic paragraph. The TEI presents also different elements to highlight the specific segments in the text like <seg> element an <s> element.

From this collection of TEI elements, we attempt to create a TEI model for the corpus of *Tafsīr al-Ṭabarī*. The next subsection presents this model.

Proposed TEI Model

In order to annotate the different parts of the text of *Tafsīr al-Ṭabarī*, we base first on the norm TEI to represent the *Tafsīr* corpus from the body of the document to the different segments in the text. Fig. 2 shows an extraction from the TEI model that we prepared for the TEI encoding of the corpus of *Tafsīr al-Ṭabarī*. For most of the corpus, *Tafsīr al-Ṭabarī* maintains one regular structure that supports the interpretation presentation and the Ṭabarī opinion statement about each *ayah* and the related justification or argumentation with the associated *hadiths* and the poetic expressions. Moreover, the text contains the suggestions of reading methodology and the author analyses.

Fig. 2: Extraction from TEI encoding model for the corpus of *Tafsīr al-Ṭabarī*

To represent this structure, we employed the TEI elements that allow the annotation of those parts in the text. This modelling begins by separate the different divisions where each one illustrates the

interpretation of one *Surah* from the Quran. This division is presented as element that englobes all the elements and text inside it. This upper element have an attribute "xml:id" to give the *Surah* number as a direct identification. In fact, this element include first a <head> element to represent the name of the *Surah* or the heading used by Ṭabarī for announcing the new upper section. Second, this division contains a sequence of subdivisions where each one presents the Ṭabarī interpretation of each *ayah* or a part of *ayah*. These subdivisions are presented in a sequence of elements under the main division. Similarly, each element of these includes an "xml:id" attribute and a <head> element to present also the heading in the text. In this level, a <p> element is used to englobe all the text of the subdivision. The <p> element can contain the *ayaht* in <quote> elements. The following TEI code illustrates an example of using , <head>, <p> and <quote> elements in of the *Surah Al-Ma'idah*, *ayah* 1, Part 1, from the corpus of *Tafsīr al-Ṭabarī*:

```
<div xml:id="S5" xml:lang="ar">
<head>سورة المائدة</head>
<div xml:id="S5.A1">
<head>1 آية</head>
<div xml:id="S5.A1.P1">
<p>
الْقَوْلُ فِي تَأْوِيلِ قَوْلِهِ جَلَّ ثَنَاؤُهُ
<quote type ="Quranic_Text">
1 يَاأَيُّهَا الَّذِينَ آمَنُوا أَوْفُوا بِالْعُقُودِ سورة المائدة آية </quote> ، قال
<persName role="authorName">
أبو جعفر محمد بن جرير
</persName> رحمه الله
يعني جل ثناؤه بقوله
<quote type ="Quranic_Text">
1 يَاأَيُّهَا الَّذِينَ آمَنُوا سورة المائدة آية
</quote>
يا أيها الذين أقروا بوحدانية الله وأذعنوا لله بالعبودة، وسلموا له الألوهة، وصدقوا رسوله محمدا صَلَّى اللهُ عَلَيْهِ وَسَلَّمَ فِي نبوته، وفيما جاءهم به من عند ربهم من شرائع دينه،
<quote type ="Quranic_Text">
1 أَوْفُوا بِالْعُقُودِ سورة المائدة آية
</quote> …
</p>
</div> … </div> …
</div>
```

If the text contains *hadiths*, the <p> element can contain each *hadith* respectively under a <q> element that contains the relatives *Isnad* and *Matn*. The *Isnad* contains the list of narrators who transmitted the *Matn* as a citation. The <q> element contains a <persName> element for the name of each narrator. Then, it includes a <said> element to present the *Matn* of the *hadith*. Besides, the <q> element can have an "xml:id" attribute to contain the *hadith* number (Maraoui, et al., 2017). The following TEI code illustrates an example of using <q>, <said>, <persName> in the encoding of *hadith* number 10002 from the corpus of *Tafsīr al-Ṭabarī*:

```
<p> …
ذِكْرُ مَنْ قَالَ مَعْنَى الْعُقُودِ الْعُهُودُ
<q xml:id = "HT10002"> حَدَّثَنِي
<persName role = "sheikh">
الْمُثَنَّى </persName> ، قَالَ ثنا
<persName role = "rawi">
عَبْدُ اللَّهِ بْنُ صَالِحٍ </persName>
، قَالَ ثني
<persName role = "rawi">
مُعَاوِيَةُ بْنُ صَالِحٍ </persName> ، عَنْ
<persName role = "rawi">
عَلِيِّ بْنِ أَبِي طَلْحَةَ </persName> عَنِ
<persName role = "sahabi">
ابْنِ عَبَّاسٍ</persName> ، قَوْلَهُ
<said>
<quote type ="Quranic_Text">
1 أَوْفُوا بِالْعُقُودِ سورة المائدة آية
```

```
</quote>
يَعْنِي بِالْعُهُودِ
</said>
</q> … </p>
```

The text can be also poetic lines. These expressions can be encoded with <lg> element that englobes all the poetic lines under an <l> element for each line. The following example illustrates one bloc of poetic lines in the text:

```
<lg>
   <l>أتى العُجم والآفاق منه قصائد</l>
   <l>بقين بقاء الوحي فِي الحجر الأصم</l>
</lg>
```

In addition, the corpus can contain other text like an alternative reading as a segment inside the subdivision. This part of the text can be represented by <seg> elements. Moreover, the text can contain some named entities such as a place name which can be represented in the <placeName> element. The following example indicates the using of <seg> and <placeName> elements to annotate similarly an alternative reading and a place name:

```
<q xml:id="HT10088"> حَدَّثَنَا
<persName role ="sheikh">
ابْنُ حُمَيْدٍ </persName>
<persName role ="Sheikh">
، قَالَ ثنا<persName> وَابْنُ وَكِيعٍ </persName>
<persName role ="Rawi">
، عَنْ<persName> جَرِيرٌ </persName>
<persName role ="Rawi">
، أَنَّهُ قَرَأَ<persName> الأَعْمَشِ </persName>
<said who="p1">
<seg type ="alternative_reading">
وَلَا يُجْرِمَنَّكُمْ
</seg>
يُجْرِمُنِي ، مُرْتَفِعَةَ الْيَاءِ مِنْ أَجْرَمْتُهُ أُجْرِمُهُ، وَهُوَ
</said>
</q> … <placeName> الصَّفَا </placeName>
```

To attain the standardization of *Tafsīr al-Ṭabarī* corpus with the proposed TEI model, we developed a module for an automatic corpus encoding with TEI presented in the following section.

Implementation phase

The normalization of the corpus of *Tafsīr al-Ṭabarī* requires a consecutive phase starting from the text identification and segmentation and arriving at the actual encoding and annotation. Therefore, we implemented a module to apply the required processing. Then, we experimented our module to generate an Arabic normalized version of *Tafsīr al-Ṭabarī*.

The present section is divided into two parts. First, we introduce our developed module for the encoding of *Tafsīr al-Ṭabarī*. Second, we present the module evaluation phase.

Development of a module for the normalization of Tafsīr al-Ṭabarī

To create a normalized Arabic version of *Tafsīr al-Ṭabarī* based on TEI, we need two phases of processing. The first phase is a preprocessing step. This step is required to prepare the text for the XML encoding. The first part of the preprocessing step is the annotation of the text to define the typologies of each part in the text that needed to be highlighted in the encoding process. We based on a pre-annotated version which highlights the segments of the text. The second part of the preprocessing is to complete some required annotation to prevent some complications related to process optimization. The second phase of processing is the XML encoding. To realize the normalized version, we developed a module to generate automatically the TEI encoding. This encoding procedure follows our TEI model for the corpus of *Tafsīr al-Ṭabarī*. The implementation is based on different software and tools. In fact, we use Oxygen XML Editor to manipulate and experiment the TEI output XML files. Besides, we use JAVA language and the JDOM Library to develop the TEI encoding module that generates the normalized version of *Tafsīr al-Ṭabarī*. In addition, to simplify the accessibility to the different encoded parts in the normalized versions of *Tafsīr al-Ṭabarī*, we developed a relative interface. Fig. 3 illustrates the *Tafsīr al-Ṭabarī* consultation interface.

Fig. 3: *Tafsīr al-Ṭabarī* consultation interface

The developed interface allows access to the different encoded fragments respecting *Tafsīr al-Ṭabarī* structure. In fact, it allows the user to point on any specific encoded level in the hierarchy of the corpus. Also, it provides the user with the actual position of the consulted fragment of text such as the position of a specific *hadith* inside the interpretation of the relative part of *ayah*.

Evaluation and Discussion

To evaluate our TEI encoding module, we based on the text of the corpus of *Tafsīr al-Ṭabarī*. This corpus allows us to generate a TEI encoding of the *Tafsīr* of 114 *Surah* in the Holy Quran including 35751 *hadith* inside the *Tafsīr al-Ṭabarī*. In fact, the developed module starts with identifying and separating the chapters in the corpus where each chapter contains the *Tafsīr* of one *Surah.* Then, the module separates the subdivisions inside every chapter that contains the *Tafsīr* of each *ayah* of the relative *Surah.* In the same time, the module creates a folder for each *Surah* and performs the equivalent encoding process. After that, it saves the generated TEI encoding in XML files under the folder of the relative *Surah*. We calculate the quality of this module with three measures: precision, recall and F-measure. Table 5 illustrates the obtained values of the used measures.

Table 5: Summary table of the obtained results.

Evaluated corpus	Precision	Recall	F-measure
Tafsīr al-Ṭabarī corpus (114 *Surah*, 35751 *hadith*)	0.97	0.97	0.97

Table 5 shows that the precision and recall have the same amount equal to 0.97. As well, the result of the F-measure is 0.97. In view of that, the obtained results are encouraging. The module succeeded to generate a correct TEI encoding of *Tafsīr al-Ṭabarī* corpus while respecting the corresponding model. However, 1079 *hadith* which make 3% of the text is incorrectly encoded. In most cases, the incorrectness is related to some irregularity in the structure of *hadith* and some exceptional cases in the text. In the one hand, we perceive this irregularity in the context of some segments of the text especially in the citation of some *hadiths* like *hadith* number 14535. Fig. 4 shows this example of *hadith*.

Fig. 4: Exception in *hadith* number 14535.

Indeed, *hadith* number 14535 contains only a part of the Isnad with no Matn but an implicit reference to the Matn part. Furthermore, the editors in (Al-Tabari, M., 2010) mentioned that a part of the Isnad of this *hadith* was missed during the text copying phase. In the other hand, these errors are related to a wrong detection of the information related to some ambiguous parts like a missing or misplaced annotation from the pre-annotation phase.

Conclusion and Perspectives

In this work, to attain our main objective, we used TEI guidelines to elaborate an adapted module customized for *Tafsīr* structure. To achieve that, first, we started with a study of *Tafsīr al-Ṭabarī* structure. Second, we identified the data categories from the TEI standard registers, which harmonized with the *Tafsīr* corpus specification. After that, we developed an NLP module for the automatic processing of the encoding of *Tafsīr al-Ṭabarī* following the TEI model. The elaborated module allowed us to generate a normalized version of the *Tafsīr al-Ṭabarī* corpus with TEI format, which can be used in other levels of analyses and NLP applications.

As perspectives, we want to improve our model by incorporating other specifications for deeper encoding of the fundamental fragments of the corpus. Furthermore, we want to experiment the encoding of other *Tafsīr* corpora to create a normalized database for *Tafsīr* of the Holy Quran.

Abstract

The moment of occurrence and development of inflation is important in the development of the economy of each country. After inflation in the country, it will never be possible to completely get rid of it. Once this process has developed in the country, the state is only able to restrain inflation, limiting its growth. The main issue for the economy of each country remains the search for tools to reduce inflation. To date, there is no universal approach to solving this issue. Each country has its own historical, unique features that affect the further development of the entire economy. Therefore, the search for tools to overcome inflation should begin with an analysis of the causes of its occurrence.

Keywords: Non-Monetary Factors, Inflation, Interest Rate, State Policy

Introduction

For several centuries, such an economic phenomenon as inflation remains a complex problem requiring an integrated approach to its solution. The inflation crisis has an impact not only on professional participants in the economy, but also on all sectors of society to a greater or lesser extent. That is why inflation is a socio-economic phenomenon (Abiad, 2005). A negative impact on production has a rapid price growth rate. Inflation reduces the flow of investment in the economy, lowers production activity, which leads to a decrease in both real and nominal wages, and a decrease in tax revenues to the state budget. An effective solution to this problem requires a combination of fiscal and monetary policies, taking into account inflation factors (Adler, 2002).

Literature Review

In economic theory, there are different points of view on the inflation process. Followers of Marxist theory pay particular attention to the impact of inflation in the redistribution of national income. Followers of Fisher focus on the impact of inflation in the field of price regulation (Taylor, 2001). This view is one of the most common opinions among the population, since many people identify inflation with rising prices (Arias, 2019). The followers of the monetarist theory explain inflation by processes in the sphere of money circulation. Inflation is a multifactorial phenomenon, its consideration only from the point of view of price level, money supply is a rather simplified approach (Baumeister, 2015). In our opinion, it is necessary to analyze the groups of factors affecting the inflationary process. The first mention of inflation and an

explanation of the sharp rise in prices in the 16th century was made by professors of the University of Salamon D. S. and Aspilquet M.N. (Saks, 1996). The rapid price increase was caused by the influx of precious metals from America to Europe, which increased the money supply in circulation and led to their depreciation (Hatami-Marbini, 2017).

Theoretical Background

There are two types of inflation factors: monetary and non-monetary. Monetary factors have a significant impact on the money supply in circulation. The monetary factors include:

1) State budget deficit and domestic debt growth;
2) Credit expansion of banks;
3) Poor tax policy;
4) Dollarization.

Non-monetary inflation factors have a significant impact on the development of inflation. Non-monetary factors include:

1) High resource intensity of production;
2) Monopolization;
3) The presence of shadow sectors of the economy;
4) Dependence of prices in the domestic market on external;
5) Import inflation.

Experts put forward an interesting point of view: if inflation in Russia is caused by non-monetary factors, it is possible to increase the money supply without provoking inflation. The following arguments are presented: the Russian economy has insufficient capacity utilization (75-80%) and low monetization. Based on data on money supply and GDP, we calculate the level of monetization of the Russian economy (Table 1).

Table 1: level of monetization of the Russian economy for 2008-2018

Year	The level of monetization of the economy,%
2008	31,4
2009	39,3
2010	43,2
2011	40,1
2012	39,8
2013	42,6
2014	39,9
2015	42,3
2016	44,7
2017	46,0
2018	48,4

Source: own calculations based on http://www.gks.ru/wps/wcm/connect/rosstat_main (contact date 11.01.2020)

After analyzing the data, we can draw the following conclusions: every year there is an increase in the money supply in circulation, but the level of monetization of the economy remains low. The level of monetization does not have stable growth. Therefore, the proposal to issue additional cash is applicable.

The influence of monetary and non-monetary inflation factors is significant; one phenomenon is generated by another. They cannot be separated from each other. Inflation is a multifactorial process caused by the integration of monetary and non-monetary factors. Consider the relationship of these factors with an example. An unjustified increase in nominal wages entails an increase in household cash incomes, which in turn affects the depreciation of the national currency, in the future this entails a state budget deficit, and the latter is one of the monetary factors. Consider the opposite situation when monetary factors affect non-monetary. The money issue gives rise to the increase in the velocity of money, therefore, the equality in equation of the quantity theory of money PT=MV, derived by Irving Fisher, is violated, which causes an increase of the monetary mass in circulation, which affects the volume of production, generating a trade deficit, which is a non-monetary factor of inflation.

As the factors influence each other, can change from one form to another, and to combat inflation have in the same way. We believe that inflation caused by monetary factors should influence non-monetary methods, and the inflation caused by non-monetary factors can be influenced by monetary methods. For example, to fight inflation caused by monetary factors (excess emissions) will be more effective non-monetary (increase in production). It is possible to allocate two approaches to overcome inflation: monetarist and Keynesian. Neither of their approaches is not a universal solution, abandoning it in favor of another, as the choice of approach depends on the historical conditions for the functioning of the whole economy and causes inflation (Kosov, 2016). The essence of monetary policy is that Central Bank changes the quantity of money in circulation that allows you to apply interest rate which affects investment and income. The mechanism of influence of monetary circulation on the interest rate as follows: increase of money in circulation reduces the interest rate, and decrease of money in circulation increases it. The opposite approach of overcoming of inflation is the Keynesian. Its main objective is the preservation of aggregate demand. One of the methods of regulating aggregate demand is income policy (non-monetary factor of inflation, when the ill-conceived use of government). This policy involves control over the growth of wages and prices. Non-monetary methods of regulation include actions aimed at addressing structural imbalances in production, to increase production efficiency (Ricardo, 1995).

The primary role of monetary stabilization gains stimulates economic growth. Special importance is attached to fiscal policy, is able to regulate aggregate demand and aggregate supply. These methods should be applied with caution, as an ill-conceived policy of economic growth could lead to another bout of inflation, to escalate it due to the excessive increase in demand and the money supply in circulation. In practice, the most preferred methods of influence are monetary because they are aimed directly at the object of regulation and gives the result faster than non-monetary. Keynesian methods are used relatively rarely because their theory is that the increase in the mass of money in circulation leads to a decrease in interest rates, which promotes investment, employment and production. The majority of developing countries this mechanism does not apply due to the fact that the increase in money supply in circulation in their country leads to lower interest rates, and to higher prices. Also the application of this theory prevents hidden unemployment, which is common in developing countries. Was formulated two approaches to the problem:

- the exclusive use of monetary methods (Akhmadeev, 2018);
- active state regulation in combination with non-monetary methods (Sigarev, 2018).

Monetary policy, in spite of its prevalence, has both positive and negative consequences. Let us consider the example of Latin America in the 80-ies. The policy was carried out according to the recommendations of the IMF with different degrees of hardness recommendations this program was conducted in Latin America:

- reducing the budget deficit by reducing government contributions for social programs;
- tight monetary policy, limiting the issue;
- the devaluation of the national currency;

- liberalisation of economic activities;
- approval of limits on the growth of wages.

The most striking examples of the application of these principles to combat inflation became Chile since 1983 and Bolivia since 1985. The use of the above elements of "shock therapy" allowed to slow down the rate of "galloping" inflation, in Chile from 27.3% to 19.9% for the period 1983-1984, in Bolivia this indicator looks even more attractive. From 11749.6% to 276.3% for the period 1985-1986 (Kong, 2017; Ekimova, 2016). The negative consequence was a decrease in per capita GDP, a decrease in real wages, a decline in those employed in production. Monetarist politics did not lead to a prosperous economy, as evidenced by the above facts (Korableva, 2019). Regarding Chile, it cannot be said that inflation was overcome solely due to monetarism, since monetary methods were applied in a complex with non-monetary methods, namely, fixing the exchange rate of the national currency.

Discussion

Among the supporters of non-monetary factors as a prerequisite for the development of inflation in Russia (Popov, 1993). He believes that, in the period of the 90s, Russia had its own special non-monetary factors that are characteristic only for it: the outflow of foreign exchange and material resources from the country, a high degree of monopolization of the economy, etc. Afanasyev and Vite (1995) believe that inflation in Russia "is supported by prevailing wage indexation. Pulling fuel and raw materials prices to the world level". To explain the changes in consumer prices, Batinti and Congleton (2018) analyzed the events of 1993-1994. and came to the conclusion that the change in the money supply was only 30-31%, non-monetary factors, namely the change in wages, fuel and energy prices, occupied a more substantial share. Anikin (1992) adheres to this point of view; he believes that Russian inflation is caused by problems in the sphere of social production, and not monetary circulation. The problem is that the structure of domestic prices is significantly different from world prices. This price structure does not correspond to a single, global, market rate of a floating national currency (Illarionov. 1995). According to Dorofeyev (2018) in the early years of the 1990 the M3 monetary aggregate increased 186.8 times, consumer prices - 105.7 times, wholesale prices - 1863.1 times. According to the author, the above data indicate that the reason for inflation lies in non-monetary factors, since they had a greater impact, and monetary factors accounted for only 20% of the total factors (Aksenova, 2014; Kosov, 2017).

Conclusion

After a comprehensive analysis of the various approaches to inflation, we can conclude that inflation in Russia is mostly due to non-monetary factors. However, this does not mean that monetary factors do not affect the development of inflation. Inflation is a multifactorial process, the effect of each factor is affected, but to varying degrees. In our opinion, the primary goal is to identify the primary sources of inflation. This is necessary to reduce the level of inflation. The choice of model to fight inflation unique to each country. On the one hand, emerging countries have similar economic, socio-political properties. The rigid methods of the IMF program is reasonable, this is due to insufficient development of the market mechanism in the economic system of each country (Woo, 2003).

From this point of view, the Russian economy should adhere to these rules. On the other hand, there is a perception that the IMF model was developed in the interests of developed countries (Shtefan, 2017), but is focused on the underdeveloped countries and former colonies, consequently, this model is not applicable in Russia, as the country has a large production potential than other countries that adhere to this policy. This statement cannot be refuted, because the success of anti-inflationary models of the IMF in most cases was achieved in countries with high production potential. The level of monetization of the Russian economy is at a low level, which creates an artificial shortage of money. It is possible to carry out additional emission

of money, because inflation in Russia is caused by non-monetary factors will not affect the increase in the rate of inflation, and will allow you to fill the shortage of money, consequently, investments that will increase economic growth.

Transport Sector and Environmental Impact: Spatial Analysis of Greenhouse Gas Emissions in Poland

Rostyslav BUN

WSB University, Dąbrowa Górnicza, Poland, rbun@wsb.edu.pl
Lviv Polytechnic National University, Lviv, Ukraine

Abstract

A spatial inventory of greenhouse gas (GHG) emissions includes many categories of human activity. The aim of this study was to analyze, in high resolution, the spatial distribution of transport sector emissions. Statistical data to the lowest level (provinces, districts, and municipalities) were used to make a GHG spatial inventory for Poland, as a case study. Vector maps of GHG emission sources in the transport sector and algorithms to disaggregate activity data to the level of road segments were created. Using mathematical models, the emissions of carbon dioxide, methane, nitrous oxide, and other GHGs, as well as total emissions in CO_2-equivalent, at the level of road segments, were calculated for passenger cars, buses, lorries, and special cars. Gridded data, with 30 arc seconds resolution, were assessed to combine with inventory data in other categories of human activity. Vector maps conserve information regarding the administrative authorities of corresponding road segments, which enabled the spatial inventory results to be connected to municipalities and other units by taking into account administrative boundaries. The results were compared with EDGAR gridded data and correlations between the two datasets was investigated.

Keywords: Transport Sector, Environmental Impact, GHG Emissions, Spatial Analysis, High Resolution.

Introduction

Reducing greenhouse gas (GHG) emissions to prevent current and future climate change is the most important challenge facing humanity (Le Quéré et al, 2015). Therefore, effective tools are needed to provide inventories of GHG emissions and absorptions. Some international institutions, such as the United Nations Framework Convention on Climate Change (UNFCCC), the International Energy Agency (IEA), and the Carbon Dioxide Information Analysis Center (CDIAC), collect national inventory data on GHG emissions for many categories of human activity. Such national inventory reports (NIRs) play an important role in verifying compliance with emission obligations, predicting future emissions under different climate change scenarios, and establishing new international agreements. Nevertheless, decision makers and scientists need to know more about emission processes, and especially about their spatial patterns. Data presented in such a way link emissions to the territory where they appear (Olivier et al, 2005; Oda & Maksyutov, 2011; Boychuk & Bun, 2014), which is also important as input data for global circulation and transport models.

Traditionally, a regular grid is used to present spatial data for GHG emissions. Emissions in each grid cell are calculated on the basis of national/regional emission data and some complicated disaggregation algorithms using additional proxy data. The intensity of night-time lights, sensed remotely by satellites, is an effective example of such proxy data (Oda and Maksyutov, 2011). The advantage of such an approach is its potential to estimate GHG emissions for the whole globe, regular updated on monthly/yearly basis. But this technique covers only emissions from fossil fuel combustion processes (point as well as non-point emission sources), and mainly emissions of carbon dioxide (CO_2).

The grid cell size and resolution of the proxy data determine the resolution of the resulting spatial data for GHG emissions. Since higher resolution data better reflect the territorial specifics of emission processes, scientists have invested a lot of effort into reducing grid cell size (Hutchins et al., 2017), decreasing it from 1° latitude/longitude for global fossil-fuel CO_2 emissions (Andres et al, 1996), to 0.25° (Rayner et al, 2010), and to 1 km for global data on CO_2 emissions from fossil fuels, using point

source data and remote sensing data reporting night-time light intensity as a proxy (Oda & Maksyutov, 2011). Nevertheless, gridded emissions approaches do not take administrative boundaries fully into account, because a grid cell is often ascribed to an administrative unit (province, district, municipality) according to the largest part of the cell area located in the unit. This drawback can be avoided by using vector maps and analyzing GHG emissions at the level of point-, line-, and area-type (polygon) emission sources (Gurney et al, 2009; Bun et al, 2019).

Due to its consumption of fossil fuels, the transport sector has important mitigation potential in reducing GHG emissions. The share of GHG emissions from the transport sector is considerable in many countries (for example, 34% of total CO_2 emissions in the US). Included in the national emissions of this sector are emissions from road and off-road transportation, domestic aviation, railways, and domestic shipping. Estimation of GHG emissions in the transport sector may constitute a part of gridded data (for example, global gridded data with 0.1° longitude/latitude resolution (Janssens-Maenhout et al, 2019; Crippa et al, 2018), US data with 1 km resolution (Gurney et al, 2009) and datasets for part of Europe (Denier van der Gon et al, 2017)) or form a subject of separate research (Cao et al, 2017, Boychuk et al, 2012; Cong et al, 2018; Mendoza et al, 2019; Palsson & Johansson, 2016; Puliafito et al, 2015; Smit & Ntziachristos, 2014; Wassan et al, 2019)).

In this study spatial analysis was performed for GHG emissions from railways, road and off-road transportation in Poland with different types of vehicles, such as passenger cars, buses, lorries, and special cars (tractors, bulldozers, cranes, forklifts, fire engines, ambulances, etc.). Road segments are presented as line-type emission sources. Activity data, at the level of separate emission sources, were calculated using statistical data, some proxy data, and algorithms for disaggregation of the data to source level. These algorithms differ depending on category of vehicle. Since the spatial data retain information regarding the administrative assignment of road segments, GHG emissions can be analyzed at any administrative level, up to municipality, by taking into account administrative boundaries.

Methodology and Input Data

The geoinformation technology for GHG spatial analysis in the transport sector (Fig. 1) proposed here is based on an approach described in Bun et al (2019) and Hamal (2009), where emission sources are classified into point-, line-, and area-types, depending on their emission intensity and physical size, as compared to the territory under investigation. The results of previous studies of GHG emissions in the Polish transport sector (Jacyna et al, 2015; Dzikuć et al, 2017; Boychuk et al, 2012; Valakh et al, 2015) were also taken into account in this study.

The highest share of GHG emissions in the Polish transport sector is contributed by road and off-road transportation (15% of total energy sector GHG emissions). Railways in Poland are mainly electrified, so the share of their emissions is not so high (0.11% of total energy sector emissions). Because of the relatively small size and compact shape of Poland, the use of civil aviation for domestic transport is not efficient (the share of GHG emissions from domestic aviation is only 0.03% of the energy sector emissions). The share of emissions from domestic shipping in Poland is very small (only 0.0004% of the energy sector emissions), because of its relatively small rivers and comparatively short coastline. Therefore, the last two categories of emission sources were omitted from the current research, as well as emissions from the use of bunker fuels for international transportation (due to the regional scale of this research).

The digital maps of emission sources for road and railway transport were created using OpenStreetMap (Jokar Arsanjani et al, 2015) and road maps of Poland using categories. If needed, the roads or railways were additionally split into segments based on administrative boundaries to retain their administrative assignment. Such road segments were considered as separate elementary objects in the analysis. Road category was used as one of the proxies for the disaggregation algorithms in order to calculate the activity data for various categories of vehicles in the transport sector using statistical data on fossil fuel combustion.

Fig. 1: Structure of geoinformation technology for spatial analysis of greenhouse gas emissions in the transport sector

To calculate GHG emissions, the following road categories were taken into account: national, provincial, district, or community roads; and the following road types: highway, express route, dual carriageway, express carriageway, dual carriageway for heavy traffic up to 11.5 t per axle, single carriageway for heavy traffic up to 11.5 t per axle, dual carriageway for heavy traffic up to 10 t per axle, single carriageway for heavy traffic up to 10 t per axle, dual carriageway up to 8 t per axle, single carriageway up to 8 t per axle, dual carriageway, single carriageway, other road with paved surface, dirt road, or city road. The following types of vehicles were analyzed: motorcycles, cars, buses, lorries and special cars. Traffic intensity factors established by experts for these vehicle types were used (per 1 km of the road of specified type) (Valakh et al, 2015). On this basis the amounts of gasoline, diesel, and liquefied petroleum gas (LPG) used by different types of vehicles on each segment of the roads were calculated. Emissions of CO_2, methane (CH_4), nitrous oxide (N_2O), and other GHGs from burning gasoline, diesel, and LPG, were estimated, separately for all types of vehicle and in each segment of the road, using the main principles of the IPCC Guidelines (IPCC, 2006), according to which the emission is a product of the activity data and the emission factors. The total emissions of all GHGs were calculated using the global warming potentials of each GHG.

To obtain activity data at the level of the road segments, algorithms were developed to disaggregate the available statistical data at the lowest administrative level possible (municipalities, districts, and provinces). For example, the data on vehicle numbers by type, the amount of fossil fuel used and other proxies, and the emission coefficients for each type of vehicle were taken from the Local Data Bank (BDL, 2019), the Central Statistical Office (Poland) (GUS, 2019), and Poland's National Inventory Report (NIR, 2012). The errors and uncertainties of the calculated emissions, and 95% confidence intervals were estimated at the final stage using Monte-Carlo method, and symmetric distributions of the investigated parameters (IPCC, 2001; Ometto et al, 2015; Oda et al, 2019). Such an estimation was applied to the separate road segments as well as to the aggregated results for the administrative units, such as municipalities, districts, or provinces of Poland. Since information about the administrative assignment of each road segment is retained in the geospatial database, it provided us with the ability to calculate emissions for whole administrative units (even for small ones such as municipalities) without any of the loss of accuracy found in the traditional approach of gridded emission data.

Results

Road Segment Level

Using the database of road segments created as line-type GHG emission sources in Poland (312,679 km^2) and the algorithms for fossil fuel data disaggregation, a geospatial database of input data for the spatial analysis of GHG emissions was established. The GHG emissions from each road segment were calculated using appropriate mathematical models, that is the emissions of CO_2, CH_4, N_2O, and other GHGs, as well as the total emissions in CO_2-equivalents, were estimated. Following Bun et al. (2019) these results are termed GESAPU (Geoinformation technologies, spatio-temporal approaches, and full carbon account for improving the accuracy of GHG inventories) data in this research. As an example, Fig. 2 illustrates the intensity of GHG total emissions in the transport sector in the provinces of Silesia and Lesser Poland. This region consists of the highly industrialized agglomeration of Katowice and Krakow, which contains a high density road network, as well as very clean mountain territory with a limited road network. The highest bin in Fig. 2 represents the roads with an emission intensity more than 1,600 $t_{CO2\text{-}eq}$/km (such as the A4 highway). The results of such a spatial inventory can be presented separately for each vehicle category, as well as separately for different fossil fuel types, or for different GHGs.

Fig. 2: Intensity of total GHG emissions in the road transport sector by road segments: fragment of line-type sources of emissions in Silesia and Lesser Poland provinces (t/km^2, CO_2-equivalent, 2010)

The results of the GHG spatial analysis at the level of road segments can be sampled to any grid, to be compared with known gridded GHG emission data. A grid was used as a vector map, where each grid cell was a polygon. Additionally, where necessary, grid cells were split by administrative boundaries

into separate objects of the vector map. The cells of such a grid retained the administrative assignments of each road segment. Grid size was not so important, because the resolution of the maps from OpenStreetMap was higher than the grid sizes used recently to produce gridded GHG emissions data (1 km, 500 m etc.).

As an example, Fig. 3 illustrates total GHG emissions from the road transport sector in Poland and the Poznań agglomeration at 30 arc seconds grid size scale. These data include GHG emissions from all categories of vehicles. The grid size was chosen to be comparable with well known global GHG emission data based on night-time light intensity (Oda & Maksyutov, 2011). At the latitude of Poland, the cells cover approximately 1 km in latitude, and approximately 0.5 km in longitude. The cell with the highest annual emission intensity is located in Warsaw (6.978 $t_{CO2\text{-}eq}$/cell). The same results are presented in Fig. 4 for the Warsaw agglomeration, using the prism-map for better visualization of the results. This 3D presentation illustrates a non-uniform distribution of emission sources and the differences in magnitudes of their emissions. Major highways and agglomeration road networks cause emissions higher than 1 $kt_{CO2\text{-}eq}/km^2$.

Fig. 3: Total GHG emissions from the road transport sector in Poland and the Poznań agglomeration (all categories of vehicles, CO_2-equivalent, t/cell, 30 arc seconds grid size, 2010)

Municipality and province level

As the information regarding the administrative assignment of each road segment is retained, and line objects of vector maps are split by administrative boundaries, GHG emissions could be calculated at the level of any administrative unit (such as municipality, district, or province) without any loss of accuracy. As shown in Fig. 5, total GHG emissions from road transport in Poland at the level of municipality are distributed extremely unevenly (there are 2,478 municipalities in Poland; gmina in Polish). In 2010, as expected, the highest total GHG emissions from road transport were found in the big cities like Warsaw (1,104,152 $t_{CO2\text{-}eq}$), Krakow (418,649 $t_{CO2\text{-}eq}$), and Łódź (373,480 $t_{CO2\text{-}eq}$), while the lowest was from Kleszczele town in Podlaskie province (723 $t_{CO2\text{-}eq}$). But if the intensity of GHG

emissions from road transport is considered, the highest intensity occurred in Piastów, the smallest municipality in Poland, but located near Warsaw (2,429 $t_{CO2\text{-}eq}/km^2$). The lowest intensity of GHG emissions from road transport was recorded in the mountain municipality of Cisna in Subcarpathian province (16.7 $t_{CO2\text{-}eq}/km^2$).

Fig. 4: Prism-map of GHG emission intensity from road transport in the Warsaw region (CO_2-equivalent, t/cell, 30 arc seconds grid size, 2010)

Fig. 5: Total GHG emissions from road transport in Poland at municipality level (CO_2-equivalent, t/km^2, 2010)

There are 16 provinces in Poland (voivodeship in Polish). In 2010 the total GHG emissions from the transport sector (Fig. 6) were highest in Masovian province, containing the capital Warsaw (MAZ; 7,740 kt_{CO2-eq}), the most industrialized Silesian province (SLK; 5,259 kt_{CO2-eq}), and Greater Poland province (WKP; 4,926 kt_{CO2-eq}), while the lowest total GHG emissions were from Opole province (OPL; 1,265 kt_{CO2-eq}). Considering emission intensity, the first three places were as follows: Silesian province (427.8 t_{CO2-eq}/km^2), Lesser Poland province (251.9 t_{CO2-eq}/km^2), and Masovian province (218.5 t_{CO2-eq}/km^2), but the lowest emission intensity occurred in Podlaskie province (67.0 t_{CO2-eq}/km^2).

As we can see from Fig. 6, total GHG emissions caused by passenger cars dominated in all provinces (70.3% – 76.4%), with the highest share in Opole province. The share of total GHG emissions from lorries was not as high (18.1% – 23.9%), but slightly higher than the share of emissions from special cars (2.9% – 4.4%). Due to the electrified railways, the share of GHG emissions from this category of transportation was low in all provinces (0.4% – 1.3% of total emissions in the transport sector by province). Within the fossil fuel types, the highest GHG emissions were caused by diesel, with shares ranging from 58.0% of total GHG emissions in the transport sector of Łódź province to 70.1% in the province of Pomerania. GHG emissions from gasoline were lower, with contributions ranging from 22.8% in Pomeranian province to 31.8% in Opole province, and the share of emissions from LPG ranged from 6.7% in West Pomeranian province to 14.9% in Łódź province.

Fig. 6: Total GHG emissions from the transport sector by province, vehicle type, and fossil fuel type (Poland, tCO_2-equivalent, 2010)

Discussion and conclusions

The spatial analysis of GHG emissions from the Polish transport sector demonstrated considerable unevenness, in particular we could see very high emissions in the industrialized provinces with high densities of both population and road networks (such as Silesian and Masovian provinces), and low emissions in the mountainous and strongly forested regions, with low road densities (such as Opole, Lubusz, Podlaskie, and Holy Cross provinces). Such unevenness is typical for many categories of

human activity (Bun et al, 2019), therefore a positive feature of spatial analysis is the ability to identify regions and road network nodes that need more attention from local authorities.

National inventories of GHG emissions play an important role at international scale, but they cannot be used for local analyses. However, spatial data on GHG emissions at high resolutions are needed for modelling local dispersion of emitted gases, and for comparison of atmospheric concentrations of these gases with recorded measurements. In this study spatial data on transport sector GHG emissions were compared with EDGAR global gridded data (the Emission Database for Global Atmospheric Research; Janssens-Maenhout et al, 2019) with a resolution of 0.1° latitude/longitude (for Poland the grid size is 7.1 km in longitude and 11.1 km in latitude). Only the cells that fully cover Polish territory were taken into account. Then the high resolution data from this study at the level of road segments were sampled and aggregated to the EDGAR grid.

The results of the comparison for total GHG emissions in the transport sector in 2010 (Fig. 7a) demonstrate a good correspondence between the two datasets (light green bin). The EDGAR data depict higher emissions in pixels that cover major highways, while the data described here identify higher emissions from the transport sector in large agglomerations. When comparing GHG total emissions in the transport sector within Poland (4,014 pixels of EDGAR grid), we noted the following results: GESAPU high resolution dataset – 46,666 $kt_{CO2\text{-}eq}$; EDGAR gridded dataset – 48,398 $kt_{CO2\text{-}eq}$; NIR (NIR, 2012) – 48,024 $kt_{CO2\text{-}eq}$. In the main, this was a good correspondence if the following factors are taken into account: this comparison did not include pixels crossed by the Polish border (which are quite large pixels), the NIR data also contain emissions from additional sources such as civil aviation, navigation, and pipeline transport. The scatter plot in Fig. 7b illustrates the correlation between this study and EDGAR datasets for GHG total emissions in the Polish transport sector, with coefficient R = 0.848.

Fig. 7: Comparison of this study and EDGAR data for the transport sector in Poland: absolute difference (a), scatter plot and correlation (b) (GHG total emissions, CO_2-equivalent, GESAPU data aggregated to 0.1° grid, 2010)

The approach described here performs the spatial analysis of GHG emissions in the transport sector by describing road segments as linear emission sources. Therefore, unlike gridded data approaches, GHG emissions are calculated directly at the level of road segments. This make it possible to retain information on the administrative assignment of such segments and further, if necessary, to aggregate the inventory data to the level of even the smallest administrative units without losing accuracy. The results of this study made it possible to depict the real state of emission processes from small territories

or transport nodes. In addition, such data could be presented for all categories of vehicles and for all types of fuel.

For the spatial analysis of GHG emissions, vector maps of roads were used in this research, which has a positive effect on reducing uncertainty in the results, because such maps are much more accurate than their gridded representations for modeling road transport emission processes. This methodology minimized uncertainty regarding the location of GHG emission sources and reduced the overall uncertainty of the spatial inventory results. Of course, operating with vector maps required additional effort to build a map of emission sources and to form a georeferenced database of input data. However, as a result of analysis based on these maps, we gained additional knowledge in the form of GHG emission distributions for each category of transport and for each type of fuel. Data presented in such a form are important for both decision makers and scientists.

Resumen

Venezuela en estos momentos de su historia presenta un patrón migratorio nunca antes registrado, los datos sobre emigración han ido incrementándose en los últimos años. La situación de crisis por problemas económicos, políticos y sociales ha sido el detonante de esta diáspora indetenible. Bajo estas consideraciones, este trabajo tiene el objetivo de determinar las intenciones de emigración de estudiantes universitarios venezolanos, destacando hacia dónde piensan dirigirse al concretar esta decisión. La metodología utilizada fue de carácter descriptivo, con un diseño de investigación de campo; empleándose la encuesta como técnica para la recolección de datos, mediante el uso de un cuestionario que contó con 25 ítems, aplicado a una muestra de 423 estudiantes de las diferentes carreras y núcleos de la Universidad del Zulia para el año 2018. Los resultados develan que el 85,7% de los universitarios tiene la intención de emigrar, prefiriendo establecerse en Chile (33,9%) una gran cantidad, el resto tiene en la mira Colombia (16,1%), Argentina (11,3%), Estados Unidos (10,8%), entre otros países. Se concluye que, se está frente a una pérdida significativa de población joven, en preparación y perteneciente a la población económicamente activa, incidiendo negativamente en el proceso de desarrollo de la nación.

Palabras clave: Emigrantes, Estudiantes, Lugar De Destino, Crisis.

Introducción

La migración es parte de los procesos demográficos que junto a la natalidad y mortalidad introduce cambios en el tamaño, composición y distribución de la población. Este fenómeno está relacionado según De la Vega y Vargas (2017) con el movimiento o desplazamiento espacial de las personas, que tiene vigencia desde que la especie humana existe, ya que el hombre tuvo la necesidad de salir de su lugar de origen en búsqueda de alimentos, vestimenta o vivienda para él y sus afectos. Además, las grandes catástrofes naturales, pérdida de cosechas, guerras y hechos sociales como persecuciones raciales o ideológicas, han promovido el movimiento migratorio.

A medida que la sociedad fue avanzando, el hombre tuvo que migrar con la intención de encontrar mayores oportunidades de trabajo que le permitieran mejorar la calidad de vida de su familia. Con los avances tecnológicos en el marco de la globalización, este proceso demográfico tuvo mayor auge; los sistemas de comunicación y transporte representaron una nueva era que facilitaron consolidar el proceso, tratándose de migraciones incitadas por problemas sociales, económicos y políticos, dado un proceso de desigualdad creciente entre los países desarrollados y subdesarrollados y acentuados, en especial, por malas gestiones de algunos gobiernos.

En el caso de Venezuela, que en muchos años de su historia fue un país receptor de migrantes o de puertas abiertas al mundo, actualmente presenta un patrón migratorio completamente distinto, nunca antes visto en la historia. Esta situación a criterio a Freitez (2013), De la Vega (2014), Muñoz (2016) y Castillo y Reguant (2017) se debe a problemas relacionados con la sobrevivencia cotidiana, las oportunidades de desarrollo personal y profesional, la conflictividad política y los problemas relacionados con la falta de seguridad en su sentido más amplio, generando gran incertidumbre respecto al futuro, que han alentado la decisión de emigrar, teniendo como lugar de destino países como Colombia, Perú, Chile, Estados Unidos, Panamá, Ecuador, Argentina, entre otros.

Bajo estas consideraciones, la presente investigación tiene el objetivo de determinar las intenciones de migración de estudiantes universitarios venezolanos, haciendo énfasis en los factores que promueven esta decisión y los posibles lugares de destino al que piensan migrar. Cabe señalar, que este grupo poblacional está próximo a egresar de sus carreras como profesionales para aportar todos los conocimientos adquiridos, habilidades y destrezas en las diferentes actividades económicas del país, con expectativas de construir un futuro estable, por lo que es alarmante abandonen la nación en búsqueda de oportunidades.

La metodología utilizada es descriptiva, con un diseño de investigación de campo, empleándose para la recolección de datos un cuestionario de 25 ítems, aplicado en el año 2018 a una muestra de 423 estudiantes de diferentes carreras y núcleos de la Universidad del Zulia; casa de estudio centenaria, con mayor matrícula estudiantil de Venezuela; ubicada en el municipio Maracaibo, estado Zulia.

Migración: Proceso Demográfico Indetenible

Valente (2012) señala que la migración es un derecho ejercido por los individuos con la perspectiva de mejorar su situación o enfrentar circunstancias adversas, que puede producir cambios ligeros o hasta radicalmente bruscos en estas personas. Asimismo, indica que todo sujeto está expuesto a migrar en algún momento de su vida y aunque puede que esto no ocurra, existe siempre una expectativa latente de migración susceptible en cualquier lapso de tiempo.

Por su parte, el Centro Latinoamericano y Caribeño de Demografía (CELADE, 1997) expone que la migración es un fenómeno social indisoluble del cambio de la población que está determinado por la estructura social y económica de una región o país, que a la vez, repercute sobre dichas estructuras, pues es un hecho potencial que trasciende en la vida de las personas, dado que existe un traslado de residencia que exige el cruce de alguna delimitación administrativa o geográfica. De allí que, son desplazamientos de grupos humanos que los alejan de sus residencias habituales.

En el mismo orden, León (2015) y Vargas (2016) definen a la migración como el cambio de residencia de un lugar llamado “origen” hacia otro llamado “destino”, con un carácter casi permanente, el cual es motivado por razones económicas, sociales y/o políticas. De esta manera, el fenómeno se compone de la salida de un individuo (emigración) de una comunidad, estado o país (lugar de origen) por un tiempo determinado y la llegada de éste al nuevo territorio (inmigración) o lugar de destino.

Cabe destacar, que en la migración tiene características como: edad, sexo, estado civil y aspectos educativos. Al respecto, Rodríguez y Busso (2009) alegan que la mayor parte de los migrantes suele ser población joven, con mayor presencia de hombres; esto puede ser explicado debido a que la etapa de la juventud se caracteriza por decisiones y eventos cruciales como la inserción universitaria, ingreso al mercado de trabajo, nupcialidad, aventura, poco temor al riesgo, experimentación, entre otras características que promueven la migración. La supremacía del género masculino podría expresarse en el temor que las mujeres tienen ante los cambios, de allí que los hombres siguen representando la proporción más elevada de migrantes según la OIT (2015). No obstante, Martínez y Orrego (2016) afirman que la mayoría de los países de América Latina y el Caribe presenta un perfil de emigrantes feminizado en los últimos años.

Por otro lado, Valente (2012) expone que el estado civil es otro elemento que se introduce como variable explicativa de la migración, pues los solteros o matrimonios de reciente formación son los que tienen mayor disposición para probar suerte en un lugar diferente, mientras que los trabajadores casados y con niños tienen menor propensión a migrar por razones como los altos costos de traslado, mayor arraigo al medio, así como obstáculos psicológicos de otra naturaleza.

En cuanto a las características educativas, Rodríguez y Busso (2009) sostienen que la decisión de migrar se eleva con la educación, debido a que la escolaridad brinda información y habilita el desplazamiento, abre opciones de vida, ofrece más probabilidades de moverse bajo la modalidad de contratación previa, convenio, beca, intercambios y se vincula positivamente con los ingresos y la capacidad de solventar los costos de una mudanza.

La historia de la humanidad ha permitido recopilar diversos hechos migratorios en el mundo, pues desde que la especie humana existe, hay indicios de migración. Estos diversos desplazamientos de masa poblacional espontáneos o forzados vividos a lo largo de los años, tienen como causantes principales factores culturales, económicos, geográficos y políticos.

De acuerdo a la Organización Internacional del Trabajo (OIT, 2015) existen alrededor de 232 millones de migrantes en el mundo, de los cuales 150 millones son trabajadores, que representan el 65% del total. Esta cifra devela la cantidad significativa de personas que dejaron de pertenecer a la fuerza de trabajo de sus naciones para hacer vida productiva en otras tierras, por lo que son individuos en edad activa (que incluye a jóvenes) y muchos de ellos de condición calificada; situación que preocupa a dicha institución y a otros organismos internacionales que han tratado el tema para delinear políticas de migración de alcance mundial.

Por su parte, la Organización Internacional para las Migraciones, OIM (2018) indica que la cifra alcanza los 244 millones de personas, por lo que nunca antes había ocupado una posición tan prominente como problema público. Cada vez más gobiernos y políticos, así como gran parte de la opinión pública de todo el mundo, consideran que la migración es una variable política relevante, debido a la importancia que reviste para el desarrollo y la prosperidad económica de los países.

Venezuela Ante El Desafío De La Migración

En Venezuela se ha presentado una historia migratoria de puertas abiertas a los flujos poblacionales interesados en las actividades económicas nacionales (Álvarez de Flores, 2007), por lo que en la actual población está presente, una variedad étnica producto de la constante mezcla de nacionalidades, que lleva en la sangre y en los apellidos la marca indeleble de los antepasados inmigrantes (Taylhardat, 2003).

El cacao y el café durante el período colonial (siglo XIX) marcan el inicio de la presencia de migrantes en el país, compuesta principalmente por comerciantes españoles, canarios y alemanes (Muñoz, 2016). Las exportaciones de estos productos de creciente demanda en el mercado mundial, representaban el pilar de la economía venezolana, alcanzando el 92% para el año 1920 según Álvarez de Flores (2007). En el siglo XX, Venezuela continuó siendo un lugar de destino atractivo para los migrantes europeos, por su estabilidad económica y política. Situación que se extendió durante los años de la Segunda Guerra Mundial y la posguerra.

Al iniciar el nuevo milenio, los factores de atracción de inmigrantes intrarregionales empezaron a disminuir y de acuerdo con cifras del censo del año 2011, los extranjeros alcanzaron el 4,2% (1.156.578) del total de la población en Venezuela, estimada en poco más de 27.227.000 personas (INE, 2014). Siendo la principal colectividad de extranjeros la formada por los provenientes de Colombia, Perú, Ecuador, Brasil y Cuba. Escenario diferente al de décadas anteriores.

A partir del año 2013, con la llegada al poder de Nicolás Maduro Moros como presidente de la República, se ha tornado en el país una situación caracterizada por la polarización política, donde además se evidencian altos niveles de inseguridad, la caída de los precios del petróleo, altos niveles

de inflación, caída de las reservas internacionales, mayor control de precios, devaluación del bolívar, cierre técnico de numerosas empresas, escasez de productos básicos, entre otros inconvenientes provenientes de su proyecto político-económico (Gutiérrez, Romero, Díaz y Sulbarán, 2017), que mantienen hoy en día a Venezuela con las expectativas más bajas de crecimiento en la región (Romero, Hernández, Gutiérrez y Portillo, 2017), aunado al descontento político, que han provocado una serie de emigraciones nunca antes registradas (Mazuera, Albornoz, Morffe, Ramírez y Carreño, 2019).

De esta manera, el Servicio de Análisis de Entorno PERFIL 21, Consultores 21 (2017) expone que en promedio 1,97 personas han emigrado por núcleo familiar, por lo que la diáspora venezolana se acerca a 4.091.717 personas. Esta cifra también es manejada por ENCOVI (2017), quien habla de una emigración que asciende a 3 o 4 millones de venezolanos en el extranjero, que representaría del 10 al 12% de la población total. El estudio además asegura que el 80% de la emigración reciente desde Venezuela ha salido básicamente durante los años 2016 y 2017, teniendo como lugar de destino países como Colombia, Perú, Chile, Estados Unidos, Panamá, Ecuador, Argentina, entre otros.

Es preciso señalar siguiendo a Azócar (2018), que la crisis económica y política del país, ha llevado a visualizar en el extranjero una ruta segura para conseguir recursos económicos en monedas con mayor fortaleza adquisitiva. Este autor con apoyo de estadísticas de organizaciones no gubernamentales en Venezuela, muestra que en el año 2016, más de 378.500 venezolanos entraron a Colombia legalmente para estabilizar su situación migratoria. Para el 2017, se tiene un registro de 153.000 venezolanos que se han quedado más tiempo del que les permite la tarjeta de turista (90 días), por lo cual están viviendo bajo la figura de estatus ilegal.

Asimismo, Azócar (2018) afirma que hay un estimado de 750.000 venezolanos que cruzaron la frontera bajo condición emigratoria, pero del 20% al 30% de este grupo poblacional, utilizaron la ruta por Colombia para seguir su camino hacia Ecuador y Chile. Situación que cada día se agudiza y llama la atención de la Oficina del Alto Comisionado de las Naciones Unidas para los Refugiados, ACNUR (2018), ratificando que cientos de miles de venezolanos permanecen sin documentación o permiso para residir legalmente en países de acogida, exponiéndolos a la explotación, la trata de personas, la violencia, el abuso sexual, la discriminación y la xenofobia. Este organismo pide a los países tener mayor sensibilización en atención a un complejo contexto político y socioeconómico que vive Venezuela en estos momentos de su historia.

Cabe destacar, que el escenario de las migraciones también ha tocado al ámbito universitario nacional, ya que se está en presencia de una deserción estudiantil considerable y preocupante desde la óptica de las casas de estudios. Al respecto, La Universidad de Los Andes, declaró que en esa institución se observa al menos dos tipos de deserción: el retiro total y el ausentismo. Reportan que entre 2012 y 2016 hubo un incremento del 100% de estudiantes que retiraron sus documentos de la universidad, mientras que en 2017 el número de retiros se ha multiplicado por cinco o por seis (LUZ Agencia de Noticias, 2017).

De igual modo, la Universidad Metropolitana de Caracas detalló que iniciaron a finales del año 2017 el período académico con 8% menos de estudiantes que debían continuar sus estudios. Una encuesta realizada por esta misma universidad, dejó saber que la mayoría de sus estudiantes había decidido emigrar con familiares hacia otros lugares. En el caso de universidades de la región zuliana, también se presentan altos índices de ausentismo que ha causado preocupación a sus autoridades (LUZ Agencia de Noticias, 2017).

En la Universidad del Zulia (LUZ), específicamente, la deserción se dejó sentir en las distintas facultades durante el reinicio de las actividades académicas y administrativas en septiembre de 2017. Decanos han reportado algunas cifras de la deserción y mencionan que las causas de esta pueden ser atribuidas a las protestas registradas en el país, la migración, la crisis en materia de infraestructura y servicios estudiantiles de la universidad, la situación económica familiar y hasta la seguridad

personal. No obstante, la deserción no sólo es de estudiantes, sino también de profesores, personal administrativo y obrero (LUZ Agencia de Noticias, 2017).

La Vicerrectora Académica de LUZ, Dra. Judith Aular de Durán, declaró ante medios de la región que la deserción de estudiantes en LUZ para el año 2018 supera el 40%, por lo que exhorta al gobierno nacional a tomar cartas en el asunto (El Nacional Web, 2018). Esta situación que se ha ido generalizando en otras casas de estudios, demanda una seria discusión, reflexión y atención de las autoridades gubernamentales, pues está en juego la generación de relevo del país, que está saliendo de la nación en búsqueda de mejores oportunidades sociales y económicas.

Emigración De Estudiantes Universitarios Venezolanos

Es preciso aclarar siguiendo a León (2015) que la decisión de emigrar es básicamente de carácter individual, ya que, en última instancia, quien se desplaza es el sujeto, sin embargo, este tiene detrás todo la conexión y situación de la familia de la que es difícil desprenderse, por lo que la decisión muchas veces se convierte en familiar. El autor además precisa que el migrante no siempre expresa un acto completamente voluntario, pues en la mayoría de los casos, en los lugares de origen existen fuerzas expulsoras que presionan la voluntad de las personas para tomar la decisión de emigrar hacia destinos que actúan como focos de atracción porque ofrecen mayores oportunidades o simplemente se presentan como las únicas alternativas posibles.

Bajo estas consideraciones, se preguntó a los estudiantes si han pensado residenciarse en otro país y el 85,7% indicó que sí tiene la intención; mientras que un porcentaje muy bajo (14,3%) rechazó esta posibilidad. Tal situación causa preocupación dado los altos niveles de emigración registrados en los últimos años por organismos internacionales, Consultores 21 (2017) y Encovi (2017), pues esta problemática no ha recibido un reconocimiento oficial y desde las instituciones públicas poca atención se ha brindado (Freitez, 2015).

Consultores 21 (2017), registra una diáspora de 4.091.717 venezolanos hasta el año 2017. Encovi (2017) para el mismo año, habla de una emigración que asciende de 3 a 4 millones, que representaría del 10 al 12% de la población total. Por lo que este gran número de estudiantes universitarios (85,7% población en estudio) pasaría a formar parte de las personas que deciden irse a otros países; situación que Azocar (2018) ya viene advirtiendo, por lo que se estima que un 30% de la población está realizando las gestiones para emigrar.

Gráfico 1LUZ: Estudiantes universitarios según intenciones de emigrar

Fuente: Elaboración propia a partir de la encuesta (2018).

Cabe destacar, que del total de estudiantes que piensa establecerse en otro país, el 95,2% tiene entre 17 y 24 años, el 3,8% posee entre 25 y 44 años y el resto (1,1%) pertenece a la población con 45 años y más, evidenciándose un grupo etario muy joven con intenciones de migrar. Ante este panorama, Rodríguez y Busso (2009) afirman que la mayor parte de los migrantes suele ser población joven, pues la etapa de la juventud se caracteriza por decisiones y eventos relevantes como la inserción universitaria, ingreso al mercado de trabajo, nupcialidad, menor aversión al riesgo y mayor interés en experimentar, que promueven o facilitan la migración. Muchos de estos estudiantes apenas inician su carrera universitaria o están a punto de culminarla para incorporarse como profesionales en el mercado de trabajo, pero quizás sientan que sus sueños no son posibles bajo las condiciones que presenta el país, prefiriendo salir de Venezuela.

Con respecto al sexo del grupo de estudiantes que posee intenciones de emigrar, la mayor parte está comprendida por mujeres (58,6%), observándose un liderazgo del sexo femenino frente a este proceso que según Rodríguez y Busso (2009) tiene mayor presencia masculina. No obstante, Martínez y Orrego (2016) afirman que la mayoría de los países de América Latina y el Caribe, presenta un perfil de emigrantes feminizado en los últimos años, dado que han tomado la iniciativa de formarse profesionalmente e incorporarse a la fuerza productiva. Estos mismos autores manifiestan que la composición por sexo de la migración venezolana muestra un predominio de mujeres. Esta característica puede estar asociada a la actividad que buscan realizar en el lugar de destino, donde los factores educativos y laborales tienen un peso importante.

De la misma manera, del total de universitarios con intenciones de migrar, la mayor parte (92,5%) está conformada por solteros, condición que les permite mayor facilidad para desplazarse y probar suerte en otras tierras, debido a la disposición de adaptabilidad a condiciones nuevas de trabajo y menor arraigo al miedo (Rodríguez y Busso, 2009).

En relación a la Población Económicamente Activa (PEA) del grupo total de estudiantes, el 78,2% de los ocupados tiene expectativas de migrar. Lo mismo ocurre en el caso de los desocupados (91,8%) y la población inactiva (90,1%). Esta situación puede presentarse debido a que la población estudiantil observa un mercado de trabajo nacional con una remuneración que no garantiza un sustento para mantener una vida y un ejercicio de la profesión digno, optando por irse al exterior y captar ingresos en divisas. Según Romero, Hernández y Bracho (2015), la pérdida del poder adquisitivo se ha venido acentuando por los altos índices inflacionarios, que han convertido en simbólicos los ingresos por actividad económica, sumergiendo a la población en una espiral de pobreza alarmante que ronda el 87% de acuerdo a Encovi (2017).

Gráfico 2 LUZ: Migración de estudiantes universitarios

Fuente: Elaboración propia a partir de la encuesta (2018).

Con respecto a los factores que están detrás de esta decisión de emigrar, los estudiantes en atención a un listado de problemas que integra necesidades básicas insatisfechas, problemas de seguridad, contrariedades en la universidad, en el sistema de salud, factores económicos generales, en el ámbito laboral y factores políticos; indicaron que los más significativos son la alimentación (41,9%) y realización personal (35,2%), seguido de los atracos (36,1%) y la violencia (25,9%), así como el deterioro de la infraestructura universitaria (42,5%) y la falta de personal en la casa de estudios de educación superior (33,90%).

Igualmente, se encuentran como factores determinantes la escasez de medicamentos (45,4%) y las malas condiciones de los centros de salud (32,8%); respectivamente los estudiantes destacaron la escasez de bienes y servicios (34,4%) y la inflación (37,4%). En cuanto a problemas en el ámbito laboral, sobresalen los bajos salarios (46,8%) y las pocas oportunidades de encontrar empleo (20, 4%). Por último, como factores políticos motivantes de la migración, los estudiantes seleccionaron la corrupción (44,6%) y el modelo político implementado (30,4%)

Gráfico 3 LUZ: Factores que promueven la migración de estudiantes universitarios

Fuente: Elaboración propia a partir de la encuesta (2018).

Todos estos factores son el reflejo de un panorama dramático para Venezuela, pues se está en presencia de una crisis generalizada en términos de alimentación, seguridad, salud, economía, educación, entre otros inconvenientes que hacen que los jóvenes universitarios busquen mayores oportunidades y mejores condiciones de vida en otros países.

¿Hacia Dónde Van Los Estudiantes Universitarios?

En atención al lugar de destino, los estudiantes prefieren establecerse en Chile (33,9%), que de acuerdo a ACNUR (2018) es un país que ha dispuesto de buena recepción para los migrantes, sin embargo, a mediados de abril de 2018, decretó algunas políticas para frenar el proceso migratorio de venezolanos, solicitando una visa para poder ingresar a este territorio.

Gráfico 4 LUZ: Estudiantes universitarios según posible lugar de destino

Fuente: Elaboración propia a partir de la encuesta (2018).

Otro lugar de destino preferido por la población universitaria es Colombia (16,1%), país que ya cuenta con una gran cantidad de venezolanos; de hecho, un 30,4% de los estudiantes manifestó que sus familiares se encuentran radicados en esa nación, por lo que es más fácil establecer conexión y de acuerdo a su cercanía fronteriza, es un viaje que apenas tarda hora por carretera. También tienen previsto migrar a Argentina (11,3%), Estados Unidos (10,8%), entre otros países.

Por último, la encuesta evidencia que, de la población con propensión a migrar, el 61,8% consolidaría el proceso demográfico sin compañía alguna y el 38,2% está planificando viajar con la familia. Esta decisión de emigrar sin acompañamiento posiblemente se deba a los altos costos que demanda el fenómeno, además el grupo que predomina es joven y está libre de compromisos matrimoniales, condición que les permite asumir mayores riesgos y experimentar nuevas

experiencias. Situación que no ocurre con las personas de mayor edad, casadas y con familia, donde el miedo y otros factores se hacen presentes.

Gráfico 5 LUZ: Estudiantes universitarios con intenciones de migrar según tipo de acompañamiento

Fuente: Elaboración propia a partir de la encuesta (2018).

También ocurre que, al migrar sin compañía, pueden establecerse sin mayor responsabilidad, encontrar empleo, ahorrar y crear condiciones para recibir en el futuro al resto de la familia con mayor seguridad y estabilidad. Es importante mencionar, que autores como Freitez (2011), Muñoz (2016), Castillo y Reguant, (2017), De La Vega y Vargas (2017), Azócar (2018), entre otros, han insistido sobre un cambio de modelo político para Venezuela, ya que el proyecto político bolivariano encabezado por Hugo Chávez y continuado desde 2013 por Nicolás Maduro, ha fracasado, generando una diáspora incalculable. Sencillamente, ha recrudecido la situación del país hasta sumergirla en una espiral de crisis permanente, manifestada en la pauperización de los empleos o la falta de ellos, la carencia de productos básicos, la inflación, la delincuencia, decadencia de los sistemas de educación y salud y corrupción, entre otros problemas.

Conclusiones

Como aspectos concluyentes se tiene un número significativo de estudiantes universitarios jóvenes con intenciones de abandonar el país. Este grupo que ha declarado asumir este reto está representado de manera predominante por el sexo femenino, connotando un liderazgo de la mujer en este proceso demográfico que hipotéticamente se esperaría correspondiera a los hombres.

Igualmente, se evidencia que la gran parte de las personas que desea emigrar está compuesta por solteros, condición que les ofrece mayor facilidad para desplazarse. Y de acuerdo a la actividad que realizan en la actualidad, tanto la población activa como inactiva manifiestan la intención de salir de Venezuela. Por lo que se está en frente de una pérdida de capital humano en formación invalorable, que incidiría negativamente en el desarrollo del país.

Estas intenciones se derivan en esencia por problemas económicos, sociales y políticos concurrentes en el país, que no están permitiendo cubrir la mayoría de las necesidades de la pirámide de Maslow, primordiales para cualquier grupo humano; pues la alimentación, la realización personal, atracos, violencia generalizada, deterioro de la infraestructura universitaria y falta de personal en la casa de estudios, están siendo los factores trascendentales para la migración de estudiantes. A esto se suma la escasez de medicamentos, las malas condiciones de los centros de salud, la inflación, escasez de bienes y servicios, los bajos salarios y la corrupción.

Este panorama dramático con el que la población tiene que lidiar día a día, devela la falta de condiciones mínimas de vida, que violan los derechos humanos, que demanda la atención inmediata del gobierno y un cambio de políticas que mejoren las condiciones internas para contrarrestar la emigración.

Abstract

Sustainable development represents a process of continuous and permanent improvement, learning and perfecting and the introduction of sustainable development policies into a society or company guarantees the creation of sustainable (not only immediate) value and consequently long-term benefits. In the age of knowledge, each organization is constantly changing. The success of the organization depends on how the crises that occur during this period are managed. An important factor in managing these crises is the intellectual capital. During the process of assimilating the intellectual capital, a transformation of the individual's identity is also realized. Identity transformation is an important social process that employs dissonance, attributions and divides the role of expectations. In this paper we want to highlight the concept of intellectual capital, which is it role into organizations and societies and which are the benefits for institutional health.

Keywords: People, Intellectual Capital, Society, Sustainable Development

Introduction

In this moment the concept of sustainable development is widely used in almost all areas and it’s necessary to be applied in order to satisfy the basic material needs, in order to provide the resources for optimizing the quality of life in terms of health and education.

Sustainable development represents a complex process whose metrics involve a system of common indicators, but which also differs from country to country.

The human resource is considered to be the most important, the only one able to attract, combine and use the other resources necessary for a company, to achieve the proposed objectives.

Human capital has developed as a concept in the economy, where it is regarded in particular as "estimating a person's ability to generate income through work" (Di Bartolo, 1999).
The notion of intellectual capital appeared in the business world in the 1990s, and at the center is the information that gives rise to intellectual capital.

In the present paper, I aimed to describe what sustainable development means for a multinational automotive company in Romania, the city of Braila having the code CAEN 2931 Manufacture of electrical and electronic equipment for cars and for motor vehicles / section C where a significant number of people work where they come from both rural and urban areas and how the intellectual capital influences the health of the institution, but also of the society in which they live.

Material and Method

The AK model developed by Paul Romer and Sergio Rebelo studies the effects of accumulation of knowledge. The phenomenon considered endogenous is that, using new technologies, the economy accumulates experiences and knowledge which, in turn, favors the introduction of new technologies, generating growth.

Starting from the Cobb-Douglas formula, with neutral technical progress, the production function is written:

$Y(t)=K^{\alpha}(t)[A(t), L(t)]^{1-\alpha}$

Where:

K= capital;
L = work;
A = technical progress.
The model assumes that technical progress is the result of learning through practice, being a function of capital growth.

$A(t) = BB^{\emptyset}(t)$, B>0, Ø>0

Where:

B= coefficient of growth of K factor
The growth rate of the population is constant, the rate of economies is exogenous.
δ – depreciation of capital
And we have:
s(t) = I(t) and s(t) = sY(t) – saving rate;
K(t) = I(t) – δK(t) = capital rate;
For Ø = 1 și n = 0 – growth is self-sustaining
By substitutions, we obtain:

$Y(t) = K^{\alpha}(t)[BK^{\emptyset}(t)L(t)]^{1-\alpha}$

The engine of endogenous growth is the stock of technological knowledge. Technological knowledge and physical capital are the accumulating factor; The accumulation of knowledge is realized inside the company through the process of learning through practice: the more it is produced, the more the technological knowledge develops, which will allow to increase the efficiency of the production in the following periods for quantities of invariable factors of production.

The assessment of intellectual capital can be considered a good starting point for a more efficient management, in order to increase the competitiveness, but it can also provide a reporting tool.

For the multinational company with CAEN CODE 2931 Manufacture of electrical and electronic equipment for vehicles and for motor vehicles / C-section in the city of Brăila, the concept of intellectual

capital plays a very important role because, at the moment, it is focused on technology, each factory belonging to this company, not only from the city of Braila, but from all the countries where there are work points, it is equipped with the latest generation working / technological machines, which work on the basis of a software, in which the engineer introduces the information so that the operators can process the raw material from which the finished product results.

Finally, the finished product is sold to the customer, of course according to valid contracts in which prices and conditions are agreed by mutual agreement.

At present, everything related to the supply, production and sale of a product cannot be achieved without the help of the technology set up and directed by the person / employee.

The person / employee to be able and authorized to use the working machines correctly must first be trained. The more people trained in this regard, the better the production goes; in other words, the role of the intellectual capital is to ensure the health of the institution of which it is a part and for which it works and, of course, to ensure the sustainable development of the organization, later of the society.
As a statistic at the local factory level, we can say that:

- 40% of the employees are people who have completed high school and a college, which means they have a computer, technical knowledge and a foreign language.
- 60% being assigned to studies belonging to the vocational schools, but following the training offered by the factory where they work they are authorized to use the production equipment at a certain level and in different ways, depending on the locations where they were positioned.

As a result, over time it has been observed that many companies have higher incomes because they have employees with higher intellectual capital, which is why more and more companies, both large and small, want to recruit in their own personal team with a high level of qualification and education, which can respond to the future demands and requirements of the economy and society.

Critical success factor for all types of organizations intellectual capital, is based, first of all, the evolution of education and studies.

It is the ability of employees to innovate in thousands of ways to improve the efficiency of a factory. It is the electronic network that carries information at light speed through a company, so that the answer is faster and faster than the rivals. It is the collaboration between a company. and its clients, their strong connection, which brings the client back again and again. It is the power of the collective mind.

The importance of investing in intellectual capital is the first step towards economic stability, even in these times of economic crisis.

The intellectual capital, through its forms, determines the performance of the organization, and the relationship between the intellectual capital and the performance of the organization leads to the establishment of a new trajectory in the evolution of the career, based on the acquisition of a portfolio as complete as possible. The evolution of the professional career must be part of a knowledge map within the organization. This map is very valuable for the organization, because it includes the knowledge networks that are created between the employees, as well as the way in which they are organized around the production.
In the current economy, more and more managers are fighting to effects of the financial crisis, trying to find all kinds of solutions to increase the value of the company, and the importance of intellectual capital and its components are very important and even vital for some companies. This new era of technologies, new inventions and innovation has a great impact on the strategies, objectives and goals of many

companies, which is why many researchers in the economic field regard intellectual capital as a sure source of growth in business value.

Most of the times, intellectual capital is considered a hidden wealth of companies, which, despite not being presented in its financial statements, offers an added value for the company. In today's economy, intellectual capital seems to be one of the safest things to prevent the effects of the current economic crisis, but also for the sustainable development of the economic entity. For this reason, more and more companies tend to invest more and more in intellectual capital, because they represent the engine of successful business.

Results and Discussions

Sustainable development has also a profound impact on many businesses, their operations and their supply chains.

The complex and interdependent nature of environmental problems will cause businesses to go beyond simply complying with environmental regulations to develop innovative responses to environmental challenges.

Companies that act according to the principles of sustainable development often obtain high performances (even in the short and medium term) compared to the other companies due to a better control of the different categories of risks to which they are exposed.

In the global civilization, the new economies that are based on innovations have as a priority the technological development that leads to a high level of competitiveness and to human development and the proven fact is that technological progress is essential for human progress.

Digital innovations open up new perspectives and "break the boundaries" of how people can use technologies to expand knowledge, stimulating growth and development.

New technologies are diffused, both between different countries and within them.
A rational starting point in examining the notion of intellectual capital is the analysis of the organization made from the perspective of resources. Viewed from this perspective, any organization or firm presents itself as a system consisting of a set of resources mobilized within a given structure.

Technological innovations can improve human potential and abilities, in other words they are a source of ensuring human development.

The financial advantages for companies obtained from investing in people, mainly in their education and training, are already proven and known. This investment has a high rate of recovery, respectively benefits in the form of increased labor productivity, professional skills development, innovation capacity, increased mobility of workers. However, many organizations still see employee education and training programs as a cost and not as an investment.

To clearly define the concept of intellectual capital, the following statements are defining:

- intellectual capital is the sum of all the people in an organization know, giving it competitive advantages on the market;
- intellectual capital is recognized as a value in most organizations, but also the key to the success of that organization
- Intellectual capital represents the intellectual material that has been formalized, captured and valued to produce even more valuable assets. He is given by those knowledge that can be transformed into values.

The most important factors for sustainable development within an organization or company are: structural capital and human capital.

Structural capital refers to ownership of information systems, distribution networks, supply chains.

Human capital, which includes human resources, as well as customers and suppliers - is made up of educational capital (skills acquired by individuals in the school education process, but also outside it) and biological capital (physical abilities of individuals, most often synthesized by the state of health).

Types of indicators used to measure intellectual capital:

- Leadership;
- Motivation;
- The ability to execute delegated tasks;
- Networking;
- Number of Employees;
- Age in the company;
- Stability in the position;
- Number of managers;
- Number of women managers;
- Percentage of managers with higher education;
- Average age of employees;
- Average duration of training programs (hours / employee);
- The average cost of training programs (hours / employee);
- IT knowledge.

Conclusions

In order to realize the potential of some businesses, it is very important to attract and retain the right combination of people who have collective expertise and have access to information networks. All the more so given the rapidity of many of the technological advances and the potential profits for private sector organizations, which exploit the first new market opportunities.

In the age of knowledge, each organization is constantly changing. The success of the organization depends on how the crises that occur during this period are managed. An important factor in managing these crises is the intellectual capital. During the process of assimilating the intellectual capital, a transformation of the individual's identity is also realized. Identity transformation is an important social process that employs dissonance, attributions and divides the role of expectations.

It is very important to understand the true value of intellectual capital and to invest in it, because it provides companies with a much greater well-being than similar companies, but they do not invest in this type of resource. The current economy is based on these ways of developing the company, because they are reliable methods not only to keep the company afloat but even to develop it.

Abstract

This work describes a case study carried out in a manufacturing company that intends to apply some concepts of Industry 4.0 in a maintenance pilot machine. To achieve this, maintenance machine problems were analyzed, and afterward, an action plan was proposed to start adopting predictive maintenance with the help of sensors connected to an information system. Thus, a new way of working was achieved, creating a smarter and more competitive maintenance field with the application of Industry 4.0, which in turn, represents more value to the company.

Keywords: Industry 4.0; Predictive Maintenance; Sensors; Integrated Information System.

Introduction

Globalization contributes to attending the growing world's demand for capital and consumer goods — ensuring, at the same time, a sustainable evolution in different fields.

Market requirements such as efficiency, flexibility, adaptability, stability, and sustainability are increasing. This fact justifies the need for companies to adopt new approaches supported by Information and Communication Technologies (ICTs) to deal with such challenges. Today, ICTs have an important role in the context of organizations, generally used to create and define new business models (Brettel, Friederichsen, Keller, & Rosenberg, 2014). However, while some organizational fields have been taking advantage of the integration of ICTs for a long time, the maintenance field has only recently started to use ICTs to automate their processes. Maintenance planning is an important management activity in making production more efficient, increasing the availability of equipment and, consequently, improving product quality (Upasani, Bakshi, Pandhare, & Lad, 2017). For that, correct information at the right place and time is a critical factor in supporting decision-making and promoting new opportunities in the maintenance field (Kans & Ingwald, 2016). In this context, new models related to maintenance activities in companies are emerging, to ensure the success of operations and reduction of costs. Although several types of maintenance can be applied, the literature suggests that condition-based maintenance (predictive maintenance) is one of the best for reducing costs and eliminating production stops. It should be noted that this type of maintenance could be improved through the use of smart technologies (Ferreiro, Konde, Fernández, & Prado, 2016).

Additionally, and considering the current technological context, some studies in the literature already indicate that predictive maintenance will be predominant in the industry's future — where machines will be connected, resembling a collaborative community. However, this situation requires the use of advanced prediction tools. This is so that data can be systematically processed into information, which explains uncertainties and supports more informed decisions (Lee, Kao, & Yang, 2014).

This paper describes part of a work carried out in an industrial company that intends to increase the availability of machines (press), and at the same time reduce maintenance costs. To improve the maintenance press process, reduce costs and generate a higher availability, it is necessary to: (i) gather and organize information; (ii) analyze more common problems; (iii) discover what type of solutions can solve said problems; and (iv) plan the implementation of the solution.

The remaining content of this paper is organized as follows: a brief theoretical background of the topics addressed in this work is provided in section 2; namely, maintenance, industry 4.0 (I4.0) and their possible connection. Section 3 presents the practical case, specifically a preliminary study to implement smart predictive maintenance. Finally, some conclusions about the study and proposals for future work are presented in section 4.

Theoretical Background

Concept and types of maintenance Subjects or Participants

Maintenance is the set of all activities that are applied to restore machines to the specified condition of operation or to prevent the machine from breaking down, for them to remain in a functional state (Pintelon & Gelders, 1992). It represents a critical shop floor activity since it guarantees good performance of the production process and the final product's quality (Sipsas, Alexopoulos, Xanthakis, & Chryssolouris, 2016).

Depending on the circumstances and characteristics of each industry, different maintenance processes can be used. However, there is no consensus among the different authors regarding the classification of maintenance types. Due to the divergence of classifications, the one used by the European standard will be considered in this work (NP EN 13306, 2007). According to the European norm, maintenance can be curative or preventive. Preventive maintenance can still be further divided into systematic maintenance or conditional maintenance (or predictive maintenance). Table 1 compiles the main characteristics of these three types of maintenance.

Table 1: Types of maintenances and their main characteristics (Blischke & Murthy, 2003) (Hashemian, 2011).

Type	Curative	Systematic preventive	Conditional preventive (Predictive)
Characterization	An **unplanned** maintenance executed when a malfunction occurs or when equipment performs below expected performance indexes	A **planned** maintenance that consists of actions to increase the functional life of equipment or a system and tries to prevent its failure Maintenance without any previous control of the state of the equipment, assuming that it fails in a relatively predictable way	A **planned** maintenance that consists of actions to increase the functional life of equipment or a system and also tries to prevent its failure; however, in this case it is performed according to the condition of the equipment

Costs	There is a reduced continuous and unnecessary maintenance cost. However, when a component eventually fails, it can damage other system components or the entire machine, which can make it more expensive	Usually history-based, which is not the most adequate. Consequently, preventive maintenance is sometimes carried out more often than necessary, which entails unnecessary high maintenance costs	Costs are better adjusted to the needs of the equipment – better investment
Advantages	Does not require previous work or money, because it only acts upon a machine's failure	Works to prevent problems in advanced	Uses objective evidence of a fault or failure condition, in order to reduce costs, minimize the risk of catastrophic failures and maximize system availability
Disadvantages	Sometimes implies having long and unexpected downtimes, which can affect production — big risk	Sometimes leads to unnecessary wastes of money	Requires an integrated, real time or online approach to data collection, analysis and interpretation, using wireless sensors and analysis in order to work in an effective manner

Industry 4.0 and its main technological components

Currently, in industrialized countries, the demand for industrial value creation and development is shaped by the development of the fourth phase of industrialization, called Industry 4.0 (Stock & Seliger, 2016).

The first three industrial revolutions were the result of mechanization and electricity, as well as computers and automation, with I4.0 being the result of cyber-physical systems (CPS) (Lukac, 2015).

Industry 4.0 is a name given to the current trend of automation and data exchange in the manufacturing environment, which includes different technological components, such as cyber-physical systems (CPS), Internet of Things (IoT), cloud computing, big data analytics, and cognitive computing, among others.

I4.0 is characterized by digitalization process, enabling automation and data exchange between different systems without human intervention (Vijaykumar, Saravanakumar, & Balamurugan, 2015) (Wan et al., 2016) (Obitko, V., & Jirkovský, 2015) (Lu, 2017) (Gruber, 2013). I4.0 contemplates a new era of intelligence, with a decentralized production, focused on continuous communication between people, machines, and products (Albers, Gladysz, Pinner, Butenko, & Stürmlinger, 2016).

IoT notably represents a key technological component in I4.0, since it uses equipment with sensing and identification processes, along with communication and network capabilities (Xu, He, & Li, 2014); connecting humans and machines and integrating knowledge between and within organizations (Thames & Schaefer, 2016).

Microprocessors and artificial intelligence technology transformed machines, making them intelligent in the sense that they not only have the ability to compute, communicate and control, but also have autonomy and can connect with others (Wang, Wan, Li, & Zhang, 2016).

Many other important technologies are at the core of the infrastructure required for IoT, which includes sensors, circuits, actuators, controllers and Radio Frequency Identification (RFID). For example, RFID consists of a method of automatic identification through radio signals, retrieving and storing data remotely (Trappey, Trappey, Hareesh, Chuang, & Sun, 2016). The use of sensors in data collection will play a decisive role in developing industrial services, with particular relevance in the maintenance field (Albers et al., 2016).

The cloud is another important technological key solution for I4.0, in so far as it allows for a great storage capacity when gathering large amounts of data, enabling advanced analyses. Cloud computing technologies allow organizations to collect and analyze a large amount of data using sensors, converting data into useful information. It is also helping companies improve customer relationships, track tools, deliver products faster, and reduce costs (Yang, Shen, & Wang, 2016).

Other important technological components for I4.0 are related to big data analytics and data mining, which applies intelligent techniques to extract data patterns, helping to plan better, following real previous data and their interceptions (Bubeník & Horák, 2014). The overall goal of the data mining process is to extract information from a data set and transform it into an understandable structure for further use. Two factors that may emerge from the use of data mining are productivity and transparency since with the support of the big data analysis and the subsequent advantages in coordination, there is work optimization of the machines and resources — generally, resulting in optimized processes and productivity growth (Wang et al., 2016).

With the automation of some operations, there is also a reduction in the daily tasks that workers need to do. On the other hand, the support of big data for analysis, software with efficient tools and more friendly interfaces, allows for an easy way to run diagnostics and correct maintenance (Wang et al., 2016).

For all this be possible, intelligent hardware and software are needed, including ways to control intelligent machine parts, large data analysis software, and embedded information systems (Wang et al., 2016).

Industry 4.0 In Preventive Maintenance

Nowadays, industrial maintenance will also be a revolutionary area. Data and information in the right place at the right time are critical factors for new management, with new opportunities available in the maintenance field (Kans & Ingwald, 2016).

Efficient preventive maintenance is important to ensure the reliability of the systems, helping in reducing unplanned downtime and avoiding defects (Hashemian, 2011).

In the practices, maintenance is usually done less often than necessary, which makes it ineffective and several breakdowns continue to occur, i.e., unplanned breaks (Upasani et al., 2017). Because of this, failures and long periods of inactivity happen, resulting in large repair costs, misuse of resources, production delays, and operating costs.

The use of proper technologies makes the existence of smarter systems possible, which makes the anticipation of problems and more intelligent production processes possible (Kans & Ingwald, 2016).

It is important to mention that Industry 4.0's principles are characterized by providing different individual assets with intelligence, which can always evolve into a more intelligent operation, through the application of sensors. Researchers are working on ways to make the most intelligent assets, in the case of maintenance, for example, monitoring the conditions, forecast, and diagnostics, as well as artificial intelligence, to obtain more information about the components and therefore allowing a more precise maintenance plan (Upasani et al., 2017).

Other important components in reaching smart preventive maintenance are Information Systems (IS). Smart preventive maintenance includes the concept of electronic maintenance, to optimize the maintenance in a process that involves data acquisition, data processing, and decisions based on the resulting information.

Several types of IS allow to centralize and collect data from different physical resources connected, making information available to different users in terminals such as PCs, tablets or mobile phones (Pintzos, Rentzos, Papakostas, & Chryssolouris, 2014).

Practical Case: A Study to Implement Smart Predictive Maintenance

Objectives and problem contextualization

The present project is related to a maintenance plan of a critical machine, integrated into a manufacturing company. Maintenance represents a high cost for the company, and additionally, the machine chosen for the pilot study (press machine) has a very important function, since it produces many different essential components that integrate into the final product marketed by the company. Thus, the main goal of this project is to plan a proper maintenance strategy for this machine to (i) reduce maintenance costs and (ii) increase availability of the work, avoiding delays in planned production.

The company was working with curative and preventive maintenance. So, there was no maintenance based on the real condition of the machine, i.e., predictive maintenance.

Therefore, to reduce the cost of maintenance for these critical machines, while reducing unexpected breaks, and production and financial impacts, a project was created to analyze and perceive the causes and how to solve them in a better way. Work was organized into four steps: (i) get information related with maintenance occurrences and costs; (ii) analyze the most common problems and their impact on the company; (iii) present the best solution to solve the identified problems; and finally, (iv) define how the solution could be implemented.

Problem Analysis

To understand the reasons behind higher costs, the kind of maintenance that was applied and how to improve it in an intelligent way, it is important to know the most common reasons why the machine stopped. As such, the first step was to analyze every cost and maintenance report in the last years, to know which parts of the machine encounters problems more regularly and which problems required a higher cost and time to solve.

After analyzing the information (figures 1 and 2), it became evident that most of the problems and costs came from issues with one specific component of the press machine – the press tools. Of all the machine's parts, press tools are the most crucial, because they are what shapes the material and pieces cannot be made without them. It is also an expensive component.

Fig. 1: Costs distribution of maintenance

Fig. 2: Time distribution of maintenance

Additionally, the OEE (Overall Equipment Efficiency) report was consulted. OEE is an indicator of the overall equipment's efficiency, which takes into account the availability, efficiency, and quality of the machine. Therefore, it is useful for companies to have knowledge of the effective work of their machines and where the greatest losses of efficiency come from. In this case, using the OEE reports, it was concluded that 5% of OEE losses are related to press tools maintenance; therefore, improving the maintenance of the press tools can improve the OEE as well.

The second step of the analysis was in understanding what type of maintenance had been applied and the most common causes of press tool damage.

Fig. 3: Time/ Type of maintenance

Fig. 4: Costs/Type of maintenance

Figures 3 and 4 depict the analysis of the most used maintenance types, in terms of cost and time consumed, when it comes to the maintenance of the most critical machines, i.e., press tool. Both factors (time and cost) indicate that in the majority of cases, the press tool has more curative maintenance than preventive maintenance. It is important to point out that this solution is not beneficial to the company, because when curative maintenance is more dominant, it means that the company has less control over the process, leading to more breakdowns and consequently to unplanned production stops.

A good maintenance plan should work to avoid the problems more than to solve them, i.e., more preventive maintenance than curative ones. It will reduce unplanned downtimes and the costs of solving a machine's problems later on, which are often more expensive or even result in the purchase of a new tool.

To determine the problems and complete the information, a more in-depth data collection was carried out. Data was gathered through both systems and paper reports. Data on all types of maintenance and damages for this press tool machine was collected and several meetings with maintenance technicians and press machine operators were done. As a result, a list of the most common root problems was

identified: burr, waste material/scrap; bad cuts in the separations of pieces; a broken part of the press tool, and mistake or delay in a change process of a press tool.

It became evident that all problems were the result of a lack of adequate maintenance since it could all be avoided with a more periodic intervention (periodic preventive maintenance) and ideally, the effective work of the press tools would be taken into consideration; which required a more efficient and evolved maintenance – such as predictive maintenance.

Proposed Solution: Plan smart predictive maintenance using the I4.0 concept.

The preventive maintenance carried out by the company was developed based on the machine's problem history. How much time it took for the tool to have problems was taken into consideration and actions were planned to avoid such an outcome. Despite this type of maintenance being better than a curative one, it is important to consider the real effort and effective wear, to predict the problems more efficiently and in real-time. As such, the next step was having a way to predict the right time to do maintenance and how it would work daily; considering the wear of the press tools, this prediction would probably be based on the number of strokes. Doing maintenance based on this makes it possible to measure the effective work in real-time and not just based on past events, which allows for the use of such knowledge when determining what to do and the most common type of problems. With this, it is possible to adjust the maintenance to what is necessary, instead of dealing with defects and excesses, leading to more effective and optimized performance and reducing downtime and unnecessary costs.

This makes it possible to lubricate, arrange or replace the necessary components of the press tools and clean accumulated scrap or burr, promptly; which, as previously mentioned, was a significant source of the problems.

For this to happen reasonably, it is essential to use two technological supports: (i) sensors to count the number of strokes, and (ii) an information system to support the information flow, for example, an enterprise information system (ERP) to collect data and notify the maintenance team in real-time.

Number of strokes through sensors in the predictive maintenance applying I4.0 concept

Regarding the change in the maintenance method, threshold values must be defined and each time the required number of strokes for maintenance (on average) is met, the system will notify the maintenance team.

Initially, to define the number of strokes needed to perform maintenance it was considering the historical maintenance. Over time the number of stokes will be adjusted. For example, if a module needs monthly maintenance, and it is known that, for that module, 15000 strokes occur on average within a month, this will be the number of strokes needed to perform the predictive maintenance. Over time, as knowledge increases, the number of strokes required to perform maintenance will be continuously adjusted and improved upon (see Figure 5).

Fig. 5: The continuous process of stroke number adjustment.

Information system to support the information flow in the predictive maintenance applying I4.0 concept

Practically speaking, each press tool will be identified and sensors will count the number of strokes for each. The data captured by the sensors will be used for: (i) counting the number of press tool strokes/process reference, which will be used when defining the threshold (for example, every 15000 strokes triggers a notification to the maintenance team, then restarts the count); and, (ii) counting the number of strokes/process reference during the lifetime of press tool (relevant information to be analyzed later).

To implement a smart predictive maintenance solution, it is necessary to consider an information system that receives the data from the sensors and sends notifications to the maintenance team when the programmed threshold is reached. Additionally, the IS should allow for the visualization of the relevant information at any time and by any authorized user.

It should be mentioned that this type of solution for predictive maintenance, makes it possible to collect certain information that, because of its nature, is often not perceived or not easily accessible to operators.

Additionally, the integration of a mobile solution in the system can improve the working process. In this project, a mobility solution was planned, focusing on the needs of the maintenance technicians to work on the shop floor. It enables the maintenance technicians to receive notifications at any time or place within the company and also to have access to all the information they need about the equipment; for example, the planned maintenance actions for each press tool or to automatically request the material for a maintenance intervention. With this additional feature, it is expected that maintenance will further improve productivity and efficiency while reducing the loss of time when consulting information systems and notifications.

With the system and the installation of sensors connected to an information system, maintenance smartly advances in a revolutionary way (I4.0) and becomes a more productive and valuable field.

Conclusions and future work

Predictive maintenance increases the gains and new challenges, insofar as it contributes to the reduction of costs and production stops. This fact motivates a maintenance expert to investigate new ways to carry out the maintenance process and make use of opportunities related to ICTs that could not be exploited before.

This work presented a study that was performed to implement better preventive maintenance – predictive maintenance – on a specific press machine, to reduce the downtime for repairs, and consequently the maintenance costs. For this, and to guarantee the information about the state of the machine in real-time, the study considered the application of a smarter way of working with predictive maintenance, using I4.0's principles, more specifically sensors connected with a proper information system.

The study about the implementation process defined for this press machine can be replicated in any other type of machine, changing the type of information that needs to be controlled for maintenance (this case being the number of strokes), representing thus one possible future work. In the future, it would also be interesting to extend the present process of analysis to include other relevant parameters that help to verify the state of the press machine. However, this extension can lead to another interesting area of knowledge – data mining –, which applies techniques to discover useful relationships between data; representing an important technological component for the growth of I4.0's solutions.

Acknowledgment

This work was financially supported by Institute of Electronics and Informatics Engineering of Aveiro (UIDB/00127/2020) and by Governance, Competitiveness and Public Policy (project POCI-01-0145-FEDER-008540) funded by National Funds through FCT - Foundation for Science and Technology.

Abstract

The efficiency of the control of harmful organisms of the batch of grain cereal seeds is an essential component in the effort to maintain unaltered the quality of the stored seed lots, in terms of physical integrity, especially their longevity, by maintaining germination indices at the optimum level, for as long as possible. The primary purpose of the research was to identify and describe the specific pests and their grouping, depending on the specific types of attack, as well as estimating potential damage in the event of an uncontrolled attack. The second component of the research was to monitor the possible ways of infestation with the identified harmful organisms of storage as well as the specific way in which they can be controlled so as not to produce irreversible damage to the consignments of stored grain cereal seed. The paper proposes concrete control schemes that harmoniously combine physicochemical methods and biological methods to prevent and combat pest infestation during storage. Modern theories of protection against harmful organisms are based on the economic threshold of harm (PED), which can be defined by the level of losses caused by the harmful organisms, the cost / benefit ratio and the expenditure of resources for protection actions.

Keywords: Harmful Organisms, Seed Lots, Integrated Control, Storage, Physical Methods.

Introduction

The seasonal character of the vegetable agricultural production requires its preservation / conservation for a variable period of time, depending on the needs of the consumption requirements.

Wheat production is an important factor in ensuring Romania's food security. Wheat cultivation is a very old practice in Romania. Research conducted by Stanciu (2017) showed that wheat production obtained in the last period of Romanian agriculture was not directly influenced by the government's

investments in irrigation systems or by the additional quantities of chemical fertilizers. Government and private measures could increase the volume of wheat production, and Romania could be a major exporter worldwide.

Bacanu (Serban) et. al, (2018) analysed of the agricultural area allocated to wheat and the seed production in Romania, Braila County. Using the data of the Territorial Inspectorate for the Quality of Seeds, the main wheat seeds used by the Braila farmers were presented and described. The results of the study showed that the most common varieties of wheat seeds in the agriculture of Braila County are indigenous, better suited to the local conditions of cultivation, to high temperatures and to a lower level of rainfall, which are in fact cultivated on the widest agricultural areas.

Seed conservation has as its main objective the prevention of possible quantitative and qualitative losses by maintaining and / or improving the specific physiological and cultivation characteristics (Ion, 2010). The study proposed by Stanciu (2017) analysed the concentration of investments in storage facilities in Romania, using the Gini Struck index. The results showed that there has been significant progress at national level in terms of seed storage capacity. However, in Romania the storage facilities are characterized by a low technological level and by the prevalence of the chop type installations, which do not offer good storage conditions, quantitative and qualitative losses for the local farmers and the premature sale of the production.
